MINERALS YEARBOOK

U.S.
DEPARTMENT
OF THE
INTERIOR

BUREAU
OF
MINES

1993

UNITED STATES DEPARTMENT OF THE INTERIOR • Bruce Babbitt, Secretary

BUREAU OF MINES

As the Nation's principal conservation agency, the Department of the Interior has responsibility for most of our nationally owned public lands and natural resources. This includes fostering the sound use of our land and water resources; protecting our fish, wildlife, and biological diversity; preserving the environmental and cultural values of our national parks and historical places; and providing for the enjoyment of life through outdoor recreation. The Department assesses our energy and mineral resources and works to assure that their development is in the best interests of all our people by encouraging stewardship and citizen participation in their care. The Department also has a major responsibility for American Indian reservation communities and for people who live in Island Territories under U.S. administration.

Foreword

This edition of the Minerals Yearbook discusses the performance of the worldwide minerals and materials industry during 1993 and provides background information to assist in interpreting that performance. Content of the individual Yearbook volumes follows:

Volume I, Metals and Minerals, contains chapters on virtually all metallic and industrial mineral commodities important to the U.S. economy. A chapter on survey methods with a statistical summary of nonfuel minerals, and a chapter on trends in mining and quarrying in the metals and industrial mineral industries are also included.

Volume II, Area Reports: Domestic, contains chapters on the minerals industry of each of the 50 States, and Puerto Rico. This volume also has a chapter on survey methods used in data collection, including a statistical summary of domestic nonfuel minerals.

Volume III, International Review, contains the latest available mineral data on more than 175 foreign countries and discusses the importance of minerals to the economies of these nations. The reports also incorporate location maps, industry structure tables, and an outlook section.

The annual international review is presented as five area reports and one world overview: Mineral Industries of Africa, Mineral Industries of Asia and the Pacific, Mineral Industries of Latin America and Canada, Mineral Industries of Europe and Central Eurasia, Mineral Industries of the Middle East, and Minerals in the World Economy. Due to budget constraints detailed mineral trade statistics by country will no longer be included in this publication. However, in the future abbreviated trade data for the major mineral trading countries will be made available by electronic or other means. For information on trade statistics call the Chief, Section of International Data at (202) 501-9700.

The U.S. Bureau of Mines continually strives to improve the value of its publications to users. Constructive comments and suggestions by readers of the Yearbook are welcomed.

Acknowledgments

Volume I, Metals and Minerals, of the Minerals Yearbook presents data on more than 60 minerals and materials commodities that were obtained as a result of the information gathering activities of the U.S. Bureau of Mines.

The collection, compilation, and analysis of domestic minerals industry data were performed by the staffs of the Division of Mineral Commodities and the Division of Statistics and Information Services. Statistical data were compiled from information supplied by mineral producers and consumers in response to canvasses, and their responses are gratefully appreciated. Information obtained from individual firms by means of the U.S. Bureau of Mines canvasses has been grouped to provide statistical aggregates. Data on individual firms are presented only if available from published or other nonproprietary sources or when permission of the respondent has been granted. The chapter "Survey Methods and Statistical Summary of Nonfuel Minerals" discusses in greater detail procedures for canvassing the minerals industry and the processing and evaluation of these data. Other information appearing in this volume was obtained from the trade and technical press, industry contacts, and additional sources; this cooperation is gratefully acknowledged.

Statistics on world production were compiled in the Division of Statistics and Information Services and Division of International Minerals from numerous sources, including reports from the U.S. Department of State. U.S. foreign trade data were obtained from reports of the U.S. Department of Commerce, Bureau of the Census. The U.S. Bureau of Mines also was assisted by numerous cooperating State agencies.

Ronald F. Balazik
Chief, Division of Mineral Commodities

SURVEY METHODS AND STATISTICAL SUMMARY OF NONFUEL MINERALS

By Jacqueline A. McClaskey and Stephen D. Smith

Ms. McClaskey, an operations research analyst with 8 years of Government experience, has been with the U.S. Bureau of Mines Branch of Statistics and Methods Development since 1990.

Mr. Smith, industry data analyst in the Section of Industry Data Analysis and Coordination, was assisted in the preparation of the Statistical Summary by Imogene P. Bynum, Chief, Section of Metals Data; Maria Arguelles and Christopher Lindsay, co-chiefs, Section of Industrial Minerals Data; Ivette E. Torres, Chief, Section of International Data; and Raymond L. Cantrell, physical scientist, Branch of Industrial Minerals.

SURVEY METHODS

The U.S. Bureau of Mines (USBM) Information and Analysis Directorate collects worldwide data on virtually every commercially important nonfuel mineral commodity. These data form the base for tracking and assessing the health of the minerals sector of the U.S. economy.

The USBM's data collection activity was instituted by the 47th Congress in an appropriations act of August 7, 1882 (22 Stat. 329), which placed the collection of mineral statistics on an annual basis. The most recent authority for the USBM survey activity is the National Materials and Minerals Policy, Research and Development Act of 1980 (Public Law 96-479, 96th Congress). This act strengthens protection for proprietary data provided to the U.S. Department of the Interior by persons or firms engaged in any phase of mineral or mineral-material production or consumption.

Data Collection Surveys

The USBM begins the collection of domestic nonfuel minerals and materials statistics by appraising the information requirements of Government and private organizations of the United States. Requirements that can be met by collecting data from minerals establishments are posed as questions on USBM surveys. Figure 1 shows a typical survey form.

Specific questions about the production, consumption, shipments, etc., of mineral commodities are structured in the survey forms to provide meaningful aggregated data. Thus, the entire mineral economic cycle from production through consumption is covered by 149 monthly, quarterly, semiannual, and annual surveys.

After the survey form has been designed, a list of the appropriate establishments to be canvassed is developed. Many sources are used to determine which companies, mines, plants, and other operations should be included on the survey mailing list. USBM State Mineral Officers, State geologists, Federal organizations (e.g., Mine Safety and Health Administration), trade associations, industry representatives, and trade publications and directories are some of the sources that are used to develop and update survey listings. With few exceptions, a complete canvass of the list of establishments is employed rather than a sample survey. The iron and steel scrap industry is one of the exceptions where a sample survey is conducted.

The Paperwork Reduction Act requires that any Government agency wishing to collect information from 10 or more individuals or establishments first obtain approval from the Office of Management and Budget (OMB). OMB approves the need to collect the data and protects industry from unwarranted Government paperwork.

Survey Processing

The USBM surveys approximately 25,000 establishments. Each year the USBM mails about 43,500 forms that gather information for 149 different surveys. Each completed survey form returned to the USBM undergoes extensive scrutiny to ensure the highest possible accuracy of the mineral data. The statistical staff monitors all surveys to ensure that errors are not created by reporting in physical units different from the units requested on the form. Relationships between related measures, such as produced crude ore and marketable crude ore, are analyzed for consistency. Engineering relationships, such as recovery factors from ores and concentrates, are also employed. The totals for each form are verified, and currently reported data are checked against prior reports to detect possible errors or omissions.

For the majority of the surveys, which are automated, the forms are reviewed to ensure that data are complete and correct before entering into the computer. The computer is programmed to conduct a series of automated checks to verify mathematical consistency and to identify discrepancies between the data reported and logically acceptable responses.

The USBM is modernizing and automating all of its survey processing and data dissemination functions. Automated commodity data system functions include computerized preparation of statistical tables; the use of desktop publishing to integrate text and tables; and the implementation of a microcomputer bulletin board, known as MINES-DATA, for electronic dissemination of minerals data. Also, information on minerals and mineral-related publications is now available through an easy-to-use automated facsimile (fax) response system known as MINES FaxBack.

Survey Responses.—To enable the reader to better understand the basis on which the statistics are calculated, each commodity annual report includes a section entitled "Domestic Data Coverage." This section briefly describes the data sources, the number of establishments surveyed, the response percentage, and the method of estimating the production or consumption for nonrespondents.

To produce reliable aggregated data, the USBM employs efficient procedures for handling instances of nonresponse. Failure to return the initial survey form results in a second mailing of the form. If the second form is not returned, telephone calls are made to the nonrespondents. The followup calls provide the necessary data to complete the survey forms and/or verify questionable data entries. Periodic visits to important minerals establishments are also made by USBM commodity specialists or State Mineral Officers to gather missing data and to explain the importance of the establishment's reporting. By describing the use of the published statistics and showing the impact of nonresponse, the USBM strives to encourage respondents to give a complete and accurate reply.

The OMB "Guidelines for Reducing Reporting Burden" stipulates that the minimum acceptable response rate shall be 75% of the panel surveyed. In addition, the USBM strives for a minimum reporting level of 75% of the quantity produced or consumed (depending on the survey) for certain key statistics. Response rates are periodically reviewed. For those surveys not meeting the minimum reporting level, procedures are developed and implemented to improve response rates.

Estimation for Nonresponse.—When efforts to obtain a response to a survey fail, it becomes necessary to employ estimation or imputation techniques to account for missing data. These techniques are most effective when the response rate is relatively high. Some of the estimation methods depend on knowledge of prior establishment reporting, while other techniques rely on external information to estimate the missing data. When survey forms are received after the current publication has been completed, the forms are edited, necessary imputations are made for missing data, and the survey data base is updated. The revised data are reported in later publications.

Protection of Proprietary Data.—The USBM relies on the cooperation of the U.S. minerals industry to provide the mineral data that are presented in this and other USBM publications. Without a strong response to survey requests, the USBM would not be able to present reliable statistics. The USBM in turn respects the proprietary nature of the data received from the individual companies and establishments. To ensure that proprietary rights will not be violated, the USBM analyzes each of the aggregated statistics to determine if the data reported by an individual establishment can be deduced from the aggregated statistics. If, for example, there are only two significant producers of a commodity in a given State, the USBM will not publish the State total because either producer could readily estimate the production of the other. It is this obligation to protect proprietary information that results in the "Withheld" or "W" entries in the published tables. However, if a company gives permission in writing, the USBM will publish the data as long as the data from other respondents are protected from disclosure.

International Data

International data are collected by country specialists in the USBM Division of International Minerals with assistance from the Section of International Data. The data are gathered from various sources, including published reports of foreign Government mineral and statistical agencies, international organizations, the U.S. Department of State, the United Nations, the Organization of Petroleum Exporting Countries, and personal contact by specialists traveling abroad. Each February an annual "Minerals Questionnaire" is sent through the Department of State to more than 70 U.S. Embassies asking them to provide estimates of mineral production for the host country for the preceding year. Missing data are estimated by USBM country specialists based on historical trends and specialists' knowledge of current production capabilities in each country.

Publications

The USBM disseminates current and historical minerals information through a broad range of printed publications.

The Minerals Yearbook summarizes annually, on a calendar-year basis, the significant economic and technical developments in the mineral industries. Three separate volumes are issued each year: Volume I, Metals and Minerals; Volume II, Area Reports, Domestic; and Volume III, Area Reports, International. Chapters in Volume I are issued separately as annual reports before the bound volume is available. Chapters in Volume II are issued separately as Mineral Industry Surveys before the bound volume is available. Volume III country reports appear in bound volume only.

Volume I of the Minerals Yearbook presents, by mineral commodity, salient statistics on production, trade, consumption, reserves, and other measures of economic activity.

Volume II of the Minerals Yearbook reviews the U.S. minerals industry by State and island possessions.

Volume III of the Minerals Yearbook contains the latest available mineral data for the year of review on more than 180 foreign countries and discusses the importance of minerals to the economies of these nations. Volume III is presented as five area reports and one world overview: Mineral Industries of Africa, Mineral Industries of Asia and the Pacific, Mineral Industries of Latin America and Canada, Mineral Industries of Europe and Central Eurasia, Mineral Industries of the Middle East, and Minerals in the World Economy.

Mineral Industry Surveys contain timely statistical and economic data on minerals. The surveys are designed to keep Government agencies and the public, particularly the mineral industry and the business community, informed of trends in the production, distribution, inventories, and consumption of minerals. Frequency of issue depends on the demand for current data. Mineral Industry Surveys are released monthly, quarterly, semiannually, or annually.

Mineral Commodity Summaries, an up-to-date summary of about 80 nonfuel mineral commodities, is the earliest Government publication to furnish estimates covering the previous year's nonfuel mineral industry data. It contains information on the domestic industry structure, Government programs, tariffs, 5-year salient statistics, and a summary of international mining news.

State Mineral Summaries provide estimated data and summaries of mineral activities at the State level for the previous year. These summaries have been prepared in cooperation with State geological surveys or related agencies.

Metal Industry Indicators, published monthly, contains indexes that measure the current and future performance of four U.S. minerals industries. For each of the four industries, a composite coincident index and a composite leading index have been developed based on procedures and data similar to those used to construct the U.S. Department of Commerce's coincident and leading cyclical indicators for the national economy.

Information Circulars are primarily concerned with USBM economic reviews and interpretative analyses. The series also includes surveys of mining and operating activities, guides to marketing of mineral commodities, and compilations of historical information and statistical and economic data on minerals.

Order free copies of the Mineral Industry Surveys or the Metal Industry Indicators from Publication Distribution, U.S. Bureau of Mines, Cochrans Mill Road, P.O. Box 18070, Pittsburgh, PA 15236, (412) 892-4338.

To purchase Annual Commodity Reports, Minerals Yearbook, Mineral Commodity Summaries, and State Mineral Summaries, order from the Superintendent of Documents, U.S. Government Printing Office, Washington, DC 20402, (202) 783-3238.

Information Circulars, Mineral Commodity Summaries, and State Mineral Summaries also may be purchased from the National Technical Information Service, Springfield, VA 22161, 1-800-553 NTIS (in Virginia and foreign countries: 1-703-487-4650).

Electronic Data Dissemination

In addition to the USBM's printed publications, current Mineral Industry Surveys for all commodities and 85 annual reports from the Minerals Yearbook are now available through the USBM's MINES-DATA computer bulletin board. Using this system, the public may obtain information up to 4 weeks before published copies of the reports would arrive in the mail. The MINES-DATA system may be accessed by calling (202) 501-0373 using a modem set to 1200 or 2400 baud, 8 data bits, no parity, and 1 stop bit. Further information on how to use the MINES-DATA system may be obtained from the system operator by calling (202) 501-0406.

Also, current information on minerals and mineral-related publications from the USBM is now available through an easy-to-use automated fax response system. The MINES FaxBack service allows callers to retrieve information and order some publications for delivery to their fax machines in minutes, 24 hours per day, 7 days per week. MINES FaxBack makes monthly and quarterly Mineral Industry Surveys publications available to the public at the same time they are forwarded to the printer.

MINES FaxBack works from any Group III-compatible fax machine equipped with a touch-tone telephone (either a built-in handset with touch-tone capability or a separate touch-tone telephone plugged into the fax machine's phone jack). After calling MINES FaxBack, the requestor is guided by a series of voice messages that assist the caller in ordering the desired documents. The caller pays for the phone call that also includes the time needed to deliver the requested document to the caller's fax machine.

To access the MINES FaxBack System, use a touch-tone handset attached to a fax machine or connect a touch-tone telephone to the fax machine's telephone jack and dial (202) 219-3644. Listen to the menu options and select an option using the touch-tone telephone. After completing a selection, press the start button on the fax machine.

STATISTICAL SUMMARY

This annual report summarizes data on crude nonfuel mineral production for the United States, its island possessions, and the Commonwealth of Puerto Rico. Also included are tables that show the principal nonfuel mineral commodities exported from and imported into the United States and that compare world and U.S. mineral production. The detailed data from which these tables were derived are contained in the individual annual reports of Volume I and in the State reports of Volume II of this edition of the Minerals Yearbook.

Although crude mineral production may be measured at any of several stages of extraction and processing, the stage of measurement used in this annual report is what is termed "mine output." It usually refers to minerals or ores in the form in which they are first extracted from the ground, but customarily includes the output from auxiliary processing at or near the mines.

Because of inadequacies in the statistics available, some series deviate from the foregoing definition. For copper, gold, lead, silver, tin, and zinc, the quantities are recorded on a mine basis (as the recoverable content of ore sold or treated). However, the values assigned to these quantities are based on the average selling price of refined metal, not the mine value. Mercury is measured as recovered metal and valued at the average New York price for the metal.

The weight or volume units shown are those customarily used in the particular industries producing the commodities. Values shown are in current dollars, with no adjustments made to compensate for changes in the purchasing power of the dollar.

[1] Production as measured by mine shipments, sales, or marketable production (including consumption by producers).

[2] Recoverable content of ores, etc.

[3] Content of ore and concentrate.

[4] The Riddle nickel smelter uses lateritic ore mined on Nickel Mountain, lateritic ore imported from New Caledonia, and small tonnages of recycled Ni-bearing catalysts. In 1989, the Glenbrook Nickel Co. purchased the idled mining and smelting complex and restarted the operation. Production of ferronickel on a contained Ni basis has been as follows: 1991—7,065 metric tons (mt) valued at $57.6 million; 1992—8,962 mt valued at $62.7 million; and 1993—4,878 mt valued at $28.0 million.

[5] Rounded.

[6] Grindstones, pulpstones, and sharpening stones; excludes mill liners and grinding pebbles.

[7] Beginning in 1992; aplite is combined with feldspar.

[8] Excludes abrasive stone and bituminous limestone and sandstone; all included elsewhere in table.

[9] Canvassing discontinued beginning 1993.

TABLE 2
TOTAL U.S. NONRENEWABLE ORGANIC MATERIALS PRODUCTION, BY QUANTITY AND VALUE[1]

(Million metric tons, unless otherwise specified)

[p] Preliminary. [r] Revised.

[1] Quantities valued at the fossil fuel prices given in the Department of Energy, Energy Information Administration, Annual Energy Review 1992, June 1993, p. 71.

Note: Nonrenewable organic materials represent all nonfuel uses in physical structure applications. The petrochemical industries category includes feedstocks for the production of plastics, synthetic rubber, synthetic fibers, pesticides, coatings, solvents, fertilizers, and other petrochemicals.

TABLE 3
NONFUEL MINERALS PRODUCED IN THE UNITED STATES AND PRINCIPAL PRODUCING STATES IN 1993

Mineral	Principal producing States, in order of quantity	Other producing States
Abrasives[1]	AR, WI, OH	
Antimony[2]	ID	
Asbestos	CA and VT	
Barite	GA, NV, MO, MT	IL.
Bauxite	AL and GA	
Beryllium concentrate	UT	
Boron minerals	CA	
Bromine[e]	AR	
Brucite	NV	
Calcium chloride (natural)	(3)	
Cement:		
Masonry	FL, IN, AL, PA	All other States except AK, CT, DE, IL, LA, MA, MN, MS, MT, NV, NH, NJ, NC, ND, OR, RI, VT, WI, WY.
Portland	CA, TX, MI, PA	All other States except AK, CT, DE, LA, MA, MN, NM, NJ, NC, ND, RI, VT, WI.
Clays	GA, AL, WY, NC	All other States except AK, DE, HI, RI, VT, WI.
Copper[2]	AZ, UT, NM, MI	CO, ID, IL, MO, MT, NV, OR, TN, and WI.
Diatomite	CA, NV, WA, OR	
Emery	NY and OR	
Feldspar	NC, VA, CA, OK	GA, ID, SD.
Fluorspar	IL, TX, NV	
Garnet (abrasive)	NY and ID	
Gemstones (natural)[4]	TN, ME, AZ, AR	All other States.
Gold[2]	NV, CA, UT, SD	AK, AZ, CO, ID, MT, NM, SC, WA, WI.
Greensand marl	NJ	

See footnotes at end of table.

TABLE 3—Continued

NONFUEL MINERALS PRODUCED IN THE UNITED STATES AND PRINCIPAL PRODUCING STATES IN 1993

Mineral	Principal producing States, in order of quantity	Other producing States
Gypsum (crude)	OK, MI, IA, TX	AR, AZ, CA, CO, IN, KS, LA, NM, NV, NY, OH, SD, UT, VA, WY.
Helium (crude and Grade-A)	KS, WY, TX, CO	
Iodine	OK	
Iron ore (usable)[6]	MN, MI, MO, UT	CA, MI, MO, MT, NM, SD, TX.
Iron oxide pigments (crude)	MO, GA, VA, MI	AZ.
Kyanite	VA	
Lead[2]	MO, AK, ID, MT	CO, IL, NY, TN, WA.
Lime	TX, OH, MO, PA	All other States except AK, CT, DE, FL, GA, HI, KS, ME, MD, MS, NH, NJ, NM, NY, NC, RI, SC, VT.
Lithium minerals	NC and NV	
Magnesite	NV	
Magnesium compounds	MI, CA, DE, UT	FL and TX.
Magnesium metal	TX, UT, WA	
Manganiferous ore	SC	
Mercury	NV, UT, CA	
Mica (scrap)	NC, NM, GA, SC	SD.
Molybdenum	AZ, CO, UT, MT	NM.
Nickel ore	OR	
Olivine	WA and NC	
Palladium metal	MT	
Peat	MI, FL, MN, IL	CO, IA, IN, MA, ME, MT, NC, ND, NJ, NY, OH, PA, SC, WA, WI, WV.
Perlite	NM, AZ, CA, NV	CO.
Phosphate rock	FL, NC, ID, UT	MT.
Platinum metal	MT	
Potash	NM, UT, CA, MI	
Pumice	CA, OR, AZ, NM	ID and KS.
Pyrites (ore and concentrate)	AZ	
Rare-earth metal concentrates	CA and FL	
Salt	NY, OH, LA, MI	AL, AZ, CA, KS, NM, NV, OK, TX, UT, WV.
Sand and gravel:		
Construction	CA, OH, TX, NY	All other States.
Industrial	IL, CA, WI, NJ	All other States except AK, DE, HI, KY, ME, NH, NM, OR, SD, UT, VT, WY.
Silver[2]	NV, AZ, ID, UT	AK, CA, CO, IL, MI, MO, MT, NM, NY, SC, SD, TN, WA, WI.
Sodium compounds:		
Soda ash	WY and CA	
Sodium sulfate (natural)	CA, TX, UT	
Staurolite	FL	
Stone:		
Crushed	PA, IL, FL, NC	All other States except DE.
Dimension	VT, IN, MA, GA	All other States except AK, DE, FL, HI, KY, LA, MS, NE, NV, NJ, ND, OR, RI, WV, WY.

See footnotes at end of table.

TABLE 3—Continued

NONFUEL MINERALS PRODUCED IN THE UNITED STATES AND PRINCIPAL PRODUCING STATES IN 1993

Mineral	Principal producing States, in order of quantity	Other producing States
Sulfur (Frasch)	TX and LA	
Talc and pyrophyllite	MT, NY, TX, VT	AR, CA, NC, OR, VA.
Tin	AK	
Titanium concentrates	FL and CA	
Tripoli	IL, WI, AR, OK	PA.
Tungsten[2]	CA	
Vanadium[2]	ID	
Vermiculite (crude)	SC and VA	
Wollastonite	NY	
Zeolites	TX, NM, OR, AZ	ID.
Zinc[2]	AK, TN, NY, MO	CO, ID, IL, MT, WA.
Zircon concentrates	FL	

[e] Estimated.

[1] Grindstones, pulpstones, and sharpening stones; excludes mill liners and grinding pebbles.

[2] Content of ores, etc.

[3] Canvassing discontinued.

[4] Principal producing States based on value.

[5] No production reported.

[6] Includes byproduct material.

TABLE 4

VALUE OF NONFUEL MINERAL PRODUCTION IN THE UNITED STATES AND PRINCIPAL NONFUEL MINERALS PRODUCED IN 1993

State	Value (thousands)	Rank	Percent of U.S. total	Principal minerals, in order of value
Alabama	$561,776	18	1.76	Cement (portland), stone (crushed and broken), lime, sand and gravel (construction).
Alaska	377,616	29	1.18	Zinc, sand and gravel (construction), gold, lead.
Arizona	2,775,840	2	8.70	Copper, sand and gravel (construction), cement (portland), molybdenum.
Arkansas	347,081	30	1.09	Bromine, stone (crushed and broken), sand and gravel (construction), cement (portland).
California	2,440,234	3	7.65	Sand and gravel (construction), gold, boron.
Colorado	399,485	25	1.25	Sand and gravel (construction), cement (portland), stone (crushed and broken), gold.
Connecticut	90,676	44	.28	Stone (crushed and broken), sand and gravel (construction), sand and gravel (industrial), clays.
Delaware[1]	10,301	50	.03	Sand and gravel (construction), magnesium compounds, gemstones.
Florida	1,310,623	8	4.11	Phosphate rock, stone (crushed and broken), cement (portland), sand and gravel (construction).
Georgia	1,431,718	6	4.49	Clays, stone (crushed and broken), cement (portland), barite.
Hawaii	138,704	41	.43	Stone (crushed and broken), cement (portland), sand and gravel (construction), cement (masonry).
Idaho	274,210	35	.86	Phosphate rock, sand and gravel (construction), gold, silver.

See footnotes at end of table.

TABLE 4—Continued

VALUE OF NONFUEL MINERAL PRODUCTION IN THE UNITED STATES AND PRINCIPAL NONFUEL MINERALS PRODUCED IN 1993

State	Value (thousands)	Rank	Percent of U.S. total	Principal minerals, in order of value
Illinois	$734,305	16	2.30	Stone (crushed and broken), sand and gravel (construction), cement (portland), sand and gravel (industrial).
Indiana	472,994	22	1.48	Stone (crushed and broken), cement (portland), sand and gravel (construction), lime.
Iowa	397,526	26	1.25	Stone (crushed and broken), cement (portland), sand and gravel (construction), gypsum.
Kansas	442,112	24	1.39	Helium (Grade-A), salt, stone (crushed and broken), cement (portland).
Kentucky	387,503	28	1.21	Stone (crushed and broken), lime, cement (portland), sand and gravel (construction).
Louisiana	231,609	37	.73	Salt, sand and gravel (construction), sulfur (Frasch), sand and gravel (industrial).
Maine	60,128	45	.19	Sand and gravel (construction), cement (portland), stone (crushed and broken), gemstones.
Maryland	313,519	32	.98	Stone (crushed and broken), cement (portland), sand and gravel (construction), cement (masonry).
Massachusetts	160,212	39	.50	Stone (crushed and broken), sand and gravel (construction), stone (dimension), lime.
Michigan	1,504,245	4	4.71	Iron ore (usable), cement (portland), sand and gravel (construction), magnesium compounds.
Minnesota	1,298,724	9	4.07	Iron ore (usable), sand and gravel (construction), stone (crushed and broken), sand and gravel (industrial).
Mississippi[1]	103,651	43	.32	Sand and gravel (construction), clays, cement (portland), stone (crushed and broken).
Missouri	855,424	12	2.68	Stone (crushed and broken), cement (portland), lead, lime.
Montana	484,030	21	1.52	Gold, copper, cement (portland), sand and gravel (construction).
Nebraska	126,176	42	.40	Cement (portland), sand and gravel (construction), stone (crushed and broken), lime.
Nevada	2,828,551	1	8.86	Gold, sand and gravel (construction), silver, diatomite.
New Hampshire	37,193	47	.12	Sand and gravel (construction), stone (dimension), stone (crushed and broken), clays.
New Jersey	262,347	36	.82	Stone (crushed and broken), sand and gravel (construction), sand and gravel (industrial), clays.
New Mexico	804,049	15	2.52	Copper, potash, sand and gravel (construction), cement (portland).
New York	851,507	13	2.67	Stone (crushed and broken), salt, sand and gravel (construction), cement (portland).
North Carolina	617,390	17	1.93	Stone (crushed and broken), phosphate rock, lithium minerals, sand and gravel (construction).
North Dakota	25,043	48	.08	Sand and gravel (construction), lime, sand and gravel (industrial), clays.
Ohio	850,634	14	2.67	Stone (crushed and broken), sand and gravel (construction), salt, lime.
Oklahoma	298,339	34	.93	Stone (crushed and broken), cement (portland), sand and gravel (construction), sand and gravel (industrial).
Oregon	226,108	38	.71	Stone (crushed and broken), sand and gravel (construction), cement (portland), diatomite.

See footnotes at end of table.

TABLE 4—Continued

VALUE OF NONFUEL MINERAL PRODUCTION IN THE UNITED STATES AND PRINCIPAL NONFUEL MINERALS PRODUCED IN 1993

State	Value (thousands)	Rank	Percent of U.S. total	Principal minerals, in order of value
Pennsylvania	$913,162	10	2.86	Stone (crushed and broken), cement (portland), lime, sand and gravel (construction).
Rhode Island[1]	23,152	49	.07	Sand and gravel (construction), stone (crushed and broken), sand and gravel (industrial), gemstones.
South Carolina	391,047	27	1.23	Stone (crushed and broken), cement (portland), gold, clays.
South Dakota	337,156	31	1.06	Gold, cement (portland), sand and gravel (construction), stone (crushed and broken).
Tennessee	509,665	19	1.60	Stone (crushed and broken), zinc, cement (portland), sand and gravel (construction).
Texas	1,448,113	5	4.54	Cement (portland), stone (crushed and broken), sand and gravel (construction), magnesium metal.
Utah	1,313,537	7	4.12	Copper, gold, magnesium metal, cement (portland).
Vermont[1]	52,706	46	.17	Stone (dimension), stone (crushed and broken), sand and gravel (construction), talc and pyrophyllite.
Virginia	464,747	23	1.46	Stone (crushed and broken), cement (portland), sand and gravel (construction), lime.
Washington	505,193	20	1.58	Sand and gravel (construction), magnesium metal, gold, stone (crushed and broken).
West Virginia	149,452	40	.47	Stone (crushed and broken), cement (portland), sand and gravel (construction), salt.
Wisconsin	313,312	33	.98	Stone (crushed and broken), sand and gravel (construction), copper, sand and gravel (industrial).
Wyoming	856,485	11	2.68	Soda ash, clays, helium (Grade-A), cement (portland).
Undistributed	102,530	—	.32	
Total[2]	31,912,000	XX	100.00	

XX Not applicable.

[1] Partial total, excludes values that must be concealed to avoid disclosing company proprietary data. Concealed values included with "Undistributed" figure.

[2] Rounded.

TABLE 5

VALUE OF NONFUEL MINERAL PRODUCTION PER CAPITA AND PER SQUARE MILE IN 1993, BY STATE

State	Area (square miles)	Population (thousands)	Total value (thousands)	Per square mile		Per capita

TABLE 6—Continued

NONFUEL MINERAL PRODUCTION[1] IN THE UNITED STATES, BY STATE

Mineral	1991 Quantity	1991 Value (thousands)	1992 Quantity	1992 Value (thousands)	1993 Quantity	1993 Value (thousands)
UNDISTRIBUTED						
Delaware, Hawaii (1991-92), Mississippi (1993), New Hampsire (1991-92), North Dakota (1991), Rhode Island, Vermont, Wisconsin (1991-92), and Undistributed (1991)	XX	[r]$77,972	XX	[r]$94,923	XX	$102,530

[e] Estimated. [r] Revised. NA Not available. W Withheld to avoid disclosing company proprietary data, value included with "Combined value" data. XX Not applicable.
[1] Production as measured by mine shipments, sales, or marketable production (including consumption by producers).
[2] Excludes certain clays; kind and value included with "Combined value" data.
[3] Excludes certain stones; kind and value included with "Combined value" data.
[4] Recoverable content of ores, etc.
[5] Grindstones, pulpstones, and sharpening stones; excludes mill liners and grinding pebbles.
[6] Less than 1/2 unit.
[7] Calcium chloride (natural) canvassing discontinued beginning 1993.
[8] Partial total, excludes values that must be concealed to avoid disclosing company proprietary data. Values excluded from partial total included with "Undistributed States."
[9] Value excluded to avoid disclosing company proprietary data.
[10] Excludes salt in brines; value included with "Combined value" data.
[11] The Riddle nickel smelter uses lateritic ore mined on Nickel Mountain, lateritic ore imported from New Caledonia, and small tonnages of recycled Ni-bearing catalysts. In 1989, the Glenbrook Nickel Co. purchased the idled mining and smelting complex and restarted the operation. Production of ferronickel on a contained Ni basis has been as follows: 1991—7,060 metric tons (mt) valued at $57.6 million; 1992—8,962 mt valued at $62.7 million; and 1993—4,878 mt valued at $28.0 million.
[12] Aplite combined with feldspar beginning 1992.

Ships, boats, and other vessels for scrapping	do.	92	7,622	162	13,213
Used rails for rerolling and other uses (contains used plus new rails)	do.	22	5,998	43	11,760
Lead:					
Ash and residues (lead content)	do.	2,141	1,031	1,728	1,326
Ore and concentrate (lead content)	do.	72,323	22,202	41,766	7,839
Scrap	do.	63,212	15,165	54,101	14,431
Unwrought metal and alloys (lead content)	do.	64,340	44,624	51,443	32,240
Wrought metal and alloys (lead content)	do.	5,251	19,637	7,141	19,703
Magnesium:					
Alloys	do.	1,473	5,365	1,953	8,219
Metal	do.	35,824	96,221	26,518	71,852
Powder, sheets, tubing, ribbons, wire, and other forms	do.	12,158	24,367	8,337	18,772
Waste and scrap	do.	2,496	5,907	2,007	4,636
Manganese:					
Ferromanganese (all grades)	do.	13,404	12,996	18,040	14,842
Metal (including alloys, waste, and scrap)	do.	5,005	11,946	3,835	9,397
Ore and concentrates	do.	13,086	2,295	15,923	1,791
Silicomanganese	do.	9,171	6,500	9,420	6,717
Mercury	do.	977	2,760	389	1,229
Molybdenum (molybdenum content):					
Ferromolybdenum	do.	^{r}320	^{r}4,404	224	2,958
Ore and concentrates	do.	^{r}33,439	125,405	28,280	74,225
Oxides and hydroxides	do.	^{r}557	^{r}2,890	1,042	5,611
Molybdates (all)	do.	1,030	4,976	958	4,783
Powder	do.	350	5,811	226	4,191
Unwrought	do.	74	640	52	801
Wire	do.	^{r}356	14,972	260	10,266
Wrought	do.	144	5,772	93	4,791

See footnotes at end of table.

TABLE 8—Continued
U.S. EXPORTS OF PRINCIPAL MINERALS AND PRODUCTS, EXCLUDING MINERAL FUELS

Mineral		1992		1993	
		Quantity	Value (thousands)	Quantity	Value (thousands)
METALS—Continued					
Nickel (nickel content):					
Alloyed (bars, foil, ingot [unwrought], pipes, profiles, rods, sheets, strip, tubes, wire, and other articles)	metric tons	15,184	$208,105	14,941	$230,359
Unwrought:					
Primary (briquets, cathodes, chemicals [catalysts and salts], ferronickel, flakes, oxide (metallurgical grade), pellets, powder, and shot)	do.	8,560	84,175	7,183	80,137
Secondary (scrap [stainless steel and waste])	do.	25,307	187,797	26,016	187,904
Wrought (bars, foil, pipes, profiles, rods, sheets, strips, tubes, and wire)	do.	447	7,955	551	5,755
Platinum-group metals (concentrates, iridium, ores, osmium, palladium, platinum, rhodium, ruthenium, and waste and scrap)	kilograms	[r]57,830	382,016	78,521	441,053
Rare-earth metals (rare-earth oxide content):					
Cerium compounds	do.	1,935,021	10,089	1,621,942	11,717
Compounds (inorganic and organic)	do.	1,306,463	12,771	1,087,584	14,123
Ferrocerium and pyrophoric alloys	do.	2,737,342	15,842	4,806,785	20,382
Metals (includes scandium and yttrium)	do.	36,452	1,098	161,421	2,395
Selenium (metal, waste and scrap, selenium content)	do.	174,788	1,658	261,393	2,195
Silicon:					
Ferrosilicon	metric tons	55,996	45,825	39,506	36,759
Metal	do.	8,531	93,813	10,618	133,297
Silver:					
Bullion (refined)	kilograms	910,587	125,531	705,225	100,191
Doré and precipitates	do.	88,894	16,104	103,289	16,032
Ores and concentrates	do.	8,505	1,503	2,269	395
Waste and scrap	do.	745,221	110,381	892,407	141,921
Tantalum:					
Ores and concentrates (includes synthetic)	thousand kilograms	19	50	11	111
Unwrought (alloys, metal, powders, and waste and scrap)	do.	131	24,329	242	24,876
Wrought	do.	66	22,668	50	18,674
Thorium:					
Compounds	kilograms	93	12	189	68
Ore (monazite concentrate)	do.	5,000	11	W	W
Tin:					
Ingots and pigs	metric tons	1,888	8,957	2,598	11,377
Tin scrap and other tin bearing material (except tinplate scrap, includes bars, rods, profiles, wire, powders, flakes, tubes, and pipes)	do.	127,191	89,298	92,585	63,240
Tinplate and terneplate	do.	272,549	162,302	200,794	120,068
Titanium:					
Metal:					
Scrap	do.	2,770	7,201	3,892	9,074
Sponge	do.	178	1,102	104	748
Other unwrought (billet, blooms and sheet bars, ingots, etc.)	do.	2,640	43,372	1,511	27,113
Wrought (bars, rods, etc.)	do.	2,431	[r]81,027	2,386	72,678
Ores and concentrates	do.	34,665	10,566	15,202	4,893
Pigments (dioxides and oxides)	do.	270,422	420,372	290,192	405,165

See footnotes at end of table.

U.S. EXPORTS OF PRINCIPAL MINERALS AND PRODUCTS, EXCLUDING MINERAL FUELS

Mineral		1992		1993	
		Quantity	Value (thousands)	Quantity	Value (thousands)
METALS—Continued					
Tungsten (tungsten content):					
Ammonium paratungstate	metric tons	470	$3,354	166	$2,211
Carbide powder	do.	715	18,098	1,250	22,484
Metal and alloy powder	do.	316	8,380	416	7,859
Miscellaneous tungsten-bearing materials (ferrotungsten and ferrosilicon tungsten, unwrought, wire [metal and alloy], wrought, other compounds [other tungstates], and other metal)	do.	684	28,332	550	24,029
Ore and concentrate	do.	38	284	63	309
Vanadium:					
Aluminum-vanadium master alloy	kilograms	545,198	9,564	865,291	10,757
Compounds (pentoxide [anhydride], and other [excludes vanadates], vanadium content)	do.	1,138,653	4,921	1,020,590	5,255
Ferrovanadium	do.	325,656	3,727	290,845	2,776
Zinc:					
Compounds (chloride, lithopone, oxide, sulfate, sulfide, and compounds n.s.p.f.)	metric tons	16,081	59,593	17,270	50,400
Ore and concentrates	do.	[r]307,118	[r]212,203	311,278	117,137
Zirconium:					
Ore and concentrates	do.	27,853	14,323	35,932	13,177
Unwrought and waste and scrap	do.	389	13,070	248	6,145
Total[1]		XX	18,450,000	XX	22,387,000
INDUSTRIAL MINERALS					
Abrasive materials (includes reexports):					
Natural		XX	177,542	XX	202,549
Manufactured		XX	205,732	XX	218,741
Asbestos (includes reexports):					
Manufactured		XX	134,102	XX	141,087
Unmanufactured	metric tons	24,860	6,724	27,643	8,435
Barite: Natural barium sulfate	do.	12,469	1,806	18,486	2,608
Boron:					
Boric acid	thousand metric tons	80	53,652	74	50,498
Sodium borates	do.	489	159,492	481	181,310
Bromine:					
Compounds (contained bromine)	thousand kilograms	16,946	26,445	13,351	21,750
Elemental	do.	5,320	5,542	6,013	7,441
Calcium chloride	metric tons	38,365	8,808	(2)	(2)
Cement: Hydraulic and clinker	thousand metric tons	747	48,720	625	47,772
Clays:					
Ball	do.	49	3,120	60	3,197
Bentonite	do.	591	53,652	606	55,392
Fire clay	do.	228	23,537	148	14,842
Fuller's earth	do.	27	4,022	63	7,632
Kaolin	do.	3,000	490,869	2,984	488,053
Other (includes chamotte or dinas earth, activated clays and earths, and artificially activated clays)	do.	262	88,278	293	100,404

See footnotes at end of table.

TABLE 8—Continued

U.S. EXPORTS OF PRINCIPAL MINERALS AND PRODUCTS, EXCLUDING MINERAL FUELS

Mineral		1992		1993	
		Quantity	Value (thousands)	Quantity	Value (thousands)
INDUSTRIAL MINERALS—Continued					
Diatomite	thousand metric tons	163	$50,704	165	$49,874
Feldspar	metric tons	17,700	2,212	17,669	1,835
Fluorspar	do.	13,646	1,983	12,739	2,126
Gemstones (includes reexports):					
Diamonds (excludes industrial diamond)	carats	[r]1,924,578	[r]1,361,400	1,630,447	1,499,100
Other precious stones (cut but unset, or rough other than diamonds, pearls, and synthetics)		XX	241,200	XX	103,100
Synthetic		XX	21,200	XX	19,300
Natural, cultured, and imitation pearls (not set or strung)		XX	6,700	XX	7,300
Graphite:					
Artifical (includes artifical, and colloidal or semicolloidal)[3]	metric tons	34,487	32,689	17,358	11,149
Natural (amorphous, crystalline flake, lump or chip, and natural n.e.c.)	do.	20,217	12,244	35,039	30,851
Gypsum:					
Boards	thousand metric tons	137	39,177	91	24,618
Crude	do.	98	3,946	69	3,640
Plasters	do.	137	22,303	156	21,173
Other	do.	XX	31,557	XX	28,198
Helium (Grade-A)	million cubic meters	31	72,108	28	67,000
Iodine:					
Crude-resublimed	thousand kilograms	1,625	15,139	1,016	8,557
Potassium iodide	do.	182	402	203	1,178
Iron oxide pigments:					
Pigment grade	metric tons	21,117	32,173	22,368	32,022
Other grade	do.	172,162	115,935	139,461	92,539
Lime	do.	58,513	7,540	69,045	7,825
Lithium compounds:					
Carbonate	kilograms	8,225,957	27,008	6,255,942	22,238
Hydroxide	do.	2,911,116	13,183	3,058,801	13,176
Metal	do.	62,232	NA	NA	NA
Magnesium compounds:					
Calcined dolomite	metric tons	19,584	3,314	13,744	2,818
Caustic-calcined magnesia	do.	5,262	2,404	4,453	2,459
Compounds (chlorides, hydroxide and peroxide, and sulfates)	do.	9,586	8,253	9,892	7,932
Dead-burned and fused magnesia	do.	56,758	22,257	59,847	21,807
Magnesite (crude)	do.	5,926	[r]4,218	7,390	2,911
Other magnesia	do.	19,075	11,540	22,014	11,148
Mica:					
Scrap and flake:					
Powder	do.	3,954	2,054	4,614	2,604
Waste	do.	475	204	335	99
Sheet:					
Unworked	do.	170	307	292	511
Worked	do.	436	7,180	617	9,019
Nitrogen compounds (major):					
Anhydrous ammonia	thousand metric tons	431	NA	460	NA

See footnotes at end of table.

Mineral		1992		1993	
		Quantity	Value (thousands)	Quantity	Value (thousands)
METALS—Continued					
Copper—Continued:					
Sulfate	metric tons	8,290	NA	9,431	NA
Unmanufactured (anode, ash, blister, concentrates, matte, ore, precipitates, and refined, copper content)	do.	457,233	$923,815	480,251	$919,870
Gallium (unwrought, waste and scrap)	kilograms	8,479	3,126	15,585	4,128,242
Germanium materials	do.	13,229	4,871	15,499	5,295
Gold:					
Bullion (refined)	do.	141,251	1,568,186	130,045	1,495,434
Doré and precipitates	do.	17,092	175,542	12,539	134,904
Ore and concentrates	do.	351	3,877	1,240	13,531
Waste and scrap	do.	15,649	66,376	25,480	65,360
Hafnium (unwrought, and waste and scrap)	metric tons	2	431	3	669
Indium (unwrought, and waste and scrap)	kilograms	54,417	10,824	73,426	11,464
Iron ore:					
Pellets	thousand metric tons	8,880	314,372	9,794	332,973
Usable (agglomerates, byproduct ore, concentrates, and direct-shipping ore, [less than 5% manganese])	do.	12,504	395,791	14,097	420,799
Iron and steel:					
Direct-reduced iron	metric tons	544,715	56,445	924,046	90,796
Ferroalloys not elsewhere listed:					
Ferrophosphorus	do.	7,492	1,920	9,973	2,325
Ferrotitanium and ferrosilicon-titanium	do.	1,357	3,202	45,428	8,068
Ferrozirconium	do.	1	2	267	506
Ferroalloys (n.e.c.)	do.	16,518	23,830	16,521	34,909
Pig iron	do.	496,547	[r]72,784	828,168	116,736
Products:					
Cast	thousand metric tons	191	196,428	228	217,478
Fabricated	do.	1,762	2,887,517	2,054	3,756,072
Steel mill	do.	15,490	7,892,621	17,691	8,626,028
Other steel	do.	NA	NA	28	59,709
Scrap:					
Iron and steel	do.	1,316	147,616	1,545	175,825
Ships, boats, and other vessels for scrapping	do.	([1])	31	([1])	82
Used rails for rerolling and other uses	do.	78	15,583	70	13,571
Stainless steel (bars, pipe, plate, semifinished, shapes, sheet, strip, tube, wire and wire rods)	metric tons	400,077	NA	611,030	NA
Lead:					
Base bullion (lead content)	do.	218	94	18	62
Ore and concentrates (lead content)	do.	5,310	3,422	483	347
Pigments and compounds	do.	30,239	36,197	30,892	33,640
Pigs and bars (lead content)	do.	190,723	106,433	195,572	85,100
Scrap (reclaimed, includes ash and residues, lead content)	do.	236	65	90	39
Wrought (all forms, including wire and powders, gross weight)	do.	7,094	10,548	6,889	10,288

See footnotes at end of table.

TABLE 9—Continued

U.S. IMPORTS FOR CONSUMPTION OF PRINCIPAL MINERALS AND PRODUCTS, EXCLUDING MINERAL FUELS

Mineral	1992		1993	
	Quantity	Value (thousands)	Quantity	Value (thousands)
METALS—Continued				
Magnesium:				
Alloys (magnesium content) metric tons	3,839	$14,545	8,084	$27,544
Metal do.	4,244	11,030	24,236	53,100
Powder, sheets, tubing, ribbons, wire, and other forms (magnesium content) do.	1,336	4,281	1,469	4,622
Waste and scrap do.	2,425	2,821	3,459	4,522
Manganese:				
Chemicals (manganese dioxide and potassium permanganate) do.	22,193	33,024	25,397	38,200
Metal do.	13,952	21,991	15,124	22,476
Ore and concentrates (manganese content) do.	240,800	59,934	231,540	49,855
Ferromanganese (all grades, manganese content) do.	476,940	333,631	541,939	335,190
Silicomanganese (manganese content) do.	169,047	118,464	208,266	133,413
Mercury (metal, mercury-bearing waste and scrap) do.	92	403	40	143
Molybdenum (molybdenum content):				
Ferromolybdenum do.	1,096	6,974	2,190	12,725
Molybdates (all) do.	86	763	317	2,634
Ore and concentrates do.	831	4,081	3,398	16,976
Oxides and hydroxides (gross weight) do.	1,032	3,928	622	2,875
Powder do.	52	1,784	52	2,086
Unwrought do.	46	1,437	136	1,753
Wire (gross weight) do.	1	177	3	308
Wrought (gross weight) do.	46	3,004	49	3,426
Other (inorganic compounds, orange, waste and scrap, and other, gross weight) do.	1,029	4,476	1,879	5,549
Nickel (nickel content):				
Alloyed (bars, foil, ingot [unwrought], pipes, profiles, rods, sheets, strips, tubes, wires, and other articles) do.	5,944	72,517	7,049	80,827
Ore do.	3,584	W	2,966	W
Unwrought:				
Primary (briquets, cathodes, chemicals [catalysts and salts], ferronickel, flakes, oxide [metallurgical grade], pellets, powder and shot) do.	118,760	871,086	126,352	739,305
Secondary (scrap [stainless steel and waste]) do.	9,506	47,791	6,713	39,305
Wrought (bars, foil, pipes, profiles, rods, sheets, strips, tubes, and wire) do.	951	15,319	991	15,436
Platinum-group metals (iridium, ores, osmium, palladium, platinum, rhodium, ruthenium, ores, and waste and scrap) kilograms	132,006	1,483,680	153,165	1,310,895
Rare-earth metals (rare-earth oxide content):				
Cerium compounds (includes chlorides, hydroxides, nitrates, oxides, oxilate, and sulfates) do.	[r]806,241	[r]8,010	1,267,784	10,025
Compounds (includes hydroxides, nitrates, oxides, and others, except chlorides) do.	[r]4,132,819	[r]34,572	4,976,002	39,401
Chloride mixtures (except cerium chloride) do.	1,583,402	7,692	2,355,802	8,088
Ferrocerium and other pyrophoric alloys do.	105,630	1,613	118,082	1,654
Oxide mixtures (except cerium oxides) do.	294,971	14,853	249,493	10,557
Rare-earth metals (whether intermixed or alloyed) do.	[r]293,093	[r]3,167	195,866	2,644

See footnotes at end of table.

U.S. IMPORTS FOR CONSUMPTION OF PRINCIPAL MINERALS AND PRODUCTS, EXCLUDING MINERAL FUELS

Mineral		1992		1993	
		Quantity	Value (thousands)	Quantity	Value (thousands)
METALS—Continued					
Rhenium:					
Ammonium perrhenate	kilograms	5,694	$2,833	3,168	$1,601
Metal	do.	6,385	7,522	2,698	3,333
Selenium: (selenium content)					
Selenium dioxide	do.	9,484	196	14,518	143
Unwrought, and waste and scrap	do.	361,043	6,776	367,195	6,884
Silicon:					
Ferrosilicon	metric tons	247,601	113,911	20,014	110,528
Metal	do.	32,716	92,734	72,232	125,613
Silver:					
Bullion (refined)	kilograms	2,661,622	340,898	2,183,146	296,716
Doré and precipitates	do.	528,715	102,118	281,217	78,590
Ore and concentrates	do.	25,352	3,885	35,692	6,405
Waste and scrap	do.	1,774,085	54,492	1,270,486	46,036
Tantalum:					
Ores and concentrates (includes synthetic)	thousand kilograms	1,367	35,600	1,294	32,740
Unwrought (alloys, metal, powders, and waste and scrap)	do.	103	5,757	165	14,770
Wrought	do.	2	768	3	547
Tellurium (unwrought, and waste and scrap)	kilograms	48,384	3,700	44,997	3,183
Thallium (unwrought waste and scrap)	do.	838	NA	273	35
Thorium:					
Compounds	do.	13,505	526	18,330	479
Ore metal (excludes monazite)	do.	186,803	36	—	—
Tin:					
Compounds	metric tons	510	3,883	431	3,145
Metal (unwrought)	do.	27,314	163,023	33,682	174,497
Miscellaneous tin and tin manufactures (alloys [n.s.p.f.], dross, flitters, foil, metallics, powder, residues, scrap, skimmings, and manufactures [n.s.p.f.])	do.	XX	60,208	XX	30,305
Tinplate and terneplate	do.	[r]295,231	200,534	237,356	160,714
Tinplate scrap	do.	28,500	7,070	12,559	1,424
Titanium:					
Concentrates:					
Ilmenite	do.	294,585	20,414	301,447	18,426
Rutile (natural and synthetic)	do.	317,399	129,758	371,481	135,028
Titaniferous iron ore	do.	32,381	1,564	66,253	2,854
Titanium slag	do.	537,118	155,943	475,522	150,401
Metal:					
Ingots and billets	do.	241	2,062	272	3,034
Powder	do.	50	886	37	813
Unwrought	do.	684	5,363	2,163	10,473
Waste and scrap	do.	6,257	19,436	5,519	18,105
Wrought (bars, castings, foil, pipes, plates, profiles, rods, sheet, strip, tubes, wire, and other)	do.	456	12,830	600	17,237
Other (includes bars, blooms, sheet, slabs, and other unwrought)	do.	78	491	131	761
Pigments (dioxides and oxides)		169,260	284,843	171,939	284,046

See footnotes at end of table.

TABLE 9—Continued

U.S. IMPORTS FOR CONSUMPTION OF PRINCIPAL MINERALS AND PRODUCTS, EXCLUDING MINERAL FUELS

Mineral		1992		1993	
		Quantity	Value (thousands)	Quantity	Value (thousands)
METALS—Continued					
Tungsten (tungsten content):					
Ammonium paratungstate	metric tons	378	$2,647	1,176	$6,481
Ferrotungsten	do.	414	2,194	652	2,827
Miscellaneous tungsten-bearing materials (carbide, chlorides, oxides, unwrought, tungstates [calcium and sodium], waste and scrap, wrought, and other tungsten-bearing material)	do.	3,375	50,152	3,960	42,306
Ore and concentrates	do.	2,477	16,265	1,721	7,843
Vanadium:					
Ferrovanadium (vanadium content)	kilograms	592,490	7,038	1,627,897	12,235
Pentoxide (anhydride, vanadium content)	do.	205,956	1,364	69,830	381
Vanadium-bearing materials (ash, residues, slag, other [includes spent catalyst], pentoxide content)	do.	1,495,199	3,500	2,594,973	3,316
Zinc:					
Compounds (chloride, lithopone, oxide, sulfate, sulfide, and compounds n.s.p.f.)	metric tons	49,072	59,594	48,572	53,210
Zirconium:					
Ore and concentrates	do.	37,439	6,906	70,035	9,323
Unwrought and waste and scrap	do.	115	821	121	1,164
Total[2]		XX	24,938,000	XX	30,989,000
INDUSTRIAL MINERALS					
Abrasive materials (natural and artificial)		XX	482,134	XX	529,003
Asbestos (unmanufactured)	metric tons	31,602	7,210	30,840	6,956
Barite:					
Barium chemicals	do.	32,173	24,322	30,347	24,520
Crude and ground	do.	353,665	17,324	803,766	34,180
Boron (contained boric oxide):					
Borax	thousand metric tons	16	5,328	40	1,226
Boric acid	do.	6	4,337	17	11,910
Colemanite	do.	30	[r]16,050	90	48,600
Ulexite	do.	42	[r]11,340	149	40,677
Bromine:					
Compounds (contained bromine)	thousand kilograms	14,646	32,559	18,399	47,741
Elemental	do.	851	522	850	513
Calcium:					
Metal	kilograms	815,264	4,452	(3)	(3)
Chloride (crude)	metric tons	128,253	17,653	(3)	(3)
Other compounds	do.	69,818	32,825	(3)	(3)
Cement: Hydraulic and clinker	thousand metric tons	[r]6,166	297,174	7,060	331,337
Clays:					
Kaolin (China clay)	do.	4,221	2,122	7,622	3,461
Fire clay	do.	8,089	937	1,096	282
Fuller's earth and decolorizing earths	do.	160	31	101	29
Bentonite	do.	2,527	1,257	1,994	664
Ball and common blue clay	do.	753	262	687	228
Other (chamotte or dina's earth, artifically activated clay and activated earth)	do.	25,553	10,926	27,930	12,900

See footnotes at end of table.

TABLE 10—Continued

COMPARISON OF WORLD AND U.S. PRODUCTION OF SELECTED NONFUEL MINERAL COMMODITIES

---

[e] Estimated. [r] Revised. NA Not available. W Withheld to avoid disclosing company proprietary data.

[1] The world production totals on commodities for which U.S. data are withheld exclude U.S. production; therefore percent of world production cannot be reported.

[2] Content of ore and concentrate.

[3] U.S. figures represent dried bauxite equivalent of crude ore; to the extent possible, individual country figures that are included in the world total are also on the dried bauxite basis, but for some countries available data are insufficent to permit this adjustment.

[4] World total does not include an estimate for output in China.

[5] Shipments.

[6] World total does not include estimates for output in the former U.S.S.R. or China.

[7] Less than 1/2 unit.

[8] Includes total production of refined copper, whether produced by pyrometallurgical or electrolytic refining methods and whether derived from primary unrefined copper or from scrap. Copper cathode derived from electrowinning processing is also included.

[9] Includes bullion.

[10] Refined nickel plus nickel content of ferronickel, nickel oxide, and other nickel salts.

[11] Includes tin content of alloys made directly from ore.

[12] Quantity sold or used by producers.

[13] Data for the United States include Puerto Rico.

[14] Synthetic anhydrous ammonia; excludes coke oven byproduct ammonia.

[15] Data for the United States exclude proprietary amounts of fuel peat.

[16] World total does not include an estimate for output in the former U.S.S.R.

[17] Data for the United States exclude proprietary pyrophyllite production.

Approval Expires: 12/31/93

INDIVIDUAL COMPANY DATA-PROPRIETARY

Unless authorization is granted in the section above the signature, the data furnished in this report will be treated in confidence by the Department of the Interior, except that they may be disclosed to Federal defense agencies or to the Congress upon official request for appropriate purposes.

UNITED STATES
DEPARTMENT OF THE INTERIOR
BUREAU OF MINES
WASHINGTON, D.C. 20241

IRON ORE (Usable ore)

FACSIMILE NUMBER
1-800-543-0661

(Please correct if name or address has changed.)

Public reporting burden for this collection of information is estimated to average 30 MINUTES per response, including the time for reviewing instructions, searching data sources, gathering and maintaining the data needed, and completing and reviewing the collection of information. Send comments regarding this burden estimate or any other aspect of this collection of information, including suggestions for reducing this burden to: Bureau of Mines, Branch of Statistics and Methods Development, Washington D.C. 20241; and Office of Information and Regulatory Affairs, Office of Management and Budget, Washington D.C. 20503.

Please complete and return this form in the enclosed envelope by the 15th of the month following the report period. Additional forms are available upon request.

In completing this form, reasonable estimates may be used wherever exact figures are not available. Use zero (0) when appropriate. DO NOT REPORT DECIMALS OR FRACTIONS.

"Collection of non-fuel minerals information is authorized by Public Law 96-479 and the Defense Production Act. This information is used to support executive policy decisions pertaining to emergency preparedness and defense and analyses for minerals legislation and industrial trends. The Bureau relies on your voluntary and timely response to assure that its information is complete and accurate."

SECTION 1. Mine or group covered by this report.

Name ____________________ State ____________ County ____________

SECTION 2. Stocks, production, and shipments of usable ore for the report month.
Report only ore products as shipped to consumer, such as direct-shipping ore, concentrates, or agglomerates.
Report ores produced in the United States only; do not include imports.

Usable ore (1)	Code	Weight unit Mark (X) one (2)		Physical inventory Adjustment only (3)	Beginning stocks (4)	Production (5)	Shipments (6)	Ending stocks (7)
		Long tons (4)	Metric tons (6)					
Iron ore (Containing less than 5% Mn, natural) ..	201							

SECTION 3. Please indicate any mines opened or closed by your company during the month. ____________

Remarks:

Name of person to be contacted regarding this report			Tel. area code	No.	Ext.
Address	No.	Street	City	State	Zip

May tabulations be published which could indirectly reveal the data reported above? ☐ (1) Yes ☐ (2) No

Signature Title Date

MINING AND QUARRYING TRENDS IN THE METALS AND INDUSTRIAL MINERALS INDUSTRIES

By Donald P. Mickelsen and Jean K. Moore

Mr. Mickelsen, a supervisory data analyst with 22 years of U.S. Bureau of Mines experience, has been with the Branch of Data Collection and Coordination since 1991. Survey data were prepared by Miss Moore, an industry data analyst with 23 years of U.S. Bureau of Mines experience.

The mining and quarrying trends data shown in this report were reported to the U.S. Bureau of Mines (USBM) by mining and quarrying companies on the Mine Information Supplement survey, as well as by mineral producers on 58 annual USBM production and consumption surveys covering 59 nonfuel mineral commodities. The 1993 data, presented in the tables of this chapter, were processed for the first time using the USBM Automated Mineral Information System.

Domestic mining of nonfuel mineral materials totaled 3.7 billion metric tons in 1993, including 2.2 billion tons of crude ore mined or quarried and 1.5 billion tons of mine waste and ore from development. This was an overall increase of 11% over that of 1992. These data do not include construction sand and gravel which until 1993 has been surveyed biennially. Starting in 1994, construction sand and gravel and the stones, which were also surveyed biennially, will be surveyed annually.

Of the nonfuel mineral materials mined, 57% was for the production of metals and 43% was for the production of industrial minerals. Crude ore mining alone increased 24% for industrial minerals but remained practically unchanged for metals.

Surface mining and quarrying of nonfuel materials increased overall 9% to 3.6 billion tons and underground mining although small, almost doubled, increasing to 129 million tons. Surface mining for industrial minerals totaled 1.5 billion tons, of which 1.2 billion tons was crude ore mined and the remainder was waste and ore from development. Underground mining for industrial minerals was minor, amounting to 94 million tons, practically all of which was crude ore.

Surface mining for metal ores totaled 2.1 billion tons, of which about 921 million tons amounted to crude ore mined, while the remaining 1.1 billion tons was waste and ore from development. Underground mining of metal ores was small, amounting to 35 million tons, almost all of which was crude ore.

The major States in which mining for nonfuel materials occurred were Nevada, Arizona, Florida, Minnesota, and California. These States accounted for slightly over one-half of the mining conducted in the United States and three of these five States have shown significant decreases from mining in the previous year. Virtually all of the mining in these five States was surface mining.

The overall average value of mineral products of surface and underground nonfuel minerals mined in the United States remained virtually unchanged at $10.23 per ton. The average value of principle mineral products, including industrial sand and gravel and stone, increased slightly to $9.47 per ton while mineral byproducts were valued at $0.76 per ton. Average values for metal ore products increased slightly to $11.68 per ton overall, $10.74 for principle mineral products, and, $0.93 for byproducts; average values for industrial mineral products also increased slightly to $9.22 per ton overall, $8.57 for principle mineral products, and $0.64 for byproduct materials.

1993	2,105	1,449	3,554	127	2	129	2,232	1,451	3,683

[r] Revised.

[1] Includes materials from wells, ponds, and pumping operations.

[2] Includes solution mining.

[3] Data may not add to totals shown because of independent rounding.

[4] Includes ore and waste from development operations.

[5] Construction sand and gravel data were not available because of biennial canvassing.

[6] Crushed and broken and dimension stone data were not available because of biennial canvassing.

[7] Less than 1/2 unit.

TABLE 2—Continued

MATERIAL HANDLED AT SURFACE AND UNDERGROUND MINES IN THE UNITED STATES IN 1993, BY COMMODITY AND STATE[1]

W Withheld to avoid disclosing company proprietary data; included with "Other" or "Undistributed."

[1] Data may not add to totals shown because of independent rounding.

[2] Includes materials from wells, ponds, and pumping operations.

[3] Includes solution mining.

[4] Includes ore and waste from development operations.

[5] Includes bauxite, beryllium, gold-silver ore, lead-zinc ore, magnesium metal, manganiferous ore, molybdenum, platinum-group metals, rare earths, titanium, uranium, and metal items indicated by symbol W.

[6] Includes aplite.

[7] Excludes volcanic cinder and scoria, included with crushed and broken stone.

[8] Includes boron, fluorspar, greensand marl, iron oxide, kyanite, lithium, magnesite, olivine, sulfur (Frasch), wollastonite, zeolites, and industrial mineral items indicated by symbol W.

[9] Includes Delaware, North Dakota, Utah, and State items indicated by symbol W.

TABLE 3
VALUE OF PRINCIPAL MINERAL PRODUCTS AND BYPRODUCTS OF SURFACE AND UNDERGROUND ORES MINED IN THE UNITED STATES IN 1993

(Dollars per metric ton)

	Surface			Underground			All mines		
	Principal mineral product	By-product	Total[1]	Principal mineral product	By-product	Total[1]	Principal mineral product	By-product	Total[1]

ABRASIVE MATERIALS

By Gordon T. Austin

Mr. Austin, a physical scientist with more than 30 years of industry and Government experience, has been the commodity specialist for abrasive materials since 1986. Mr. William Field, statistical assistant, prepared the domestic data tables.

The combined value of production of natural abrasives, which include tripoli, special silica stone, garnet, staurolite, and emery, increased in 1993. The increase in the value of tripoli production was the result of an increase in total production. Special silica stone experienced an increase in unit value but decrease in the quantity produced. Garnet showed a 19% decrease in quantity and an 8% decrease in value. Staurolite increased about 51% in the quantity produced and 136% in value compared with those of 1992. Staurolite's significant increase in value of production resulted from a 56% increase in the unit value.

The fused aluminum oxide industry showed an 8% decrease in the quantity produced and a 13% decrease in the value of production. The silicon carbide industry saw an 11% decrease in the quantity produced and an 8% decrease in the value of production. Combined, the industries decreased 9% in quantity and 11% in value compared with those of 1992.

The quantity of metallic abrasives sold and shipped increased slightly in quantity and decreased 7% in value compared with those of 1992. The industry includes the primary producers of steel, chilled and annealed iron, cut wire shot and grit, and shot and grit reclaimed by primary producers. Shipments in 1993 were about 9% below the industry's high of 239,619 metric tons[1] in 1979. *(See table 1.)*

The United States continued as the world's largest manufacturer, exporter, importer, and consumer of synthetic industrial diamond. The estimated apparent U.S. consumption of industrial diamond stones was 2.0 million carats, a decrease of 60% compared with that of 1992, but was still greater than the 48-year low in 1987.

DOMESTIC DATA COVERAGE

Domestic production data for abrasive materials were from seven separate voluntary U.S. Bureau of Mines (USBM) surveys. Of the 61 operations producing natural and manufactured abrasives canvassed, all responded, representing 100% of the total production shown in tables 1, 5, 6, 8, 12, and 14.

FOREIGN TRADE

The total value of abrasive materials, exports plus reexports, was $421.3 million, about a 10% increase compared with the 1992 value.

The total value of abrasive materials imported was $529 million, an increase of 9% compared with the 1992 value.

The United States has shown a trade deficit in abrasive materials for every year of the past 10 years. In 1993, the deficit was $107.7 million, an increase of 9% compared with that of 1992. *(See tables 2, 3, and 4.)*

TRIPOLI

The category of tripoli, as broadly defined, is composed of extremely fine-grained crystalline silica in various stages of aggregation. The particle sizes usually range from 1 to 10 micrometers, but particles as small as 0.1 to 0.2 micrometer are common. Commercial tripoli contains 98% to 99% silica and minor amounts of alumina (as clay) and iron oxide. Tripoli may be white or some shade of yellow, brown, or red depending on the percentage of iron oxide. The USBM includes not only tripoli, but other fine-grained, porous silica materials that have similar properties and end uses such as rottenstone and novaculite. It does not include fine-grained or porous silica materials included in other Mineral Annual Report chapters, such as pumice.

Annual Review

Production.—In 1993, the quantity of crude tripoli produced increased 11% and the value of production increased 7% compared with those of 1992. In the United States four firms produced tripoli. Malvern Minerals Co., Garland County, AR, produced crude and finished material. Malvern also produces a black material from novaculite. American Tripoli Co. produced crude material in Ottawa County, OK, and finished material in Newton County, MO. Unimin Specialty Minerals Inc.'s Alco and Tamms plants, in Alexander County, IL, produced crude and finished material. Keystone Filler and Manufacturing Co. in Northumberland County, PA, processed rottenstone, a decomposed fine-grained siliceous shale, produced by B. J. Ulrich & Sons, also in Northumberland County, PA. *(See table 5.)*

Consumption and Uses.—Processed tripoli, sold or used, increased 3% in quantity and 10% in value compared to those of 1992.

Tripoli is processed in mills that are

jasper lined using flint or jasper pebbled in closed circuit with banks of mechanical classifiers. Materials from the mechanical classifiers are fed to micronizing mills, in which it is ground and sized at the same time. Material that is 100% minus 10 micrometers and 96% minus 5 micrometers is the smallest particle-size material sold. Even this very fine particle material is not the result of fragmentation of individual crystals; instead, clusters of quartz crystals, many less than 1 micrometer in size, that are joined at their points are broken apart. The ultrafine-grained tripoli is a collection of clusters and individual quartz crystals.

Tripoli has had unique uses as an abrasive because of its hardness and its grains lack distinct edges and corners. It is a mild abrasive, making it suitable for use in toothpaste and tooth polishing compounds, industrial soaps, and metal and jewelry polishing compounds. The automobile industry uses it in buffing and polishing compounds in lacquer finishing.

The end-use pattern for tripoli has changed significantly in the past 20 years. In 1970, nearly 70% of the processed tripoli was used as an abrasive. Today, 76% is used as a filler and extender in paint, plastic, rubber, caulking compounds, and enamel.

The largest use of tripoli is as a filler and extender in paints. These uses are estimated to account for as much as 85% of the tripoli used as filler and extender. Its use in exterior latex paints is as a low-micrometer-grade micronized product. In these paints, tripoli aids in tint retention, durability, leveling, and flowability. In enamels, it permits higher loading with no appreciable increase in vehicle demand and improves sheen. Because of its controlled grain or particle size, paints containing tripoli disperse easier and result in a uniform film. Additionally, because of its abrasive qualities, the paints are more resistive to wear and to chemicals than those in which water-ground whitings and other reactive fillers are used.

Plastics, rubbers, and resins each use about 5% of total annual tripoli filler and extender production. It is used extensively in plastics for electrical uses because of its dielectric properties and its effects on flexural and compressive strengths. Its chemical resistance, weatherability, and resistance to salt spray also are important to its use in plastics. Its physical properties allow high loading in most compounds, but its abrasiveness results in high wear in extruding nozzles and molds. The same properties that makes tripoli useful as a filler and extender in plastics make it valuable to the rubber and resin industries.

Tripoli contains essentially 100% crystalline silica, so its use can cause silicosis and falls under the jurisdiction of the Occupational Safety and Health Administration's (OSHA) Hazard Communication Standard. The International Agency for Research on Cancer (IARC) and other independent studies have determined that crystalline silica is a probable carcinogen for humans. As a result, OSHA is required to regulate materials containing more than 0.1% crystalline silica. To date, it does not appear that these regulations have adversely affected the use of tripoli, but all tripoli must be labeled in compliance with OSHA regulations.

In the filler and extender uses listed, ground calcium carbonate, ground silica sand, pyrogenic and precipitated silica, calcined kaolin, and talc can be substituted.

The use of tripoli as an abrasive increased about 4% in 1993, ending 8 consecutive years of decline. During the 8-year period, consumption declined about 50%.

After 4 consecutive years of decline, from 1988 through 1991, the amount of tripoli used as filler increased. The 2% increase in 1993 followed a 10% increase in 1992, a 7% decrease in 1991, a 10% decrease in 1990, an 8% decrease in 1989, and an additional 4% decrease in 1988. USBM data show that tripoli use in the United States as a filler is about 74% of the total; abrasive, 21%; and other uses, about 1%.

Prices.—The average reported value of abrasive tripoli, sold or used, in the United States was $152 per ton. The value of abrasive tripoli has increased over the past 11 years and the increase has been continuous.

The average reported value of filler tripoli, sold or used, in the United States was $212 per ton. The average reported value has increased for the past 11 years.

SPECIAL SILICA STONE PRODUCTS

Special silica stone products include hones, whetstones, oilstones, stone files, grindstones, grinding pebbles, tube-mill liners, deburring media, and certain specialty products. These do not include products made from artificially bonded abrasive grains. Manufacture of these products was from novaculite, quartzite, or other quarried microcrystalline quartz rock.

Annual Review

Production.—Plants manufactured oilstones, hones, whetstones, and files in Arkansas. Additional production includes grindstones in Ohio, deburring media in Arkansas and Wisconsin, and grinding pebbles and mill liners in Minnesota. Production of the crude materials was in the same State as the products manufactured.

The production of oilstones, hones, whetstones, files, and grindstones decreased about 21% in quantity to 267 tons and 17% in value to $3.8 million. *(See tables 6 and 7.)*

The industry manufactured four main grades of Arkansas whetstone. They ranged in grade from the high-quality Black Hard Arkansas Stone down to the Washita Stone. The Black Hard has a porosity of 0.07% and a waxy luster, while Washita Stone has a porosity of 16% and resembles unglazed porcelain.

Arkansas accounted for essentially 100% of the value and total quantity of special silica stone products reported as sold or used by U.S. producers.

Consumption and Uses.—The domestic consumption of special silica stone products is a combination of residential, industrial, leisure, and craft uses. The major residential uses were the sharpening of knives and other cutlery such as scissors, shears, and lawn and garden tools. Major industrial uses were the sharpening and honing of cutting surfaces, polishing of metal surfaces, and the deburring of metal and plastic castings. The manufacture, repair, and modification of guns also make use of stone files. The recreational uses were the sharpening of sports knives, arrowheads, spear points, fish hooks, and other recreational items. Craft applications included uses in sharpening tools for wood carving, gun engraving, jewelrymaking, and other engraving work.

Prices.—The value of crude novaculite suitable for cutting into finished products varied from $13 per ton to $895 per ton. The low value was for Washita grade and the high for Black Hard Arkansas grade. The manufacture of deburring media or special-purpose crushed stone is from material not suited for making oilstones, hones, or whetstones. The value of these materials ranged from $469 per ton to $1,176 per ton. The average value in 1992 of oilstones, hones, whetstones, and grindstones, sold or used by U.S. producers, was $14,107 per ton. New products can be duplicated by competitors quickly because the special silica stone products industry is not high technology. This very quickly results in short-term price pressures.

Foreign Trade.—The value of exported special silica stone products was $7.2 million, a decrease of 5% compared with that of 1992.

The value of imported products was $2.4 million, down 4% from the record high of 1992. The United States continues to be a net exporter of special silica stone products. A portion of the finished products imported was from crude novaculite produced within the United States and exported for processing. In 1993, the trade surplus in special silica stone products was $4.8 million, a decrease of about 8%.

GARNET

Technical-grade industrial garnet from the United States is a solid solution of almandite and pyrope that, when under pressure, breaks into sharp chisel-edged plates. Industry uses this garnet as an abrasive powder and to manufacture coated abrasives. Low-quality industrial garnet found uses primarily as airblasting or hydroblasting media and as filtration media.

Background

Definitions, Grades, and Specifications.—Garnet is a general name for a family of complex silicate minerals having similar physical properties and crystal form. The general formula for garnet is $A_3B_2(SiO_4)_3$, where A can be calcium, magnesium, ferrous iron, or manganese and B can be aluminum, ferric iron, or chromium, or rarely titanium. The most common garnet species are $Mg_3Al_2Si_3O_{12}$ (pyrope) and $Fe_3Al_2Si_3O_{12}$ (almandite). Almandite and almandite-pyrope solid solution garnets are the best abrasive garnets, but andradite, grossularite, and pyrope also are used. Garnet displays the greatest variety of color of any industrial mineral, having been found in all colors except blue. For example, grossularite can be colorless, white, gray, yellow, yellowish green, various shades of green, brown, pink, reddish, or black. Andradite garnet can be yellow-green, green, greenish brown, orange-yellow, brown, grayish black, or black. Pyrope is commonly purplish red, pinkish red, orange-red, crimson, or dark red; almandite is deep red, brownish red, brownish black, or violet-red. Spessartite garnet can be red, reddish orange, orange, yellow-brown, reddish brown, or blackish brown.

The Mohs hardness of garnet varies from 6.5 to 9.0. Grossularite and uvarovite have a hardness of 6.5 to 7.5; andradite is 6.5 to 7.0; and pyrope, almandite, and spessartite are 7.0 to 7.5 in hardness. There are reports of almandite having a hardness of between 8.0 and 9.0.

As with hardness, the specific gravity of garnet varies considerably. The specific gravity may be as low as 3.2 grams/cubic meter or as high as 4.3 grams/cubic meter depending on chemical composition.

Consumers purchase garnet that has been crushed, ground, and graded to different particle sizes for different end uses. Descriptions of testing methods for materials to be used in the manufacturing of coated abrasives are contained in American National Standards Institute (ANSI) Specifications B74.18-1977, "Specifications for Grading of Certain Abrasive Grains on Coated Abrasive Products."[2] Other specifications are contained in ANSI Specification B74.12-1976, "Specification for Size of Abrasive Grains-Grinding Wheel, Polishing, and General Industrial Uses."[3]

If the garnet is to be used as a sandblasting medium at a U.S. Navy shipyard or a private shipyard working on U.S. Navy vessels, then it must meet MIL-A-22262(SH) specifications that qualify it for product list QPL-22262. These specifications set forth limits on the content of total metals, soluble metals, and radiation; specify the acceptable level of chemical conductivity; and require that the material be certified by the California Air Resources Board.

The California Air Resources Board (ARB) requires all loose-grain abrasives used in the State to be certified at the ARB testing facility. The testing is conducted according to "Methods of Test of Abrasive Media Evaluation," Test Method No. Ca 371-A, and as required under ARB's Title 17, Subchapter 6 entitled "Abrasive Blasting." Copies of these documents are available from the Compliance Division of the California Air Resources Board, Sacramento, CA. In addition, air pollution control agencies in Utah, Minnesota, and Louisiana have adopted the ARB tests and require that only ARB-certified abrasives be used on State projects requiring sandblasting. The ARB's testing procedures and standards are focused on the environmental impact of sandblasting abrasives, not on their qualities or cutting performance and/or efficiency.

The Steel Structures Painting Council, a technical organization in Pittsburgh that has a committee on abrasives, is currently drafting abrasive specification SSPC-XAB1X, "Mineral and Slag Abrasives," which will address garnet specifically. The specification defines the requirements for selecting and evaluating mineral and slag abrasives used in blast cleaning steel and other surfaces for painting and other purposes.

The American Water Works Association (AWWA) has established specification B100-89, "Standards for Filtering Materials," but this specification does not cover high-density media such as garnet and ilmenite. The AWWA plans to include garnet and ilmenite in the updated specification B100-94. In general, specifications for filtration involve garnet's particle shape, specific gravity, effective grain size, coefficient of grain-size uniformity, content of acid-soluble impurities, and content of radioactive and heavy metals.

The sale of garnet for sandblasting, water filtration, and abrasive cutting is by screen size. In U.S. sandblasting, the most widely used domestically produced garnet is -1.0 + 0.3 millimeters, followed by -0.59 + 0.21 millimeters. The most popular grade of imported garnet in the U.S. market is the -0.59 + 0.25-millimeter grade from Australia. In U.S. multimedia water filtration systems, two grades of garnet are used, a coarse grade that is -4.75 + 1.41 millimeters, and a fine grade that is either -0.84 + 0.3 or -0.71 + 0.25 millimeters. Abrasive cutting applications most popular grade of garnet is -0.25 + 0.177 millimeters, which may account for as much as 90% of the garnet used.

There is no definitive method for testing the quality of garnet or any other loose-grain abrasive except by actual application. There are tests and examinations that can indicate a garnet product's probable abrasive performance in use. The fracture, sharpness, shape, and structure of the garnet and the presence of inclusions all can be studied with a microscope. The hardness and friability of the garnet can be evaluated by placing a sample between two glass microscope slides and rubbing them together. The relative scratch hardness of the grains and their degree of breakdown (attrition) can be measured in this manner. Additionally, ANSI Standard B74.8-1965, "American Standard Test for Ball Mill Test for Friability of Abrasive Grain," can be used to determine the friability of garnet grains.

The U.S. National Institute for Standards and Technology developed an apparatus for evaluating the abrasive quality of corundum. This tester can be adapted for use with any loose-grain abrasive. Testing of loose-grain abrasives also can be performed with various production-scale and laboratory machines where the removal of glass from flat plates is evaluated. Data from such tests can be correlated with the anticipated performance of any abrasive grain relative to the other material to be abraded. In these tests abrasive performance is determined by the amount of stock removed, as found either by weighing or by dimensional measurements.

In judging the abrasive quality of garnet, stock removal is not the only important factor. Surface finish is just as important. If an abrasive is too hard or contains too-coarse grains for use on a certain material it can cause deep scratches in the surface, which cannot be removed in subsequent finishing operations. Additionally, if an abrasive does not have the proper grain shape or does not break down in such a manner as to resharpen itself, it will tend to burn or gouge the material being abraded, thus defeating the purpose of its use.

The California ARB's testing facility tests loose-grain abrasives for certification for use in the State. The test is focused on the environmental impact of sandblasting abrasives, not on their abrasive quality.

Other firms or laboratories that test the quality of loose abrasive grains include three firms involved in the abrasive cutting industry, Flow International Corp., Ingersoll Rand Corp., and Jet-Edge, Inc., that have laboratories for testing and evaluating garnet for use in their systems. Most of the evaluations in these laboratories involve the comparative testing of various abrasive grits, including measurements of particle size distribution and mechanical properties.

KTA-Tator, Inc. of Los Angeles, CA, is a major consulting/engineering/testing firm whose laboratory tests and evaluates the quality of garnet and other abrasives. Much of its work is oriented to the Steel Structures Painting Council (SSPC) specifications. The SSPC also can carry out comparative testing of garnet and other loose-grain abrasives to determine whether they meet military specifications, how clean the material is, how well the material cleans, the amount of degradation during use, and other quality factors. SSPC is part of the Carnegie-Mellon Research Institute and must be careful not to conduct research that favors one abrasives supplier over another supplier who may be a member of the Council.

Industry Structure.—Currently four firms produce garnet from four plants in two States. Each domestic producer has distinctive products. The Barton Mines Corp., Warren County, NY, garnet is a mixture of almandite and pyrope and is at the top of the garnet hardness range. It occurs as large crystals and exhibits incipient lamellar parting planes that break under pressure into sharp chisel-edged plates. It retains this chisel-edged shape even when crushed to a very fine size. Its garnet is used in coated abrasives, glass grinding and polishing, and metal lapping. The NYCO Div. of Processed Minerals Inc., Essex County, NY, and International Garnet Abrasive Inc., Clinton County, NY, garnet is a mixture of andradite and grossularite, and the crude garnet concentrate may contain diopside-hedenbergite ($Ca[MgFe]Si_2O_6$). NYCO recovered garnet as a byproduct from its wollastonite operation. It sold both crude garnet concentrate for additional refining and refined garnet for use as blasting and filtration media. International Garnet Abrasives produced refined garnet from NYCO's crude garnet concentrate for use as blasting and filtration media. Emerald Creek Garnet Milling Co. was purchased by Hawkeye Development Co., an Idaho corporation, in November 1991. Under the new name of Emerald Creek Garnet Co., it continued mining and milling operations in Benewah County, ID. Blasting and filtration media were the primary uses of the garnet.

Abrasive garnet production in the United States began in 1878 at the Gore

Mountain site of Barton Mines, near North Creek, Warren County, NY. During the first year, production was less than 100 tons. It was used in coated abrasives, both paper and cloth.[4] Barton Mines Corp. mined and processed the abrasive-grade garnet on Gore Mountain until the company moved the mining operation and processing plant in 1982 to the adjoining Ruby Mountain. Barton Mines has been a family owned operation since its formation. Reported past domestic garnet production was from California, Connecticut, Florida, Maine, New Hampshire, North Carolina, and Pennsylvania.[5]

Nine manufacturers at ten plants produced garnet-coated abrasive papers and cloths. The plants are in New York and Virginia, two in each, and Massachusetts, Michigan, Minnesota, Mississippi, Ohio, and Pennsylvania, one in each.

Geology-Resources.—Garnet is found as an accessory mineral in a wide variety of rocks. Most commonly it is found in gneisses and schists, but it also is found in contact metamorphic rocks, crystalline limestones, pegmatites, volcanic rocks, eclogites, and serpentinites. Additionally, garnet is found in the gangue of veins formed at high temperatures. Because garnet is resistant to chemical and mechanical weathering, it is common in the sands of current or ancestral beaches, streams, and other types of alluvial deposits. Commercially attractive industrial garnet occurrences are not common. Many garnets that occur in deposits of economic size degrade during processing because of internal stresses. These stresses developed in the garnet crystal during formation and cooling. Stress relieving is not economical; therefore, these deposits have no commercial value as a high-grade abrasive material source.

Garnets are usually small in size. Grossularite crystals range up to about 15 centimeters in diameter. Almandite approximates the same range in size except at Gore Mountain and North Mountain, NY, where crystals range up to 60 centimeters in diameter. Spessartite crystals from Brazil can weigh as much as several kilograms. Most garnet crystals are less than 2.54 centimeters in size.

The majority of world garnet production is from alluvial deposits in the United States, Australia, China, and India. Possibly the world's highest quality garnet is mined, however, from almandite-bearing rock of uncertain origin in the Adirondack Mountains of New York.

New York and Maine have the only known high-quality garnet reserves in the United States. The Wing Hill garnet deposit, near Rangeley in western Maine, is one of the largest and highest grade garnet deposits in the world. The host rock is a homogeneous garnet granofels that consists of 50% to 70% almandite garnet. It is medium grained and consists essentially of garnet and andesine plagioclase along with biotite and minor quartz. The garnet is present as discrete, well-formed crystals from less than 1 millimeter to about 10 millimeters in diameter but averaging 1.5 to 2 millimeters. The granofels is an east-west trending, tabular body more than 1,000 meters in length and as much as 700 meters thick. The garnet ranges in Mohs hardness from 7 to 8 and in density from 3.6 to 4.3 grams/cubic meter. When crushed, the garnet breaks into blocky grains, a shape that persists down to the finest fragment. The garnet is amenable to gravity and magnetic concentration when the ore is crushed to -3.36 millimeters. The estimate of reserves in the igneous rock deposit near Rangeley, ME, is more than 1.8 million tons of garnet.

Deposits of industrial garnet are found at two locations in New York. In the Gore Mountain area, technical-grade garnet is mined as the primary product, and near the town of Willsboro, commercial-grade garnet is recovered as a byproduct of wollastonite mining.

The deposit near Gore Mountain is an almandite-bearing diorite of uncertain, igneous or metamorphic origin. The ore body is approximately 2 kilometers long and 15 to 90 meters wide. The ore grade varies from less than 5% to about 20% garnet and averages slightly less than 10%. Hornblende and plagioclase feldspar make up 40% to 80% of the host rock, while hypersthene, magnetite, biotite, apatite, and pyrite are present in minor amounts. A rough estimate suggests that more than 600,000 tons of high-quality garnet can be recovered from the Barton Mines Corp. deposit on Ruby Mountain in New York. The garnet is present as imperfectly developed crystals surrounded by a rim of coarsely crystalline hornblende. The crystals range from about 1 millimeter to almost 1 meter in diameter but average about 100 millimeters in diameter. The garnet has a pronounced laminated structure, which enables it to naturally break into thin plates from about 2 to 6 millimeters in thickness. Garnet fragments maintain this platy particle shape even as they are crushed smaller and smaller.

Garnet is recovered as a byproduct from a wollastonite deposit on the western side of Lake Champlain near Willsboro. The deposit is in a belt of wollastonite-bearing rocks that is about 10 kilometers long and 0.4 kilometer wide. The largest zone of wollastonite rock within the belt is from about 9 meters to more than 20 meters thick but averages about 13 meters thick. The wollastonite is interbanded with andradite garnet and iron-rich diopside. The garnet and diopside together comprise 10% to 20% of the ore. Both the garnet and diopside are feebly magnetic and are easily separated from the wollastonite by magnetic separators.

Alluvial deposits of almandite garnet were discovered in the early 1880's near Fernwood in Benewah County, but commercial mining did not start until the early 1940's. The deposits are on Emerald, Carpenter, and Meadow Creeks about 6.4 kilometers from a mica-garnet schist formation. The source schist is estimated to be about 1,200 meters thick. The garnet-bearing gravels are from nearly 1 meter to about 1.2 meters thick and contain 8% to 15% garnet. Garnets from these gravels range up to 40 millimeters in diameter, although about 95% of the garnet is smaller than 7 millimeters in diameter. The quantity of garnet-bearing gravels reported at Emerald Creek and Carpenter Creek in Idaho is large. A minimum of 450,000 tons of garnet is available in the Emerald Creek Garnet Co. deposits.

There can be little doubt that tremendous reserves of garnet similar to the lower priced materials can be located as needed.[6] Also, the production of byproduct garnet from many current mining operations is possible if demand improved.

Reserves are significant in Australia, China, India, and the Newly Independent States, (formerly U.S.S.R.), but accurate data are not available. Huge inferred and undiscovered resources are likely to exist throughout the world.[7]

***Technology.*—Exploration.**—Successful exploration for garnet deposits begins with selection of target areas based on the presence of known favorable host rocks. Geologic studies and maps, topographic maps, and aerial photographs are used to identify favorable metamorphic, igneous, alluvial, or eolian geological formations.

The second step is field examination of the selected targets. This may include geologic mapping and limited sampling but in many cases reconnaissance studies are sufficient. The next step, if warranted, is to sample the deposit in detail, the purpose being to measure the physical parameters of the deposit, specifically its grade and size.

The method of sampling used depends upon the type of deposit. Hard-rock deposits, igneous or metamorphic, are sampled differently than alluvial or eolian deposits.

Hard-rock deposits can be either diamond core drilled or trenched. Trenches should be oriented perpendicular to the strike of the formation and can be dug by hand, with a dozer, or with a backhoe.

Placer deposits can be sampled by drilling, trenching, or by excavating pits or shafts. The physical nature of the deposit, its thickness, hardness, grain size, and whether it is above or below the water table influence the method of sampling chosen. For shallow deposits, hand augers or power augers can be used to drill sample holes. In deposits that are too hard to hand auger because of the presence of clay, iron oxide cement, or mild calcium carbonate cement, two-person motor-driven augers or vehicle-mounted augers (such as post hole diggers or telephone pole hole diggers) work well. However, augering does not always provide uncontaminated samples and is not effective below the water table.

Truck-mounted water-jet drills and rotary hammer drills are used to test thick deposits and deposits that are too hard to drill with other methods. A water-jet drill uses flush-jointed drill pipe with perforations near the bit to direct jets of water forward and downward from the bit. A hammer advances the drill bit and casing at the same time. Water from the jets flushes out the hole and returns cuttings to the surface in the annulus between the drill pipe and casing. Also, truck-mounted rotary drills equipped with double-pipe drill string and downhole hydraulic hammers can be used. Compressed air is forced down the inner pipe and returns samples to the surface in the annulus between the inner pipe and outer casing. Bits are selected depending on the type of material to be drilled.

Trenching can be carried out using either a dozer or a backhoe, depending on the size and depth of the deposit. In unconsolidated sediments it is difficult to maintain the stability of the walls of trenches, and samples can be contaminated by material sloughing from above. Bulk samples can be collected from 1-cubic-meter pits or shafts. However, here again, wall stability can be a problem unless some form of shoring is used.

Evaluation of Deposits.—The evaluation of garnet deposits to determine their suitability for commercial production can be divided into five major factors: (1) size and grade of the reserves; (2) mining conditions; (3) quality of the garnet; (4) location of the deposit relative to markets and infrastructure; and (5) milling costs. The relative importance of each of these factors will vary from one deposit to another, but the final determination of economic viability will depend upon all of them.

1. Size and grade of reserves: An economic garnet deposit has reserves that are large enough and high enough in grade to provide full project capital recovery, meet all operating costs, and furnish a reasonable profit over the depreciable life of the project, which is normally at least 10 to 20 years. Generally, a deposit should contain a minimum of 2 million tons of ore. The cutoff grade used in calculating reserves will depend on the economics of the specific deposit, but cutoff grades for most deposits average about 20% garnet.

2. Mining conditions: Mining conditions greatly affect the economics of a deposit and can even control whether the deposit can be developed. Early field examinations should identify any conditions, such as nearby houses, historical sites, national monuments, archaeological or paleontological sites, wildlife refuges, municipal watersheds, etc., that could preclude mining the deposit. Local, county, and State zoning regulations, environmental regulations, and other constraints should be checked to establish their effects on mining the deposit.

Hard-rock garnet deposits are mined in benched open pits using conventional drill-and-blast methods. Some placer deposits are mined with dredges. The configuration and structure of the deposit should be such that there are no blocks of waste rock within the ore body and that the garnet is, ideally, uniformly distributed throughout the ore. All physical and chemical features of the ore and overburden will influence whether the deposit is amenable to open pit mining and will impact the total mining cost per ton.

3. Quality of the garnet: The garnet in a deposit must be tested to evaluate its performance and marketability as an abrasive. It should be recognized in this regard that most garnet used in abrasive applications is either the almandite or almandite-pyrope type. The garnet should be present in the deposit as discrete crystals that are at least 6 to 13 millimeters in size and that are liberated when the ore is crushed to -2 millimeters. The crystals should be free of any inclusions, such as quartz, mica, hornblende, and feldspar, and also should be free of alteration. The garnet should

be relatively uniform in hardness and density throughout the deposit. It should not be badly weathered or highly friable. If an incipient parting is present in the garnet crystals, the effect this parting has on the quality of the final product and the distribution of such crystals within the deposit should be determined.

4. Location relative to markets and infrastructure: The location of a garnet deposit must be evaluated relative to its proximity to the markets for garnet abrasives and filter media. If the deposit itself is not near major market areas, then it must be near adequate and inexpensive means of transportation, especially by rail or water. Deposits should be reasonably accessible from existing roads.

5. Milling costs: The type of milling required and the cost of processing the ore must be analyzed carefully. Ideal ore is that from which the garnet can be liberated with minimum crushing and can be recovered using gravity/density-based methods of mechanical concentration and where size classification of the concentrate yields a complete range of product sizes. In some cases portions of the concentrate will be ground to achieve proper particle size distribution.

Mining.—At the Barton Mine in New York, the Ruby Mountain ore body covers approximately 41,000 square meters, which is nearly the entire mountain. The ore is mined by open pit methods with benches 9 meters high. The ore is drilled and blasted, a drop ball provides secondary breakage, and power shovels load ore into trucks for haulage to mill, about 0.4 kilometer away.

At Emerald Creek and Carpenter Creek, Benewah County, ID, backhoes are used to strip 1 to 2 meters of overburden, exposing the garnetiferous gravel. Mining is then carried out with draglines, and ore is trucked to a mill for processing.

Wollastonite mining at Willsboro, NY, yields a byproduct concentrate containing garnet, diopside-hedenbergite, and minor amounts of wollastonite. After drilling, blasting, and loading, the ore is transported 22 kilometers to the plant for separation of the wollastonite from the garnet-diopside.

Beneficiation.—The primary factors controlling the behavior of garnet ore during processing are the identity and characteristics of the minerals present, the percentage of each mineral present, and the size of the garnet grains. The major minerals associated with garnet in most deposits are feldspar, mica, hornblende, pyroxene, and quartz. Magnetite, pyrite, ilmenite, limonite, pyrrhotite, and occasionally chalcopyrite, rutile, zoisite, chlorite, and corundum may be present in much smaller amounts. Sodium feldspar is the most common feldspar, biotite is the most common mica, and hypersthene and diopside are the most common varieties of pyroxene present. The most important physical property controlling the behavior of the major and minor minerals during concentration of the garnet is their specific gravity.

At Barton Mines Corp.'s plant in New York, garnet is liberated, concentrated, and further processed by combinations of crushing and grinding, screening, tabling, flotation, magnetic separation, water sedimentation, drying, heat treating, and air separation. Occasionally, a single process will accomplish both sizing and the removal of gangue minerals, but this usually requires several processes. Particle size control can be difficult but is important for the concentration processes to work effectively.

The process used by Barton Mines to recover garnet has evolved over time. It began in 1924 with construction of the first "modern" plant where separation was accomplished using jigs. In 1941, heavy-media separation was added to the system, and in 1945 flotation was added. The current state-of-the-art mill is a combination of heavy-media and flotation circuits. Ore crushed to -7 millimeters is screened to 3.36 to 2.38 millimeters with the coarse fraction going to a heavy-media circuit using a density of 3.02 grams/cubic meter for primary separation and a density of 3.20 to 3.40 grams/cubic meters for secondary separation. The fine fraction from the screen goes to a flotation circuit where it is first ground to -0.3 millimeter in ball mills and then fed to float cells. The concentrate from the heavy-media circuit is roll crushed, combined with the float concentrate, and then dried and heat-treated in a rotary kiln.

At Emerald Creek Garnet Co.'s operation in Idaho, the ore is first processed through trommels to remove the gravel and is then concentrated in jigs and on shaking tables. The garnet concentrate is dried, crushed, and screened. The maximum grain size of finished products is 46 millimeters.

At NYCO Minerals' mill in New York, beneficiation of the wollastonite-garnet ore requires two stages. The first stage involves drying, crushing, screening, and recrushing the feed to -1.19-millimeters. In the second stage, the -1.19-millimeter ore passes over a series of screens to attain -1.19 + 0.84-, -0.84 + 0.42-, -0.42 + 0.25-, and -0.25-millimeter splits. A battery of magnetic separators then removes the garnet from each of these fractions. Four sizes of final product are bagged for shipment.

Today, practically all grade-grain abrasive garnet is heat treated as a processing function, not to improve its inherent abrasiveness. Impurities picked up during processing stick to the garnet particle surfaces. These impurities destroy the cleanliness and capillarity needed in later processing to give adhesion for bonding. In the early 1960's, scientific investigations determined that heat treating only cleaned the particle surfaces and that too high a temperature could destroy the abrasive quality of garnet. In the mid-1960's, the coated abrasive industry accepted uniform color standards. These standards ensured the cleanliness of the grain surface and a color most closely approaching the natural red color of abrasive garnet. The heat treatment needed to do this is the RT treatment.[8]

Annual Review

Production.—In 1993, the four U.S. firms produced 43,995 tons of crude garnet concentrate worth $4.4 million, an 18% decrease in quantity and a 4% increase in value compared to those of 1992.

Consumption and Uses.—In 1993, the quantity of garnet sold or used by producers was 55,760 tons, an increase of 21%, and the value increased 18% to $15.4 million. *(See table 8.)*

The major industrial use for high-quality, high-value garnet since before 1880 has been as loose-grain abrasive for applications such as optical lens grinding and plate-glass grinding. In recent years, its applications included the high-quality, scratch-free lapping of semiconductor materials and other metals. The finishing of wood, leather, hard rubber, felt, and plastics often requires the use of garnet-coated abrasive papers and cloths.

The aluminum aircraft and shipbuilding industries in California and the Pacific Northwest use lower quality, lower cost alluvial garnet, primarily from Idaho, for sandblasting. Similar uses in the Eastern United States are for the cleaning and conditioning of aluminum and other soft metals and for the cleaning of metal by structural steel fabrication shops. Mixed-media water filtration, using a mixture of sand, anthracite, and garnet, has displaced older filtration methods because it is more reliable and gives a better quality of water. Garnet also is used in hydrojet cutting—it is entrained in a high-pressure stream of water to cut many different materials. Demand for these uses has greatly increased. The manufacturers of nonskid floor paint also use alluvial and other low-cost garnets.

Garnet has obtained an intermediate place in the coated-abrasive field between low-cost quartz sand and more costly synthetic abrasives (silicon carbide and fused alumina). Garnet is reportedly more efficient based on unit production costs than quartz sand. It also produces a more desirable finish on items made of wood, leather, hard rubber, felt, and plastic.

Garnet, especially the lower grades, cannot compete with synthetic abrasives for most metalworking applications requiring substantial metal removal because of its friable nature and lower hardness.

Prices.—The average value per ton of crude garnet concentrates was $100, a 12% increase compared with the 1992 average. In 1993, the average value per ton of garnet sold or used was $299, a 12% increase from that of 1992.

Foreign Trade.—Garnet exports, as reported to the USBM, by producers were about 11,400 tons, a 50% increase from that of 1992. Export data on garnet were not available from the Bureau of the Census (Department of Commerce). Producers have reported exports to the USBM for the past 7 years. According to reports by producers, exports, with the exception of those for 1992, have increased significantly.

Mineral brokers and other garnet importers reported to the USBM about 12,200 tons of imported garnet, essentially unchanged from that of 1992. Import data for garnet also were not available from the Bureau of the Census. The United States was a net importer of garnet in 1992 for the first time in history and continued this new trend in 1993.

World Review.—The United States was the dominant world producer and consumer of garnet, accounting for approximately 45% of the estimated world output and nearly 40% of estimated world consumption. Studies are under way on two new garnet operations; Bitteroot Resources Ltd. is evaluating an almandite deposit in Arizona, and Royalstar Resources is evaluating an andradite deposit in New Mexico.

European Garnet Ltd. announced plans to install garnet recovery plants at gravel pits in the Po Valley of northern Italy. The company plans to recover up to 20,000 tons of garnet per year from its first 10 plants.[9]

Target Mines Ltd. (a subsidiary of Barton Mines) continued to produce at near capacity from its Australian garnet sand operation.

The Chinese mines continued to increase production of garnet for the domestic and world market. Two mineral sand mining operations in India continued to produce garnet as a byproduct of mineral sands production. Turkey and the Newly Independent States (formerly the U.S.S.R.), primarily produce for local markets.

Outlook

The U.S. production and consumption of industrial garnet during the next 5 years will be a function of the installed capacity and imports. Currently, the industry is operating at or near capacity. If capacity can be added, production and consumption will increase to approximately 80,000 tons per year by 1998. If garnet were not available, other abrasives could be used in its place, but in many cases with some sacrifices in work volume, quality of work, or cost.

Substitution of other natural and synthetic material is present to some extent for all major end uses of garnet. Fused alumina and staurolite compete with garnet as a sandblasting material in the transportation equipment industries. Ilmenite and plastics compete as filtration media. Diamond, corundum, and fused alumina compete for lens grinding and for many lapping operations. Finally, sand, silicon carbide, and fused alumina compete for grinding and finishing of plastics, wood furniture, and other products.

EMERY

Emery is a gray to black rock containing various minerals, including corundum, magnetite, hematite, or hercynite, and trace minerals such as mullite, titania, silica, and magnesia. Its hardness ranges between 7 and 9 on the Mohs scale and its specific gravity ranges from 3.2 to 4.5, depending upon its composition. It is used as an abrasive aggregate for nonskid, wear-resistant floors, pavements, and stair treads; as tumbling or deburring media; and in the manufacture of coated abrasives.

Annual Review

Production.—A single firm, Oregon Emery, Albany, OR, produced emery in 1993 using open pit mining methods. U.S. production of emery decreased about 34% in quantity and value compared with those of 1992.

Consumption.—The USBM estimated that the United States consumed approximately 10,000 tons of emery in 1993. Imports from Greece and Turkey accounted for most of the material consumed. Four firms processed and distributed emery for domestic consumption: Washington Mills Abrasives Co., Emeri-Crete Inc., Oregon Emery, and General Abrasives Co.

Foreign Trade.—The United States did not export emery in 1993, nor has it done so in the past 10 years. The Bureau of the Census reports emery imports, exports, and reexports in mineral group categories; thus, exact data on emery are not available.

World Review.—Turkey was the world's largest producer of emery. Its production is handled by Etibank in Ankara, by Ranar Minerals Industries Corp. in Istanbul, and by Lutfullah E. Kitapci Minerals Co., Ltd. in Izmir. Total production in 1993 was estimated to be in excess of 20,000 tons. Prices of Ranar emery ranged from $34 to $48 per ton for crude and from $220 to $460 per ton for micronized grades.

The second largest producer was Greece. In Greece, Government-owned deposits on the Island of Naxos are worked by villagers. It is estimated that 1993 production was about 10,000 tons.

STAUROLITE

Staurolite is a naturally occurring, complex, hydrated aluminosilicate of iron having a variable composition. The mineral most commonly occurs as opaque, reddish-brown to black crystals. It has a specific gravity ranging from 3.74 to 3.83 and Mohs hardness of between 7 and 8.

Annual Review

Production.—Georgia, North Carolina, and Virginia produced mineral specimen staurolite crystals. The crystals were in the cruciform twinned form commonly called "fairy crosses." E.I. du Pont de Nemours & Co. Inc. produced industrial-grade staurolite in Florida. Publishing production data would disclose company proprietary data, but production of industrial staurolite increased 51% in quantity and 136% in value compared with those of 1992.

Industrial staurolite was a byproduct of heavy-mineral concentrates recovered from a beach sand deposit in Clay County, north-central Florida. Electrical and magnetic separators remove staurolite from the concentrates after scrubbing, washing with caustic, rinsing, and drying. The resulting material was about 77% clean, rounded, and uniformly sized grains of staurolite, with minor amounts of tourmaline, ilmenite and other titanium minerals, kyanite, zircon, and quartz. A nominal composition of this staurolite sand is 45% aluminum oxide (minimum), 18% ferric oxide (maximum), 5% silica (maximum), and 3% zirconium dioxide (maximum).

Consumption.—During 1993, shipments of staurolite decreased 4% in tonnage but increased 49% in value compared with those of 1992. Staurolite, marketed under the trade name Biasill, was used as molding material in nonferrous foundries because of its low thermal expansion, high thermal conductivity, and high melting point. Its low softening temperature often restricts its use to nonferrous casting. The major use of staurolite was as an abrasive for impact finishing of metals and sandblasting of buildings. The blasting media trade names were Starblast (80 mesh) and Siasill (90 mesh). A coarse grade (55 mesh) also was used as an abrasive. Some portland cement formulations consumed a minor amount. As regulations limiting the amounts of free silica in airblasting media became more stringent, the demand for staurolite increased.

Foreign Trade.—Neither the Bureau of the Census nor the staurolite industry reported any exports or imports of staurolite. Given the limited market and the low price per ton, no international market for staurolite should develop in the near term.

World Review.—India continued to produce small amounts of staurolite for local consumption. Other countries sometimes produce small amounts of staurolite as a byproduct of mineral sands or gemstone production.

INDUSTRIAL DIAMOND

Industrial diamond is natural diamond that does not meet the standards of gem diamond because of its color, size, or other imperfection. Also, it may be a synthetic diamond that is tailor-made for industrial applications.

Background

Definitions, Grades, and Specifications.—Natural industrial diamond is diamond that, because of color, structure, size, or shape, is unsuitable for use as gemstones. Major categories are industrial stones (die stones, tool stones, and drilling stones), crushing bort, and grit and powder. The distinction between stone and grit is not well defined; generally, the dividing line is a range of sizes. Stones usually are particles larger than 16 to 20 mesh, grit from 16 to 20 mesh to 325 to 400 mesh, and powder as particles smaller than 325 to 400 mesh. These categories are subdivided further into more than 100 groups.[10]

Bort is natural diamond that occurs in finely crystalline aggregates and usually is crushed into finer material. Originally, the term was the name for all crystalline diamonds not usable as gems. Later it designated those diamonds not usable as gems, tool stones, die stones, or drill stones. Currently, the term refers to low-grade industrial diamond suitable only for use in a fragmented form.

Most synthesized diamond marketed to date is 20 to 30 mesh and smaller. Recently, producers began to manufacture synthetic stones of 2 carats or larger. Marketing of these stones to date is of engineered pieces of the stones, not the entire stone. Polycrystalline synthetic diamond compacts and shapes can replace some larger stones. There are several types of synthetic diamond. They range from very friable material with a highly irregular shape to blocky, regular shapes with excellent crystal structure. The manufacture of industrial diamond stones is not commercially viable.

The metric carat, 0.2 gram, is the unit of measure for industrial diamond. One pound contains 2,268 carats, and 1 kilogram contains 5,000 carats. The carat is equal to 100 points. Diamond grit and powder sizes are identified by U.S. standard screen classifications, by ANSI Specification B74.16-1971,[11] ANSI Specification B74.20-1981,[12] and by a proposed standard developed by the Industrial Diamond Association[13] for subsieve micron-sized diamond or cubic boron nitride powders. The terms "sand," "grit," and "powder" also describe decreasing orders of fine diamond.

Machine-shop waste containing diamond is sludge if obtained from wet grinding and is called swarf if obtained from dry grinding.

Industry Structure.—The original discoveries of diamond in India, Borneo, and Brazil, and later in the Republic of South Africa, were due to chance finds by local inhabitants. Certain desirable characteristics in diamond were noted first in India and led to active search by open pit workings and to concentration by hand methods.

Probably the first industrial use of diamond was as diamond powder for polishing gem diamonds and other precious stones. The art of diamond cutting and polishing was known in India, probably well before A.D. 1400.

Glasscutting was an early application of diamond in industry. It was the most important use of industrial diamond until the 1860's.

England issued a patent in 1819 for drawing wire through a diamond die. Diamond wiredrawing dies gave close dimensional accuracy to wire, even after long periods of use.

The use of diamond for metalcutting began in the 1860's, but the high price of diamond tools was a drawback to their acceptance. As the economic advantages of using diamond tools became known, demand increased rapidly.

The use of the first diamond drill was in 1864. The discovery of diamond in South Africa in 1867 provided ample supply for the new and growing demand for diamond drill bits.

With the introduction of cemented tungsten carbide cutting tools during World War I, industrial diamond use increased. The cause of the increase was that diamond was the most effective agent in grinding tungsten carbide. Requirements for industrial diamond expanded tremendously because of World War II, when demand increased for grinding wheels, die stones, tool stones, drill bits, dresser stones, and polishing dust. The apparent supply of industrial diamond decreased rapidly following World War II.

In 1955, General Electric Co. announced the development of a process for the manufacturer of diamond at its Schenectady, NY, laboratories. Commercial production started in 1957 at its plant in Detroit, MI. In 1969, production moved to Worthington, OH. In 1959, De Beers Consolidated Mines Ltd. announced the manufacture of industrial diamond at its laboratory in Johannesburg, Republic of South Africa. Since these two announcements, the production of synthetic diamond by General Electric, De Beers, and others continued to increase. Today it exceeds the production of natural diamond worldwide about five times.

Geology.—The major source of inplace diamond is kimberlite, an altered, dark-green basic rock of igneous origin. Throughout the world there are approximately 1,000 occurrences of kimberlite, but most do not contain diamonds or do not contain diamonds in economic quantities. The term "diamond pipe" refers to an occurrence of kimberlite large enough and sufficiently diamondiferous to be mined. The size and shape of these pipes depend on the manner in which molten kimberlite passed through the country rock. They may be columnar, tabular, or irregular in shape. Where mining is deep enough, the diamond pipe always decreases in area and assumes a dikelike habit. The diamond may contain inclusions of many minerals, and many of these minerals have inclusions of diamond. These accessory minerals include olivine, garnet, diopside, ilmenite, magnetite, rutile, and phlogopite. Every mine has some diamond that is typical of it, but most diamond is indistinguishable from that of other mines.

Currently, approximately 40% of diamond is from alluvial deposits. These may be alluvial placers, recent or elevated marine beach placers, or glacial deposits. Often the distance of transport has been great. In many areas, the diamond-bearing, alluvial placers were deposited in former drainage systems unrelated to any present system.[14]

Technology.—**Mining.**—Currently, the United States has no commercial deposits of diamond. In other countries, mining methods range from very crude hand mining and panning to block caving of kimberlite pipes. Large-scale surface mining operations in Australia, Zaire, Angola, Namibia, and Sierra Leone[15] use modern equipment, such as continuous bucket wheel excavators, power shovels, draglines, scraper-loaders, and motor trucks, to remove overburden and to mine and transport the diamond ore.

Processing.—The type of ore, size of operation, and other factors decide the types of processing equipment used. Crushing, where necessary, is done mostly with gyratory and roll crushers to avoid impact to diamond stones. Additional grinding is done with attrition and ball mills to further separate the gangue from diamond stones. Clayey ore may require the use of log washers. Diamond washing pans, jigs, heavy-medium separators, or hydrocyclones collect the primary or intermediate concentrates. Depending on the types, shapes, and sizes of diamond present, various final treatments are used. They include the use of grease tables and grease belts, electromagnetic separators, electrostatic separators, optical sorters, X-ray sorters, and other devices. In all processing plants, hand sorting is the final recovery process.[16]

Reclaiming industrial diamond stones from drill bits and grit from the wastes generated in grinding, sawing, and other operations is common. This is because of the high unit value of diamonds. Reclamation processes include physical methods such as distillation to remove coolants and lubricants, followed by electrostatic, magnetic, or flotation separation. Reclamation also uses chemical methods, including combustion, acid treatment, and fusion with alkalies.[17] The treatment used depends primarily on the contaminants present.

Commercial production of synthetic diamond grit is by two basic methods. Currently, the primary method used involves the application of ultrahigh pressure and high temperature to carbon-metal catalyst mixtures by powerful hydraulic presses. This method uses pyrophyllite and other materials for the reaction vessel. Pyrophyllite for this purpose is from the Republic of South Africa, where the local name for it is wonderstone. The major user of the method now uses synthetic reaction-vessel materials, alleviating the dependency on foreign sources for pyrophyllite. The material used for these replacement reaction vessels is proprietary. The other method employs explosive shock to the carbon-metal catalyst mixtures.

Industrial diamond particles of good quality up to 20 mesh and perhaps larger are produced. The shape and other characteristics can be controlled by proper manipulation of the variables, pressure, temperature, time, and catalyst type. Only micrometer-size particles are presently available from the explosive process. Other methods of diamond synthesis exist, but none are in commercial use in the United States. Other countries produce diamond grit; all of these apparently use the ultrahigh-pressure, high-temperature method involving hydraulic presses.

Polycrystalline synthetic diamond compacts are a laminated structure of synthetic diamond powder bonded to a cemented carbide substrate. Their production is by a proprietary high-pressure, high-temperature process that gives the product excellent uniform physical properties.[18]

The polycrystalline synthetic diamond shape is a dense, nonporous, fully intergrown product that is thermally stable to 1,200° C. Production uses a proprietary high-pressure, high-temperature process using a special binder phase that is retained as an integral part of the product and results in high resistance to shock loading.[19]

Annual Review

Government Programs.—The National Defense Stockpile (NDS) for industrial diamonds, as of December 31, 1993, had a goal of zero and an inventory of 4.0 million carats for crushing bort. The goal for industrial stones was 3.0 million carats and the inventory was 6.46 million carats. There is currently legislative authority for disposal of 4.0 million carats of bort and 3.0 million carats of industrial stones. The inventory of small diamond dies was 25,473 pieces compared with a goal of zero pieces, but no disposal authorization was issued.

Production.—The United States was the largest producer of synthetic industrial diamond. This has made the United States independent of foreign sources for crushing bort or similar diamond except for grit sizes larger than about 20 mesh. Having no production of natural diamond, it was dependent on other countries for its natural diamond supply.

Three domestic firms produced synthetic industrial diamond in the United States: Du Pont Industrial Diamond Div., Gibbstown, NJ; General Electric Co., GE Superabrasives, Worthington, OH; and Suprahards, Inc. Cedar Knolls, NJ. Two firms, Megadiamond Industries Inc., a subsidiary of Smith International Inc., Provo, UT, and U.S. Synthetics Corp., Orem, UT, manufactured polycrystalline diamond from purchased synthetic diamond grit. Both firms had the capability to manufacture synthetic industrial diamond grit, but chose not to for economic reasons. Publishing production data would disclose company proprietary data. Domestic production did increase significantly. The United States continued to be the largest single producer of synthetic industrial diamond, a role it has enjoyed since 1957.

U.S. secondary production of industrial diamond was from six firms. They were Amples Corp., Bloomfield, CT; Diamondsharp Corp., Keene, NH; Industrial Diamond Laboratory Inc., Bronx, NY; Industrial Diamond Powders Co., Pittsburgh, PA; International Diamond Services Inc., Houston, TX; and National Research Co., Fraser, MI. The firms reclaimed a total of about 16.1 million carats from used drill bits, diamond tools, and wet and dry diamond-containing waste.

Consumption and Uses.—The United States continued to be the largest single consumer of industrial diamond. The USBM estimate of apparent consumption of industrial diamond was approximately 149 million carats, an increase of about 51% compared with 1992 consumption.

Diamond is far harder than any other natural or artificial abrasive material, so it was essential for some uses and much more efficient than other abrasives for many others. The principal uses of industrial diamond stones are in drilling bits and reaming shells, single- or multiple-point diamond tools, diamond saws, diamond wheels, abrasive, and diamond wiredrawing dies. Miscellaneous uses include: engraving points, glasscutters, bearings, surgical instruments, and special tools. Changes in technology and conventional wisdom have resulted in an increased use of synthetic industrial diamonds and polycrystalline diamond shapes (PDS) and compacts (PDC) for many of the uses listed. There has been an increased use of PDS, PDC, and matrix set synthetic diamond grit in drilling bits and reaming shells in the past 3 years. Diamond saws, diamond wheels, and diamond abrasive grit and powder are almost exclusively made from synthetic diamond. PDS and PDC are used in the manufacture of single- and multiple-point tools, and PDC is used in a majority of the diamond wiredrawing dies.

Mineral, oil, and gas exploration were the primary uses of drilling bits and shells. Foundation testing for dams, buildings, and other construction also used diamond bits and shells, as did masonry drilling in buildings for conduits and access and testing of concrete in various structures and other similar applications. The primary uses of diamond tools were for dressing and trueing grinding wheels and for cutting, machining, boring, and finishing. Beveling glass automobile windows also were a use. Cutting dimension stone, ceramics, and concrete in highway reconditioning were the major uses of diamond saws. The forming of refractory shapes for furnace linings also uses diamond saws. Diamond wire dies were essential for high-speed drawing of fine wire, especially from hard, high-strength metals and alloys.

Diamond grit, powders, and fragmented bort go into diamond grinding wheels, saws, impregnated bits and tools, and loose abrasives compounds for lapping and polishing.

Three major types of grinding wheels were made—resinoid, metal, and vitrified bonds—in many shapes and sizes designed for specific applications. The sizes range up to 1 meter in diameter for very large industrial wheels. Sharpening and shaping of carbide machine tool tips, grinding of dies, edging of plate glass, and optical grinding were among the primary applications of diamond grinding wheels. The cutting of concrete, stone, ceramics, and composite materials were uses of saws made with diamond grit. Very fine saws sliced wafers from brittle metals and crystals for use in electronic and electric devices.

Finishing optical surfaces, jewel bearings, gemstones, wiredrawing dies, cutting tools, and metallographic specimens were the primary uses of polishing and lapping powder and compounds. Hundreds of other important items made from metals, ceramics, plastics, and glass also were finished with diamond compounds.

Prices.—The USBM does not collect price data on industrial diamonds. It did track the average import value of various classifications of industrial diamonds. The average value of U.S. imports of natural grit and powder, synthetic grit and powder, and industrial stones was $1.14 per carat, $0.64 per carat, and $4.56, respectively.

Foreign Trade.—The United States was the largest exporter of industrial diamond grit and powder in the world. The United States exported and reexported a record 106.6 million carats of natural and synthetic grit and powder, an increase of 23% over the record set in 1992. The material was worth a record $139.3 million. Additionally, the U.S. exported and reexported approximately 3.4 million carats of industrial stones, valued at $49.1 million.

Imports of dust, grit, and powder in 1993 were about 37% more than those in 1992, a record high 132.8 million carats.

The 1993 imports of diamond stones were about 47% less than 1992 imports. *(See table 9.)*

World Review.—Botswana and the Republic of South Africa were the largest producers of good-quality industrial diamond stones. Australia and Zaire were the world's largest producers of natural industrial diamond and were the primary sources of natural crushing bort as well as substantial producers of industrial stones. Estimates suggest that the former U.S.S.R. was the third largest producer of natural industrial diamond, but reliable data were lacking.[20] The next largest, in order of volume, were Botswana and the Republic of South Africa. Other smaller but significant producers were Angola, Brazil, China, Ghana, and Venezuela.[21] Total world output of natural industrial diamond in 1993 was approximately 50.4 million carats, a 3% increase over that of 1992.

Synthetic industrial diamond production is significantly larger than the production of natural industrial diamonds. The countries that have synthetic diamond production, in declining order, are the United States, Ireland, Russia, South Africa, China, Germany, Japan, Sweden, Republic of Korea, Czechoslovakia, Romania, France, and Greece.

Outlook

Diamond grit and powder should experience substantial increases in domestic demand for every end use during the next 5 years. The increases for synthetic grit and powder are expected to be greater than for natural. The constant-dollar prices of these materials, especially the synthetic diamond products, should continue to decrease or at least remain constant. This is because planned production increases will make them more cost-effective. The contract construction industry is an area in which the greatest increases will occur. This is because large quantities of saw-grade diamond will be required for highway and bridge repair and replacement. Large increases also are expected in the dimension stone industry as a cutting and polishing media. The stone, clay, and glass industries will increase their uses in cutting, shaping, and polishing media. Additionally, polycrystalline synthetic diamond compacts and shapes will continue to displace natural diamond stone and tungsten carbide drill bits in the mineral services sector. The probable average annual growth rate in U.S. production is about 10%, based on estimates by the U.S. producers. U.S. production of synthetic material is sufficient to supply U.S. diamond grit and powder demand. The United States will continue to be a major exporter.

The major domestic end use for industrial stones in the next 5 years will continue to be in the oil, gas, and mineral industries. These stones are natural and cannot yet be manufactured commercially. Polycrystalline synthetic diamond compacts and shapes have had a major negative impact on the natural industrial diamond stone markets. This will limit the growth of U.S. demand for stone during the next 5 years. U.S. consumption should average between 6 and 7 million carats per year for the next 5 years. Approximately 50% of the potential natural stone applications will be replaced by the synthetic compacts and shapes by the year 2000. *(See table 10.)*

MANUFACTURED ABRASIVES

Manufactured abrasives include fused aluminum oxide, silicon carbide, alumina-zirconia oxide, and metallic shot and grit. Production data for fused aluminum oxide, silicon carbide, and alumina-zirconia oxide were for the United States and Canada. Data for metallic shot and grit were for the United States only.

The fused aluminum oxide, silicon carbide, and metallic abrasives industries continued to undergo consolidation and reorganization during the year. *(See table 11.)*

Fused Aluminum Oxide

Government Programs.—The NDS, as of December 31, 1993, contained 223,959 tons of crude fused aluminum oxide and 43,614 tons of abrasive-grain fused aluminum oxide. There is no NDS goal for abrasive-grain fused aluminum oxide or crude fused aluminum oxide; all of the material is targeted for disposal. During 1993 the NDS disposed of 3,193 tons of crude fused aluminum oxide and 2,555 tons of abrasive-grade fused aluminum oxide.

Production.—At yearend, four firms were producing fused aluminum oxide at seven plants in the United States and Canada. Production of regular-grade fused aluminum oxide in 1993 was 132,403 tons, a decrease of about 7% from that of 1992.

Production of high-purity fused aluminum oxide decreased 12% to 21,276 tons. Total 1993 production of 153,680 tons was 8% less than that of 1992.

Consumption and Uses.—Fused aluminum oxide has a number of different end uses in the form of graded grain. The total value of sales of fused aluminum oxide-graded grain for all uses decreased 7% compared to that of 1992, which was a 10-year high. The value of sales for use in bonded abrasives declined 4%, coated abrasives increased 4%, refractories decreased 24%, tumbling media increased 14%, blasting abrasives increased 5%, polishing cake and buffing compounds decreased 21%, antislip abrasives decreased 21%, polishing abrasives decreased 10%, and all other uses increased 13%. *(See table 12.)*

Prices.—The USBM did not collect data on the prices of various grades of fused aluminum oxide. It did collect data on the value of fused aluminum oxide production. The average value of regular-grade fused aluminum oxide, as reported by producers, was approximately $366 per ton. In 1993, the average value of high-purity fused aluminum was $621. The average value of all grades of fused aluminum oxide in 1993 was $401 per ton. Mineral price quotations in various December issues of trade magazines listed prices for regular-grade fused aluminum oxide of $555 to $660 per ton, while high-purity was quoted at $810 to $938 per ton.

Foreign Trade.—The quantity of exports plus reexports of fused aluminum oxide decreased 8% to 11,019 tons; the value of exports plus reexports increased slightly to $28.5 million. The average value per ton of fused aluminum oxide, exported or reexported, increased 9% to $2,588.

Imports increased about 16% in 1993 to 158,000 tons, and the value of imports increased about 4% to $76.9 million.

Silicon Carbide

Government Programs.—The NDS, as of December 31, 1993, contained 31,508 tons of silicon carbide; the goal was zero. During 1993, the Defense National Stockpile Center of the Defense Logistics Agency disposed of 5,797 tons of silicon carbide. Existing legislation authorizes disposal of all of the silicon carbide.

Production.—During 1993, three firms produced silicon carbide at four plants in the United States and Canada. Production of abrasive-grade material decreased 14% to 38,296 tons. Production of metallurgical-grade silicon carbide decreased about 7% to 36,650 tons. Total production of silicon carbide decreased 11% in 1993 to 74,945 tons.

Consumption and Uses.—Silicon carbide has a number of different end uses in the form of graded grain. The total value of sales of silicon carbide graded grain for all uses decreased 8% in 1993. The total value of sales by individual end use was a mixture of increases and decreases. Sales for use in bonded abrasives were down slightly, coated abrasives were up 3%, refractories increased 8%, tumbling media decreased slightly, blasting abrasive increased 12%, wiresawing abrasive was down 22%, polishing cake and buffing compounds were down 33%, antislip abrasives were up 14%, polishing abrasives were down 24%, metallurgical was up 11%, and all other uses were up 8%. *(See table 12.)*

Prices.—The USBM did not collect price data on the various grades of silicon carbide. Data were available on the value of production of the various grades. The average value per ton of abrasive-grade silicon carbide, as reported by producers, was $539; metallurgical-grade averaged $526; and the average value of all grades was $533. Mineral price quotations in various December issues of trade magazines listed prices for abrasive grade as $900 to $1,425 per ton.

Foreign Trade.—Exports plus reexports of silicon carbide in 1993 were 16,754 tons, a 24% increase compared to that of 1992. While the total value of silicon carbide exported plus reexported increased 31% to $15.8 million, the value per ton increased 6% to $942.

Imports of silicon carbide in 1993 increased 29% in quantity to 115,000 tons, the total value increased 14% to $57.9 million. The average value per ton decreased 23% to $441.

Alumina-Zirconia Oxide

One firm produced fused alumina-zirconia oxide in two plants, one each in the United States and Canada. Abrasive applications accounted for all the production. Publishing production data would disclose company proprietary data. Export and import data were not available.

Metallic Abrasives

Production.—Nine firms produced metallic abrasives in 10 plants in 1993. The quantity and value of steel shot and grit produced decreased about 2% and 6%, respectively. The average value per ton was $389, a 3% decrease compared with that of 1992. Michigan, Pennsylvania, Virginia, and Ohio, in decreasing order of quantity, supplied the production of steel shot and grit.

During 1993, two firms, one in

Michigan and one in New York, reported production of cut wire shot. Production of shot and grit other than steel inclined significantly in 1993, 34% in quantity to 15,389 tons, and decreased 6% in value to $7.7 million. The average value per ton decreased about 30% to $503. *(See tables 13 and 14.)*

Consumption.—The quantity of steel shot and grit sold or used decreased slightly to 202,925 tons, the total value decreased 8% to $79.2 million, and the average value per ton decreased 6% to $390.

The quantity of other shot and grit sold or used increased 31% to 15,855 tons. The value was essentially unchanged at $8.7 million. The average value per ton decreased 24% to $547.

The estimated apparent domestic consumption of all types of metallic shot and grit increased 4% in quantity to 203,555 tons, decreased slightly in total value to $79 million, and decreased 4% in average value per ton to $388. The formula to calculate U.S. estimated apparent consumption is U.S. sold or used plus imports minus exports.

Foreign Trade.—U.S. exports of metallic shot and grit increased 9% to 29,305 tons. The total value of exports decreased 40% to $14.7 million, and the average value per ton decreased 44% to $502.

U.S. imports of metallic abrasives increased 105% in quantity to 26,140 tons, increased about 59% in total value to $14.2 million, and decreased 22% in value per ton to $542.

The United States was a net exporter of metallic abrasives in 1993, a position it has enjoyed for the past 10 years with the exception of 1984.

TABLE 1
SALIENT U.S. ABRASIVES STATISTICS

Abrasive materials		1989	1990	1991	1992	1993
Production of:						
Natural abrasives:						
Tripoli (crude)	metric tons	105,230	94,390	88,642	84,924	93,943
Value	thousands	$2,537	$3,194	$3,271	$3,256	$3,493
Special silica stone (crude)[1]	metric tons	898	3,709	2,205	1,732	528
Value	thousands	$147	$230	$161	$239	$240
Garnet[2]	metric tons	42,605	47,009	50,860	54,139	43,995
Value	thousands	$4,408	$6,939	$7,534	$4,842	$4,441
Emery	metric tons	W	W	W	W	W
Value	thousands	W	W	W	W	W
Staurolite	metric tons	W	W	W	W	W
Value	thousands	W	W	W	W	W
Manufactured abrasives[3 4]	metric tons	535,213	514,869	454,572	468,772	447,532
Value	thousands	$227,761	$218,207	$195,635	$208,560	$189,337
Foreign trade (natural and artificial abrasives):						
Exports (value)[5 6]	do.	$260,363	$270,928	$295,743	$351,187	$369,090
Reexports (value)[5 6]	do.	$33,771	$24,545	$24,209	$32,088	$52,200
Imports for consumption (value)[5 7]	do.	$419,084	$512,766	$450,880	$482,134	$529,003

W Withheld to avoid disclosing company proprietary data.

[1] Includes crude material used for producing grindstones, oilstones, whetstones, and deburring media; excludes data on material used for grinding pebbles and tube-mill liners.

[2] "Primary" garnet; denotes the first marketable product and includes crude concentrate.

[3] Includes Canadian production of crude silicon carbide and fused aluminum oxide plus shipments of metallic abrasives by producers.

[4] Excludes U.S. and Canadian production and value of aluminum-zirconium oxide.

[5] Source: Bureau of the Census, U.S. Department of Commerce.

[6] F.a.s.

[7] Customs value.

TABLE 2
U.S. EXPORTS OF ABRASIVE MATERIALS, BY KIND

Kind		1992		1993	
		Quantity	Value (thousands)	Quantity	Value (thousands)
NATURAL					
Industrial diamond, natural or synthetic, powder or dust	thousand carats	81,474	$119,146	105,233	$136,570
Industrial diamond, natural or synthetic, other	do.	2,920	14,997	1,036	4,982
Natural abrasives, crude	thousand kilograms	2,193	1,741	1,463	1,161
Natural abrasives, other	do.	14,778	13,426	11,613	12,852
MANUFACTURED					
Artificial corundum (fused aluminum oxide)	do.	11,531	27,407	10,719	27,934
Silicon carbide, crude or in grains	do.	13,512	11,844	16,742	15,775
Grinding and polishing wheels and stones:					
Diamond	thousands of items	812	22,973	792	23,811
Polishing stones, whetstones, oilstones, hones, and similar stone	do.	1,969	7,365	1,985	6,758
Wheels and stones, n.e.c.	do.	1,608	7,044	2,280	11,340
Abrasive paper and cloth, coated with natural or artificial abrasive materials	thousand kilograms	14,924	101,096	14,507	113,260
Metallic abrasive: Grit and shot, including wire pellets	do.	26,587	24,147	29,183	14,646
Total[1]		XX	351,187	XX	369,090

XX Not applicable.

TABLE 5
PROCESSED TRIPOLI[1] SOLD OR USED BY PRODUCERS IN THE UNITED STATES, BY USE

Use		1989	1990	1991	1992	1993
Abrasives	metric tons	26,192	24,090	21,239	18,603	19,385
Value	thousands	$3,172	$3,083	$3,382	$2,779	$2,955
Filler	metric tons	63,080	56,468	52,334	57,603	58,877
Value	thousands	$9,185	$11,041	$10,009	$11,326	$12,571
Total quantity[2]	metric tons	89,272	80,558	73,575	76,205	78,262
Total value	thousands	$12,357	$14,124	$13,391	$14,105	$15,526

[1] Includes amorphous silica and Pennsylvania rottenstone.

[2] Data may not add to totals shown because of independent rounding.

TABLE 6

SPECIAL SILICA STONE FINISHED PRODUCTS SOLD OR USED, AS REPORTED BY U.S. PRODUCERS[1]

Year	Quantity (metric tons)	Value (thousands)
1989	377	$5,459
1990	450	6,328
1991	272	3,600
1992	340	4,554
1993	267	3,767

[1] Includes grindstones, oilstones, and whetstones. Excludes grinding pebbles, tube-mill liners, and deburring media.

TABLE 7

U.S. PRODUCERS OF SPECIAL SILICA STONE PRODUCTS IN 1993

Company and location	Type of operation	Product
Arkansas Abrasives, Inc.:		
Hot Springs, AR	Stone cutting and finishing	Whetstones and oilstones.
Do.	Quarry	Crude novaculite.
Buffalo Stone Corp.:		
Hot Springs, AR	Tumbling and sizing novaculite	Metal finishing media and deburring media.
Cleveland Quarries Co.:		
Amherst, OH	Stone cutting and finishing	Grindstones.
Do.	Quarry	Crude silica stone.
Dans Whetstone Cutting Co., Inc.:		
Royal, AR	Stone cutting and finishing	Whetstones and oilstones.
Do.	Quarry	Crude novaculite.
B&J Construction:		
Paron, AR	do.	Do.
Hall's Arkansas Oilstones, Inc.:		
Pearcy, AR	Stone cutting and finishing	Whetstones and oilstones.
Hardrock Mining, Inc.:		
Hot Springs, AR	Tumbling and sizing novaculite	Metal finishing media and deburring media.
Hiram A. Smith Whetstone Co., Inc.:		
Hot Springs, AR	Stone cutting and finishing	Whetstones and oilstones.
Do.	Quarry	Crude novaculite.
Ed Kramer & Sons:		
Baraboo, WI	Crushing and sizing	Deburring media.
Do.	Quarry	Crude silica stone.
Norton Co. Oilstones, Norton Pike Div.:		
Hot Springs, AR	do.	Do.
Littleton, NH	Stone cutting and finishing	Whetstones and oilstones.
Pioneer Whetstone Co. (Blue Mountain):		
Hot Springs, AR	do.	Do.
Taylor Made Crafts:		
Lake Hamilton, AR	do.	Do.
Wallis Whetstone:		
Malvern, AR	Quarry	Crude novaculite.

TABLE 8
GARNET SOLD OR USED, AS REPORTED BY U.S. PRODUCERS

Year	Quantity (metric tons)	Value (thousands)
1989	41,320	$9,768
1990	45,935	11,759
1991	48,051	13,044
1992	46,098	13,049
1993	55,760	15,433

DIAMOND: WORLD PRODUCTION, BY TYPE AND COUNTRY[1]

(Thousand carats)

Country	1992				1993[e]			
	Natural			Synthetic[4]	Natural			Synthetic[4]
	Gem[2]	Industrial	Total[3]		Gem[2]	Industrial	Total[3]	
Zaire	[r][7]8,934	[r][7]4,567	[r]13,501	—	9,500	5,500	15,000	—
Total	[r]56,757	[r]48,773	[r]105,521	[r]419,250	57,205	50,390	107,620	456,000

[e]Estimated. [r]Revised. W Withheld to avoid disclosing company proprietary data.

[1] Table includes data available through June 8, 1994. Total natural diamond output (gem plus industrial) for each country actually is reported, except where indicated by a footnote to be estimated. In contrast, the detailed separate production data for gem diamond and industrial diamond are U.S. Bureau of Mines estimates except Brazil (1989-90), and Central African Republic (1989-90), for which source publications give details on grade as well as totals. The estimated distribution of total output between gem and industrial diamond is conjectural, and for most countries, is based on the best available data at time of publication.

[2] Includes near-gem and cheap-gem qualities.

[3] Natural gem and industrial data may not add to totals shown because of independent rounding.

[4] Includes all synthetic diamond production.

[5] Figures do not include smuggled artisanal production.

[6] Figures are estimates based on reported exports and do not include smuggled diamonds.

[7] Reported figure.

[8] Formerly part of Czechoslovakia.

[9] Dissolved on Dec. 31, 1992.

[10] "Gem" vs. "Industrial" diamond breakdown has been revised to reflect the value of near-gem material, classified as industrial prior to 1991, but which was ultimately being sold for well above industrial prices.

[11] Data for 1989 do not include smuggled production. Data for 1990-92 are estimates of artisanal production, likely smuggled out of Liberia, but which are comparable to that hitherto reported to the Government.

[12] Formerly part of Yugoslavia.

[13] Other De Beers' Group output from the Republic of South Africa includes Kimberley Mines, Koffiefontein Mine, and Namaqualand Mines.

[14] Dissolved in Dec. 1991.

[15] Dissolved in Apr. 1992.

TABLE 11

CRUDE ARTIFICIAL ABRASIVES MANUFACTURERS IN 1993

Company	Location	Product
The Exolon-Esk Co.	Hennepin, IL	Silicon carbide.
Do.	Thorold, Ontario, Canada	Fused aluminum oxide (regular).
General Abrasives Triebacher, Inc.	Niagara Falls, NY	Fused aluminum oxide (regular and high-purity).
Do.	Niagara Falls, Ontario, Canada	Fused aluminum oxide (regular) and silicon carbide.
Praxair Surface Technologies, Inc.	Indianapolis, IN	Fused aluminum oxide (high-purity).
Saint-Gobain/Norton Industrial Ceramics Corp.	Huntsville, AL	Fused aluminum oxide (high-purity) and aluminum-zirconium oxide.
Do.	Worcester, MA	General abrasive processing.
Do.	Chippawa, Ontario, Canada	Fused aluminum oxide (regular and high-purity) and aluminum-zirconium oxide.
Do.	Shawinigan, Quebec, Canada	Silicon carbide.
Superior Graphite Co.	Hopkinsville, KY	Do.
Washington Mills Electro Minerals (Canada) Corp.	Niagara Falls, Ontario, Canada	Fused aluminum oxide (regular).
Washington Mills Electro Minerals (US) Corp.	Niagara Falls, NY	Fused aluminum oxide (high-purity).
Washington Mills Ltd.	Niagara Falls, Ontario, Canada	Fused aluminum oxide (regular).

TABLE 12
END USES OF CRUDE SILICON CARBIDE AND ALUMINUM OXIDE (ABRASIVE GRADE) IN THE UNITED STATES AND CANADA, AS REPORTED BY PRODUCERS

Use	1992 Quantity (metric tons)	1992 Value (thousands)	1992 Yearend stocks	1993 Quantity (metric tons)	1993 Value (thousands)	1993 Yearend stocks

W Withheld to avoid disclosing company proprietary data; included with "Other." XX Not applicable.

[1] Excludes secondary (recycle) producers.

[2] Total quantity of the various types of metallic abrasives that a plant could have produced during the year, working three 8-hour shifts per day, 7 days per week, allowing for usual interruptions, and assuming adequate fuel, labor, and transportation.

[3] Includes cut wire, aluminum, stainless steel shot, and items indicated by symbol W.

[4] Data may not add to totals shown because of independent rounding.

ALUMINUM, BAUXITE, AND ALUMINA

By Patricia A. Plunkert and Errol D. Sehnke

Ms. Plunkert, a physical scientist with 25 years of U.S. Bureau of Mines experience, has been the commodity specialist for aluminum since 1987. Domestic survey data for aluminum were prepared by Shonta E. Osborne, lead statistical assistant; and the international data table was prepared by Harold D. Willis, international data coordinator.

Mr. Sehnke is a physical scientist with 20 years of minerals industry and U.S. Bureau of Mines experience. Domestic survey data for bauxite and alumina were prepared by Shonta E. Osborne, lead statistical assistant; and international data tables were prepared by Harold D. Willis, international data coordinator.

Aluminum is the second most abundant metal element in the Earth's crust after silicon, yet it is a comparatively new industrial metal that has been produced in commercial quantities for just over 100 years. It weighs about one-third as much as steel or copper; is malleable, ductile, and easily machined and cast; and has excellent corrosion resistance and durability. Measured either in quantity or value, aluminum's use exceeds that of any other metal except iron, and it is important in virtually all segments of the world economy.

Domestic primary aluminum production decreased significantly in 1993 to its lowest level in 6 years. Thirteen companies operated twenty-two primary aluminum reduction plants and 1 plant remained temporarily closed. Montana, Oregon, and Washington accounted for 34% of the production; Kentucky, North Carolina, South Carolina, and Tennessee, 22%; and other States, 44%. The value of primary metal produced domestically in 1993 was estimated at $4.3 billion. In response to rising world inventories and depressed prices, more than one-half of the domestic primary aluminum smelters announced temporary shutdowns in production capacity during the year.

Aluminum recovered from purchased scrap, however, increased to more than 2.9 million metric tons. Forty-five percent of this recovered metal came from new (manufacturing) scrap and 55% from old scrap (discarded aluminum products). The recycling rate for aluminum used beverage can (UBC) scrap decreased slightly compared with that of the previous year, but remained above the 60% level for the fifth consecutive year.

Aluminum consumption, by an estimated 25,000 firms, was centered in the East Central United States. Packaging accounted for an estimated 30% of domestic consumption; transportation, 26%; building, 17%; electrical, 9%; consumer durables, 8%; and other uses, 10%.

U.S. imports for consumption increased dramatically in 1993 and reached an alltime high. Although there were increased imports from several different countries, one of the most significant increases was the rise in the level of imported ingot from the former U.S.S.R. Total exports, however, decreased to their lowest level since 1987.

The price of primary aluminum ingot trended downward during 1993 on the domestic and world markets. Prices in the aluminum scrap markets paralleled the general trend of primary ingot prices.

World inventories of metal continued to rise during the year. By yearend, inventories on the London Metal Exchange (LME) reached record levels, approaching 2.5 million tons. Inventories held by producers, as reported by the International Primary Aluminium Institute (IPAI), exceeded 2 million tons.

Primary aluminum was produced in 44 countries in 1993. The United States was the largest producer with 19% of the world total, followed by Russia with 15% and Canada with 12%. World metal production remained relatively unchanged compared with that of the previous year. Announced production cutbacks, particularly in the United States and Europe, were counterbalanced by increased smelter capacity that started production during the year. The flow of metal from the former U.S.S.R. to Western markets continued. In late 1993, the Government of Russia invited representatives from several major aluminum-producing countries to Moscow to prepare the framework for informal multilateral meetings to discuss the crisis in the world aluminum market.

U.S. mine production of bauxite increased in 1993; however, imports continued to dominate the domestic market. U.S. bauxite mine production amounted to less than 1% of total world production. Three companies operated surface mines in Alabama and Georgia. Virtually all of the domestic ore was consumed in the production of nonmetallurgical products such as abrasives, chemicals, proppants, and refractories. The United States remained totally dependent on foreign sources of metallurgical-grade bauxite, and approximately 92% of the total bauxite consumed in the United States during 1993 was utilized for the production of alumina.

World production of bauxite and alumina, feedstocks for the aluminum industry, increased by modest amounts in 1993. Mine production of bauxite was reported from 26 countries, and alumina was produced in 29 countries.

Identified world bauxite resources (reserves plus subeconomic and undiscovered deposits) at yearend 1993 were estimated by the U.S. Geological Survey to be 55 to 75 billion tons, in South America (33%), Africa (27%), Asia (17%), Oceania (13), and elsewhere (10%). The world reserve base was estimated by the U.S. Bureau of Mines at 28 billion tons and world reserves at 23 billion tons.

DOMESTIC DATA COVERAGE

Domestic production and consumption data for aluminum, bauxite, and alumina are developed by the U.S. Bureau of Mines from five separate, voluntary surveys of U.S. operations. Typical of these monthly, quarterly, and annual surveys is the "Aluminum" survey. Of the 13 companies canvassed by this form, all responded, representing 100% of the total domestic primary aluminum production.

ANNUAL REVIEW—ALUMINUM

Production

Primary.—Domestic primary aluminum production, totaling 3,694,752 tons, decreased compared with 1992 production levels. At the beginning of 1993, one smelter was temporarily closed and the other 22 smelters were operating at or near full capacity levels. During the year, several companies announced temporary reductions in primary metal capacity levels. In their company annual reports and press releases, the companies stated that these reductions were in response to shortages of available electricity and/or depressed metal prices. By the end of the year, domestic primary aluminum production capacity had been reduced by a total of 790,000 tons, 20% of engineered capacity levels. *(See tables 1 and 2.)*

Secondary.—According to a survey conducted by the Aluminum Association Inc., the Institute of Scrap Recycling Industries, and the Can Manufacturers Institute, 59.5 billion aluminum UBC's were recycled in 1993, equivalent to a recycling rate of 63.1%. This was the fifth consecutive year that the recycling rate of aluminum UBC's has exceeded 60%. *(See tables 3, 4, and 5.)*

Consumption and Uses

The container and packaging industry remained the largest domestic consumer of aluminum products, representing about 30% of the domestic shipments of aluminum products. The Can Manufacturers Institute reported that 95.1 billion aluminum beverage cans were shipped in 1993, representing more than 97% of the total metal beverage can shipments.

The transportation industry accounted for about 26% of domestic aluminum shipments. According to a factsheet, "Aluminum Applications in the Automotive Industry," published by the Aluminum Association in October 1993, the use of aluminum by the auto industry has more than doubled from an average of 35 kilograms (77 pounds) per car in 1971 to 87 kilograms (191 pounds) in 1991. Aluminum is used to make hundreds of parts in the automotive industry. The report provided the following examples of aluminum's widespread use. Approximately 30% of all wheels are aluminum, and some forecasts call for that number to increase to 50% by 1995. Almost all passenger car heat exchanger systems produced in the United States are aluminum. Virtually all passenger car transmission cases are now produced in aluminum, as well as some differential carriers. *(See tables 6, 7, and 8.)*

Stocks

Inventories of aluminum ingot, mill products, and scrap at reduction and other processing plants, as reported by the U.S. Department of Commerce, increased from 1.875 million tons at yearend 1992 to 2.046 million tons at yearend 1993.

The LME reported that its U.S. warehouses held a total of 167,600 tons of primary aluminum metal ingot at yearend 1993, a decrease from the 213,525 tons of metal reportedly held in these warehouses at yearend 1992. The LME also reported that aluminum alloy ingot held at its U.S. warehouses at yearend 1993 decreased to 980 tons, a mere fraction of the 10,120 tons of alloy held at yearend 1992. Increased demand by the domestic automotive diecasting industry reportedly contributed to this major decrease in LME alloy inventories.

There were no releases of aluminum metal from the National Defense Stockpile (NDS) during the year, and the inventory level remained at 57,010 tons.

Markets and Prices

The monthly average U.S. market price of primary aluminum metal, as reported by Platt's Metals Week, fluctuated throughout the year but with a general downward trend. The monthly average price began the year at a high of 56.132 cents per pound and posted a low of 49.950 cents per pound in November. The average price for the year was 53.326 cents per pound, slightly more than 4 cents per pound lower than the 1992 average annual price of 57.519 cents per pound. The LME cash price for high-grade primary aluminum ingot followed the same general trend as the U.S. market price. The 1993 average annual LME cash price was 51.667 cents per pound.

Purchase prices for aluminum scrap, as quoted by American Metal Market (AMM), fluctuated during the year and closed the year at lower levels than those at the beginning of the year. The yearend price ranges for selected types of aluminum scrap were as follows: mixed low-copper-content aluminum clips, 39.5 to 40.5 cents per pound; old sheet and cast, 34.5 to 35.5 cents per pound; and clean, dry aluminum turnings, 34 to 35 cents per pound. Prices for UBC's trended downward for most of the year and closed about 6 cents per pound lower than prices at the beginning of the year. Aluminum producers' buying price range for processed and delivered UBC's, as quoted by AMM, began the year at 40 to

42 cents per pound. The price range at the end of the year widened and decreased to 33 to 37 cents per pound.

In mid-July, AMM discontinued the publication of secondary aluminum ingot prices and substituted an indicator price series. The yearend 1993 indicator price for selected secondary aluminum ingots were as follows: alloy 380 (1% zinc content), 61.96 cents per pound; alloy 360 (0.6% copper content), 67 cents per pound; alloy 413 (0.6% copper content), 67.09 cents per pound; and alloy 319, 64.52 cents per pound.

The LME began cash trading of a secondary aluminum contract in January. The 1993 annual average price, based on 11 months of prices, was 45.13 cents per pound. Metals Week published an annual average U.S. price of 55.46 cents per pound for A-380 alloy (3% zinc content), the alloy comparable to that traded on the LME.

Foreign Trade

Exports of all forms of aluminum from the United States decreased from those of 1992 and reached their lowest level since 1987. Most of the decrease occurred in the crude metal and alloys category.

Imports for consumption, however, increased dramatically to a record high. As with exports, the major change in shipments occurred in the crude metal and alloy category. Shipments from most countries increased from those of the previous year. Canada remained the major shipping country to the United States, accounting for two-thirds of the ingot imports in 1993. The most dramatic increase, however, was in the level of imports from Russia, which became the second largest shipping country of aluminum ingot into the United States. Combined imports from Russia and Tajikistan approached 440,000 tons compared with slightly more than 16,000 tons of ingot imports from countries in the former U.S.S.R. in 1992. *(See tables 9, 10, 11, and 12.)*

World Review

World production of primary aluminum metal was relatively unchanged in 1993 compared with that of the previous year. Increased smelter capacity that started production during the year was offset by cuts in production in Europe and the United States. The continued slowdown in world economic activity outside of the United States, and the buildup of inventory levels, especially those inventories held by the LME, kept world metal prices at a depressed level. Russian metal exports continued to flow onto the world market. Estimates of the quantity of metal exported from the former U.S.S.R. ranged from 1.6 million tons to more than 2 million tons.

Primary aluminum inventories held by members of the IPAI, which represent the bulk of stocks held outside the former centrally planned economy countries and the LME, increased from 1.717 million tons at yearend 1992 to 2.007 million tons at yearend 1993. IPAI reported that total metal inventories, including secondary aluminum, increased from 3.283 million tons at yearend 1992 to 3.532 million tons at yearend 1993.

Inventories of primary aluminum metal held by the LME reached record levels in 1993. LME inventories increased by almost 1 million tons during the year. At the beginning of the year, LME inventories totaled 1.527 million tons. By yearend, the total had climbed to 2.486 million tons.

In August, the European Commission announced the introduction of a 60,000-ton limit on aluminum imports from the former U.S.S.R. effective until the end of November. The limit was subsequently extended to allow another 45,000 tons of imports through the end of February 1994. The import quotas were imposed on all aluminum metal, whether it arrived directly from states in the former U.S.S.R. or through a third country. The imposition of the import quotas was seen as a temporary measure while negotiations for an agreed-upon level of imports continued.

In October, the Russian Government invited several world aluminum-producing countries to Moscow to prepare the framework for informal multilateral meetings to address the crisis in the world aluminum market. Representatives from Australia, Canada, the European Community (EC), Norway, Russia, and the United States met to discuss the oversupply situation that resulted from the downturn in the major Western economies and the introduction of the former U.S.S.R. as a major exporter of aluminum. The 2-day meeting ended with a commitment by all participants to meet again in Washington, DC, in December.

The second round of meetings held in Washington, DC, brought together the same group of producing nations along with their industry representatives, who were invited to give presentations outlining their analyses of the crisis in the aluminum market. Industry participation was limited to a general session on the first day of the meetings and included most of the presidents and chief executive officers of the world's major aluminum-producing companies, as well as representatives from the IPAI. Industry estimated that between 1.5 and 2 million tons of aluminum had to be taken out of production to return the market to balance by 1996. Although no solution was reached by the government representatives at the meeting, the framework for future meetings was outlined. *(See table 13.)*

Current Research

Bench-scale tests by the U.S. Bureau of Mines have shown that magnesium and zinc can be readily distilled from common aluminum alloys. The results showed that temperature and pressure strongly influenced distillation rates. Changes in the alloy composition, however, did not have a noticeable effect on the distillation rates. Even though the distillation rates were high, they were less than predicted by distillation equations, and possible explanations were explored. A conceptual apparatus for integrating distillation into a secondary aluminum smelter was discussed.[1]

OUTLOOK—ALUMINUM

The world demand for aluminum metal

showed signs of improvement during the first half of 1994. Demand for aluminum remained strong in the United States, and other areas of the world appeared to be edging out of the recent economic downturn. Aluminum metal prices had improved, and inventories, both LME and IPAI, began to slowly decrease. Exports of aluminum metal continued to flow out of Russia but were beginning to be absorbed by slowly expanding aluminum markets. If these positive economic signs persist, the excess metal inventory supply overhanging the market should begin to fade away and eventually return to a more economically acceptable level. Thereafter, the long-term growth rate for aluminum metal should average about 2% per year.

ANNUAL REVIEW—BAUXITE AND ALUMINA

World production of bauxite and alumina increased only modestly during 1993; bauxite production rose by 4% and alumina output was up 3% over the previous year's total. Mine production of bauxite was reported from 26 countries. Domestic consumption of bauxite in 1993 rose over 1992 consumption levels, but remained below a previous recent high reached in 1991. Within the specialty products area, consumption of abrasive-grade bauxite fell below 1992 usage, but bauxite consumption by the chemical and refractory industries increased in 1993. Demand for alumina was sluggish throughout the year, mainly in response to reduced primary aluminum smelter operating levels. U.S. production of smelter-grade alumina increased by 2% in 1993, while shipments declined by a very slight amount, less than 1%. U.S. alumina consumption moderated slightly from 1992 levels and a continued softening of the alumina market developed throughout 1993 as a buildup occurred in alumina stocks. Alumina reportedly was produced in 29 countries around the world. *(See table 14.)*

Legislation and Government Programs

There were no additions of bauxite to the NDS in 1993; however, 508,000 tons of Jamaican-type metallurgical-grade bauxite was released from the NDS as part of two individual, 5-year sales arrangements begun in fiscal 1993 by the Defense Logistics Agency (DLA). Reynolds Metals Co. bought 245,000 tons of this material at $8.29 per ton and Kaiser Aluminum and Chemical Corp. bought a similar amount at $6.40 per ton. Under terms of the separate agreements, the purchase price accepted in fiscal 1993 will be indexed in future years to average quarterly LME primary aluminum prices. Additionally, at the close of the 1993 fiscal year, 49,000 tons of calcined refractory-grade bauxite was sold from the NDS.

Under the new Department of Defense Annual Materials Plan (AMP) for fiscal year 1994, released in mid-1993, DLA was authorized to dispose of a further 914,000 tons of metallurgical-grade bauxite—approximately 610,000 tons of Jamaica type and 305,000 tons of Suriname type. In fact, on December 16th, under this new authority, the DLA agreed with Kaiser and Reynolds on terms of sale for the fiscal year 1994 quotas in their separate long-term contracts to purchase metallurgical-grade bauxite from the NDS. Kaiser was awarded 305,000 tons of Jamaican-type bauxite at $8.53 per ton, while Reynolds was awarded 305,000 tons at $6.59 per ton. In addition, as a part of the 1994 AMP, DLA expects to release 51,000 tons of calcined refractory-grade bauxite in fiscal year 1994. This is the maximum amount recommended for disposal during the fiscal year, and the actual level of sales will depend upon prevailing market conditions.

At yearend 1993, NDS holdings for metallurgical-grade bauxite were 11.6 million tons of Jamaica type and 5 million tons of Suriname type with both of these amounts authorized for total disposal. The NDS calcined refractory-grade bauxite inventory was listed as 231,000 tons, with 161,000 tons authorized for disposal.

Production

The total U.S. bauxite production during 1993 was 29% greater than that reported for 1992. The only currently active bauxite mines remaining in the United States are the surface operations in Alabama and Georgia that produce bauxitic materials, a natural mixture of bauxitic clay and bauxite with a very low iron oxide content, primarily used for the production of alumina calcines. Demand for these domestic ores increased by a moderate amount during 1993. Within this market sector, the Harbison-Walker Refractories Div. of INDRESCO Inc. shipped bauxite from mines in Alabama to its local calcining plant and to Carbo Ceramic Co.'s proppant plant at Eufaula, AL. Throughout the year, C-E Minerals continued to operate and maintain its mines in Alabama and Georgia, with the raw ore shipped to its Andersonville, GA, facility for the production of refractory products.

In 1993, Kaiser Aluminum and LaRoche Chemicals Inc. formed a worldwide joint venture to market alumina trihydrate. The marketing venture, Kaiser LaRoche Hydrate Partners, reportedly will focus its marketing efforts on companies that produce flame retardants, catalysts, zeolites, aluminum sulfate, and other specialty chemicals. *(See tables 15 and 16.)*

Consumption and Uses

Weak demand for smelter-grade alumina lowered the consumption of crude and dried metallurgical-grade bauxite to a level below that of 1992. Consumption of bauxite by the abrasive industry decreased by nearly 10% in 1993, while consumption within the chemical and refractory industries increased by moderate amounts for the year. Approximately 92% of the bauxite consumed in the United States during 1993 was refined to alumina, and an estimated average of 2.08 tons of dried bauxite was required to produce 1 ton of calcined alumina. Twenty-two primary aluminum smelters reported a consumption of 7.42 million tons of calcined alumina in 1993, a 9% decrease from the consumption level reported for 1992. This lower rate of consumption, coupled with a lower level of U.S. alumina imports, resulted in the development of a reduced supply of smelter-grade alumina for the domestic alumina market. An estimated 91% of the alumina shipped by U.S. refineries went to domestic primary smelters for metal production. Consumption in various forms by the abrasives, chemicals, refractories, and specialties industries accounted for the balance of the alumina usage. *(See tables 17, 18, 19, and 20.)*

Markets and Prices

Contract terms for the purchase of metallurgical-grade bauxite and smelter-grade alumina in world markets are not normally made public, and, consequently, prices for these commodities are not published by trade journals. Price quotes are generally limited to certain specialty forms of bauxite and alumina for nonmetallurgical uses.

In 1993, the U.S. Bureau of Mines estimated the average value of domestic crude bauxite shipments, f.o.b. mine or plant, to be $21 per ton. The average value of calcined domestic bauxite was estimated to be $195 to $200 per ton. Base prices quoted by Industrial Minerals magazine and independent sources for imported calcined refractory-grade bauxite were as follows: Chinese, typical 85% alumina (Al_2O_3), f.o.b. barge, Burnside, LA, $85 to $120 per ton; and Guyanese, f.o.b. rail car, Baltimore, MD, or f.o.b. barge, Gulf Coast, $175 ton. Abrasive-grade bauxite, minimum 86% Al_2O_3, c.i.f. main European ports, was priced at $95 to $108 per ton. Base prices were subject to adjustment for various grain-size specifications, size of order, and fuel cost factors.

A growing alumina surplus on world markets led to prices easing from the very high levels established during the previous 2 years. The average value of domestic calcined alumina shipments was estimated to be $192 per ton. Trade data released by the Bureau of the Census indicated the average value of imported calcined alumina was $182 per ton, f.a.s. port of shipment, and $194 per ton, c.i.f. U.S. ports. Beyond these current prices, medium-term projections support a reasonably resilient market outlook for alumina toward the mid-1990's.

For 1993, the International Bauxite Association (IBA) once again recommended that its members set their minimum c.i.f. price for metallurgical-grade bauxite at between 2% and 2.5% of the composite reference price for primary aluminum ingot and for metallurgical-grade alumina between 14.5% and 16.5% of the composite reference price for primary aluminum ingot. In 1993, IBA member countries produced 38% of the world's bauxite and 16% of its alumina.

A second United Nations Conference on Trade and Development (UNCTAD) ad hoc review meeting on bauxite was held April 29-30, 1993, in Geneva, Switzerland, to provide the world's bauxite-producing countries with a forum in which to discuss the need for a producer-consumer dialogue. The meeting focused on the need for improved market transparency, especially improved statistical data, and particularly, information regarding the republics of the former U.S.S.R. *(See table 21.)*

Foreign Trade

Dried bauxite exports from the United States totaled 85,000 tons in 1993, a major increase over the 1992 total of 54,400 tons; Canada received 98% of the 1993 exports. U.S. exports of calcined refractory-grade bauxite totaled 2,800 tons for 1993; Mexico received 57% and Canada 43%. Exports of all other grades of calcined bauxite (chiefly abrasive grade) amounted to 2,000 tons for the year. Specialty aluminum compounds exported included 6,800 tons of aluminum sulfate, 7,800 tons of aluminum chloride, 10,700 tons of aluminum oxide abrasives, and 26,900 tons of various fluoride-based compounds of aluminum, including synthetic cryolite and aluminum fluoride.

Imports for consumption of crude and dried bauxite increased by 6% from the level of 1992 receipts, and the four principal suppliers, Jamaica, Guinea, Brazil, and Guyana, in order of shipments, provided 93% of the total. As in previous years, China and Guyana remained the dominant suppliers of calcined bauxite to the United States. Australia continued to be the primary source of U.S. alumina imports, accounting for approximately 70% of the total receipts for the year. *(See table 22, 23, 24, and 25.)*

World Review

World production of bauxite and alumina increased in spite of a continued sluggishness in demand for primary aluminum metal and a protracted surge of aluminum from the former U.S.S.R. Twenty-six countries reportedly mined bauxite in 1993, and the total world production of bauxite increased to 105.6 million tons, an increase of 4% over 1992 production. Australia, Guinea, Jamaica, and Brazil, in order of volume, accounted for slightly more than 70% of the total bauxite mined during the year. The corresponding world output of alumina increased to 43 million tons, which was 3% above the 1992 production level. The four principal producing countries, Australia, United States, Russia, and Jamaica, in order of volume, supplied approximately 60% of the total world production.

Capacity.—The 1993 world annual rated capacity of plants producing alumina remained essentially unchanged from the 1992 level. At the same time, apparent worldwide refinery capacity utilization for 1993 was estimated at approximately 89% and represented a increase of about 2% from the previous year. As has been the case in recent years, further increases in smelter-grade alumina production capacity are primarily expected to develop from incremental expansions of existing plants and only in very special situations from new greenfield refineries, which normally demand a 4- to 5-year design, engineering, and construction period, plus very significant levels of capital investment.

Australia.—In 1993, production levels rose in this, the world's largest bauxite- and alumina-producing country. Bauxite output was up by about 5% and alumina increased by nearly 7%.

As a result of the decision by Australia's High Court on the Mabo native claims case in mid-1992, several Mabo-style land claims were filed by Aboriginal groups in 1993, including those that challenged Comalco Ltd.'s bauxite mining leases at Weipa, on the Cape York Peninsula in the far north of Queensland. However, the Native Title Act 1993, which was passed into law by Australia's Federal Government in late 1993, validated all mining leases granted before 1975 and thereby ensured that Comalco's bauxite operations in Queensland were not subject to native title claims.

Alcoa of Australia Ltd. announced plans to increase production capacity at its Wagerup alumina plant in Western Australia by a further 200,000 tons per year to an annual capacity of approximately 1.7 million tons, with this new capacity expected to come on-stream in mid-1994.

In an effort to strengthen its presence in the Pacific Basin market area, Alusuisse-Lonza announced that the majority of its bauxite, alumina, and alumina trihydrate trading activities would be moved from Zurich, Switzerland, to Sydney, Australia. This marketing activity will be managed by a newly incorporated group, Alusuisse Australasia Pacific Pty. Ltd.

Brazil.—Mineraçao Rio do Norte (MRN), operator of Brazil's large Trombetas bauxite mining operation in the Amazon Basin, reportedly signed an agreement to supply alumina plants in Ukraine and Kazakhstan with 500,000 tons of bauxite in 1993. The price of the bauxite was expected to be between $22.50 and $23 per ton, f.o.b. Trombetas.

Plans reportedly were undertaken to resume construction work on a limited scale at the long-delayed 1.1-million-ton-per-year Alunorte alumina plant near Belém in northern Brazil. State-controlled Companhia Vale do Rio Doce (CVRD) indicated that it would finance construction using its own resources, Government funds, and capital from two recent joint ventures.

Canada.—Alcan Aluminium Ltd. of Canada announced the development of a new variant of the Bayer process designed to exploit the different dissolution temperatures of alumina minerals in the recovery of alumina from bauxite. The new process, designated as counter-current digestion, reportedly provides energy savings of 7% to 10%.

Ghana.—Ghana reportedly was once again seeking foreign investors for the development of an alumina plant to fully exploit its bauxite resources at Nyinahin and Kibi.

Greece.—It was announced that Russia and Greece are to resume the construction of the stalled 700,000-ton-per-year alumina plant near Thísvi in central Greece. Russia now plans to acquire a 51% share in the Hellenic Alumina Industries S.A. (Elva) joint-venture project by providing $178 million in direct financial investment. Alumina produced by the facility would be supplied to Russia under long-term contracts, with Russia providing natural gas as payment for the material.

Hungary.—The Hungarian aluminum producer, Hungalu, secured alumina-aluminum barter agreements with Russian partners covering approximately 400,000 tons of its alumina exports in exchange for 60,000 tons of Russian metal imports in 1993. These trade contracts are expected to provide short-term relief to Hungary's struggling bauxite and alumina industries.

India.—Alcoa signed a joint-venture agreement with India's Associated Cement Companies Ltd. (ACC) to manufacture and market raw materials for the Indian refractories and ceramic industries. The new business partners plan to build a facility at Falta, in West Bengal, capable of producing 10,000 tons of tabular alumina and magnesium aluminate spinel aggregates when it becomes operable in the second quarter of 1994.

India's privately owned Indian Aluminium Co. (Indal) and Tata Industries have joined with Norsk Hydro of Norway to set up an export-oriented company that will build an alumina plant with an annual installed capacity of 1 million tons per year in India's eastern State of Orissa. The facility, which will be based on Alcan and Alusuisse technology, is expected to cost 24,000 million Rupees (US$774.2 million) and projected to come on-stream in 1998.

Indonesia.—Another country interested in joining the alumina-producing countries of the world is Indonesia. The Indonesian Government entered into a joint-venture project to study the feasibility of establishing a 900,000-ton-per-year alumina plant on Bintan Island in the Riau Archipelago. This is a reactivation of a project initiated in the early 1980's.

Jamaica.—In Jamaica, alumina output at Jamalco was increased to 700,000 tons per year and was scheduled to be expanded to 1 million tons per year by 1994. Jamalco is a joint venture of Alcoa and the Jamaican Government.

Russian Federation.—A Russian-registered joint stock company, Boksit Timana, was reportedly awarded the tender to develop the Middle Timan bauxite deposits of the Komi Republic. The development costs for this project have been estimated at several billions of dollars.

Saudi Arabia.—Saudi Arabia reported the identification of additional bauxite reserves near Az Zabirah in the northern part of the country. Bauxite occurrences in this area were evaluated in the late

1970's to early 1980's.

In a related matter, the Gulf Organization for Industrial Consulting (GOIC) attempted to attract financial interests in Saudi Arabia and the United Arab Emirates to invest in developing the region's first alumina plant. Presently, the majority of the region's alumina requirements are supplied by Australia.

South Africa, Republic of.—Royal Dutch/Shell indicated it had entered discussions with South Africa's Gencor Ltd. for the purchase of the major portion of the metal assets owned by companies within the Royal Dutch/Shell Group. Gencor reportedly has expressed a specific interest in the aluminum industry assets that Royal Dutch/Shell holds in Australia, Brazil, and Suriname. They comprise various joint-venture holdings in bauxite and alumina operations.

Suriname.—Suriname Aluminium Co. (Suralco) declared a force majeure on alumina shipments in early February due to an unexpected labor action at its Paranam operations. The union and company management were able to reach agreement in about 2 weeks, and the force majeure was lifted following settlement of the strike.

In 1993, Billiton Maatschappij Suriname commenced mining operations at the Accaribo bauxite deposit near Paranam.

Venezuela.—By midyear, various reports indicated that Venezuela's CVG intended to merge its aluminum industry holdings—Bauxiven, Interalumina, and Venalum—into one single operating company.

ICF Kaiser Engineers announced that it was awarded a 9-month, $1 million contract to conduct a feasibility study for expanding CVG Interalumina's alumina plant at Puerto Ordaz, Venezuela, to an annual capacity of 3 million tons per year. The study is being funded by the U.S. Trade and Development Agency. *(See tables 26 and 27.)*

OUTLOOK—BAUXITE AND ALUMINA

Known world bauxite reserves are sufficient to meet cumulative world demand well into the 21st century. Considering the high probability of discovering additional bauxite deposits, plus the added possibility of employing lower grade bauxite deposits and other alternative sources of alumina, world resources of aluminum remain adequate to satisfy demand for the foreseeable future.

The continued and extended economic restructuring of Eastern Europe and the newly independent republics of the former U.S.S.R. appears to provide substantially increased market opportunities for the established bauxite- and alumina-producing countries of the world. The quality and quantity of bauxite resources within the former Eastern bloc nations are believed to be incapable of sustaining an economically viable market-based aluminum industry. To become truly competitive in the "new global economy," major amounts of imported bauxite and alumina feedstocks will be required to supply the primary aluminum production facilities of the former U.S.S.R. The most crucial element in the development of this trade pattern will be the implementation of adequate and reliable payment or tolling mechanisms for the continued timely transfer of these vital raw materials to the aluminum industry of the former U.S.S.R.

In the short term, the outlook for the metallurgical markets of bauxite and alumina seem rather bleak owing to the oversupply of primary aluminum metal that has been provoked by substantial exports from the former U.S.S.R. and excess primary metal production capacity in the Western World. On a more positive note, nonmetallurgical consumers of bauxite and alumina are expected to provide the fastest growing markets in the 1990's. In these specialty product areas it is envisioned that bauxite and alumina will lose some market share within the refractory and abrasive materials sectors, but gain very substantially in the ceramics and plastics markets.

Total of all scrap consumed	[r]80,453	3,187,468	3,186,414	81,507

[r] Revised.

[1] Includes imported scrap. According to reporting companies, 8.41% of total receipts of aluminum-base scrap, or 265,305 metric tons, was received on toll arrangements.

[2] Includes inventory adjustment.

[3] Includes data on foil, can stock clippings, and other miscellaneous.

[4] Used beverage cans toll treated for primary producers are included in secondary smelter tabulation.

[5] Includes municipal wastes (includes litter) and fragmentized scrap (auto shredder).

TABLE 5

PRODUCTION AND SHIPMENTS OF SECONDARY ALUMINUM ALLOYS BY INDEPENDENT SMELTERS IN THE UNITED STATES

(Metric tons)

	1992		1993	
	Production	Net shipments[1]	Production	Net shipments[1]
Die-cast alloys:				
13% Si, 360, etc. (0.6% Cu, maximum)	41,921	[r]44,703	45,539	44,724
380 and variations	[r]465,503	[r]465,009	517,948	516,863
Sand and permanent mold:				
95/5 Al-Si, 356, etc. (0.6% Cu, maximum)	78,089	67,146	85,064	84,406
No. 12 and variations	W	W	W	W
No. 319 and variations	[r]52,852	[r]52,931	67,373	65,654
F-132 alloy and variations	52,652	51,483	24,025	25,844
Al-Mg alloys	645	644	639	641
Al-Zn alloys	3,086	2,881	3,218	3,468
Al-Si alloys (0.6% to 2.0% Cu)	10,680	10,705	10,840	11,018
Al-Cu alloys (1.5% Si, maximum)	1,664	1,588	1,738	1,726
Al-Si-Cu-Ni alloys	1,352	1,326	1,360	1,395
Other	[r]2,707	[r]2,771	3,792	3,812
Wrought alloys: Extrusion billets	[r]71,486	[r]65,861	80,914	84,880
Miscellaneous:				
Steel deoxidation	3,345	3,413	—	—
Pure (97.0% Al)	59	69	—	—
Aluminum-base hardeners	93	97	93	93
Other[2]	34,262	33,433	34,244	35,233
Total	[r]820,396	[r] [3]804,063	876,787	879,757
Less consumption of materials other than scrap:				
Primary aluminum	65,351	—	79,643	—
Primary silicon	35,573	—	39,192	—
Other	3,620	—	4,601	—
Net metallic recovery from aluminum scrap and sweated pig consumed in production of secondary aluminum ingot[4]	[r]715,852	XX	753,351	XX

[r] Revised. W Withheld to avoid disclosing company proprietary data; included with "Sand and permanent mold: Other." XX Not applicable.

[1] Includes inventory adjustment.

[2] Includes other die-cast alloys and other miscellaneous.

[3] Data do not add to total shown because of independent rounding.

[4] No allowance made for melt-loss of primary aluminum and alloying ingredients.

TABLE 6
U.S. APPARENT ALUMINUM SUPPLY AND CONSUMPTION

(Thousand metric tons)

	1989	1990	1991	1992	1993
Primary production	4,030	4,048	4,121	4,042	3,695
Change in stocks:[1]					
Aluminum industry	+61	+2	+45	-100	-171
LME stocks in U.S. warehouses	—	—	-168	-46	+46
National Defense Stockpile	—	—	—	-55	—
Imports	1,470	1,514	1,490	1,725	2,545
Secondary recovery:[2]					
New scrap	1,043	1,034	969	[r]1,144	1,312
Old scrap	1,011	1,359	1,317	1,612	1,632
Total supply	7,615	7,957	7,774	[r]8,322	9,059
Less total exports	1,615	1,659	1,762	1,453	1,207
Apparent aluminum supply available for domestic manufacturing	6,000	6,298	6,012	[r]6,869	7,852
Apparent consumption[3]	4,957	5,264	5,043	5,725	6,540

[r] Revised.

[1] Positive figure indicates a decrease in stocks; negative figure indicates an increase in stocks.

[2] Metallic recovery from purchased, tolled, or imported new and old aluminum scrap expanded for full industry coverage.

[3] Apparent aluminum supply available for domestic manufacturing less recovery from purchased new scrap (a measure of consumption in manufactured end products).

TABLE 7
DISTRIBUTION OF END-USE SHIPMENTS OF ALUMINUM PRODUCTS IN THE UNITED STATES, BY INDUSTRY

Industry	1991		1992		1993	
	Quantity (thousand metric tons)	Percent of grand total	Quantity (thousand metric tons)	Percent of grand total	Quantity (thousand metric tons)	Percent of grand total
Containers and packaging	2,210	[r]28.5	2,259	[r]28.1	2,181	26.2
Building and construction	1,052	13.6	1,144	[r]14.2	1,237	14.9
Transportation	[r]1,414	[r]18.2	[r]1,591	[r]19.8	1,904	22.9
Electrical	579	7.5	587	7.3	609	7.3
Consumer durables	472	6.1	523	6.5	563	6.8
Machinery and equipment	426	5.5	448	5.6	477	5.7
Other markets	241	3.1	256	3.2	259	3.1
Total to domestic users[1]	[r]6,395	[r]82.5	[r]6,809	84.6	7,231	86.9
Exports	1,357	[r]17.5	[r]1,236	15.4	1,092	13.1
Grand total[1]	[r]7,752	100.0	[r]8,045	100.0	8,324	100.0

[r] Revised.

TABLE 8
U.S. NET SHIPMENTS[1] OF ALUMINUM WROUGHT AND CAST PRODUCTS, BY PRODUCERS

(Metric tons)

	1992	1993[p]
Wrought products:		
Sheet, plate, foil	4,097,009	4,030,039
Rod, bar, pipe, tube, and shapes	1,185,893	1,293,910
Rod, wire, cable	303,475	296,935
Forgings (including impacts)	61,705	126,865
Powder, flake, paste	43,035	58,796
Total	5,691,117	5,806,545
Castings:		
Sand	98,761	NA
Permanent and semipermanent mold	197,848	NA
Die	594,531	NA
Other	26,703	NA
Total	917,843	NA
Grand total	6,608,960	NA

[p] Preliminary. NA Not available.

[1] Net shipments derived by subtracting the sum of producers' domestic receipts of each mill shape from the domestic industry's gross shipments of that shape.

TABLE 13—Continued

ALUMINUM, PRIMARY: WORLD PRODUCTION,[1] BY COUNTRY

(Thousand metric tons)

Country	1989	1990	1991	1992	1993[e]
United Arab Emirates: Dubai	168	174	239	[e]240	225
United Kingdom	297	[r]294	294	[r]244	235
United States	4,030	4,048	4,121	4,042	[2]3,695
Venezuela	540	590	601	[r]561	570
Yugoslavia[6] [13]	331	349	315	—	—
Total[14]	[r]19,010	[r]19,299	[r]19,575	[r]19,467	19,816

[e]Estimated. [r]Revised.

[1] The U.S. Bureau of Mines defines primary aluminum as "The weight of liquid aluminum as tapped from pots, excluding the weight of any alloying materials as well as that of any metal produced from either returned scrap or remelted materials." International reporting practices vary from country to country, some nations conforming to the foregoing definition and others using different definitions. For those countries for which a different definition is given specifically in the source publication, that definition is provided in this table by footnote. Table includes data available through June 16, 1994.

[2] Reported figure.

[3] Primary ingot plus secondary ingot.

[4] Dissolved Dec. 31, 1992.

[5] All production in Czechoslovakia from 1989-92 came from Slovakia.

[6] Primary ingot.

[7] Ingot and rolling billet production.

[8] Excludes high-purity aluminum containing 99.995% or more as follows, in metric tons: 1989—15,696; 1990—16,292; 1991—19,652; 1992—19,605 (revised); and 1993—20,258.

[9] Primary unalloyed ingot plus secondary unalloyed ingot.

[10] Primary unalloyed metal plus primary alloyed metal, thus including weight of alloying material.

[11] Formerly part of Czechoslovakia; data were not reported separately until 1993.

[12] Dissolved in Dec. 1991.

[13] Dissolved in Apr. 1992.

[14] Data may not add to totals shown because of independent rounding.

TABLE 14

SALIENT BAUXITE STATISTICS

(Thousand metric tons and thousand dollars)

	1989	1990	1991	1992	1993
United States:					
Production: Crude ore (dry equivalent)	W	W	W	W	W
Value	W	W	W	W	W
Exports (as shipped)	44	[r]74	51	[r]63	90
Imports for consumption[1]	10,893	12,144	11,871	10,939	11,621
Consumption (dry equivalent)	11,810	12,042	12,204	[r]11,873	11,917
World: Production	[r]103,722	[r]109,042	[r]107,916	[r]101,145	[e]105,550

[e]Estimated. [r]Revised. W Withheld to avoid disclosing company proprietary data.

[1] Excludes calcined bauxite. Includes bauxite imported to the U.S. Virgin Islands.

TABLE 15
PRODUCTION AND SHIPMENTS OF ALUMINA IN THE UNITED STATES

(Thousand metric tons)

Year	Calcined alumina	Other alumina[2]	Total[1]	
			As produced or shipped[3]	Calcined equivalent
Production:[e]				
1989	4,580	605	5,180	5,000
1990	4,775	655	5,430	5,230
1991	4,805	610	5,415	5,230
1992	4,740	640	5,380	5,185
1993	4,835	655	5,490	5,290
Shipments:[e]				
1989	4,665	605	5,270	5,090
1990	4,750	575	5,325	5,150
1991	4,865	630	5,500	5,305
1992	4,805	650	5,455	5,260
1993	4,775	660	5,435	5,230

[e] Estimated.

[1] Data may not add to totals shown because of independent rounding.

[2] Trihydrate, activated, tabular, and other aluminas. Excludes calcium and sodium aluminates.

[3] Includes only the end product if one type of alumina was produced and used to make another type of alumina.

TABLE 16
CAPACITIES OF DOMESTIC ALUMINA PLANTS,[1] DECEMBER 31

(Thousand metric tons per year)

Company and plant	1991	1992	1993
Aluminum Co. of America: Point Comfort, TX	1,735	1,735	1,735
Kaiser Aluminum & Chemical Corp.: Gramercy, LA	1,000	1,000	1,000
Ormet Corp.: Burnside, LA	545	600	600
Reynolds Metals Co.: Corpus Christi, TX	1,700	1,700	1,700
Virgin Islands Alumina: St. Croix, VI	635	635	635
Total	5,615	5,670	5,670

[1] Capacity may vary depending on the bauxite used.

TABLE 17
U.S. CONSUMPTION OF BAUXITE, BY INDUSTRY

(Thousand metric tons, dry equivalent)

Industry	1991	1992	1993
Alumina	11,383	11,066	11,002
Abrasive[1]	204	223	203
Chemical	218	190	225
Refractory	328	[r]334	429
Other	71	60	58
Total	12,204	[r]11,873	11,917

[r] Revised.

[1] Includes consumption by Canadian abrasive industry.

TABLE 18
PRODUCTION AND SHIPMENTS OF SELECTED ALUMINUM SALTS IN THE UNITED STATES IN 1992

Item	Number of producing plants	Production (thousand metric tons)	Total shipments, including interplant transfers	
			Quantity (thousand metric tons)	Value (thousands)
Aluminum sulfate:				
Commercial and municipal (17% Al_2O_3)	73	950	921	$108,739
Iron-free (17% Al_2O_3)	21	194	194	20,161
Aluminum chloride:				
Liquid and crystal	6	21	W	W
Anhydrous (100% $AlCl_3$)	4	18	18	15,292
Aluminum fluoride, technical	4	W	W	W
Aluminum hydroxide, trihydrate [100% $Al(OH)_3$]	10	768	770	174,512
Aluminates	18	114	108	32,353
Other aluminum compounds[1]	XX	XX	XX	163,617

W Withheld to avoid disclosing company proprietary data. XX Not applicable.

[1] Includes light aluminum hydroxide, cryolite, etc.

Source: Data are based on Bureau of the Census 1992 Current Industrial Reports, Series MA-28A, "Inorganic Chemicals."

TABLE 19
STOCKS OF BAUXITE IN THE UNITED STATES,[1] DECEMBER 31

(Thousand metric tons, dry equivalent)

Sector	1992	1993
Producers, processors, and consumers	2,319	1,045
Government	17,805	16,938
Total	20,124	17,983

[1] Domestic and foreign bauxite; crude, dried, calcined, activated; all grades.

TABLE 20
STOCKS OF ALUMINA IN THE UNITED STATES,[1] DECEMBER 31

(Thousand metric tons, calcined equivalent)

Sector	1992	1993
Producers	492	529
Primary aluminum plants	[r]1,224	1,211
Total	[r]1,716	1,740

[r] Revised.

[1] Excludes consumers' stocks other than those at primary aluminum plants.

TABLE 21
AVERAGE VALUE OF U.S. IMPORTS OF CRUDE AND DRIED BAUXITE[1]

(Per metric ton)

Country	1992		1993	
	Port of shipment (f.a.s.)	Delivered to U.S. ports (c.i.f.)	Port of shipment (f.a.s.)	Delivered to U.S. ports (c.i.f.)
Australia	$17.55	$30.55	$12.41	$20.81
Brazil	29.40	40.51	28.67	36.18
Guinea	28.65	35.88	25.43	32.68
Guyana	30.13	40.38	32.06	42.00
Jamaica	28.13	33.63	28.95	34.46
Weighted average	28.58	36.25	27.84	34.84

[1] Computed from quantity and value data reported to U.S. Customs Service and compiled by the Bureau of the Census, U.S. Department of Commerce. Not adjusted for moisture content of bauxite or differences in methods used by importers to determine value of individual shipments.

TABLE 22
U.S. EXPORTS OF ALUMINA,[1] BY COUNTRY

(Thousand metric tons, calcined equivalent, and thousand dollars)

Total[9]	[r]103,722	[r]109,042	[r]107,916	[r]101,145	105,550

[e]Estimated. [r]Revised. W Withheld to avoid disclosing company proprietary data; not included in "Total."

[1] Table includes data available through July 20, 1994.

[2] Reported figure.

[3] Dry bauxite equivalent of crude ore.

[4] Less than 1/2 unit.

[5] Bauxite processed for conversion to alumina in Jamaica plus kiln-dried ore prepared for export.

[6] Public-sector production only.

[7] Dissolved in Dec. 1991. In addition to the bauxite reported in the body of the table, Russia produces nepheline syenite concentrates and Azerbaijan produces alunite ore as sources of aluminum. Nepheline syenite concentrate, produced in Russia was as follows, in thousand metric tons: 1989—1,697; 1990—1,650 (estimated); 1991—1,500 (estimated); 1992—1,000 (estimated); 1993—800 (estimated). Estimated alunite ore produced in Azerbaijan was as follows, in thousand metric tons: 1989—600; 1990—550; 1991—500; 1992—300; and 1993—200. Nepheline syenite concentrate grades 25% to 30% alumina, and alunite ore grades 16% to 18% alumina; these commodities may be converted to their bauxite equivalent by using factors of 1 ton of nepheline syenite concentrate equals 0.55 ton of bauxite and 1 ton of alunite equals 0.34 ton of bauxite.

[8] Dissolved in Apr. 1992.

[9] Data may not add to totals shown because of independent rounding.

TABLE 27

ALUMINA: WORLD PRODUCTION,[1] BY COUNTRY[2]

(Thousand metric tons)

[e] Estimated. [r] Revised.

[1] Figures represent calcined alumina or the total of calcined alumina plus the calcined equivalent of hydrate when available; exceptions, if known, are noted.

[2] Table includes data available through July 20, 1994.

[3] Dissolved Dec. 31, 1992.

[4] All production in Czechoslovakia from 1989-92 came from Slovakia.

[5] Reported figure.

[6] Hydrate.

[7] Data presented are for alumina used principally for specialty applications. Gross weight of aluminum hydrate for all uses was as follows, in thousand metric tons: 1989—863; 1990—890; 1991—864; 1992—714 (revised); and 1993—704.

[8] Formerly part of Czechoslovakia; data were not reported separately until 1993.

[9] Dissolved in Dec. 1991.

[10] Dissolved in Apr. 1992.

[11] Data may not add to totals shown because of independent rounding.

ANTIMONY

By James F. Carlin, Jr.

Mr. Carlin, a physical scientist with more than 30 years of industry and U.S. Bureau of Mines experience, has been the commodity specialist for antimony since 1993. Domestic survey data were prepared by Joi Brown, statistical assistant; and international data were prepared by Ted Spittal, international data specialist.

Domestic consumption of primary antimony products increased substantially in 1993, as did production of primary antimony. Imports of antimony products declined slightly while exports declined substantially.

Primary antimony metal and oxide were produced by six companies operating six plants using both foreign and domestic feed material. Two plants were in Texas, and there was one each in Idaho, Montana, Nebraska, and New Jersey. A very small amount of antimony was recovered as a byproduct from the smelting of lead and silver-copper ores. Virtually all antimony metal (unalloyed) and oxides produced domestically originated from imports. The estimated value of primary antimony metal and oxides produced in 1993 was $62 million. The estimated distribution of primary antimony uses was as follows: flame retardants, 57%; transportation, including batteries, 22%; chemicals, 8%; ceramics and glass, 7%; and other, 6%.

Antimony produced from domestic source materials was derived mainly from recycled lead-acid batteries. Recycling plus U.S. mine output supplied less than one-half of the estimated domestic demand.

Antimony was mined as a principal product and produced as a byproduct of the smelting of base metal ores in 19 countries. China, the world's leading producer, accounted for 68% of the total world estimated mine production during 1993. China, together with the other three major producing countries, Bolivia, Russia, and the Republic of South Africa, accounted for about 87% of the total world estimated mine antimony production. *(See table 10.)*

Identified world antimony reserves at yearend 1993 were estimated to be 4.2 million metric tons.

DOMESTIC DATA COVERAGE

Domestic primary production data for antimony are developed by the U.S. Bureau of Mines from a voluntary survey of U.S. operations. Of the six operations to which a survey request was sent, all responded, representing 100% of the primary smelter production shown in table 1. *(See table 1).*

ANNUAL REVIEW

Strategic Considerations

Public Laws 99-661 and 102-484 provided authorization for additional antimony monthly sales through 1994 or until the 3,507 short tons authorized for fiscal year 1993 is disposed. Sales of antimony from the National Defense Stockpile took place for the first time since 1988. Sales were conducted on a sealed bid basis, commencing on June 27 and were held the third Thursday of each month. Each month a maximum of 500 short tons of antimony, either Grade A or Grade B, was offered, usually in the form of ingots or cakes. In 1993, a total of 2,656 short tons was sold.

Antimony is stockpiled in Government warehouses in 13 locations, with the Somerville, NJ, depot holding the largest amount.

Domestic Production

Mine Production.—In the Coeur d' Alene district of Idaho, Sunshine Mining Co. produced antimony as a byproduct of the treatment of tetrahedrite, a complex silver-copper-antimony sulfide ore.

Smelter Production.—**Primary.**—The producers of primary antimony metal and oxide products were ASARCO Incorporated, Omaha, NE; Amspec Chemical Corp., Gloucester City, NJ; Anzon Inc., Laredo, TX; Laurel Industries Inc., La Porte, TX; Sunshine Mining Co., Kellogg, ID; and U.S. Antimony Corp., Thompson Falls, MT.

Secondary.—Old scrap, predominantly lead battery plates, was the source of essentially all of the secondary antimony output. New scrap, mostly in the form of drosses and residues from various sources, supplied the remainder. The antimony content of scrap was usually recovered and consumed as antimonial lead. *(See table 2.)*

Consumption and Uses

Domestic consumption of primary antimony increased substantially in 1993. The most significant increases occurred in the categories of antimonial lead, ceramics and glass, and plastics (especially as flame retardants). Lead-antimony alloys were used in starting-lighting-ignition batteries, ammunition, corrosion-resistant pumps and pipes, tank linings, roofing sheets, solder, cable sheaths, and antifriction bearings.

Antimony compounds were used in plastics as stabilizers and as flame retardants. Antimony trioxide in an organic solvent was used to make textiles, plastics, and other combustibles flame resistant. Antimony was used as a decolorizing and refining agent in some forms of glass, such as optical glass. The estimated distribution of antimony uses was flame retardants, 74%; transportation, including batteries, 11%; chemicals, 9%; ceramics and glass, 2%; and other, 4%. *(See tables 3, 4, and 5.)*

Markets and Prices

The New York dealer antimony metal price, published by Metals Week, averaged $0.77 per pound for the year, continuing the generally downward trend of recent years. The price range for high-tint antimony trioxide was $1.10 to $1.20 per pound at the beginning of the year and declined to a range of $1.00 to $1.10 per pound by the fourth quarter.

Foreign Trade

Total imports of antimony materials were about the same as those in 1992. China supplied about 60% of the total imported materials. Exports of antimony oxide were about 19% lower than those of the previous year. *(See tables 6, 7, 8, and 9.)*

OUTLOOK

Antimony demand rose to a new plateau in 1993, but it is not clear whether it can maintain that level or continue increasing. Some of that increased demand was probably due to continued lower antimony prices during the year. Most of the increased demand was registered in the category of flame retardants, and it is anticipated that field should grow, although tin and other metals are gaining as acceptable substitutes with commendable qualities of their own.

It is anticipated that China's dominance as a supplier of antimony will continue for the foreseeable future.

BARITE

By James P. Searls

Mr. Searls, a physical scientist and economist with 17 years of institute, government, and U.S. Bureau of Mines experience, is the commodity specialist for barite. Domestic survey data were prepared by Maria Rosa Arguelles, statistical assistant; and international data were prepared by Virginia Woodson, international data coordinator.

Domestic sales of barite as reported decreased 3% to 315,000 metric tons. Apparent consumption, as reported, increased 67% to about 1.1 million tons. A different measure of domestic consumption, which is referred to as "shipments from crushers and grinders" of both domestically produced and imported barite, indicated a much smaller trend. These operations reported an increase in sales of 4% to 1.0 million tons. Exports were 18,000 tons while imports rose strongly to 766,000 tons.

DOMESTIC DATA COVERAGE

Domestic production data for barite are developed by the U.S. Bureau of Mines (USBM) from a voluntary survey of U.S. operations. Of the 37 operations to which a survey request was sent, 4 had closed, 5 were idle, 11 were estimated, and 17 reported data. Reported data represented 51% of "sold or used by producers" and 48% of "crushed and ground (sold or used by processors)" shown in table 1. *(See table 1.)*

BACKGROUND

Definitions and Specifications

The term "primary barite," as used in this report, refers to the first marketable product and includes crude barite, flotation concentrate, and other beneficiated material such as washer, jig, heavy media, table, or magnetic separation concentrate. Most primary barite requires fine grinding before it is used for drilling muds, the principal end use. This grinding may or may not be done at the mine site.

Barite is the mineralogical name for barium sulfate and was derived from the Greek word "barus," meaning heavy. In commerce, the mineral is sometimes referred to as "heavy spar" or "barytes." "Spar" means almost any transparent or translucent, readily cleavable, crystalline mineral having a vitreous luster.[1] One domestic barite producer has commenced naming its white, technical-grade barite as "baryte" to separate it from the American Petroleum Institute (API) barite. API barite can be blue, black, brown, or gray depending on the ore body. Few mines in the United States produce a "spar-grade" barite.

Specifications for barite vary according to different uses. Material for weighing muds must only be finely ground, dense, and chemically inert; consequently, barite for this purpose must have a specific gravity of 4.2 or higher, it must be free of soluble salts, and 90% to 95% of the material must pass through a 325-mesh screen. A small percentage of iron oxide is not objectionable. Technical-grade barite, "barytes" to some, is also graded on reflectivity (e.g., 90%) and color. In chemical manufacturing, purity is the principal concern, and a maximum of 1% each of ferric oxide (Fe_2O_3) and strontium sulfate ($SrSO_4$) and a trace of fluorine usually are specified, with a minimum of 94% barium sulfate ($BaSO_4$). If the mineral is to be used in the production of lithopone, the $SrSO_4$ content may be somewhat higher. Mesh size is important to chemical manufacturers; if the material is too fine, dust is lost, and if it is too coarse, mixing with carbonaceous material is poor. Most chemical manufacturers specify a size range of 4 to 20 mesh; some purchase lump barite and grind it to their own needs.

Products for Trade and Industry

The principal use for barite, as a weighing material in well-drilling muds, accounted for 90% of total U.S. consumption in 1993 using "Crushed and ground (sold or used by processors)" data. Drilling muds have five main functions: (1) transport drill cuttings to the surface; (2) control formation pressures; (3) maintain bore hole stability; (4) protect producing zones; and (5) cool and lubricate the bit and drill string. Barite's lack of hardness (Mohs scale 2 to 3.5) is a plus in this application. The principal function of the barite constituent is as a weighing agent to suppress high formation pressures and prevent blowouts. The deeper the hole, the more barite is needed as a percentage of the total mud mix because hydrocarbon pressures rise strongly with increasing depth after about 2,130 meters (7,000 ft) of depth. The added weight of the barite in the column of mud in the drill string is used to counteract the dangerous pressures when deep reservoirs of hydrocarbons are encountered. High pressure hydrocarbons, if uncontrolled, can cause extremely dangerous pressure releases and/or fires at the drilling rig.

The use of barite as a filler or extender and other uses accounted for about 10% of total U.S. consumption in 1993. Barite has a high specific gravity, low oil absorption, easy wettability by oils, and good sanding qualities. Unbleached barite may be substituted for bleached barite when brightness is not a factor. In painting automobiles, barite is used as a filler for the primer coat where the barite contributes to the gloss of the topcoat and inertness to chemical attack. When the primers are applied by the electrodeposition process, the body structure is dipped into a tank containing water and paint primer. The method eliminates one of the primary coats, thus reducing the quantity of barite used.

Barite also is used as a filler or extender in some plastic and rubber products. Processors of polyurethane foam use barite in manufacturing such products as floormats and carpet-backings to add weight and improve processing qualities. Barite is used in white sidewalls for tires; sidewalls consist mainly of rubber, zinc oxide, and a small quantity of barite.

Other industries use small quantities of barite fillers. In the paper industry, the white and dense barite coatings serve as a base for the sensitized layers in photographic prints. In the printing industry, barite is used in inks.

In glassmaking, barite is added to the glass melt to reduce the heat-insulating froth that forms on the melt surface, thus saving fuel, and to act as an oxidizer and decolorizer, making the glass more workable and increasing its brilliance. Glass manufacturers usually require a minimum of 95% $BaSO_4$ with a maximum of 2.5% silicon dioxide (SiO_2) and 0.15% Fe_2O_3. The particle-size range generally preferred is -30 to +140 mesh. Finely ground barite can be substituted when crushed material is not available. In glass manufacture, barite reduces seeds and annealing time and increases toughness and brilliancy.

Minor uses include ballast for ships, heavy concrete aggregate for radiation shielding and pipeline-weighing in swampy or aquatic areas, friction products, and applications in foundries.

Barite is also a raw material for barium chemical manufacturing. Barite is the leading commercial source of barium and barium compounds in the United States. About 200 tons of witherite ($BaCO_3$) was imported from Canada, China, and Japan in 1993 and may be a starting point for barium chemical end uses. The major barium chemicals are the manufactured carbonate, chloride, hydroxide, nitrate, oxide, peroxide, and sulfate.

The most important barium chemical is precipitated barium carbonate, which is a raw material for production of many of the other compounds. It is also used in brick and tile manufacturing to control scum caused by gypsum or magnesium sulfate in the clay (the barium combines with the sulfate to form the insoluble barium sulfate) and to diminish porosity and prevent discoloration in brick. Other uses are in television picture tubes as a radiation barrier, optical glass, ceramic glazes, porcelain enamel, ferrites, and miscellaneous ceramic products. Barium-base glass (using barium carbonate) is considered to be more brilliant than lime glass and more durable than lead glass. Barium carbonate is replacing lead oxide in television tube faceplates to stop X-ray radiation. The same amount of strontium carbonate will be used with the barium as was used with the lead. The X-rays occur when the high voltage electrons from the "gun" that excite the phosphors have been stopped quickly at the faceplate.

Blanc fixe, chemically precipitated barium sulfate, is used as a white filler in paints, rubber, inks, and other material where a degree of purity higher than natural barite is required. Barium chloride is used in case-hardening and heat-treating baths, in leather and cloth, in making magnesium metal, in water treatment, and as a laboratory reagent. Fused barium chloride may be electrolyzed to produce barium metal.

Barium metal also is produced by reduction of barium oxide. The metal is used as a "getter" to remove traces of gas from vacuum tubes, or in alloys for spark plugs and electronic emission elements in electronic tubes.

Barium nitrate is used in green signal flares, tracer bullets, primers and detonators, and enamels. Barium oxide is used in electric furnace ferrous metallurgy to increase the life of acid furnace linings, to give a quieter and steadier arc, to reduce the sulfur content of the iron, and to lower the slag viscosity.

Barium hydroxide us used to prevent scumming in ceramics, to make soap for lubricating oils and greases, and to recover sugar from molasses by the barium saccharate process. Barium titanate finds use in miniature electronic and communication equipment.

Industry Structure

Currently, much of the barite that is supplied to the drilling mud industry is supplied by barite from China and India. The domestic industry is undergoing changes with downsizing in the United States and movement toward Asia and countries in and around the former U.S.S.R. Several U.S. firms import barite and grind the barite to size in plants along the gulf coast instead of producing from U.S. mines owing to the lower cost of the imported barite delivered at the grinding plant. A Nevada mine reopened during 1992 owing to transportation cost reductions. Seven mining firms, operating 10 mines, continue to compete in the industry. One U.S. mine is owned by a Canadian company and one mine is owned by a French company. Only one barium chemical firm competes in the barium chemical industry using its domestically mined barite from another division, mixed with imported barite, as feedstock.

Geology

Pure barite has a specific gravity of 4.5. Barite varies considerably in appearance depending on source and treatment. It is a moderately soft crystalline material with a Mohs hardness between 3 and 3.5. In residual deposits, it ranges in size from large boulders to fines. Shades of white to dark gray and black, depending on impurities and surficial coating, are common in commercial deposits.

Vein and cavity-filling deposits are those in which barite occurs along faults, joints, bedding planes, and other solution channels or sink structures. These deposits are found most often in limestone. Most of the vein deposits are believed to be of hydrothermal origin.

In central Missouri, barite occurs in circular deposits in karst or collapse and sink structures. These ores are rich, but the deposits are generally small in overall extent. These deposits are also important as the source of the residual ore upon weathering.

Residual barite deposits are formed by weathering of preexisting deposits. The principal residual deposits are found in southeastern Missouri; the Appalachian region; Sweetwater, TN; Cartersville, GA; and in the Rio Grande area of Texas. A concentration of at least 60 to 180 kilograms of barite per cubic meter is required in a commercial deposit. In Washington County, MO, the residuum is 3 to 4.6 meters thick, while in Cartersville, GA, the ore is 45 meters thick in some areas. This form of deposit has been of considerable economic significance.

The most important commercial deposits are of bedded barite. These are principally in Arkansas, California, and Nevada. The barite in these areas is generally dark gray to black and has a characteristic fetid odor when struck with a hammer. The beds, which vary in thickness from 5 centimeters to more than 15 meters, occur interbedded with dark chert and siliceous siltstone and shale. In most of the deposits, the barite is laminated. In some areas, barite nodules and rosettes make up a large part of the beds. Many of the beds contain 50% to 95% barite. Originally, it was thought that these deposits were the result of the replacement of carbonate rocks; however, current thought is that the deposits are of sedimentary origin. The actual environment of deposition has not been established, but theories range from submarine volcanic emissions to hydrothermal solutions to recycling of barite from preexisting rocks.

ANNUAL REVIEW

Legislation and Government Programs

The antidumping duty on barium carbonate from Germany continued for another year. The proposed exemption of barium sulfate from reporting requirements of the category "barium compounds" of the list of toxic chemicals under section 313 of the Emergency Planning Act of 1986 (EPCRA) was announced for comment but not completed in 1993.

Producers

Dresser Industries Inc., an equipment manufacurer (through M.W. Kellog) for refineries, petrochemicals, and liquefied natural gas production, announced its intention to buy Baroid Corp. in September. The purchase was not completed by the end of the year due to the Justice Department's concerns for: (1) Dresser's partial (64%) ownership of M-I Drilling Fluids, and (2) Baroid's diamond drill bit subsidiary DBS. Dresser was expected to sell its portion of M-I Drilling Fluids. Halliburton maintained its ownership of the 36% of M-I Drilling Fluids. Milpark Drilling Fluids became part of Baker Hughes Inteq, a drilling equipment company, in March 1993. It would appear that the oil-well drilling fluids companies went through a consolidation phase in the early 1980's as consumption dropped and recently have been drawn into vertically integrated companies that have drilling equipment, drill bits, drilling fluids, other equipment, and services.

Of the 37 operations that were surveyed, 23 were mills (processing or beneficiating plants, and crushing and grinding operations) and 14 were mines. Seventeen mills were operating, two mills were idle during the year, and four mills had closed. Eleven mines were operating and three mines were idle. Only one mine reported run-of-mine ore sales, therefore run-of-mine ore was not included in table 1. The recently reopened mine was not surveyed and did not verbally report until after the USBM data entry window had closed and therefore was estimated.

Sales

For 1993, beneficiated product was 100% of reported sales because the small amount of run-of-mine ore sales was withheld. *(See table 1.)* For 1993, "Sold or used by producers" is incorrect and should be 100,000 to 125,000 tons more, which would also increase apparent consumption figure by the same amount. *(See tables 2 and 3.)*

Consumption and Uses

The consumption of crushed and ground barite, as reported in table 1, increased about 4% from 1 million tons in 1992. Apparent consumption, as calculated by "Sold or used by producers" minus exports plus imports, rose by 67% as reported in the table. The oil- and gas-well-drilling industry was estimated to have completed more than 24,900 wells and drilled nearly 42.3 million meters (139 million feet) of hole.[2] This is 4% above 1992's revised number of holes and more than 9% above 1992's revised total distance. From a table reporting oil, gas, and dry well completions, total oil wells for 1993 were estimated to be 8,274, a more than 7% drop from 8,943 wells in 1992 and much less than the 11,916 wells in 1991. Gas wells in 1993 rose more than 16% from the 1992 total gas wells. The first three quarters of 1992 averaged 1,762 gas well completions per quarter, the last quarter of 1992 and the first quarter of 1993 averaged 3,087 gas wells per quarter, and the final three quarters of 1993 were estimated to have averaged 2,187 gas wells per quarters. This would seem to support the renewed interest in natural gas production in the United States that caused some increase in barite consumption. *(See table 4.)* For end of year 1993 (week ending December 24), the week-average-oil-futures price for light sweet crude oil had fallen by 27.5% from $19.92 in the same week of 1992 while the natural gas price had fallen by about 1.1% on the same basis.[3] The future price for light sweet crude in the week ending July 9, 1993, was $18 per barrel, so the decrease in oil futures price occurred later in the year.

At the beginning of the year, the Baker Hughes' monthly average active U.S. rig count reported that there were 922 drilling rigs with 368 directed toward oil prospects or developments and 527 rigs directed toward gas prospects or developments. At midyear, there were 353 oil rigs and 346 gas rigs. At the end of the year, there were 385 oil rigs and 423 gas rigs for a total of 814 rigs, down 12% from 922 rigs at the beginning of the year.

Prices

Price quotation in Industrial Minerals Magazine for API grade on the U.S. gulf coast was $85 per ton through March when the series switched to prices paid by grinders for Chinese and Indian lump barite.

The reported average value per ton of domestic barite, based on reported value of direct-ship, beneficiated, and floated material, increased slightly, f.o.b. plant, from $60.22 to $61.16. The average value of crushed or ground barite, sold or used by processors, was $74.16, a 12% decline from $84.49 per ton reported in 1992. Within this group, the average value of barite for well-drilling end use was $64.26, down 14% from $75.55 per ton, while the average value for barium chemicals, filler and extender, and glass was essentially unchanged at $163.10 per ton. The average c.i.f. value of imported crude barite was $37.72 per ton, while the c.i.f. value of imported ground barite was $139.78 per ton.

Foreign Trade

Exports of natural barium sulfate or barite rose by 50% to 18,500 tons but was still well under the 1991 figure of 43,000 tons. Export data provided by the Bureau of the Census did not indicate the grades of barite traded; however, based only on the per-ton value of individual shipments, which varies from about $40 to nearly $2,000 per ton, drilling-, filler-, glass-, chemical-, and pharmaceutical-grade were all exported. *(See table 5.)*

Imports for consumption of crude barite rose sharply (137%) from 1992 to nearly 766,000 tons. The principal source countries, in descending order, were China, India, and Mexico. The shipment listed from Switzerland was probably from India, according to its price. The higher priced material was chiefly crude filler and extender-quality barite. Most of the crude barite entered through customs districts along the gulf coast for delivery to grinding plants in the area. *(See tables 6 and 7.)*

World Review

Little change in overall barite production occurred around the world because production has moved closer to the areas of petroleum drilling. The former U.S.S.R. and Asia are the areas of present and future petroleum exploration and development. It is less likely that barite will be hauled long distances to these areas, given barite's worldwide distribution. Some areas, such as Turkey and Kazakhstan, will produce more barite in the near future for drilling in nearby countries, and some countries, probably including the United States, will produce less barite as drilling profits decline. The forecast for the United States is not perfectly clear as gas exploration may be profitable due to the environmental friendliness of gas consumption according to the new administration.

The Ballynoe Mine, owned by Magcobar (Ireland) Ltd., closed permanently in October. *(See table 8.)*

OUTLOOK

With several countries moving away from socialist beliefs and toward greater acceptance of international development of petroleum resources for expertise and financial backing, the petroleum exploration and development effort has moved away from North America and into the former U.S.S.R. and countries in the Pacific Basin. The large volumes of barite that will be needed for the exploration will be more likely to be supplied from mines and mills nearby to those regions and not from the United States. Drilling will continue in the United States, albeit at a slower pace, and for gas.

The domestic barite industry may change its production away from drilling mud barite, dominated by China and India, and toward higher valued products, planning to displace imports from several countries.

[e]Estimated. [r]Revised.

[1] Table includes data available through June 21, 1994.

[2] In addition to the countries listed, Bulgaria also produces barite, but available information is inadequate to make reliable estimates of output levels.

[3] Data are for fiscal year beginning Mar. 21 of that stated.

[4] All production in Yugoslavia from 1989-91 came from Bosnia and Herzegovina.

[5] Barite concentrates.

[6] Data are for fiscal year beginning Apr. 1 of that stated.

[7] Dissolved on Dec. 31, 1992. Production in Czechoslovakia from 1989-91 came from the Czech Republic and Slovakia; all production for 1992 came from Slovakia.

[8] Formerly part of the U.S.S.R.; data were not reported separately until 1992.

[9] Reported figure.

[10] Formerly part of Czechoslovakia; data were not reported separately until 1993.

[11] Dissolved in Dec. 1991.

[12] Sold or used by producers.

[13] Dissolved in Apr. 1992.

BORON

By Phyllis A. Lyday

Mrs. Lyday has covered boron for 15 years. Domestic survey data were prepared by Pam Shorter, statistical assistant; and international data were prepared by Harold Willis, international data coordinator.

U.S. production and sales of boron minerals and chemicals increased during the year. Domestically, glass fiber insulation was the largest use for borates, followed by sales to borosilicate glass, textile-grade glass fibers, and agriculture.

California was the only domestic source of boron minerals. The United States continued to provide essentially all of its own supply while maintaining a strong position as a source of sodium borate products and boric acid exported to foreign markets.

Supplementary U.S. imports of Turkish calcium borate and calcium-sodium borate ores, borax, and boric acid, primarily for various glass uses, continued.

DOMESTIC DATA COVERAGE

Domestic data for boron are developed by the U.S. Bureau of Mines from two separate, voluntary surveys of U.S. operations. Of the three operations to which a sold and used survey request was sent, two responded, representing 99% of the total boron sold or used shown in tables 1 and 8. A U.S. Bureau of Mines canvass of the three U.S. producers also collected data on domestic consumption of boron minerals and compounds shown in tables 3 and 4. *(See table 1.)*

BACKGROUND

Definitions, Grades, and Specifications

Few of the many minerals that contain boron are commercially valuable. Only colemanite and ulexite minerals, primarily imported from Turkey, are marketed in the United States. The boron oxide content of both minerals is usually marketed at about 40%. *(See table 2.)*

Tincal and kernite ore and brines are the U.S. source of refined borate chemical compounds. The most common refined borates, borax pentahydrate and its derivative anhydrous borax, are marketed in technical and agricultural grades. Lesser quantities of borax decahydrate are produced in technical, United States Pharmacopeia, and special quality grades.

Boric acid is a white, odorless, crystalline solid sold in technical national formulary and special quality grades as granules or powder. Boron oxide is a hard, brittle, colorless solid resembling glass that is ground and marketed most often under the name anhydrous boric acid.

Elemental boron is a dark brown powder in the amorphous form and a yellowish-brown, hard, brittle solid in the monoclinic crystalline form. Boron is marketed in grades from 90% to 99% purity.

Ferroboron is a name given to a variety of boron-iron alloys containing 0.2% to 24% boron used primarily to introduce small quantities of boron into specialty steels.

In the boron hydride series are diborane, a gas; pentaborane, a liquid; and decaborane, a solid. These compounds range from 31,220 British thermal units (Btu) per pound for diborane to 27,850 Btu per pound for decaborane.

Boron nitride, a soft, white, highly refractory solid resembling graphite, can withstand significant oxidation to temperatures up to 650°C. Boron nitride produced in fibrous form equals glass fibers in strength and modules of elasticity, but is lighter in weight and more resistant to high temperature. When subjected to extremely high pressure and temperature, boron nitride forms cubic crystals that rival the hardness of diamond. Boron carbide, produced by reacting carbon and boric acid at 2,300° C, is a highly refractory material and one of the hardest substances known. Most commonly used for both abrasive and abrasion-resistant applications as well as nuclear shielding, boron carbide is marketed in technical and high-purity grades.

Geology

At the Kramer borate deposit of the Boron open pit mine, tincal consists of more than 80% of high-grade beds, with claystone only between the crystals. In low-grade beds, tincal is less than 50% of the beds and is disseminated in a claystone matrix. The lower portions of the beds consist of kernite, a secondary mineral formed by the dehydration and recrystallization of borax resulting from high temperature and pressure. Probertite is found radiating prismatic crystals, or rosettes, commonly within claystone and exclusively where kernite is the dominant sodium borate. The sodium borate facies is enveloped by ulexite, colemanite, and barren claystone facies. The barren facies contain calcareous nodules but are barren of borates.[1]

Searles Lake in southeastern California is a closed structural basin filled with alluvian and lacustrine evaporites. The flat area of about 100 square kilometers overlies two separate salt structures. The evaporite beds were formed during periods of high evaporation and low rainfall. Mud beds were formed during full lake conditions. The upper salt structure is 21 to 27 meters thick and the lower one is 8 to 12 meters thick. The brines in these salt structures are high in sodium carbonate and low in sodium chloride. The important chemical ions are bicarbonate, carbonate, borate, chloride, potassium, and sulfate as halite, hanksite, trona, nahcolite, burkeite, borax, and thenardite. An impervious mud parting layer 4 meters thick divides the upper and lower salt layers. The upper brine contains 1.63% borax and is rich in potash. The lower brine contains 1.97% borax and more carbonate.[2]

The Fort Cady colemanite deposit is in the Mojave Desert near Barstow, CA. The known deposit extends over 154 hectares at an average depth of 411 meters from the surface. The deposit is encapsulated in clay beds, which make it an ideal setting for in situ mining technology. Ground water in the ore body is brackish with a total dissolved solids figure in the 20,000-milligram-per milliliter range.[3]

Technology

Problems with the discovery, processing, and transporting of boron minerals and compounds from remote and hostile locations became a part of the history of the borax industry. The location of the ore and the methods of production remained a guarded secret for many centuries. It was not until the end of the 17th century when Amsterdam had replaced Venice as the center of borax production that the mineral source and methods of process were commonly known. Producers of boric acid from the steam vents of Tuscany, Italy, prospered because of a lack of competition in the world market. Large reserves of borates were found in Turkey in 1865 and in the Western United States in 1856. With the discovery of new minerals, new processes were developed. The history of boron production and processing has continued for thousands of years because of the benefits derived from using the product. The use and processing have varied little over the past 100 years. Modern changes in processing are a result of improved equipment and processing controls.

Byproducts and Coproducts

More than four-fifths of the U.S. production comes from mineral deposits mined only for their boron content. The remainder is produced from lake brines, which also supply sodium carbonate, sodium sulfate, potassium sulfate, and potassium chloride. Turkish colemanite, ulexite, and tincal ores are worked only for their boron content. Most Soviet borates also are mined only for their boron content, but the Gulf of Kara-Bagaz-Gol and the Sivash (lagoon) borates are extracted with coproduct chloromagnesium from brines. South American boron has been mined from ores and also has been produced as a coproduct of nitrate and iodine production.

Economic Factors

Costs.—Energy costs are especially high for producing anhydrous products. The anhydrous products were originally introduced to decrease freight costs per ton of contained boron oxide. Domestic producers now use cogeneration facilities to reduce the cost of energy for processing and supplying excess electricity for sale.

Depletion Provisions.—The domestic and foreign depletion allowances for boron are 14% of gross income and may not exceed 50% of net income without the depletion deduction.

Operating Factors

Occupational Safety and Health Administration's (OSHA) Hazard Communication Standard went into effect November 1985 and May 1986. It is OSHA's most comprehensive worker protection regulation. It provides for information and training for workers encountering chemical exposures in the workplace. The standard requires the use of labels and material safety data sheets for all regulated chemicals. Part of the standard includes the Threshold Limit Values (TLV) from the American Conference of Governmental Industrial Hygienist. TLV's refer to airborne concentrations of substances and represent conditions under which nearly all workers might be repeatedly exposed day after day without adverse effect. The only hazard listed for boron chemicals produced at the mine site was a Time Weighted Average for borax decahydrate, listed as 5 milligrams per cubic meter per 8-hour workday, 40-hour workweek, to which nearly all workers may be repeatedly exposed without adverse effect. Sodium borates, boric acid, and boron oxide are not present to any significant degree in air and are placed in the same hazard category as general dust.[4]

Small quantities of boron are essential for all plant life. Boron is added in trace levels to fertilizers; however, quantities well below concentrations affecting humans and animals are so extremely toxic to vegetation that boron compounds also are used commercially as herbicides. Concentrated boric acid is used to control certain insects and in dilute solutions as a preservative to control the growth of bacteria.

Owens-Corning detailed the results of four new studies on fiberglass and human health, which were completed. One of the four studies was an extensive animal inhalation study. The studies, in conjunction with epidemiology, provided strong evidence that working with fiberglass does not pose a significant human health risk. These studies were consistent with the results of animal inhalation studies. Direct injection of fibers into test animals has produced tumors, but the relevance has been challenged most recently by the World Health Organization.[5]

ANNUAL REVIEW

Legislation and Government Programs

The Senate Energy Committee approved a bill October 5 for the California Desert Protection Act. Under the proposed bill, 1.8 million hectares (4.3 million acres) of public land would be designated wilderness. In addition to the wilderness designation, the bill would add 0.5 million hectares (1.3 million acres) of Federal lands to the existing Death Valley National Monument and 83,000 hectares (200,000 acres) to the Joshua Tree National Monument. The land under discussion contains numerous mineral deposits, including most known boron reserves. At yearend, H.R. 2929 had passed the House and was sent to the Senate for further consideration. The U.S. Bureau of Mines published OFR 62-92 (NTIS:PB 92-238237/AS) in May 1992 that presents nine case histories to highlight the diversity of deposits, commodities, and markets represented in the California Desert Conservation Area.

The Department of the Interior, Bureau of Land Management, published in the December 23, 1993, Federal Register the availability of Final Environmental Impact Report/Environmental Impact Statement (EIR/EIS) for the Fort Cady Minerals Corp. borate solution mining project. The decisions generated from the EIR/EIS will be consistent with the California Desert Conservation Plan as Amended.

The Environmental Protection Agency published a proposed rule on Boric Acid and its Salts, Borax (Sodium Borate Decahydrate), Disodium Octaborate Tetrahydrate, Boric Oxide (Boric Anhydride), Sodium Borate and Sodium Metaborate; Tolerance Exemptions in the Federal Register on June 30. The document proposes an exemption from the requirements of a tolerance to be established in or on raw agricultural commodities when used as an active ingredient in insecticides, herbicides, or fungicides preharvest or postharvest in accordance with good agricultural practices.

The Department of Health and Human Services ordered a review of research that concludes fiberglass insulation is a possible carcinogen. Scientists believe that fiberglass insulation may cause cancer in humans. The health threat is to construction workers who install the insulation, not to occupants of the dwelling.

Congress continued to debate the fate of the Mining Law of 1872 as amended and its affect on the hard-rock mineral industry. Boron is leasable as sodium borate. Other colemanite and probertite minerals are locatable because they also contain calcium and are deposited as placer deposits. Changes in the mining law will probably affect royalty rates for minerals, including these locatable industrial minerals in addition to the commonly thought of hard-rock minerals such as gold and copper.

Production

The majority of boron production continued to be from Kern County, with the balance from San Bernardino and Inyo Counties, CA.

American Borate Co. (ABC), a wholly owned subsidiary of Owens-Corning, was sold in December 1990 to a private firm. ABC renewed its mine permits and began to mine small amounts of colemanite and ulexite from the Billie Mine. Colemanite was processed at Lathrop Well, NV. Storage and grinding facilities were at Dunn, CA.

North American Chemical Co. operated the Trona and Westend plants at Searles Lake, in San Bernardino County, to produce refined sodium borate compounds and boric acid from the mineral-rich lake brines. North American is owned by the Harris Chemical Group, with corporate headquarters in New York City and operating headquarters in Overland Park, KS. At the Trona plant, a differential evaporative process produced borax with potash as a byproduct. Boric acid was produced by solvent extraction. The Westend plant used two lines to supply brines to the plant. The first line fed lake brine to the Argus plant where sodium carbonate was produced. The effluent borax-rich brine then is pumped to the Westend plant where it supplied about two-thirds of the brine feed. The effluent was blended with fresh lake brine from a second feed line that supplied about one-third of the brine feed. The blended brine was then cooled to 18° C to precipitate decahydrate borax. The effluent was cooled to 8° C, and the precipitated Glauber's salt was used to produce sodium sulfate. North American was in the process of evaluating technical changes in it production operation that were to be implemented during 1993.

U.S. Borax, Inc. (Borax), a part of Borax Consolidated Ltd. of the RTZ Corp. PLC of London, United Kingdom, continued to be the primary world supplier of sodium borates. RTZ is traded on the New York Stock Exchange. Borax combined its corporate headquarters and Research Center and moved to Valencia, CA, in March 1993.

Borax mined and processed crude and refined sodium borates, their anhydrous derivatives, and anhydrous boric acid at Boron, in Kern County, CA. A second plant at Boron used a proprietary process to produce technical-grade boric acid from Borax's extensive kernite ore reserves. The boric acid was produced to compete with imported colemanite used in glass manufacture.

The majority of material was shipped to Borax's storage in Wilmington, CA. Products made at Wilmington included ammonium borates, potassium borates, sodium metaborates, and zinc borate.

Consumption and Uses

U.S. consumption of borates increased. Glass accounts for three major borate applications as follows: glass fiber insulation, textile glass fiber, and borosilicate glass.

The use of borates in glass fiber thermal insulation, primarily used in new construction, was the largest area of demand for borates and the principal insulating material used in the construction industry. Composed of very thin fibers spun from molten glass, its purpose is to trap and hold air. Typically between 4% and 5% boron oxide is incorporated in the formulation to aid melting, inhibit devitrification, and improve the aqueous durability of the finished product. Cellulosic insulation, the ninth largest area of demand, increased.

The fifth major market for borates, manufacturing high-tensile-strength glass fiber materials for use in a range of products, showed a decrease in demand. The process of producing glass fiber uses a borosilicate E-glass formulation that is continuously drawn through platinum alloy bushings into continuous filaments of between 9 to 20 microns in diameter. The plastic industry uses roving or chopped strand fibers and the textile industry uses yarn fibers.[6] E-Glass, or textile fiber glass, typically contains between 6% and 8% boron oxide.

Originally these glasses were used for electrical purposes, and low sodium levels were important. Now their major applications are reinforcements for plastics, but the low sodium tolerance still applies. The nonconductive and low dielectric properties of high-strength glass-reinforced materials make them transparent to radar and thus valuable for "stealth" applications. Carbon-fiber-reinforced resins can be stronger than metals and, with higher modules, more stable. Although composites can be 10 times more expensive than typical aerospace-grade aluminum, the flexibility they offer in design and consolidation of parts allows large, complex structures to be fabricated to exacting specifications. In addition, their light weight and ability to withstand high temperatures have made them the material of choice for a variety of aerospace applications.

Annual production of fiber glass was reported to be 2 million metric tons per year at a value of $2.3 billion. This represented 18% of the total energy used to produce glass products. Typical glass industry cost for an 80-ton-per-day-capacity fiberglass plant was estimated at $45 million for a product that sells for $750 per ton.[7]

Owens-Corning planned to reopen its Jackson, TN, glass fiber plant that closed in 1987. Capital investment was between $30 and $40 million to install new equipments. When the plant reopens in 1994, it will employ about 80 people and produce wet-process mat glass fiber for use in making roofing shingles.[8]

Consumption of borates in borosilicate glasses remained the third major end use, and demand decreased. Boron added in amounts of between 10% and 13% to glass reduced the viscosity of the melt, assisted with fiber formation during processing, allowed for improved specific optical properties, increased resistance to aqueous or chemical attack, enhanced certain mechanical properties, and reduced the thermal expansion coefficient and thermal shock resistance of the product. Scientific glassware products are usually fabricated in Pyrex borosilicate glass. This type of glass is resistant to heat up to 400° C and to chemical corrosion from liquids and gases.[9]

Construction of the Nation's first facility to produce a borosilicate glass from solid nuclear waste was completed at Savannah River Site, Aiken, SC. High-level nuclear waste that has accumulated during 35 years will be reprocessed and stored in stainless steel canisters for temporary storage before interment in a geologic repository. Boron and lithium are added to the sludge to improve the viscosity of the glass. The viscosity of the borosilicate glass is a function of temperature. Viscosity determines the rate of melting of the raw feed, the rate of glass bubble release (foaming and fining), the rate of homogenization, and therefore, the quality of the final glass product. If the viscosity is too low, excessive convection currents can occur, increasing corrosion and erosion. After vitrification at 1150° C, the glass is pored into the stainless steel canisters for interim storage.[10]

Glazes and enamels are the thin, glassy coatings fused onto ceramics and metals, respectively. Examples include wall and floor tiles, tableware, earthenware, bone china and porcelain, cookers, washing machines, pots and pans, and architectural panelling. The surface decoration of glass articles can now be made with lead-free enamels. A glass enamel composition has a low softening point glass frit and inorganic pigment in a ratio of approximately 9:1. Traditional frits are composed of boric acid, lead, and silica. Traditional lead-bearing frits fired between 540° C to 740° C allow the glass enamel manufacturer to meet requirements of the hand-blown and bent glass industries. Metal in various forms give different colors, such as cobalt silicate for a deep blue; zinc and alumina for lighter shades of blue; chrome oxide for green; and iron, zinc, chrome, and aluminum oxides for brown. Durability can be improved by the addition of titanium dioxide or zirconium oxide. The most common lead-free decorating formulations in frits are zinc borosilicate and bismuth borosilicate, although some barium is being used as a lead replacement. The only difference in lead-bearing enamels is the inability to develop the cadmium sulfoselenide series of yellows, oranges, and reds. At firing, the frit softens and approaches a molten state and wets the pigment and the surface of the article being decorated, thus permanently bonding the glass substrate. Low lead release frits fire at higher temperatures and have low levels of leachability of the lead pigments.[11]

Boron compounds continued to find application in the manufacture of biological growth control chemicals for use in water treatments, algicides, fertilizers, herbicides, and insecticides. Boron can be applied as a spray and incorporated in herbicides, fertilizers, and irrigation water. Sodium polyborate can be used in carpets to control fleas.[12] The Potash & Phosphate Institute of Atlanta, GA, recommended 0.9 kilogram (one-half pound) of boron for every ton of expected yield of alfalfa in the spring 1992 Agi-Briefs. The brief recommended that micronutrient levels in the soil be monitored by soil testing. The Tennessee Valley Authority published Commercial Fertilizer 1993 that list total boron compounds consumed as secondary and micronutrients by region in the United States for 1992 and 1993 as 14,666 and 16,350 metric tons, respectively.

A growing and important use of zinc borate, ammonium pentaborate, and boric oxide is as fire retardants in the cellulosic materials such as chipboard, cellulose insulation, and cotton mattresses. Zinc borate is of commercial importance in synthetic polymers.

Boron compounds also were used in metallurgical processes as fluxes, shielding slag in the nonferrous metallurgical industry, and components in electroplating baths. Small amounts of boron and ferroboron were constituents of certain nonferrous alloys and specialty steels, respectively.

Neodymium-iron-boron alloys used in magnets are produced commercially by melt spinning and sintering. In melt spinning, molten alloy is ejected onto a rotating disk where a ribbon 30 to 50 micrometers thick and 1 to 3 millimeters wide of solid material "spins" off the disk. The process is conducted in an inert atmosphere. In the sintered process, the alloy powder is oriented in a magnetic field, pressed, and sintered. The ingots of the alloy are crushed, milled, and pulverized to a powder of about 3 micrometers in diameter. The alloys of the nonmetal boron and the metals neodymium and iron produces the strongest magnetic material known. The magnets then are used in automotive direct-current motors, computer disk drives, portable power tools, and home appliances.[13]

Boron also is used as a bleaching agent in detergents and cleaning products, such as compact washing powders. Perborates carry active oxygen that forms hydrogen peroxide in solution. Perborate tetrahydrate has been displaced by perborate monohydrate, which is more soluble in cool laundry wash temperature conditions. In the United States, two companies now produce a low-temperature activate perborate bleach.

Recycling

Research attempts have been made at recycling fiber-reinforced plastics, but at present it is not economical. Canada's Enviromental Ministry funded in 1992 a recycling plant reportedly to be the first of its kind in North America. The facility will create new raw materials from old fiberglass boat hulls, bathtubs, and auto parts by separating the glass fibers from the resins.

Prices

Prices for Turkish colemanite and ulexite increase slightly. The price for high-purity boric acid decreased 52%. All other reported prices remained the same. *(See table 5.)*

Foreign Trade

The majority of material from the Borax facility in Boron was shipped to storage, loading, and shipping facilities at Wilmington, CA. A large part of the output was exported to Western Europe from Wilmington to Botlek, Netherlands.

Imports of Turkish colemanite ore totaled 81,650 tons, primarily destined for Owens-Corning Fiberglass, Toledo, OH, through a port in Moreheady City, NC. Carolina Shipping of Charleston, SC, also imported two shiploads through the port of Charleston.

Colemanite exports totaled 16,597 tons. American Borate, Virginia Beach, VA, shipped 8,487 tons of that amount to Keelung and Kaohsiung, China. A company named ITC Inc., Balitmore, MD, shipped 3,146 tons to the Republic of Korea and 887 tons to Hong Kong. American Borate also shipped 2,268 tons to Australia and 1,052 tons to the Republic of South Africa.

Imports of Turkish ulexite ore totaled 135,071 tons, primarily destined for Owens-Corning Fiberglass through the port at Morehead City, NC. A small amount of ulextie from Chile was imported by F & S Alloys & Minerals Corp., New York, NY, through the port of Houston, TX. *(See tables 6 and 7.)*

World Review

Argentina.—The Argentina Mining Plan was announced. The plan changed the collection of taxes to encourage foreign investment. FMC Corp. will begin development of a lithium and boron production facility at the Salar del Hombre Muerto in the northern region because of the new mining plan. FMC plans to utilize new extraction technologies for the brine that will be developed from the salar.

Boroquimica SA continued production of tincal from the Salar del Hombre Muerto and boric acid from Tincalayu in Salta Province. Tincal between 16% and 18% boron oxide is concentrated by washing and crystallizing to a 99.9% borax product. At Sijes in Salta Province, hydroboracite and colemanite are produced. Ulexite is produced by Boroquimica at Cauchari in Jujuy Province and at Diablillos in Salta Province.[14]

Bolivia.—During March 1992, Boron International Inc. entered into an agreement with Teck Corp. to finance an $8 million expansion at Capina for the production of 60,000 tons per year of calcium borate manufactured from ulexite. Current mining in the area of 30,000 tons annually resulted in 8,000 tons of ulexite (40% boron oxide), 4,000 tons of boric acid, and 1,500 tons per year of sodium octaborate.[15]

Compania Minera Tierra Ltd., a small company formed in 1988 for producing borates in an area of the Department of Potosi, has important concessions of ulexite and sulfur near the Chilean border in the southwestern tip of the country. About 120,000 tons per year of ulexite is exported to Brazil and other neighboring countries. In 1990, the company employed 120 persons. In 1993, a boric acid plant was operational and producing 10,000 tons per year.

The company has interest in ulexite mineral concessions that cover an area of 4,800 hectares, and reserves have been estimated by the company to exceed 13 million tons of raw ulexite with grades ranging from 20% to 37%. Ulexite is extracted and dried by plowing with a tractor. The dried ulexite is washed and roasted. The processed ulexite of about 42% borate content is bagged and exported by trucks and rail.

Various borate deposits are in the southwestern part of the Altiplano. Llipi Llipi, in the south of Salar de Uyuni, contains an estimated 12 million tons of ulexite. Copla Ltda. was mining ulexite for export. Production of ulexite in 1989 was 9,609 tons.[16]

The Salar de Uyuni is the largest salt flat in the Central Andes salt basin. The flat is composed of lithium, potassium, and boron salts in the form of brines. In 1988, the Ministry of Mines and Metallurgy and the Complejo Industrial de los Recursos Evaporiticos del Salar de Uyuni (Ciresu) began negotiation with Lithium Corp. of America (LITHCO), a subsidiary of FMC. FMC announced on January 15, 1993, to the Ministry that it was ending plans to explore and develop the brine of the Salar de Uyuni.[17]

Chile.—New legislation in 1992 allowed Corporación Nacional del Cobre de Chile (Codelco) to associate with private national and international firms for exploration and development. State-owned Empresa Nacional de Minería (ENAMI) will be given some smaller prospects at yearend.

Boratom Quimica Processes Ltda. had operated in Chile since 1986 by providing technology and sales support to producers. In 1986, Boratom shipped 3,000 tons of ulexite to the United States in connection with Borichem Inc. The ulexite mines are in the I and II Regions of Chile. Boratom operates a refining plant near Iquique. In March 1992, Boratom's assets and technology were sold to Boron International Inc. (Canada). In November, Boron entered into an agreement with Teck Corp. called Boron Chemicals Processes Chile S.A.[18]

Quimica & Industrial del Borax (Quiborax) was the main producer of boric acid and concentrated ulexite. The second stage of an expansion was completed in 1992. Included in the expansion were about 70,000 square meters of evaporation ponds, a ulexite washing plant, a water purification osmosis plant, and a boric acid plant. Quiborax operated a mine at Surire, Parindacta, with a crude annual output of 1,000,000 tons per year of ulexite. The ulexite is washed and upgraded from 30% to 40% boron oxide by centrifugal action and flotation prior to filtration. Calcium borate is produced by adding calcium hydroxide to the washed ulexite.[19] Beginning in 1993, the boric acid production was estimated to be 20,000 tons and calcium borate production was expected to be 20,000 tons. The plant facilities are at El Aguila, Arica.[20]

The National Boraxx Corp. (Cleveland, OH) packages and distributes boric acid in the United States for Quimica E Industrial del Borax Ltda. (Quiborax Ltda.).[21]

Compania Minera Salar de Atacama (Minsal) is a joint-venture project between AMAX Inc. of the United States, Molibdenos Y Metales (Molymet) of Chile, and Corporacian de Fomento de la Produccion (CORFO). CORFO established the joint venture as a result of an international public licitation in 1986, in which LITHCO was the only other bidder. The project was designed to produce lithium carbonate, potassium chloride, potassium sulfate, and boric acid from the Salar de Atacama in the II Region. Future production was expected to be 26,000 tons of boric acid per year. In February 1991, the project was placed on hold for a second year, under the terms of AMAX's original contract. Sociedad Quimica y Minera del Chile (SQM) acquired the 63.75% stake held by AMAX. Plans were to limit the production to about 300,000 tons per year of potassium chloride and possibly lithium. SQM indicated a target date of mid-1995 for production.[22]

China.—The borates in the salt lakes of China are mainly found on the Qinghai-Xizang (Tibet) Plateau. Boron is distributed in many saline lakes from the southern side of the Gilian Mountains to the north side of the Gangdisi-Tanggula Mountains.

In Liaoning Province, 700,000 tons of ore was mined in 1991. Other provinces where borax was reported were Beijing, Hebei, Heilongjiang, Jilin, Qinghai, Shaanxi, and Tianjin.[23]

France.—An agreement between Callery Chemical Co. and the French Sipsy division of Jouveinal was finalized to develop and produce chemical reagents. Callery is a producer of borane reagents.[24]

Iran.—At Deh-e-Shotoran near Sirjan, the region is of tourmaline-rich granites that have invaded metamorphosed sandstones. Ulexite is found in depressions. At Tonkar near Sabzevar, there are several sources of borates in consolidated sediments of thin beds of limestone, marl, and clays. Ulexite also occurs close to the village of Ashin near Anarak.[25]

Italy.—In 1992, EniChem, part of Ente Nazionale Idrocarburi SpA (ENI), the state-owned petroleum company, announced a plan that provides for the sale of nonstrategic operations in the core business of chemicals, oil, and gas. In 1992, negotiations began on the sale of Societa Chimica Larderello (SCL), Tuscany, a producer of ultrahigh-purity boric acid and other boron compounds. The sale was finalized in 1993 when SCL became part of the Harris European affiliates of the D. George Harris & Associates holding company. High-purity boric acid produced at Larderello was marketed in the United States by EniChem Americas Inc. SCL exported about 50% of production to more than 30 countries worldwide, primarily for use in ceramics, borosilicate glasses, for the production of fluoborates, and other boron compounds. The company was founded in 1818 and extracted boric acid from geothermal sources. These fumaroles now supply electrical energy and chemicals, such as carbon dioxide and ammonia, to the plant. The first chemical plant in Italy to produce boric acid from imported colemanite ores was built in 1963 with a capacity of 11,000 tons per year. A newer plant was built in 1981 with a capacity of 66,000 tons per year of refined boric acid and approximately 16,500 tons per year of high-purity sodium borate pentahydrate, decahydrate, and other boron specialties. In 1984, SCL developed Boric Acid NS 99.99% (nuclear grade), which is marketed to nuclear power companies because it exceeds PD Specifications 52205 AP Revision F. No. 79500 for use in powerplant applications.

Mexico.—The 1992 Mining Law eliminated the National Mining Reserves and released more than 3 million hectares into the public lands that are now concessionable by mining companies. Foreign companies can invest and participate in exploration and exploitation of governmental concessionable mineral deposits through investment trusts with 100% ownership. Without the investment trust, a foreign investor is limited to 49% ownership.

Metamin Enterprises Inc., with the support of Dauntless Developments, has terminated two claims, Carlos and Carlos Uno, in the Tubutama evaporite basin. The claims, covering beds of colemanite and gypsum, are about 31 kilometers south of the U.S. border in the State of Sonora. Work by the Government organization Consejo de Recursos Minerales identified a reserve of all classes of about 30 million tons grading 8.33% boron oxide. The 160-hectare area covered by the Carlos claims has a potential for an open pit colemanite deposit of up to 40 million tons. The mineralization occurs as beds of colemanite and possibly howlite, with clay and silt bands, and gypsum and celestite beds. Chemical analysis indicates very low values of arsenic between 2 and 7 parts per million. Mining costs were expected to be less than $5 per ton.[26]

U.S. Borax continued as a partner with Vitro Corp. for the Magdelena colemanite deposit. The processing development work had been halted because of high arsenic content in the ore that was difficult to remove. Vitro was in the process of selling U.S. Borax's ownership in the deposit.

U.S. Borax acquired claims to the Tubutama colemanite reserve, which surrounded the Carlos claims of Ainsworth Jenkins, when the Government eliminated the National Mining Reserves in 1992.[27]

Netherlands.—Morton International planned to transfer sodium hydride manufacturing operations from Beverley, MA, to Delfzijl where Morton now produces sodium borohydride. When the plant is completed in 1994, Morton planned to stop production in the United States and supply that market from the Delfzijl plant.[28]

The Silenka glass fiber factory in Hoogezand, northern Holland, was founded in 1961 as a joint venture between PPG and Akzo. The state-owned Development Co. for the Northern Netherlands assisted by purchasing a 30% share in 1977 when the company was struggling because of rising energy costs. PPG purchased the remaining shares in 1990 and renamed the site PPG Industries Fiber Glass bv. PPG is the second biggest fiberglass manufacturer in Western Europe.

Peru.—The quantity and number of minerals produced in Peru and the likelihood of significant deposits to be discovered attracted attention to the privatization plants. The Government continued its privatization program to reactivate the entire mining sector selling many properties at prices below comparable resources in the international market. Boron continued to be produced in Arequipa by Compania Minera Ubinas S.A. A total of 34 metric tons of sodium borate and sodium calcium borates was imported by Fertilizer Corp. of America into Miami, FL, and Wilmington, NC.

Russia.—Primorsky Industrial Amalagmation, in Dalnegorsk, produces boron minerals from datolite containing 20% boron oxide. Amalgamation is part of the Russian Agricultural Joint Stock Co. known as ROSAGROCHIM. ROSAGROCHIM coordinates the activities of about 100 companies.

Boron minerals also were reported to be produced in Kazakhstan, the second largest newly independent republic of the former U.S.S.R. The Government was actively pursuing foreign investment to increase production capacity by improving efficiency to increase exports.[29]

Turkey.—Turkey's boron operations are under the control of the Government corporation Etibank. Colemanite is mined at Bigadic, Emet, and Kestelek; tincal at Kirka; and ulexite at Bigadic. Etibank was reported to have an ore production capacity of 8,000 tons of colemanite, 500,000 tons of tincal, and 115,000 tons of ulexite. Etibank operates refining facilities to produce refined sodium borates and boric acid from tincal concentrates at Bandirma and Kirka. Boron minerals and compounds are shipped from the Port of Bandirma on the Sea of Marmara and Izmir on the Aegean Sea. Bandirma can produce 55,000 tons of borax, 35,000 tons of boric acid, and 20,000 tons of sodium perborate per year. Kirka can produce 50,000 tons of borax, 160,000 tons of pentahydrate borax, and 50,000 tons of anhydrous borax per year.[30]

The Government announced that Etibank would become two separate divisions as a prelude to privatization of the banking business. Sixty days after the July 13 announcement, the two divisions became affiliated companies and the process will begin for privatization of the banking division.

The Turkish Government now owns all boron and trona minerals, and private concessions of these minerals could not be sold to private investors. Boron is a profitable operation for Etibank and the privatization of this sector is unlikely.[31]

United Kingdom.—Borax Consolidated, a subsidiary of RTZ Corp., was building a 5,580-square-meter (60,000-square-foot) technical center at the University of Surrey Research Park, near Guildford. The move will involve a total of 120 people from the research, technical, and development functions and the technical marketing operations.[32]

Imperial Chemical Industires Plc planned to close the 38,000 tons per year Sodium perborate plant at Runconrn at yearend. The remaining sodium perborate capacity will be supplied by German producer Degussa A.G. and Netherlands producer Interox S.A. with 285,000 and 240,000 tons per year of capacity, respectively.[33]

Current Research

The use of oxygen-fuel firing of glass melting furnaces has been in use for several decades. Sixteen States have one oxy-fuel conversion and some States have several conversion plants. Twenty-one plants using borosilicate glass have converted to oxy-fuel—9 were fiberglass and 12 were lighting, tableware, and television conversions. Both types of conversions were designed to limit particulate matter. Advancements in technology and the need to reduce air emissions have been an added incentive to the conversions. Glass melting will be affected by titles I, II, and V of the Federal Clean Air Act Amendment of 1990 (CAAA). Oxy-fuel conversions are a way to decrease capital expenditures for post-treatment systems such as electrostatic precipitators or bag houses required under title I of the CAAA.[34]

A group of research chemists developed a triply bonding silicon using a borate anion that offers new synthesis routes for certain types of silicones. The silicon cation already has been used to catalyze the formation of silicones of commercial importance. A boron compound was chosen as the anion for the tricoordinate silicon because it is stable in toluene and does not react with silicon cations.[35]

A typical glass wool formation uses

5% boron oxide. Virtually any borate can be used for the boron oxide source, although refined pentahydrate borax is preferred. Studies reinforced the uniqueness of boron oxide in improving glass durability and assisting melting in fiberglass formation by reducing the viscosity-related temperature. Increasing the alumina content increased the aqueous durability of glass wool. Increasing sodium oxide greatly reduces the durability. Other alkali oxides have small positive or negative effects.[36]

A new automated instrument is able to decrease the time needed to separate sugars using a sodium cyanoborohydride solution. Previous separations took weeks or months using mass and nuclear magnetic resonance. The new instrument can have a "fingerprint" of the glycoproteins (proteins bonded to carbohydrates) in 48 hours that can be used in research on many biochemical functions such as cell interaction with hormones, antibodies, and other cells.[37]

Two independent research teams have verified superconductivity for the first time in quaternary intermetallic compounds. The new compounds have the potential for better superconducting wires than the niobium compounds now in use. Both mixtures consist of four elements that are both metals and nonmetals. The two new compounds are mixture of yttrium-nickel-boride carbide and yttrium-palladium-boride carbide.[38]

Adding boron to polymers can transform low-cost polymers to material that rival engineering plastics such as polycarbonate. Normally, polyolefins do not adhear to carbon and glass fibers. The addition of boron can yield polyolefins that cling without interferring with the production of the raw material or the processing of the polymer into finished products.[39]

Studies on the effect of boron content for the mass manufacture of rectangular pipes for the storage of spent nuclear fuel resulted in the manufacture of a 19%Cr-8%NI-0.6%B steel. Hot workability of steel decreases with increasing boron content after 0.76% mass percent but is improved by forging. The decrease in hot workability with increasing boron content is due to precipitates of iron and chrome borides.[40]

OUTLOOK

Production of boron minerals and compounds have decreased between 1983 and 1993. One reason is that production and imports reported in 1 year may be utilized over a period of years. In addition, environmental concerns may change the demand for boron significantly in a short period. The regulation of fire retardants in products has resulted in changes in boron usage as a fire retardant. More recent decreases in domestic consumption have been attributed to decreases in glass consumption because of less demand resulting from a recession. Moreover, one-half of domestic production is exported. Because of increases in production in other coutries, this amount has decreased significantly during the past few years.

Agriculture

Boron usage in agriculture increased significantly in 1993. The primary reason was attributed to the decline in the number of farms during the same time period. Farming exports are showing increased strength, and demand for boron usage in agriculture increased during 1993.

Ceramics and Glass

Reported consumption of boron minerals in glass and ceramic uses was 211,656 tons of boron oxide content representing 60% of total demand consumed. This was down from the 214,411 tons representing 62% of total demand consumed in 1992. Ceramics and glass both have faced competition with polymers. The U.S. fiberglass industry was reported to be feeling the effects of recessionary pressures. The sagging economy produced a decline in demand for fiberglass reinforcements. Fiberglass is closely related to construction and transportation.

Coatings and Plating

Primarily used as a protective coating for steel products and as a glazing on ceramic tiles, boron usage increased 37% during the year.

Fabricated Metal Products

Boron usage decreased in metal products during the year. Many traditional metal products that require soldering now are produced from polymers as one piece. Usage in specialized metal was expected to increase.

Soaps and Detergents

This usage declined primarily as chlorine bleaches and cold water washes replace boron soap powders. Recent concern for environmental effects of chlorine has reversed the decline. Perborate bleaches have returned to name brand soap products. The usage of boron in soaps and bleaches was expected to increase by 4% per year during the next 5 years.

TABLE 2

BORON MINERALS OF COMMERCIAL IMPORTANCE[1]

Mineral	Chemical composition	B_2O_3 weight percent
Boracite (stassfurite)	$Mg_6B_{14}O_{26}Cl_2$	62.2
Colemanite	$Ca_2B_6O_{11} \bullet 5H_2O$	50.8
Hydroboracite	$CaMgB_6O_{11} \bullet 6H_2O$	50.5
Kernite (rasortie)	$Na_2B_4O_7 \bullet 4H_2O$	51.0
Priceite (pandermite)	$CaB_{10}O_{19} \bullet 7H_2O$	49.8
Probertite (kramerite)	$NaCaB_3O_9 \bullet 5H_2O$	49.6
Sassolite (natural boric acid)	H_3BO_3	56.3
Szaibelyite (ascharite)	$MgBO_2(OH)$	41.4
Tincal (natural borax)	$Na_2B_4O_7 \bullet 10H_2O$	36.5
Tincalconite (mohavite)	$Na_2B_4O \bullet 5H_2O$	47.8
Ulexite (boronatrocalcite)	$NaCaB_5O_9 \bullet 8H_2O$	43.0

[1] Parentheses include common names.

TABLE 3

U.S. CONSUMPTION OF BORON MINERALS AND COMPOUNDS, BY END USE

(Metric tons of boron oxide content)[1]

End use	1992	1993
Agriculture	9,186	16,261
Borosilicate glasses	29,288	38,488

[e] Estimated. [r] Revised.

[1] Table includes data available through May 25, 1994.

[2] B_2O_3 equivalent.

[3] Data are for years beginning Mar. 21 of that stated.

[4] Less than 1/2 unit.

[5] Concentrates from ore.

[6] Dissolved in Dec. 1991.

[7] Minerals and compounds sold or used by producers, including both actual mine production and marketable products.

[8] Reported figure.

[9] Data may not add to totals shown because of independent rounding.

BROMINE

By Phyllis A. Lyday

Mrs. Lyday, a physical scientist with the U.S. Bureau of Mines, has been the commodity specialist for bromine for 15 years. Domestic survey data were prepared by Gail Mason, statistical assistant; and international data tables were prepared by Jeremy Tidwell, international data assistant.

Production of bromine worldwide in 1993 was as follows: United States, 45%; Israel, 34%; the United Kingdom, 7%; and other countries, 14%. The U.S. portion of world production has decreased steadily since 1973, when the United States produced 71% of the world supply. The decrease in world share has been a result of environmental constraints and the emergence of Israel as the world's second largest producer. Domestic capacity decreased 14% during the same period of time. The quantity of bromine sold or used in the United States was 177 million kilograms (kg) valued at $123 million. The value of bromine sold or used was 69 cents per kg. Primary uses of bromine compounds were in flame retardants (27%), agriculture (16%), water treatment and sanitizing (15%), petroleum additives (12%), well drilling fluids (10%), dyes and photographic (10%), pharmaceutical (6%), and other (4%).[1]

DOMESTIC DATA COVERAGE

Domestic production data for bromine were developed by the U.S. Bureau of Mines from a voluntary survey of U.S. operations. Of the six operations to which a survey request was sent, six responded, representing 100% of total elemental bromine sold or used. *(See table 1.)*

BACKGROUND

Definitions, Grades, and Specifications

In the elemental form, bromine is a very dark, reddish-brown liquid. Bromine is the only nonmetallic element that is liquid at ordinary temperature and pressure. The natural form of bromine is a solution of sodium bromide in natural brines, saline deposits, salt lakes and seas, and oceans.

Elemental bromine is marketed in a "purified" grade with the following specifications: Specific gravity not less than 3.1 at 10° to 20° C; bromine, not less than 99.7%; iodine, none; and chlorine, not more than 0.1%.

Specifications for the various grades of bromine compounds include technical bromine, 99.5% pure, with the chief impurities consisting of chlorine, traces of moisture, and organic matter. Specifications of the United States Pharmacopoeia and the American Chemical Society Committee on Analytical Reagents allow 0.3% chlorine, 0.05% iodine, 0.0002% sulfur (0.006% as sulfate), and no more organic matter in 1 milliliter than will saturate 50 milliliters of 5% sodium hydroxide solution. The term "chemically pure" signifies a minimum of impurities.

Geology-Resources

Bromine is widely distributed in the Earth's crust, but in small quantities. By far the largest potential source of bromine in the world exists in the oceans. At a concentration of only 65 parts per million (ppm), large amounts of seawater are processed to obtain the bromine.

Arkansas brines contain about 5,000 ppm at depths of 2,591 meters (8,500 feet) in limestone of the Smackover Formation of Jurassic age. In Michigan, brines containing about 2,600 ppm of bromine occur in the Sylvania Sandstone Formation of the Detroit River Group of Devonian age.

In Israel, bromine is produced as a byproduct of salt, sodium chloride, and potash production from the Dead Sea. The waste brines contain 14,000 ppm bromine.

Technology

Processing.—The Arkansas Geological Commission reports three east-west bromine-rich brine fields. Wells are drilled down to the brine level, and a submersible pump is lowered to pump the liquid to the surface. Brine is separated by gravity from any residual gas at the surface and pumped to one of six processing facilities.

At the processing facility, bromine is separated from the brine by a steaming-out process. The brine is pumped into the top of a tower constructed of granite and filled with ceramic packing. As the brine falls through the packing material, it reacts with chlorine and steam that are injected at the bottom of the tower. One pound of chlorine yields 1 kg of bromine. About 95% of the bromine, or about 0.7 to 0.8 kg of bromine per barrel of brine, is recovered if the raw brine is first acidified to a pH of 3.5. The chlorine replaces the bromine in the brine, and the gaseous bromine rises with the steam out of the top of the tower; there it is condensed to a reddish-brown liquid. Bromine is separated from gases. The bromine liquid can be further purified or reacted with other materials to form bromine compounds. Bromine vapor, a little chlorine, and water vapor are captured at the top of the tower. Hot bromine-free liquor emerges from the bottom of the tower. After neutralizing with lime, the waste liquor is pumped through a heat exchanger to a waste pond. Brine from the pond is reinjected into the same producing zone to maintain hydrostatic pressure.

Seawater contains about 60 to 70 ppm of bromine as sodium bromide or magnesium bromide. Production of bromine from seawater uses the blowing-out process. Raw seawater is acidified by adding sulfuric acid and then chlorine. Air is drawn into the base of the tower and rises as the brine descends. Air containing bromine passes to the absorption tower. In the absorption tower, bromine reacts with sulfur dioxide to form a hydrogen bromide. The bromine is separated by adding acid to the solution and is distilled by steam. The gaseous bromine is condensed, separated, and purified.

Recycling.—Bromine containing waste from other processing is recycled into elemental bromine. The waste is reprocessed through the absorption towers to produce a high-quality elemental bromine. It was estimated that about 90 million kg of elemental bromine was produced by recycling during 1993.

The byproduct hydrogen bromide that arises from elemental brominations is not suitable for direct use as a feedstock when generated in streams that are too dilute or concentrated. Similar aqueous liquors can arise from the use of organic bromides as chemical building block intermediates, where the bromide is displaced by other functional groups.

These streams can generally be processed after essential cleanup for elemental bromine recovery in purpose-built units employing chlorine oxidation. Both Associated Octel Co. Ltd. in the United Kingdom and Great Lakes Chemical Corp. in the United States operate such bromide recovery units, serving local customers and their own internal demand.[2]

Byproducts and Coproducts

Some bromine-bearing brines contain hydrogen sulfide gas. This gas has a disagreeable odor, is highly toxic, and when burned, will oxidize to sulfur dioxide, an acid-producing gas. To prevent the emission of the gas to the atmosphere where sulfur dioxide may form, environmental regulations require the recovery of the sulfur. Hydrogen sulfide gas was chemically removed from the incoming brine and converted into elemental sulfur or other nontoxic sulfur-containing compounds. The cost of recovery was greater than the selling price of the sulfur, but recovery prevented emission of a gas that may contribute to the formation of acid rain. The hydrogen sulfide can be scrubbed with caustic soda to make sodium sulfite for low levels of hydrogen sulfide.

Aromatic bromination processes normally generate hydrogen bromide gas as a byproduct, which can often be used in the production of other derivatives. For instance, calcium bromide can be produced by adsorption of byproduct hydrogen bromide, primarily from flame retardant manufacture in aqueous slurries of lime.

The production of tetrabromobisphenol-A (TBBA) is produced by bromination of bisphenol A in aqueous methanol. The hydrogen bromide generated reacts in situ with methanol to provide methyl bromide as a byproduct, which can be used in agriculture.[3]

Substitutes

Various materials are used in flame retardants as replacements for bromine in engineering and high-performance thermoplastic polymers and blends, and polymeric composites. The distinguishing characteristic of engineering polymers is that they have properties that lend themselves to structural applications over a wide range of temperatures, high mechanical stress, and harsh chemical and physical environments. The high-performance polymers are also distinguished by their special properties such as extremely high-temperature tolerance and outstanding optical properties or conductivity, but they are not necessarily designed for structural integrity.[4]

The Federal Register for October 18, 1993, announced that the Halon Recycling Corp. is officially open for business after receiving a Business Review Clearance from the Department of Justice. The Defense Logistics Agency also is forming a reserve of ozone-depleting substances for mission-critical uses and is accepting recycled Halon 1301 from the public.

Three fluoride compounds were evaluated as candidates for Halon 1301 replacements. Perfluorobutane and perfluoropropane show significant promise for both new and retrofit applications. Small-scale cup burner tests have shown these compounds to be effective fire suppressants in the range of 6% to 8% volumetric concentrations. Technical data needed are the quantity and character of thermal decomposition products. Regulatory issues associated with these compounds include global warming potential.[5]

Economic Factors

Costs.—The cost of drilling and maintaining a bromine-producing well is estimated to be in excess of $1 million per well, with about 100 wells in operation. Chlorine, the largest manufacturing cost factor, represented about 30% of the manufacturing cost of bromine. Other cost factors include brine (22%), operating cost (15%), utilities (14%), overhead (12%), and other (7%).

Taxes.—During 1993, brines produced in Arkansas required the payment of $2 per 1,000 barrels in severance taxes, and capital equipment was subject to the payment of property taxes. Bromine produced in the United States was subject to Superfund taxes of $4.91 per metric ton ($4.45 per short ton). Bromine was manufactured using chlorine, which was subject to a Superfund tax of $2.98 per metric ton of chlorine ($2.70 per short ton).

Depletion Provisions.—Bromine producers (domestic and foreign) are granted a 5% depletion allowance under the Federal Income Tax Law on the value of bromine produced from brine wells.

The depletion allowance can be calculated by the actual cost method.

Operating Factors

Toxicity.—Bromine is highly toxic and corrosive and must not be allowed to escape into the atmosphere. Many bromine compounds are also poisonous or irritating and must be packaged in leakproof containers to avoid personal injury. If bromine spills on paper, rags, wood shaving, etc., it will generate considerable heat, which may lead to spontaneous combustion. Bromine reacts with living tissue and must be removed immediately to avoid serious injury.

Bromine vapors are hazardous to the eyes and lungs. Any concentration above 1 ppm in the air for an 8-hour exposure is considered a health hazard. Bromine can be detected by its odor even at this level. Exposure to concentrations of 500 to 1,000 ppm for as little as one-half hour is lethal. The Occupational Safety and Health Administration (OSHA) regulates the working conditions of bromine plants.

When handling bromine, a person should use safety goggles, a face shield, rubber gloves, rubber boots, and under some conditions, a self-contained breathing apparatus. Bromine spills are neutralized with a solution of sodium thiosulfate. Gaseous bromine is neutralized with controlled amounts of gaseous ammonia. All metal, such as electrical switches and connections, that may be exposed to bromine vapors should be made of corrosion-resistant materials and/or completely sealed from contact with the room air.

OSHA established a phase-in schedule that gives operators until 1996 to complete process-hazard analyses (OSHA 29 CFR 1910.119) for any operator who uses, stores, manufacturers, handles, or moves highly hazardous chemicals that include bromine, bromine chloride, bromine pentafluoride, bromine trifluoride, and propargyl bromide. The fines that apply to the new standard are the same as those specified by other OSHA safety regulations. A willful violation can result in a fine up to $70,000. A serious violation can result in a fine up to $7,000 per violation. A criminal violation can result in fines up to $250,000 to any responsible individuals and up to $500,000 against the corporation. Jail terms may be imposed for criminal violations.[6]

An Environmental Protection Agency (EPA) funded computer network began in May that would allow States to exchange technical and legal information about Superfund programs. Through a computer bulletin board, users would have access to four data bases: listing of more than 650 EPA policies and guidance documents; State Superfund program information; State settlement, including information on contaminants, technologies, costs, and timetables; and a record of State decisions.[7]

Employment.—During 1992 an estimated 1,600 employees were employed by the bromine industry in Arkansas. About 1,175 are employees of the companies and about 450 are contract workers.

Energy Requirements.—The manufacturing cost of bromine was heavily dependent on chlorine and brine cost. Of the total brine cost, 46% was power related and 53% was maintenance cost. Brine cost is dependent on well maintenance cost and energy cost associated with well pumping. Approximately 14% of the bromine manufacturing cost was energy related.

Transportation.—The Research and Special Programs Administration (RSPA), U.S. Department of Transportation, published rules for hazardous substances (49 CFR, parts 171 and 172). The action complies with a 1986 amendment (Public Law 99-499) to section 306(a) of the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) of 1980 (Public Law 96-510). The law mandates that RSPA regulate all EPA-designated hazardous substances. The amendment required shippers and carriers to identify CERCLA hazardous substances, to comply with the hazardous materials regulations (HMR), and to make the required notifications if a discharge of a hazardous substance occurs.

The Hazardous Material Transportation Act gives wide powers to the Department of Transportation (DOT). The DOT RSPA listed a final rule for performance-oriented packaging standards that included several bromine compounds under HMR (49 CFR, parts 173.193 and 228). The rule comprehensively revises the HMR with respect to hazard communication, classification, and packaging requirements. On January 1, 1991, the new DOT/United National Performance Oriented Packaging Standards (POPS) were phased into the current DOT HMR. On that date, compliance with domestic shipping was voluntary. However, shipping materials internationally or domestically by air or international waters must comply with the POPS regulations. POPS involves changes to every aspect of shipping activities, including selecting packages; preparing shipping documents; and labeling, marking, and placarding shipments of hazardous materials and waste.

The chemical and railroad industry reached a voluntary agreement through the Interindustry Rail Safety Task Force to transport 10 halogenated compounds, including ethylene dibromide (EDB), in sturdier tank cars. The Chemical Manufacturers Association, Association of American Railroads, and Railway Progress Institute agreed to the more stringent specifications. After the agreement was signed, the DOT proposed expanding the 10 substances to include the EPA's list of 100 toxic chemicals and making the tank car regulations more stringent, which would involve more costly construction than the voluntary agreement. The DOT will allow comments and study the proposal, and a decision whether to proceed with new standards for tank cars should be made by yearend 1995. Until DOT decides to proceed with new rulemaking, the Interindustry Rail Safety Task Force agreement will not be implemented because new standards may be promulgated by DOT that make the tank cars obsolete.[8]

ANNUAL REVIEW

Legislation and Government Programs

A notice of proposed rulemaking was published by the EPA in the Federal Register September 30, 1991, to conform its stratospheric ozone protection regulations (40 CFR, part 82) to the requirements of Title VI of the Clean Air Act Amendments of 1990 (Public Law 101-549). The notice proposes amended regulations implementing the 1992 and later requirements of section 604, as well as the related provisions of sections 603, 607, and 616, in a manner consistent with continuing U.S. obligations under the Montreal Protocol as amended.

The EPA proposed a Significant New Alternatives Policy (SNAP), which was required by the 1990 Clean Air Act Amendments. The list will have acceptable and unacceptable substitutes for ozone-depleting compounds. A range of factors, including ozone-depletion potential, air and water pollution issues, flammability, and worker and consumer safety, will be considered in determining acceptability as a substitute. Under SNAP, manufacturers or importers must notify EPA of the intent to sell, use, or distribute substitutes 90 days before introducing them into interstate commerce and provide EPA with health and safety studies. The list will be published in 1994.

On December 30, 1993, the EPA published in the Federal Register baseline production and consumption allowances for chemicals that were added to the list of class I ozone-depleting substances. These substances are methyl bromide and hydrobromofluorocarbons (HBFC's). EPA was establishing baseline production and consumption allowances for producers and importers of methyl bromide and HBFC's from data collected from companies that produced, imported, exported, and transformed or destroyed these substances in 1991. Baseline production allowances were as follows for methyl bromide: Great Lakes, 19,946 metric tons; and Ethyl Corp., 8,234 tons. Allowances for HBFC's was Great Lakes, 46 tons. Baseline consumption allowances for methyl bromide were as follows: Great Lakes, 15,515 tons; Ethyl, 6,380 tons, AmeriBrom Inc., 3,524 tons; and, TriCal Inc., 109 tons. Baseline consumption allowances for HBFC 22B1 was Great Lakes, 40 tons.[9]

A production freeze of methyl bromide at 1991 levels beginning on January 1, 1994, and usage as an agricultural fumigant for which no satisfactory substitute has been identified is to be phased out by 2000. The rule bans only production and importation of ozone-depleting chemicals, not their use.

The superior court in San Francisco refused to issue a temporary restraining order that would require a warning when crops are sprayed with methyl bromide. A State rule requiring a warning when houses are sprayed for termites took effect January 1, 1994.[10]

The United States asked the United Nations Environmental Program (UNEP) to exempt four uses of halons from the ban on the ozone-depleting chemicals' production that would be effective January 1, 1994. Under the Montreal Protocol on Substances that Deplete the Ozone Layer, countries may petition for the right to continue producing the fire suppressants for essential uses. Requests for exemption were forwarded from the nuclear power industry, the aerospace industry, and the oil companies for use in refinery control rooms and on older offshore drilling platforms.

Affirming a decision by the Ninth U.S. Circuit Court of Appeals, the Supreme Court ruled in February that Federal agencies must comply with a strict interpretation of the Delaney Clause's zero-risk standard. The EPA must change its policy on exemptions of cancer-causing pesticides, which included bromoxynil, a herbicide. Test have shown that the chemicals involved induce cancer in laboratory animals and are known to concentrate in processed food. The court said the Delaney amendment to the 1958 Food, Drug & Cosmetic Act gives EPA no discretion to allow pesticide residues in processed foods at levels greater than those allowed in raw food, if the pesticide has been found to induce cancer in animals.[11]

Production

Ethyl Corp. and Great Lakes Chemical Corp. produced and marketed bromine chemicals from plants in Arkansas. Small amounts of unpurified bromine were produced in Michigan as a byproduct in the extraction of magnesium from brine and reprocessed for consumption in Arkansas. The Arkansas plants accounted for 97% of U.S. elemental bromine capacity at yearend 1993 and 100% of bromine sold or used.

At yearend 1993, Ethyl Corp., of Richmond, VA, acting on the approval of a committee of outside directors, announced plans to form a publicly traded specialty chemicals segment with the Gottwald family, holders of 18% of Ethyl's stock, taking a major share in the new company. The new company will focus on the chemicals business and make it more competitive on the world market. An early retirement and work force reduction that affected 155 salaried employees, or about 10% of employees, at certain locations was a result of the formation of the new company. The employees were located at the Richmond headquarters and operations in Baton Rouge, LA.[12] Earlier, Ethyl completed the separation of First Colony Corp. in the form of a tax-free dividend stock.

Consumption and Uses

Methyl bromide is a broad spectrum pesticide that is widely used as fumigant in the control of insects, nematodes, weeds, pathogens, and rodentia. Worldwide it is primarily utilized for soil fumigation (80%), commodity and quarantine treatment (15%), and structural fumigation (5%).[13] Regulation requires that methyl bromide be used for fumigation of imported produce. About three-quarters of the 29,000 tons consumed domestically is for soil application. In colder climates, the onset of winter controls pests and diseases. But in California and Florida, where it is relatively warm year round, farmers fumigate the soil to kill insects, weeds, fungi, nematodes, and other organisms that attack roots of seedlings.

Fire retardants were primarily and

TBBA and decabromodiphenyl oxide (DBPO). Great Lakes expanded TBBA production capacity at its El Dorado, AR, facility to meet growing demand as a flame retardant for acrylonitrile-butadiene-styrene (ABS) polymers. The expansion increased Great Lakes' capacity by 25%. The U.S. International Trade Commission (USITC) publication entitled "Synthetic Organic Chemical, 1993" (SOC) listed Ethyl and Great Lakes as the only producers of TBBA.

TBBA is the largest volume brominated flame retardant. Its primary markets are epoxy circuit boards, ABS, and polycarbonates. DBPO is the second largest volume brominated flame retardant. Its primary markets are in television cabinets, video cassette recorder housings, wire, cable, and textile coatings. Tetrabromophthalic anhydride (TBPA) is used as a reactive flame retardant in unsaturated polyester resins. It also is used as an intermediate to make other flame retardants, which are used in polyolefin and polyvinyl chloride wire and cable coatings, rigid polyurethane foam insulation, and fabric and wood treatments. Brominated fire extinguishers are used to protect closed spaces, such as computer rooms, and in portable fire extinguishers. Ethyl and Great Lakes are primary suppliers to the domestic market.

Bromine combinations with antimony pentoxide were marketed with hydrobromic or hydrochloric acid to form volatile compounds that terminate combustion reactions and extinguish flames. Compounds with 32% bromine are used in textile coatings, spray-bonded nonwovens, adhesives, and fibers.[14]

The first commercial brominated aromatic phosphate ester flame retardant for use in polymers contained 60% bromine and 4% phosphorus. The flame retardants can be used in engineering thermoplastics, including polycarbonated, polybutylene terephthalate, and polyethylene terephthalate.[15]

USITC publication SOC listed Ethyl Corp. as the only producer of hexabromocyclododecane and Great Lakes as the only producer of hexabromocyclodecane. Sales of flame retardants account for one-half of the worldwide plastic additives market and are growing. Brominated hydrocarbons are the major materials used to make flame retardants. Demand for EDB is in gasoline additives as a scavenger for lead antiknock. The USITC's SOC listed Great Lakes and Ethyl as the only producers of EDB used in gasoline additives. Bromine was used in clear brine drilling fluids used in workover and completion fluids and other uses. Great Lakes's wholly owned subsidiary, OSCA, Inc., entered into a joint venture with M-I Drilling Fluids Co., a division of Dresser Industries. This venture provides access for marketing OSCA's completion fluids and ancillary services to the oil and gas industry in more than 40 countries.

Halogenated synthetic rubber consumption has grown. Exxon Chemical Co. is the only domestic manufacturer of bromobutly rubber. This rubber is more heat resistant than other types of rubber and is used primarily in truck tires. The International Institute of Synthetic Rubber Producers in Houston, TX, projected growth rates of 2.1% per year through 1996 for all synthetic rubber consumption, with the exception of polychoroprene.

Great Lakes continued to offer extraction of precious metals with bromine salts.

Prices

Prior to 1982, the price of bulk elemental bromine reported by U.S. producers, f.o.b. plant, was an average value of the quantity of bromine reported as sold. Statistical data published beginning in 1982 gave the total quantity and value of bromine sold and used. This total is equivalent to a weighted average of the value of bromine used by the producing company plus the value of bromine sold to other companies as reported prior to 1982.

Bromine was sold under contracts negotiated between buyer and seller. Price quotations do not necessarily represent prices at which transactions actually occurred, nor do they represent bid and asked prices. They were quoted in table 3 to serve only as a guide to yearend price levels.

Foreign Trade

Israel received duty-free treatment on its bromine products in all major world markets except the United States, where duties are paid on two significant bromine products, sodium bromide and potassium bromide. The duty on all bromine products will drop to zero in 1995. Following the removal of the 20% duty, imports can be expected to increase.

More than 117 nations approved the General Agreement of Tariffs and Trade (GATT) and brought the eighth round of multilateral trade negotiations to a close on December 15. The negotiators gave up their battle to guarantee U.S. entertainment companies access to the European Community's government-controlled television markets to close the talks. A bitter quarrel between the United States and France over reductions in subsidies for farm exports was settled. Major issues that affect the chemical industry will remain unresolved until next year. The President will submit the final agreement to the U.S. Congress for approval.

The North American Free Trade Agreement, commonly known as NAFTA, was signed into law.

The U.S. bromine chemical industry petitioned the Japanese Ministry for International Trade and Industry (MITI) for a temporary suspension of select Japanese duties. Imports from Israel currently receive duty-free treatment while imports from the United States receive no such preferential treatment. As a result, U.S. exports are losing markets. The U.S. Trade Representative stated that the best and most expeditious solution to the problem is temporary suspension through the Japanese Tariff Council Procedure, while efforts continue to seek full-multilateral resolution through the Uruguay Round. The Japanese market is almost totally served by imports of bromine chemicals. Japanese producers are not vocal opponents of liberalization of the tariffs because they already face competition from duty-free Generalized Systems of Preference imports and often purchase U.S. intermediate or finished products subject to duty.[16]

World Review

Methyl bromide emissions continued as a topic of world concern. The European Commission's proposals, which were sent to the European Council, were being examined. The proposals stipulate that hydrochlorofluorocarbons (HCFC's) be banned by 2015 and that methyl bromide use and pollution freeze start in 1996. Opposition is being voiced by France, Greece, Portugal, and Spain with minor reservations by Belgium. Worldwide, major production was divided as follows: United States, 30,000 tons; Israel, 20,000 tons; and France, 5,000 tons. Methyl bromide users have launched a $400,000 program to develop technology to prevent emissions of the gas, which is used mainly as a soil fumigant. In 1990, France's methyl bromide production was 5,000 tons. European consumption of 14,000 tons was met mainly by United States and Israeli imports. Worldwide methyl bromide production was 65,000 tons and growth was estimated at 5% per year.[17]

Producers of methyl bromide in Europe, Japan, and the three largest sellers in the United States, Great Lakes, Dead Sea Bromine's U.S. subsidiary Ameribrom, and Ethyl, banded together to form the Methyl Bromide Global Coalition. The group has provided $1.5 million to examine methyl bromide's effects on the environment.[18]

Canada.—Ethyl Corp. announced plans to close the Sarnia, Ontario, tetraethyl lead (TEL) plant on March 31, 1994. Bromine is a major component of leaded gasoline because it prevents the lead from depositing in the engine.

China.—Israel's Dead Sea Works expects to complete details on a potash project in China at yearend. Construction was planned to begin in 1994 and take 3 years to complete.

Joint ventures were sought in several bromine compounds plants in the Shouguang Province by Weifang Salt & Chemical Industry Group General Corp. The state-owned enterprise is the largest base for the production of salt and salt chemicals in China. Projects are to include technology and equipment. Project No. 7 is a 1,000-ton-per-year decabromodiphenol oxide project of the Shouguang Salt Industrial Co. that would consist of 6,000 tons per year of bromine from 2.26 million tons per year of salt. The products were intended for sale in China. Project No. 26 would produce lithium bromide at the Shouguang Salt Chemical Industrial Factory that presently produces sodium and ammonia bromide. Project No. 29 is with the Shouguang Chahe Saltworks and would produce 300 tons of lithium bromide as a byproduct; present production is 460,000 tons of salt, 1,500 tons of bromine, and 100 tons per year of bromate per year. The bromate has been sold on the international market. Project No. 32 is with Shouguang Chahe Saltworks and would produce hydrobromic acid as a byproduct of the present production of 460,000 tons of salt, 1,500 tons of bromine, and 100 tons of bromate per year.

Weifang City is situated in the middle of Shandong Province and Peninsula and has been qualified by the Government of the People's Republic of China as a "key" city with the capacity of conducting its own business with the world. The Jiaoji railway traverses the east and west and radiates in all directions. The leading industries are light-industry, textiles, electronics, machinery, chemical, and building materials. More than 400 projects introduced or run by foreign investment have been approved by the local government, with nearly 120 joint-venture, cooperative, and solely foreign-investment enterprises.[19]

European Union.—The entry into force of the Maastrich Treat on European Union on November 1, 1993, introduced some changes into terminology regarding the European Community (EC) and some of its institutions. The European Union is now the umbrella term encompassing the EC and the two new pillar Common Foreign and Security Policy and Justice and Home Affairs. The EC continues to exist as a legal entity within the broader framework of the Union.[20]

France.—Ethyl's French subsidiary Potasse et Produits Chimiques (PPC), formerly owned by Rhône-Poulenc, located at Thann, France, continued to process bromine derivatives and is the European center for sales. PPC was purchased by Ethyl in 1992.[21]

Great Lakes agreed to sell certain assets of the lubricant additives business of Great Lakes Chemical France, SA (GLCF) to Lubrizol. Headquartered near Paris, GLCF acquired Societe Francaise d'Organo Synthese from Rhône-Poulenc. GLCF will focus on its plastics additives business, but will continue to manufacture certain lubricant additives for Lubrizol under a long-term contract.[22]

Elf Atochem was Europe's only methyl bromide producer. Autochem, a joint venture at Port-de-Bouc 50% owned by Octel, operated a seawater bromine production facility.

Germany.—Bromine is produced from the waste bittern of potash production in Germany. German potash and salt producers Kali und Salz AG, based in Kassel, and Mitteldeutsche Kali AG, based in Sondershausen, planned to combine operations. The merger was seen as a means of achieving lower unit costs and increasing their competiveness by merging the entire German potash industry under one company. The exact form of the joint venture and the date at which it will come into operation are still under discussion. At yearend, the Bischofferode Mine, located in Thuringia, received a stay from closing. The 600,000-ton-per-year Mine planned to operate until the end of the year at a much reduced level of production and guaranteed employment for the workers until the end of 1995.[23]

The east German state of Thuringia has called for talks in east and west Germany to discuss dissatisfaction in terms between the potash producers and the Treuhandanstalt on a merger of BASF's subsidiary Kali und Salz and east German's potash holding Mitteldeutscher Kali.[24]

GLCF acquired Chemische Werke Lowi GmbH & Co. The acquisition will expand the Great Lakes worldwide plastics additives business with a technology base in antioxidants and ultraviolet (UV) absorbers to include hindered amides (HALS).[25]

Israel.—Bromine is produced as a byproduct from waste bitterns associated with potash production from the Dead Sea. After potash is removed in solar ponds, the waste bitterns are processed with chlorine to remove bromine. The bromine-free bitterns are then processed to remove magnesium.

Israeli Chemical Co. Ltd. (ICL) planned to split Dead Sea Bromine (DSB) from Dead Sea Works (DSW). Government approval was being sought to enable ICL to hold a direct stake of 89% in DSB; the balance will be held by the public. DSB has two production plants at Sodom and Ramat Hovav.[26] DSB announced plans to implement a $500 million expansion over the next 5 years that will increase bromine production to 200,000 tons per year. Part of the expansion effort involves construction of a salt refinery at Sodom that will use solar salt to produce electrolysis-grade salt.[27] Present salt production is used to produce chlorine, which is vital to the bromine process. Another $525 million project allocates $350 million magnesium plant and expansion of bromine compounds production. Part of the investment will include a 25,000-ton-per-year metallic magnesium plant in 30 months with another doubling of capacity by the late 1990's.[28]

DSB and Dead Sea Periclase Ltd. (DSP) will jointly build a plant to produce surface treated and untreated magnesium hydroxide flame retardants. The investment is expected to be about $12 million and should reach 6,000 tons per year. Technical support will be provided by DSB and its worldwide subsidiaries, already active in flame retardant technology. Sales are expected to reach $11 million per year. Both DSB and DSP are part of the integrated ICL. DSP produces magnesia products using the Aman process from brines supplied by DSW. DSW also supplies brine to DSB, which supplies byproduct caustic soda to DSP for the Aman process.[29]

DSW also has developed a flame retardant product that combines bromine and antimony under pressure to form granules, thus avoiding the use of a binder or carrier.[30]

The Government began efforts in 1985 to sell a share of ICL to offset an investment program. Much of the organic and inorganic chemical activity takes place within the framework of the massive ICL, which in 1986 was composed of 28 companies with a work force of 7,000. Formal bids were accepted in 1990, but a number of Government representatives favored a public sale rather than sale to a foreign investor. In 1991, privatization terms for ICL were approved, and ultimately 25% of ICL was sold by 1993. The Government was reportedly willing to reduce ownership to 49% at some point in time. The Knesset approved the Dead Sea Mineral Rights Law Interim Amendment November 10, 1993, clearing the way for DSW to proceed with expansion projects already under way. Unlike companies in the United States, all production is exported.[31]

Japan.—According to a study by DIA Research Institute Inc., Tokyo, organic brominated flame retardants for plastics experienced an annual growth rate of 27%, and aluminum hydroxide is showing the fastest growth in the inorganic flame retardants. Consumption of flame retardants for plastics has grown nearly 700% between 1976 and 1991.[32]

Russia.—Russia holds first place in the world for explored and potential reserves of rock salt and potash salts. The value of the deposits is markedly increased by the possibility of extracting lithium, bromine, and other useful constituents. The most important salt basins are confined to the Paleozoic sedimentary deposits filling intercontinental structures. The largest is the Upper Kama salt basin in the Perm region of European Russia. There the Permian sequences contain more than 60% of the total salt reserves of the former U.S.S.R.[33]

United Kingdom.—Great Lakes's affiliate, Associated Octel, was renovating and repacking a blowing out tower used for extracting bromine from seawater at the Anglesey site.[34] Octel signed a long-term agreement to supply Ethyl's requirement for lead antiknock compounds, effectively making Octel the world's only producer of TEL. Octel also signed an agreement to supply antiknock compound to E. I. du Pont de Nemours & Co. (Dupont) for the Mexico market. Octel's three facilities in Paimboeuf, France, Bussi, Italy, and Ellsmere Port, United Kingdom, will become the only significant sources of TEL in the world. In the United States, Dupont ended production at its Deepwater, NJ—based plant in 1991. Dupont closed its operation in Mexico in November 1992. PPG Industries Inc., Pittsburgh, PA, closed its Beaumont, TX, facility in 1983, and Nalco Chemical Co. closed its Freeport, TX, facility in 1985. Ethyl closed a plant in Baton Rouge, LA, in 1985 and another in Pasadena, TX, in 1980.[35]

Under the Montreal Protocol, production of halons ceases at the end of this year, except for those uses deemed essential by all parties to the protocol. The United Kingdom listed six uses on the list covering Halons 1211 and 1301 in aircraft, airport vehicles, offshore oil and gas installations, and certain trains' engine rooms. The essential uses must be agreed upon by the end of 1994.[36]

Current Research

The National Aeronautics & Space Administration (NASA) has been monitoring the stratosphere from space for 14 years. NASA and the National Oceanic & Atmospheric Administration (NOAA) have been measuring chlorofluorocarbons (CFC's) in the atmosphere since 1978. Halons are fluorocarbons that contain bromine. Research has confirmed that fully halogenated compounds are essentially inert in the troposphere, gradually floating unchanged into the stratosphere. Ozone is produced continually in the upper stratosphere where solar ultraviolet (UV) radiation dissociates molecular oxygen to form atomic oxygen. The intense concern regarding the fate of ozone in Earth's atmosphere stems from its ability to shield Earth's surface from potentially harmful solar UV radiation. Once halons rise above the bulk of the ozone layer, which is most dense between 15- and 30-kilometers altitude, depending on the altitude, they are photolyzed by UV light, producing halogen atoms.

Chlorine and bromine top the list of suspects causing the thinning of ozone in the Northern Hemisphere to accelerate. Although ozone researchers believe chlorine- and bromine-catalyzed destruction is responsible for the global ozone thinning, the process has not been quantified. The total amount of chlorine and bromine in the stratosphere is virtually uniform worldwide. Only in Antarctica do all elements take forms that attack ozone long enough to destroy massive amounts of ozone. Despite a growing perception that the problem of ozone depletion is solved, scientists are still struggling to understand its complexities.[37]

While in theory any halogen compound can function as a flame retardant, only chlorine and bromine compounds are actually used because of their molar effectiveness and the thermal stability of organohalogen compounds. Iodine, although the most effective, is never used because of cost and the instability of the organoiodine compounds. Aromatic bromine compounds are typically used with a synergist, such as antimony oxide, which promotes the formation of volatile bromine species. Aliphatic bromine compounds are commonly used without a synergist, but are limited to relatively low processing temperatures.[38]

Great Lakes' proprietary product, FM-200, received the Underwriters Laboratory listing mark. FM-200 matches Halon 1301's superior, people-safe fire fighting capabilities, yet poses no threat to the stratospheric ozone layer. FM-200 is under evaluation as a CFC replacement in testing in military applications.[39]

Bromine injected into an aquifer can help in understanding the spread of pollution under the site. The U.S. Geological Survey used an array of 10,000 test wells to sample ground water. Streamers of light mimic the path of pollutants.[40]

The selective oxidation of organics has been an important industrial reaction for intermediates in agrochemical, perfumery, pharmaceutical, polymers, and other areas. Solvay Interox developed two approaches to oxidation: one indirect and one direct. The indirect process involves reaction of the substrate with bromine generated in situ from hydrogen peroxide and hydrobromic acid. The actual product composition is determined by the reactivity of the substrate and the reaction conditions chosen. The direct oxidation method employs a cobalt (Co) catalyst in the presence of a promoter, such as the bromide ion, using peroxide to assist the oxidation of CoII or CoIII.[41]

Bromination of fullerene (C_{60}) yields a variety of materials. Surprisingly, the halogenation reaction is reversible. Heating a brominated fullerene regenerates C_{60}, supporting the idea that the fullerene cage remains intact during halogenation.[42]

Electrochemical technology can be used to produce sodium bromide and sodium bromate using electrodes and membrane material. The system operates on-site and can add sodium bromide or sodium bromate directly to the water system for use as a biocide. The use of selective anodes can minimize electrical consumption and avoid unwanted secondary reactions.[43]

Environmental concerns have pressured the pulp and paper industry to study new approaches for bleaching. Research and development facilities are investigating the suitability of bromine in aqueous solution as an on-site bleaching agent.[44]

OUTLOOK

Sales of bromine, primarily in compounds, have decreased about 25% since 1979. This represents an annual rate of decrease of about 2% per year. These decreases have been offset by increased use of bromine in fire retardants, sanitizers, and well-drilling fluids. Bromine is expected to increase in demand at the same 1.1% rate through the next 5 years. Demand as a fire retardant will offset any decreases in other uses. Bromine usage in well-drilling fluids was expected to increase.

Petroleum

Demand for bromine as a gasoline additive has declined each year since the EPA issued regulations in the 1970's to reduce the lead in gasoline. Bromine in the form of EDB is used as a "scavenger" for the lead to keep the lead from depositing in the engine. In 1979, the amount of bromine sold reached a peak of 225 million kg. The rapid decline to 141 million kg in 1986 was a direct result of the limits on lead in leaded gasoline. The EC continued discussions to reduce lead levels in gasoline.

Federal laws enacted to encourage alternative forms of power in automotive engines are likely to have a depressive effect on increases in petroleum demand. The Clean Air Act Amendments of 1990 has an amendment that will require mobile sources, such as cars and trucks, to use the most effective technology possible to control emission. Electric cars that do not require bromine gasoline additives are already on the market in California.

Sanitary Preparations

Bromine has found usage in swimming pools, hot tubs, and whirlpools. The sanitary preparation field is an area where bromine has been found to be safer than its substitutes because bromine has a higher biocidal activity level for the same amount of product. Applications in the pulp and paper industry and in cooling towers and Government-regulated food-washing applications are growth areas. The use of bromine will continue to grow in this area, closely following the gross national product in real growth.

Fire Retardants

Federal regulations covering flammability of private and public building materials and furnishings have required greater amounts of fire retardant chemicals to be used in these materials and furnishings. Fire retardants are expected to grow as organic materials replace metals in transportation, infrastructure, and packaging. Several State governments continue to support strong consumer laws that protect State residents from products with potential fire hazards produced in other States.

Other Uses

Usage of calcium bromide and zinc bromide in well-drilling fluids decreased during the 1980's as the domestic petroleum industry suffered a severe recession. Both the Baker Hughes and the Smith rig count published each week in the Oil & Gas Journal showed a decrease in activity at yearend 1993 when compared with that of 1992. The 1993 yearend workover rig count showed a 4% increase over that of yearend 1992. Oilfield chemicals used in drilling, completion and workover, and production operations have remained significantly more profitable internationally than in U.S. operations. The competition market included corrosion inhibitors, bactericides, viscosities and defoamers, as well as commodities such as calcium chloride and calcium bromide brines used to maintain well productivity.

CEMENT

By Cheryl Solomon

Ms. Solomon, a physical scientist with 8 years of U.S. Bureau of Mines (USBM) experience, has been the commodity specialist for cement since 1992. Domestic survey data were prepared by Eric Dunkelberger, statistical assistant; and international survey data were prepared by Dave Mann, international data coordinator.

The industry's main product, portland cement, makes up 96% of the total domestic production. The remainder comes from masonry, hydraulic, and aluminous cements.

In 1993, U.S. demand for cement increased by approximately 8%. Domestic production of portland cement increased by 6%. Cement imported for consumption increased for the first time in 5 years to 7.06 million metric tons. Portland cement values increased to approximately $55 per metric ton.

The International Trade Commission (ITC) reaffirmed that the U.S. cement industry had been materially injured or threatened by imports of Japanese gray portland cement and cement clinker into the United States. The action was in response to an order from the Court of International Trade.

The International Trade Commission completed its review of gray portland cement and clinker from Mexico. The preliminary rates were revised. The final dumping margins ranged from 30.44% to 53.26%.

The ITC began an investigation of French calcium alumina cement and cement clinker shipped to the United States. The Commerce Department was to begin a pricing investigation of the shipments.

DOMESTIC DATA COVERAGE

Domestic production and consumption data for cement are developed by means of the portland and masonry cement voluntary survey. Of the 121 cement manufacturing plants to which an annual survey collection request was made, 110 responded, representing 91% of the cement production and consumption data shown in table 1. Estimates were made for nonrespondents using monthly survey data and data received from previous annual surveys. *(See table 1.)*

BACKGROUND

Definitions, Grades, and Specifications

Section 4 of the Annual Book of the American Society for Testing and Materials (ASTM) publishes standards, test methods, definitions, recommended practices, classifications, and specifications for cement, lime, and gypsum.[1] Following is a brief discussion of various types of hydraulic cements and the materials from which they are made.

Clinker.—Clinker is produced by heating a properly proportioned mixture of finely ground raw materials containing calcium carbonate, silica, alumina, and iron oxide in a kiln to a temperature of about 2,700° F at which partial fusion occurs. The fused material, which ranges from fine sand grains to walnut size, is ground with small amounts, 3% to 5%, of calcium sulfate, usually gypsum or anhydrite, to make portland cement.

Portland Cement.—ASTM specification C-150 covers five types of portland cement: Type I, for use when special properties specified for other types are not required; Type II, for general use, especially when moderate sulfate resistance or moderate heat of hydration is desired; Type III, for use when high early strength is required; Type IV, for use when a low heat of hydration is desired; and Type V, for use when high sulfate resistance is required. ASTM specifications also include Type IA, Type IIA, and Type IIIA for the same uses but with the addition of air entraining compounds to protect concrete against freeze-thaw damage.

White Cement.—White cement is made from iron-free materials of exceptional purity, usually limestone, china clay or kaolin, and silica. The clinker is burned with a reducing flame in the kiln and rapidly quenched in a water spray to keep any iron in the ferrous state to avoid coloration by ferric ions. The clinker is then ground with high-purity white gypsum using ceramic balls and liners in grinding mills. White cement is used in decorative concrete, including terrazzo, median barriers, and architectural concrete.

Masonry Cement.—Masonry cement is a hydraulic cement used in mortars for masonry construction. It contains one or more of the following materials: portland cement, portland-pozzolan cement, slag cement, or hydraulic lime, usually with hydrated lime, limestone, chalk, calcareous shale, talc, slag, or clay interground for plasticity. ASTM designation C-91 contains specifications for masonry cement.

Blended Hydraulic Cement.—ASTM Specification C-1157, first developed in 1992, covers blended hydraulic cements for both general and special applications.[2] This is a specification giving performance requirements. There are no restrictions on the composition of the cement or its constituents. The specification classifies cements by type based on specific requirements for general use, high early strength, resistance to attack by sulfates, and heat of hydration. As a performance standard and not a rigid formula of ingredients, it does not replace ASTM's existing standards (C-595 for blended cement described below) but is an additional way to specify blended cements. ASTM designation C-595 covers four kinds of blended hydraulic cements, each with an optional provision for air entraining.

Portland-Blast Furnace Slag.—This is essentially an intimately interground mixture of portland cement clinker and granulated blast furnace slag, or an intimate and uniform blend of portland cement and fine granulated blast furnace slag in which the slag constituent ranges between 25% to 70% of the total weight of the cement.

Pozzolan.—Pozzolan is a siliceous and aluminous material that in itself possesses little or no cementitious value but will, in a finely divided form and in the presence of moisture, chemically react with calcium hydroxide at ordinary temperatures to form compounds possessing cementitious properties. Fly ash is a pozzolanic material obtained from flue gases produced by coal combustion. Natural pozzolans are naturally occurring materials, such as diatomaceous earths, opaline cherts and shales, tuffs, volcanic ash, and pumicites. ASTM C-618 covers fly ash and natural pozzolans.

Portland-Pozzolan Cement.—Portland-pozzolan cement is produced by intergrinding portland cement clinker and pozzolan, by blending portland cement or portland-blast furnace slag cement and finely divided pozzolan, or a combination of intergrinding and blending in which the amount of the pozzolan is between 15% and 40% of the total weight of the cement.

Pozzolan-Modified Portland Cement.—The constituents in this type of cement are the same as those for portland-pozzolan cement, and the methods of production are also the same. However, pozzolan makes up less than 15% of the total weight of the blended cement.

Slag Cement.—Slag cement is a finely divided material made from a uniform blend of granulated blast furnace slag and hydrated lime. The slag constitutes at least 70% of the total weight of the blended cement.

Oil-Well Cement.—Oil-well cement was developed to seal oil and gas wells under pressures of 18 to 20,000 pounds per square inch and temperatures up to 400° F in oil and gas wells and 500° F in steam wells. This cement must remain fluid up to about 4 hours to be effective. The cement is modified by service companies to fit individual well conditions using additives. The average well depth is 4,600 feet, but can range from grass roots depth to 30,000 feet.

The American Petroleum Institute (API) specifications cover requirements for manufacturing eight classes of well cements—A, B, C, D, E, F, G, and H—and Grades O-Ordinary, MSR-Moderate Sulfate-Resistant Grade, and HSR-High Sulfate Resistant Grade.[3] Changes in the API specification were set down in 1991, including the elimination of specific well depths in classes A-H cement and the abolition of mandatory testing for classes A, B, and C cement among other changes. The physical and chemical requirements set down previously remained the same.

Expansive Cement.—Expansive cement is a hydraulic cement that tends to increase in volume after setting during the early hardening period. There are three types of expansive cements, types K, M, and S. Expansive cements are used primarily in shrinkage-compensating concrete. ASTM specification C-845 covers all expansive cements.

Aluminous Cement.—Sometimes known as calcium aluminate cement, or high-alumina cement, aluminous cement is a hydraulic nonportland cement. Special applications of aluminous cement are based on its rapid-hardening qualities, resistance to sulfate action, and refractory properties when used as "castable refractories" and mortars for furnaces and kilns.

Concrete.—Concrete is a proportioned mixture of coarse mineral aggregates of sand and gravel or crushed stone, bound together by a paste of hydraulic cement and water. Volume 04.02 of ASTM standards covers concrete and aggregates.

Admixtures.—Admixtures allow the concrete to be altered to the particular job. Factors such as the durability, appearance, versatility, and cost effectiveness of the concrete, can be manipulated. Most additives modify the hydration of portland cement in some way, by changing the speed of reaction or by dispersing the cement particles more thoroughly throughout the mix. Admixtures reduce the water-cement ratio required in the concrete mix. The following are admixtures in cement:[4]

Plasticizers.—Plasticizers are water-reducing agents that effectively reduce the quantity of cement required to achieve certain strength or workability characteristics.

Superplasticizers.—Superplasticizers produce highly workable flowing concrete that, for example, can be used for pumping applications. Superplasticizers also can produce high-strength concrete that has a reduced water content and a high compressive strength.

Air-Entraining Agents.—Air-entraining agents cause microscopic air bubbles to be distributed uniformly throughout the concrete. These act as reservoirs for the water when it freezes, allowing it to expand without harming the structure of the concrete. They also can act as crack inhibitors by preventing small cracks enlarging beyond the extent of the nearest air void. Concrete may be air-entrained to give protection from freeze-thaw cycles. Air-entraining mixtures may entail loss of compressive and tensile strength, and thus may be used with plasticizers to restore the strength properties. Fly ash and slag have an air-entraining effect.

Accelerators.—Accelerating admixtures increase the hardening rate of concrete, giving high early strength development. Calcium chloride is the most common accelerator and has been in use since 1885. Accelerators are used mainly in cold weather to normalize the setting time for concrete in a similar way that retarding plasticizers may be used in hot weather to slow down the process.

Waterproofing Aids.—Waterproofing aids are chemical admixtures that provide protection against the wind and rain and reduce the intake of ground water. Waterproofing aids form a water repellent surface on the concrete and thin hydrophobic layers and voids within the concrete structure.

Polypropylene Fibers.—Polypropylene fibers can inhibit cracks. The fibers take up the stress from drying concrete, thus reducing the tendency for it to crack. They add little to the overall strength of the hardened concrete; however, they impart elasticity during the initial plastic stage of the concrete, which is important for the inhibition of cracks.

Products For Trade and Industry

Portland cement makes up 96% of total domestic output; the remainder is mostly masonry cement with white, expansive, portland slag and pozzolan, waterproof, and a variety of miscellaneous cements accounting for a small percentage of the remainder.

Industry Structure

The industry is composed of 119 cement-producing plants in 37 States and 2 in Puerto Rico. Multiplant operations were being run by 18 companies. Fifteen independent importers have constructed terminals to receive foreign cement for markets near coastal areas.

The cement industry has been very active in vertically integrating the cement companies since 1985, when the Federal Trade Commission removed the ruling that prevented vertical integration in the construction materials industries. Vertical integration would include owning ready-mix concrete, concrete products, aggregate, and construction businesses that buy the cement. In addition, the cement companies own crushed stone, sand and gravel, hot-mix asphalt, and precast and prestressed concrete companies. Other companies may own fly ash, slag, chemical admixtures, colored cement, waste material including fuel, and cement distribution companies. Therefore, cement companies have moved beyond simply acquiring the cement consumers, but also are owning the fuel and cement distribution companies.

In 1993, one of the activities in the U.S. cement industry with respect to vertical integration was the sale of Blue Star Ready Mix of Moorpark, CA, to Southdown Corp., based in Houston, TX.[5] Other news relating to a vertically integrated company involved Centex Corp., which announced that its construction products subsidiary, Centex Construction Products (CCP), filed a registration statement for the intended sale of 51% of CCP's common stock in an initial public offering. CCP was comprised of Centex's cement, ready mix concrete, aggregate and gypsum wallboard operations.[6] Most of the vertically integrated cement companies in the United States were foreign-owned.[7] Such companies included Beazer U.S.A., owned by Hanson Industries; Blue Circle Cement Inc.; Calaveras Cement of Cimenteries CBR, S.A.; Dragon Products Co., owned by Cementos del Norte; Essroc Corp., owned by Ciments Francais; CSR; Lafarge Corp.; National Cement Co., owned by Ciments Vicats; Mitsubishi Cement Corp.; California Portland Cement, owned by Onoda Cement; and Tarmac. Southdown Inc. a wholly owned U.S. cement company, was integrated in California.

Resources

Primary raw materials required for cement clinker production are, in order of importance, limestone, clay and shale, and iron ore. In instances where essential chemical components are not present in primary raw materials in the required amount, other mined materials or industrial products may be used as additives to correct these deficiencies. Gypsum is added during the clinker grinding process to make finished portland cement.

Although raw materials for cement manufacturing have not been quantified, they are abundant in most countries. Some countries deficient in raw materials meet their requirements by importing. Many domestic companies have reported reserves of raw materials exceeding 100 years of supply.

Technology

Principal steps in manufacturing portland cement consist of crushing, grinding, mixing, and burning raw materials and grinding the resultant clinker. About 1.8 short tons of raw materials is required to make 1 short ton of cement.

Raw Material Grinding.—Both dry and wet grinding are used to obtain a fineness that may range from 75% to 90% passing through a 200-mesh sieve. In wetmilling, water is added with the mill feed to produce a slurry containing about 65% solids. The raw material then is dried and ground for burning.

Burning.—Burning is the most important operation in manufacturing cement. Because fuel consumption is a major expense, plant capacity is measured by kiln output, and strength and other properties of cement depend on the quality of the clinker. Burning takes place in a rotary kiln that is a refractory-lined steel cylindrical shell. It rotates on an axis inclined at 3/8 to 1/2 inch per foot toward the discharge end. U.S. kilns range in size from 116 to 760 feet long and 8 to 24 feet in diameter.

Byproducts and Coproducts

Cement kiln dust, which is captured in

the baghouse of a cement plant, is a byproduct which can be used for agricultural uses among others. Some kiln dusts with high-alkali content have been collected and used as fertilizer or processed to recover potash. Flotation, a method of beneficiation used by some companies to remove undesirable constituents from raw materials and usually to increase the calcium carbonate content of the kiln feed, produces waste, such as silica sand or mica fines, that may be marketed. Waste rock quarried in selective mining of usable raw material has been sold for riprap and fill materials or crushed and sold as aggregate for concrete or for road base.

Economic Factors

Prices.—Cement prices are greatly influenced by local or regional markets and by the availability of energy and raw materials required for cement manufacturing. Discounts for cash and large-quantity purchases, absorption of freight charges, and the cost of packing bags and pallets add to the complexity of cement price patterns. Competition among producers and, in some instances, stiff competition from imports also are factors that contribute to depressed prices and ultimately limit investment dollars available for capital improvement or expansion.

Costs.—The cement industry has cut energy consumption and costs considerably during the past 30 years by modernizing the kilns, utilizing secondary fuel burning, and improving efficiency. Energy costs account for about 35% of the total production costs for cement. Plant operating costs may make up 70% of the value of cement.

Tariffs.—For countries with most-favored-nation status, duties are imposed only on white cement in the amount of $0.22 per metric ton, including the weight of containers. Other hydraulic cement and clinker are duty free. The statutory import duty for countries without most-favored-nation status is $1.76 per metric ton and $1.32 per metric ton for white cement and for all other types of cement and clinker, respectively.

Operating Factors

Energy Requirements.—The U.S. cement industry consumed an average of 4.8 million British thermal units per short ton (Btu/short ton) in 1993.[8] Types of fuel consumed in the cement kiln were natural gas, bituminous and anthracite coal, and petroleum coke. High sulfur petroleum coke may be blended with coal and used as fuel in the cement kiln. (See tables 7 and 8).

The cement industry also has been using wastes derived from other industries as fuel for cement kilns since the 1980's. The waste fuel market is divided into two broad areas: hazardous waste and nonhazardous waste.[9] The hazardous-waste area contains wastes such as printing inks and dyes, paints, solvents, chemicals, plastics, and any other materials that have come into contact with these industrial wastes. Nonhazardous wastes include scrap tires, medical waste, used oil, nonhazardous plastics and chemicals, and municipal wastes.

During the past 6 years, the use of hazardous waste-derived fuels has increased steadily. Cement kilns are described by the industry as ideal waste disposal units because the clinkermaking process requires high temperatures, long burning times, and a high level of turbulence. Liquid wastes, solvents, used motor oil, and scrap tires can be burned effectively, cutting down on fuel costs.[10]

Currently, liquids are used more commonly as hazardous waste-derived fuels.[11] Solids and sludges can be introduced into the kiln in a variety of ways. Solids can be suspended in liquids and pumped into the kiln, or injected directly into the calcining zone. Preprocessed solids and sludges are dried, ground into powder, and air-conveyed into the hot end of the kiln. With any of these three processes, as fuel is consumed, the organic compounds are destroyed. The inorganic compounds recombine with the raw materials and are incorporated into the matrix of cement. Cement kilns may need to be modified to burn some of these wastes. Some kilns already have been retrofitted to use waste oil. Using scrap tires as fuel for preheater kilns is well known, but had not been an option for long kilns. New technology will allow whole tires to be inserted into the calcining zone. One automated bulk tire feeder can run unattended with a programmable controller.[12] The costs involved in converting to using wastes as fuel depend upon the type of waste, with hazardous waste being the most expensive and tires the least expensive. However, the cement kilns are paid approximately $50 per short ton for using hazardous liquids and $250- to $400-per short ton for solids. Other waste fuels that cement kilns may be recycling in the future include municipal wastes or waste timber.[13]

ANNUAL REVIEW

Legislation and Government Programs

The EPA has a mandate under the Bevill Amendment of the Resource Conservation and Recovery Act (RCRA) to study cement kiln dusts and to present a report to Congress by January 1995.[14]

Issues

The cement industry, in an effort to increase profitability, increased prices which had remained flat for at least a decade. The industry also attempted to increase profitability by retiring old plants, cutting costs, and improving the efficiency of cement plants.

The vertical integration which had taken place in the cement industry since the mid-1980's slowed somewhat; however cement company acquisitions and mergers were strong. (See Corporate Changes section of this report).

Production

One State agency and 45 companies operated 119 plants in 37 States. In addition, two companies operated two plants in Puerto Rico, manufacturing hydraulic cement. The production data obtained are listed by State or groups of States that form cement districts. A cement district may represent a group of States or a portion of a State. The States of California, Illinois, New York, Pennsylvania, and Texas are divided to provide more definitive marketing information within those States, as follows:

California, Northern.—Points north and west of the northern borders of San Luis Obispo and Kern Counties and the western borders of Inyo and Mono Counties.

California, Southern.—All other counties in California.

Chicago, Metropolitan.—The Illinois counties of Cook, DuPage, Kane, Kendall, Lake, McHenry, and Will.

Illinois.—All other counties in Illinois.

New York, Western.—All counties west of a dividing line following the eastern boundaries of Broome, Chenango, Lewis, Madison, Oneida, and St. Lawrence Counties.

New York, Eastern.—All counties east of the aforementioned dividing line, except Metropolitan New York.

New York, Metropolitan.—The five counties of New York City (Bronx, Kings, New York, Queens, and Richmond) plus Nassau, Rockland, Suffolk, and Westchester Counties.

Pennsylvania, Eastern.—All counties east of the eastern boundaries of Centre, Clinton, Franklin, Huntingdon, and Potter Counties.

Pennsylvania, Western.—All other counties in Pennsylvania.

Texas, Northern.—All counties north of a dividing line following the northern borders of Burnet, Crockett, Jasper, Jeff Davis, Llano, Madison, Mason, Menard, Milam, Newton, Pecos, Polk, Robertson, San Jacinto, Schleicher, Tyler, Walker, and Williamson Counties.

Texas, Southern.—All counties south of the aforementioned dividing line.

Clinker Production.—Clinker production in the United States, excluding Puerto Rico, increased by 4% to 65.7 million metric tons. California continued to lead all States in clinker production, followed by Texas, Pennsylvania, Missouri, and Michigan.

By yearend, multiplant operations were being run by 18 companies. The size of individual companies, as a percentage of total U.S. clinker production capacity, ranged from 0.4% to 12%. The 5 largest companies with clinker capacity provided about 40% of total clinker capacity; the 10 largest companies with clinker capacity provided a combined 60%. The 10 largest companies, in decreasing order of size of clinker production, were Holnam Inc.; Lafarge Corp.; Southdown Inc.; Lone Star Industries Inc.; Blue Circle Inc.; Ash Grove Cement Co.; Lehigh Portland Cement Co.; Medusa Corp.; Essroc Materials Inc.; and RC Cement.

Portland Cement.—Portland cement production, excluding Puerto Rico, increased by 6% to 70.85 million metric tons. The increase was attributed to greater demand for cement, primarily in Mountain states and others, such as Arkansas, Florida, Georgia, Louisiana, Massachusetts, Mississippi, Oklahoma, Tennessee, and Texas.

The industry operated 119 plants, including 8 grinding facilities, to produce various types of finished hydraulic cement.

The size of individual companies, as a percentage of total U.S. finished cement production capacity, ranged from 0.3% to 13%. The top 10 producing companies, in declining order of production, were Holnam Inc.; Lafarge Corp.; Southdown Inc.; Lone Star Industries, Inc.; Blue Circle Inc.; Ash Grove Cement Co.; Lehigh Portland Cement Co.; Medusa Cement Co.; Essroc Materials Inc.; and RC Cement Co., Inc.

Masonry Cement.—Production of masonry cement increased by 8% to 2.96 million metric tons. At yearend, 83 plants were manufacturing masonry cement in the United States.

Aluminous Cement.—Aluminous cement continued to be produced by Lehigh, Buffington, IN; Lafarge, Chesapeake, VA; and Aluminum Co. of America, Bauxite, AR.

Fuel Consumption.—Approximately 70% of all U.S. clinker was produced by the dry process method. Fuels consumed in this process included coal, 10 million metric tons; natural gas, 668 million cubic feet; and oil, 46 million liters. In addition, 70,000 metric tons of tires, 90,000 metric tons of solid waste fuel, and 743.7 million liters of liquid waste fuel were consumed in the cement kilns.

Corporate Changes.—Ash Grove Cement opened a new 2,200 ton per day plant on the Duwamish Waterway, close to downtown Seattle, WA.[15]

Carlow Group, based in Zanesville, OH, early in 1993, closed its subsidiary Midwest Portland Cement Co. plant in East Fultonham, OH. Essroc Materials, Inc., based in Nazareth, PA, acquired Midwest's marketing and sales areas.

Hanson Industries of Hanson PLC located in London, England, sold its interest in North Texas Cement Company of Midlothian, TX, to Ash Grove Cement Co. of Overland Park, KS.[16]

Heidelberger Zement AG of Heidelberger, Germany, acquired the controlling interest in the Belgian firm CBR (Cimenteries). In North America, CBR owned Calaveras Cement Co. in California and Inland Cement and Tilbury Cement Companies in Canada.[17]

Holnam, Inc., the wholly owned U.S. subsidiary of Holderbank Financiere Glaris Ltd., based in Switzerland, purchased the Boxcrow Cement Co. plant in Midlothian, TX.[18] Assets to be acquired in the transaction included the cement plant, related quarry operation, and working capital. The 1 million ton per year Box Crow plant was built in 1987 and had been operating under the supervision of a court-appointed trustee since the company declared bankruptcy in late 1992. Holnam was to hold 75% of the company and was to manage the company which would be a wholly owned Holnam subsidiary.

Holderbank, which had owned 95% of Holnam, Inc. shares, approved a merger designed to give it ownership of 100 percent of Holnam's shares.[19]

KRC Aggregates, a subsidiary of MDU Resources Group, Inc., with holdings in utilities, coal, and oil, acquired the assets of Alaska Basic Industries, Inc. and Anchorage Sand and Gravel.[20]

Lafarge Coppee, based in Paris, France, announced a $318 million share-swap bid for full control of Asland, the second-biggest Spanish cement company in which Lafarge already held a 54% share.[21]

Lafarge Corp., the U.S. cement subsidiary of Lafarge Coppee, installed new equipment in its Davenport, Iowa plant. Production was boosted to 940,000 tons, and testing of alternative fuels, such as tires and used plastics, was made possible by this equipment.

Lafarge Corp. restructured and consolidated its 11 operating units into six in its two main business lines, cement and construction materials.[22] The cement group was divided into Western, Eastern and U.S. regions, with regional headquarters in Calgary, Alba.; Montreal, Que.; and Southfield, MI. Corporate headquarters remained in Reston, VA, according to a Lafarge Corp. announcement.

Lone Star Industries, Inc. settled two class-action law suits brought against it and some of its officers for $40 million.[23] The suit charged that Lone Star provided certain investors with misleading financial information.

At yearend, Cuba reportedly was considering giving to Cemex of Mexico, the Lone Star Cement plant that it had seized in 1959 in order to settle some of the country's debt with Mexico.

Lone Star Industries, Inc. announced plans to sell its Nazareth, PA, cement plant and several joint ventures as part of a bankruptcy reorganization.[23]

Medusa Corp. purchased an 810,000-ton single-kiln cement plant in Demopolis, AL, and nine cement distribution terminals from Lafarge Corp. for $45 million.[24]. After the sale, Lafarge operated 15 full production cement plants in North America and more than 100 distribution terminals with an annual cement production capacity in excess of 15 million tons. Medusa operated 4 cement plants in Alabama, Georgia, Michigan, and Pennsylvania, in addition to 16 cement distribution terminals in the Midwest and Southeast.[25]

Southdown, Inc., the third largest cement producer in the United States in 1993 and one of only a handful of U.S.-owned cement companies, set aside its plans to sell up to 50% of its cement and concrete products operations in Florida and California. [26]

Consumption and Uses

Consumer demand for cement in the United States, excluding Puerto Rico, increased by 8%. According to U.S. Department of Commerce (DOC) data, housing starts increased 7% to 1.29 million units, in 1993. The value of new construction increased 7.1% to $466 billion. The value of residential construction increased 12% to $210 billion, primarily in single-unit structures. The value of nonresidential construction increased 3.2% to $90 billion, owing primarily to increases in commercial building construction other than industrial, office and education. Public construction climbed by 6.2% to $55.1 billion, partly resulting from spending for miscellaneous public construction, including recreation, power generating, and open parking facilities, transit systems, and airfields, among other categories. Other public construction experiencing increases were highways and streets, schools, and conservation and development.[27]

California continued to lead all States in the amount of portland cement consumed, followed by, in order of shipments received, Texas, Florida, Illinois, Ohio, and Pennsylvania. Together, these States consumed 38% of the total U.S. tonnage.

On a regional basis, six of the Bureau of Census districts experienced increases in consumption. The largest increases were experienced by the Mountain, West South Central, South Atlantic, and East South Central districts with increases, respectively, of 16.4%, 8.5%, 7.2% and 7.0%. New England and East North Central districts showed increases in consumption of 5.0% and 3.3%. Although the Pacific, West North Central, and Middle Atlantic districts had decreases respectively of 3.1%, 1.7% and 0.4%, respectively, not all of the states in those districts experienced declines. For example, in the Pacific district, Oregon, Northern California and Washington experienced increases, respectively, of 5.8%, 1.6% and 0.1%. In the West North Central district, Nebraska, South Dakota and Kansas had increases of 8.6%, 6.0% and 2.3% and in the Middle Atlantic district, New Jersey, Eastern New York, Western New York, and Eastern Pennsylvania had respective increases of 6.8%, 6.0%, 2.9% and 1.2%.

Shipments of domestically produced portland cement from U.S. mills increased by 4%, as shown in table 11, while masonry cement shipments climbed 13%. *(See table 11.)* Cement shipments that were not reported to the USBM according to the type of customers are shown under Government and Miscellaneous *(See table 13.)* Ready-mix concrete producers were the primary consumers of cement, accounting for about 59% of the total, followed by concrete product manufacturers, 11.5%; building material dealers, 6.1%; roadpaving contractors, 2.9%; and other contractors, including those that were unspecified contractors, 4.9%. Smaller amounts were consumed by Federal, State, and other government agencies, and by a variety of uses, such as waste stabilization and mining.

Markets and Prices

The average mill value of portland cement was approximately $55.48 per metric ton and the value of masonry cement was $77.32 per metric ton. The average value of cement by yearend reported by Engineering News Record (ENR), was $63.39 per short ton. The ENR prices are based on an average per-ton value of cement delivered to 20 cities.

The average price change for portland cement for October 1993 increased by 7.4% compared with October 1992.[28]

Foreign Trade

The U.S. International Trade Commission (ITC) reaffirmed that the United States was materially injured or threatened with injury by imports of Japanese gray portland cement and cement clinker into the United States. The action was in response to an order from the Court of International Trade (CIT). The original determination was made in April 1991 when the U.S. Department of Commerce had determined that Japanese cement and clinker were being sold in the United States at less than fair value. Subsequently, the determination was appealed to the CIT, and the CIT sent back the ITC's original determination.[29]

The ITC completed its review of gray portland cement and clinker from Mexico. The preliminary rates were revised. The final dumping margins ranged from 30.44 % to 53.26% [30]

The ITC began an investigation of French calcium alumina cement and cement clinker shipped to the United States.[31] The Commerce Department was to begin a pricing investigation of the shipments.

Exports of hydraulic cement and clinker, as reported by the Bureau of the Census, decreased 16% to 625,000 metric tons. Canada received 80% of the total.

New York led all States in the amount of imports received, with 16% of total U.S. imports, or 1,154,000 metric tons. Of this total, 54% were shipped through the Buffalo Customs District, 20% were shipped through the New York City Customs District, and 27% were shipped through the Ogdensburg Customs District. These imports comprised 53% of New York's portland cement consumption compared with total imports representing 9% of apparent consumption nationally. Eighty percent of imports into New York came from Canada, 16% came from Greece, 2% each came from Spain and from the United Kingdom. Michigan was the second largest recipient of imported cement, receiving 1.02 million tons or 14% of the total. All of the Michigan imports were shipped through the Detroit Customs District, and virtually all came from Canada.

Chinese cement continued to enter the United States through Lone Star Northwest's terminals in Seattle, WA, and Portland, OR. By yearend, the Chinese had exported 286,000 tons. SsangYong Cement shipped 33,000 tons of cement from its plant in Korea to a CenCal terminal, which was jointly owned by SsangYong and Riverside Cement Co. The last previous cement shipments from Korea were at the end of 1991.[32]

World Review

World cement production increased by 5% to 1.3 billion tons. China continued to lead all nations with 27% of production, followed by Japan with 7%, and the United States with 6%.

Large-scale consolidations continued to take place in the international cement industry. The largest world cement companies have been bent on acquiring other cement and building concerns with the goal of becoming even larger. This was the case with the five largest international cement companies: Holderbank Glaris of Switzerland, Lafarge-Coppee of France, Italcementi/Ciments Francais of Italy, Heidelberger Zement of Germany and Cementos Mexicanos of Mexico.

Many cement companies around the world were poised to export a large part of their production to developing countries, especially in Asia. Indonesia, Malaysia, the Phillipines, Singapore, and Vietnam all needed cement to build their infrastructure, although they were also busy installing their own cement capacity.

Countries with excess capacity continued to export cement to the United States. Twenty-four countries exported cement to the United States in 1993, one more than in 1992. The amount of cement imports increased by 14% because of increased demand in U.S. markets.

The high level of exports brought many anti-dumping cases in the international cement market. While anti-dumping investigations in the United States continued against France, Japan, and Mexico, Mexico was investigating cement from Venezuela, and Germany was charging that East European cement producers were dumping cement into Germany at unfair prices.[33]

Belgium.—Both cement consumption and shipments were estimated to have dropped about 5% to 5.4 million tons and 6.8 million tons, respectively.[34] Belgium was a net exporter of cement.

S.A. Cimenteries CBR announced that Societe Generale de Belgique sold its controlling interest in CBR to Heidelberger Zement A.G. of Germany.[35] The two cement companies were of comparable size and their combined sales of more than $3 billion made the new group the fourth largest European cement industry. Geographically, their business areas were very complementary, both in Europe and in North America. In Europe, CBR operated 10 cement plants in Belgium, the Netherlands, the Czech Republic, and Poland. CBR also had six cement plants in Western Canada and Western United States. *(See World Review, Germany for Heidelberger plants.)*

Brazil.—Cimento Correa Industrial, one of Brazil's leading cement producers, opened the Bodoquena plant, Mato Grosso do Sul, with a cement production capacity of 1,800 tons per day.[36] Lone Star Industries, Inc., sold its 49.6% share in its Brazilian cement subsidiary, Cimento Portland, to Paris-based Lafarge Coppee. Lafarge owned the other 50.4% of the company. Cimento Portland operated four plants in Brazil with about 2.2 million mt/yr capacity, according to R. Huhta of Rock Products.

Canada.—Essroc Canada merged its Quebec operations with those of Ciment Quebec, forming a new company. The new company included all of the cement manufacturing and distribution facilities of both Essroc and Ciment Quebec, as well as their ready-mixed concrete, concrete products, and aggregate operations.

China.—Guangzhou Investment Co. of Hong Kong purchased a 41% controlling stake in the Chinese Zhujiang Cement plant, of Guangzhou, Hong Kong, for $51 million from Guangzhou International Trust and Investment Corp. (GITIC). GITIC will retain a 49% holding in the plant, which produces 1.2 million mt/yr. The company was to operate as a special joint venture and have a 25-year production license.[37]

France.—Ciments Francais became the first western company to invest in the Russian cement industry by acquiring a 15% stake in the 1.9 million mt/yr Zelenogorsk plant in the Urals for approximately US$100,000.[38]

Germany.—Heidelberger Zement acquired a 42.6% controlling interest in CBR of Belgium for US$640 million. The new grouping was to become the fourth largest building materials supplier in the world. It was to operate either directly or through minority shares, about 39 cement plants in Northern Europe and North America with a combined production capacity of 38 million mt/yr.[39] Combined sales of both companies were expected to be $3 billion. Heidelberger operated six cement plants in Baden-Wurttemberg, Bavaria, and Rhineland in Germany, and held controlling interest in other Germany cement plants, two cement firms in the Czech Republic, three cement plants in Hungary, and one in Croatia. Heidelberger also had a minority interest in S.A. Vicat, a French cement company with seven plants. In North America, Heidelberger had controlling interest in Lehigh Portland Cement Co. with eight cement plants.[40]

Greece.—Greece exported 6.9 million metric tons of cement and clinker, a 15% increase compared to 1992.[41] It produced 13.9 million tons of cement, up 2.2% from the prior year, while it shipped 7.1 million tons within Greece, a 6.3% decrease over the prior year.

Italy.—Italcementi SpA acquired control of Ciments Francais, holding 45.63% of the voting-rights stock of Ciments Francais by yearend 1992. This moved Italcementi into one of the top three cement-producing companies worldwide.[42]

Calcestruzzi SpA, a cement producer, was to acquire Greece's Halkis Cement Co., but was sued by Halkis when it broke off discussions with the Greek company. A Greek court ordered the seizure of $208.7 million in assets in the Greek Heracles General Cement, acquired by Calcestruzzi in 1992.[43]

Japan.—Japan's fourth largest cement producer, Onoda Cement Co., and its sixth largest, Chichibu Cement Co., planned to merge their operations in 1994. The merger was expected to make the company the top cement producer in Japan with a 24% market share. Onoda and Chichibu each operated three plants.[44] In North America, Onoda owns California Portland Cement Co., with three plants and three terminals located in Northern California, Southern California, and another near Phoenix, Arizona. Onoda also has a 50% holding in CPC Terminals, an import operation near Los Angeles, CA.

Korea, Republic of.—Cement production was expected to reach around 50 million tons in 1993. Domestic demand was expected to be less than 46 million tons. The overcapacity seemed to indicate that Korea was planning to export significant amounts of cement. Korea's exporting companies were SsangYong Cement, Tong Yang Cement Corp. and Halla Cement Corp. Cement exports from these companies were likely to find potential markets in China, Hong Kong, Malyasia, Singapore, Taiwan, and Vietnam.[45]

Tong Yang completed kiln 7 at its Samchok plant, raising the company's production capacity to more than 11 million mt/yr.[46] The company was expected to extend its product range to include slag cement. A slag cement facility was to be constructed in Kwang Yang in the southern part of the peninsula and was expected to be operational in 1994. Blast furnace slag would be used from the Pohang Iron and Steel Co. operations.[47]

Halla Cement began construction of a fourth kiln at its Okke plant on the Eastern coast of Korea.[48] The project was to raise production capacity from the existing 5.6 million mt/yr to more than 7 million mt/yr upon completion in 1994. With domestic activity slowing, cement was likely to be exported from the plant, not only to Southeast Asia but also to North America and Latin America.

Mexico.—Cementos Mexicanos (Cemex), Mexico's largest cement producer and among the largest cement companies in the world, acquired Cementos Hidalgo, with a production capacity of 1,750 mt/d in Hidalgo, Nuevo Leon, Mexico.[49] Cemex also acquired eight concessions for port facilities offered by the Mexican government in its effort to privatize the country's port operations. The concessions were granted for the construction and operation of modern terminals at government-owned ports and were granted for a 20-year period.

Cementos Apasco, Mexico's second-largest producer, was to invest in a new plant in Tecoman, Colima in Mexico.[50] The cement plant, expected to start production in 1994, was to have a production capacity of 1.25 million mt/yr. The cement was not destined for the export market.

The U.S. Department of Commerce (DOC) increased the dumping margin on Cemex's cement exports to the United States from 30.44% to 40.72% for the period between April 1, 1990 and July 31, 1991. DOC also made a final determination that Cemex's dumping margin for the period August 1, 1991 to July 31, 1992 was 42.74%. Both decisions were made after the Department completed two of its three administrative reviews of the anti-dumping order issued against cement exported from Mexico. The third review, covering the period from August 1, 1992 to July 31, 1993, was still under administration review at yearend. The Mexican cement industry filed a complaint under the General Agreement on Tariffs and Trade (GATT) on the U.S. imposition of tariffs on cement exported to the United States.

Spain.—Ciments Francais purchased an additional 10% of the shares of Cementos Molins. This gave Ciments Francais 35.3% control of Cementos Molins equity. Cementos Molins operated two plants in Spain, producing about 3.5 million mt/yr.[51]

CURRENT RESEARCH

As in past years, research continued on the subject of the use of supplementary cementing materials (SCM's). Use of SCM's in reducing expansion of concrete and mortar caused by alkali-aggregate reaction was investigated by the Canada Centre for Mineral and Energy Technology (CANMET).[52] A total of 15 fly ashes, slags, condensed silica fumes and natural pozzolans were chosen to represent the wide range of physical and chemical features of SCM's commercially available in Canada. The effectiveness of SCM's in reducing expansion was compared with that of a low-alkali cement.

Coal-burning powerplants have generated a large amount of fly ash in the United States. A small fraction of the fly ash generated was being utilized in various applications, but a need persists to further utilize the fly ash. At Rutgers University in Piscataway, NJ, results from a recent study on development of a cement composite utilizing large amounts of fly ash were presented.[53] A flowable fly ash-cement sand composite was investigated for strength and permeability characteristics at various stages of maturity. The independent variables considered were fly ash content, sand content, and ratio of water to cementitious materials. Results of the study showed that high-volume fly ash composite could be proportioned to obtain compressive strengths as high as 21 Megapascals (MPa) or 3,000 psi after 180 days.

At the University of Pennsylvania in University Park, PA, the potential for use of fly ash and slag to be used as the main components in cement was studied. Alkali-activated fly ash-slag cement (AFC) was studied as a matrix for immobilization of nuclear waste.[54] The AFC was characterized by high early strength, high ultimate strength, low porosity, lower solubilities of the hydrates, and high resistance to chemical corrosion, in addition to freezing and thawing. All of these advanced properties are favorable to the immobilization of nuclear wastes.

An investigation was carried out at the Delft University of Technology in The Netherlands involving the cement equivalence factors for fly ash in concrete.[55] The work was part of research aimed at taking the contribution of fly ash to strength development and other properties of concrete into account with respect to the minimum cement content and maximum water-cement ratio required to achieve these properties. Dutch Concrete Standards were used. Three cements were studied — ordinary Portland, rapid hardening and Portland blast furnace slag cement. Four fly ashes, including two with low NO_x, were used for the study. Concrete compositions with a range of water-cement ratios, two fly-ash cement ratios, and three curing regimes were studied as functions of concrete compressive strength. The test results showed that the contribution of fly ash to strength was strongly dependent on the water-cement ratio, the type of cement, the fly ash quality, and the concrete age. The equivalence factor increased when the water-cement ratio decreased. This dependence was highest for rapid hardening Portland cement and lowest for the Portland blast furnace slag cement.

At the Building Research Establishment in Watford, England, studies were conducted on blended high alumina cement (HAC) that could lead to its use in structural concrete.[56] Cements were studied that were made by blending HAC with granulated blast furnace slag. The compressive strength of such concretes increased with time when kept in hot, wet conditions.

Research at the Slovak Academy of Sciences in the Slovak Republic was devoted to the study of the influence of the developed alkali-silicate admixture on mortar properties.[57] The results showed that the admixture significantly increased the strength of the mortars made from portland cement and silica fume or blast furnace slag. Further results showed that the mortars with alkali-silica admixture had an increased content of hydration products and had a substantially more dense pore structure than mortars of the same composition, but without the admixture.

Research at the Israel Institute of Technology was intended to clarify the nature of concrete strengthening in the presence of silica fume.[58] Compressive strength development of high-strength concrete and its paste-matrix was investigated. The results indicated that carbon black was effective in modifying the basic concrete-matrix strength relationship to an extent similar to that obtained by silica fume. It was suggested that the mechanism by which silica fume affects the concrete behavior was of a physical origin and was based on microfiller effect, prior to its action as a pozzolanic material. The microfiller effect was of greater significance to strength enhancement.

In the United Kingdom, the introduction and progressive development of soil stabilization of the natural soil conditions at Gatwick, Stansted, Heathrow and Glasgow Airports was studied.[59] The dual use of both lime and cement to modify and strengthen the natural subgrades and earthwork formation were described. The prime object of the paper was to make available full practical details of large-scale lime and cement soil stabilization work.

Continuing interest has been shown on materials that can be used in developing countries to complement cement. At the Wisconsin Department of Transportation, rice husk ash (RHA) was studied and found to possess some pozzolanic properties.[60] RHA could reduce the cost of building in Nigeria, since it can be used to replace cement in sandcrete blocks that are the major cost component of the most common building forms in the country. For a given hydration period and mix proportions, the strength of the blocks decreased with increasing RHA content. RHA could replace cement up to 30% or 40% for a sandcrete block or sandcrete mix respectively.

Developed countries could use sludge from municipal sewage treatment together with limestone and clay as raw materials for making cementitious building material.[61] A ground mixture of the raw materials was incinerated to produce cement. The effects of mixture compositions, incineration temperatures, and incineration durations on the properties of cement were investigated. From the results, an optimum condition of mixture composition of the raw materials, incineration temperature and duration, and curing condition upon the highest possible strength development of the cement was determined. The study showed that sewer sludge could be used to produce cement satisfying the strength requirements for masonry cement.

In Australia, the manufacture of cements based on calcium sulfoaluminate energy, as compared with ordinary portland cements, was studied.[62] The manufacture of cements based on calcium sulfoaluminates required lower firing temperatures and lower grinding energy when compared with ordinary portland cements. Some of the low-energy cements could be formulated in order to develop high early strength and other performances similar to ordinary portland cements. It was found that a number of industrial wastes and by-products such as phosphogypsum, bauxite fines, as well as fly ash and blast furnace slag, could be employed without negatively affecting the hydraulic behavior of these cements.

At the Institute of Materials in Athens, Greece, the diffusion of water into hardened cement samples containing different kinds of additives was studied for the first time using nuclear magnetic resonance imaging (NMRI).[63] The results indicated that NMRI could be used as a research and industrial method to evaluate the properties (e.g., permeability and durability) of the final cement product.

Composite cements were being considered for use in the construction of low-to-intermediate level radioactive waste repositories.[64] The interactions of ordinary portland cement and pulverized fuel ash mixes with high-sulfate- and high-carbonate-bearing ground waters at temperatures that could be attained in a repository were investigated as part of a larger work being carried out at the Building Research Establishment in the United Kingdom.

Other research focused on improvements to cement plant equipment.[65] The Group Cementos Lemona, S.A. in Spain, constructed a covered storage area for an effective capacity of 47,000 tons of cement clinker. The purpose was to avoid handling materials in open spaces, to increase storage capacity, to reduce the dust emission that is unavoidable in an open air store with overhead cranes, and to facilitate loading and unloading operations for lorries.

A large number of cement plants are still based on the wet process. This process includes preparation of slurry that is either fed directly to the kiln or first treated in a filtration unit.[66] The evaporation of the large amount of water results in elevated fuel bills. Plants could convert to a semi-dry-process—somewhat between the wet and dry—in order to increase market production, reduce production costs, and generally modernize the plant. The wet-process kiln could be converted to the semi-dry process by converting the kiln to a cyclone preheater kiln, with or without calciner, and then drying the feed to raw meal in a separate dryer. A dryer with a conventional preheater or a compact kiln system could be used for this purpose.

Gas leakage through a cemented wellbore annuli has been a major problem in many oil wells in the world and specifically in the United States.[67] Gas leakage could occur as a result of bad cement-formation bonding caused by incompatible contraction-expansion mechanism during cement setting. Work at the University of Oklahoma proposed the use of new cementing additives that could reduce the effect of the expansion-contraction mechanism during the cement slurry setting. The additives-filled contraction induced voids within the cement structure and between the pipe and cement, leading to an impermeable cement, thus eliminating the existence of micro-fractures and micro-annulus. The materials were economical to use and readily available. It was proposed that the cement bond index be estimated in the laboratory using the ultrasonic test prior to the cement job.

OUTLOOK

Demand for cement was expected to increase due to pent-up demand for highway construction and some residential construction. In addition, heavy flooding in the Midwest damaged many homes and structures that would eventually need to be replaced.

Cement prices were forecast to continue to rise following cement price increases that began in 1993.

Cement imports were expected to continue to increase as cement plants met their capacity.

TABLE 1
SALIENT CEMENT STATISTICS

(Thousand metric tons unless otherwise specified)

	1989	1990	1991	1992	1993
United States:[1]					
Production[2]	70,025	69,954	[r]67,193	[r]69,585	73,807
Shipments from mills[2] [3]	78,234	78,199	[r]68,999	[r]69,203	72,770
Value[2] [3] [4] thousands	$4,242,931	$4,280,105	[r]$3,832,096	[r]$3,779,286	$4,049,820
Average value per ton[2] [3] [4]	$54.23	$54.73	[r]$55.54	[r]$54.61	$55.65
Stocks at mills,[2] Dec. 31	5,715	5,637	[r]6,009	[r]5,272	4,788
Exports	464	503	633	746	625
Imports for consumption	14,280	12,041	7,893	6,166	7,060
Consumption, apparent[5] [6]	82,260	81,305	[r]74,000	[r]75,400	81,700
World: Production	[r]1,148,912	[r]1,149,369	[r]1,184,530	[r]1,241,217	[e]1,303,360

[e]Estimated. [r]Revised.

[1] Excludes Puerto Rico and the U.S. Virgin Islands.

[2] Portland and masonry cement only.

[3] Includes imported cement shipped by domestic producers.

[4] Value received, f.o.b. mill, excluding cost of containers.

[5] Quantity shipped plus imports minus exports.

[6] Adjusted to eliminate duplication of imported clinker and cement shipped by domestic cement manufacturers.

[r] Revised. W Withheld to avoid disclosing company proprietary data; included in "Total or average."

[1] Includes Puerto Rico. Includes data for three white cement facilities as follows: California (1), Pennsylvania (1), and Texas (1). Includes data for grinding plants as follows: California (1), Florida (2), Iowa (1), Michigan (1), Ohio (1), Pennsylvania (1), and Texas (1).

[2] Includes cement produced from imported clinker.

[3] Grinding capacity based on fineness necessary to grind Types I and II cement, making allowance for downtime required for maintenance.

[4] Includes imported cement. Source of imports withheld to avoid disclosing company proprietary data.

[5] Data may not add to totals shown because of independent rounding.

TABLE 3

CLINKER CAPACITY AND PRODUCTION IN THE UNITED STATES IN 1993,[1] BY DISTRICT

District	Active plants Process used			Total	Number of kilns	Daily capacity (thousand metric tons)	Average number of days maintenance	Apparent annual capacity[2] (thousand metric tons)	Production[3] (thousand metric tons)	Percent utilized

Puerto Rico	—	1	1	2	7	7	15	2,437	1,212	49.7

NA Not available.

[1] Includes Puerto Rico and white cement producing facilities.

[2] Calculated on individual company data; 365 days minus average days for maintenance times the reported 24 hour capacity.

[3] Includes production reported for plants that added or shut down kilns during the year.

[4] Data may not add to totals shown because of independent rounding.

TABLE 4

RAW MATERIALS USED IN PRODUCING PORTLAND CEMENT IN THE UNITED STATES[1]

(Thousand metric tons)

Raw materials	1991	1992[r]	1993
Calcareous:			
Limestone (includes aragonite, marble, chalk)	[r]71,213	70,897	78,958
Cement rock (includes marl)	[r]19,140	23,388	19,186
Coral	1,577	1,577	754
Argillaceous:			
Clays	[r]4,275	4,432	4,200
Shale	[r]4,147	4,142	5,066
Other (includes staurolite, bauxite, aluminum dross, alumina, volcanic material, other)	[r]354	314	442
Siliceous:			
Sand and calcium silicate	[r]1,794	1,954	2,046
Sandstone, quartzite, other	[r]541	571	571
Ferrous: Iron ore, pyrites, millscale, other iron bearing material	[r]886	914	1,097
Other:			
Gypsum and anhydrite	[r]3,287	3,531	3,696
Blast furnace slag	[r]79	72	38
Fly ash	[r]670	957	888
Other, n.e.c.	[r]390	378	224
Total[2]	[r]108,352	113,127	117,165

[r] Revised.

[1] Includes Puerto Rico.

[2] Data may not add to totals shown because of independent rounding.

TABLE 5

[r] Revised. XX Not applicable.

[1] Includes Puerto Rico. Includes data for three white cement facilities as follows: California (1), Pennsylvania (1), and Texas (1). Includes data for grinding plants as follows: California (1), Florida (2), Iowa (1), Michigan (1), Ohio (1), Pennsylvania (1), and Texas (1).

[2] Includes cement produced from imported clinker.

[3] Data may not add to totals shown because of independent rounding.

[4] Cement imported and distributed by domestic producers only.

[5] Does not include cement consumed at plant.

[r] Revised. W Withheld to avoid disclosing company proprietary data; included with "Foreign countries."

[1] Includes cement produced from imported clinker and imported cement shipped by domestic producers, Canadian cement manufacturers, and other importers. Includes Puerto Rico.

[2] Has no cement producing plants.

[3] Less than 1/2 unit.

[4] Data may not add to totals shown because of independent rounding.

[5] Direct shipments by producers to foreign countries and U.S. possessions and territories; includes States indicated by the symbol W.

[6] Includes cement produced from imported clinker by domestic producers.

[7] Imported cement distributed by domestic producers, Canadian cement manufacturers, and other importers. Origin of imports withheld to avoid disclosing company proprietary data.

TABLE 12

CEMENT SHIPMENTS,[1] BY DESTINATION (REGION AND SUBREGION)

Idaho, Montana, Nevada, Utah	46	159	1,538	200	38	52	2,035
Alaska, Hawaii, Oregon, Washington	90	175	1,080	150	—	24	1,518
California, northern	102	209	1,486	37	86	14	1,935
California, southern	424	717	3,980	474	99	38	5,732
Total[6] or average	4,237	7,988	41,377	5,473	998	9,722	69,794
Puerto Rico	536	118	590	19	—	46	1,309

[1] Includes Puerto Rico.

[2] Concrete product manufacturers included in thousand metric tons: brick-block—1,127 in the United States, 22 in Puerto Rico; precast—675 in the United States, 2 in Puerto Rico; pipe—55 in the United States, 5 in Puerto Rico; and other—5,633 in the United States, and 90 in Puerto Rico. Other includes unspecified amounts of brick/block, precast, and pipe.

[3] Contractors included in thousand metric tons: roadpaving—2,055 in the United States; soil cement—333 in the United States and other—2,427 in the United States and 19 in Puerto Rico. Other includes unspecified amounts of road paving, and soil cement.

[4] Oil well, mining, and waste included in thousand metric tons in the United States: oil well drilling—885; mining—42; and waste stabilization—72.

[5] Included in this amount are cement shipments which were unspecified by type of customer.

[6] Data may not add to totals shown because of independent rounding.

Sulfate resisting (Type V)	1,176	1,570
Block	W	471
Oil well	836	804
White	[r]376	263
Portland slag and portland pozzolan	285	264
Expansive	W	W
Regulated fast setting	80	W
Miscellaneous[3]	[r]650	137
Total[4] [5] or average	[r]67,842	71,104
Total thousand short tons	[r]74,783	78,379

[r] Revised. W Withheld to avoid disclosing company proprietary data; included in "Total or average."

[1] Includes Puerto Rico.

[2] Values of portland cement types not collected in 1993: value of grey portland cement $54.97; value of white portland cement $192.40.

[3] Includes waterproof and lowheat (Type IV).

[4] Data may not add to totals shown because of independent rounding.

[5] Does not include cement consumed at plant.

TABLE 15

AVERAGE MILL VALUE, IN BULK OF CEMENT IN THE UNITED STATES[1]

(Per metric ton)

Year	Portland cement	Prepared masonry cement[2]	All classes of cement
1989	53.94	76.15	54.80
1990	54.53	75.93	55.34
1991[r]	54.65	76.46	55.46
1992[r]	54.53	74.99	55.30
1993	55.48	77.32	56.36

[r] Revised.

[1] Includes Puerto Rico. Mill value is the actual value of sales to customers, f.o.b. plant, less all discounts and allowances, less all freight charges from producing plant to distribution terminal if any, less total cost of operating terminal, if any, less cost of paper bags and pallets.

[2] Masonry cement made at cement plants only.

XX Not applicable.

[1] Free alongside ship (f.a.s.) value is the value of exports at the U.S. seaport, or border port of export, based on the transaction price, including inland freight, insurance, and other changes incurred in placing the merchandise alongside the carrier at the U.S. port of exportation. The value excludes the cost of loading.

[2] Includes 47 countries in 1991; 59 in 1992; and 60 in 1993.

[3] Data may not add to totals shown because of independent rounding.

XX Not applicable.

[1] Customs value price actually paid or payable for merchandise when sold for exportation to the United States, excluding U.S. import duties, freight, insurance, and other charges incurred in bringing the merchandise to the United States.

[2] C.i.f. (Cost, insurance and freight) import value represents the landed value of the merchandise at the first port of arrival in the United States. It is computed by adding "import charges" to the "customs value."

[3] Data may not add to totals shown because of independent rounding.

[6] Dissolved in Dec. 1991.

[7] Dissolved in Apr. 1992.

CHROMIUM

By John F. Papp

Dr. Papp, a physical scientist with 22 years of U.S. Bureau of Mines experience, has been the commodity specialist for chromium since 1983. Domestic survey data were prepared by Nicole Picciotta, statistical assistant; and chromite and ferrochromium world production data, by country, were prepared by Amy Burke, international data specialist. Cost of production data were prepared by Edward H. Boyle, Minerals Availability Field Office, Division of Resource Evaluation. (All tonnages are in metric tons unless otherwise specified.)

Chromium has a wide range of uses in metals, chemicals, and refractories. It is one of the Nation's most important strategic and critical materials. Chromium use in iron, steel, and nonferrous alloys enhances hardenability and resistance to corrosion and oxidation. The use of chromium to produce stainless steel and nonferrous alloys is one of its more important applications. Other applications are in alloy steel, plating of metals, pigments, leather processing, catalysts, surface treatments, and refractories.

Because the United States has no chromite ore reserves and a limited reserve base, domestic supply has been a concern during every national military emergency since World War I. World chromite resources, mining capacity, and ferrochromium production capacity are concentrated in the Eastern Hemisphere. The National Defense Stockpile (NDS) contains chromium in various forms, including chromite ore, chromium ferroalloys, and chromium metal in recognition of the vulnerability of long supply routes during a military emergency.

Research is conducted by the Federal Government to reduce U.S. vulnerability to potential chromium supply interruption. That research covers both domestic resource utilization and alternative materials identification. Domestic chromium resources include mineral deposits and recyclable materials. The U.S. Geological Survey and the U.S. Bureau of Mines evaluate U.S. territory for chromium mineral deposits. The U.S. Bureau of Mines also studies minerals extraction and processing and materials substitution and recycling. Alternative materials research also is conducted by the National Aeronautics and Space Administration, the National Institute of Standards and Technology, the Department of Defense, and the Department of Energy.

World chromite ore reserves are more than adequate to meet anticipated world demand.

DOMESTIC DATA COVERAGE

Domestic data coverage of the primary consuming industries—chemical, metallurgical, and refractory—are developed by the U.S. Bureau of Mines by means of the voluntary monthly "Chromite Ores and Chromium Products" survey. The companies listed in table 10 by industry accounted for 100% of the chromite consumption data by industry in the current year of table 12. All of the metallurgical, refractory, and chemical companies that consumed chromite in 1993 reported to the U.S. Bureau of Mines.

Domestic production data for chromium ferroalloys and metal are developed by the U.S. Bureau of Mines by means of two separate, voluntary surveys. These two surveys are the monthly "Chromite Ores and Chromium Products" and the annual "Ferroalloys." Production by the metallurgical companies listed in table 10 represented 100% of the domestic production shown in the current year of table 11.

BACKGROUND

Chromium owes its prominence as a commodity to its use in stainless steel. Stainless steel was invented in the early 1900's. Soon thereafter electric furnaces evolved that could smelt chromite into ferrochromium. Before about 1960, ferrous alloys required the addition of as little carbon as possible because carbon could not efficiently be removed from molten steel. Thus, the production of low-carbon, high-chromium alloys (typically less than 0.1% carbon and more than 65% chromium) in or near steel-producing centers was the common practice. To make this ferrochromium, high chromium-to-iron ratio ores were required (ratios greater than about 2:1).

Since 1960, major changes have occurred in the chromium industry because of changes in steelmaking technology. The development of ladle refining techniques (i.e., processes that permit the chemical modification of liquid metal), such as argon-oxygen decarburization, permitted the steel industry to shift from the more costly low-carbon ferrochromium to the less costly high-carbon ferrochromium as its major source of chromium units. This shift in ferrochromium grade has been accompanied by a shift in quantity of production among ferrochromium-producing countries. Since the 1970's, chromite ore-producing countries have developed their own ferrochromium production capacities. As a result, ferrochromium production has moved from the major stainless steel-producing centers in Japan, the United States, and

Western Europe to chromite-producing countries—Finland, the Republic of South Africa, Turkey, and Zimbabwe. With the exception of Japan, only minor ferrochromium production remains in the major stainless steel-producing countries. In particular, the Republic of South Africa, whose ores have a chromium-to-iron ratio of about 1.2:1, has increased its high-carbon ferrochromium production dramatically. Significant, but declining, quantities of ferrochromium continue to be produced in Japan.

Once chromium is incorporated into stainless steel, it is used in many different ways. Stainless steel is used in many industrial applications that benefit from oxidation or corrosion resistance or in applications that benefit from the ease with which stainless steel may be cleaned. Uses that are common to the experience of many people include kitchen and eating utensils, sinks, and automobile exhaust components or systems. Chromium also is used in chemicals for a variety of purposes.

Chromite, the mineral from which chromium is derived for use in the metallurgical and chemical industries, is used directly by the refractory industry to produce heat-, spalling-, corrosion-, and abrasion-resistant bricks for metallurgical and high-temperature industrial mineral processing applications. Chromite is not mined domestically; thus, the United States is 100% import dependent to meet domestic chromite demand. Some domestic chromium demand is met by recycling. Chromium is a critical and strategic material contained in the NDS to ensure adequate supply in the event of a national defense emergency.

Definitions, Grades, and Specifications

U.S. industry sets chemical and physical specifications for chromium materials through the American Society for Testing and Materials (ASTM). Other organizations also make specifications for chromium materials. The Defense Logistics Agency (DLA), in cooperation with the Department of Commerce, maintains purchase specifications for chromium materials contained in the NDS. The Department of the Treasury, in cooperation with the Department of Commerce and signatories to the General Agreement on Tariffs and Trade, maintains definitions of chromium materials for the purpose of recording trade and applying tariff duties.

The import category "chromite ore and concentrates made therefrom" is subdivided by chromic oxide content as follows: containing not more than 40% chromic oxide, containing more than 40% and less than 46% chromic oxide, and containing 46% or more chromic oxide. Producers of chromite ore and concentrate typically specify chromic oxide content; chromium-to-iron ratio; and iron, silica, alumina, magnesia, and phosphorus contents. They also specify the size of the ore or concentrate. Typically, chromic oxide content ranges from 36% to 56%, with values in the 40% to 50% range being most common. Chromium-to-iron ratios typically range from about 1.5:1 to about 4:1, with typical values of about 1.5:1 to 3:1. In trade, the chromite ore also is called chromium ore, chromite, chrome ore, and chrome.

The import category "chromium ferroalloys" is subdivided into ferrochromium and ferrochromium-silicon. Ferrochromium-silicon, also called ferrosilicon-chromium and chromium silicide, is not further classified. Ferrochromium is classified by its carbon content as containing not more than 3% carbon, more than 3% but not more than 4% carbon, or more than 4% carbon. Producers of ferrochromium typically classify their material as low- or high-carbon or charge-grade ferrochromium. Charge-grade ferrochromium also is called charge chrome. Producers of chromium ferroalloys typically specify chromium, carbon, silicon, phosphorus, and sulfur contents and material size. Ferrochromium-silicon typically contains 24% to 40% chromium, 38% to 50% silicon, and 0.05% to 0.1% carbon. Ferrochromium typically contains 50% to 75% chromium and 0.05% to 8% carbon. Low-carbon ferrochromium typically contains 55% to 75% chromium and 0.02% to 0.1% carbon. High-carbon ferrochromium typically contains 60% to 70% chromium and 6% to 8% carbon. Charge-grade ferrochromium typically contains 50% to 55% chromium and 6% to 8% carbon.

Products for Trade and Industry

Chromium is primarily used in the metallurgical industry as an alloying element. Small quantities of chromium are alloyed with a base metal to achieve certain desired properties not attainable with the base metal alone. Before its use as an alloying element, chromium was used predominantly in chemicals to make pigments or to plate metals. Chromite is used as a refractory material. Refractories resist degradation when exposed to heat. As a pigment, chromium provides color to many end products and corrosion protection to ferrous metals. As a plating material, chromium provides a lustrous or a hard finish and corrosion protection to the substrate metal. As a refractory, chromite found major use in blast furnace iron production. The decline in use of this process has resulted in a corresponding decline in chromite refractory use. Environmental concern over hexavalent chromium contamination has resulted in reduced use or increased expense of chromium use in pigments and plating. Chromium is traded primarily as chromite ore or as ferrochromium. Substantial amounts of chromium chemicals, pigments, and metal also are traded.

Industry Structure

Stainless steel was developed in about 1900. Since then, stainless steel has grown to become the major end use of chromium. Chromium is used in stainless steel production in the form of ferrochromium, a product of smelting chromite ore with a carbonaceous material (chemical reductant) and silicious materials (flux material). The production of stainless steel evolved in association with the major steel-producing centers. The production of ferrochromium developed in conjunction with the production of stainless steel at those steel-producing locations.

In a trend toward vertical integration, chromite-producing countries have been developing ferrochromium and stainless steel production capacity. This trend has worldwide impact. Formerly, ferrochromium was produced mainly by Europe, Japan, and the United States, the major steel producers. The U.S. trend to obtain chromium in the ferroalloy form is a result of the world trend to produce ferrochromium in chromite-producing countries.

The structure of the chromium industry from a material processing perspective begins with mining of chromite ore. (See figure 1, chromium material flow.) Once mined, ore that is not sold directly is beneficiated. The resulting chromite ore or concentrate made therefrom may be consumed in the refractory, chemical, or metallurgical industry. Chromite ore is consumed in the refractory industry for its chromite mineral content. The chromite is typically crushed, ground, and sized. It then is mixed with magnesite to make chrome-magnesite bricks that are subsequently consumed in the steel, glass, or cement industry. The chromite refractories are used to line steelmaking furnaces, cement kilns, or heat exchangers associated with glass production. *(See figure 1.)*

Chromite ore consumed in the chemical or metallurgical industry is processed to extract the chromium from the chromite mineral. Chromite ore consumed in the chemical industry is kiln roasted. Using water, the chromium is leached out of the kiln roast product in the form of sodium chromate. The sodium chromate is processed further to make chromic acid, sodium bichromate, and other chromium chemicals and pigments. Chromic oxide is a chemical industry product. Chromite ore consumed in the metallurgical industry is smelted to produce ferrochromium. In effect, the oxygen is removed from the iron-chromium-oxygen mineral, leaving an iron-chromium alloy, ferrochromium. Ferrochromium is produced to meet a variety of chemical and physical specifications. Several variations of the ferrochromium production process are practiced; the submerged electric arc furnace is central to each process. Ferrochromium is the source of chromium units for alloys, especially ferrous alloys. When nonferrous alloys require chromium and the iron is undesirable, chromium metal is used. Chromium metal is produced from ferrochromium by an electrolytic process or from chromic oxide by an aluminothermic process.

The major vertical structure of the chromium industry is mining-smelting-stainless steelmaking. In some instances, the ownership of mining operations, smelters, and stainless steel production facilities is integrated. In many other cases, integration is limited to mining and smelting or to smelting and stainless steelmaking. Often the ownership of operations is shared. Major mining, smelting, or stainless steel production facilities are typically privately owned by large companies or groups of companies. *(See tables 1 and 2.)*

Geology-Resources

The geology of many chromium deposits has been characterized.[1] The data in table 21 are rated reserves and reserve base for major chromite ore-producing countries.[2] The data on chromite reserves and resources are categorized according to a general U.S. Bureau of Mines-U.S. Geological Survey classification system applicable to all minerals. The definition of reserves and reserve base are published in Geological Survey Circular 831, "Principles of a Resource/Reserve Classification for Minerals." The distribution of chromite deposits into reserves, reserve base, and resources categories is determined by the physical and chemical nature of the ore (physical factors) and by mining and market economics (economic factors). Resources are a concentration of naturally occurring material from which a commodity may currently or potentially be extracted. Resources are divided into identified and undiscovered. As used here, resources refers only to identified resources that are further subdivided into demonstrated and inferred resources. The reserve base is the in-place demonstrated (measured plus indicated) resource from which reserves are estimated. The reserve base includes those resources that are currently economic, marginally economic, and some of those that are currently subeconomic.

Reserves are that part of the reserve base that could be economically extracted or produced at the time of determination. Reserves include only recoverable materials. Reserve values are included in reserve base values.

The term "reserves" is commonly used with a variety of definitions. Even when the definition given here is used, the quantitative value of reserves could vary owing to differing physical and economic criteria applied to a deposit by different analysts.

Technology

Mining.—A wide variety of mining technology is applied to the surface and subsurface mining of chromite ore. Most ore comes from large mechanized mines. However, small labor-intensive mining operations contribute to world supply.

Beneficiation.—The amount of beneficiation required and the techniques used depend on the ore source and end-use requirements. When the chromite is clean, only hand sorting of coarse material and gravity separation of fine material may be required. When the ore is lumpy and mixed with host rock, heavy-media separation may be used. When the chromite mineral occurs in fine grains intermixed with host rock, crushing may be used in conjunction with gravity separation and magnetic separation.

Smelting.—The smelting of chromite ore to produce ferrochromium requires electric arc furnace technology. Early electric furnaces having power ratings in the kilovolt-ampere range have developed into modern furnaces having power ratings of about 50 megavolt-amperes. Closed and partially closed electric arc furnaces replaced open furnaces in the 1970's to improve pollution control, efficient furnace operation, and safety.

Ferrochromium is produced from chromite ore by smelting a mixture of the ore, flux materials (e.g., quartz, dolomite, limestone, and aluminosilicates), and a carbonaceous reductant (wood, coke, or charcoal) in an electric arc furnace. If the ore is lumpy, it can be fed directly into the furnace. However, if the ore is not lumpy, it must be agglomerated before it is fed into the furnace. (See Energy Requirements under Operating Factors.) Efficient operations recover chromium lost to furnace fume by collecting and remelting the dust and recover chromium lost to slag by crushing and beneficiating the slag. The chromium content of the ferrochromium is determined by the chromium-to-iron ratio of the chromite ore.

The shift from high-chromium, low-carbon ferrochromium to low-chromium, high-carbon ferrochromium, commonly called charge-grade ferrochromium, permitted the use of low chromium-to-iron ratio ore for smelting to ferrochromium. The Republic of South Africa is the most abundant and low-cost source of such ore. Unfortunately, this ore is friable (breaks easily into small pieces), and the finer fractions of such ore are blown out of a furnace before it can be smelted. Agglomeration technology has been developed to permit the use of fine chromite ore in the electric arc furnace. Briquetting and pelletizing are practiced. Efficient production technology uses prereduced and preheated pelletized furnace feed. Industry is developing new production technologies using high-temperature plasmas or using alternatives to electrical power supply. The new production technologies are expected to be more cost competitive than traditional production technology under some conditions. Advanced smelting technologies that use abundant friable ore have been and are being developed. Plasma processes, including transferred and nontransferred arc processes, have been applied to ferrochromium production. The kiln roasting prereduction process has been applied to ferrochromium production.

Recycling.—Recycling is the only domestic supply source of chromium. Stainless steel and superalloys are recycled, primarily for their nickel and chromium contents. As much as 50% of electric furnace stainless steel production can result from recycled (i.e., new and old) stainless steel scrap. Advanced stainless steel production technology such as continuous casting reduces prompt scrap generation and permits a higher product yield per unit of raw material feed. See figure 2 depicting the general recycling of chromium material flow industry structure. *(See figure 2.)*

Byproducts and Coproducts

Chromite ore is mined as a primary product. Chromite is not a byproduct or coproduct of the mining of any mineral, nor are there byproducts or coproducts associated with chromite mining. Chromite has the potential of becoming a byproduct of platinum mining in the Republic of South Africa or of lateritic nickel mining. Platinum and chromite are present in the UG2 seam of the Bushveld Complex in the Republic of South Africa. At present, most platinum mining is from the Merensky Reef. However, as platinum mining from the UG2 seam continues and as new mining operations that exploit the UG2 seam are developed, chromite-containing tailings will continue to grow. The feasibility of utilizing these resources has been demonstrated, and new ferrochromium production facilities under development by Samancor Ltd. are designed to permit the use of these resources. It appears to be only a matter of time before economic conditions favor the use of those tailings, thereby making chromite a byproduct of some platinum operations.

Economic Factors

Prices.—Inadequate supplies of ferrochromium in the late 1980's resulted from strong demand for stainless steel in all three major producing regions: Europe, Japan, and the United States. This inadequate supply resulted in increasing ferrochromium prices until mid-1989, when supply exceeded demand and prices began to decline. In 1989 and 1990, new ferrochromium plants and plant expansions were under construction or being completed. Increased supply of ferrochromium, resulting from producer expansions and new plant construction, resulted in declining ferrochromium prices in 1990. The dissolution of the U.S.S.R. in 1991, along with political and economic reforms and reduced demand for materials in the Commonwealth of Independent States (C.I.S.), permitted C.I.S. chromite ore and ferrochromium producers to enter Western markets, further exacerbating excess supply and low prices.

The historical values of chromite ore by grade, ferrochromium by grade, and chromium metal imported to the United States are shown in tables 3 and 4. These values show that as chromite ore is processed to ferrochromium and to chromium metal, the added value is quite large. On a per unit of contained chromium basis for recent years, the value of ferrochromium is about 5 times that of chromite ore and the value of chromium metal is about 30 times that of chromite ore. Variations of the value of ore are shown to follow those of ferrochromium, indicating values of chromite ore change in response to demand, with ferrochromium value first to reflect demand changes.[3] Ferrochromium values show greater variation than those of chromite ore. The unit value of chromium materials has increased by 10% to 15% per year in actual value since 1963. *(See tables 3 and 4.)*

Costs.[4]—Operation and transportation are the two major components of chromite ore cost in the marketplace.

Operating cost includes mining (the production of run-of-mine ore) and beneficiation (the production of marketable chromite ore or concentrate from the run-of-mine ore). Mining cost is typically in the range of 70% to 90% of operating cost but exceeds 90% in some cases. Labor cost is the major component of mining and of beneficiation cost. Labor cost is typically in the range of 20% to 70% of mining cost and from 25% to 90% of beneficiation cost, but can be higher.

Excluding the delivered cost of chromite ore, electrical energy, other raw materials, and labor are the major components of smelting (i.e., production of ferrochromium from chromite ore) cost. (Note that smelting cost excludes the cost of chromite ore feed material.) Electrical energy cost is in the range of 20% to 55% of smelting cost; raw materials (excluding chromite ore), 15% to 35%; and labor, 10% to 30%.

The U.S. Bureau of Mines has studied the availability of chromium and analyzed the cost and availability of chromium materials. The chromium materials included exportable chromite products (metallurgical, chemical, refractory, and foundry sands) and chromium ferroalloy products in 10 market economy countries (MEC's). These various chromium materials were simultaneously analyzed for cost and availability. The product breakdown among chromium materials was based on mine and smelter production capacities and known operating relationships circa the 1987-88 time period.

A total of about 874 million tons, gross weight, of in situ material containing about 203 million tons of chromium was analyzed. Extraction and beneficiation of this material were estimated to yield about 475 million tons of chromite products, of which 289 million tons would be available for export and the remaining 187 million tons would be smelted in the country in which it was mined to produce about 80 million tons of chromium ferroalloys. The chromium ferroalloys would then be available for use in the country of production or for export. The 80 million tons of chromium ferroalloys included about 74 million tons of high-carbon ferrochromium, 4 million tons of low-carbon ferrochromium, and 2 million tons of ferrochromium-silicon.

The countries of the Republic of South Africa and Zimbabwe contained about 80% of the in situ chromium contained in chromite ore. Finland and India accounted for an additional 11% of the contained chromium; another 8% of the contained chromium was fairly evenly split among Brazil, the Philippines, Turkey, and the United States; and the remainder was in Greece and Madagascar.

Based on Cr_2O_3 content of in situ chromite ore, the 10 MEC's split into 2 groups, a high-grade group and a low-grade group. The high-grade group, those with ore grades ranging from 34% to 43% Cr_2O_3, included India, Madagascar, the Republic of South Africa, Turkey, and Zimbabwe. The low-grade group, those with ore grades ranging from 9% to 27% Cr_2O_3, included Brazil, Finland, Greece, the Philippines, and the United States. The grade differences between the two groups resulted in a wide disparity in their respective weighted average Cr_2O_3 contents. The high-grade group averaged 39% Cr_2O_3 and the low-grade group only 16% Cr_2O_3.

Table 5 shows the results of the U.S. Bureau of Mines analysis. Chromium material costs were calculated on a weighted average basis, f.o.b. ship at the port of export. Chromite costs shown in table 5 include chromite ore mining and beneficiating (including mine capital and operating costs and taxes) and chromite product transportation to port facilities. Chromium ferroalloy costs include chromite ore but exclude smelter capital cost. On a weight basis, the U.S. Bureau of Mines analysis shows that the Republic of South Africa and Zimbabwe could produce about 78% of metallurgical chromite ore, 93% of chemical chromite ore, 85% of refractory chromite ore, and 93% of foundry chromite ore that could be produced at their respective estimated break-even cost. The Republic of South Africa and Zimbabwe also could produce about 69% of the high-carbon ferrochromium, 89% of the low-carbon ferrochromium, and 100% of ferrochromium-silicon that could be produced at their respective estimated break-even cost. *(See table 5.)*

The low-carbon ferrochromium availability curve is shown in figure 3; high-carbon ferrochromium is shown in figure 4. The costs shown in figures 3 and 4 include mining and beneficiation operating and capital costs, transportation to specific smelters, smelting operating costs, taxes, and transport costs to specific port cities for export. Recovery of initial capital costs at the ferrochromium smelters has not been included. Figure 3 shows that the MEC's studied support total production of 4 million tons of low-carbon ferrochromium at a cost ranging from about $0.42 to $0.95 per pound, contained chromium, for 0 percent discounted cash-flow rate of return. Figure 4 shows that the same MEC's studied support total production of about 74 million tons of high-carbon ferrochromium at a cost of about $0.28 to $1.07 per pound, contained chromium, at a 0 percent discounted cash-flow rate of return. *(See figures 3 and 4.)*

Consumer cost and producer competitiveness can be significantly impacted by currency exchange rates. Ferrochromium is usually sold on a U.S. dollar basis. Production costs are mostly based in local currency. In the short term, a ferrochromium producer whose local currency declines in value relative to the U.S. dollar, without a change in its local production cost structure, achieves a competitive advantage. It can earn the same amount of local currency while selling its product for fewer U.S. dollars because of the change in exchange rates. In the long term, the producer may become less competitive if it must buy new equipment, replacement parts, or get capital in U.S. dollars.

An economic analysis of the South African ferroalloy industry[5] identified those business factors that were perceived as most important to determining new plant feasibility. In descending order of importance, the study found those factors to be: market opportunities for the salable product, local metal-ore deposits, energy costs and availability, and exchange-rate projections. Factors of less importance, again in descending order of importance, were as follows: capital costs and availability, escalation in other production and transport costs, State export incentives, skilled work force availability, domestic consumption of the final product, and other (including taxation and labor relations). The study found that domestic processing of South African ore increased from 6.8% in 1960 to 61% in 1988 and estimated that domestic processing could reach 80%. The cost distribution of charge-grade ferrochromium production in the Republic of South Africa was found to be, in dollars per ton of product: electricity (at 4,390 kilowatt-hours per ton), $135; transport (from plant to market), $122; ore, $75; carbon materials, $58; labor, $36; fluxes, electrodes, etc., $16; working capital, $10; and other direct costs, $97. In this study, exchange rate stability was found to be important because lack of exchange rate stability makes projected income indeterminate in cost analysis studies.

Tariffs.—Import tariffs are typically imposed to protect the domestic industry. Where there is no domestic industry, such as chromite ore production in the United States, there is no tariff. (See Foreign Trade section of this report for U.S. tariff duties on chromium materials.) In some cases, such as ferrochromium imports to the European Community, import tariffs are used with import quotas. That is, a duty-free quota is allocated to member countries. The quotas may be revised as necessary to meet the needs of domestic consumers and producers. Only in a few cases, such as ferrochromium exports from China and certain grades of chromite ore exports from India, are export duties applied.

Operating Factors

Environmental Issues.—Chromium is an essential trace element for human health. However, some chromium compounds are acutely toxic, chronically toxic, and/or carcinogenic. Chromium releases into the environment are regulated by the Environmental Protection Agency (EPA). Workplace exposure is regulated by the Occupational Safety and Health Administration.

Health.—Chromium is a trace mineral required by the human body for good health.[6] A daily intake in the range of 50 to 200 micrograms has been recommended. Chromium is a cofactor for insulin, a hormone that participates in carbohydrate and fat metabolism. A cofactor is a material that acts with the material. The dietary chemical compound form of chromium is trivalent. Because humans cannot convert trivalent (III) chromium to hexavalent (VI) chromium, the carcinogenicity of hexavalent chromium compounds bears no relevance to the nutritional role of trivalent chromium.

Toxicity.—The effect of an element on the human body depends on several factors. These factors include the chemical or class of chemical, the route of exposure, the quantity and duration of exposure, and characteristics of the exposed subject.[7]

The chemical distinctions typically made about chromium chemicals include whether the compound is synthetic or naturally occurring. Synthetic chromium compounds are typically classified by their oxidation state. Trivalent and hexavalent chromium compounds are two such classifications. Exposure to chromium compounds could typically occur through one or more of three routes: skin contact, ingestion, or inhalation. Exposure can also vary in intensity (concentration of the chemical) and duration (length of time for which exposure occurs). Response to chemical exposure is dependent on such human characteristics as age, sex, general health, and sensitivity. The effect of chemical exposure on the human body can be good or bad. Chromium is one of those elements that is both essential to good health and detrimental to good health. The detrimental effects of chemical exposure are classified as acutely toxic when small amounts of the chemical cause significant damage in a short time; chronically toxic when exposure over a long time causes measurable damage; and carcinogenic when exposure can result in cancer.

Background levels of chromium may be estimated from natural abundances. At about 185 parts per million, chromium is the 13th most common element in the Earth's crust, and at 0.2 parts per billion, the 26th most common element in seawater.

Under some conditions, chromium compounds cause systemic damage to the human body.[8] Because experimentation on human subjects is morally unacceptable, most toxicity data result from workplace, coincidental, or accidental human exposure or animal experimentation. EPA concluded that there is sufficient evidence in animals and humans for the carcinogenicity of chromium (VI) compounds, while evidence for the carcinogenicity of chromium (III) compounds in humans and animals is largely nonpositive. The acute toxicity of chromium (III) compounds is low whereas the acute toxicity of chromium (VI) compounds is in the high to moderate range. Chronic toxicity of chromium (III) is considered low.

Chromium generally forms chemical compounds in which chromium has either the hexavalent or trivalent oxidation state. Hexavalent chromium compounds are generally recognized as toxic. Chronic occupational exposure to hexavalent chromium has been associated with an increased incidence of bronchial cancer. The toxic status of trivalent chromium compounds is not clear. However, trivalent chromium compounds are less toxic than hexavalent chromium compounds. Chemical compounds containing chromium in lower valence states are generally recognized as benign.

The American Congress of Governmental Industrial Hygienists (ACGIH) adopted new threshold limit values for chromium materials. The time weighted average threshold value in units of milligrams per cubic meter of air recommended by ACGIH are as follows:

chromium metal, 0.5; trivalent chromium compounds, 0.5; hexavalent (insoluble) chromium compounds, 0.5; and hexavalent (soluble) chromium compounds, 0.1. ACGIH reported hexavalent chromium compounds to be "confirmed human carcinogens," and chromium metal and trivalent chromium compounds to be "not classifiable as human carcinogens."[9]

The U.S. Department of Health & Human Services, Public Health Service, updated its toxicological profile for chromium.[10] It found trivalent chromium to be an essential nutrient that helps the body use sugar, protein, and fat. It also report that breathing in high levels (i.e., greater micrograms per cubic meter of air) of hexavalent chromium can cause irritation to the nose and that long-term exposure could result in lung cancer.

Environmental Releases and Transfers.[11]—The EPA regulates and monitors industrial impact on the environment. As part of its monitoring activity, EPA collects data on toxic chemicals; that information is made available in the Toxic Release Inventory (TRI). TRI is mandated under title III of the Superfund Amendments and Reauthorization Act (SARA) of 1986.

Chromium has been identified as a toxic material by the EPA. Companies that release chromium-containing materials into the environment are required to report those releases to EPA. In turn, EPA collates the reported information and makes it publicly available in the form of the TRI data base.

EPA has been collecting environmental release information since 1987 from manufacturing facilities that employ 10 or more persons and used a threshold amount of chromium contained in chromium compounds. [A manufacturing facility is one whose product is included in Standard Industrial Classification (SIC) Division E Codes 20 through 39. EPA does not cover Division B, Mining, Groups 10 through 14.] The threshold amount decreased from 1987 to 1989, after which time it remained constant. The threshold limit for a facility that manufactured or processed chromium compounds was about 34 tons of contained chromium in 1987, about 23 tons in 1988, and about 11 tons in 1989 and subsequent years. The threshold limit for facilities that otherwise used chromium compounds has been and remains about 5.4 tons. (Note that EPA has definitions for the terms manufacture, process, and "otherwise use" for the purpose of reporting releases.) When reporting chromium releases, a facility must add up the chromium released from all sources that exceed a DeMinimis amount. The DeMinimis amount for chromium compounds is 0.1%. Facilities report the amount of chromium released to the air, water, and earth environment; the amount of chromium recovered onsite; and the amount transferred to offsite locations. The collected data are called the TRI. EPA reported total releases and transfers of chromium in chromium and chromium compounds.

EPA reported releases and transfers have averaged (1987 through 1992) to about 40,000 tons of chromium contained in chromium and chromium compounds per year.

Energy Requirements.—Electric arc furnace ferrochromium production is an electrical energy-intensive process (requiring about 4,000 kilowatt-hours per ton of ferrochromium produced) that produces similar volumes of ferrochromium and slag. However, heat recovery can reduce energy requirements. Energy-efficient processes using preheating can reduce the energy requirements to about 2,500 to 2,800 kilowatt-hours per ton of ferrochromium produced. Typically, all of the energy required to smelt chromite is supplied in the form of electricity. Electrical energy requirements can be reduced by preheating or prereducing charge material using alternative energy sources such as coal, natural gas, or fuel oil. Advanced production technology permits the use of liquid or gas fuel to provide part of the energy required. Alternative production technology is being developed that would permit nonelectrical energy sources to supply a significant fraction of the energy required to smelt chromite ore. Western World power consumption per ton of ferrochromium product was estimated to range from 2,000 kilowatt-hours to 5,000 kilowatt-hours and averaged 3,950 kilowatt-hours from 1988 to 1991.[12]

Transportation.—Chromite ore is typically transported by trackless truck or conveyor belt from the mine face to storage or processing facilities on the mine site. From there it is transported by truck from the mine site to the local railhead. It is then transported by rail to ports or to smelters. Smelters that do not have associated loading and unloading facilities for ships transport their product by rail to ports. Following transport by ship to consumer countries, chromium materials typically are barged or hauled by truck and/or rail to end users who have no loading and unloading facilities for ships.

ANNUAL REVIEW

In 1993, chromium apparent consumption was about 523,000 tons of contained chromium. The reported consumption of chromite by the chemical and metallurgical industry and by the refractory industry decreased. Chemical and metallurgical industry chromite consumption includes material consumed as part of the NDS program to convert chromite ore to ferrochromium. Imports of chromite ore increased. Reported consumption of chromium ferroalloys decreased while imports decreased. *(See table 6.)*

U.S. supply consisted of recycled and imported chromium materials. The United States recycled about 606,000 tons, gross weight, of stainless steel scrap and imported about 677,000 tons of chromite ore, ferroalloys, chemicals, and pigments valued at about $279 million. The United States exported about 48,000 tons of chromium materials valued at about $65 million. Compared to those of 1992, both quantity and value of imports of chromium materials decreased, while both quantity and value of exports increased in 1993.

Legislation and Government Programs

Dissolution of the U.S.S.R. into the C.I.S. and other independent states at the end of 1991 resulted in the reevaluation of the NDS. The absence of a single large adversary encouraged many to advocate reduction of the NDS. Others argued that history has demonstrated the need for a stockpile because periods of relative peace have been interspersed with conflict and that there is no reason to expect this pattern to change. Based on new international political conditions, DLA submitted to Congress its annual materials plan and identified the following for disposal: 299,371 tons of chromite ore in 1993, and 335,658 tons of chromite ore and 43,359 tons of ferrochromium in 1994.[13]

In accordance with the President's November 1982 directive and Public Law 99-591, the DLA continued to upgrade NDS chromite ore to high-carbon ferrochromium. The Agency reported conversion of chromite ore to ferrochromium on a contract year basis. DLA signed a contract with Macalloy Corp., Charleston, SC, in 1990 to upgrade NDS chromite ore. The contract period covers the years 1990-94, the last 2 years of which are optional for DLA. DLA contracted with Macalloy to have chromite ore converted to about 73,000 tons ferrochromium between September 1992 and October 1993. DLA has the option of extending its contract to have about another 7,000 tons produced to satisfy the public law mandating the program. *(See table 8.)*

As part of its plan to modernize the NDS, DLA contracted with Elkem Metals Co., Marietta, OH, to upgrade NDS nonspecification-grade low-carbon ferrochromium into electrolytic (vacuum melting-grade) chromium metal. Elkem converted low-carbon ferrochromium to chromium metal in 1989, 1990, and 1991. In 1992, DLA contracted with Elkem to convert low-carbon ferrochromium to about 1,600 tons of chromium metal. *(See table 9.)*

Strategic Considerations

Supply Security.—There is no production of chromite ore in the United States; primary consumption of chromium by U.S. industry is by companies that use chromite ore to produce ferrochromium, chromium chemicals, and chromite refractories and by chromium metal producers that use ferrochromium. World chromite ore reserves are abundant, ensuring adequate long-term supply. However, supply sources are few and remote from the United States, making supply vulnerable to disruption. The problem for the United States is one of national security. Ferrochromium is essential to stainless and some alloy steel production, which are in turn essential to the domestic economy and to the production of military hardware.

Use.—Strategic use of chromium is primarily in the metallurgical and chemical industries. Chromium is used in stainless steel and nickel- and cobalt-base superalloys. There are no substitutes for chromium in these uses. Stainless steel is essential to many industrial applications. Superalloys are essential to the production of gas turbine engines and to other high-temperature applications. Chromium chemicals are used for metal surface treatment and pigments.

Stockpile.—The NDS contains the following chromium materials: chromite ore, chromium ferroalloys, and chromium metal. The purpose of the NDS is to supply military, essential civilian, and basic industrial needs of the United States during a national defense emergency; by law, the stockpile cannot be used for economic or budgetary purposes. In addition to private and Government stocks, there exists a large unreported inventory of chromium contained in products, trader stocks, and scrap. The amount of these stocks varies with demand and price of the material. Under severe price pressures resulting from primary chromium shortages, recycling of consumer materials could add to the supply.

Chromite ore must be converted to ferrochromium before it can be used to make steel. Prompt response during a national defense emergency requires that conversion be carried out by domestic industry. However, domestic ferrochromium production capacity is not adequate to meet anticipated domestic demand under mobilization conditions. To ensure prompt NDS response to a national defense emergency, the President chose to convert stockpiled chromite ore to ferrochromium. Changes in industrial capacity and new manufacturing and technological developments have rendered selected chromium materials in the NDS inventory obsolete, either in quality or form or both, and in need of upgrading. Subsequent to legislative mandate, DLA began modernizing chromium materials in the NDS by converting nonspecification-grade low-carbon ferrochromium into chromium metal. (See Legislation and Government Programs section of this report.)

As a result of reduced threat to the territory of the United States, stockpile goals have been reduced and may be reduced further. Disposals of stockpile material have been made and were expected to continue until all excess material is disposed. Disposal takes the form of sale or payment for services contracted by DLA. In 1993, the DLA disposed of 192,000 tons of metallurgical-grade chromite ore and 59,000 tons of high-carbon ferrochromium, together containing about 97,124 tons of chromium. *(See table 9.)*

Issues

World ferrochromium production capacity in 1993 significantly exceeded demand, resulting in low capacity utilization. Strong demand for ferrochromium, resulting from high levels of stainless steel production worldwide in 1987-89, resulted in ferrochromium plant expansions and new plant construction. Since 1970, the trend has been for ferrochromium production capacity to move from major stainless steel-producing countries (e.g., Japan, the

United States, and Western Europe) to major chromite ore-producing countries (e.g., Finland, India, Kazakhstan, the Philippines, the Republic of South Africa, Turkey, and Zimbabwe). This has occurred through the creation of new plants or furnaces in chromite ore-producing locations and the closure of furnaces in other geographic areas where ferrochromium production was formerly strong. The increase in and change in location of world annual gross weight production capacity has continued that trend. Most of the added capacity was in chromite ore-producing countries. All of the capacity contraction was in nonchromite-producing countries. The largest addition to national annual capacity was in the Republic of South Africa, increasing the Republic of South Africa's capacity by about 30% in the 1989-90 time period. The supply shortage in 1988 was estimated to have been about 200,000 tons or about 5% of 1988 world production capacity. The expansion of 1989 and 1990 represented about 16% of 1988 world production capacity.

Stainless steel is the major chromium end use. Despite strong stainless steel production in 1993, ferrochromium production capacity exceeded demand, and weak prices resulted. Ferrochromium producers limited production and planned plant closings to reduce supply of ferrochromium in the expectation that reduced supply would stimulate prices to increase.

With Western World stainless steel production growing at a long-term average annual rate of 3% to 4%, it is estimated that it will take until 1995 (about 5 years of average industry performance) for demand to catch up with added capacity. Experience shows that short-term variations in chromium consumption and production can be significantly larger than long-term trends. The integration of the former U.S.S.R. with Western country economies started with the dissolution of the U.S.S.R. in 1991. This event complicated the recovery process by introducing additional chromite ore and ferrochromium supply capacity. As a result of political and economic changes, demand for chromium materials in the former U.S.S.R. declined. It was anticipated that a new world market balance would be achieved and that demand in the former U.S.S.R. would recover as production facilities in that region converted to cost-based pricing systems.

Production

The major marketplace chromium materials are chromite ore and chromium metal, ferroalloys, and chemicals. In 1993, the United States produced chromium metal, ferroalloys, and chemicals, but no chromite ore. *(See tables 10 and 11.)*

Consumption and Uses

Domestic consumption of chromite ore and concentrate was 336,582 tons in 1993. Of the total chromite consumed, the chemical and metallurgical industry used 313,708 tons, and the refractory industry, 22,874. Much of the chromite consumed and ferrochromium produced by the metallurgical industry were part of the NDS conversion program. (See Legislation and Government Programs section of this report.)

Chromium has a wide range of uses in the three primary consumer groups. In the metallurgical industry, its principal use in 1993 was in stainless steel. Of the 357,614 tons of chromium ferroalloys, metal, and other chromium-containing materials reported consumed, stainless steel accounted for 78.2%; full-alloy steel, 7.7%; high-strength, low-alloy, and electric, 3.1%; cast irons, 1.4%; superalloys, 1.6%; and other end uses, 8.0%. The primary use of chromium in the refractory industry was in the form of chromite to make refractory bricks to line metallurgical furnaces.

The chemical industry consumed chromite for manufacturing sodium bichromate, chromic acid, and other chromium chemicals and pigments. Sodium bichromate is the material from which a wide range of chromium chemicals are made. *(See tables 12 and 13.)*

Stocks

Reported consumer stocks of chromite in the United States decreased from 320,973 tons in 1992 to 274,756 tons in 1993. Chemical and metallurgical industry stocks decreased as did refractory industry stocks. At the 1993 annual rate of chromite consumption, consumer stocks represented about 10 months of supply in the chemical and metallurgical industry and 8 months of supply in the refractory industry. Producer stocks of chromium ferroalloys, metal, and other materials decreased from 5,723 tons in 1992 to 5,612 tons in 1993. Consumer stocks decreased from 17,628 tons in 1992 to 16,685 tons in 1993. At the 1993 annual rate of chromium ferroalloy and metal consumption, producer plus consumer stocks represented about a 0.7-month supply. *(See table 14.)*

Prices

Chromite ore price information indicated a price decline in 1993. Published prices indicated a decrease for South African chemical-, foundry-, and refractory-grade ore while Philippine ore remained steady, as reported by Industrial Minerals. U.S. minimum, maximum, and weighted average chromite ore import unit values declined. The price of South African and Turkish chromite ore remained steady, as reported by Metals Week. Import unit values are from import quantity and value data collected by the Department of the Treasury, distributed by the Department of Commerce, and edited and published by the Department of the Interior, U.S. Bureau of Mines, and represent imports from Philippines, South Africa, and Turkey in 1992 and from Philippines and South Africa in 1993.

The Metals Week price of the Republic of South African Transvaal chromite, 44% Cr_2O_3 (no specific chromium-to-iron ratio), ranged from $50 to $60 per ton, f.o.b. the Republic of South African ports throughout the year.

The Metals Week price of Turkish ore ranged from $105 to $110 per ton, f.o.b. Turkish ports throughout the year.

Domestic ferrochromium prices remained steady throughout the year. The published price of domestic high-carbon ferrochromium (50% to 55% chromium) remained unchanged at 52 cents per pound of chromium content (¢/lb-Cr) throughout the year. The published price of domestic low-carbon [0.05% and 0.015% (Simplex) carbon] ferrochromium remained unchanged at 166 ¢/lb-Cr throughout the year.

The published price of electrolytic chromium metal remained at 370 ¢/lb throughout the year. The price of elchrome-grade electrolytic chromium metal remained at 450.0 ¢/lb. (Elchrome is a vacuum degassed chromium metal product produced by Elkem Metals Co.)

The published price of imported high-carbon (50% to 55% and 60% to 65% chromium) ferrochromium varied throughout the year. The published price of 50% to 55% high-carbon ferrochromium started at a range of from 36 to 39 ¢/lb-Cr and ended the year at 35.5 to 38 ¢/lb-Cr. The published price of imported 60% to 65% high-carbon ferrochromium started the year at a range of 33.5 to 34.5 ¢/lb-Cr and ended the year at 35 to 36 ¢/lb-Cr. The published price of imported low-carbon (0.05% carbon) ferrochromium varied throughout the year from a range of from 71.5 to 74 ¢/lb-Cr to a range of from 71 to 73 ¢/lb-Cr. *(See table 15 and figures 5 and 6.)*

Foreign Trade

Chromium material exports from and imports to the United States included chromite ore and chromium metal, ferroalloys, chemicals, and pigments. *(See tables 16 through 20.)*

World Review

Industry Structure.—The chromium industry is composed primarily of chromite ore producers, ferrochromium producers, and stainless steel producers. Other industry components are chromium chemical and chromite refractory producers. Brazil, Finland, India, Japan, Turkey, the Republic of South Africa, and Russia are countries that mine chromite ore, produce ferrochromium, and produce stainless steel. In Finland, Outokumpu Oy, a major share of which is state-owned, owns and operates the only chromite mining, ferrochromium production, and stainless steel production facilities, making it completely vertically integrated. In the Republic of South Africa, chromium-related companies are privately owned. Typically, major shares of a company are owned by other companies and the remainder, if any, is openly traded. Samancor owns and operates chromite mining, ferrochromium production, and the only stainless steel production facilities. In Brazil, the mining and smelting of chromium is vertically integrated, but stainless steel production is independent of the mining-smelting operations. The major mining companies are subsidiaries of Cia. de Ferro Ligas da Bahia S.A. Stainless steel is produced primarily by Companhia Acos Especiais Itabira. Other chromite operations in Brazil are also vertically integrated. Bayer AG (Germany) owns a chromite mine and chromium chemical plant. Refractory chromite operations also are vertically integrated from chromite production through refractory material production. Chromite mining and ferrochromium production in India is mostly vertically integrated. Ferro Alloys Corp. is the only stainless steel producer in India that is integrated from chromite ore mining through ferrochromium and stainless steel production. In Japan and Russia, chromite ore production is minor. In Japan, some ferrochromium producers are associated with stainless steel plants by location, ownership, or both. In Russia, production facilities are Government owned. In Kazakhstan, chromite ore mining and ferrochromium production is vertically integrated. In Turkey, the chromium industry is composed of both large and small chromite ore producers, with one major producer, Etibank, integrated from mining through ferrochromium production. The chromium industry of Zimbabwe is composed of large companies vertically integrated from chromite mine production through ferrochromium production, small independent chromite mines, and chromite mines operated independently on behalf of the large vertically integrated companies.

Capacity.—Rated capacity is defined as the maximum quantity of product that can be produced in a period of time at a normally sustainable long-term operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure. Because not all countries or producers make production capacity information available, historical chromium trade data have been used to estimate production capacity. Rated production capacity changes result both from changes in facilities and changes in knowledge about facilities. Capacities have been rated for the chromite ore, ferrochromium, chromium chemical, and chromium metal industries. *(See table 21.)*

Reserves.—The United States has no chromite ore reserves. However, the United States has a reserve base and resources that could be exploited. (For further information on domestic reserves, reserve base, and resources, see Geology-Resources section of this report.) *(See table 21.)*

Production.—World chromite ore production in 1993 was estimated at about 10.0 million tons, a 10% reduction from that of 1992. World ferrochromium production in 1993 was estimated at about 3.1 million tons, a 9% reduction from that of 1992. *(See tables 22 and 23.)*

Albania.—**National Developments.**—Albchrome, a semiautonomous organization responsible for chromite mining and ferrochromium production industry, was established in 1992 for the purpose of encouraging private investment in the country's chromium industry. The chromium industry was previously under the control of the Chrome Bureau under the Ministry of Industry, Mines and Energy. Albchrome was formed in preparation for the privatization of the Albanian chromium industry. With the assistance of the European Bank for Reconstruction and Development, Albania invited, received, and negotiated proposals from prospective investors. Albania sought an 8-year development program to build upon its current chromium industry, including chromite mining and ferrochromium production with an emphasis on increasing domestic ferrochromium production. Basic infrastructure, including access roads, electrical power lines, and water pipelines, are in place and there is excess electrical power supply. Several problems were identified by Albchrome. Included among them were the following: (1) The cooperatives, including the mining cooperatives, were used for social control with political and criminal elements assigned to some chromite mines as forced labor. (2) Inadequate historical investment has resulted in antiquated inefficient operations. Only a small portion of chromium industry income was reinvested in the chromium industry, a condition characteristic of the mining industry in general. (3) As a result of the country having been run by decree, the legal system was ambiguous and did not recognize and spell out the rights of private ownership. (4) The national Government did not appear to have decided the degree to which private entities will be granted autonomous control.

Chromite Ore.—Chromite ore production was reported to have been about 316,000 tons in 1989 and 38,300 tons in 1992 at an average grade of 44% Cr_2O_3.

Ferrochromium.—Albania also operated two ferrochromium plants, one at Burrel and one at Elbasan. Each plant had three 9 megavolt-ampere furnaces of Korean construction; however, owing to a lack of spare parts, only three of the furnaces were operational. The Burrel ferrochromium plant was commissioned in 1979 with two furnaces; a third was added in 1987. Nameplate capacity of the three furnaces was in the range of 40,000 to 60,000 tons of ferrochromium per year. The Elbasan plant started ferrochromium production in 1988 with three furnaces. Production was reported to have been 22,000 tons of high-carbon ferrochromium in 1992 and projected to reach 35,000 tons in 1993 from two furnaces at Burrel and one at Elbasan. Albania planned to increase ferrochromium production capacity up to 120,000 to 200,000 tons per year during the next 8 years through private investment.

Australia.—Dragon Mining NL continued development of its Range Well lateritic chromiferous deposit in Western Australia. Dragon planned to truck chromite ore from the mine to the port city of Geraldton where it would be smelted in a 12-megawatt electric arc furnace to produce a 10% to 12% iron-chromium alloy that would then be cast for use as a high-chromium grinding medium. Dragon planned to mine about 50,000 tons per year of lateritic chromite ore from a surface resource of about 31 million tons. Dragon was having Commonwealth Steel perform the semicommercial-scale smelting and casting tests.

Brazil.—**National Developments.**—Brazil imposed a 13.6% duty on imports of high-carbon ferrochromium from South Africa effective in February for a duration of 5 years. The duty resulted from a dumping complaint filed in 1991. Companhia de Ferro-Ligas da Bahia S.A. requested the Government to review the duty, arguing that it should be increased owing to economic changes since the request was made in 1991. Brazil imposed a provisional 18.97% duty on imports of low-carbon ferrochromium from the C.I.S. effective in September for a duration of 120 days. The duty was based on a request by Associação Brasileira Dos Produtores De Ferroligas (ABRAFE) made in September 1992.

Chromite Ore and Ferrochromium.—ABRAFE identified two ferrochromium producers in 1992—Companhia de Ferro-Ligas da Bahia S.A. and Companhia de Paulista Ferro-Ligas—with capacity in December 1992 rated at 120,000 tons of high-carbon ferrochromium from five furnaces rated together at 96.5 megawatts; 10,000 tons of ferrochromiumsilicon from one furnace rated at 10 megawatts; and 14,000 tons of low-carbon ferrochromium from two furnaces rated together at 7 megawatts. ABRAFE reported production in 1992 as 85,085 tons of high-carbon ferrochromium, 6,015 tons of low-carbon ferrochromium, and 6,759 tons of ferrochromiumsilicon from 248,113 tons of chromite ore; exports as 23,915 tons of high-carbon ferrochromium and 400 tons of ferrochromiumsilicon; and imports as 5,155 tons of high-carbon ferrochromium and 3,536 tons of low-carbon ferrochromium.[14] The Departamento Nacional da Produção Mineral reported chromite ore and concentrate production in 1992 as 460,044 tons graded at 43% Cr_2O_3.[15] Brazilian chromium apparent consumption was about 174,000 tons of contained chromium in 1993.

The chemical and textural characteristics of the chromitite found along the Jacobina fault of the Campo Formoso ultramafic complex located in Bahia State were found to have characteristics peculiar to podiform- and stratiform-type deposits. The chromite deposit of the Campo Formoso district was subdivided into seven levels ranging in width from 1/2 to 8 meters and to have a chromite chemistry of 45% to 56% Cr_2O_3 by weight.[16]

Bulgaria.—The Dobromvitsi chromite deposits were reported in southern Bulgaria near the border of Greece and near the border between the Plovdiv and Khaskovo oblast boundaries. There was insufficient information to indicate the current status of chromite resources.

Canada.—**National Developments.**—The Hall and Hall extension chromite ore bodies were studied. These ore bodies are 5 kilometers south of Thetford Mines, Coleraine Township, Quebec. The deposit was found to be composed of dunitic rock hosting chromitite. The chromitite was found to show three textures; massive, antinodular, and chain.[17]

Ferrochromium.—The Provincial government of Manitoba, in cooperation with Dow Corning Energy Systems Inc., studied the possibility of master alloy containing chromium and nickel being produced for the stainless steel industry. Dow started to study the possibility of converting its silicon furnace at Selkirk, Manitoba, to nickel-chromium master alloy production.

Ressources Minières Coleraine Inc. planned a high-carbon ferrochromium plant in Quebec with a production capacity of about 23,000 tons per year. Coleraine sought to raise $C40 million to finance the project, including construction through the first 6 months of operation.

China.—**National Developments.**—China had a 40% export tax on ferrochromium. Tax exempt economic zones were established in February. China reported trade statistics for 1992 and 1993. Chinese chromium trade has been dynamic. China imported chromite ore as follows: 641,267 tons in 1990, 544,648 tons in 1991, 901,020 tons in 1992, and an estimated 620,000 tons in 1993. The dramatic increase in Chinese imports of chromite ore reportedly resulted from the conversion of ferroalloy production capacity to ferrochromium partly for foreign sale. China exported ferrochromium as follows: 11,463 tons in 1990, 29,767 tons in 1991, 60,543 tons in 1992, and an estimated 130,000 tons in 1993. China imported 964 tons of ferrochromium in 1992. In addition to chromium ferroalloys, China also produces chromium chemicals, chromium metal, and stainless steel. Chinese stainless steel production was estimated to have been about 450,000 tons in 1993 accounting for about 226,000 tons of domestic ferrochromium consumption.

Chromite Ore.—Chromite ore deposits in China were reviewed. Chromite deposits in China were characterized as being of podiform, stratiform, or sedimentary type. The Dadao deposit in the Qilian-Qinling ophiolite belt was identified as the largest exploited stratiform deposit.[18]

Ferrochromium.—China shifted ferroalloy production capacity to ferrochromium production, resulting in a greater role for China in chromite ore and ferrochromium markets starting in 1991 and continuing into 1992 and 1993. Ferrochromium producers in China were reported to have been: Xibei, Gansu Province; Hanzhong, Shanxi Province; Jilin, Jilin Province; Liaoyang and Jinzhou, Liaoning Province; Nanjing, Jiangsu Province; Shanghai, Shanghai Municipality; Hengshan, Zhejiang Province; Minfu, Fujian Province; Lianyuan, Hunan, and Xiangtan, Hunan Province; and Fuling, Chongqing, and Emei, Sichuan Province.

Commonwealth of Independent States.—It was reported that since the major chromite ore deposits in the Ural mountain range were discovered in 1937, chromite exploration was limited to that region. The major, exploited deposits are the Donskie deposit in the Kempirasi massif in the southern part of the Ural mountain range (Kazakhstan) and the Saranovskoye deposit in the middle part of the Ural mountain range (Russia). A third, as yet unexploited chromite deposit was recently found (reported in 1986) in the Burqakovskij massif, northern region of Karelia (Russia).[19]

Croatia.—Dalmacija Dugi Rat operated a high-carbon ferrochromium smelter. Dalmacija closed one furnace in December 1992 owing to insufficient power supply. The remaining furnace was closed in February for the same reason. Dalmacija did not restart production until November because the area experienced its worst drought in more than 100 years, causing short supply of hydroelectric power.

Egypt.—The mineralogy and geochemistry of chromite resources from the Abu Dahr and El Galala areas of the Eastern Desert were studied. The chromite was found to occur as lenses with grades ranging from 7.55% Cr_2O_3 to 51.9% Cr_2O_3.[20]

Ethiopia.—Podiform chromitites from Kenticha Hill, southern Ethiopia, were studied. The deposit was found to be of Precambrian age and to contain chromite grading in excess of 58% Cr_2O_3. The mineralogy, mineral chemistry, and platinum-group element distribution were found to establish the podiform or layered affinity of these chromitites and, possibility, their geodynamic environment.[21]

European Community.—The European Community imposed an antidumping penalty duty on low-carbon (i.e., 0.05% or less carbon) ferrochromium imported from Kazakhstan, Russia, or Ukraine. The duty was provisionally imposed in April at the rate of about $0.23 per pound of contained chromium. However, the final duty was introduced in October at the rate of about $0.26 per pound of contained chromium. The European Community planned to impose packaging legislation to limit the chromium content of chromium to 100 parts per million. Sociopolitical changes in Eastern Europe in the early 1990's were found to have a profound impact on the minerals industries of that region, which, in turn, will impact the European Community.[22]

Finland.—The chromium industry of Finland is vertically integrated from chromite ore mining through stainless steel production under Outokumpu Steel Oy. The Kemi chromite deposit was discovered in 1959 followed by a decision to mine in 1964 and industrial scale production in 1968. It is 7 kilometers northeast of Kemi city. Reserves reportedly are about 150 million tons of 26% Cr_2O_3 average grade. The ferrochromium plant started production in 1968 with an annual production capacity of 30,000 tons of ferrochromium. Periodic upgrades, including the addition of a new pelletizing plant in 1989, boosted production capacity to its current annual level of 230,000 tons of high-carbon ferrochromium graded at 52% chromium and 6% to 8% carbon. Commercial stainless steel production began in 1976 with a planned annual production capacity of 50,000 tons of stainless steel. Today, molten ferrochromium is transported by train to the stainless steel works. The stainless steel plant capacity is about 250,000 tons of cold-rolled stainless steel and 100,000 tons of hot-rolled products.[23] Reorganization of the world chromium industry reportedly impacted Finland's chromium industry. Finland produces chromite ore and ferrochromium for world markets in addition to consuming much of its own production. Previously, before anti-Apartheid sanctions were lifted and the former U.S.S.R. began reorganizing its economy, Sweden was a secure market for Finnish ferrochromium. As a result of the fact that Sweden is now free to import South African ferrochromium and the C.I.S. ferrochromium producers have entered the European market, Finland planned to enter the North American market to maintain its exports.

France.—MG France, a wholly owned French subsidiary of Metallgesellschaft (Germany), purchased Chromeurope and converted it into a stainless steel dust recycling plant. MG France planned to process about 40,000 tons of stainless steel dust per year in one of Chromeurope's two furnaces to produce 7,200 tons per year of chromium-containing alloy for steel industry use.

Greece.—Hellenic Ferroalloys SA (HFA) closed in June 1991 and, under Government administration, was offered for sale. The Government planned to sell Hellenic Ferroalloys, which includes the ferrochromium smelter at Tsingeli and mines at Vourinos and Skoumisa in Macedonia. The smelter produced high-carbon ferrochromium graded at 52% chromium with annual production capacity of about 50,000 tons from one 27-megavolt-ampere furnace built in 1984 by Krupp (Germany). The Vourinos Mine produced chromite ore with a run-of-mine annual production capacity of 100,000 tons and a concentrator with an annual production capacity of 50,000 tons. The Skoumisa Mine produced chromite ore with a run-of-mine annual production capacity of 180,000 tons and a concentrator with an annual production capacity of 80,000 tons.

The results of drilling for chromite in the Voidolakkos ore district of the Vourinos ophiolite complex were reported. There are about 780 chromite occurrences in the Vourinos complex. The largest deposit in the complex is contained in the Xerolivado dunite with reported potential resources of 6 million tons of 22% modal Cr_2O_3.[24]

Greenland.—Chromite mineralization is found in a layered and folded anorthosite complex in the Archaean belt that covers about 650 kilometers along the southwest coast of Greenland. Chromite horizons are distributed over an area of about 3,200 square kilometers. Reported resource estimates include 2.5 million tons of 32.7% Cr_2O_3 at one location and a more spread out 100 million tons of lower grade mineralization.

India.—National Developments.—The Indian Government opened its chromite mining industry to private and foreign investment of up to 50% ownership.

Chromite.—India reported total chromite ore geological resources of 182 million tons, 96% of which was in Cuttack district of Orissa State. Reserves were 88.351 million tons (98% in Orissa, 1% in Karnataka, and the remainder in Andhra Pradesh, Bihar, Maharashtra, Manipur, and Tamil Nadu). The major chromite mining companies were Tata Iron and Steel Co. Ltd., Orissa Mining Corp. Ltd., Ferro Alloys Corp. Ltd., and Mysore Minerals Ltd. Chromite production was 926,148 tons in 1988-89, 1,050,406 tons in 1989-90 (average Cr_2O_3 content of 43%), and 916,386 tons in 1990-91. India reported a chromite ore domestic consumption of 395,700 tons in 1987, 427,500 tons in 1988, and 448,100 tons in 1989-90. The distribution of production in 1989-90 was 86% to ferrochromium production, 8% to refractory production, and 6% to chemical production.[25]

Orissa Mining Corp. started production from its new chromite ore beneficiation plant at its Kaliapani Mine, Cuttack district, Orissa State. The plant was planned to consume about 100,000 tons per year of chromite ore graded at 50% Cr_2O_3 to produce about 84,000 tons per year of chromite ore concentrate (62,000 tons of sand and 22,000 tons of fine concentrate) graded at 54% to 55% Cr_2O_3. SiO_2 was to be kept at less than 1%.

Indian Metals and Ferro Alloys sought to increase its chromite ore leases to avoid the necessity of buying ore from its competitors. Holdings were distributed as follows: Tata Iron and Steel Ltd., 69%; Orissa Mining Corp, 21%; and Ferro Alloys Corp., 4%. Indian Metals and Ferroalloys and other companies held the remainder.

The geology, geochemistry, and petrography of chromite mineralization in the mafic-ultramafic complex of the Usgaon, Goa, were reported. Ultramafics host chromite mineralization at Usgaon, Bondla, southwest of Paikul and Ganji areas. Chromite mineralization is mainly observed to be of disseminated, blotchy, or cumulus type forming the "leopard ore"; massive chromitite layers are generally of granular type and occasionally of remobilized, vein type associated with asbestos veinlets. In the Bondla forest area, a major chromite body of 19.5% to 28.5% Cr_2O_3 extends over a length of 1,200 meters with an average width of 200 meters. A bulk sample of float ore from Bondla forest analyzed 21% Cr_2O_3 with a beneficiated concentrate analyzed at 43% Cr_2O_3.[26]

Ferrochromium.—India reported ferrochromium (i.e., ferrochrome plus charge chrome) production of 151,167 tons in 1988-89, 137,301 tons in 1989-90, and 130,465 tons in 1990-91. The major ferrochrome producers were Ferro Alloys Corp. Ltd., Visvesvaraya Iron and Steel Ltd., and Indian Development Corp. The major charge chrome producers were Orissa Mining Corp., Ferro Alloys Corp. Ltd., Indian Metals and Ferro-alloys, and Indian Charge Chrome Ltd. with a combined annual capacity of 145,000 tons. India reported 1989-90 ferrochrome consumption of 15,500 tons, 89% of which went into alloy steel.[27]

Indian Metals and Ferro Alloys Corp. Ltd. operated two ferrochromium plants, Indian Charge Chrome Ltd. (ICCL) at Choudhar and Indian Metals and Ferro Alloys (IMFA) at Therubali. ICCL operated one 48-megavolt-ampere furnace with an annual charge-grade high-carbon ferrochromium production capacity of 60,000 tons and a captive 108 megawatt, coal-fired powerplant. The captive powerplant supplied both plants.

Chemicals.—Narco Chemicals Ltd. planned to manufacture sodium dichromate, basic chrome sulfate, and sodium sulfate at the Fatuha Industrial Area of Bihar. Production was to have started in June with an annual production capacity of 875 tons of sodium dichromate, 3,500 tons of basic chromium sulfate, and 2,100 tons of sodium sulfate. The chemicals were to supply the leather tanning industry.

Iran.—Iran signed a bilateral agreement with China to co-operate in establishing ferrochromium production.

Italy.—Britton Commerce and Merchandise, a company based in Dublin, Ireland, and representing Saudi Arabian interests, purchased Ferroleghe SpA. Ferroleghe had an annual production capacity of about 45,000 tons of high-carbon ferrochromium. Britton planned to invest $7 million to renovate the existing furnaces and add one furnace to attain an annual production capacity of about 80,000 tons in 1994.

Japan.—Japan operated a two-part stockpiling program, Government and private. Japan's long-term goal was to acquire a stockpile of chromium materials adequate to serve the needs of Japanese industry for 60 days. Japan planned to have the Government finance and stockpile 70% of the material, the private sector the remaining 30%, and the 60 day-supply target to be reached in 1995. Metal Mining Agency of Japan, under the supervision of the Ministry of International Trade and Industry, operated the Government stockpile, while Japan Rare Metals Stockpiling Association operated the private stockpile. In fiscal year 1992 (April 1992-March 1993), Metal Mining Agency of Japan acquired 5,145 tons of ferrochromium. As of March 1993, the Government stockpile reached the equivalent of 32.7 days of chromium supply while the private stockpile reached the equivalent of 14 days of chromium supply. In fiscal year 1993, Metal Mining Agency of Japan acquired 4,484 tons of ferrochromium and Japan Rare Metals Stockpiling Association acquired 1,939 tons of ferrochromium. Japan planned to continue its stockpiling program despite the dissolution of the former U.S.S.R. in 1990 because its stockpile is intended to serve as both a strategic and economic purpose. Stockpile planners anticipated growth in stainless steel demand that would result in demand growth for stockpiled chromium materials and noted that new investments in production facilities have not been made for a long time, resulting in the potential for tight supply.

Japan imported 601,629 tons of chromite ore, 548,581 tons of ferrochromium, 1,468 tons of chromium metal, and 203,344 tons of stainless steel scrap. Japan's ferroalloy industry produced about 224,963 tons of ferrochromium, a decline of 25% compared with that of 1992. (Japan's annual ferrochromium production has ranged from about 225,000 tons to 360,000 tons in the 1980-93 time period with the lower limit set in 1993.) Japan reported a hot-rolled stainless steel production of 2,649,127 tons in 1992, an increase of 0.1% compared to that of 1992. Japan exported 1,277 tons of ferrochromium and 896,393 tons of stainless steel. Ferrochromium imports represented 71% of market share (up 11% over those of 1992) while stainless steel exports represented 33.8% of production. Japan's ferrochromium industry lost its market share in 1993. This was attributed to lower ferrochromium prices (down 20% based on unit value of imports) and a 13% yen value rise. Ferrochromium consumers reportedly were shifting their strategy from buying 10% to 15% of their demand on the spot market to buying about 50% of their demand on the spot market to take advantage of currently low spot market prices. Based on chromite ore, ferrochromium, and chromium metal trade, chromium apparent consumption in Japan was about 483,000 tons contained chromium in 1993.

Tosoh Corp. planned to cease production of chromic acid and electrolytic chromium metal at its Yamagata City, Yamagata Prefecture plant. Chromic acid anhydride production stopped in October, and chromium metal production was planned to cease by 1995. Tosoh's chromium metal annual production capacity was about 3,600 tons; its production in 1992 was about 2,800 tons. Tosoh closed its plant as part of Yamagata City's urban development program. Tosoh and Samancor (South Africa) studied the feasibility of establishing a chromium metal plant in South Africa. The planned plant development was abandoned owing to weak market conditions.

Nippon Denko, a ferrochromium producer, made a joint-venture agreement with Samancor (South African chromite ore and ferrochromium producer). (See South Africa in this section.) Japan Metals and Chemicals' Kyushu works relined and repaired its rotary kiln over a 2-month period. Japan Metals and

Chemicals' Oguni works planned to close its ferrochromiumsilicon furnace, electing to use imported ferrochromiumsilicon instead for its low-carbon ferrochromium. Nippon Steel, a stainless steel producer, studied the possibility of a joint-venture agreement with Anglo American (South African chromite ore and ferrochromium producer). Nippon Denko is a coowner of Integrated Charge Chrome (Philippines).

Nippon Steel Corp. planned a joint venture with Consolidated Metallurgical Industries (South Africa) to develop a chromite ore mine in South Africa. (See South Africa in this section.)

Kazakhstan.—**National Developments.**—Chromium-related activity centered around reorganization of the industry as a result of national economic and political reorganization. The Kazakhstan chromium industry moved from state control of the chromite ore mining and two ferrochromium plants in 1990 to semi-independent operations in 1991. As a result of that change and the subsequent entrance of Kazakhstani chromium producers into the world market, Kazakhstan is developing its new organization and the role it will play relative to its old and new trading partners. Kazakhstani ferrochromium producers have been assessed import duties for dumping in Brazil, Europe, and the United States. The necessity for the Kazakhstani chromium industry to respond to foreign litigation resulted in the formation of the International Chrome Committee of Kazakhstan. Internally, the Kazakhstan chromium industry and politicians debated the export of chromite ore, especially to China and Russia, two countries that compete with Kazakhstani ferrochromium, a downstream chromium industrial product. There was reported disparity between Kazakhstan and Russia in chromite ore pricing with domestic ferrochromium producers getting the lowest prices. Russian chromite ore consumers reportedly built up large debts. The situation is complicated by the fact that Kazakhstani ferrochromium producers are dependent on Russian electrical power. The Kazakhstani and Russian chromium industry companies briefly organized under the name Kazrochrom. Efforts to organize the Kazakhstani chromium industry were started by the industry itself and by the Government. No solution to issues of pricing, payment schedules, competitive products, and reinvestment have evolved yet. The Government instituted an export tax on ferrochromium only to withdraw it later in the year. The Government organized the chromium industry into holding companies with Donskoy and Aktubinsk in one company (Kramds) and Yermakovsky in another. The Government planned to develop a vertically integrated chromium industry from chromite ore mining through ferrochromium production to stainless steel production through Kramds.

Chromite Ore.—Donskoy Ore Dressing Complex mines and beneficiates chromite ore, annually producing about 3.5 million tons and exporting about one-third of production. Mining was primarily from the 40th Anniversary of Kazakhstan Soviet Socialist Republic open pit and the Molodiozhnaya underground mines with capacities of 1.8 million tons (ore grade of 47% to 49% Cr_2O_3) and 2 million tons (ore grade of about 44.9% Cr_2O_3), respectively. The Tsentralnaya Mine was under development. The Tsentralnaya Mine was planned to come into production in the year 2000 whereupon annual production capacity would increase to 4 million tons. Run-of-mine chromite ore was processed in one of two chromite ore beneficiation plants operated at the mine site. To upgrade marketable product, the Donskoy was constructing a briquetting plant of 200,000-ton-per-year capacity for commissioning in 1994 and a pelletizing plant of 700,000-ton-per-year capacity for commissioning in 1995.[28]

Ferrochromium.—Aktubinsk Ferroalloy Plant put in pollution control equipment to control effluent discharged into the Ilek River. Aktubinsk produced about 120,000 tons of ferrochromium in 1992 from an annual ferrochromium production capacity of 300,000 to 340,000 tons. Aktubinsk, in cooperation with Donskoy Mining Complex, planned to build a 125-megawatt electrical powerplant fueled by Kazakhstani natural gas at a cost of about $88 million.

Yermakovsky Ferroalloy Plant planned to convert six furnaces to ferrochromium production. Yermakovsky was building a briquetting plant with an annual capacity of 200,000 tons to improve production. It also planned a slag beneficiation program with the capacity to process 600,000 tons per year of slag and to put in a baghouse for dust collection.

Korea, Republic of.—Korea implemented a tariff change on ferrochromium imports. Under the new system, the tariff on the first 50,000 tons of ferrochromium is 2.5% ad valorem; after 50,000 tons, 5% ad valorem. Korea planned to increase its stainless steel production capacity to about 120,000 tons by 1996. Korea reported consumption of more than 110,000 tons of ferrochromium in 1992.

Madagascar.—Kraomita Malagasy operated mined chromite ore. It reported that in 1992 chromite ore production was 157,000 tons, export was 109,000 tons, and in 1993 production was 145,000 tons, and export was 119,000 tons. Thus despite significant typhoon-caused damage to rail and road systems, Kraomita increased its production and shipments.

Mexico.—Cia. Minera Autlan SA de CV was privatized when it was sold to Grupo Ferrominero, a consortium of Mexican companies, for $23 million. Autlan has produced ferrochromium but is not currently doing so. Autlan operates two plants, one at Tamos and one at Teziutlant. Quimica Central reportedly suspended sodium bichromate production.

Oman.—Oman reported 2 million tons of chromite ore reserves distributed over more than 450 sites. The Oman Chromite Co. operated southwest of Sohar in the area of Far Far and Simera.

Small producers operated near Rajmi. Because most deposits are small, the Government of Oman encouraged native Omani tribes to mine them.

Philippines.—**National Developments.**—National Power Corp., the national electrical energy supplier on Mindanao Island proposed a 40% price increase in electricity for major electrical energy consumers. The price increase was to be implemented in 1994.

Chromite Ore.—Chromite ore production is centered on Luzon Island where Benguet Corp mines refractory-grade chromite from the Coto Mine.

Ferrochromium.—Ferrochromium producers on Mindanao Island were closed for part of the year owing to lack of electrical power owing to low water levels.

Romania.—Ferom-Joint Stock Co., a Government-owned ferroalloy company, produced low-carbon and high-carbon ferrochromium. Ferom operated a 33-megavolt-ampere furnace with an annual production capacity of 52,000 tons of high-carbon ferrochromium and a 3.5-megavolt-ampere refining furnace to produce low-carbon ferrochromium from high-carbon, with an annual capacity of 9,600 tons. Ferom installed a dust collection system. It also requested the Government limit imports from the C.I.S. to protect its domestic market.

Russia.—**Ferrochromium.**—Chelyabinsk Electrometallurgical Works reported production of about 210,000 tons of ferrochromium, of which 168,000 tons was low-carbon and 42,000 tons was high-carbon. As a result of antidumping cases against C.I.S. ferrochromium in Europe, Chelyabinsk contracted with Mannesman Demag (Germany) to convert low-carbon ferrochromium production capacity to high-carbon ferrochromium at a cost of $4 to $5 million.

Serovsk reported annual marketable product production capacity at 80,000 tons of high-carbon ferrochromium, 150,000 tons of medium- and low-carbon ferrochromium, and 40,000 tons of ferrochromiumsilicon. Serovsk produced 228,000 tons of ferrochromium, of which 148,000 tons was low-carbon and 80,000 tons was high-carbon. Serovsk used chromite ore from Russia and Kazakhstan. To produce high-carbon ferrochromium, Serovsk required lump ore from Kazakhstan to mix with Russian fines. To reduce dependence on Kazakhstan lump ore, Serovsk planned to put in a briquetting plant with production capacity of 300,000 tons per year. Serovsk produced low-carbon ferrochromium from nine furnaces, ferrochromiumsilicon from five furnaces, and high-carbon ferrochromium from four furnaces.

Chromium Metal.—Polema, Tula Chermet Complex, Tula City, reported electrolytic chromium metal production with an annual production capacity of about 1,000 tons.

Slovakia.—Ovarske Ferozria Inarske Zavody, Istebne City, produced high-carbon ferrochromium with an annual production capacity of about 45,000 tons graded at 62% to 70% chromium.

Slovenia.—Tovarna Dušika Ruše produced high-carbon ferrochromium at about 60% of capacity in 1993. Tovarna stops ferrochromium production from December through March when electrical energy cost is highest.

South Africa, Republic of.—South African economic policy is one of vertical integration of industries that are based on its domestic mineral assets. To this end, the chromium industry of South Africa has moved from being a major world chromite ore supplier to being the major supplier of chromite ore and ferrochromium to Western markets. South Africa planned to increase stainless steel annual production capacity to 526,000 tons in 1995, most of which was destined for export.

Chromium production capacity utilization in South Africa was low in 1993. The high price of ferrochromium in 1988-89 that resulted from demand by stainless steel producers in excess of capacity put capital in the ferrochromium producers' hands and stimulated investment in new ferrochromium plants and equipment. In 1990, existing ferrochromium producers increased their production capacity by acquiring smaller producers or by expanding their production facilities. At this time, CMI added a furnace and acquired Purity Ferrochrome, a new producer; Samancor added furnaces at its Tubatse smelter; MS&A started construction of a new ferrochromium production facility using a new production process (kiln furnace prereduction followed by electric furnace smelting) at Middelburg and increased the transformer capacity of its DC transferred plasma arc furnace at Krugersdorp; and Chromecorp Technology added a furnace. (Feralloys made no changes.) In 1991, Samancor bought MS&A.

During and following the introduction of this new ferrochromium production capacity in South Africa and other capacity around the world, Western stainless steel production continued to grow steadily. However, because ferrochromium production capacity was added faster than stainless steel demand growth, the world ferrochromium market moved into a state of excess supply and prices declined. In addition, actions in the former U.S.S.R. and China exacerbated the situation. The collapse of the U.S.S.R. followed by the integration of C.I.S. with Western economies, a process that may continue for years to come, changed the chromium markets. Economic recession in the East (i.e., former U.S.S.R.) resulted in declining chromium demand in Eastern markets and the entry of Eastern raw materials suppliers into Western markets adding to chromium excess supply and downward pressure on prices. China, seeing an opportunity to increase ferroalloy sales, shifted some of its production capacity to ferrochromium. China has been increasing (about doubling annually) its ferrochromium exports since 1990. China's significant ferrochromium exports in 1992-93 added to excess supply. (See Kazakhstan and China in this section.)

With an annual ferrochromium production capacity of about 1.6 million tons (gross weight) per year, nearly one-third of world ferrochromium production capacity, South Africa is greatly impacted by these changes. Ferrochromium accounts for nearly one-half of South African ferroalloy export earnings, and ferroalloys are about the third largest export earner following gold and coal and about equal to that of platinum-group metal export earnings. South Africa has lost chromium market share because of changing market conditions resulting in low-capacity utilization. South African chromium producers carried out major company restructuring, including closing mines, shutting down furnaces, reducing production rates, and reducing personnel to accommodate changing world market conditions. The South African chromium industry thus bore the major share of the integration of the chromium industry of the former U.S.S.R. into the world economy.

By yearend 1993, South African ferrochromium producers ranked by production capacity as follows: Samancor, 1,000 kt/yr (thousand metric tons, gross weight, per year); CMI, 320 kt/yr; CCT, 200 kt/yr; and Feralloys, 100 kt/yr. Samancor's annual chromite ore production capacity was about 4,000 kt/yr or nearly one-third of world annual production. Hernic's annual chromite ore production capacity was about 300,000 tons.

South Africa's Minerals Bureau reported 1992 South African (including Bophuthatswana) chromite ore production at 3,363,000 tons, a decrease of 34% over that of 1991. Reported 1992 chromite ore sales were domestic, 2,039,000 (down 46% over that of 1991), and foreign, 1,087,000 tons (up 8% over that of 1991). Reported 1992 chromium ferroalloy production was 664,900 tons, a decrease of 41% over that of 1991. Reported 1992 chromium ferroalloy sales were domestic, 39,900 tons (down 43% over that of 1991), and foreign, 663,700 tons (down 31% over that of 1991).[29]

Chromite Ore.—The chromite ore industry suffered work force reductions and reduced production. In 1992, the South African chromite mining industry work force was reduced about 2,800 persons (34% of 1991 work force). Additional work force reductions were announced in 1993.[30]

Consolidated Metallurgical Industries (CMI), Nippon Steel Corp. (Japan) (NSC), and Mitsui and Co. (Japan) studied the feasibility of starting a new chromite mining operation at Thorncliff, Transvaal. CMI planned an operation with annual marketable production capacity of 600,000 tons, primarily to feed its smelter but also for export. CMI would increase its vertical integration through such a mine development, and NSC would gain access to secure ore supply for its domestic ferrochromium suppliers. NSC elected to not pursue the project when its ferrochromium suppliers pursued alternative strategies. In particular, Nippon Denko supplemented its production through a joint venture with Samancor; Japan Metals and Chemicals switched to using Kazakhstani chromite ore; and Pacific Metals shifted from producer to sales agent for South African-, Chinese-, and C.I.S.-produced ferrochromium.

The Chroombronne and Cashan Mines were operated by Chrome Corp. Technology in the western outcrop of the Bushveld Complex. Chroombronne Mine started production in 1979 and currently has a run-of-mine chromite ore production capacity of about 1.2 million tons per year with reserves of about 36 million tons. Ore is crushed and sized and fines are beneficiated by spirals. Cashan Mine has a production capacity of about 320,000 tons per year.

Ferrochromium.—Samancor and Nippon Denko (Japan) made a joint-venture agreement under the name NST Ferrochrome Pty. Ltd. wherein Nippon Denko purchased interest in production from one furnace at Samancor's Tubatse smelter. The furnace has a transformer capacity of 37 megavolt-amperes and high-carbon ferrochromium annual production capacity of 60,000 tons. Through this agreement, Samancor gains a more secure consumer market and Nippon Denko can use this capacity to displace its more expensive domestic capacity.

CMI produced ferrochromium at near 50% of capacity owing to weak market conditions. CMI tried to control cost and increase productivity at its Lydenburg and Rustenburg plants. CMI reported that the weakening rand exchange rate provided some financial relief.

Feralloys, a subsidiary of Associated Manganese Mines of South Africa that produces low-carbon ferrochromium, reported operating at only 35% of annual capacity.[31]

Chromecorp Technology (CCT) operated one ferrochromium plant at Rustenburg with an annual ferrochromium production capacity of about 185,000 tons from three electric furnaces. CCT started operation in 1988 with two furnaces of 30-megavolt-ampere electrical power capacity. A third furnace of 33-megavolt-ampere electrical power capacity was added in 1990. CCT acquired the Chroombronne Mine in 1987 and the Cashan Mine in 1992. The mines are about 18 kilometers from the plant. CCT reported consumption of about 3 to 3.2 tons of chromite ore and 4,200 kilowatt-hours per ton of ferrochromium product. CCT can recover about 20,000 tons per year of ferrochromium from slag.[32]

Samancor, South Africa's largest chromite ore and ferrochromium producer, found it necessary to make major reorganizations owing to weak market conditions. Samancor sold a share of Columbus Joint Venture to the parastatal Industrial Development Corp., reducing Samancor to an equal joint partner with Highveld Vanadium and Industrial Development Corp.[33]

Samancor operated five ferrochromium plants: Batlhako, with an annual production capacity of about 20,000 tons; Ferrometals at Witbank, with an annual production capacity of about 300,000 tons; Tubatse at Steelpoort, with an annual production capacity of about 300,000 tons; Middelburg plant at Middelburg, with an annual production capacity of about 280,000 tons (including the yet-to-go-into-commercial-production kiln process); and Krugersdorp plant at Krugersdorp, with an annual production capacity of about 100,000 tons. Samancor has a total ferrochromium production capacity of about 1 million tons. Owing to weak demand, Samancor reduced its production in 1993 by closing some furnaces to reach from 40% to 60% of production capacity. Samancor closed all except one of its ferrochromium furnaces in the first half of the year, restarted one furnace at each plant in the second half of the year, and was operating at near 50% of capacity at yearend. Samancor planned to lay off about 2,000 of its 7,000 employees as a result of production cutbacks.

Stainless Steel.—Columbus Joint Venture (CJV) was organized and scheduled for formal recognition as a new company in January 1993. CJV was planned to be co-owned by Highveld Steel & Vanadium, Samancor, and Industrial Development Corp. (a state-owned corporation), each with one-third ownership. CJV planned to develop Southern Cross Stainless from its current annual production capacity of 120,000 tons to 500,000 tons in 1995. CJV reported that all major contracts had been left for the project and that construction was underway as follows: Davy International for the hot and cold mills, Voest Alpine for the steel plant, and Danelli for the slab grinding equipment. The new plant will produce liquid steel from a 100-ton electric furnace, after which the liquid steel will be refined in an Argon-Oxygen-Decarburization vessel before being continuously cast into slabs.[34]

Taiwan.—Taiwan reported ferrochromium production and consumption for 1991. No ferrochromium was produced, compared with 1990 production of 5,952 tons. Ferrochromium consumption was 45,017 tons, up from 1990 consumption of 34,905 tons.

Thailand.—Chromite mineralization was found to occur in strongly serpentinized ultramafic rocks along the Nan-Uttaradit mafic-ultramafic belt. Chromite was found to occur in massive, banded, disseminated, and a few centimeters thick veins in serpentinized-pyroxenite sometimes transformed to amphibolite, lherzolite, and harzburgite. Cr_2O_3 contents were found to range from 50% to 66%.[35]

Turkey.—Etibank, a state-owned company, is Turkey's major chromite ore producer and only ferrochromium producer. The other major chromite ore producers include Hayri Ögelman Madencilik and Bilfer Madencilik AŞ. Etibank operated a low-carbon smelter at Antalya and a high-carbon ferrochromium plant at Elazığ. High-carbon ferrochromium production started at Elazığ in 1977 from two 17-megavolt-ampere furnaces. Production capacity was increased by 100,000 tons per year when two additional 30-megavolt-ampere furnaces were completed in 1989. Chromite ore exports have declined in value from 1991 to 1993 by more than 50%. Chromite ore is one of Turkey's major primary mineral export income sources. Turkish chromite ore exports were effected by the change in status of the former U.S.S.R. previously described. (See South Africa in this section.)

United Kingdom.—Harcros Chemical is the primary chromium chemical producer in the United Kingdom and one of the largest producers worldwide. (Bayer, based in Germany, and Oxychem in the United States are the other major world producers with Chinese and C.I.S. producers also reportedly active in world markets.) Harcros produced under the name British Chrome and Chemicals in the United Kingdom and American Chrome and Chemicals in the United States with an annual sodium bichromate production capacity of 200,000 tons and operated distribution terminals in Canada, the United Kingdom, and the United States. Harcros production capacity was distributed as follows: United Kingdom, 150,000 tons of sodium bichromate per year from two equal-sized kilns; and United States, 50,000 tons of sodium bichromate per year. It was estimated that 40% of Harcros' sodium bichromate goes into leather tanning and that 90% of the leather is tanned with chromium chemicals. Chromic acid used for plating and for wood treatment is the second largest outlet for Harcros' chromium chemicals followed by chromic oxide, which is used for chromium metal or pigment production.

Zimbabwe.—The Government of Zimbabwe granted Midlands Distributors the right to export chromite ore. The Minerals Marketing Corp. (Government owned) also sought to export chromite ore. Government policy has been to export only ferrochromium.

Two ferrochromium producers operated in Zimbabwe—Zimbabwe Mining and Smelting and Zimbabwe Alloys. Zimbabwe Mining and Smelting is a subsidiary of Union Carbide (United States). It produces high-carbon ferrochromium at Kwekwe with an annual capacity of about 178,000 tons from six electric furnaces. Zimbabwe Alloys is a subsidiary of Anglo American (South Africa). It produces low-carbon ferrochromium with an annual capacity of about 22,000 tons and ferrochromium-silicon at Gweru. Both companies experienced reduced demand and increased production costs because of increased electrical power cost in Zimbabwe. The Chamber of Mines sought power rate reduction from the Ministry of Transport and Energy on behalf of the country's ferrochromium producers.

Current Research

Mineral Processing and Industrial Applications.—U.S. Bureau of Mines research provides fundamental scientific and technical information essential for advancing mineral science, processing technology, and conserving and developing domestic mineral resources.

This research is conducted in support of the Strategic and Critical Materials Stock Piling Act of 1946 as amended, the Defense Production Act of 1950 as amended, the Mining and Minerals Policy Act of 1970, and the National Materials and Minerals Policy, Research and Development Act of 1980. Recent research related to chromium the study of chromium-containing corrosion and wear-resistant steels.

The Council for Mineral Technology (Mintek) of the Republic of South Africa conducts Government-sponsored and commercially sponsored and cosponsored research and development on chromite ore and ferrochromium. Recent Mintek research has included chromite beneficiation, agglomeration, smelting, recovery from slag, and stainless steel alloying. Mintek reported development of its Enviroplas process for the recovery of fine chromium-containing dusts resulting from stainless steel production.[36] A historical study of ferritic stainless steels found that their use increased substantially in the 1950-60 time period as a result of automotive demand for trim. Since then, the primary use of ferritic stainless steels for automotive applications has been in automotive exhaust systems.[37]

Environmental.—Environmental concerns about chromium have resulted in a wide variety of studies to determine chemical characteristics, the natural background levels, sources of environmental emissions, movement of chromium in the environment, interaction of chromium with plants and animals, effect of chromium on plants and animals, measurement methods, and recovery technology.

The EPA reported on the potential carcinogenicity of chromium compounds[38] and on the atmospheric release of hexavalent chromium from hard chromium plating operations.[39]

OUTLOOK

On average (from 1983 through 1992), U.S. chromium consumption by end-use industry has been: 87%, metallurgical; 10%, chemical; and 3%, refractory. Stainless steel, by definition, contains at least 11% chromium but may contain up to 36% chromium. Stainless steel production accounts for about 79% of the reported metallurgical chromium consumed in the United States. The remaining 2% of metallurgical industry consumption is for the production of other ferrous and nonferrous alloys. Some of the chemical and refractory products are consumed in the steel production process.[40]

On average internationally, about 79% of chromium is consumed by the metallurgical industry, 13% by the chemical industry, and 8% by the refractory industry. Of the chromium consumed in the metallurgical industry, about 60% is consumed in stainless steel. Thus, stainless steel production accounts for about one-half of the chromium consumed internationally.[41]

The outlook for chromium consumption in the United States and internationally is the same as that for stainless steel. Stainless steel is estimated to be the major end use for chromium worldwide. Thus, stainless steel industry performance determines chromium industry demand worldwide. *(See next section and table 24.)*

The trend to supply chromium in the form of ferrochromium by chromite mining countries is expected to continue. The rate at which new ferrochromium plants come into production is expected to diminish now that all major chromite producers have such facilities. With new, efficient ferrochromium production facilities and excess capacity in chromite-producing countries, both production and capacity are expected to diminish in traditional ferrochromium-producing countries, except where domestic industries are protected by quotas and tariffs. Further upward integration of the chromium industry is expected as chromite-producing countries expand current capacity or develop new stainless steel production capacity.

Since the dissolution of the U.S.S.R. in 1991, the industries of the former U.S.S.R. have been reorganizing and integrating into the rest of the world economy. This process is expected to continue, at different rates for different C.I.S. republics depending on the rate of political, legal, and economic structure within those countries and the conditions of the world economy to accommodate changes. The first impact of this integration has been on the globalized minerals markets. The low cost of chromite ore and ferrochromium from the former U.S.S.R. has resulted in that material displacing former suppliers to Western markets. New stable relationships are expected to develop as cost-based pricing is introduced in former U.S.S.R. countries and as those countries complete the process of legal, political, and economic reform that they have begun. It is anticipated that industrial renovation and unfulfilled consumer demand in the former U.S.S.R. could stimulate recovery in those countries and add to world demand for chromium-containing products.

China is emerging as a potential major factor in the world chromium market. China is primarily a chromium processing and consuming country. Chromite ore production in China is minor. Continued industrial growth in China could result in increased demand for stainless steel because stainless steel use is characteristic of the larger and more technologically developed economies.

Stainless Steel

As pointed out before, chromium demand is driven by stainless steel demand. Stainless steel demand is price sensitive, and an important part of stainless steel cost is nickel cost (about 70% of stainless steel requires nickel). One factor that could affect chromium demand is the availability of inexpensive nickel. Nickel availability is adequate to meet current demand and anticipated stainless steel demand until about 1995, at which time new nickel production capacity may be needed to meet demand. (Projected cost of production from new nickel production capacity could be substantially higher than that of currently available material.)[42] After 1995, possible increasing cost of nickel may result in increased stainless steel cost, which could result in reduced demand for stainless steel. Thus, just when stainless steel demand for chromium is anticipated to come into equilibrium with ferrochromium production capacity, demand may decline, reducing chromium industry growth after 1995.

Several factors could modify this scenario. Nickel supply and stainless steel demand from the previously centrally planned economy countries is uncertain. Reduction in cost of stainless steel, owing to greater production rates, may offset some nickel cost increases. Stainless steel producers could substitute manganese for nickel in some cases, thereby reducing the impact of nickel cost increases. Short-term fluctuations in demand could exceed these longer term average projections.

Chromium Chemicals[43]

Chromium chemical markets were reviewed in 1991. U.S. demand for sodium bichromate was reported to have been 130,200 tons in 1990 and was projected to be 130,800 tons in 1991 and 133,400 tons in 1995. The domestic chromium chemicals market showed -0.7% growth from 1981 through 1990 and was expected to show a positive 1% growth from 1991 through 1995. Reported price in 1991 for sodium bichromate crystals was $0.60 per pound of sodium bichromate dihydrate equivalent content (for pricing purposes, sodium bichromate dihydrate equivalent content of crystals is 100%) and for sodium bichromate liquor was $0.55 per pound of sodium bichromate dihydrate equivalent content (typically the sodium bichromate dihydrate equivalent content of liquor ranges from 69% to 70%). Sodium bichromate was used as follows: chromic acid, 55%; chromium oxide, 10%; leather tanning, 8%; pigments, 7%; wood preservatives, 2%; drilling mud additives, 2%; other uses (including metal finishing, water treatment, textiles, and catalysts), 3%; and export, 13%. Environmental concerns were seen as driving the chromium chemicals markets.

Demand for chromic acid was expected to continue to grow at an annual rate of about 2% to 3% through 1995. Domestic chromic acid producers, American Chrome and Chemicals and Occidental Chemicals, increased their chromic acid production capacity to the current annual rate of 71,000 tons to meet increasing demand. Chromic acid prices were about $1.10 to $1.15 per pound in 400-pound drums. Chromic acid was consumed for the production of wood preservatives, metal finishing, and chromium dioxide. Wood preservation currently accounts for about 70% of chromic acid demand and was expected to increase even though chromium chemicals account for about 70% of the U.S. wood treatment market. Environmental restrictions on the use of creosote (in marine pilings) and pentachlorophenol (in utility poles) are expected to result in greater use of chromic acid for wood preservation. The most widely used chromium-containing wood preservative is chromium copper arsenate (CCA). CCA-treated wood is resistant to decay and termite attack, and wood treated with CCA is easier to paint than wood treated with oil-based formulations. CCA-treated wood thus finds use in roofing, outdoor decks, and house foundations. Metal finishing accounts for about 27% of chromium oxide demand. Metal finishing includes chromium plating, aluminum anodizing, and other metal treatments. No growth was anticipated for metal finishing. The remaining 3% of chromic acid consumption included the production of chromium dioxide, a growth market that included the production of magnetic particles for use in magnetic recording media (audiotapes and videotapes and computer disks).

EPA regulations limiting chromium releases have encouraged recycling of chromium chemicals and the use of substitutes to reduce releases. As a result, demand is expected to be reduced for many end uses.

^{p}Preliminary. ^{r}Revised.

[1] Customs value per ton of chromium contained in imported material.

NOTE.—Constant dollar value is actual value multiplied by gross domestic product (GDP) ratio. GDP ratio is 1987 GDP divided by annual GDP index. GDP ratio calculated as the ratio of GDP indices reported in Economic Report of the President, U.S. Government, Feb. 1992, available from Superintendent of Documents, U.S. Government Printing Office.

[p] Preliminary. [r] Revised. NA Not available.

[1] Customs value per ton of chromium contained in imported material.

[2] Carbon not more than 4%.

[3] More than 4% carbon.

NOTE.—Constant dollar value is actual value multiplied by gross domestic product (GDP) ratio. GDP ratio is 1987 GDP divided by annual GDP index. GDP ratio is calculated as the ratio of GDP indices reported in Economic Report of the President, U.S. Government, Feb. 1992, available from Superintendent of Documents, U.S. Government Printing Office.

TABLE 5
AVAILABILITY OF CHROMITE AND CHROMIUM FERROALLOYS FROM 10 MARKET ECONOMY COUNTRIES

Chromium materials	Quantity available (million metric tons, gross weight)	Cost[1] (dollars per metric ton)	
		Weighted average	Range
Chromite:			
Chemical grade	64.3	53	$35- $174
Foundry sand grade	16.4	49	39- 83
Metallurgical grade:			
Primary product	145.4	101	42- 705
Secondary product	35.6	54	33- 117
Subtotal	181.0	92	33- 705
Refractory grade	26.8	87	54- 180
Total	288.5		
Chromium ferroalloys:			
Ferrochromium:			
High-carbon ferrochromium	74.3	473	417- 1,286
Low-carbon ferrochromium	3.9	937	635- 1,309
Ferrochromium-silicon	2.0	737	578- 814
Total	80.2		

[1] Cost of production for zero percent discounted cash-flow rate of return in Jan. 1989 dollars per metric ton, gross weight, of product f.o.b. at port of export.

[r]Revised. W Withheld to avoid disclosing company proprietary data; included with "Miscellaneous and unspecified."

[1]Low-carbon ferrochromium contains less than 3% carbon.

[2]High-carbon ferrochromium contains 3% or more carbon.

[3]Data may not add to totals shown because of independent rounding.

[4]Includes structural and hard-facing welding material.

[5]Includes cutting materials and magnetic, aluminum, copper, nickel, and other alloys.

[6]Withheld to avoid disclosing company proprietary data; included with "Other."

[7]Includes estimates.

[8]Includes 3,585 tons of chromium metal.

[9]Includes 433 tons of chromium metal.

[10]Includes 3,819 tons of chromium metal.

[11]Includes 438 tons of chromium metal.

[12]Includes 4,120 tons of chromium metal.

[13]Includes 524 tons of chromium metal.

TABLE 14
U.S. CONSUMER STOCKS OF CHROMITE, CHROMIUM FERROALLOYS, AND METAL, DECEMBER 31

(Metric tons, gross weight)

Industry	1989	1990	1991	1992	1993
Chromite:					
Chemical and metallurgical	368,482	333,224	310,111	307,829	259,267
Refractory	23,791	21,437	11,114	13,144	15,489

TABLE 16
U.S. EXPORTS OF CHROMIUM MATERIALS, BY TYPE

Type	1990	1991	1992	1993		Principal destinations, 1993
	Gross weight (metric tons)	Gross weight (metric tons)	Gross weight (metric tons)	Gross weight (metric tons)	Value (thousands)	
Chromite ore and concentrate	6,321	8,759	7,042	10,011	$2,136	Canada (77%); Mexico (21%).
Metal and alloys:						
Chromium metal[1]	338	424	299	472	4,476	Canada (52%); Japan (32%); Venezuela (3%).
Chromium ferroalloys:						
High-carbon ferrochromium[2]	[3]5,795	[4]7,820	[5]8,292	[6]10,071	7,804	Canada (69%); Mexico(28%).
Low-carbon ferrochromium[7]	[8]2,521	[9]2,084	[10]1,860	[11]4,391	5,374	Canada (39%); Mexico (28%); Japan (15%); Netherlands (5%); Venezuela (4%).
Ferrochromium-silicon	[12]802	[13]745	[14]671	[15]800	759	Canada (90%); Mexico (8%).
Total ferroalloys	[16]9,118	[17]10,649	[18]10,823	[19]15,262	13,937	
Chemicals:						
Chromium oxides:						
Chromium trioxide	4,082	3,967	5,269	5,014	9,350	Canada (28%); Japan (12%); Mexico (11%); Republic of Korea (10%); Taiwan (8%); Australia (6%).
Other	1,226	1,500	1,640	2,043	11,464	Canada (37%); Japan (14%); Netherlands (9%).
Chromium sulfates	44	48	6	31	71	Argentina (53%); Mexico (35%); Canada (12%).
Salts of oxometallic or peroxometallic acids:						
Zinc and lead chromate	209	627	477	501	4,303	Canada (59%); Germany (17%); Singapore (11%).
Sodium dichromate	16,663	16,860	15,241	11,743	7,799	Mexico (38%); China (15%); Colombia (9%); Taiwan (6%).
Potassium dichromate	48	42	48	34	88	Canada (75%); Hong Kong (10%); Japan (4%).
Other chromates, dichromates, and peroxochromates	228	193	139	635	1,844	Australia (45%); Canada (24%); United Kingdom (9%); Mexico (8%).
Pigments and preparations	2,643	1,969	2,554	2,312	9,403	Canada (32%); Philippines (17%); Thailand (8%).

[1] Articles thereof and waste and scrap.
[2] More than 4% carbon.
[3] Contained 3,477 tons of chromium.
[4] Contained 4,617 tons of chromium.
[5] Contained 4,907 tons of chromium.
[6] Contained 5,992 tons of chromium.
[7] Not more than 4% carbon.
[8] Contained 1,517 tons of chromium.
[9] Contained 1,263 tons of chromium.
[10] Contained 1,085 tons of chromium.
[11] Contained 2,673 tons of chromium.
[12] Contained 333 tons of chromium.
[13] Contained 261 tons of chromium.
[14] Contained 235 tons of chromium.
[15] Contained 280 tons of chromium.
[16] Contained 5,327 tons of chromium.
[17] Contained 6,141 tons of chromium.
[18] Contained 6,227 tons of chromium.
[19] Contained 8,945 tons of chromium.

Waste and scrap	85	18	192	437	$2,000	China (91%); Canada (4%).
Other than waste and scrap	6,579	5,747	5,259	5,733	35,902	China (39%); United Kingdom (18%); Japan (17%); France (16%).
Ferrochromium-silicon	[1]3,801	[2]5,301	[3]9,379	[4]8,751	6,180	Zimbabwe (88%); China (6%).
CHEMICALS						
Chromium oxides and hydroxides:						
Chromium trioxide	1,677	1,196	390	362	1,284	Japan (47%); Mexico (29%); Germany (6%); Netherlands (4%).
Other	3,512	3,976	3,309	3,094	10,253	Germany (34%); Japan (23%); Kazakhstan (17%); Netherlands (7%).
Sulfates of chromium	192	186	122	162	97	Turkey (75%); Mexico (24%).
Salts of oxometallic or peroxometallic acids:						
Chromates of lead and zinc	425	334	283	252	772	Japan (53%); France (18%); Norway (16%); Poland (12%).
Sodium dichromate	1,661	4,895	4,372	10,280	5,857	United Kingdom (88%); Argentina (4%); Canada (4%).
Potassium dichromate	680	464	587	522	754	Russia (31%); Brazil (20%); Mexico (15%); United Kingdom (15%).
Other chromates and dichromates; peroxochromates	1,860	859	782	668	1,593	United Kingdom (63%); France (29%).
Chromium carbide	123	77	103	124	1,123	United Kingdom (75%); Japan (19%).
PIGMENTS AND PREPARATIONS BASED ON CHROMIUM						
Chrome yellow	3,643	3,468	3,507	3,609	8,003	Canada (74%); Mexico (10%); Hungary (9%).
Molybdenum orange	916	812	894	680	2,023	Canada (99%).
Zinc yellow	436	218	220	246	554	Norway (59%); France (23%); Germany (9%).
Other	657	441	2,322	446	2,113	Germany (59%); Poland (13%); France (7%).

[1] Contained 1,459 tons of chromium.
[2] Contained 2,046 tons of chromium.
[3] Contained 3,643 tons of chromium.
[4] Contained 3,307 tons of chromium.

NA Not available.

[1] World resources derived in consultation with the U.S. Geological Survey.

[2] Data and total rounded to nearest 100,000 metric tons.

[3] The reserve base includes demonstrated resources that are currently economic (reserves), marginally economic (marginal reserves), and some of those that are currently subeconomic (subeconomic resources).

[4] Less than 1/2 unit.

[5] Less than 50,000 metric tons.

TABLE 22

Total	[r]14,006,464	[r]12,958,832	[r]13,320,278	[r]10,992,570	9,300,600

[e] Estimated. [r] Revised.

[1] Table includes data through June 14, 1994.

[2] Figures for all countries represent marketable output unless otherwise noted.

[3] Reported figure.

[4] Average Cr_2O_3 content was as follows: 1989—39.5%; 1990—38.9%; 1991—42.0%; 1992—43.0% (revised); and 1993—43.0% (estimated).

[5] Direct-shipping ore plus concentrate.

[6] Concentrate.

[7] All production in Yugoslavia from 1989-91 came from Macedonia.

[8] Includes production by Bophuthatswana.

[9] Salable product: direct-shipping lump ore plus concentrate.

[10] Dissolved in Dec. 1991.

[11] Dissolved in Apr. 1992.

Total	[r]3,893,583	[r]3,618,984	[r]3,619,481	[r]3,424,597	3,128,696

[e] Estimated. [r] Revised.

[1] Table includes data available through June 14, 1994.

[2] Includes high- and low-carbon ferrochromium.

[3] Reported figure.

[4] Czechoslovakia was dissolved on Dec. 31, 1992. All production in Czechoslovakia from 1989-92 came from Slovakia.

[5] Includes ferrochrome and charge chrome.

[6] Formerly part of Czechoslovakia; data were not reported separately until 1993.

[7] Includes high- and low-carbon ferrochromium and ferrochromium silicon.

[8] Includes production from Bophuthatswana.

[9] Dissolved in Dec. 1991.

[10] Includes high- and low-carbon ferrochromium, ferrochromium silicon, chromium metal, and other chromium materials.

[11] Dissolved in Apr. 1992.

CLAYS

By Robert L. Virta

Mr. Virta, a physical scientist with 18 years of U.S. Bureau of Mines experience, has been the commodity specialist for clays since 1991. Domestic survey data were prepared by Maria Arguelles, statistical assistant; and international tables were prepared by Virginia Woodson, Amy Durham, and Amy Burke, international data coordinators.

The amount of clay sold or used by domestic producers increased slightly in tonnage to 41.1 million metric tons, valued at $1.5 billion. Production of all types of clay increased in 1993. Common clays accounted for 61% of the tonnage. Kaolin accounted for 64% of the value of clays produced in 1993. Imports decreased 5% in tonnage to 39,430 tons and increased 13% in value to $17.6 million. Exports were essentially unchanged in tonnage at 4.2 million tons although they increased slightly in value to $669.5 million. (*See table 1.*)

Clays were produced in 44 States and Puerto Rico. The 10 leading producer States, in descending order, were Georgia, Alabama, Wyoming, North Carolina, Texas, Ohio, California, South Carolina, Missouri, and Michigan. (*See table 2.*)

DOMESTIC DATA COVERAGE

Domestic production data for clays are developed by the U.S. Bureau of Mines (USBM) from one voluntary survey of U.S. operations. Of the 649 operations covered by the survey, 480 responded, representing 73% of the total clay and shale production sold or used shown in table 1.

BACKGROUND

Definitions, Grades, and Specifications

Clays are categorized into six groups by the USBM. The categories are ball clay, bentonite, common clay and shale, fire clay, fuller's earth, and kaolin. The definitions listed in this work for ball clay, fire clay, high-alumina clays, and kaolin are similar to those in USBM Information Circular 8335.[1]

Ball clay is a plastic, white-firing clay used mainly for bonding in ceramicware. The clays are sedimentary in origin and consist mainly of kaolinite, sericite mica, and organic matter. Ball clays usually are much finer grained than kaolins and are renowned for their plasticity. They are classified according to the method of preparation (crude, shredded, air-floated, water-washed, or slurry) and specific physical and chemical properties.

Bentonite is a clay composed predominately of smectite minerals. The primary smectite mineral is montmorillonite. Swelling-type bentonite has a high-sodium ion concentration. Its volume increases 15 to 20 times its dry volume when wetted with water. Nonswelling bentonites usually are high in calcium. Bentonite is classified according to its physical and chemical properties, with particular emphasis on particle size and swelling index.

Common clay is defined as a clay or claylike material that is plastic enough to mold easily. Its vitrification point is usually below 1,100° C. Shale is a laminated sedimentary rock that is formed by the consolidation of clay, mud, or silt. The common clays and shales are composed mainly of illite or chlorite. They also may contain kaolin and montmorillonite. Common clays and shales usually contain more alkali, alkaline earth, and ferruginous minerals and less aluminum than high-quality kaolins, fire clays, and ball clays. Iron present in the clay usually imparts a reddish color to the final product after firing. There is no formal classification of common clays and shales, although a clay may sometimes be referred to as common, brick, sewer pipe, or tile clay. Clay and shale are used in the manufacture of structural clay products such as brick, drain tile, and roofing tile as well as portland cement clinker and expanded lightweight aggregates.

Fire clay is defined as detrital material, either plastic or rocklike, that commonly occurs as underclay below coal seams. Low concentrations of iron oxide, lime, magnesia, and alkalies in fire clay enable the material to withstand temperatures of 1,500° C or higher. It is composed mainly of kaolinite. Fire clays also contain other clays such as ball clay, bauxitic clay and shale, burley, burley-flint, and diaspore. Fire clays generally are used for refractories or to raise vitrification temperatures in structural clay products. The fired colors of fire clays range from buffs to grays. Fire clays are classified according to their physical and chemical properties and the characteristics of the products made from them.

The term "fuller's earth" is derived from the first major use of the material, which was for cleaning textiles by fullers. Fuller's earth does not refer to a clay with a specific composition or mineralogy. It is defined as a nonplastic clay or claylike material, usually high in magnesia, that is suitable for decolorizing and purifying mineral and vegetable oils. They are composed mainly of the needle- and/or lath-shaped clay mineral attapulgite or varieties of montmorillonite. Fuller's earths containing opal or other forms of colloidal silica also are produced. Fuller's earths are classified according to their physical and chemical properties. Sepiolite-type clays are grouped with fuller's earths under the USBM classification system.

Kaolin, or china clay, is defined as a white, claylike material composed mainly of kaolinite and other kaolin-group minerals, such as halloysite and dickite. Kaolin has a specific gravity of 2.6 and a fusion point of 1,785° C. Kaolin is classified according to the method of preparation (crude, air-separated, water-washed, delaminated, air-dried, calcined, slip, pulp, slurry, or water suspension) and on specific physical and chemical properties.

The American Society for Testing and Materials, American Foundrymen's Association, American Oil Chemist's Society, American Petroleum Institute, Technical Association of the Pulp and Paper Industry, and other national organizations have developed tests and set standards for some applications. Many producers and consumers, however, use nonstandardized tests that are applicable to their specific needs. Individual companies often set the acceptable limits of mineralogical composition, particle size, and other physical and chemical properties. Detailed data on specifications have been published by the USBM.[2]

Products for Trade and Industry

Because of the many types of clay and different qualities within each type, the consumption pattern and the products for trade and industry are constantly changing. Consumption of kaolin in refractories has been growing since 1970 because of the increasing popularity of castable, ramming, gunning, and plastic mixes that use calcined kaolin aggregates (grog) in their formulations.[3] The consumption of calcined kaolin grogs also has increased in refractory brick manufacturing, replacing imported calcined refractory-grade bauxite grogs. Bentonite used for waterproofing and sealing in construction and disposal sites and in pet waste absorbents has grown significantly in the past few years.

Industry Structure

An estimated 330 companies operating 989 clay pits or mines reported production in 1993; of these, 90 companies, most with multiple operations, accounted for approximately 68% of the tonnage and 77% of the value for all types of clay produced and sold or used. Clay production was reported in all States and Puerto Rico except Alaska, Delaware, Hawaii, Rhode Island, Vermont, Wisconsin, and the District of Columbia.

The leading clay-producing States were Georgia, 9.8 million tons; Alabama, 2.5 million tons; Wyoming, 2.4 million tons; North Carolina, 2.4 million tons; Texas, 2.2 million tons; Ohio, 2.2 million tons; California, 2 million tons; South Carolina, 1.5 million tons; Missouri, 1.2 million tons; and Michigan, 1.2 million tons. (*See table 2.*) Most of the clay is mined by open pit methods. Less than 1% of U.S. clay output was from underground mines in 1993. Most of the underground production was in Pennsylvania, Ohio, and West Virginia, where the clays are mainly underclays associated with coal and suitable for refractory uses.

The ball clay industry was small, with 7 producers operating 27 mines in 6 States in 1993. Three of the producers were large, diversified firms with widespread foreign and domestic mineral interests. Tennessee ball clay production represented about 76% of the total output.

Firms producing bentonite operated 141 mines in 13 States. Four producers were large, diversified firms with international mineral operations; three of the firms had interests in other types of clay in the United States. Wyoming was the leading State, accounting for 78% of the total output. Swelling-type bentonite was produced mainly in Montana and Wyoming and nonswelling-type bentonite was produced mainly in Alabama, California, and Mississippi. The United States was the world's largest producer and exporter of bentonitic clays.

Firms producing common clay and shale in 1993 were manufacturers of structural clay products such as clay pipe, sewer pipe, lightweight aggregates, and cement. Most companies mined the clays used in making their products. Less than 10% of the total output usually is sold. Private mining contractors and haulers were employed in many of the operations. Some producers were diversified firms having interests in metals and other nonclay products. Some companies owned and operated several clay pits and plants to cover a large market area. The economic radius for shipment of common clay or shale products was usually 320 kilometers or less. The high cost of transport promotes the development of local ownership companies, or in the case of a large firm, the ownership and operation of several strategically located pits and associated fabricating plants.

Fireclay producers were mostly refractories manufacturers that used the clays in firebrick and other refractories. Seventy-eight mines were operated in 1993 by 22 firms in 10 States.

Nineteen companies produced fuller's earth from 33 mines in 12 States. Seven of the mines were in the attapulgite-fuller's earth areas of Florida and Georgia; these two States accounted for most of the domestic attapulgite production. Most producers were small, independent firms, but three were large, diversified corporations with international mineral interests. The United States is the world's largest producer and user of fuller's earth.

Thirty-nine firms operated 136 kaolin mines in 12 States. In 1993, three large, diversified firms accounted for about 60% of total domestic kaolin output. Most large kaolin producers have operations in Georgia, which accounted for 83% of the kaolin production.

Geology-Resources

Clay is formed by the mechanical and chemical breakdown (weathering) of rocks. The weathering products consist of mineral grains and rock fragments of different size and different physical and chemical properties. The nonplastic portion consists of altered and unaltered rock fragments (grit), which are usually feldspar, iron oxides, micas, and quartz. The plastic portion usually is composed of clays and is low in grit.

Clays may be classified as residual or sedimentary. Residual clays are deposited in the same location in which they were formed. Sedimentary clays are those that have been transported, usually by water, and deposited elsewhere.[4] Sedimentary clays often undergo further alteration and classification during transport. Kaolin deposits in Georgia and South Carolina are sedimentary. Kaolin deposits in North Carolina and English china or kaolin clay deposits are residual.[5] The Kentucky and Tennessee ball clays and the Missouri fire clays are sedimentary deposits. Most bentonites, montmorillonites, and fuller's earths were formed in place through the weathering of volcanic ash or tuff. The attapulgite-type fuller's earth deposits of Florida and Georgia were probably not formed from volcanic ash or tuff. Geologists have never found any evidence of volcanic materials associated with these deposits.[6]

The definitions of reserves and reserve base are published in U.S. Geological Survey Circular 831, "Principles of a Resource/Reserve Classification for Minerals." Reserves are the part of an ore body that can be economically extracted at the time of evaluation. Reserve base is the part of an ore body that meets specified minimum physical and chemical criteria related to current mining and production practices. Reserve base includes reserves, marginal reserves, and subeconomic resources.

Common clay and shale deposits are found throughout the United States and domestic resources are almost unlimited. Not all deposits, however, are near potential markets, and most deposits are not suitable for all applications. For example, most common clay or shale deposits can be used to manufacture common brick, but the color or strength of the final product may not meet the requirements of the local market. Relatively few deposits are suitable for manufacture of lightweight aggregate. Even with these limitations of location and use, resources of common clay and shale are "virtually unlimited."

U.S. reserves of other types of clays that are owned or controlled by domestic producers are estimated to be about 700 million tons. U.S. reserves of kaolin are estimated to be 400 million tons; ball clay, 30 million tons; fire clay, 100 million tons; bentonite, 120 million tons; and fuller's earth, 60 million tons.

Large quantities of high-quality kaolin suitable for paper-coating and paper-filler applications are found in Georgia. A small area in Florida and Georgia contains sizable reserves of attapulgite-type fuller's earth. Most bentonite for iron ore pelletizing and oil-well-drilling muds is mined in Wyoming. Fire clay deposits, such as those found in Missouri, are widespread. Kentucky and Tennessee are two of only a few States that have sizable deposits of ball clay.

Technology

Exploration.—Exploration begins with an understanding of the geological occurrence of the clays of interest. With this knowledge, potential economic deposits can be located. Auger or core drills are then made to delineate the size and shape of the deposit and to obtain material for testing.

Kaolins usually are evaluated for filler and ceramic applications. The grit, particle size, brightness, and leachability are determined. Air-floated clays normally require only grit and brightness determinations. Kaolin, ball clay, and fire clay for ceramic and/or refractory applications are analyzed for grit, brightness, green and dry strengths, fired color, and iron and alumina contents. The common clays and shales usually are tested according to the intended end use, such as brick, drain tile, or lightweight aggregate. Usually, prepared specimens are tested for plasticity, green strength, shrinkage, vitrification temperature range, etc. For lightweight aggregates, the bloating range is determined. Bentonites and fuller's earth clays are difficult to evaluate because there are no standard testing procedures or specifications. Generally, they are processed to meet the purchaser's specifications.

Mining.—Most clays are mined from open pits using modern surface mining equipment such as draglines, power shovels, front-end loaders, backhoes, scraper-loaders, and shale planers. Some kaolin is extracted by hydraulic mining and dredging. A few clay pits are operated using crude hand-mining methods. A small number of clay mines, principally in underclays in coal mining areas, are mined underground using room-and-pillar methods. Clays usually are transported by truck from the pit or blending areas to the processing plants. Rail, conveyor belt, and in the case of kaolin, pipelines also are used.

About 100% of the clay is recovered from the minable beds in most open pit operations. Approximately 75% is recovered in underground operations. The waste-to-clay ratio is highest for kaolin, about 7:1, and lowest for common clay and shale, about 0.25:1.

Processing.—Clays are used in a large number of products, so they must be treated in different ways. Processing can consist of very simple and inexpensive grinding or shredding and screening for some common clays. Very complex and expensive grinding or shredding, sizing, leaching, delamination, etc., may be required for paper-coating clays and high-quality filler clays for use in rubber, paint, plastic, and other products. In general, processing does not appreciably alter the chemical or mineralogical characteristics of the clays. The two exceptions are calcining and cation exchange.

Significant processing losses occur with kaolin and fuller's earth. About 40% of the kaolin and 30% of the fuller's earth delivered to the processing plants is discarded. Waste material from processing consists mostly of off-grade clays and small quantities of feldspar, iron-bearing minerals, mica, and quartz.

Ball Clay.—Processing involves drying, shredding, pulverizing, air floating, and slurrying.

Bentonite.—Processing involves weathering, drying, grinding, sizing, granulation, and the use of additives for cation exchange.

Common Clay and Shale.—Processing involves shredding, blunging, extruding, and drying. Common bricks, tile, lightweight aggregate, etc., require firing in a kiln. The kiln firing or drying operation produces a finished manufactured product.

Fire Clay.—Processing involves shredding, calcining, and blending.

Fuller's Earth.—Processing involves blunging, extruding, drying, crushing, grinding, sizing, and dispersing.

Kaolin.—Processing involves one or more of the following: shredding, blunging with dispersant, degritting, water fractionation, magnetic separation, ultraflotation, acid treatment, calcination, air floating, attrition grinding, slurrying, and delaminating. Kaolins used for paper-coating applications may be leached and further delaminated by grinding, deflocculation, and centrifugation to special sizes. Ultraflotation or wet magnetic separation treatment may be used to remove iron- or titanium-bearing minerals to obtain a whiter product.

Processing costs for clays range from a few cents per ton for some common clays to more than $400 per ton for some special paper-coating clays and high-quality clays that require very elaborate and expensive treatments.

Price schedules, although not complete, are available and are published regularly in trade journals such as the American Paint and Coatings Journal, Chemical Marketing Reporter, and Industrial Minerals (London).

Federal tax laws allow clay producers a depletion allowance on domestic and foreign gross income not to exceed 50% of net income with depletion deduction. Depletion allowances are as follows: ball clay, bentonite, kaolin or china clay, sagger clay, and clay used or sold for purposes dependent on its refractory properties, 14% domestic and 14% foreign; fuller's earth, 14% domestic and 14% foreign; and clay used for extraction of alumina or aluminum compounds, 22% domestic; clay used or sold for use in manufacturing drainage and roofing tile, flower pots, and kindred products, 5% domestic and 5% foreign; and clay and shale used for making brick, tile, and lightweight aggregate, 7.5% domestic and 7.5% foreign. Severance taxes are levied by some producing States.

Byproducts and Coproducts

Firms in California, Florida, and Texas produce silica glass sand as a coproduct of its kaolin production. Flake mica is a byproduct in one kaolin operation in North Carolina. Bauxite is a coproduct in clay operations in Alabama and Georgia. Clay and limestone for cement manufacture commonly are produced from the same property and reported as coproducts or byproducts even though they are usually mined separately from different formations or beds. Sand, gravel, and stone aggregates are occasionally produced together with common clays.

Economic Factors

Economic factors affecting clays vary in importance with type, quality, and intended end use. The cost of transportation is an important factor for the common clay and fire clay industries; mines must be close to consumers to be cost competitive. Other types of clays are less abundant and have higher unit values. They can be shipped greater distances from the mines and still be cost competitive. For example, paper-coating clay from Georgia and attapulgite-type fuller's earth from Florida and Georgia can be shipped nationwide. Bentonite for iron ore pelletizing from Montana and Wyoming can be shipped a considerable distance to the iron ore centers. In some of these cases, the shipping costs exceed the value of the clays at the mine or processing plant. Other important factors to consider are associated with land acquisition, severance taxes, land rehabilitation, energy requirements, and environmental factors.

Because most clays are relatively low-cost materials in the crude state, mining costs must be kept as low as possible. Cost of the crude clays ranges from less than $3 per ton for some common clays to more than $20 per ton for some of the higher quality materials.

Very little clay is imported because transportation costs would make the clays noncompetitive in price. Consequently, import duties have little impact on the amount of clays imported.

Operating Factors

To manufacture finished clay products, producers require equipment to mine the clay; crushers, blungers, centrifuges, settling tanks, rotary vacuum filters, spray dryers, etc., to process the clay and kilns to prepare fired clay products. These require high initial capital outlays and constant maintenance and/or replacement for proper operation. Additionally, customer needs vary so suppliers must produce a multitude of products. This greatly increases the complexity (and cost) of the milling process.

Losses in mining are extremely small, except in underground mining where recovery will average about 75%. Processing losses for material receiving, crushing, grinding, mixing, shredding, blending, and drying also are insignificant. Losses from washing, sizing, etc., reach 30% or 40%. Producers attempt to maximize the efficiency of the recovery process in an effort to reduce costs associated with the handling and processing of waste material.

Clay mining lacks many of the hazards associated with other types of mining because only a few deposits require the use of explosives and most mines are open pit earth-moving operations. Domestic mine employment in 1993 was estimated to be 2,000 workers. Domestic mill employment was estimated to be 9,100 workers.

ANNUAL REVIEW

Issues

Clay mining has an environmental impact because of the disturbance to the land. Overburden is moved and clays are removed, leaving a depression or pit. State laws usually require leveling or recontouring of the disturbed area and planting trees or grasses to prevent or minimize erosion. For processing, the impoundment of slimes and dust control are usually required. The rules for disposal of coarse tailings are similar to or included with those laws governing reclamation of the mined area.

Production

Ball Clay.—Production of domestic ball clay increased 11% to 949,250 tons valued at $39.8 million. Tennessee supplied 64% of the Nation's output, followed by, in descending order of production, Kentucky, Texas, Indiana, Mississippi, and Ohio. Production increased in Indiana, Kentucky, Tennessee, and Texas and was unchanged in Mississippi. Water-slurried ball clay was produced in Tennessee and air-float ball clay was produced in Indiana, Kentucky, Mississippi, and Tennessee. (*See table 3.*)

Bentonite.—The quantity and value of bentonite sold or used increased slightly to 3.09 million tons and $112.3 million, respectively. Wyoming was the largest bentonite producer, accounting for 78% of the total bentonite production and 92% of the swelling bentonite production. Wyoming was followed by Montana, California, Utah, Oregon, Texas, Nevada, Virginia, and Tennessee, in decreasing order of production. Production of swelling bentonites increased in California, Nevada, Oregon, and Wyoming.

Mines in Alabama and Mississippi accounted for more than 47% of the nonswelling or calcium bentonite production. Mississippi was followed by Alabama, California, Texas, Arizona, Nevada, Oregon, Utah, Colorado, and Montana, in decreasing order of production. Increases in production of nonswelling bentonite were reported in Alabama, California, and Nevada. Decreases were reported in other producing States. *(See table 5.)*

Tremont Corp. announced plans to sell its subsidiary, Bentonite Corp., to Baroid Corp. for $20 million. Major markets for Bentonite Corp.'s bentonite are foundry use, civil engineering applications, and oil drilling muds.[7]

Common Clay and Shale.—Domestic sales or use of common clay and shale increased slightly in tonnage to 25.3 million tons and value to $136.9 million. The 10 major producing States were North Carolina, Texas, Alabama, Ohio, California, Georgia, Michigan, South Carolina, Missouri, and Arkansas, in descending order of tonnage. Of these States, production increased in Alabama, California, Georgia, and North Carolina. Common clay and shale represented about 61% of the quantity but only 9% of the value of total domestic clay production. *(See table 7.)*

Fire Clay.—Fire clay sold or used by domestic producers increased 20% in tonnage to 459,000 tons and 11% in value to $11.5 million. Missouri, was the leading producing State, followed by Ohio, Alabama, Georgia, Arkansas, New Mexico, Montana, New Jersey, Washington, and Colorado. Production increased in Arkansas, Georgia, Missouri, Montana, Ohio, and Washington. *(See table 9.)*

Fuller's Earth.—Production of fuller's earth increased 3% to 2.5 million tons valued at $230 million. Production from the region that includes Attapulgus, Decatur County, GA, and Quincy, Gadsden County, FL, was composed predominantly of the lath-shaped amphibolelike clay mineral attapulgite. Georgia accounted for most of the domestic attapulgite production followed by Florida and Nevada, in decreasing order of production.

Most of the fuller's earth produced in other areas of the United States contains varieties of montmorillonite and/or other clays. Illinois, Mississippi, and Missouri accounted for most of the production, followed by California, Florida, Tennessee, Georgia, Kansas, Virginia, Texas, and Utah, in decreasing order of production. Production increased in California and Florida. *(See table 11.)*

J. M. Huber Corp. announced an agreement to market sepiolite for Tolsa SA in North America. Tolsa SA mines sepiolite in Spain primarily for cat litter. J. M. Huber will market the sepiolite in North America to the paint, ink, and adhesives industries.[8]

Kaolin.—Domestic production of kaolin increased 3% in tonnage to 9 million tons, valued at $957.9 million. Georgia was the largest kaolin producer with 83% of U.S. production, followed by South Carolina with 6% of production. Other producing States were Alabama, Arkansas, California, Minnesota, Nevada, North Carolina, Florida, Texas, Pennsylvania, and Colorado, in decreasing order of production. Production increased in all States except Pennsylvania. *(See table 13.)*

Approximately 47% of the kaolin produced was water-washed; followed by calcined, 18%; delaminated, 14%; air-floated, 13%; and unprocessed, 9%. *(See table 14.)* Delaminated kaolin was produced exclusively in Georgia. Georgia also accounted for 99% of the production of water-washed kaolin and 69% of the calcined kaolin. Georgia and South Carolina accounted for 94% of the air-floated kaolin. Production/sales of air float and calcined and unprocessed kaolin increased in 1993. *(See tables 14, 15, 16, and 18.)* Some of the unprocessed kaolin was used in bricks, pottery, roofing granules, etc. The low value of the clay used in these applications suggests that some of the clay should be classified as common clay rather than kaolin.

Kentucky-Tennessee Clay Co. increased the capacity of its Sandersville, GA, slurry facilities by approximately

50%. The company installed an automated system for batch processing, increased screening capacity, and enlarged its storage facilities.[9]

Engelhard Corp. announced plans to increase its facilities for producing calcined kaolin. Capacity will be increased by approximately 40,000 tons. Calcined kaolin will be marketed to the paper industry.[10]

Kemira Inc. announced its intention to acquire 20% of Nord Kaolin Co. Kemira is a major supplier of TiO_2 for the paper industry. Nord Kaolin produces kaolin for the paper industry, with one product being a kaolin-extended TiO_2 product.[11]

Consumption and Uses

Ball Clay.—Ball clays are extremely refractory, and their use, largely in whitewares, imparts a high green strength as well as plasticity to the bodies. Although white-firing ball clays are preferable, fired products that range to cream or buff colors do not generally impair the quality of the whiteware products.

The principal ball clay markets were pottery, floor and wall tile, fillers and extenders, and sanitaryware with 14%, 25%, 21%, and 22%, respectively, of the domestic consumption. No major changes were observed in domestic consumption patterns except in fillers and extenders where animal feed applications increased significantly. Producers reported increased exports in 1993. *(See table 4.)*

Bentonite.—The swelling sodium bentonites were used largely in drilling muds, in foundry sands, and in pelletizing taconite iron ores. The nonswelling or calcium bentonites were used mostly in conjunction with the swelling bentonites in foundry sand mixes in which the sodium bentonites provide dry strength and the calcium bentonites provide high green strength.

Bentonite also was used for foundry casting by the steel, iron, and nonferrous casting. The bentonite provided good green strength and desirable dry strength characteristics. Sodium bentonites were used in steel casting. Ion-exchanged bentonites were used for iron and nonferrous casting. There has been an increased use of mixtures of ion-exchanged and sodium bentonites to meet the more stringent demands of the casting industry. Calcium bentonite produced in Alabama and Mississippi was suitable for the production of absorbent, acid-activated, and foundry products.

The major end uses were drilling mud, foundry sand, iron ore pelletizing, and pet waste absorbents with 20%, 30%, 18%, and 11%, respectively, of total domestic sales. Sales of swelling bentonite for pet waste absorbents increased in 1993 largely due to the marketing success of clumping kitty litters. Similarly, sales of swelling bentonite for foundry sand applications also increased. The increase was not as great as shown in table 16 because some of the 1992 data was concealed to avoid disclosing company proprietary data. Based on the trend over the past 5 years, sales of 700,000 tons to 750,000 tons would be expected rather than the 803,420 tons reported by producers. A large decrease in sales for filtering and clarifying was reported. Much of this decrease was attributed to a large one-time sale of bentonite for clarification of acids in 1992. Increased sales of bentonite for drilling muds correspond to increased drilling activity. Again, producers that sold bentonite for pelletizing iron ore did not separate domestic and foreign shipments. An estimated 100,000 tons was exported for pelletizing. *(See table 6.)*

Bentonite Corp. completed construction of a new processing plant in Wyoming. The plant produces premixes, consisting of bentonite, coal, and proprietary additives, for the metal casting industry. The plant has a capacity of 127,000 tons.[12]

Common Clay and Shale.—Common clay was used most frequently in the manufacture of heavy clay products, including (1) building brick; flue linings, sewer pipe, drain tile, structural tile, and terra cotta; (2) portland cement clinker; and (3) lightweight aggregate, accounting for 52%, 30%, and 14%, respectively, of total domestic consumption. Consumption increased 4% for heavy clay products and lightweight aggregates and decreased 4% for portland cement clinker. *(See table 8.)*

Fire Clay.—Fire clays were used mostly in commercial refractory products such as firebrick and block, grogs and calcines, high-alumina brick and specialties, saggers, refractory mortars and mixes, and ramming and gunning mixes. Fire clays also were used to produce lightweight aggregates, portland cement, pottery, and common brick.

Consumption of fire clay increased 20% in 1993. Firebrick accounted for 28% of fire clay use followed by heavy clay products, 10%; and ceramics and glass, 4%. The large increase in sales for firebrick is contrary to industry trends. Based on previous trends, sales of approximately 200,000 tons would be expected. *(See table 10.)*

Fuller's Earth.—Fuller's earth and calcium bentonite were used for decolorizing and purifying mineral, vegetable, and animal oils. Clays activated by acid treatment were used to process animal or vegetable oils. Acid treatment produced a highly absorbent sievelike structure. Attapulgite is used in drilling muds instead of sodium bentonites for drilling saltwater formations. Sodium bentonite flocculates in brine, thereby destroying the gel-like colloidal suspension required for drilling. The major uses for attapulgite and montmorillonite types of the fuller's earths were in pet waste and oil and grease absorbents because of their absorbent properties.

Attapulgite, a fuller's earth-type clay, found wide application in absorbent and gelling and/or thickening areas. The thixotropic properties of attapulgite clays provided important thickening and viscosity controls necessary for suspending solids. Mineral thickeners were used in such diverse markets as paint, joint compound cement, and saltwater drilling mud.

Overall consumption of all types of fuller's earth increased 3% in 1993. The major use was in pet waste absorbents, which accounted for 63% of the fuller's earth consumption. Other major domestic uses were oil and grease absorbents (11%) and pesticide carriers (8%). Consumption of fuller's earth in oil and gas absorbents declined. Sales of attapulgite and montmorillonite-type fuller's earth increased for animal feed and pesticide carrier applications. *(See table 12.)*

The major use for montmorillonite-type fuller's earth was in pet waste absorbents. The next largest use was in pesticides, followed by oil and gas absorbents, animal feed additives, fertilizer carriers, and clarifying animal and mineral oils. There was a 46% decrease in the use of montmorillonite-type fuller's earth for oil and grease absorbent applications and a 13% increase in sales of montmorillonite-type fuller's earth for pet waste absorbents. Montmorillonite-type fuller's earth was the dominant clay used in pet waste absorbents (74%). The largest use of attapulgite was in pet waste absorbents (292,000 tons). Sales of attapulgite for pet waste absorbents decreased 21% in 1993. Other major markets for attapulgite were oil and grease absorbents (20%) and fertilizer carriers (8%). No other significant changes in consumption patterns were reported for fuller's earth.

Kaolin.—Kaolin had many industrial applications, and many grades were specifically designed for use as a filler in paper, paint, rubber, plastics,[13] and ceramics.[14] New uses are constantly being developed. Kaolin is a unique industrial mineral because it is chemically inert over a relatively wide pH range, is white in color, and has good covering or hiding power when used as a pigment or extender in coated films and filling applications. It also is relatively nonabrasive, has low conductivity of heat and electricity, and costs less than most materials with which it competes. Fillers and extenders must meet very rigid specifications such as particle size, color, brightness, and viscosity.[15]

Kaolin producers reported major domestic end uses as paper coating, 37%; grogs and calcines, 14%; paper filling, 14%; fiberglass, 5%; paint, 4%; rubber, 4%; brick, 3%; portland cements, 3%; and catalysts, 3%. *(See table 20.)* The largest decline in tonnage was in paper applications where coatings and filler declined 6% and 17%, respectively. Besides facing a slumping paper industry, kaolin sales have been affected slightly by the increased use of ground and precipitated calcium carbonate in the alkaline papermaking process. Despite the decline domestically, producers reported increased exports of kaolin for the paper industry. The increase in catalyst applications was not as great as shown in table 20 because some of the 1992 data were concealed to avoid disclosing company proprietary data. No other major changes were observed in the domestic consumption patterns.

There were distinct differences in markets for kaolin from Georgia and South Carolina. Major domestic markets for kaolin from Georgia were paper coating (48%), paper filling (18%), fiberglass (5%), and paint (4%). Major markets for kaolin from South Carolina were rubber, fiber glass, catalyst, and adhesives, in decreasing order of consumption. No significant changes were observed in markets for South Carolina kaolin. Changes in consumption patterns for Georgia were mentioned in the preceding paragraph concerning paper. *(See tables 17 and 19.)*

Absorbent Uses.—Absorbent uses for clays accounted for about 2.1 million tons or 5% of total clay consumption. Consumption was for oil and grease absorbents, 15%; pet waste absorbents, 84%; and miscellaneous absorbent applications, 1%. Demand for absorbents decreased slightly in 1993. Fuller's earth was the principal clay used for absorbent purposes, followed by bentonite. *(See tables 6 and 12.)* Small amounts of ball clay and kaolin also were used for absorbent applications.

Ceramics.—Pottery and related products required good ceramic qualities, including plastic formation, desirable firing temperatures, color, etc. The principal clays meeting these and other specifications were ball clay, common clay, and kaolin. Total demand for clay in the manufacture of pottery, sanitaryware, china and dinnerware, and related products (excluding clay flower pots) exceeded 750,000 tons. Common clay and shale, ball clay, and kaolin, in order of volume, were used in manufacturing floor, wall, and quarry tile. Demand in floor, wall, and quarry tile applications was 603,000 tons in 1993. *(See tables 4, 8, 10, and 20.)*

Construction.—Common clays and shales were used to manufacture a wide variety of construction materials such as expanded aggregates, hydraulic cement, and structural clay products.

Expanded Clay and Shale.—Materials with specific bloating properties and strength are required for this use. Lightweight concrete blocks, floors, walls, and other products made from expanded clay and shale have a lower overall weight and better insulating qualities than equivalent products made with sand and gravel and crushed stone aggregates.

Consumption of common clay and shale in the production of lightweight aggregate increased slightly to 3.5 million tons. Concrete block accounted for 63% of total lightweight aggregate production. Structural concrete accounted for 22% of the market. Highway surfacing accounted for 7% of lightweight aggregate production. *(See tables 8, 10, and 21.)*

Hydraulic Cement.—Clays provide the alumina and silica required to manufacture hydraulic cements. Common clays, kaolin, fuller's earth, fire clay, and bentonite, in decreasing order of consumption, were used in cement products. Approximately 97% of the clay consumed by the cement industry was common clay. *(See tables 8, 12, and*

20.)

Structural Clay Products.—Structural clay products include such items as building brick, drain tile, flue linings, roofing tile, sewer pipe, and terra cotta. Clays for structural applications must be plastic and easily shaped, must not warp during firing, and must produce a product with adequate strength. Common clay is most commonly used in these applications. Other clays, such as ball clay, bentonite, fire clay, and kaolin, are not used in large tonnages because of their higher cost.

Slightly more than 13.5 million tons of clay was consumed for structural clay products. Common and face brick accounted for 93% of this total or 12.6 million tons. Other markets, in decreasing order of consumption, were sewer pipe, flue linings, terra cotta, flower pots, structural tile, drain tile, and roofing tile. *(See tables 8, 10, 20, and 22.)*

The value reported by the Bureau of the Census for shipments of building and face brick was 6.6 billion bricks valued at $985 million, an increase from that of 1992. Shipments of clay floor and wall tile increased to almost 49 million square meters valued at $678 million. Shipments of vitrified clay and sewer pipe fittings decreased to 129,839 tons valued at $33 million.

Drilling Mud.—Drilling mud is a scientifically designed mixture of several items. The clays are used to adjust the viscosity and gel strength of the drilling fluid and to coat the drill-hole walls to prevent fluid loss. Drilling muds contain, in addition to bentonite or attapulgite, ground barite for its high specific gravity.[16] Demand for clays in rotary-drilling muds decreased to approximately 559,000 tons. Swelling-type bentonite remained the principal clay used in drilling mud mixes, although fuller's earth, used mostly in saltwater drilling techniques, and nonswelling sodium-activated bentonites also were used to a limited extent. *(See tables 6 and 12.)*

Filler.—Clays are used as binders, extenders, and fillers in a wide variety of products, ranging from adhesives to flooring products to paint to rubber. They are added to products for widely varying reasons. For example, clays displace more expensive product components in paint, paper, and plastics; improve the ink retention and opacity in paper; prevent pigment settling in paints; act as carriers for fertilizers and pesticides; and increase the strength of plastics.

More than 5 million tons of clays was used as fillers and extenders. Kaolin accounted for approximately 82% of this amount, followed by fuller's earth, bentonite, ball clay, and common clay, in decreasing order of consumption. *(See tables 4, 6, 8, 12, and 20.)* Approximately 84% of the kaolin was used for paper-coating and paper-filling applications. Kaolin also was used in the manufacture of products such as adhesives, cosmetics, fertilizer, ink, linoleum, paint, pesticides, plastics, and rubber. *(See table 20.)* Fuller's earth was used mainly in pesticides, fertilizers, and animal feed. Smaller amounts were used in adhesives, paint, and asphalt emulsion, in decreasing order of consumption. *(See table 12.)* Bentonite was used mainly in animal feed with smaller amounts used for the manufacture of paint, adhesives, asphalt emulsions, cosmetics, and pesticides. *(See table 6.)* Major ball clay uses were in animal feed, asphalt emulsion, wallboard, asphalt tile, paper, and plastic. Common clay was used mainly in asphalt emulsions and wallboard. Small amounts of fire clay were used in animal feeds.

Glass.—Exacting chemical and physical specifications are required for clay used in glass manufacturing. Approximately 347,000 tons of kaolin was used in fiberglass. A small amount of bentonite was used as a raw material feed for manufacturing mineral wool. *(See table 20.)*

Iron Ore Pelletizing.—Demand for bentonite in iron and steel production is based on its ability to form strong iron ore pellets from fine-grained taconite concentrates. Easily handled hard pellets are essential for efficient blast furnace operation. Demand decreased to 487,000 tons in 1993. *(See table 6.)* Small amounts of common clay also were used for iron ore pelletizing. *(See table 8.)*

Paper Products.—Kaolin serves to provide a smooth coating to paper, improves its ink retention and brightness, increases the paper density, fills interstices in the paper, and improves opacity. Kaolin accounted for essentially all of the clay used for paper coating (2.5 million tons) and 99% of the clay used for paper filling (947 thousand tons). *(See table 20.)* Small amounts of ball clay were used in paper-filling applications and a small amount of bentonite was used for paper coating. Growth in consumption rates declined in recent years in response to poor paper markets. Also affecting consumption was the increased use of calcium carbonate as paper manufacturers converted to the alkaline process.

One new area of interest involved the use of positively charged kaolin particles for removing pitch during the papermaking process. Traditionally, pitch is controlled using chemical means or adsorbing the pitch onto talc platelets. Favorable results were obtained by applying a high positive charge density onto kaolin platelets. The pitch was negatively charged by adding organic fatty acids to the solution. The negatively charged pitch was bound to the kaolin through a cationic exchange mechanism. The kaolin was most effective at pH levels below 6.[17]

In situ production of iron hydrosulfite, as opposed to the use of commercial sodium hydrosulfite, was investigated as a means of bleaching kaolin. Iron powder and sulfite in the form of sodium sulfite, sodium bisulfite, sodium metabisulfite, and sulfur dioxide were mixed in a kaolin slurry. These reacted to form iron hydrosulfite. The brightness of kaolin bleached with iron hydrosulfite was equivalent or better than that bleached with sodium hydrosulfite and costs for bleaching were lower.[18]

Refractories.—Refractories require strength at high temperatures, resistance to corrosion, low coefficient of expansion, and many other physical and chemical properties, depending on application. The current trend is for refractories designed for a specific use and castable mixes containing refractory aggregates and calcium aluminate cements.[19] Bentonite, both swelling and nonswelling, was used as a bonding agent in proprietary foundry formulations imparting both hot and green strength to the sand.

More than 2.5 million tons of clays was used for the manufacture of refractories. Ball clay, bentonite, common clay, fire clay, and kaolin accounted for 2%, 35%, 6%, 14%, and 43%, respectively, of the refractories markets. Ball clay, common clay, and fire clay were the most commonly used clays for firebrick; bentonite for foundry sand for bentonite; and kaolin for grogs and calcines. *(See tables 6, 10, and 20.)*

Markets and Prices

Ball Clay.—The average unit value for ball clay reported by domestic producers was $41.89 per ton. The unit value of imported ball clay was $190.39. The unit value of exported ball clay was $53.28 per ton.

Bentonite.—The unit value reported by domestic producers for nonswelling bentonite was $48.51 per ton. The unit value for swelling bentonite was $34.12 per ton. The unit value for all bentonite was $36.31 per ton. The unit value of imported bentonite was $289.36 per ton. The unit value of exported bentonite was $91.41 per ton.

Common Clay and Shale.—The average unit value for all common clay and shale produced in the United States and Puerto Rico was $5.41 per ton. The unit value of clay and shale used in lightweight aggregate was $8.34 per ton.

Fire Clay.—The unit value for fire clay reported by domestic producers was $25.13 per ton. The unit of imported fire clay was $217.27 per ton. The unit value of exported fire clay was $100.28 per ton.

Fuller's Earth.—The unit value of attapulgite-fuller's earth reported by domestic producers was $125.75 per ton. The unit value of montmorillonite-fuller's earth was $68.18 per ton. The average unit value of all types of fuller's earth was $92.48 per ton. The unit value of imported fuller's earth was $206.78 per ton. The unit value of exported fuller's earth decreased to $121.14 per ton.

Kaolin.—The unit value of kaolin was $106.94 per ton for all kaolin grades. The unit value for air-float kaolin was $56.98 per ton; for high-temperature calcined kaolin, $148.29; for low-temperature calcined kaolin, $334.39; for all types of calcined kaolin, $158.13 per ton; for delaminated kaolin, $114.44 per ton; for water-washed kaolin, $116.34 per ton; and for unprocessed kaolin, $17.12 per ton. The unit value of the imported kaolin was $347.28 per ton. The unit value of exported kaolin was $163.56 per ton.

Foreign Trade

Ball Clay.—Ball clay exports increased 22% to 60,000 tons valued at $3.2 million, according to the Bureau of the Census. Shipments were made to 25 countries. The major importer was Mexico, with 66% of the exports. *(See table 23.)* Domestic ball clay producers reported that 116,085 tons of ball clay was exported in 1993. The exports were used mainly for floor and wall tile production and sanitaryware production. Other major uses are asphalt emulsions and filler and extender applications. *(See table 4.)*

The discrepancy between the Bureau of the Census and the tonnage producers reported as exports probably resulted because some shipments of clays may be classified under a nonspecific mineral category by the Bureau of the Census. Shipments classified under the nonspecific mineral category would not appear in the Bureau of the Census' ball clay export statistics.

Approximately 93% of the ball clay imported was from the United Kingdom. Imports decreased slightly to 687 tons valued at $228,000. *(See table 24.)*

Bentonite.—Bentonite exports increased slightly to 606,000 tons valued at $55.4 million. Bentonite was exported to 60 countries with Japan and Canada accounting for 55% of the exports. Domestic bentonite producers reported exports of 431,241 tons, 175,000 tons less than that reported by the Bureau of the Census. This discrepancy is partially explained by the inclusion of an estimated 100,000 tons of bentonite for Canadian iron ore pelletizing under domestic sales. The largest markets for exported bentonite were foundry sand (61%) and drilling mud (21%). Other major export markets were absorbent, decolorizing and clarifying animal oils, desiccant, paint, and refractories. *(See tables 6 and 23.)*

Bentonite imports consisted mainly of untreated bentonite clay and chemically or artificially activated materials. Imports of untreated bentonite decreased 21% to 1,994 tons valued at $664,000. Most of this material was imported from Canada (47%). Imports of chemically activated material decreased 14% to 12,922 tons valued at $10.7 million. Mexico supplied 77% of the chemically activated bentonite imported into the United States. *(See table 24.)*

Fire Clay.—Exports of fire clay decreased 35% to 148,000 tons valued at $14.8 million. Fire clay was exported to 30 countries. The major importers were Japan, Mexico, and the Netherlands. These countries accounted for 68% of the exports. According to the Bureau of the Census, 1,096 tons of fire clay valued at $282,000 was imported in 1993. Most of the fire clay was imported from the Philippines (48%). *(See tables 23 and 24.)*

Fuller's Earth.—Exports of fuller's earth were 63,000 tons valued at $7.6 million. Fuller's earth was exported to 44 countries. The major importers were Canada (14%) and the Netherlands (25%). Domestic producers reported more than 137,818 tons exports in 1993. *(See table 12.)* As with ball clay, the discrepancy between the producers' and the Bureau of the Census' statistics is probably one of clay classification (see discussion under Ball Clay). The major market for exported fuller's earth was pet waste absorbents. Other markets were ceramic tile, foundry sand, cosmetics, oil and grease absorbents, paint, and pesticide carriers. Small amounts of decolorizing fuller's earth (101 tons) were imported from Canada and Germany. *(See tables 12, 23, and 24.)*

Kaolin.—Exports of kaolin reported by the Bureau of the Census were essentially unchanged at 3 million tons valued at $488 million. Kaolin was exported to 69 countries. Major importers were Japan, Canada, Finland, Italy, and the Netherlands. Major end-use markets reported by producers were paper coating (76%) and paper filling (13%). *(See tables 20 and 23.)* Other major markets included paint and rubber.

Kaolin imports for consumption increased 81% to 7,622 tons valued at $3.5 million. The United Kingdom supplied 78% of the kaolin imports. *(See table 24.)*

World Review

World production of kaolin increased 8%, bentonite production decreased 4%, and fuller's earth production increased slightly from productions of 1993. *(See tables 25, 26, and 27, respectively.)*

Australia.—Browns Creek Gold NL continued evaluating a sodium bentonite deposit in New South Wales. The deposit consists of flat to gently dipping beds that are 2 to 10 meters in thickness, extending over an area of at least 6 kilometers by 1 kilometer. Additional drilling is proposed to further delineate the deposit.[20]

Venture Exploration NL began evaluating a kaolin deposit in northern Queensland. The deposit has proven resources of 27 million tons.[21]

Brazil.—The proposed kaolin mine in Rio Capim Quimica remained under study. The mine, which was proposed as a joint venture by Rio Capim Quimica Companhia Vale do Rio Doce and Caemi Mineracao e Metalurgia SA, is in northern Brazil. The kaolin deposit has measured reserves of 40 million tons and estimated reserves of 150 million tons. The companies will focus sales on the papermaking markets in Europe and Asia. The major focus of concern is the environmental impact that the mine and slurry pipeline could have on what is considered to be an environmentally sensitive jungle region.

Canada.—Lang Bay Resources continued its evaluation of a kaolin deposit near Powell River, British Columbia. The company has produced paper-grade kaolin in pilot studies and is looking into local paper markets.[22]

OUTLOOK

U.S. clay demand between 1982 and 1993 has rebounded slowly from 32 million tons to 44 millon tons. This is well below the levels of the early 1970's. In general, there has been a decrease in construction activity in the public, private, and commercial sectors due to a slow economy. Demand for common clay and shale, which are strongly tied to the construction industry, has declined over the past 10 years. Kaolin, ball clay, and fuller's earth have fared better than their common clay and shale counterparts because they are used in more diversified applications and industries. Domestic demand for specialty clays should remain strong in the near future.

[e] Estimated.

[1] Data may not add to totals shown because of independent rounding.

[2] Includes Indiana, Kentucky, Mississippi, Ohio (1993), and Texas.

TABLE 4
BALL CLAY SOLD OR USED BY PRODUCERS IN THE UNITED STATES, BY USE

(Metric tons)

Use	1992	1993
Filler, extenders, and binders[1]	133,137	172,865
Floor and wall tile	202,029	204,676
Miscellaneous ceramics[2]	33,275	39,798
Pottery	113,944	115,825
Refractories[3]	36,075	41,974
Sanitaryware	173,823	185,237
Miscellaneous[4]	61,868	72,790
Exports[5]	99,678	116,085
Total	853,829	949,250

[1] Includes adhesives, animal feed, asphalt tile, paint, paper filling, plastics, rubber, asphalt emulsions, wallboard, and other filler, extenders, and binders.

[2] Includes electrical procelain, fine china/dinnerware, and miscellaneous ceramics.

[3] Includes firebrick, blocks, and shape, high-alumina brick and specialties, kiln furniture, and other uses unknown.

[4] Includes heavy clay products, absorbents, waterproofing seals, brick (common), flue lining, and other uses unknown.

[5] Includes ceramics and glass, fillers, extenders and binders, floor and wall tile, refractories, and other uses unknown.

[r] Revised. W Withheld to avoid disclosing company proprietary data; included with "Other."

[1] Less than 1/2 unit.

[2] Includes Alabama (1993), Arizona, Montana, Tennessee, Texas, Utah, Virginia, and items indicated by symbol W.

[3] Data may not add to totals shown because of independent rounding.

TABLE 6
BENTONITE SOLD OR USED BY PRODUCERS IN THE UNITED STATES, BY USE

(Metric tons)

Use	1992	1993
Domestic:		
Absorbents:		
Pet waste absorbents	[r]148,349	302,055
Other absorbents[1]	[r]145,801	66,436
Adhesives	8,804	5,835
Animal feed	[r]112,478	94,333
Ceramics (except refractories)[2]	31,324	25,805
Drilling mud	[r]481,874	528,424
Filler and extender applications[3]	30,259	28,441
Filtering, clarifying, decolorizing:		
Animal oils, minerals oils and greases, and vegetable oils	116,157	13,678
Foundry sand	[r]487,287	803,420
Pelletizing (iron ore)	[r]505,506	486,716
Miscellaneous refractories and kiln furniture[4]	47,001	69,485
Miscellaneous[1]	243,638	46,038
Waterproofing and sealing	[r]176,224	191,050
Total	[r]2,534,702	2,661,716
Exports:		
Drilling mud	[r]71,994	90,440
Foundry sand	[r]276,549	264,354
Other[5]	[r]70,909	76,447
Total	[r] [6]419,451	431,241
Grand total	[r] [6]2,954,154	3,092,957

[r] Revised.

[1] Includes data that was withheld in 1992, by kind.

[2] Includes catalysts (oil-refinings), glazes, glass, and enamels, mineral wools and insulation, and pottery.

[3] Includes fertilizers, medical, pharmaceutical, cosmetics, paint, paper coating, pesticides and related products, plastics, rubber, asphalt emulsions, and miscellaneous filler and extender applications.

[4] Includes firebrick, blocks, and shapes, plugs, taps, wads, and miscellaneous refractories.

[5] Includes absorbents, ceramics and glass, waterproofing seals, fillers, extenders and binders, animal oils, desiccants, and other uses unknown.

[6] Data do not add to total shown because of independent rounding.

[r] Revised. W Withheld to avoid disclosing company proprietary data; included with "Other."

[1] Includes Florida, Idaho, Minnesota, Montana (1993), New Hampshire, North Dakota, and Tennessee.

[2] Data may not add to totals shown because of independent rounding.

TABLE 8

COMMON CLAY AND SHALE SOLD OR USED BY PRODUCERS IN THE UNITED STATES, BY USE

(Metric tons)

Use	1992	1993
Ceramics and glass[1]	[r]173,251	159,470
Civil engineering and sealing	84,064	84,246
Floor and wall tile:		
Ceramic	[r]404,277	274,218
Other[2]	[r]63,476	100,415
Heavy clay products:		
Brick, extruded	[r]10,251,543	10,909,565
Brick, other	1,603,858	1,453,597
Drain tile and sewer pipe	[r]138,146	142,207
Flowerpots	44,568	35,667
Flue linings	52,113	55,277
Structural tile	36,108	35,005
Other[3]	[r]561,828	581,596
Lightweight aggregate:		
Concrete block	2,113,910	2,214,950
Highway surfacing	252,503	243,277
Structural concrete	[r]723,352	786,786
Miscellaneous[4]	309,868	286,220
Portland and other cements	[r]7,862,445	7,539,952
Refractories[5]	99,518	152,790
Miscellaneous[6]	[r]287,149	230,799
Total	[r]25,061,977	25,286,037

[r] Revised.

[1] Includes crockery/earthenware, pottery, roofing granules, and abrasives.

[2] Includes quarry tile and miscellaneous floor and wall tiles.

[3] Includes roofing tile, terra cotta, and miscellaneous clay products.

[4] Includes miscellaneous lightweight aggregates.

[5] Includes firebrick, blocks and shapes, and miscellaneous refractories.

[6] Includes manufacturing, pelletizing (iron ore), exports, and other uses unknown.

TABLE 9

FIRE CLAY[1] SOLD OR USED BY PRODUCERS IN THE UNITED STATES, BY STATE

(Thousand metric tons and thousand dollars)

State	1992		1993	
	Quantity	Value	Quantity	Value
Alabama	[r]71	[r]2,962	71	2,861
Missouri	178	3,878	208	3,917
Ohio	108	3,258	142	4,136
Other[2]	[r]25	[r]340	37	621
Total[3]	[r]383	[r]10,438	459	11,536

[r] Revised.

[1] Refractory uses only.

[2] Includes Arkansas, Colorado, Georgia, Montana, New Jersey, New Mexico, and Washington.

[3] Data may not add to totals shown because of independent rounding.

TABLE 10

FIRE CLAY SOLD OR USED BY PRODUCERS IN THE UNITED STATES, BY USE

(Metric tons)

Use	1992	1993
Ceramics and glass[1]	16,285	19,146
Heavy clay products and lighweight aggregates[2]	[r]71,329	43,711
Refractories:		
Firebrick, block and shapes	169,873	235,766
Other refractories[3]	[r]103,079	129,706
Miscellaneous	[r]22,804	31,090
Exports	W	W
Total	[r]383,370	459,419

[r] Revised. W Withheld to avoid disclosing company proprietary data; included in "Miscellaneous."

[1] Includes glazes, glass and enamels, and pottery.

[2] Includes brick (common), portland cement, terra cotta, highway surfacing, and other uses unknown.

[3] Includes foundry sand, grogs and calcines, high-alumina brick and specialties, and other uses unknown.

TABLE 11

FULLER'S EARTH SOLD OR USED BY PRODUCERS IN THE UNITED STATES, BY STATE

(Thousand metric tons and thousand dollars)

State	Attapulgite		Montmorillonite		Total	
	Quantity	Value	Quantity	Value	Quantity	Value
1992						
Florida	332	33,767	(1)	(1)	332	33,767

Exports:		
Paint	26,764	74,959
Paper coating	1,357,724	1,683,235
Paper filling	200,639	279,888
Rubber	17,250	4,497
Undistributed[8]	156,562	127,017
Total	1,758,939	2,169,596
Grand total	[r]7,386,607	[9]7,443,201

[r] Revised. W Withheld to avoid disclosing company proprietary data; included in "Undistributed."

[1] Includes high-temperature calcined, low-temperature calcined, and delaminated.

[2] Includes crockery/earthenware, fine china/dinnerware, glazes, glass, and enamels, pottery, roofing granules (1992), sanitaryware (1992), and miscellaneous ceramics.

[3] Includes asphalt tile, fertilizers, gypsum products, medical, pharmaceutical and cosmetics, pesticides and related products, textiles and miscellaneous fillers, extenders, and binders.

[4] Includes data withheld in 1992 for paint and plastic.

[5] Includes brick (common and face), flue lining, portland cement, and miscellaneous clay products.

[6] Includes firebrick, blocks and shapes, grogs and calcines, high-alumina, kiln furniture, and miscellaneous refractories.

[7] Includes chemical manufacturing, civil engineering and sealings, drilling mud, filtering, clarifying, and decolorizing, floor and wall tiles, and other uses unknown.

[8] Includes fiber glass, sanitaryware, ink, miscellaneous fillers, extenders and binders, and other uses unknown.

[9] Data do not add to total shown because of independent rounding.

TABLE 18
SOUTH CAROLINA KAOLIN SOLD OR USED BY PRODUCERS, BY KIND

(Thousand metric tons and thousand dollars)

Kind	1992		1993	
	Quantity	Value	Quantity	Value
Airfloat	370	23,728	391	25,903
Unprocessed	154	819	143	902
Total	[r] [1]523	24,547	534	26,805

[r] Revised.

[1] Data do not add to total shown because of independent rounding.

TABLE 19
SOUTH CAROLINA KAOLIN SOLD OR USED BY PRODUCERS, BY KIND AND USE

(Metric tons)

Kind and use	1992	1993
Airfloat:		
Adhesives	W	W
Animal feed and pet waste absorbent	W	W
Ceramics[1]	2,939	3,435
Fertilizers, pesticides and related products	8,018	6,821
Fiber glass	W	W
Paint	W	W
Paper coating and filling	4,473	W
Plastics	W	W
Rubber	164,728	165,182
Refractories[2]	W	W
Other uses[3]	159,435	185,393
Exports[4]	30,111	30,627
Total	369,704	391,458
Unprocessed: Face brick and other uses	153,672	142,697
Grand total	523,376	534,155

W Withheld to avoid disclosing company proprietary data; included with "Other."

[1] Includes crockery and earthenware, electrical porcelain, fine china/dinnerware, floor and wall tile, pottery, and roofing granules.

[2] Includes refractory calcines and grogs, firebrick, blocks and shapes, refractory mortar and cement, and high-alumina refractories.

[3] Includes animal oil, catalysts (oil refining), chemical manufacturing, ink, medical, sewer pipe, and unknown uses.

[4] Includes ceramics, adhesives, paper filling, pesticides and related products, and rubber.

TABLE 20
KAOLIN[1] SOLD OR USED BY PRODUCERS IN THE UNITED STATES, BY USE

(Metric tons)

Use	1992	1993
Domestic:		
Ceramics:		
Catalyst (oil and gas refining)	[r]46,809	224,359
Electrical porcelain	11,636	16,767
Fine china and dinnerware	15,194	10,393
Floor and wall tile	45,054	11,824
Pottery	23,756	24,123
Roofing granules	10,914	12,234
Sanitaryware	41,321	48,316
Miscellaneous	179,735	157,823
Chemical manufacture	167,484	145,694
Civil engineering	W	20,497
Glass fiber, mineral wool	379,176	346,829
Filler, extender, and binder:		
Adhesive	[r]69,538	69,167
Fertilizer	6,206	W
Medical, pharmaceutical cosmetic	1	1
Paint	242,000	242,192
Paper coating	2,674,908	2,512,890
Paper filling	1,144,302	947,212
Pesticide	12,310	15,839
Plastic	49,061	28,181
Rubber	215,849	243,144
Miscellaneous	169,947	62,736
Heavy clay products:		
Brick, common and face	218,810	223,148
Miscellaneous	18,314	6,532
Portland cement	179,320	207,232
Refractories:		
Firebrick, block and shapes	21,178	48,605
Grogs	[r]859,450	938,304
High alumina brick, specialties, and kiln furniture	31,390	34,496
Foundry sand, mortar, cement, and miscellaneous refractories	62,153	67,504
Miscellaneous applications	32,571	72,111
Total	[r]6,928,387	6,738,153
Exports:		
Ceramics	103,279	63,922
Foundry sand, grogs and calcines; other refractories	W	W
Paint	26,764	75,060
Paper coating	1,402,484	1,683,235
Paper filling	200,874	279,903
Rubber	47,361	35,123
Miscellaneous	26,055	82,169
Total	1,806,817	2,219,412
Grand total	[r]8,735,204	8,957,565

[r] Revised. W Withheld to avoid disclosing proprietary data; included with "Miscellaneous applications" or "Miscellaneous."

[1] Includes high-temperature calcined, low-temperature calcined, and delaminated kaolin.

[e] Estimated. [r] Revised.

[1] Table includes data available through July 26, 1994.

[2] In addition to the countries listed, Canada and China are believed to produce bentonite, but output is not reported, and available information is inadequate to make reliable estimates of ouput levels.

[3] Includes bentonitic clays.

[4] Reported figure.

[5] Year beginning Mar. 21 of that stated.

[6] May include other clays.

[7] Dissolved in Dec. 1991; however, information if inadequate to formulate reliable estimates for individual countries.

[8] Dissolved in Apr. 1992.

[e]Estimated. [r]Revised.

[1] Table includes data available through July 26, 1994.

[2] In addition to the countries listed, China, Lebanon, Morocco, and Suriname may also have produced kaolin, but information is inadequate to make reliable estimates of output levels.

[3] Data for year ending June 30 of that stated.

[4] Formerly part of Czechoslovakia; data were not reported separately until 1993.

[5] Dissolved in Dec. 1992. Production in Czechoslovakia from 1989-92 came from the Czech Republic and Slovakia.

[6] Data for year ending July 6 of that stated.

[7] Includes kaolinitic clay.

[8] Reported figure.

[9] Includes crude and washed kaolin and refractory clays not further described.

[10] Dissolved in Dec. 1991. This commodity is believed to be produced mainly in Uzbekistan and Ukraine; however, information is inadequate to formulate reliable estimates of individual country production.

[11] Kaolin sold or used by producers.

[12] Dissolved in Apr. 1992.

COBALT

By Kim B. Shedd

Ms. Shedd is a physical scientist (geologist) with more than 14 years of combined experience working for the U.S. Bureau of Mines (USBM) in research and mineral commodities. She has been the commodity specialist for cobalt since 1988. Domestic survey data and trade data were prepared by Jo-Ann S. Sterling, statistical assistant; and international production data were prepared by Amy M. Burk and Amy Durham, international statistical assistants, in coordination with USBM country specialists.

Cobalt is a strategic and critical metal used in many diverse industrial and military applications. The largest use of cobalt is in superalloys, which are alloys designed to resist stress and corrosion at high temperatures. The main use for superalloys is in jet engine parts. Another important use of cobalt is to make permanent magnets, which are used in a wide range of electrical devices. Cobalt metal powder acts as a binder in cemented carbides and diamond tools, which are used for metal cutting and forming, mining, and oil and gas drilling. Cobalt compounds are used in catalysts for the petroleum and chemical industries; drying agents for paints, varnishes, and inks; ground coats for porcelain enamels; pigments for ceramics, paints, and plastics; battery electrodes; steel-belted radial tires; and magnetic recording media.

The United States is the world's largest consumer of cobalt, but has no domestic production, so it relies on imports to meet its primary cobalt needs. The United States stocks significant quantities of cobalt metal in the National Defense Stockpile (NDS) for military, industrial, and essential civilian use during a national emergency.

World cobalt production decreased for the third year in a row. Most of the decrease occurred in Zaire, which fell from its historical position as the world's largest cobalt producer to sixth place. Decreasing prices during most of 1993 suggested that there were sufficient supplies of cobalt to meet demand. Russian cobalt, releases from Government and industry stocks, and production increases from Canada, Finland, and Norway contributed to supply, while recessionary economic conditions in some cobalt-consuming countries, decreased defense spending, and a drawdown of consumer stocks held back demand.

DOMESTIC DATA COVERAGE

Domestic data on cobalt processing and consumption are developed by the USBM from three separate, voluntary surveys of U.S. operations. In the cobalt processors survey, seven of the eight companies canvassed responded. Most of the data on cobalt chemical uses were obtained from this survey. The second survey covers a broad range of metal-consuming companies, such as superalloy producers, magnetic alloy producers, and tungsten carbide producers. For this survey, more than 100 cobalt consumers were canvassed on a monthly or annual basis. The USBM also canvasses 13 superalloy scrap recyclers to determine the consumption of secondary cobalt in superalloy production. The data in tables 3 through 6 contain estimates to account for nonrespondents.

BACKGROUND

Definitions, Grades, and Specifications

Cobalt is a metallic element. It is silvery gray in color, hard, ductile, somewhat malleable, and magnetic. Other properties include atomic number, 27; atomic weight, 58.93; melting point, 1,493° C; boiling point, 3,100° C; and Curie temperature, 1,121° C. Cobalt-60 (^{60}Co) is produced by irradiating cobalt metal in a nuclear reactor. This radioactive isotope is used in radiation therapy, for the sterilization of medical supplies, and more recently, to treat fresh foods.

Currently, there are no internationally recognized specifications for cobalt metal. The Zairian and Zambian cobalt producers proposed specifications for five grades of cobalt in 1988.[1] The U.S. Government has purchase specifications for NDS cobalt. The current NDS specification, P-13-R6, has been in effect since December 18, 1985. It provides physical and chemical requirements for three grades of refined cobalt metal. Grades A and B must be in the form of electrolytic cathode; grade C can be either cathode or granules. Chemical requirements specify the weight percentage, in order of abundance, of cobalt, nickel, iron, and manganese, as well as maximum levels of 26 impurities.

Products for Trade and Industry

Less than one-half of the cobalt used in the United States was consumed as primary cobalt metal. Most of this metal was in the form of electrolytic cobalt (cathode or rounds), granules (shot), ingot, or metal powder of various grades (particle-size ranges). About one-fourth of U.S. reported consumption in 1993 was from purchased scrap. Cobalt-bearing scrap originated from alloy processing, parts manufacturing, and used cobalt-containing products. The remainder of the cobalt used in the United States, about one-third of total consumption, was in the form of cobalt chemical compounds. These included cobalt oxide of various types, inorganic cobalt compounds (acetate, carbonate, chloride, hydroxide, nitrate, and sulfates), and organic cobalt compounds.

Industry Structure

More than 90% of the world's cobalt is refined in six countries: Canada, Finland, Norway, Russia, Zaire, and Zambia. Until recently, more than three-quarters of world production was from three countries: Zaire, Zambia, and Russia. Zaire was historically the dominant producer, supplying more than one-third of the world's refined cobalt. The ranking of the top six producing countries changed significantly in 1993. A drastic decrease in production caused Zaire to fall from its position as the world's largest producer to sixth place. Zambia became the world's largest producer. Varying estimates for Russian production place it somewhere between second and fifth place.

Zairian and Zambian production was from domestic ores. Canada and Russia produced cobalt from both domestic and imported raw materials. All of the cobalt produced in Norway and most of the cobalt produced in Finland was from imported raw materials. The United States was not a cobalt producer. U.S. mine production of cobalt ceased at the end of 1971, and the sole U.S. cobalt refinery discontinued processing imported nickel-cobalt matte in late 1985. World producers of refined cobalt and producers of intermediate cobalt-containing products are listed in tables 1 and 2. *(See tables 1 and 2.)*

Cobalt processors represent an important source of supply for various industries. Processors differ from producers in the feed materials they use, although some overlap exists. Producers refine cobalt primarily from materials originating from mining or refining operations—ores, concentrates, mattes, or residues—although some refineries supplement their feedstock with cobalt-bearing scrap. In contrast, processors use refined cobalt metal or cobalt-bearing scrap as feed materials. The world's largest cobalt processor is Union Minière S.A. in Belgium (formerly Metallurgie Hoboken-Overpelt S.A.).

Byproducts and Coproducts

Cobalt is rarely produced as the primary product of a mining or refining operation. Zaire and Zambia produce cobalt as a byproduct of copper. Cobalt production in most other countries is a byproduct of nickel. Exceptions are Morocco, where cobalt is produced as a primary product, and the Republic of South Africa, where cobalt is produced as a byproduct of platinum. Future production from Belgium will include cobalt recovery from residues produced during electrolytic zinc refining. A Canadian company plans to produce cobalt from old silver tailings.

Economic Factors

Most of cobalt's production costs are attributed to the primary metal produced at a given operation. The incremental costs applied to cobalt production include costs to separate cobalt from the primary metal, usually during the refining stage; transportation costs; and marketing costs.

Operating Factors

The U.S. Environmental Protection Agency (EPA) regulates releases of cobalt into the environment under various programs. Workplace exposures are regulated by the Occupational Safety and Health Administration (OSHA). In addition to these regulatory agencies, the following groups issue guidelines or develop scientific positions for consideration by Government agencies when making regulations: American Conference of Governmental Industrial Hygienists (ACGIH), International Agency for Research on Cancer (IARC), and Agency for Toxic Substances and Disease Registry (ATSDR). A review of U.S. environmental legislation and regulation pertinent to cobalt was presented in 1993.[2]

Effective March 23, OSHA reverted back to permissible exposure limits (PEL's) for air contaminants in place before January 19, 1989. The suspension of OSHA's stricter PEL's was the result of a 1992 Federal court decision that OSHA could not issue broad standards for hundreds of chemical substances without scientifically justifying changes to each individual standard. As a result of this change, the PEL for cobalt metal, dust, and fume reverted back to an 8-hour time-weighted average of 0.1 milligram per cubic meter of air (mg/m^3). PEL's set in January 1989 for previously unregulated cobalt carbonyl and cobalt hydrocarbonyl were revoked.

On May 18, ACGIH restated its intention to decrease its threshold limit value (TLV) for cobalt from an 8-hour time-weighted average of 0.05 mg/m^3 to 0.02 mg/m^3. ACGIH TLV's are used by regulatory agencies such as OSHA in setting permissible exposure levels. The proposed change in the TLV was still under consideration at yearend.

ANNUAL REVIEW

Legislation and Government Programs

On March 24, 1993, the Defense Logistics Agency (DLA) began bimonthly sales of cobalt from the NDS. The sales were intended to bring the NDS cobalt inventory down to the goal set in the Department of Defense (DOD) 1992 Report to the Congress on National Defense Stockpile Requirements. Approximately 113 metric tons (250,000 pounds) of cobalt granules was available for sale on the second Wednesday of each month and 45 tons (100,000 pounds) of cobalt rondelles was available on the fourth Wednesday of each month. In August, the DLA increased the quantity of cobalt rondelles available each month to 68 tons (150,000 pounds). In September, the DLA decreased the quantity of cobalt granules available each month to 91 tons (200,000 pounds).

The quality of the cobalt for sale by the DLA reflects the technological requirements in existence at the time of its purchase more than 30 years ago. The cobalt content of the granules ranged from 99.20% to 99.83% and the cobalt content of the rondelles ranged from 98.16% to 99.60% cobalt. During the year, the DLA accepted bids at prices close to those quoted by Metal Bulletin for 99.3% cobalt ingot from Russia. Participants in the bidding included trading firms, chemical processors, alloy producers, a scrap processor, a metal powder processor, and a copper refiner.

The DLA sold 276 tons of cobalt during fiscal year 1993 (October 1, 1992, through September 30, 1993). Sixty percent of the sales was cobalt rondelles (164 tons) and 40% was cobalt granules (112 tons). The sales represented just 13% of the quantity allowable for sale under the Annual Materials Plan (AMP) for the fiscal year—2,087 tons (4.6 million pounds). According to DLA's AMP for fiscal year 1994, the maximum amount of cobalt that could be sold in the year beginning October 1, 1993, also would be 2,087 tons (4.6 million pounds).

The DLA sold 418 tons of cobalt during calendar year 1993. Fifty-eight percent of the sales was cobalt granules (244 tons) and 42% was cobalt rondelles (174 tons). At yearend, the total uncommitted cobalt inventory reported by the DLA was 23,650 tons, contained cobalt. The DOD revised the NDS requirement for cobalt to zero in its 1993 Report to the Congress on National Defense Stockpile Requirements. However, the DOD did not recommend adopting new NDS goals until a DOD strategic review was completed and updated ratios relating demand for manufactured goods to demand for strategic and critical materials were received from the Department of Commerce. At that time DOD was to reestimate NDS requirements and submit a revised set of requirements to Congress.

Strategic Considerations

Cobalt is considered a strategic and critical metal because of its many industrial and defense-related uses and because the United States is highly dependent on imports for its supply. The United States is the world's largest consumer of cobalt. In 1993, the United States consumed about 40% of estimated world refinery production. There was no domestic production, so demand was met primarily from imports, with the exception of about 20% to 25% from purchased scrap.

To ensure an adequate supply for military, industrial, and essential civilian needs, cobalt metal is included in the NDS. Stockpile quantities are intended to sustain the United States for a period of not less than 3 years during a national emergency situation. However, most of the cobalt in the stockpile was purchased prior to 1980 and does not meet current quality requirements for vacuum-melted superalloys.

World cobalt production is concentrated in a limited number of geographic areas. More than one-half of the world's refined cobalt is produced in three countries: Russia, Zaire, and Zambia. Political and economic conditions in the producing countries can impact cobalt production, transportation, and/or exports.

Production

There was no domestic mine or refinery production of cobalt in 1993. Formation Capital Corp., of Vancouver, British Columbia, acquired and explored the Blackpine property southwest of Salmon in Lemhi County, ID. The Blackpine property is a copper-cobalt-gold-silver sulfide deposit in the same mineral belt that contains Noranda Mining Inc.'s Blackbird Mine. Formation Capital's exploration program included geophysics, soil geochemistry, trenching, and drilling. The company is considering three options for possible development: open pit mining followed by heap leaching and solvent extraction; open pit mining followed by milling; and underground mining on the higher grade beds.[3]

U.S. cobalt supply included secondary cobalt from the recycling of superalloy and other forms of scrap. Cobalt was recovered from spent petroleum catalysts at the AMAX Metals Recovery plant in Braithwaite, LA, and by Gulf Chemical and Metallurgical Corp. in Freeport, TX.

Hecla Mining Co. produced cobalt chemicals at its Apex Unit's hydrometallurgical processing plant in St. George, UT. The company reported sales of more than 43 tons of cobalt chemicals in 1993.[4] Hecla continued process trials of cobalt-bearing residues, with plans to develop a business based on the recycling of residues and other cobalt-bearing feedstocks.

Two cobalt processors produced extra-fine cobalt metal powder in the United States. Carolmet, owned by Union Minière of Belgium, produced cobalt metal powder from imported primary metal at its Laurinburg, NC, plant. Osram Sylvania Inc. (formerly GTE Products Corp.) produced cobalt metal powder from recycled materials in Towanda, PA. Production and shipments of extra-fine cobalt metal powder are withheld to avoid disclosing company proprietary data.

Domestic cobalt processors produced 1,979 tons of cobalt contained in cobalt oxide and hydroxide, inorganic cobalt compounds, and organic cobalt compounds in 1993, essentially the same amount as the 1,969 tons produced the previous year. Because this figure includes production of intermediate forms, it does not represent net production. Shipments are defined as sales, transfers, or consumption to make end-use products such as paint driers or catalysts. In 1993, shipments by domestic cobalt processors included 1,793 tons of cobalt contained in cobalt oxide and hydroxide, inorganic cobalt compounds, and organic cobalt compounds, a slight decrease from 1992 shipments of 1,838 tons.

Consumption and Uses

Apparent consumption, as calculated

from net imports, consumption from purchased scrap, and changes in Government and industry stocks increased 12% in 1993 to approximately 7,300 tons. The following factors contributed to the increase: cobalt was shipped from the NDS, industry stocks continued to decrease, and much less cobalt was exported. U.S. reported consumption was unchanged from reported consumption in 1992. As a whole, metallurgical industries consumed approximately the same amount of cobalt in 1993 as they did in 1992. On an industry-by-industry basis, cobalt consumption by superalloy melters and magnetic alloy producers decreased in 1993, while cobalt consumption by producers of cemented carbides, welding materials, mill products from metal powders, steel, and other alloys increased. Total cobalt consumption for chemical uses was essentially unchanged in 1993 as compared with 1992. *(See tables 3, 4, and 5 and figure 1.)*

Stocks

The total amount of cobalt contained in stocks held by U.S. processors and consumers was basically the same as that at yearend 1992. However, 1993 yearend stocks of cobalt metal and scrap were slightly higher than those of 1992 and 1993 yearend stocks of cobalt chemicals were 11% lower than stocks of cobalt chemicals at yearend 1992. *(See table 6.)*

Markets and Prices

During most of 1993, the U.S. spot price for cobalt cathode reported by Platt's Metals Week continued to decline from the high levels of December 1991-January 1992. The highest prices during the year occurred in February and March when the price of cathode increased to $16 to $16.50 per pound. The brief increase in cathode price was in response to reports of renewed violence in Zaire and a tightening of supplies of lower quality Russian cobalt. By mid-March the cathode price resumed its decline and dropped below $11 per pound by early December. The decrease was attributed to weak demand, particularly from Europe and Japan, consumption from stocks, and availability of cobalt on the free market. Russian cobalt imports to Western markets and regular offers of NDS cobalt from the DLA contributed to total cobalt supply, although cobalt from these sources was low quality.

In mid-December, free market prices for both cathode and Russian cobalt rapidly increased. By yearend, the price of cathode was $15 per pound and Russian cobalt exceeded $14 per pound. These price increases reflected a growing concern over cobalt supply prompted by the following factors: delays by the African producers in announcing their 1994 pricing policy; consumers' reduced stock levels resulting from buying on an as-needed basis; press reports that Zaire's Shaba Province, where the copper-cobalt industry is located, declared autonomy from the rest of the country; expectations for reduced production in 1994 from Zambia and from Canadian producer Inco Ltd.; and traders' reports of reduced supplies of Russian cobalt. However, the magnitude and speed of the price increases suggest trader manipulation. Platt's Metals Week reported an average annual U.S. spot cobalt cathode price of $13.79 per pound for the year. *(See table 3 and figure 2.)*

Metal Bulletin reported free market prices for two grades of cobalt—minimum 99.3% cobalt from Russia and higher quality minimum 99.8% cobalt. Prices for the two grades of cobalt more or less paralleled one another, although price increases and decreases for Russian cobalt tended to be steeper than those for the 99.8% cobalt. In January, price quotes for Russian cobalt were $3 to $4 per pound lower than quotes for higher quality cobalt. The price differential narrowed to $2 per pound by March and to $1 per pound in August. In December, price quotes for Russian cobalt overlapped quotes for higher quality cobalt.

The 1993 cobalt producer price was set by La Générale des Carrières et des Mines (Gécamines) of Zaire and Zambia Consolidated Copper Mines Ltd. (ZCCM) at $18 per pound in November 1992. Because of the increasing differential between the producer price and lower free market prices, the African producers reportedly began using free market price quotes as the basis of their transactions by mid-1993.[5] The 1993 price expired on November 20, 1993. At yearend, a new producer price had not been set for 1994. *(See table 7.)*

Foreign Trade

U.S. imports of unwrought cobalt and cobalt in chemicals increased slightly in 1993. More than 90% of these imports was supplied by six countries. Zambia was the leading supplier of cobalt to the United States, followed by Norway, Canada, Finland, Zaire, and Russia. Cobalt imports from Finland, Norway, and Russia increased significantly in 1993 as compared with imports in 1992. *(See tables 8 and 9 and figure 3.)*

In 1993, the United States imported 175 tons, gross weight, of unwrought cobalt alloys valued at $4.7 million. Five countries supplied 94% of these materials: the United Kingdom (53%), Sweden (18%), the Republic of South Africa (14%), France (5%), and Belgium (3%). The United States imported 405 tons, gross weight, of cobalt matte, waste, and scrap, valued at $4.3 million. Four countries supplied 82% of these materials: the United Kingdom (41%), Germany (21%), Japan (15%), and Russia (5%). The United States also imported 172 tons, gross weight, of wrought cobalt and cobalt articles valued at $7.9 million. The leading suppliers of these materials were the United Kingdom (41%) and Japan (30%), followed by Germany (9%), France (6%), and Canada and the Netherlands (5% each).

U.S. net import reliance as a percentage of apparent consumption was estimated to be 79% in 1993. The net import reliance would be 100% if no cobalt was recovered from secondary sources (scrap).

The import duty on cobalt acetates, carbonates, and chlorides was 4.2% ad valorem for most favored nations (MFN) and 30% ad valorem for non-MFN. The duty on cobalt oxides and hydroxides was $0.026 per kilogram for MFN and $0.44 per kilogram for non-MFN. The duty on cobalt sulfates was 1.4% for MFN and 6.5% for non-MFN. Imports of unwrought cobalt metal; cobalt ores and concentrates; and cobalt matte, waste, and scrap were duty free. The duty on unwrought cobalt alloys and wrought cobalt and cobalt articles was 5.5% for MFN and 45% for non-MFN. Special rates of duty are applied to certain cobalt-containing materials under the following programs: Andean Trade Preference Act, Caribbean Basin Economic Recovery Act, Generalized System of Preferences, United States-Canada Free-Trade Agreement, and the United States-Israel Free Trade Area.[6]

U.S. exports of unwrought cobalt and cobalt contained in chemicals decreased 44% as compared with exports in 1992. More than three-quarters of this cobalt was shipped to seven countries: Brazil, Canada, Indonesia, Japan, Mexico, Taiwan, and the United Kingdom. The remainder was shipped to 39 other countries. *(See table 10.)*

Exports also included 249 tons, gross weight, of wrought metal and cobalt articles valued at $11.4 million. More than three-fourths of these materials was sent to eight countries: Canada and the Republic of Korea (each 16%); Norway (10%); France, Sweden, and the United Kingdom (each 8%); and Belgium and Japan (each 6%). The remainder was shipped to 21 other countries. In addition, the United States exported 9 tons, gross weight, of material under the category entitled, "Cobalt ores and concentrates." The material, valued at $77,755, was sent to Canada.

World Review

World cobalt production decreased for the third consecutive year in 1993. Refinery production reported by the seven Cobalt Development Institute (CDI) member producers—Falconbridge Ltd.; Gécamines; Inco Ltd.; OM Group, Inc.; Sherritt Inc. (formerly Sherritt Gordon Ltd.); Sumitomo Metal Mining Co. Ltd.; and ZCCM—decreased 23% from 17,891 tons in 1992 to 13,843 tons in 1993.[7] The decrease was primarily due to the continuing decrease in production by Gécamines, dropping Zaire out of its historical position as the world's largest cobalt producer. If production by Gécamines is excluded, production by the remaining six CDI member producers shows an increase of 3% as compared to production in 1992. Three producers, Falconbridge, OM Group, and Sherritt, reported record-high production levels in 1993. Production by Sumitomo also increased, while production by Inco and ZCCM decreased.

The CDI estimated the following additional cobalt supplies available to Western consumers in 1993: 3,000 tons in nonconsumer stocks from yearend 1992; 1,000 tons produced in Brazil, China, France, and the Republic of South Africa; 420 tons released from the NDS; and 2,000 tons exported from Russia. This resulted in a total availability of approximately 20,260 tons. The CDI concluded that, assuming Western demand was similar to that of 1992 at 19,200 tons, 1993 supply and demand were roughly in balance.

Capacity.—The data in table 11 are rated capacity for refineries as of December 31, 1993. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable long-term operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure. Because not all countries or producers make production capacity information available, historical reported or estimated cobalt production data have been used to estimate refinery capacity in some cases. Changes in refinery capacity can result from changes in facilities, changes in the grade of raw materials processed, and/or changes in knowledge about the facilities. *(See table 11.)*

Australia.—QNI Ltd. produced cobalt sulfide from nickel laterites at the Yabulu nickel-cobalt refinery in Townsville, Queensland. About 85% of the feed for the refinery was imported from Indonesia and New Caledonia. The remainder was from the company's Brolga mine in Queensland, which came on-stream in 1993. During the year the company worked on the construction of a pilot plant for upgrading its cobalt sulfide to value-added products. QNI's cobalt sulfide is currently refined to cobalt metal powder, oxide, and salts by OM Group's Kokkola Chemicals Oy refinery in Kokkola, Finland. Kokkola Chemicals' contract to purchase QNI's cobalt sulfide expires at yearend 1996.

Western Mining Corp. (WMC) produced intermediate cobalt products as a byproduct of mining, smelting, and refining nickel sulfide ores in Western Australia. Some of the nickel-copper-cobalt matte produced at WMC's Kalgoorlie smelter was exported to other refiners, including Sumitomo Metal Mining Co. of Japan. The remainder was refined by WMC at its Kwinana nickel refinery. The Kwinana refinery produced cobalt in a nickel-cobalt mixed sulfide. The mixed sulfide has traditionally been refined by Sherritt Inc. in Canada.

WMC continued its evaluation of the Bulong nickel-cobalt laterite deposit east of Kalgoorlie in Western Australia. The company has been investigating the recovery of nickel and cobalt by acid pressure-leaching at high temperatures. Sulfuric acid for the process could be produced from sulfur dioxide generated at WMC's Kalgoorlie smelter. Current annual production estimates from Bulong are 18,000 tons of nickel and 1,200 tons of cobalt.[8]

MIM Holdings Ltd. continued pilot plant studies on the recovery of cobalt from its Mount Isa copper concentrates by bioleaching. Potential production was estimated at 600 tons of cobalt per year.[9]

Cobalt Resources N.L. was incorporated in May to explore and develop manganese-cobalt deposits in the

Mount Tabor district 125 km northeast of Augathella in central Queensland. The deposits are in the form of cobalt mineralization associated with manganiferous wads (a soft mixture of manganese and other oxides formed in weathering zones). The company planned an exploration program to locate all potential cobalt-bearing occurrences, define minable deposits, and prove reserves. The exploration target was 3 million tons of ore averaging 0.3% cobalt. Based on previous laboratory-scale testing by Commonwealth Scientific and Industrial Research Organization (CSIRO), the following process flowsheet was proposed. Run-of-mine ore would be crushed, then acid leached under agitation with added sulfur dioxide gas. The leached pulp would undergo a solid/liquid separation, cobalt would be selectively recovered by solvent extraction, then cobalt metal would be produced by electrowinning.[10]

Belgium.—Union Minière (UM) converted cobalt metal, residues, and other cobalt-bearing materials into cobalt metal powders, oxides, hydroxide, and chloride at its facilities in Olen, Belgium. During the year, UM developed a process to recover cobalt from residues generated during zinc refining. The company upgraded its Olen facilities to treat a wider range of cobalt-bearing feeds and to increase the throughput of secondary materials from 50 tons per month to 100 tons per month. By treating more secondary materials, UM planned to reduce its annual purchases of cobalt metal by several hundred tons.[11]

Botswana.—BCL Ltd. mined nickel-copper ores from company mines in the Selebi-Phikwe district. Copper-nickel-cobalt matte produced by BCL was sent to refineries in Norway and Zimbabwe to be refined. BCL is 85% owned by Botswana RST Ltd. (BRST). At midyear, Amax Inc. sold its 29.8% interest in BRST to the Botswanan Government.

Brazil.—Cia. Niquel Tocantins produced cobalt cathode at its nickel refinery in Sao Miguel Paulista, Sao Paulo State.

Canada.—Cobalt was produced as a byproduct of nickel by three Canadian companies, Falconbridge, Inco, and Sherritt. In 1993, Falconbridge produced 800 tons of cobalt from nickel-copper ores at its Sudbury, Ontario, operations.[12] Cobalt-containing nickel-copper matte from the Sudbury smelter was refined at Falconbridge's Nikkelverk refinery in Norway.

Inco produced cobalt oxide at its Thompson, Manitoba, refinery and cobalt cathode at its Port Colborne refinery. Feed materials for the two refineries originated from nickel mines in Thompson, Manitoba, and Sudbury, Ontario, respectively. In response to excess supply in the nickel market, Inco reduced its nickel production by 8% in 1993. Production of byproduct cobalt decreased 4%. Inco refined 1,410 tons of cobalt in 1993 as compared with 1,465 tons in 1992.[13]

Sherritt refined nickel-cobalt materials from Australia, Canada, Cuba, and the Republic of South Africa at its Fort Saskatchewan refinery in Alberta. During 1993, Sherritt completed the expansion of its nickel-cobalt refinery. The refinery uses a new cobalt-nickel separation process that can treat a wider range of feed materials. At yearend, the cobalt plant was operating at an annual rate of about 1,600 tons (3.5 million pounds). During a plant performance run in the first quarter of 1994, the cobalt plant was run at the design capacity of about 2,000 tons (4.5 million pounds). In 1993, Sherritt produced a record 1,218 tons of cobalt, an increase of 78% over the 686 tons of cobalt produced in 1992.[14]

Cobatec Ltd., a wholly owned subsidiary of Ego Resources Ltd. of Toronto, developed a hydrometallurgical process to produce cobalt from silver-cobalt tailings and ores from the historic silver mining town of Cobalt, in eastern Ontario. The process involved pressure leaching in the presence of oxygen, solvent extraction, then electrolysis to produce cobalt cathode and byproduct nickel cathode. Ego Resources was considering adjusting the process to produce cobalt compounds. The company planned to begin construction in 1994 of a plant with the capacity to produce approximately 300 tons of cobalt per year. Ego Resources reported that it had acquired sufficient feed for approximately 4 years of full production and planned to acquire additional feed to extend production.[15]

In June 1993, the British Columbia government designated the Tatshenshini-Alsek region in northwestern British Columbia as a protected wilderness area, thus preventing any future development of mineral claims in the region. Geddes Resources Ltd. of Vancouver, British Columbia, terminated the permitting process for its Windy Craggy copper-cobalt-gold deposit and began seeking compensation from the government. The deposit had been called "Canada's largest undeveloped source of cobalt."[16] The company estimated reserves at 297 million tons of ore grading 1.38% copper, 0.069% cobalt, 3.83 grams silver per ton, and 0.2 gram gold per ton.[17]

China.—Cobalt was produced at various locations in China from both domestic and imported raw materials. At Jinchuan, Gansu Province, cobalt metal was produced as a byproduct of nickel from the refining of domestic nickel sulfide ores. The Ganzhou cobalt refinery in Jiangxi Province produced cobalt metal and salts from cobalt arsenide concentrates imported from Morocco. Minor production sites included the Zibo Cobalt Works in Shandong Province, where cobalt metal was produced from iron ore from Shandong Province and copper ore from Shanxi Province.

Côte d'Ivoire.—Falconbridge Ltd. and Trillion Resources Ltd. of Canada signed an agreement with Société de Développement Minière de la Côte d'Ivoire (SODEMI) for the exploration of nickel-cobalt laterite deposits near Biankouma, western Côte d'Ivoire. CRU International Ltd. estimated an annual cobalt output of 1,300 tons in a sulfide precipitate, with 1998 as the earliest startup date for the project.[18]

Cuba.—Unión de Empresas del Níquel (UNI) produced nickel-cobalt sulfides at its Moa Bay plant and nickel-cobalt oxide and oxide sinter at its Nicaro and Punta Gorda plants. All three plants used Cuban laterites as their feedstock. The nickel-cobalt sulfides contained a greater percentage of cobalt than the oxide and sinter, roughly 5% as compared with about 1%. Historically, all of the sulfides were refined at the Yuzhural Nickel refinery at Orsk in the southern Ural Mountains in Russia. Since 1991, some of the sulfides have been refined at Sherritt's Fort Saskatchewan nickel-cobalt facility in Canada. Reports indicate that in 1993, two-thirds of the nickel-cobalt sulfides from Moa Bay were sent to Sherritt and approximately 3,000 tons of sulfides were sent to Yuzhural Nickel.[19]

UNI continued with plans to produce cobalt from its nickel-cobalt intermediate materials. The company hoped to begin production within 5 years, assuming foreign investment was secured to develop the nickel-cobalt separation technology. The cobalt separation plant would be built at UNI's fourth nickel refinery, currently under construction at Las Camariocas. Nickel-cobalt intermediate materials from all four of UNI's nickel refineries would be treated at Las Camariocas. Output from the cobalt plant was forecast at 3,000 tons nickel and 1,000 tons cobalt.[20]

Finland.—In June, Outokumpu Metals & Resources Oy decided to expand and upgrade its Harjavalta nickel refinery. Feed for the Harjavalta refinery was traditionally from Finnish nickel mines. As ore reserves in Finland declined, Outokumpu has imported an increasing amount of its nickel feed from Western Australia. The shift from high-copper Finnish concentrates to high-magnesia Australian concentrates created the need for a change in the refining process. As part of the expansion and upgrade, Outokumpu designed a circuit to refine its cobalt hydroxide sludge to cobalt metal powder. Annual cobalt output was expected to double from about 250 tons to about 500 tons of contained cobalt. Feed for Harjavalta would be primarily concentrates from Outokumpu's Forrestania Mine, which is currently producing, and WMC's Mount Keith Mine, which was expected to begin production in 1995.

In October, Outokumpu sold its entire 96% share of OM Group, Inc. in a public offering. OM Group was formed in October 1991 when Outokumpu and U.S.-based Mooney Chemicals, Inc. merged their chemical businesses. OM Group produces cobalt products at three locations: Kokkola, Finland; Ezanville, France; and Franklin, PA. In 1993, OM Group's Kokkola Chemicals Oy refinery produced a record 2,200 tons of cobalt in cobalt metal powders, oxides, and salts.[21] The refinery uses cobalt sulfide from QNI Ltd. in Queensland, Australia, cobalt slag from Gécamines in Zaire, and cobalt hydroxide sludge from Outokumpu's Harjavalta refinery as its raw materials feed. OM Group planned to build a facility at Kokkola in 1994 to produce carboxylates for the European market.[22] Cobalt carboxylates are used by chemical processing, coatings, and tire industries.

Indonesia.—State-owned PT Aneka Tambang (ANTAM) was under contract to supply 1 million wet tons of lateritic nickel ore to QNI Ltd.'s Yabulu nickel-cobalt refinery in Queensland, Australia. The ore was to come from ANTAM's Oeboelie Mine on Gebe Island in eastern Indonesia.

Japan.—Sumitomo produced electrolytic cobalt, cobalt oxide, and cobalt salts as a byproduct of nickel production at its Niihama Nickel Refinery in Ehime Prefecture. According to Japan's Ministry of International Trade and Industry (MITI), 1993 Japanese cobalt consumption increased 8% to 2,417 tons. Cobalt consumption by industry was reported as follows: cobalt in catalysts increased 8% to 385 tons, cobalt in hard-metal tools decreased 6% to 276 tons, cobalt in magnetic materials increased 15% to 547 tons, cobalt in specialty steels increased 6% to 691 tons, cobalt in tube, plate, rod, and wire increased 15% to 234 tons, and cobalt in other uses increased 16% to 285 tons. Japanese demand for cobalt was met primarily from imports. Japan imported 4,009 tons of cobalt in 1993, a slight decrease from the 4,275 tons imported in 1992. Industry stocks also contributed to supply. In 1993, industry stocks decreased from 1,437 tons of cobalt at the beginning of the year to 1,110 tons at yearend.[23]

Mexico.—International Curator Resources Ltd. of Vancouver, British Columbia, began diamond drilling the Boleo copper-cobalt property near Santa Rosalia, Baja California. The drilling program was designed to confirm and expand the known reserves, quantify the cobalt content, and provide information on rock mechanics. Ore samples were sent for metallurgical testing to confirm the use of solvent extraction-electrowinning to process the ore.

New Caledonia.—Three New Caledonian mining companies were under contract to supply lateritic nickel ore to QNI's Yabulu nickel-cobalt refinery in Queensland, Australia. J.C. Berton Mines was to supply 500,000 wet tons of ore from its Bienvenue Mine, Nickel Mining Corp. was to supply 800,000 wet tons from its Kouaoua Mine, and Société des Mines de la Tontouta was to supply 300,000 wet tons from its Moneo and Nakety Mines.

Inco continued exploring the Goro nickel-cobalt property in southern New Caledonia. A bulk sample of lateritic ore was sent to Inco's research laboratory in Mississauga, Ontario, for extraction trials.

Norway.—The Falconbridge Nikkelverk refinery produced a record 2,414 tons of cobalt cathode in 1993,[24] a 5% increase from the previous record of 2,293 tons set in 1992. Feedstock for the refinery was in the form of matte from company operations in Sudbury, Canada; BCL Ltd. in Botswana; and Norilsk Nickel in Russia. During the past few years, Falconbridge has gradually increased the Nikkelverk refinery's annual cobalt capacity from 2,000 tons to 2,600 tons.

Russia.—Most of the cobalt produced in Russia is a byproduct of Russian nickel mining and/or refining. Nickel and cobalt production in Russia involves a complex flow of ores, concentrates, and mattes between various production sites. Russian nickel-cobalt production is organized into two "Complexes." Norilsk Nickel Complex's production is from nickel sulfide ores mined, smelted, and refined at Norilsk in eastern Siberia and at various locations on the Kola Peninsula. In recent years, Norilsk Nickel has also toll-refined nickel and cobalt-bearing scrap and residues at its Monchegorsk refinery at Kola. Yuzhural Nickel Complex's smelters and refineries are in the Ural Mountains. Feedstock to Yuzhural Nickel's plants has included nickel laterites mined from the Ural region, cobalt-arsenide concentrates mined and beneficiated in the Tuva Autonomous Republic, nickel-cobalt sulfides from Cuba, and white alloy from Zaire.

Cobalt mine and refinery production in tables 12 and 13 for the former U.S.S.R. and Russia were increased based on estimated production from various sources. Production estimates for 1993 ranged from 1,850 tons to 4,200 tons. Russian cobalt continued to enter Western markets in 1993, although reportedly at lower levels than those of the previous year. Russian cobalt exports in 1993 were estimated at 1,000 to 3,000 tons.

South Africa, Republic of.—Cobalt was produced as a byproduct of South Africa's platinum industry. Two companies produced refined cobalt: Rustenburg Base Metal Refiners Pty. Ltd. produced cobalt sulfate and Impala Platinum Ltd. produced cobalt metal powder. A third company, Western Platinum Ltd., produced nickel sulfate containing minor amounts of cobalt. Most of South Africa's cobalt was exported.

According to preliminary figures from South Africa's Minerals Bureau, South African cobalt production decreased 27% in 1993 to 172 tons. Local cobalt sales decreased to 46 tons in 1993 from 50 tons in 1992. Exports of cobalt from South Africa decreased to 196 tons in 1993 from 211 tons in 1992.

Taiwan.—Mechema Chemicals International began production of cobalt acetate catalysts in Taiwan. The company purchased the Mechema name, technology, and plant facilities from Mechema Chemicals Ltd. of Port Talbot, Wales. The Welsh plant was dismantled, then rebuilt in Taoyuan. Cobalt acetate catalysts are used in the production of terephthalic acid, which is used to produce polyester textile fibers and polyethylene terephthalate films and bottles.

Tanzania.—Sutton Resources Ltd. and BHP Minerals International Exploration Inc. continued drilling nickel sulfide deposits in the Kabanga region of northwestern Tanzania and began drilling in the adjacent Kagera region. Sutton reported a resource at Kabanga of 25.5 million tons ore at 1.19% nickel, 0.20% copper, and 0.10% cobalt.

Uganda.—In September, the Kasese Cobalt Co. Ltd. completed a detailed feasibility study on the extraction of cobalt from cobaltiferous pyrites stockpiled at the Kilembe copper mines. The Kasese Cobalt Co. is a joint venture between Uganda's state-owned Kilembe Mines Ltd. (45%), Bureau de Récherches Geologiques et Minières (BRGM) of France (27.5%), and Barclays Metals Ltd. of the United Kingdom (27.5%). The study recommended the construction of a bioleaching-solvent extraction-electrowinning plant to produce 1,000 tons of cobalt cathode per year. The recommendations were based on an extensive analysis of the stockpile, followed by tests on an 8-ton sample at BRGM's laboratories in Orleans, France. A pilot plant was built in Uganda to assist with the engineering design of the commercial plant and training of the plant operators. By yearend, financing for the project was underway with a guarantee of $10 million for direct project investment by the World Bank's Multilateral Investment Guarantee Agency and $40 million insurance to commercial banks lending funds for the project.

Zaire.—The political stalemate in Zaire persisted through 1993, causing sporadic periods of political and social unrest, the postponement of much-needed foreign investment, rampant inflation, and continued shortages of consumables and spare parts at state-owned Gécamines. Under these adverse conditions, Gécamines' cobalt production continued to decrease. In 1993, cobalt supply to Gécamines' concentrators (cobalt content of ore milled) decreased to about 5,000 tons from 13,300 tons in 1992. As a result, the cobalt content of concentrates produced decreased to about 2,500 tons from 5,700 tons in 1992. Gécamines 1993 cobalt production dropped to about 2,100 tons from 6,600 tons produced in 1992. These figures include cobalt in matte, slag, and alloys that require further refining before they can be used by consumers. In terms of finished cobalt (cathode from the Luilu refinery and granules and low-quality cathode from Shituru), Gécamines produced only 831 tons in 1993 as compared with 5,049 tons in 1992. As a result of this large decrease in production, Zaire fell from its historical position as the world's largest cobalt producer to sixth place.

In 1993, increased amounts of cobalt-bearing materials were exported from Zaire to be refined. Early in the year, Gécamines sent 45,000 wet tons of cobalt slag from its Lubumbashi smelter to OM Group's Kokkola refinery in Finland. OM Group took delivery and title to the slag, but was not required to pay for it until it was refined. Gécamines also reportedly sent white alloy and matte to Russia for refining.

In mid-December, press reports stated

that Zaire's Shaba Province, where the country's copper-cobalt industry is located, reverted to its former name Katanga and declared autonomy from the rest of the country. The Province reportedly planned to impose taxes on imports and exports to generate revenue. The Zairian Government did not give an official response to the declaration.

Zambia.—In 1993, Zambia replaced Zaire as the world's largest cobalt producer. ZCCM produced 4,211 tons of cobalt metal between January and December 1993, a 9% decrease from the 4,610 tons produced in calendar year 1992.[25] In addition to refining cobalt concentrates from its mining and milling operations, ZCCM has been treating high-cobalt content smelter slags since July 1992. To improve cobalt quality, ZCCM made the following plant modifications: ion exchange columns were installed at the Nkana refinery to reduce nickel levels, and solvent extraction circuits were installed at both the Nkana and Chambishi refineries to reduce zinc levels. In addition, ZCCM planned to increase the installed capacity at its Nkana refinery from 2,500 tons of cobalt per year to 3,000 tons per year during the financial year beginning April 1, 1994.

ZCCM outlined a major mining project intended to maintain current production levels for the next 25 years or more.[26] The Konkola Deep Mining Project would replace production from the Nchanga open pit. Nchanga currently accounts for about 30% of ZCCM's copper production, but it is expected to be mined out by the year 2001. The Konkola project would involve the sinking of a new shaft system and building a new concentrator. At a mining rate of 6 million tons of ore per year, average annual production would be 180,000 tons of finished copper metal and 600 tons of finished cobalt. The total capital cost of the project was estimated at $545 million in 1991 dollars. Once started, the project was expected to take 6 years to complete.

The Zambian Government commissioned a firm of international consultants to study various options and make recommendations on privatizing ZCCM.

Zimbabwe.—Minor amounts of impure cobalt hydroxide were produced in Zimbabwe as a byproduct of nickel mining and refining. The cobalt hydroxide was exported to be refined. *(See tables 12 and 13.)*

Current Research

The USBM researched methods for recycling magnet scrap. The research included a study of mixed grinding swarf generated during magnet fabrication. The grinding swarf was composed of neodymium-iron-boron and samarium-cobalt alloys, cooling and lubricating oils, and grinding media such as silicon carbide. Variations on three metal-recovery methods were investigated: a single-stage sulfuric acid leach, a two-stage sulfuric acid leach, and a simultaneous flotation-leach process. In the simultaneous flotation-leach process, the neodymium-iron-boron leached and remained in solution while the samarium-cobalt concentrated in the froth and the grinding media concentrated in the tails.[27]

The CDI of Wickford, Essex, United Kingdom, published abstracts on cobalt research, articles on selected cobalt uses, and annual and semiannual data on cobalt production by institute members in quarterly issues of Cobalt News. In September, the CDI held a conference on cobalt supply, chemical and metallurgical uses, occupational and environmental exposure, and legislation.[28]

OUTLOOK

Total world cobalt production continued to decline in 1993. This was primarily because of the ongoing decrease in production by Zaire, which has led to several changes in the cobalt market. Political and economic conditions in Zaire were not resolved, and production was not anticipated to return to former levels in the near term.

Cobalt refiners, processors, and consumers have reevaluated their feed material requirements and, where possible, have been making adjustments to their processes to accommodate a wider range of cobalt materials. Several existing cobalt refiners have increased their capacities, and plans are underway for new refiners to begin production in Canada and Uganda. Belgian production of cobalt from residues generated by the zinc industry also would be considered new production. In terms of quantity, these increases in production will not equal the loss of production from Zaire. In addition, the products made—electrolytic cobalt, metal powders, or chemicals—will determine how the increased production will influence the cobalt market.

Cobalt demand is expected to increase as the economies of the major consuming countries improve. Of particular importance to the cobalt market is the outlook for the aerospace industry because of the quantities and quality of cobalt required to make jet engine parts. Although there may be adequate quantities of cobalt available when demand improves, the question remains whether there will be a shortage of high-quality cobalt. One analyst estimated that in addition to high-quality cobalt from other producers, 1,000 to 2,000 tons of electrolytic cobalt would be required annually from Zaire to satisfy market demand during the next 2 to 3 years.[29] Of the new refiners expected to begin production, only Uganda currently plans to produce electrolytic cobalt. At an anticipated rate of 1,000 tons per year, Ugandan cobalt could help ease, but may not eliminate, a potential shortfall in high-quality cobalt metal. Upgrading lower quality cobalt to higher quality cobalt may become an economically viable solution.

TABLE 1
WORLD PRODUCERS OF REFINED COBALT IN 1993

Country	Company	Cobalt products
Brazil	Companhia Niquel Tocantins	Cathode.
Canada	Inco Ltd.	Cathode, oxide.
Do.	Sherritt Inc.	Metal powder, briquettes.
China	China National Nonferrous Metals Industry Corp.	Cathode,[1] oxide, salts.
Finland	OM Group, Inc.	Metal powder, oxide, salts.
France	Eramet-SLN	Chloride.
Japan	Sumitomo Metal Mining Co. Ltd.	Cathode, oxide, salts.
Norway	Falconbridge Ltd.	Cathode.
Russia	Norilsk Nickel Complex	Ingot, cathode, oxide, salts.
Do.	Yuzhural Nickel Complex	
South Africa, Republic of	Impala Platinum Ltd.	Metal powder.
Do.	Rustenberg Base Metal Refiners Pty. Ltd.	Sulfate.
Zaire	La Générale des Carrières et des Mines.	Cathode, granules.
Zambia	Zambia Consolidated Copper Mines Ltd.	Cathode, crushed bar.

[1] Other metal forms possible.

TABLE 2
WORLD PRODUCERS OF INTERMEDIATE COBALT PRODUCTS[1] IN 1993

Country	Company	Cobalt-containing products
Australia	QNI Ltd.	Cobalt sulfide.
Do.	Western Mining Corp.	Nickel-cobalt sulfide, nickel matte.
Do.	Pacific Smelting and Mining Co. Ltd.	Impure cobalt oxide.
Botswana	BCL Ltd.	Nickel-copper matte.
Cuba	Unión de Empresas del Níquel	Nickel-cobalt sulfide.
Morocco	Compagnie de Tifnout Tiranimine	Cobalt concentrate.
New Caledonia	Société Metallurgique le Nickel	Nickel matte.
South Africa, Republic of	Western Platinum Ltd.	Nickel sulfate, nickel matte.
Zimbabwe	Bindura Nickel Corp. Ltd.	Cobalt-nickel hydroxide.
Do.	Rio Tinto (Zimbabwe) Ltd.	Do.

[1] Excludes companies producing refined cobalt.

TABLE 11

WORLD ANNUAL COBALT PRODUCTION CAPACITY, DECEMBER 31, 1993

(Metric tons, cobalt content)

Country	Refinery capacity
Brazil	300
Canada[1]	3,400
China[e]	500
Finland[e] [2]	3,000
France[3]	600
Japan[2] [4]	2,800
Norway	2,600
Russia[e]	8,000
South Africa, Republic of[2]	750
United States[5]	900
Zaire	18,000
Zambia	5,000
Total	45,850

[e] Estimated.

[1] Includes oxide.

[2] Includes salts.

[3] Cobalt chloride.

[4] Includes an estimated standby capacity of 1,900 metric tons.

[5] Standby capacity.

Total	[r]42,873	[r]42,420	[r]32,906	[r]27,131	22,224

[e] Estimated. [r] Revised.

[1] Table includes data available through July 11, 1994. Figures represent recoverable cobalt content of ores, concentrates, or intermediate products from copper, nickel, platinum, or zinc operations. Morocco was the only country where cobalt was mined as a primary product.

[2] In addition to the countries listed, Bulgaria, China, Germany, Indonesia, and Poland are known to produce ores that contain cobalt, but information is inadequate for reliable estimates of output levels. Other copper-, nickel-, platinum-, or zinc-producing nations may also produce ores containing cobalt as a byproduct component, but recovery is small or nil.

[3] Calculated from reported and estimated weight of nickeliferous ore.

[4] Figures represent cobalt contained in intermediate metallurgical products (cobalt oxide, cobalt sulfide and nickel-cobalt sulfide) produced from Australian and imported ores. Cobalt content of lateritic nickel ore, nickel concentrate, and zinc concentrate originating in Australia was estimated as follows, in metric tons: 1989—2,268 (revised); 1990—1,870 (revised); 1991—1,670 (revised); 1992—1,270 (revised); and 1993—1,270.

[5] Reported cobalt content of pelletized nickel-copper matte.

[6] Figures represent the assay content of cobalt in concentrates produced. The cobalt content of all products derived from ores of Canadian origin, including cobalt oxide shipped to the United Kingdom for further processing and nickel-copper-cobalt matte shipped to Norway for refining, was reported as follows, in metric tons: 1989—2,344; 1990—2,184; 1991—2,171; 1992—2,223 (revised); 1993—2,370.

[7] Reported figure.

[8] Determined from reported nickel-cobalt content of granular and powder oxide, oxide sinter, and sulfide production.

[9] Cobalt content of concentrates.

[10] Series represents estimated recoverable content of ores and intermediate metallurgical products exported from New Caledonia to France. The estimated cobalt content of total ores mined is as follows, in metric tons: 1989—6,000; 1990—6,000; 1991—6,000; 1992—6,000; and 1993—6,000.

[11] All production in the U.S.S.R. from 1989-91 came from Russia.

[12] Dissolved in Dec. 1991.

[13] In addition to concentrates, cobalt hydrates and scrap are used as feed to the refineries. Cobalt content of these materials was as follows, in metric tons: Hydrates: 1989—0; 1990—3,194; 1991—5,483; 1992—4,106; and 1993—not available. Scrap: 1989—27; 1990—49; 1991—517; 1992—1,113; and 1993—not available.

[14] Fiscal years beginning Apr. 1 of that stated. Cobalt content of ore milled was as follows, in metric tons: 1989—10,590; 1990—10,870; 1991—10,976; 1992—11,366; and 1993—8,700 (estimated).

[15] Estimated cobalt content of ore.

TABLE 13

COBALT: WORLD REFINERY PRODUCTION, BY COUNTRY AND PRODUCT[1]

(Metric tons, cobalt content)

Country[2]	1989	1990	1991	1992	1993[e]
Albania: Oxide[e]	10	20	[r]15	[r]3	1

COLUMBIUM (NIOBIUM) AND TANTALUM

By Larry D. Cunningham

Mr. Cunningham, a physical scientist with 14 years of U.S. Bureau of Mines experience, has served as the commodity specialist for columbium and tantalum since 1983. Domestic survey and trade data were prepared by Mr. Dwayne Penn, statistical assistant; and columbium and tantalum world production data, by country, were prepared by Ms. Amy Durham, international data coordinator.

Columbium (Cb) is vital as an alloying element in steels and in superalloys for aircraft turbine engines and is in greatest demand in industrialized countries. Columbium is critical to the United States because of its defense-related uses in the aerospace, energy, and transportation industries. Acceptable substitutes are available for some columbium applications, but in most cases they are less desirable.

Tantalum (Ta) is used mostly in the electronics industry, mainly in capacitors, and in aerospace and transportation applications. Tantalum is also critical to the United States because of its defense-related applications in aircraft, missiles, and radio communications. Substitution for tantalum is made at either a performance or economic penalty in most applications.

Domestic columbium and tantalum resources are of low grade and are not commercially recoverable. The last significant mining of columbium and tantalum was during the Korean conflict when increased military demand resulted in columbium and tantalum ore shortages.

The United States continued to be dependent on imports of columbium and tantalum materials. Brazil remained the major source for columbium imports, and Australia remained the major source for tantalum imports. Columbium and tantalum price quotations remained stable.

The Generalized System of Preferences (GSP), which expired on July 4, 1993, was extended to September 30, 1994. Additionally, legislation prohibiting GSP benefits to the countries that made up the former U.S.S.R. was removed. In September, the President designated Russia as a beneficiary developing country for purposes of the GSP. In October, Congress voted to close down the Department of Energy's (DOE) Superconducting Super Collider (SSC) project in Texas.

There was a slight increase in overall reported consumption of columbium in the form of ferrocolumbium and nickel columbium. Overall demand for tantalum was at the highest level since 1988.

Cabot Corp. acquired a 100% interest in the Bernic Lake, Manitoba, tantalum mining operation of the Tantalum Mining Corp. of Canada Ltd. (Tanco).

DOMESTIC DATA COVERAGE

Domestic production data for ferrocolumbium are developed by the U.S. Bureau of Mines from the annual voluntary domestic survey for ferroalloys. Of the four operations to which a survey request was sent, two responded. Thus, ferrocolumbium production data for 1993 were incomplete at the time this report was prepared.

BACKGROUND—COLUMBIUM

Columbium and niobium are synonymous names for the chemical element with atomic number 41; columbium was the first name given, and niobium was the name officially designated by the International Union of Pure and Applied Chemistry in 1950. The metal conducts heat and electricity relatively well, has a high melting point (2,480° C), is readily fabricated, and is highly resistant to many chemical environments. Columbium exhibits superconductivity at about 9° K, a temperature still too low for most commercial applications. (Superconductivity is the virtual loss of electrical resistance that occurs at a specific material-dependent temperature and results in energy conservation and more rapid operation of electrical circuits.)

Definitions, Grades, and Specifications

Columbium pentoxide (oxide) is a stable, white- to buff-colored compound that is produced in metallurgical, ceramic, and optical grades. Purity of oxide generally exceeds 99%.

Ferrocolumbium is categorized into three grades by American Society for Testing and Materials (ASTM) Specification A550: low-alloy steel grade, alloy and stainless steel grade, and high-purity grade. For all grades, the composition is approximately 65% columbium, with the balance iron; principal impurities are aluminum, silicon, and tantalum. Nickel columbium typically contains 63% columbium, with the balance nickel. Aluminum, iron, silicon, and tantalum are the principal impurities.

Columbium carbide is available as a powder containing about 87% columbium and the balance carbon.

Columbium metal is available in many forms and shapes. Purity of unalloyed metal is usually more than 99%. Iron, tantalum, and zirconium are principal common metallic impurities, and carbon, hydrogen, nitrogen, and oxygen are typical interstitial impurities. Alloys with hafnium, tantalum, titanium, tungsten, and zirconium are of the most commercial importance. Chemical and physical standards for columbium and columbium alloy mill shapes are given in ASTM Specifications B391-B394, B652, and B654-B655.

Products for Trade and Industry

Columbium, in the form of ferrocolumbium, is used worldwide, principally as an additive to improve the strength and corrosion resistance of steel. Columbium-containing, high-strength corrosion-resistant steel is used in applications such as high-strength linepipe, structural members, lightweight components in cars and trucks, and exhaust manifolds. Because of its refractory nature, appreciable amounts of columbium in the form of high-purity ferrocolumbium and nickel columbium are used in nickel-, cobalt-, and iron-base superalloys for applications such as jet engine components, rocket subassemblies, and heat-resisting and combustion equipment. Columbium-base alloys also are used in aerospace applications such as rocket nozzles. Columbium carbide is used in cemented carbides to modify the properties of the cobalt-bonded tungsten carbide-based material. It is usually used with carbides of metals such as tantalum and titanium. Columbium oxide is the intermediate product used in the manufacture of high-purity ferrocolumbium, nickel columbium, columbium metal, and columbium carbide.

Geology-Resources

Columbium is almost always found in nature as an oxide in association with other minerals but not in elemental form or as a sulfide. Columbium has an overall crustal abundance estimated as 20 parts per million and a strong geochemical coherence with tantalum. Pyrochlore and bariopyrochlore (also known as pandaite), its barium analog, have become the main sources of columbium. The minerals contain little tantalum, having a columbium oxide-to-tantalum oxide ratio of 200:1 or greater. Pyrochlore and bariopyrochlore are commonly found in the interior parts of alkalic rock complexes, frequently in association with minerals of such other elements as thorium, titanium, uranium, and those of the rare earths. Columbite, the columbium-rich member of the columbite-tantalite isomorphous series, is normally found in intrusive pegmatites and in biotite and alkalic granites. However, because most such deposits relatively high in columbium content are small and erratically distributed, most columbite has been obtained as a byproduct of mining for other commodities, mainly tin.

Reserve and reserve base data for columbium are shown in table 1 and are based on a judgmental appraisal of current information. Reserve base is defined as the in-place demonstrated (measured plus indicated) resource from which reserves are estimated. The reserve base may encompass those parts of the resources that have a reasonable potential for becoming economically available within planning horizons beyond those that assume proven technology and current economics. Reserves are defined as that part of the reserve base that could be economically extracted or produced at the time of determination. *(See table 1.)*

Technology

Exploration.—Columbium deposits of economic interest are most likely to be found in alkalic rock complexes and associated carbonatites. Aerial photography and geological mapping can be used to reveal alkalic complexes, which frequently occur with circular geometry and concentric rock arrangement. Test pitting and panning can be used to explore placer deposits for columbium by virtue of the high specific gravity of columbium minerals. The columbium content of samples can be determined rapidly by means of truck-mounted spectrographic equipment and X-ray fluorescence spectroscopy.

Mining.—Pyrochlore has been mined mainly by mechanized open pit, underground methods, or a combination of both. Currently, all mining for pyrochlore in Brazil is open pit, whereas in Canada underground mining is being done via a large-diameter blasthole method. Ore, with host rock, is usually dislodged from a working face with explosives. Beneficiation of the ore, after it has been finely ground, is achieved primarily by various flotation procedures combined with magnetic separation to remove iron minerals. A chloridizing and leaching process also can be employed to lower barium, lead, phosphorus, and sulfur contents. Methods used to mine columbite have ranged from simple hand operations in small pegmatite mines to hydraulic monitors and dredges at placer deposits.

Beneficiation.—Pyrochlore concentrates are used solely in the manufacture of ferrocolumbium for steelmaking. Aluminothermy is a process being used for making steelmaking-grade ferrocolumbium from pyrochlore concentrates. Processes also have been developed for production of columbium oxide through treatment of ferrocolumbium produced from pyrochlore concentrates. This technology is being used to produce commercial quantities of columbium oxide suitable for the manufacture of high-purity ferrocolumbium, nickel columbium, and columbium metal.

In the extraction of columbium from other mineral concentrates and tin slags, modern technology makes use mainly of digestion with hydrofluoric acid followed by liquid-liquid extraction with methyl isobutyl ketone (MIBK). This procedure efficiently recovers both columbium and tantalum in the form of separate streams that then can be further processed individually into oxides and metal. Columbium oxide is precipitated from the columbium stream by ammonia and then purified and calcined.

Columbium oxide is aluminothermically reduced batchwise to produce high-purity ferrocolumbium, nickel columbium, and columbium metal. Aluminothermically produced columbium metal is commonly purified to remove aluminum and other contaminants by remelting it in an electron-beam furnace. Several remelts may be required before the desired level of purity is reached and a ductile ingot has been produced. The basic method for production of columbium carbide is reduction of columbium oxide by carbon at high temperature under vacuum or a protective atmosphere.

Recycling.—Columbium used in steelmaking and in superalloy manufacture is essentially a dissipative use, and little is reclaimed. However, when strict scrap segregation practices are followed, small quantities of columbium-bearing superalloy scrap are recycled. Aside from sales to alloy melters, columbium metal scrap has not been recycled to any extent other than in-house as home scrap by processors.

Byproducts and Coproducts

In Africa, Australia, Brazil, Malaysia, and Thailand, columbium, as well as tantalum, is produced as a byproduct and/or coproduct of tin mining. Columbium and tantalum also can be recovered economically from some tin slags, which constitute an important raw material source for high-purity columbium and tantalum. Other elements frequently associated with columbium deposits include rare earths, thorium, titanium, and uranium; some of these have been recovered along with columbium in the past and may be coextracted in the future.

Substitutes

For established applications of columbium-bearing steels and superalloys, substitution of some alternative steel or alloy requiring less columbium ordinarily lowers performance and/or cost-effectiveness. In some high-strength low-alloy (HSLA) steels, use of columbium as a microalloying element competes with use of such elements as molybdenum, titanium, and vanadium. In other HSLA steels, it may be desirable to use one or more of these elements along with columbium in complementary fashion. Tantalum is a costly potential substitute for columbium in superalloys. Titanium can be used instead of columbium in stainless steel to improve corrosion resistance.

Economic Factors

Prices.—Time-price relationships for columbium contained in concentrates in terms of actual prices and in constant 1987 dollars are shown in table 2 and figure 1. Actual prices reported are based on historical price quotations or best available information from producers. *(See table 2 and figure 1.)*

By the end of World War II, new columbium-bearing superalloys were being used in jet airplane engines. Subsequently, the involvement of the United States in the Korean conflict and the rapid expansion of jet engine production during this period resulted in columbium concentrate shortages and increased prices. Additionally, the demand for ore to produce ferrocolumbium had outstripped the available supply of columbium-bearing materials. However, a significant activity during this period was the U.S. Government-guaranteed worldwide 100% bonus purchase program under title III of the Defense Production Act. The program was initiated to encourage increased production of columbium-tantalum ore and concentrates of both domestic and foreign origin.

In May 1952, the Defense Materials Procurement Agency (DMPA) announced its schedule for the purchase of columbium concentrates for the National Stockpile at an average price of $3.40 per pound of combined columbium-tantalum oxides. The program was such a success in the expansion of supply that in only 3 years the stockpile had acquired 6.8 million tons of columbium and tantalum oxides contained in columbium concentrates.

Having achieved its basic objectives, the U.S. Government stopped buying foreign material under the program in May 1955. Small-lot purchases of domestically produced material continued until 1958. The DMPA purchase price largely had governed the market quotations for columbium concentrates, and termination of the program was followed by lower prices and reduced production worldwide.

With the trend of increasing columbium demand, concentrate prices began to escalate in the mid-1970's with the peak year occurring in 1977. The price increase was attributed to inflation, higher labor costs, and resulting higher raw material costs.

In 1980, an important change in the nature of columbium supply occurred with the commercialization both in Brazil and the United States of plants for producing columbium oxide from pyrochlore-based materials. This event resulted in the lowering of prices for columbium oxide and high-purity columbium products. Columbium prices were lowered during much of the 1980's, owing to the large quantities of pyrochlore produced in Brazil and Canada and the products produced from this feed material. Through 1993, columbium prices were essentially the same as those in the late 1980's.

Depletion Provisions.—U.S. columbium-producing companies are granted a depletion allowance of 22% for domestic production of columbium minerals and 14% for foreign production.

BACKGROUND—TANTALUM

Tantalum is a refractory metal that is ductile, easily fabricated, has a high melting point (2,996° C), is highly resistant to corrosion by acids, and is a good conductor of heat and electricity. It combines readily with other refractory metals such as hafnium and tungsten to form alloys having high-temperature strength and stability. Tantalum forms highly stable anodic films and exhibits a rectifying, or electronic valve, action in an electrolyte. Tantalum is twice as dense as steel with a specific gravity of 16.6.

Definitions, Grades, and Specifications

Metallic forms of tantalum are produced chiefly in unalloyed form or alloyed with up to about 10% tungsten. Unalloyed metal and alloys with tungsten are available as ingot, plate, sheet, strip, bar, rod, wire, and tubing in accordance with ASTM Specifications B364, B365, and B521. Allowable impurity levels do not exceed 0.3% in most cases; the main impurities are columbium and oxygen, plus tungsten in the case of unalloyed tantalum. Purity of tantalum metal powder is usually about 99.9%. Depending on powder usage, impurities that must be controlled consist mainly of calcium, carbon, columbium, iron, nickel, nitrogen, oxygen, silicon, and sodium. Commercial tantalum carbide usually contains about 93% tantalum and about 6.3% carbon.

Products for Trade and Industry

The major end use for tantalum, as tantalum metal powder, is in the production of electronic components, mainly tantalum capacitors. Applications for tantalum capacitors include computers, communication systems, and instruments and controls for aircraft, missiles, ships, and weapon systems. The tantalum capacitor exhibits reliable performance and combines compactness and high efficiency with good shelf-life. Because of its high melting point, good strength at elevated temperatures, and good corrosion resistance, tantalum is combined with cobalt, iron, and nickel to produce superalloys that are employed in aerospace structures and jet engine components. Tantalum carbide, used mostly in mixtures with carbides of such metals as columbium, titanium, and tungsten, is used in cemented-carbide cutting tools, wear-resistant parts, farm tools, and turning and boring tools. Because of its excellent corrosion-resistant properties, tantalum mill and fabricated products are used in the chemical industry in applications such as heat exchangers, evaporators, condensers, pumps, and liners for reactors and tanks.

Geology-Resources

The principal source of tantalum is an isomorphous series of minerals containing columbium, iron, manganese, and tantalum oxides. Tantalum and columbium have strong geochemical affinity and are found together in most rocks and minerals in which they occur. Tantalite-columbite occurs mainly as accessory minerals disseminated in granitic rocks or in pegmatites associated with granites. The microlite-pyrochlore mineral series is also a source of tantalum. These minerals consist essentially of complex oxides of calcium, columbium, sodium, and tantalum in combination with hydroxyl ions and fluorides. Microlite occurs mainly in the albitized zones of granite pegmatites, often associated with tantalite or columbite. Struverite is a low-grade source of tantalum recoverable from tin-mining wastes in Southeast Asia. Struverite is a variation of the titanium mineral rutile. Tantalum also is obtained through byproduct recovery from tantalum-bearing tin slags, principally from smelters in Brazil and Southeast Asia.

Reserve and reserve base data for tantalum are shown in table 3 and are based on a judgmental appraisal of current information. Reserve base is defined as the in-place demonstrated (measured plus indicated) resource from which reserves are estimated. The reserve base may encompass those parts of the resources that have a reasonable potential for becoming economically available within planning horizons beyond those that assume proven technology and current economics. Reserves are defined as that part of the reserve base that could be economically extracted or produced at the time of determination. *(See table 3.)*

Technology

Exploration.—Exploration for tantalum is generally pursued on the basis of its known frequent association with tin and certain other elements in pegmatite environments, some features of which can be distinguished by aerial photography. Application of X-ray fluorescence analysis techniques has been helpful in measuring tantalum at the low concentrations at which it occurs. The high specific gravity of tantalum minerals makes it possible to reveal their presence in placer deposits by test pitting and panning.

Mining.—Most tantalum-related mining developments in the past generally were small, relatively high-cost intermittent operations that depended on the recovery of byproduct or coproduct minerals for economic viability. However, current mine development has shifted more to primary tantalum sources, notably operations in Australia.

Both alluvial and residual tantalum and tantalum-containing tin deposits are normally mined by hand, by hydraulic monitors, by dredges, or by mechanized open pit mining. The mining of pegmatite deposits, which may be either open pit or underground, is carried out by blasting, transporting, and crushing the rock to free the tantalum and associated coproduct minerals. The materials are then concentrated by wet gravity methods (sluices, jigs, spirals, and tables) and finally separated from associated minerals by gravity and electrostatic and electromagnetic processes.

Tantalum is recovered from slags produced at tin smelters throughout the world. Tantalum content varies in tin slag depending on ore and smelting practice.

Beneficiation.—Tantalum mineral concentrates and tin slags are the predominant feed materials for preparation of tantalum metal and compounds. Both raw materials usually contain recoverable amounts of columbium as well. Depending on circumstances, tin slags may be used directly for extraction of tantalum or they may be first upgraded. Upgrading is typically performed by means of an electric furnace process that yields a synthetic concentrate.

In the extraction of tantalum from these source materials, technology makes use mainly of digestion with hydrofluoric acid followed by liquid-liquid extraction with MIBK. This procedure efficiently recovers both tantalum and columbium in the form of separate streams that then can be further processed individually into salts, oxides, and metal. The two streams are produced by a series of countercurrent extractions that also remove impurities. The tantalum product stream is a fluotantalic acid solution from which either potassium fluotantalate (K-salt), by addition of potassium chloride or fluoride, or tantalum pentoxide, by addition of ammonia, can be precipitated. Reducing K-salt by sodium is the standard commercial method for making tantalum metal. The product of sodium reduction is a powder that is consolidated by a pressing, vacuum sintering, and melting sequence.

Tantalum carbide can be manufactured by several methods, the most common being solid-state reaction between tantalum oxide and carbon. Tantalum carbide also can be made by reacting metallic tantalum directly with carbon.

Recycling.—Recycling of tantalum largely takes place within the processing and product-producing industry and is mostly runaround or home scrap that is consumed internally. In addition, quantities of tantalum are recycled indirectly in the form of used tantalum-bearing cutting tools and high-temperature alloy melting scrap.

Byproducts and Coproducts

Economic exploitation of tantalum minerals often is dependent on the price of associated recoverable byproduct or coproduct minerals, principally tin and columbium. Tantalite-columbite minerals occur in deposits associated with beryllium, lithium, rare-earth, tin, titanium, tungsten, uranium, and zirconium minerals. Minerals associated with tantalum in pegmatite deposits include beryl, feldspar, lepidolite, mica, pollucite, and spodumene. Tantalum and columbium also can be recovered economically from some tin slags, which constitute an important raw material source for tantalum and high-purity columbium. Tantalum is usually extracted in conjunction with columbium with much the same type of equipment.

Substitutes

Substitution for tantalum is usually made at a performance or economic penalty for most uses. Also, substitution requires both investment and experimentation and does not necessarily occur quickly. Aluminum and ceramics compete strongly with tantalum for use in electronic capacitors. In cemented carbides, columbium carbide and columbium-hafnium carbide can take the place of tantalum carbide in some cutting tools. Replacements for tantalum in corrosion-resistant equipment are columbium, glass, platinum, titanium, and zirconium. Columbium, hafnium, molybdenum, tungsten, and some platinum-group metals can be substituted for tantalum in high-temperature applications.

Economic Factors

Prices.—Time-price relationships for tantalum contained in concentrates in terms of actual prices and in constant 1987 dollars are shown in table 4 and figure 2. Actual prices reported are based on historical price quotations or best available information from producers. The prices show large swings between the high and low in response to market conditions. *(See table 4 and figure 2.)*

The Korean conflict in 1950 increased demand for tantalum in military requirements. Thus, consumption rose sharply with resulting ore shortages. During this period, the U.S. Government-guaranteed worldwide 100% bonus purchase program was initiated to increase production of columbium-tantalum ore and concentrates of both domestic and foreign origin. In May 1952, a schedule was announced for the purchase of 15 million pounds of the combined columbium-tantalum oxides at prices about double prevailing world prices. The program had the effect of increasing tantalum ore prices to a high of $8 per pound of oxide.

Having achieved its basic procurement objectives, the purchase of foreign material was stopped in May 1955. Small-lot purchases of domestically produced material continued until December 1958. When Government purchase of domestic ore stopped, the immediate effect was a confused market in which production and prices of ore began to drift downward. By 1959, prices for tantalum ore had dropped to about $4 per pound of oxide.

By 1960, tantalum demand for use in capacitors, high-temperature alloys, corrosion-resistant chemical applications, machine cutting tools, and aerospace applications had increased substantially. During the 1960's, the variations in supply and demand resulted in a repetition of 2 or 3 years of oversupply with lower prices followed by 2 or 3 years of high demand with higher prices. Price peaks in 1961 and 1966 were occasioned by a sudden increase in demand for tantalum, which outstripped the supply, driving prices up. This cyclical trend continued into the 1970's.

The 1970's can be characterized as a decade of increasing tantalum demand, ore shortages, escalating prices, and substitution. A 7-year trend of declining price, 1967-73, was followed by a trend of rapid price increase that was sustained through midyear 1980. The record price levels during this period were attributed in part to a state of panic buying influenced by anticipated greater tantalum demand amidst concerns at the time of a shrinking world tantalum supply. The high prices brought about substitution for tantalum and more widespread search for and development of new tantalum sources. However, prices began declining by yearend 1980 and by midyear 1986 were the lowest since first quarter 1977, hastened by a weak tantalum demand and an increase in tantalum material stockpiles. Subsequently, prices rebounded through yearend 1988 and were at the highest level since the third quarter of 1981, responding to increased demand for feed materials along with the drawdown of stockpiles. The price of tantalum continued its cyclic pattern with the 1993 average price quote at about $26 per pound of oxide, the lowest level since 1987.

Depletion Provisions.—U.S. tantalum-producing companies are granted a depletion allowance of 22% for domestic production of tantalum minerals and 14% for foreign production.

ANNUAL REVIEW—COLUMBIUM AND TANTALUM

Legislation and Government Programs

At yearend, the National Defense Stockpile (NDS) overall goal for the columbium group was 5.047 million kilograms, and the overall goal for the tantalum group was 3.959 million kilograms. Government inventoried stocks of columbium and tantalum materials in the NDS had decreased by 5% and 6%, respectively, compared with those at yearend 1992. *(See table 7.)* The decline in stocks results from the columbium and tantalum upgrade program initiated in 1992. In its fiscal year 1992 Annual Materials plan for the NDS, the Department of Defense provided for the upgrading of some existing columbium and tantalum materials. In September 1992, the Defense Logistics Agency contracted with Cabot Performance Materials (CPM), Boyertown, PA, and Hermann C. Starck Inc. (formerly NRC Inc.), Newton, MA, to conduct the upgrade program. CPM will convert quantities of Government-owned (stockpiled) columbium-tantalum concentrates (materials) into vacuum-grade columbium and tantalum metal ingot pieces and upgrade Government-owned columbium metal powder to vacuum-grade columbium metal ingot pieces. Starck will upgrade Government-owned tantalum metal powder to vacuum-grade tantalum metal ingot pieces.

In August, the U.S. Trade Representative announced that the GSP, which had expired on July 4, 1993, was extended to September 30, 1994. The GSP extension was part of the Budget Reconciliation Act signed by the President. The legislation extending the GSP was retroactive to July 4. Additionally, the legislation removed the statutory prohibition against providing GSP benefits to the countries that made up the former U.S.S.R. Under GSP, the United States grants duty-free access to goods from more than 140 developing countries and territories. U.S. import duties for columbium and tantalum products range from duty free to 5.5% ad valorem for most-favored-nation (MFN) status and from duty free to 45% ad valorem for non-MFN status.

In Proclamation 6599 of September 30, 1993, the U.S. President designated Russia as a beneficiary developing country for purposes of the GSP. GSP status for Russia is part of the administration's overall efforts to help that country pursue badly needed market reforms. Kazakhstan, Romania, and Ukraine also were being considered for GSP status.

In October, Congress voted to close down DOE's Superconducting Super Collider (SSC), particle accelerator, project in Texas. All Federal funds for the SSC were halted except for $640 million in fiscal year 1994 for the orderly termination of the project. The SSC was approved for construction in 1987 at a cost of about $4 billion with a targeted completion date in 1996. At the time of its termination, cost estimates for the SSC had escalated to about $11 billion, with about $2 billion reportedly having already been spent. Superconducting magnets reportedly using about 1 million pounds of a 50% columbium-50% titanium alloy would have been used in the project.

Strategic Considerations

The high degree of import reliance for columbium and tantalum is the principal strategic problem faced by the United States. Summaries of important columbium and tantalum statistics are shown in tables 5 and 6, respectively. In the case of both columbium and tantalum, there has been no significant mining since the 1950's. Domestic columbium and tantalum resources are of low grade, some mineralogically complex, and most are not currently commercially recoverable. To ensure a supply of columbium and tantalum during an emergency, goals for both materials have been established for the NDS. However, inventories for both materials are substantially under set goals. Consequently, a degree of vulnerability still remains. *(See tables 5 and 6.)*

The NDS inventory for both columbium and tantalum are mostly in the form of source materials (feedstocks). However, the United States has become more reliant on the processing capability of foreign sources and the availability of intermediate products from those sources. At the start of the 1980's, there were four major processors of columbium- and tantalum-bearing source materials. One of the operations was shut down in 1985, and another shut down its processing operation at yearend 1989. Of the remaining two companies, one is dedicated solely to the processing of columbium materials and the other company processes both columbium and tantalum materials. Thus, there is some concern whether the United States would have on hand in an emergency adequate processing capacity for conversion of the stockpile materials to an upgraded form and quality required by the critical end uses. However, in 1992, the Defense Logistics Agency contracted with a U.S. company to convert (upgrade) some of the Government-owned columbium-tantalum concentrates (minerals) into vacuum-grade columbium and tantalum metal ingot pieces.

Production

In 1993, there were two processors of columbium- and tantalum-bearing source materials that were integrated from raw material processing to columbium and tantalum end products: Cabot Corp. for columbium and tantalum processing and Shieldalloy Metallurgical Corp., dedicated solely to columbium processing. Hermann C. Starck Inc., a major supplier, and Thai Tantalum Inc. produced tantalum products. Reading Alloys Inc. and Teledyne Wah Chang Albany were major producers of high-purity columbium products. Kennametal Inc. was the major producer of columbium and tantalum carbides.

Cabot Corp., Boston, MA, reported that its CPM business, Boyertown, PA, had acquired the remaining two-thirds interest in the Bernic Lake, Manitoba, tantalum mining operation of Tanco for an undisclosed sum. CPM, a major world processor of tantalum raw materials, already held a one-third interest in Tanco. Tanco is the sole Canadian producer of tantalum feed material. CPM's acquisition reportedly strengthened its raw materials supply position and insulated itself and its customers from dramatic material price swings.[1] Additionally, CPM reportedly purchased a second 1,200-kilowatt electron beam furnace for its boyertown plant for the production of columbium and tantalum metal.[2]

Kennametal Inc., Latrobe, PA, acquired an 81% interest in the German company Hertel AG, a major manufacturer of cemented carbide tools and tooling systems. The cost of the purchase consisted of $43 million in cash and $44 million of assumed debt. The transaction significantly increases Kennametal's access to European and Asia-Pacific markets.[3]

Metallurg Inc., New York, NY, a supplier of specialty alloys and metals, announced in September that it had filed a voluntary petition for protection from its creditors under chapter 11 of the U.S. Bankruptcy Code. Included in the filing was Shieldalloy Metallurgical Corp. and its manufacturing plant in Newfield, NJ.[4] Shieldalloy is a major U.S. producer of ferrocolumbium for steelmaking.

Consumption and Uses

Overall reported consumption of columbium as ferrocolumbium and nickel columbium increased slightly compared with that of 1992. *(See table 8.)* Consumption of columbium by the steelmaking industry increased by 2%, in line with a 5% increase in raw steel production. There was about a 4% decrease in the percentage of columbium usage per ton of steel produced. Columbium consumption in HSLA steel rose by about 10%, while columbium consumption in carbon, and stainless and heat-resisting steels were down. Demand for columbium in superalloys was down by about 9%. However, that portion used in the form of nickel columbium increased to about 160,000 kilograms.

Overall consumption of tantalum was up to 410,000 kilograms, the highest level since 1988, aided by increased consumption of capacitor-grade tantalum powder in the electronics sector. Factory sales of tantalum capacitors rose by about 20%, as reported by the Electronic Industries Association.

Markets and Prices

A published price for pyrochlore concentrates produced in Brazil and Canada was not available. A price for Brazilian pyrochlore has not been available since 1981, and the published price for Canadian pyrochlore was suspended in early 1989. Unchanged since June 1989, the Platt's Metals Week published price for regular-grade ferrocolumbium, produced from pyrochlore concentrates, was $6.58 per pound of contained columbium, f.o.b. shipping port.

The Metal Bulletin published price for columbite ore quoted since March 1990 at a range of $2.60 to $3.05 per pound, on the basis of a minimum 65% contained Cb_2O_5 and Ta_2O_5, fell to a range of $2.40 to $2.80 per pound in May, where it remained through December. For the year, the Metals Week published price for columbium oxide was quoted at $8.17 per pound of oxide; the published price for high-purity ferrocolumbium containing 62% to 68% columbium was quoted at $18.50 per pound of contained columbium, f.o.b. shipping point; the published price for nickel columbium was quoted at $20.50 per pound of contained columbium; and the published price for columbium metal was quoted at a range of $30 to $50.

The Metals Week published spot price for tantalite ore, on the basis of contained Cb_2O_5 and Ta_2O_5, c.i.f. U.S. ports, fell from a range of $28 to $30 to a range of $25.50 to $26.50 in late March, where it remained through December. The Metal Bulletin published price for tantalite fell from a range of $30 to $33 per pound of contained Ta_2O_5 to a range of $28 to $32 in early February, where it remained through December. The Metal Bulletin published price for tantalite produced by Greenbushes Ltd. of Australia on the basis of 40% contained Ta_2O_5 was unchanged throughout the year at $40 per pound. A published price for tantalite from the Canadian producer, Tanco, was not available. Industry sources indicated that tantalum mill products continued to be sold at an average of about $170 per pound, depending on specification, and that tantalum capacitor-grade powder continued to be sold at about $145 per pound.

A published price for columbium and tantalum carbide was not available.

Foreign Trade

Data for exports and imports are summarized in table 9. Net trade for columbium and tantalum continued at a deficit and was at the highest level since 1989. Overall trade value for exports was down by 8%, with total volume up slightly. For imports, trade value was down by 2%, with total volume down by 10%. *(See table 9.)*

Imports for consumption of columbium mineral concentrates continued to decline. *(See table 10.)* Canada was the leading supplier, providing more than 90% of both total quantity and total value. Imports at an average grade of approximately 60% Cb_2O_5 and 1% Ta_2O_5 were estimated to contain 970,000 kilograms of columbium and 25,000 kilograms of tantalum.

Imports for consumption of tantalum mineral concentrates were down by 8%, with a slight decrease in the average unit value for overall imports. *(See table 11.)* Imports from Australia, Brazil, and Rwanda (producing countries) accounted for more than 60% of both total quantity and total value. Imports at an average grade of approximately 35% Ta_2O_5 and 27% Cb_2O_5 were estimated to contain 365,000 kilograms of tantalum and 240,000 kilograms of columbium.

Imports for consumption of synthetic tantalum-columbium concentrates totaled 36,000 kilograms valued at $912,000 compared with no imports in 1992. These figures are not included in the salient statistics data.

The schedule of applied tariffs during 1993 to U.S. imports of selected columbium and tantalum materials is given in table 12. Brazil continued to be the major source for U.S. columbium imports, accounting for 60% of the total, and Australia remained the major source for U.S. tantalum imports, accounting for about 30% of the total. *(See table 12 and figures 3 and 4.)*

World Review

Industry Structure.—Principal world columbium and tantalum raw material and product producers are shown in tables 13 and 14, respectively. Brazil and Canada remained the major producers of columbium raw materials feedstock, while tantalum raw materials continued to be produced mainly in Australia, Brazil, and Canada and in Thailand in the form of high-grade tantalum-bearing tin slags. Synthetic concentrates, produced from low-grade tin slags from Germany, were an additional source of columbium and tantalum raw material supply. Annual world production of columbium and tantalum mineral concentrates, by country, is given in table 15. World tantalum supply in 1981-93 is shown in figure 5. *(See tables 13, 14, and 15 and figure 5.)*

Australia.—For its fiscal year ending June 30, 1993, Gwalia Consolidated Ltd. reported that tantalum oxide production in tantalum concentrates (tantalite) at its Greenbushes Mine, southwest Western Australia, was about 134 tons compared with about 197 tons the previous year. Most of the tantalite production was sold to overseas markets. Company sales of tantalum products were down by about 25% to 136 tons, reflecting a depressed tantalum industry in Europe and a weak spot market for the product. Gwalia is the world's largest producer of tantalum concentrates, with long-term contractual relationships with processors in Germany and North America.[5]

As reported by Pancontinental Mining Ltd. for its fiscal year ending June 30, 1993, tantalum production at the Wodgina Mine was about 94 tons of tantalum oxide contained in concentrate compared with about 107 tons the previous year. The decrease in production was attributed to the processing of lower grade tantalum ores.[6] Pancontinental has a 50% interest in, and is the operator of, the Wodgina tantalum mine, which is located in the Pilbara region of Western Australia.

Brazil.—The TEX Report reported that Brazil's production of columbium oxide in concentrates was 13,900 tons, 10,430 tons produced by Cia. Brasileira de Metalurgia e Mineração (CBMM) and 3,470 tons produced by Mineração Catalào de Goiás S.A. (Catalão). Brazil's consumption of columbium was 1,050 tons, down 13% from that of the previous year.

In December, Brazil's Commerce Secretariat reportedly proposed a 5% import duty on aluminum, cast iron, cobalt, ferroalloys, lead, and zinc. The duty was proposed at the request of domestic producers claiming a need for protection due to low world prices, increased imports from countries of the former U.S.S.R., and exchange rate difficulties. Brazil's domestic consumers, the aluminum association, and the nonferrous metals institute opposed the introduction of the proposed 5% import duty.[7]

Canada.—As reported by Teck Corp., production of Cb_2O_5 at the Niobec Mine at St. Honoré, Quebec, increased to about 3.42 million kilograms, the highest level since 1989. Niobec is a 50-50 joint venture between Teck, operator, and Cambior Inc., product marketing. Ore milled was about 812,000 tons, as the mill operated on the average of 2,225 tons of ore per day. Average recovery was 59.9% with Cb_2O_5 grade of concentrate at 70%. Teck reported that ore reserves, at the current rate of production, are sufficient for another 12 years. For the year, operating changes at the mine included automation of the grinding and flotation circuits. A completed feasibility study indicated that a capital investment of $7.5 million would be required to establish a concentrate convertor facility at the mine site. In late 1993, a decision was made to build a ferrocolumbium plant with startup of construction beginning in early 1994. Completion of construction is anticipated by yearend 1994. Once the plant is operational, Niobec will commence marketing ferrocolumbium in lieu of columbium concentrates.[8]

Since midyear 1992, tantalum mining at the Bernic Lake, Manitoba, tantalum operation of Tanco has remained suspended. However, about 40,000 kilograms of contained tantalum oxide was produced from tailings retreatment.

Japan.—According to The Tex Report, Japan's production of ferrocolumbium rose to 1,213 tons from the 1,002 tons reported in 1992. Columbium ore imported for ferrocolumbium production increased substantially to 2,045 tons, with Canada accounting for about 80% of the total. Ferrocolumbium imports increased to 4,361 tons from the 4,187 tons reported in 1992. Brazil accounted for most of the ferrocolumbium imports. Japan's demand for ferrocolumbium for steelmaking totaled 4,574 tons, an alltime high, compared with 4,412 tons in 1992.

Roskill's Letter from Japan reported that Japan's demand for tantalum, in the form of powder, compounds, and products, was 225 tons compared with 217 tons in 1992. Japan's imports of tantalum powder, compounds, and products fell to 53 tons from the 63 tons in 1992.

Thailand.—In March, it was reported that the Thai Tantalum Co. Ltd. was anticipating that its tantalum facility in Rayong Province would reach full annual production capacity by midyear 1993, about 450 tons of potassium fluotantalate (K-Salts) and about 45 tons of capacitor-grade tantalum powder. Tantalum production will be for export, likely to Japan and the United States.[9]

OUTLOOK

Columbium

The major components of U.S. supply-demand relationships for columbium in 1983-93 are given in table 16. Columbium is used principally as an additive in steelmaking, which annually accounts for more than 80% of U.S. reported consumption. No significant change to this trend is expected in the near term because there are few other significant growth markets and/or uses for columbium. Thus, future columbium demand growth will continue to be directly related to the worldwide performance of the steel industry. U.S. apparent consumption of columbium has been in the range of 3,300 to 3,500 tons of contained columbium for the period 1989-93. Any major future variations from this trend will depend on future activities of the domestic steel industry. The outlook for steel is discussed in the annual report for iron and steel. The outlook for columbium also will be dependent to a lesser degree on the performance of the aerospace industry. In recent years, reported domestic consumption of columbium in the production of superalloys continues to be no more than 20% of total demand. In 1993, columbium consumption in the production of superalloys decreased by more than 35% compared with that of the previous year. Future growth for this end use will be affected mainly by the demand for columbium-containing superalloys by the aircraft industry. Continued reduction in military spending is expected to lead to reduced aerospace shipments throughout the decade. *(See table 16.)*

Tantalum

The major components of U.S. supply-demand relationships for tantalum in 1983-93 are given in table 17. For the past decade, more than 60% of the tantalum consumed in the United States was used to produce electronic components, mainly tantalum capacitors, with major markets in recent years being computer and communication systems. In 1993, U.S. factory sales of tantalum capacitors were at an alltime high, an increase of 60% over that in 1990. However, overall tantalum demand growth in this sector has been slowed owing to the industry's continued emphasis on higher capacitance powders and the miniaturization of electronic components resulting in less tantalum used per unit. Tantalum demand in the cemented carbide sector continues to decline owing to the growing use of mixed carbides, coated cutting tools, improved tool life, and the downsizing of components. *(See table 17.)*

---

[r] Revised. NA Not available.

[1] Includes columbium and tantalum in ferrotantalum-columbium, if any.

[2] Included with "Steel: High-strength low alloy."

[3] Included with "Steel: Unspecified."

[4] Included with "Miscellaneous and unspecified."

[5] Ferrocolumbium only.

TABLE 9
U.S. FOREIGN TRADE IN COLUMBIUM AND TANTALUM METAL AND ALLOYS, BY CLASS

(Thousand kilograms, gross weight, and thousand dollars)

Class	1992		1993		Principal destinations and sources, 1993
	Quantity	Value	Quantity	Value	
EXPORTS[1]					
Columbium:					
Ores and concentrates	—	—	6	46	All to Taiwan.
Ferrocolumbium	902	8,254	815	7,313	Canada 697, $6,299; Mexico 116, $1,006; Venezuela 1, $5; Chile (2), $4.
Tantalum:					
Synthetic concentrates	2	17	—	—	—
Ores and concentrates	17	33	11	111	All to China.
Unwrought and waste and scrap	62	2,918	177	5,007	Germany 39, $2,127; Hong Kong 111, $1,276; United Kingdom 13, $962; Canada 7, $512; China 1, $70; Russia 4, $49.
Unwrought powders	61	18,741	57	17,476	United Kingdom 23, $7,771; France 18, $4,956; Germany 12, $3,666; Japan 3, $1,054; Taiwan (2), $15.
Unwrought alloys and metal	8	2,670	8	2,393	Canada 5, $1,668; Barbados 1, $377; Germany 2, $244; United Kingdom 1, $40; Mexico (2), $24; Singapore (2), $23.
Wrought	66	22,668	50	18,674	Japan 20, $8,365; Germany 9, $3,284; United Kingdom 7, $2,692; France 4, $1,449; Canada 6, $1,050.
Total	XX	55,301	XX	51,020	United Kingdom $11,500; Canada $9,500; Japan $9,400; Germany $9,300; France $6,400.[3]
IMPORTS FOR CONSUMPTION					
Columbium:					
Ores and concentrates	2,428	8,764	2,348	8,614	Canada 2,217, $7,971; Germany 73, $347; Belgium 10, $151; Nigeria 47, $146.
Oxide	792	13,473	301	5,392	Germany 161, $3,751; Brazil 91, $1,367; Russia 46, $253; Thailand 2, $11; United Kingdom (2), $10.
Ferrocolumbium	3,767	31,075	3,367	28,997	Brazil 3,262, $27,106; Germany 103, $1,878; United Kingdom 2, $14.
Unwrought alloys, metal, and powders	1	101	111	2,381	Germany 79, $1,558; Estonia 16, $429; United Kingdom 9, $162; Brazil 5, $161.
Tantalum:					
Synthetic concentrates	—	—	36	912	All from Australia.
Ores and concentrates	1,367	35,600	1,258	31,828	Australia 440, $14,637; Brazil 135, $3,187; Germany 146, $3,185; Rwanda 193, $2,996; Japan 40, $2,973; Burundi 50, $1,063.
Unwrought waste and scrap	91	3,551	101	4,269	Mexico 55, $1,342; Germany 11, $1,145; Hong Kong 7, $768; France 12, $366; China 2, $237; United Kingdom 8, $189.
Unwrought powders	8	1,571	56	9,463	Germany 31, $4,097; Thailand 17, $3,566; Japan 5, $1,165; China 3, $529.
Unwrought alloys and metal	4	635	8	1,038	Germany 7, $870; Japan (2), $168.
Wrought	2	768	3	547	Kazakhstan 3, $290; Austria (2), $64; Switzerland (2), $61; Germany (2) $54; Japan (2) $52.
Total	XX	95,538	XX	93,441	Brazil $31,800; Germany $17,000; Australia $15,500; Canada $8,800.[3]

XX Not applicable.

[1] For columbium, data on exports of metal and alloys in unwrought and wrought form, including waste and scrap, are not available; included in nonspecific tariff classifications.

[2] Less than 1/2 unit.

[3] Rounded.

^{e}Estimated. ^{r}Revised. NA Not available.

[1] Excludes columbium- and tantalum-bearing tin ores and slags. Production of tantalum contained in tin slags was, in thousand kilograms: 1989—362; 1990—343; 1991—244; 1992—160; and 1993—132 according to data from the Tantalum-Niobium International Study Center. Table includes data available through July 28, 1994.

[2] In addition to the countries listed, Bolivia, China, Russia, and Zambia also produce, or are believed to produce, columbium and tantalum mineral concentrates, but available information is inadequate to make reliable estimates of output levels.

[3] Data on gross weight generally have been presented as reported in official sources of the respective countries, divided into concentrates of columbite, tantalite, and pyrochlore where information is available to do so, and reported in groups such as columbite and tantalite where it is not.

[4] Unless otherwise specified, data presented for metal content are U.S. Bureau of Mines estimates based on, in most part, reported gross weight and/or pentoxide content.

[5] Less than 1/2 unit.

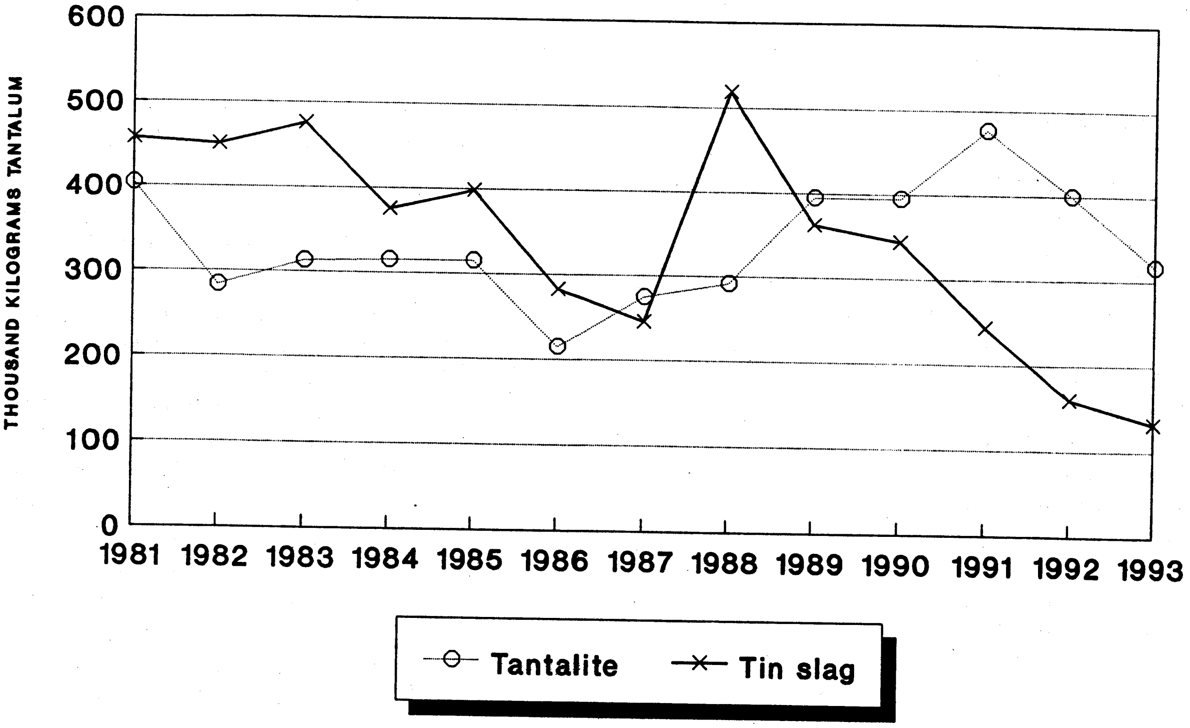
WORLD TANTALUM SUPPLY



COPPER

By Daniel L. Edelstein

Mr. Edelstein is a physical scientist with 20 years of combined experience working for the U.S. Bureau of Mines in mineral processing research, process evaluation, and mineral commodities. He has been a copper commodity specialist for 10 years as well as a specialist for the byproduct metals arsenic, selenium, and tellurium.

Domestic mines yielded one-fifth of the world's copper in 1993, maintaining the U.S. position as the world's second largest copper-producing nation. Domestic mine production continued to trend upward in 1991, to 1.8 million metric tons, valued at about $3.6 billion. More than 60 mines operating in 13 States produced reportable quantities of copper; however, the top 15 mines accounted for more than 95% of production. The principal mining States, in descending order Arizona, Utah, New Mexico, Michigan, and Montana, accounted for 98% of production. The 2% increase above the 1992 level was attributable to incremental expansion of mill capacity at several mines and the opening of one medium-sized mine. Most of the increase resulted from a full year's production from projects that were completed during 1992. Total U.S. mine capacity in 1993 was estimated at 2.06 million tons, an increase of about 50,000 tons from the year before. U.S. copper companies continued to invest heavily in South America, influenced by favorable geologic settings and a positive international investment climate there.

At yearend, 8 primary and 5 secondary smelters, 9 electrolytic and 6 fire refineries, and 15 electrowinning plants were operating in the United States. Electrowon production of about 490,000 tons accounted for 27% of domestic mine production, and was down slightly from that of the previous year. Conversion of old scrap to alloys and refined copper contributed about 555,000 tons of copper to the market, a quantity equivalent to about 22% of industrial copper consumption.

Copper was consumed, both as refined copper and as direct melt scrap, at about 35 brass mills, 15 wire rod mills, and 750 foundries, chemical plants, and miscellaneous consumers. Copper adn copper alloys found both structural and electrical use in building construction 42%; electrical products, 24%; industrial machinery and equipment, 13%; transortation equipment, 12%; and consumer and general products, 9%.

Copper was mined in 55 countries in 1993, of which the top 2, Chile and the United States, accounted for more than 40%, and the top 11 for more than 80% of the world total. Land-based world copper resources at yearend 1993 were estimated at 1.6 billion tons. The reserve base was estimated at 590 million tons, and reserves at 310 million tons. The United States has about 15% of reserves and the reserve base.

The oversupply of copper that led to rising global inventories during 1992 persisted into 1993; while world refined production and capacity increased slightly, world demand for refined copper remained stagnant. Demand in Western Europe was particularly poor, falling by almost 10%. Weak demand in Japan was partially offset by growth in other Asian markets. Refined copper demand in the United States and Canada, however, ran counter to the world trend, rising by 8.5% and 19%, respectively. Global inventories rose during the year by over 250,000 tons. Again, the United States was an exception, inventories having declined slightly by yearend. As a result of these trends, prices moved downward throughout the year, except for a period at mid-year when prices were artificially high owing to market manipulation. At yearend, tight domestic supplies of copper were pushing domestic prices above those in the rest of the world.

DOMESTIC DATA COVERAGE

Domestic production data for copper were developed by the U.S. Bureau of Mines from seven separate surveys of U.S. operations. Typical of these surveys is the lode mine production survey. Of the 117 operations to which this survey was sent in 1993, 91 responded and of those, 67 reported copper production. The respondents accounted for an estimated 99.7% of the mine production shown in tables 1, 3, and 5. The remaining production was estimated using other surveys.

ANNUAL REVIEW

Production

There were relatively few changes in the operating status of domestic mines, smelters, and refineries. One significant coproduct mine, ASARCO Incorporated's Troy Mine, closed in April owing to lower copper and silver prices. Arimetco International Inc. closed its Emerald Isle Mine in September owing to high operating costs and limited reserves. After delays associated with environmental permitting, Kennecott Corp. began production from its high-grade Flambeau Mine in Wisconsin. Though recovery of copper precipitate continued, Asarco's Silver Bell Mine remained closed throughout the year. In August, Mitsubishi Materials Corp. announced the suspension of operations at its Cox Creek refinery in Baltimore. The refinery had been operating at significantly less than full capacity, processing mainly imported anode. Mitsubishi had intended to feed the refinery from a new smelter in Texas, whose development was abandoned in 1992 when it was unable to secure necessary environmental permits.

Production of electrowon copper, which had been rising steadily over the past 8 years, declined slightly in 1993; heavy rains in the Southwest during January and February served to dilute leach solutions and reduce electrowon production at several mines. In addition, with expansion of its smelter, Cyprus AMAX Minerals Co. ceased electrowon production from surplus concentrates it was roast-leaching at its Casa Grande, AZ, operations.

Mine and Plant Labor.—Domestic mines employed an average of 13,300 mine, mill and office workers, a decline of about 300 from the previous year. Productivity, at domestic copper mines was 64 kilograms of copper per worker-hour in 1993, an increase from 63 kilograms of copper per worker-hour in 1992, and 57 kilograms in 1991. Productivity, which had increased dramatically during the early 1980's, stabilized and even decreased slightly in the late 1980's as copper prices rose. Productivity declined from a high of 58 kilograms per worker-hour in 1985 to a low of 50 kilograms in 1989, the year of peak copper prices. In the 1990's, a renewed round of capital investments and expansions of electrowinning capacity intended to lower costs in the face of declining prices, resulted in a renewed improvement in worker productivity.

Labor contracts for at least four major copper producers expired in June, but were renegotiated without disruption to production. Workers at Asarco's Ray Mine ratified a 3-year contract in June that established wage increases of $1.30 per hour over the life of the contract, as well as increases in health, illness, and pension benefits. Also included was approval of a "labor-management participation program" similar to one adopted by Magma Copper Co. in 1991. Workers at Phelps Dodge Corp.'s Chino Mine remained on the job until a new contract was ratified in July that included provisions for a $0.95 per hour increase in base salary over the life of the mine, wage bonuses tied to the price of copper, and improvements in other benefits. Workers remained on the job without a contract at Kennecott's Utah operation until a new contract was negotiated at the end of September. The new comprehensive 3-year contract included a wage increase of $1.80 per hour over the life of the contract. In November, Copper Range Co. employees ratified a new 4 1/2-year collective bargaining agreement that provided for no wage increases for 2 years. In addition, as part of their "employee share ownership program" (ESOP), workers agreed to lend the company the value of future ESOP benefits.

Costs and Earnings.—Higher operating costs and lower copper prices contributed to lower profits for the major copper producing companies. The heavy rains early in the year particularly took their toll on earnings during the first half of the year.

Asarco, whose Ray and Mission mines were hard hit by flooding, reported a net loss of $55 million during the first half of the year and a $15.6 million annual profit. Operating costs for Asarco's copper operations reportedly rose from $0.70 per pound to $0.82 per pound during the first half of the year. Startup problems with its retrofit smelter in El Paso, and mill expansions at Ray and Mission also contributed to higher costs. In the second quarter, Asarco was reorganized to bring all of its copper operations under common management at offices in Tucson, AZ.

Despite unexpected capital expenditures at the Morenci Mine as a result of flooding, Phelps Dodge reported record production at all of its copper operations. This and forward sales of copper that guaranteed a minimum of $0.95 per pound of copper for 44% of its production resulted in revenues for Phelps Dodge Mining Co. falling by only about 5%, to $1.32 billion. Net earnings, however, fell by about 39%, to $223.6 million, owing to increased mining cost and capital depreciation from recent projects.

Magma Copper Co., which also had record sales of copper, reported a 59% decline in net income, to $24.3 million. Magma calculated that it lost $15.5 million in net earnings during the first half of the year owing to flooding. Despite this, Magma reported net operating costs of 66 cents per pound of cathode, unchanged from 1992. Operating costs for December, however, were reported to be only 59.6 cents per pound.

On November 15, Cyprus Minerals Co. merged with Amax Inc. to form Cyprus Amax Minerals Co. Amax had extensive coal and gold assets; Cyprus had extensive coal, copper, lithium, and molybdenum assets. Cyprus Climax Metals Co. became the new operating company for the former Cyprus Minerals copper operations. While total copper production, sales, and revenue fell in 1993, net operating income for the copper segment was reported as increasing by $17.2 million, to $55 million, owing to nonrecurring write-downs for mine assets and reorganization expenses attributed to the copper segment in 1992. Cyprus Copper Co. in 1992 had relocated its headquarters from Colorado to Phoenix, AZ. A $5.6 million loss, net of insurance recovery, was attributed to the heavy rains in 1993. Cyprus reported full-cash costs and net-cash costs of 77 cents and 72 cents per pound of copper, respectively, down by 1 cent per pound from that of 1992.

Mines, Smelters, and Refineries.—Arimetco International Inc. operated several small leach properties in Arizona and Nevada. According to the Company's annual report for 1993, production rose slightly from 8,100 tons to 8,400 tons. This occurred despite rain-induced losses at its Johnson Camp Mine and Emerald Isle Mine. Mining at Emerald Isle was curtailed in June and leaching suspended in September. At yearend, the mine was still on care and maintenance. In addition, shaft rehabilitation work was suspended at the Van Dyke underground mine. Early in the year, Arimetco acquired the remaining 50% share of the MacArthur Mine, allowing it to consolidate operations with the adjacent Yerington Mine. By yearend, it had acquired the necessary permits to develop MacArthur and to increase leach pad areas at Yerington from 0.4 million square meters to 2 million square meters. Insufficient pad area at Yerington had limited 1993 production and resulted in higher operating costs than in 1992, though overall the company reported a decline in cash costs from 74 cents per pound in 1992 to 70 cents per pound in 1993. The company completed a 2.8-kilometer haul road to transport MacArthur ore to leach dumps at Yerington.

According to ASARCO Incorporated's 1993 annual report, the company's total copper mine production was essentially unchanged in 1993 at 280,000 tons, despite 1993 being the first full year of operation of expanded capacity at the Ray Mine. Smelter and downstream refinery production declined owing to startup problems with its new CON-TOP smelter at El Paso. By yearend, the smelter was operating at 90% of its 100,000-ton annual capacity. Asarco completed installation and startup of a new electrolyte purification facility at its Amarillo, TX, refinery. Solvent extraction-electrowinng (SX-EW) production at Ray declined slightly owing to rain-induced problems.

Metall Mining Corp., Toronto, Canada, owner of Copper Range Co., reported in its 1993 annual report that operating costs at its White Pine, MI, facilities had been reduced from 82 cents per pound to 79 cents per pound of copper. The cost savings were attributed to the purchase of concentrate to process through its smelter and refinery. Because of the relatively high cost of its mining operation, Copper Range initiated a feasibility study to determine if it could economically leach existing pillars in abandoned mine areas. The pillars reportedly contained 145 million tons of ore and 1.4 million tons of copper. The company projected a 30% recovery rate during a 30-year period. The company also was studying the construction of a new smelter with expanded capacity and was expected to reach a decision on the $200-million project by yearend 1994. If the project were to prove infeasible, Copper Range, which has faced environmental challenges, was committed to closing the existing smelter.

According to Cyprus Amax Minerals Co.'s 1993 annual report, the company's domestic copper mine production declined by about 7,000, tons to 285,000 tons. At its Bagdad Mine in Arizona, a 13% expansion of the mill to 77,000 tons of ore per day and a 25% expansion of SX-EW to 14,000 tons of copper per year were completed in late 1993. At the Sierrita/Twin Buttes consolidated operation, a 10% expansion of the Sierrita concentrator to 100,000 tons of ore per day was completed by yearend. Twin Buttes ore was transported via a 4.2-kilometer conveyor system to Sierrita. With depletion of oxide reserves, an agitation-leach process at Twin Buttes was closed at yearend 1992. In 1992, this process had yielded 18,600 tons of copper at Twin Buttes. The Miami smelter, which experienced shutdowns for repairs and modifications of the new ISAMELT furnace in 1992 and early 1993, was reported to be operating at 90% of capacity during the second half of 1993. With smooth operation of the smelter, Cyprus suspended operation of its Casa Grande, AZ, roast-leach operation during the fourth quarter, and diverted concentrates to the lower-cost smelter. Cyprus was reportedly evaluating open pit mining and heap leaching of Casa Grande oxide reserves. Construction of a new refinery at Miami, AZ, making Cyprus fully integrated, was scheduled for startup in late 1994.

According to the RTZ Corp. PLC 1993 annual report, mine production at Kennecott's Bingham Canyon Mine rose 6%, to a record 307,000 tons; Kennecott was a wholly owned subsidiary of RTZ. Though refined production rose by 5%, only 47% of mine output was processed to refined copper at Bingham Canyon; most of the balance was exported as concentrate. RTZ reported cost savings owing to high capacity utilization and improved operating procedures. Permits were secured and construction commenced in July on a new smelter. The smelter was anticipated to be on-stream by April 1995. The refinery also was undergoing modernization. In May, Kennecott's Flambeau Mine in Ladysmith, WI, was commissioned. Production in 1993 of 24,000 tons exceeded company expectations by 16%. Annual capacity over the 5-year life of the mine was expected to be 27,000 tons of copper.

According to its 1993 annual report, Magma Copper Co. produced 181,000 tons of copper, a nominal increase from the 1992 level. While Pinto Valley Mine production fell, owing to flooding during the first quarter, SX-EW production from open-pit mining at San Manuel reached a record level of 45,000 tons. Underground development at the Superior Mine, completed in 1992, allowed for a 33% increase in production at that mine. The San Manuel smelter operated in excess of its design capacity, increasing production by 12% to a record 309,000 tons. An expansion of the smelter, including the addition of a third acid plant, was expected to add 20,000 tons of capacity by mid-1994. During the third quarter, Magma began tunnel boring operations at San Manuel for development of the deep Kalamazoo ore body, scheduled to come into production in 1997. Exploration efforts at Magma's Robinson, NV, property increased reserve estimates by 25%. Pending permitting, construction at Robinson was slated to begin in 1994 and startup was planned for 1997. The 60,000-ton-per-year project was expected to cost $300 million.

Mine production at Phelps Dodge's operations increased nominally to 600,000 tons, according to the company's 1993 annual report. SX-EW production accounted for a record 47% of production. At Morenci, where a record 367,000 tons of copper was produced, Phelps Dodge continued to study the feasibility of mining the Coronado deposit, which contained an estimated 180 million tons of milling ore, and 300 million tons of lower-grade leach ore. Completion of the adjacent Northwest Extension project in May 1992 had already added 64,000 tons of SX-EW capacity at Morenci. At Chino, a $5-million expansion of the electrowinning tankhouse enabled a record production of 58,000 tons of electrowon cathode, and a record mine production of 145,000 tons. The Hidalgo smelter cast 203,000 tons of anode, surpassing a record set in 1986. In addition to reserves reported for existing operations, Phelps Dodge held various other domestic properties it believed to have strong potential for development should market conditions warrant. These deposits, including Ajo, Cochise, Copper Basin, Coronado, Dos Pobres, Lone Star, Southside, and Western Copper, contain over 17 million tons of copper. This compares with reported reserves of only 9.3 million tons at existing Phelps Dodge operations.

Foreign Investments.—In response to improved investment climates, privatization of Governmnt-owned properties, and cost reduction strategies, domestic copper companies sought to increase production capacity through investment in South American copper projects. In October, Cyprus and its joint-venture partner, Lac Minerals Ltd. of Canada., competing against other groups that included several other domestic producers, were awarded the rights to develop the El Abra copper poperty in Chile, owned by Corporacion Nacional del Cobre de Chile (Codelco). This was the fist Codelco-owned property subject to international competition following changes in Chilean mining law that allowed Codelco to enter into joint-venture arrangements for its undeveloped properties. While the initial contract called for Cyprus to pay $404 million for a controlling interest in the $1 billion project, the project was postponed in February 1994 pending resolution of a technical discrepancy concerning ore grades. In May, Cyprus submitted a new bid, following the withdrawal of Lac Minerals, that was accepted. El Abra was projected to produce 225,000 tons of electrowon copper per year beginning in 1997. In addition to oxide reserves in excess of 20 years, El Abra had sulfide reserves that were slated for future development.

In November 1993, Cyprus Amax won a second bid for a controlling interest (up to 91.5%) of the Cerro Verde Mine in Southern Peru, which, according to Cyprus, contained leachable reserves of almost 200 million tons grading 0.8% copper. An initial cash payment of $37 million was to be followed by an investment of about $110 million to upgrade SX-EW operations to produce about 45,000 tons of copper per year. Long-term plans called for studying the feasibility of developing sulfide reserves.

Phelps Dodge Mining Co. continued construction throughout 1993 on the La Candelaria copper-gold deposit in Chile. Discovered in 1987, full production of 95,000 tons per year of copper was anticipated by 1995. Phelps Dodge estimated sulfide reserves of 365 million tons grading 1.09% copper and a mine life in excess of 30 years. Total development costs for the mine, concentrator, port, and associated facilities were projected at $550 million.

Asarco has long held interests in Peruvian and Mexican mining operations. In 1993, Southern Peru Copper Corp. (SPCC), 52.3%-owned by Asarco, signed a $60-million financial agreement for the construction of a 37,000-ton-per-year SX-EW operation near its Cuajone and Toquepala mines. The plant, which was to cost $106 million, was part of 5-year, $300-million program to expand production, replace equipment and make environmental upgrades at SPCC facilities. SPCC had already secured $200 million for financing the program. The redevelopment program was part of an agreement SPCC reached with the Peruvian Government that allowed SPCC to resume cash distributions to its shareholders. Asarco received a $9.34-million distribution in 1993. Asarco also reached an agreement with Grupo Industrial Minera Mexico, S.A. de C.V. (Grupo Mexico), a publicly traded company, to restructure Asarco's 28.3% holdings in privately held Mexico Desarrollo Industrial Minero, D.A. de C.V. (MEDISMA). MEDISMA was to be combined with Grupo Mexico and Asarco was to own a 23.6% stake in the new public corporation, thus adding liquidity to Asarco's holdings.

Exxon Coal and Minerals Co. continued expansion of its investments in Chile. Production at its Los Bronces mine increased by almost 70%, reflecting the first full year of operation of an expansion completed in 1992. Expansion of the Chargres smelter was expected to be completed in 1994.

Freeport McMoran Inc.'s subsidiary, P.T. Freeport Indonesia Co., continued to explore and develop its operations in Indonesia. In 1993, its exploration activities added 2.7 million recoverable tons of copper to its reserves, principally from the Grasberg deposit. In addition, Freeport has identified at least 50 targets for further exploration. Despite caving in two of four ore passes, which resulted in reduced mill throughput for 8 weeks, production rose to almost 300,000 tons, an increase of almost 20,000 tons from 1992, and more than double production of 1989. Freeport reported that cash costs dropped from 40.7 cents per pound in 1992 to 31.1 cents in 1993. Freeport was continuing with a mill expansion program that would double capacity to 115,000 tons per day. In March, Freeport purchased a 65% interest in Rio Tinto Minera S.A.'s smelter in Spain. Plans called for expanding the smelter's capacity from 150,000 tons per year to 180,000 tons per year.

Trade

Several trade agreements were negotiated during 1993 that potentially impact the domestic copper industry. The North American Free Trade Agreement was expected to open trade between Canada, Mexico, and the United States, with tariff reductions beginning in 1994. Then in December, the 7-year-long negotiations were completed on the Uruguay Round of the General Agreement on Tariffs and Trade (GATT), though participating countries had until April 1994, to submit additional tariff reduction proposals. At yearend, U.S. copper producers continued to lobby for elimination of Japanese tariffs on refined copper before actual signing of the agreement. The goal was a zero-for-zero total elimination of tariffs in an effort to increase exports of refined copper to Japan. Because domestic production is located in the Western States and major consuming areas are in the East, a natural trade flow had developed, with the export of refined copper from the west coast to Asian consuming countries, and the importation of Canadian copper on the east coast. Canadian refineries are primarily located in the eastern Provinces. Despite the existing tariff, U.S. producers had had some success in penetrating Japanese markets: in 1992 and 1993 Japan accounted for about 50,000 tons of U.S. exported copper per year, or 30% and 22%, respectively, and in 1991, Japan was the largest recipient at 122,000 tons, 46%. U.S. producers contended that, on average, Japan was a higher-cost smelter than was the United States and was thus maintaining "noncompetetive" capacity through tariff protection.

In April 1994, Japan announced that it would phase down its copper duty over a 5-year period from a flat 15,000 yen per ton, about 8% ad valorem at prevailing prices, to a 3% ad valorem.

Prices and Stocks

Copper prices declined for the first 5 months of the year in response to a global increase in inventories. Domestic inventories, which had increased by more than 50% in 1992, remained relatively stable at the higher level of about 200,000 tons. However, while the domestic market was strong and stock levels stable, the global demand picture was much weaker. Consequently, stocks held in London Metal Exchange (LME) warehouses continued their upward climb from the previous year, rising more that 40% during the first 6 months of the year. Except for a slight dip during the first half of 1992, LME stocks had risen almost continuously since mid-1990, when they dipped below 50,000 tons. In August, an anomalous condition developed on the LME. Despite the high inventories, LME copper available for immediate delivery became tight, spot prices rose, and a pricing backwardation developed, with forward copper contracts selling at a discount to spot prices. This "artificially" high price may have served to further attract copper into LME warehouses, with the result that stocks soared to more than 600,000 tons. In the United States, though prices rose slightly, they remained in contango (forward contracts selling at a premium to spot contracts) and below LME prices. The LME price premium over the Commodity Exchange, Inc. (COMEX) price rose to more than 6.5 cents per pound, compared with an average 1.5 cents during the first 6 months of the year. On September 8, amid concerns that the pricing structure was the result of several large market participants exercising undue influence on the market, the board of the LME intervened and limited the backwardation of copper contracts. The board action had an almost immediate effect on prices. By the end of September, the LME spot price had fallen to 76 cents, the lowest price in 6 years, from an average of 88.3 cents in August, and the backwardation was eliminated. While COMEX prices followed suit, falling from 85 cents to 74 cents at monthend, the U.S. producer price was slower to follow, closing the month at 86 cents per pound, a drop of only about 6 cents per pound.

With the correction made to the "artificially" high LME prices in September, the LME/COMEX price spread narrowed, and by mid-November reversed, with COMEX copper trading at a slight premium. The spread continued to widen in December, reflecting the increasingly tight domestic supply of copper. Domestic inventories, which had been stable during the first half of the year, were down by 25% at yearend. This tight supply appeared to be the driving force for a yearend rally in prices; COMEX spot prices rose almost 10 cents per pound during December, and the price spread between spot purchases and 3-month forward contracts began to narrow. LME inventories dropped marginally at yearend to about 600,000 tons.

In March, the Defense Logistics Agency (DLA) began liquidating the approximately 20,000 tons of refined copper contained in the National Defense Stockpile. DLA held monthly offerings of 4-million-pound lots of copper from March through October. In November and December, it modified its sales and offered the balance of the refined copper inventories in two lots of about 8 million pounds each. At yearend, the stockpile still contained about 18 million pounds of brass slabs, though its sale was anticipated for 1994.

Consumption

U.S. demand for refined copper rose by 8.5% to record levels during 1993. This surge in demand overshadowed a 4% increase in refined production, resulting in a drawdown in inventories and a 12% rise in net imports. Demand was particularly strong during the second half of the year, increasing by 16% over the comparable 1992 period, when the traditional summer slowdown failed to materialize. The rise in consumption resulted from strong growth in demand in major copper consuming industries. In construction, the largest end use for copper, housing starts rose by 7.1% in 1993 and total construction spending climbed by 7.9%. According to data compiled by the Copper Development Association on mill shipments to the domestic market, building construction demand rose by 6% and accounted for 42% of mill shipments to domestic markets; electric and electronic products remained unchanged and accounted for 24% of shipments; transportation uses rose by 12% and accounted for 12% of shipments; and consumer and general products rose by about 2% and accounted for 9% of shipments. According to estimates by the U.S. Bureau of Mines, electrical applications in all the industry segments accounted for about 78% of reported demand.

World Review

World mine production of copper declined slightly in 1993 despite the addition of almost 200,000 tons of new capacity, largely in Chile, but also in the

United States and Indonesia. Mine shut-downs in Canada and the Philippines, and political turmoil and accompanying supply and infrastructure disruptions in Kazakhstan, Russia, and Zaire, accounted for much of the decline in production. Production in Chile reached a record level of slightly more than 2 million tons, owing to a 13% increase in private sector production. Major expansions were reported at La Escondida, where production rose by about 50,000 tons to 390,000 tons, and at the Los Bronces Mine, where production increased by 48,000 tons to 118,000 tons. Production at state-owned Codelco declined slightly, owing to lower ore grades and production disruptions at the Chuquicamata and El Teniente mines.

In Canada, where much of copper production is from byproduct or coproduct mines, overall low metal prices resulted in temporary mine closures, including the Gibralter and Similco mines in British Columbia. The Myra Falls copper-zinc mine remained closed throughout most of the year owing to a labor dispute. In addition, several mines closed permanently owing to exhaustion of reserves. Similarly, Atlas Consolidated Mining and Development Corp. in the Philippines reduced production because of low prices and weather-related damage. In Zaire, the copper industry remained all but shuttered in the face of continuing political turmoil and the need for a large capital infusion.

While world capacity increases in 1993 were limited, coming from incremental expansions of existing facilities, numerous projects that were in the planning stage could account for more than 2 million tons of new capacity by 1996. Key to the global expansion has been the liberalization of foreign investment and ownership laws in South America. Chile alone was anticipating more than $5 million in copper mine investments over the next 3 years that could boost production to more than 3 million tons. In addition to expansions at existing mines, as many as 12 new mines could come on stream. Much of Chile's new capacity will be from SX-EW projects. In addition to the aforementioned projects under development by U.S. companies, major Chilean SX-EW projects under development included the 75,000-ton-per-year Quebrada Blanca project; the 125,000-ton-per-year Zalvidar project; an 80,000-ton-per-year plant at La Escondida; the 40,000-ton-per-year Cerro Colorado Mine; and the 10,000-ton-per-year Ivan project. At yearend, Zambia was exploring options regarding privatization of its copper operations. Key to this was the need to attract capital for the development of reserves in the Konkola Deep Mining Project at the Nchanga Division. Reserves at the Nchanga open pit were nearing exhaustion.

The bottleneck in world smelter production that had developed in 1991 and 1992 and led to surplus concentrates and higher smelting and refining charges began to ease in the latter part of 1992 and 1993. Higher charges allowed concentrates to be shipped greater distances to underutilized smelters, including those in Zambia and Russia. In addition, numerous smelter expansions and modernizations were underway. The International Copper Study Group (ICSG) estimated yearend smelter capacity at 12.6 million tons, about 400,000 tons of which were at new or renovated smelters in Canada, Chile, China, Germany, and the United States. According to CRU International Ltd., combined spot smelting and refining charges, cif Japan, fell from 26 cents per pound of copper during the fourth quarter of 1992 to 18 cents per pound in December 1993.

Total world production of refined copper increased slightly during 1993. The United States accounted for about half of the increase, the balance being from small incremental production in several countries.

Estimated total world demand for refined copper rose marginally in 1993 on the strength of consumption in the United States and the newly industrialized Asian countries. Demand in Europe remained depressed, with estimated consumption declines of 14% in Belgium, 9% in Germany, and about 2% each in Italy and France. Of the major European consumers, only the United Kingdom reported a slight increase. While demand in Japan decreased nominally from the severely depressed 1992, level, demand in Korea, Taiwan, and Thailand continued to grow, increasing by 13%, 15%, and 30%, respectively.

As a result of both continued weak demand and growth in world refined production, the surplus supply of copper that developed in 1992 increased throughout much of 1993. Copper inventories held in commodity exchange warehouses peaked at 700,000 tons in October, a 140% increase during a 2-year period. According to the International Copper Study Group (ICSG) total reported world stocks rose by 260,000 tons, to 1.4 million tons, or the equivalent of 6 1/2 weeks of consumption.

In June 1993, the ICSG held its first Regular General Session in Lisbon Portugal. The ICSG was formally established as an autonomous intergovernmental organization in January 1992. As part of its mission to promote greater transparency in the market, the ICSG began developing an international set of copper production, consumption, and trade statistics. In January 1994, it began publishing a monthly statistical bulletin that was expected to be made available to the public beginning in 1995. The 22 member countries of the ICSG represented more than 80% of the world trade in copper.

[r] Revised.

[1] Based on source of material at smelter level.

[2] Data may not add to totals shown because of independent rounding.

[3] Includes fire-refined copper.

TABLE 7
PRODUCTION, SHIPMENTS, STOCKS, IMPORTS, AND EXPORTS OF COPPER SULFATE IN THE UNITED STATES

(Metric tons)

Year	Production		Shipments[1,2]	Stocks, Dec. 31	Imports	Exports
	Quantity	Copper content				
1989	[r]33,186	8,349	[r]33,911	3,485	13,458	571
1990	34,286	8,627	36,357	1,414	12,251	[r]560
1991	40,186	10,104	39,220	2,380	10,309	827
1992	46,777	11,782	46,296	2,860	8,290	1,049
1993	46,393	11,689	46,261	2,993	9,431	334

[r] Revised.

[1] Includes consumption by producing companies.

[2] In 1993, U.S. producers reported 59% of domestic shipments were for agriculture; 31% for industrial use; and 10% for water treatment.

TABLE 8
BYPRODUCT SULFURIC ACID (100% BASIS) PRODUCED IN THE UNITED STATES[1]

(Thousand metric tons)

Plant type	1989	1990	1991	1992[r]	1993
Copper[2]	3,076	3,381	[r]3,368	3,344	3,643
Lead[3]	156	165	[r]196	180	202
Zinc[4]	410	413	419	425	398
Total	[r]3,642	3,959	[r]3,983	3,949	4,243

[r] Revised.

[1] Includes acid from foreign materials.

[2] Excludes acid made from pyrite concentrates.

[3] Includes acid produced at molybdenum plants to avoid disclosing company proprietary data.

[4] Excludes acid made from native sulfur.

TABLE 9
CONSUMPTION OF COPPER AND BRASS MATERIALS IN THE UNITED STATES, BY ITEM

(Metric tons)

Item	Brass mills	Wire rod mills	Foundries, chemical plants, miscellaneous users	Secondary smelters-refiners[2]	Total[1]
1992:					
Copper scrap	[r][3]748,955	W	[r]66,002	[r]845,841	[r]1,660,798
Refined copper[4]	458,496	1,674,985	[r][5]45,344	(6)	[r]2,178,823
Hardeners and master alloys	714	—	[r]2,767	—	[r]3,481
Brass ingots	—	—	[r]112,536	—	[r]112,536
Slab zinc	93,049	—	16,346	3,593	112,988
Miscellaneous	—	—	—	47	47
1993:					
Copper scrap	[3]740,774	W	60,732	896,540	1,698,045
Refined copper[4]	504,128	1,819,072	[5]40,824	(6)	2,364,024
Hardeners and master alloys	875	—	3,012	—	3,886
Brass ingots	—	—	112,505	—	112,505
Slab zinc	85,822	—	19,011	3,391	108,224
Miscellaneous	—	—	—	41	41

[r] Revised. W Withheld to avoid disclosing company proprietary data; included in "Brass mills."

[1] Data may not add to totals shown because of independent rounding.

[2] Includes ingot makers.

[3] Includes consumption of copper scrap at wire rod mills to avoid disclosing company proprietary data.

[4] Detailed information on consumption of refined copper can be found in table 10.

[5] Includes consumption of refined copper at secondary smelters-refiners to avoid disclosing company proprietary data.

[6] Withheld to avoid disclosing company proprietary data; included in "Foundries, chemicals plants, miscellaneous users."

TABLE 10

REFINED COPPER CONSUMED IN THE UNITES STATES, BY CLASS OF CONSUMER

(Metric tons)

Class of consumer	Cathodes	Ingots and ingot bars	Cakes and slabs	Wirebar, billets and other	Total
1992:					
Wire rod mills	1,660,794	—	—	14,191	1,674,985
Brass mills	311,147	12,420	43,641	91,288	458,496
Chemical plants	W	—	—	870	870
Ingotmakers	W	W	W	3,035	3,035
Foundries	2,960	[r]7,713	28	4,472	[r]15,173
Miscellaneous[1]	W	W	W	[r]26,264	[r]26,264
Total	1,974,901	[r]20,133	43,669	[r]140,120	2,178,823
1993:					
Wire rod mills	1,819,072	—	—	—	1,819,072
Brass mills	313,524	32,602	56,236	101,766	504,128
Chemical plants	—	—	—	870	870
Ingotmakers	W	W	W	2,174	2,174
Foundries	1,582	5,090	W	3,534	10,206
Miscellaneous[1]	W	W	W	27,574	27,574
Total	2,134,178	37,692	56,236	135,918	2,364,024

[r] Revised. W Withheld to avoid disclosing company proprietary data; included with "Billets and other."

[1] Includes iron and steel plants, primary smelters producing alloys other than copper, consumers of copper powder and copper shot, and other manufacturers.

TABLE 11

STOCKS OF COPPER IN THE UNITED STATES, END OF PERIOD

(Metric tons)

Period	Blister and materials in process of refining[1]	Refined copper					
		Primary and secondary refiners	Wire rod mills	Brass mills	Other[2]	New York Commodity Exchange	Total
1989	131,650	23,580	31,720	12,447	23,909	15,000	106,656

May	163,479	38,339	38,208	15,435	17,939	98,239	208,160
June	146,153	33,037	39,746	11,292	16,080	95,694	195,849
July	164,073	31,118	35,222	15,252	14,285	103,241	199,118
August	153,884	33,150	29,941	17,342	12,447	90,814	183,694
September	171,769	30,128	22,822	12,571	10,975	85,379	161,875
October	160,421	31,301	19,205	7,266	9,304	87,666	154,742
November	166,982	33,276	23,942	13,540	5,607	73,065	149,430
December	145,583	33,431	34,743	14,583	3,168	67,153	153,078

[r] Revised.

[1] Includes copper in transit from smelters in the United States to refineries therein.

[2] Includes chemical plants, foundries, miscellaneous plants and the National Defense Stockpile; the 20,000 tons contained in the stockpile were sold-off beginning in Mar. 1993.

[1] Total imports of wire rod for 1992 were 6,644 tons, valued at $17,562,325 and 1993 were 16,582 tons, valued at $34,357,387.
[2] Less than 1/2 unit.
[3] Data may not add to totals shown because of independent rounding.

Total	[r]9,090.0	[r]9,077.9	[r]9,280.5	[r]9,452.7	9,352.1

[e] Estimated. [r] Revised.

[1] Data represent copper content by analysis of concentrates produced except where otherwise noted. Table includes data available through Aug. 10, 1994.

[2] Reported figure.

[3] Less than 50 tons.

[4] Copper content of pelletized nickel-copper matte produced in smelter.

[5] Reported by Comision Chilena del Cobre (COCHILCO). Includes recoverable copper content of nonduplicative mine and metal products produced from domestic ores and concentrates, and leach production for electrowinning.

Mine production data reported by Servicio Nacional de Geologia y Mineria (SERNAGEOMIN) were as follows, in thousand metric tons: 1989—1,628.3; 1990—1,616.3; 1991—1,855.0 (revised); 1992—1,967.0 (revised); and 1993—2,000.0 (estimated).

[6] Copper content of cement copper. Includes copper content of pyrite for 1989.

[7] Recoverable content.

[8] Dissolved Dec. 31, 1992.

[9] Production in Czechoslavakia from 1989-90 came from the Czech Republic and Slovakia, all production from 1991-92 came from Slovakia.

[10] Recoverable copper content by analysis of concentrates for export plus nonduplicative total of copper content of all metal and metal products produced indigenously from domestic ores and concentrates; includes leach production for electrowinning in Portugal.

[11] Formerly part of Czechoslovakia; data were not reported separately until 1993.

[12] Excludes copper content of pyrite.

[13] Dissolved in Dec. 1991.

[14] Includes electrowon from concentrates roast-leached.

[15] Dissolved in Apr. 1992.

[16] Copper content by analysis of ore mined.

[17] Recoverable content of blister, black copper, and Sodimiza concentrate.

[18] Data are for fiscal years beginning Apr. 1 of year stated. Zambian-mined copper reported recovered during smelting and electrowinning.

Primary:					
Electrowon	356.2	281.0	244.5	[r]175.0	107.0
Other	[r]8,306.6	[r]8,313.3	[r]8,224.6	[r]8,749.4	8,689.8
Secondary	[r]1,077.9	[r]1,050.6	[r]1,033.4	[r]1,033.0	1,059.6

[e] Estimated. [r] Revised.

[1] This table includes total production of copper metal at the unrefined stage, including low-grade cathode produced by electrowinning methods. The smelter feed may be derived from ore, concentrates, copper precipitate or matte (primary), and/or scrap (secondary). To the extent possible, primary and secondary output of each country is shown separately. In some cases, total smelter production is officially reported, but the distribution between primary and secondary has been estimated. Table includes data available through June 30,1993.

[2] Argentina presumably produces some smelter copper utilizing its own small mine output together with domestically produced cement copper, and possibly using other raw materials including scrap, but the levels of such output cannot be reliably estimated.

[3] Reported figure.

[4] Data may not add to totals shown because of independent rounding.

[5] Data revised to exclude high-grade electrowon production. Data include low-grade electrowon which is re-refined.

[6] Formerly part of Czechoslovakia.

[7] Dissolved Dec. 31, 1992.

[8] Data may be for year beginning Mar. 21 of year stated. Only estimated production data are available. Secondary production is estimated to be about 5% of total.

[9] Dissolved in Dec. 1991.

[10] Figures for U.S. primary smelter production may include a small amount of copper derived from precipitates shipped directly to the smelter for further processing; production derived from electrowinning and fire-refining is not included. Copper content of precipitates shipped directly to smelter are as follows, in metric tons: 1989—34,485; 1990—22,997; 1991—27,684; 1992—27,196 (revised); and 1993—19,043.

[11] Dissolved in Apr. 1992.

[12] For fiscal year beginning Apr. 1 of year stated. Electrowon is total electrowon production reported, less the quantity reported as "finished production, leach cathodes." (See table 38).

[13] Includes impure cathodes produced by electrowinning in nickel processing.

[e] Estimated. [r] Revised.

[1] This table includes total production of refined copper, whether produced by pyrometallurgical or electrolytic refining methods and whether derived from primary unrefined copper or from scrap. Copper cathode derived from electrowinning processing is also included. Table includes data available through Aug. 10, 1994.

[2] Reported figure.

[3] May not add to totals shown because of independent rounding.

[4] Includes leach cathode from Zaire, which is processed.

[5] Formerly part of Czechoslovakia; data were not reported separately until 1993.

[6] Dissolved Dec. 31, 1993. Production in Czechoslovakia from 1989-92 came from the Czech Republic and Slovakia.

[7] May include secondary.

[8] Dissolved in Dec. 1991.

[9] Dissolved in Apr. 1992.

[10] Excludes leach cathode exported for reprocessing in Belgium.

[11] Data are for fiscal year beginning Apr. 1 of that stated. Electrowon covers only presumably high-grade electrowon cathodes reported as "finished production leach cathodes." Other, in addition to electrorefined cathodes, includes a smaller amount of "finished product shapes" presumably cast from electrorefined cathodes, high-grade electrowon cathodes, or any blister-anodes and low-grade electrowon cathodes that were furnace- or fire-refined.

[12] May not include copper-nickel matte (copper content more than 6,000 tons per year) imported from Botswana for toll refining.

FLUORSPAR

By M. Michael Miller

Mr. Miller, a physical scientist with 16 years of mineral experience with the Department of the Interior, has been the commodity specialist for fluorspar since 1989. Domestic survey data were prepared by Robin Richardson, statistical assistant; and international data tables were prepared by Harold Willis, international data coordinator. All units are in metric tons, unless otherwise noted.

Traditionally, fluorspar has been considered vital to the Nation for both national security and economic reasons. It is used directly or indirectly to manufacture products such as steel, aluminum, refrigerants, insulating foams, uranium fuel, and gasoline.

In the United States, three producers supplied about 13% of the Nation's fluorspar requirements. This included fluorspar processed from mined ore, fluorspar processed from National Defense Stockpile material, fluorspar shipped from stocks, and fluorspar processed from imported ore. Supplementing fluorspar as a domestic source of fluorine was byproduct fluorosilicic acid production from some phosphoric acid producers. According to the Bureau of the Census, imports of fluorspar were essentially unchanged compared with the 1992 revised figures. Hydrofluoric acid (HF) imports were about 6% lower than those reported in the previous year.

DOMESTIC DATA COVERAGE

Domestic production and consumption data for fluorspar were developed by the U.S. Bureau of Mines from voluntary surveys of U.S. operations. Surveys were conducted to obtain fluorspar mine production and shipments and fluorosilicic acid production. The latter was formerly termed fluosilicic acid, but as a result of an international effort to standardize nomenclature, its name has been changed to fluorosilicic acid. Of the four fluorspar mining operations to which a survey request was sent, four responded, representing 100% of known domestic shipments. Actual production quantities and values in table 1 are withheld to protect company proprietary data, but an estimate of total shipments is provided. Of the 11 fluorosilicic acid operations surveyed, 8 respondents reported production, representing 100% of the quantity reported. The consumption survey was sent to 58 operations quarterly and to 28 additional operations annually. Of the operations surveyed quarterly, 80% responded. Of the operations surveyed on an annual basis, 96% responded. *(See table 1.)*

BACKGROUND

Definitions, Grades, and Specifications

Technically, pure fluorspar, or the mineral fluorite, contains 51.1% calcium and 48.9% fluorine. Natural fluorite is commonly associated with other minerals such as quartz, barite, calcite, galena, siderite, celestite, sphalerite, chalcopyrite, other sulfides, and phosphates. It occurs in well-formed isometric crystals, in massive and earthy forms, and as crusts or globular aggregates with radial fibrous texture. In crystalline form, it can be colorless or may exhibit a wide range of colors, including yellow, blue, purple, green, rose, red, bluish and purplish black, and brown. It has a hardness of 4 on the Mohs scale, a specific gravity ranging from 3.01 to 3.60, and a melting point of 1,378° C.

Three principal grades of fluorspar are available commercially: acid, ceramic, and metallurgical. Although the specifications for individual grades are generally well defined, some variation is permitted to satisfy the requirements of individual consumers.

In the United States, acid-grade fluorspar (acidspar) contains in excess of 97% CaF_2. Some manufacturers of hydrofluoric acid in the United States and Europe can use 96% CaF_2 or slightly lower if the remaining impurities are acceptable. User specifications may impose limits on silica, calcium carbonate, sulfide or free sulfur, calcite, beryllium, arsenic, lead, phosphates, and other constituents. Moisture content of the dried material is preferably 0.1% or less. Particle size and distribution are sometimes specified for proper control of the rate of chemical reaction and stack losses. Very few reserves in the world can be used to produce acid-grade fluorspar without flotation processing.

Ceramic-grade fluorspar is generally marketed as No. 1 ceramic, containing 95% to 96% CaF_2, and No. 2 ceramic, containing 85% to 90% CaF_2. An intermediate grade of about 93% to 94% CaF_2 is also available. Specifications on impurities vary, but may allow a maximum of 2.5% to 3.0% silica, 1.0% to 1.5% calcite, 0.12% ferric oxide, and trace quantities of lead and zinc. Shipments of ceramic-spar are usually tailored to the specific need of individual consumers.

Traditionally, metallurgical-grade fluorspar (metspar) has contained a minimum of 60% effective CaF_2, with effective CaF_2 units calculated by subtracting 2.5 times the silica content of the metspar from its total CaF_2 content. More recently, there has been much less emphasis on effective CaF_2 units and more emphasis simply on total CaF_2

content. Today, the term "metspar" is usually used to refer to material with a minimum content of 85%, but is sometimes used for material as high as 96%, which includes what is technically ceramic grade. Metspar is commonly traded as lump or gravel that must meet physical requirements similar to those of the National Defense Stockpile purchase specifications discussed below.

According to the current National Defense Stockpile purchase specifications (P-69b-R3), which were determined by the Federal Interagency Committee for Stockpile Purchase Specifications and Special Instructions in consultation with U.S. steel producers, metallurgical-grade fluorspar must contain a minimum of 70% by weight effective CaF_2. Specifications for maximum allowable impurities are as follows: sulfur = 0.10%, lead = 0.25%, arsenic = 0.01%, barium = 0.01%, zinc = 0.01%, phosphorus = 0.25%, tin = 0.02%, antimony = 0.02%, and copper = 0.10%. Physical requirements are that all metallurgical-grade fluorspar shall be in the form of gravel and, after washing, shall pass a 75-millimeter (3-inch) sieve, and not more than 10% by weight shall pass a 9.5-millimeter (3/8-inch) sieve.

In the domestic steel industry, various shapes and sizes of briquets or pellets are being used. Generally made to consumer specifications, briquets contain varying quantities of fluorspar mixed with binders, fillers, and fluxing agents. Typically made on roll presses and ranging in size from that of a peach seed to a 5-centimeter square, briquets contain 25% to 90% CaF_2 and steel mill waste ingredients, such as mill scale, flue dust, shredded scrap, iron ore fines, and manganese ore fines. The most popular binders are molasses and lime, which do not require baking ovens. Imported briquets are often made from fines accumulated during metspar preparation and from flotation concentrates. Pellets have been made on balling machines using sodium silicate binder.

Geology-Resources[1]

Fluorspar occurs in a wide variety of geological environments, which indicates that deposition takes place in a number of different ways. From an economic standpoint, seven of the most important modes of occurrence are as follows:

1. Fissure vein deposits commonly occur along faults or shear zones and are the most readily recognized form of fluorspar occurrence in the world. Although the vein structure may be persistent, the fluorspar mineralization commonly occurs as lenses or ore shoots separated by barren zones. Fissure veins occur in igneous, metamorphic, and sedimentary rocks.

2. Stratiform, manto, or bedded deposits occur as replacements in carbonate rocks. Some beds are replaced adjacent to structural features such as joints and faults. Frequently, there is a capping of sandstone, shale, or clay.

3. Replacement deposits in carbonate rocks along the contact with acidic igneous intrusives are another common type of deposit. Deposits do not have to be the result of contact metamorphism, but may be introduced later, following the contact zone as a conduit and replacing the limestone.

4. Stockworks and fillings in shear and breccia zones are another form in which fluorspar occurs. The Buffalo deposit in the Transvaal consists of a network of fluorspar veinlets in sill-like bodies that are inclusions in the granite of the Bushveld complex.

5. Carbonatite and alkalic rock complexes may have fluorspar at their margins. Fluorspar grades are not usually sufficient to be economic, but the Okorusu deposit in Namibia is made up of a number of bodies of fluorspar in limestones, quartzites, and related rocks that have been intruded and metamorphosed by an alkaline igneous rock complex.

6. Residual deposits of fluorspar are formed in clayey and sandy residuum that results from surficial weathering of fluorspar veins and replacement deposits. These deposits may be the sources of metallurgical-grade fluorspar. They include detrital deposits blanketing the apex of veins and the upper portions of the veins themselves that have been weathered to depths of 30 meters or more.

7. Fluorspar also may occur as a major gangue mineral in lead and zinc vein deposits. Two operations in the Parral area of Mexico have treated the tailings of lead-zinc mines to recover fluorspar from previously discarded gangue minerals.

Identified world fluorspar resources are approximately 430 million tons of contained fluorspar. As might be expected, the countries with the highest production have the largest fluorspar reserves, although their production ranking does not necessarily mirror their reserve ranking. World resources of equivalent fluorspar from phosphate rock are approximately 325 million tons, which includes about 32 million tons from domestic phosphate rock.

Technology

Mining.[2]—Mining methods vary according to geologic conditions at individual deposits around the world. Deep deposits usually require underground techniques, while wide, shallow deposits employ open pit methods. If the ground is unable to support underground mining, open pit methods may be used even though overburden removal might be substantial. In some cases, open pit methods are used until the mining reaches a practical production limit because of excessive waste removal. Mining operations then move underground.

Narrow vein mining is commonly done by shrinkage stoping and open stoping where strong walls occur, while stratiform or bedded deposits use room-and-pillar patterns. Replacement and fissure vein deposits are mined with shrinkage stoping or cut-and-fill methods if they are deep, narrow occurrences. They also may be mined by open pit or strip-mining techniques when they occur near the surface and have competent sidewalls. The replacement and stockwork deposits in the Republic of South Africa, the carbonatite deposit in Namibia, and most of the fissure veins in Thailand are mined with open pit methods. However, replacement deposits in Mexico are extracted by stoping or cut-and-fill methods.

Beneficiation.—Most fluorspar must be upgraded for marketing. Metspar is often produced by hand sorting of high-grade lump crude ore, followed by crushing and screening to remove most of the fines. In the case of fluorspar ores of lower grade and/or ores with relatively coarse interlocking of minerals, gravity concentration processes are used based on the specific gravity above 3.0 for spar and below 2.8 for most gangue minerals.

Heavy-media cone and drum separators are particularly effective in the 37.5- by 4.75-millimeter (1 1/2- by 3/16-inch) size range, either for producing metallurgical gravel or for preconcentrating crude ore for flotation feed. For the finer sizes, the heavy-media cyclone process is frequently used. The high capacity and low operating cost of heavy-media methods give very satisfactory results. Ores as low as 14% CaF_2 can be preconcentrated to yield a flotation feed of 40% CaF_2 or more. In the process, lead and zinc sulfides and barite concentrate with the fluorspar, which enriches the flotation feed with these valuable minerals. In some cases, washing plants are used prior to flotation to remove clay or manganese oxides (wad).

Ceramic and acid grades of fluorspar are produced by multistage froth flotation. Ore from the mine is crushed and ground to proper size; care is taken not to overgrind and cause fluorspar to be lost in the slimes. If lead and zinc sulfides are present, they are preferentially floated off with xanthate collector. After this process is completed, all the easy floating fluorspar is removed in a quick pass through a flotation circuit and sent on to the cleaner circuit. The tailings are discarded. The middling product is reground to separate the more finely interlocked grains of fluorspar and gangue and passed through one or more cleaner circuits. The final products generally comprise an acid-grade concentrate and, in some cases, one or more concentrates of lower grade, which are sold as ceramic grade, or pelletized and sold as metallurgical grade. Fatty acids are used as collectors for the fluorspar. Quebracho or tannin is used to depress calcite and dolomite; sodium silicate is used to depress iron oxides and silica; and chromates, starch, and dextrin are used to depress barite. Cyanide is used to depress any remaining sulfides. Lime, caustic, or soda ash can be used for acidity control. Flotation temperatures range from ambient to 80° C.

Economic Factors

Depletion allowances against Federal taxes of 22% and 14%, respectively, remained in effect for domestic and foreign production by U.S. companies.

Operating Factors

The United States is import dependent for the majority of its fluorspar supplies. Fluorspar products are transported to customers by truck, rail, barge, and ship. Most acidspar is shipped in the form of damp filter cake containing 7% to 10% moisture to facilitate handling and reduce dust.

Most acidspar imports come from China, the Republic of South Africa, and other overseas suppliers. Fluorspar is shipped by ocean freight utilizing the "Tramp" market for ships. Bulk carriers of 10,000 to 50,000 tons deadweight are normally utilized. Participants negotiate freight level, terms, and conditions. The main participants are *charterers*—generally the buyers or sellers, *ship owners*—who either own vessels or have them time chartered, *operators*—traders normally taking positions on either cargo or ships, and *brokers*—generally represent ship owners or charterers and act as go betweens. Ships are primarily owned by the following: privately held shipping companies, publicly held shipping companies, government-controlled companies, and groups of professionally managed fleets under varying ownership. The total number of ships in the 10,000- to 50,000-ton range is about 2,000, of which more than 60% is at least 15 years old. The rate of new ship construction is very low—less than 2% of the total fleet is on order. Factors or concerns currently affecting the shipping market are the age of the fleet, environmental safety and quality assurance, insurance rates, rising operating costs due to inflation, increasing port expenses, increased tax or tariffs relating to ship costs, and anticipated volatility due to changing world conditions.[3]

ANNUAL REVIEW

Legislation and Government Programs

The Defense Logistics Agency, Defense National Stockpile Center (DLA-DNSC), measures the fluorspar stockpile in standard dry tons (sdt), although actual sales are made in standard wet tons (swt). In 1993, it was authorized to sell 20,000 sdt (18,144 metric tons) of metspar and 20,000 sdt of acidspar during fiscal year 1993 (October 1, 1992, to September 30, 1993). During this period, the DLA-DNSC reported sales of 17,043 swt (15,461 metric tons) of metspar from stockpiles in Marietta, PA, and Hammond, IN; 720 swt (653 metric tons) of nonstockpile-grade metspar from a stockpile in Marietta, PA; and 7,257 swt (6,583 metric tons) of acidspar from stockpiles in Wilmington, DE. According to the DLA-DNSC's Fiscal Year 1994 Annual Materials Plan, there is an existing authority for the disposal of 20,000 sdt (18,144 metric tons) of metspar and 90,000 sdt (81,647 metric tons) of acidspar.

Owing to HF's acute toxicity, the Environmental Protection Agency (EPA) has listed it as an extremely hazardous substance with a threshold planning quantity of 100 pounds (45 kilograms), under Section 302 of the Emergency Planning and Community Right-to-Know Act. Local Emergency Planning Committees (LEPC's) are required by the act to develop comprehensive emergency plans to address facilities where HF is present in excess of it threshold planning quantity. In July 1993, EPA issued an HF Chemical Emergency Preparedness and Prevention Advisory for use by LEPC's. This advisory listed suggestions for hazards analysis and identification, recognizing HF's characteristics, vulnerability analysis, emergency planning, testing the plan, and communications. It also offered recommendations for HF facilities.[4]

The EPA continued to propose and finalize rules regulating ozone-depleting chemicals, as required by "Title VI—Stratospheric Ozone Protection" of the Clean Air Act Amendments of 1990 (CAAA). EPA finalized its regulations limiting emissions of ozone-depleting substances during their use and disposal. The regulations established a recycling program for ozone-depleting refrigerants recovered during the servicing and disposal of air-conditioning or refrigeration equipment. The regulations require persons servicing air-conditioning and refrigeration equipment to observe certain service practices that reduce refrigerant emissions and establish equipment and offsite reclaimer certification programs. In addition, EPA requires that ozone-depleting compounds contained "in bulk" in appliances be removed prior to disposal of the appliances.[5]

EPA finalized separate regulations to ban nonessential products releasing class I ozone-depleting substances consisting of chlorofluorocarbons (CFC's), halons, carbon tetrachloride, and methyl chloroform and class II substances consisting of hydrochlorofluorocarbons (HCFC's). The rulemaking prohibits the sale, distribution, or offer of sale or distribution in interstate commerce of certain products containing or produced with these substances after specified dates. There are, however, exceptions to these rulemakings for certain medical or industrial uses for which no suitable replacement has been found.[6]

EPA added 11 HCFC's to the list of toxic chemicals subject to reporting under the Emergency Planning and Community Right-to-Know Act of 1986. The rationale focused not on direct toxicity, but rather on the depleting effect HCFC's have on stratospheric ozone and the resulting increase in penetration of ultraviolet-B radiation, which is known to cause various adverse human health and environmental effects.[7]

As part of a project initiated in 1991, the U.S. Bureau of Mines, Minerals Availability Field Office continued to collect information on the fluorspar and HF industries for the purpose of addressing impacts on production costs and supply and demand resulting from regulatory requirements on the industries or new technologies to produce replacements for banned CFC's. A Network Flow Model and Supply Analysis Model will be developed for the fluorspar and HF industries to address material flow from the production of acid-grade fluorspar to HF plants and on to CFC consumers. Operating costs and transportation costs for each stage will be incorporated. During 1993, data were collected on eight European HF plants and work on the computer model began. The model is expected to be completed by the second quarter of 1994 and the final report published by the end of the year.

Issues

As required by Section 112(n)6 of Title III of the CAAA, EPA published the Hydrogen Fluoride Study Report to Congress. In the report, EPA was required to identify potential hazards to public health and the environment considering a range of events and to make recommendations for reducing hazards, if appropriate. The study determined that "owners/operators can achieve an adequate margin of protection both for their workers and the surrounding community by assiduously applying existing industry standards and practices, existing regulations, and future guidance and regulations applicable to various classes of hazardous substances in various settings."[8] The conclusions of this study should allay the concerns of producers and consumers of HF, who may have been required to spend large sums of money for new equipment and training. In particular, the petroleum refining industry estimated it could have cost $4 billion to replace HF alkylation units with sulfuric acid units.

EPA proposed rules for evaluating and regulating substitutes for ozone-depleting chemicals being phased out by the CAAA. EPA is authorized to identify and restrict the use of substitutes where other alternatives exist that reduce overall risk to human health and the environment. The program is known as the Significant New Alternatives Policy (SNAP) program. In the proposed rulemaking, EPA issued preliminary decisions on the acceptability of certain substitutes for refrigeration, foam blowing, solvents cleaning, fire extinguishing, tobacco puffing, adhesives, coatings and inks, aerosols, and sterilants.[9]

The publication of the preliminary substitute list helped allay uncertainty in the consumer markets, in particular the foam blowing, refrigeration, and air conditioning markets. Equipment manufacturers and consumers were faced with the very real uncertainty of redesigning equipment and selecting replacement compounds without knowing if the replacement compounds would be on the "approved list" or not.

In response to an animal study that detected a higher rate of bone tumors in male rats exposed to very high levels of fluoride and a few cases of skeletal fluorosis, EPA requested the National Research Council (NRC) to review available data on fluoride toxicity. The NRC is the operating agency of the National Academy of Sciences, which is chartered by Congress to conduct research for the Government. About one-half of the U.S. population drinks water from municipal supplies containing optimally 0.7 to 1.2 parts per million (ppm) fluoride, with an allowable ceiling of 4.0 ppm. The resulting report, "Health Effects of Ingested Fluoride," concluded that existing fluoride levels in drinking water do not pose a health risk for kidney failure, bone disease, or cancer. Further research was recommended on patterns of fluoride exposure from food and dental products. The findings were the result of a comprehensive review of publications and government databases. The fluoridation of drinking water has been a source of controversy and dispute since its beginning in the 1940's.[10]

Production

Illinois was the only State reporting mine production in 1993, although Nevada and Texas reported shipments from stocks and shipments of reprocessed material from Mexico, respectively.

These three sources accounted for 100% of all reported U.S. shipments. Data on shipments of fluorspar, by State and grade, are withheld to avoid disclosing company proprietary data.

Ozark-Mahoning Co., the Nation's largest fluorspar producer and a subsidiary of Elf Atochem North America Inc., operated three mines and a flotation plant in Pope and Hardin Counties, IL. Ozark-Mahoning also dried imported fluorspar and processed some material from the National Defense Stockpile to supplement its production. Seaforth Mineral & Ore Co. Inc. dried imported fluorspar at its facilities at Cave-In-Rock, IL, and East Liverpool, OH, for sale primarily to consumers in the ceramic industry. J. Irving Crowell, Jr., & Son shipped a small amount of fluorspar from stocks, but the Crowell-Daisy Mine in Nye County, NV, remained closed. Production Minerals Inc. reprocessed some fluorspar imported from Mexico at its mill in Marathon, TX.

Six companies operating eight plants processing phosphate rock for the production of phosphoric acid sold a reported 65,882 tons of byproduct fluorosilicic acid at a value of about $7.96 million. This was equal to 115,952 tons of 92% fluorspar equivalent. Because fluorosilicic acid is a byproduct of the fertilizer industry and is not manufactured for itself alone, shortages can occur when fertilizer demand goes down.

Consumption and Uses

Acid-grade fluorspar, containing greater than 97% calcium fluoride (CaF_2), was used primarily as a feedstock in the manufacture of HF. Ceramic-grade fluorspar, containing 85% to 95% CaF_2, was used for the production of glass and enamel, to make welding rod coatings, and as a flux in the steel industry. Metallurgical-grade fluorspar, containing 60% to 85% or more CaF_2, was used primarily as a fluxing agent by the steel industry. Fluorspar is added to the slag to make it more reactive. It increases the fluidity of the slag (by reducing its melting point) and thus increases the chemical reactivity of the slag. Reducing the melting point of the slag brings lime and other fluxes into solution to allow the absorption of impurities.

Reported domestic consumption by the HF industry in 1993 decreased by about 8%. Reported consumption by the steel industry in basic oxygen and electric arc furnaces decreased by about 14%, despite a 5% increase in U.S. raw steel production.

In the ceramic industry, fluorspar was used as a flux and as an opacifier in the production of flint glass, white or opal glass, and enamels. Fluorspar was used in the manufacture of aluminum, brick, cement, and glass fibers, and was also used in the melt shop by the foundry industry.

Three companies reported fluorspar consumption for the production of HF. The U.S. Department of Commerce, Bureau of the Census, reported that, based on its quarterly survey of anhydrous, technical, and aqueous HF, 100% basis, 158,988 tons was "produced and withdrawn from the system" for 1993, compared with the 1992 annual summary total of 164,562 tons.

The largest use of HF, accounting for 60% to 65% of HF withdrawn from the system, was for the production of a wide range of fluorocarbon chemicals, including fluoropolymers, CFC's, HCFC's, and HFC's. CFC's, HCFC's and HFC's were produced by six companies: Allied-Signal Corp., Ausimont USA Inc., E. I. du Pont de Nemours & Company Inc. (Du Pont), Elf Atochem North America Inc., I.C.I. Americas Inc., and La Roche Chemicals Inc. According to preliminary data from the U.S. International Trade Commission, production of trichlorofluoromethane (CFC-11) decreased by 28% to 32,803 tons and dichlorodifluoromethane (CFC-12) increased by about 16% to 83,701 tons compared with 1992 figures. Production of chlorodifluoromethane (HCFC-22) in 1993 was 132,164 tons. At present, no information is collected on production of the HCFC and HFC replacement compounds.

Some of the replacements for CFC's will be HCFC's 22, 123, 124, 141b, and 142b. These HCFC substitutes have ozone-depletion potentials much lower than that of CFC-11, CFC-12, and CFC-113, which in total have accounted for more than 90% of CFC consumption. Unfortunately, because of the recently agreed upon phaseout schedule for HCFC's and the likelihood that the schedule will be accelerated, the market for HCFC's will exist for only a relatively short time. Industry expects HCFC's to be produced and utilized at least through the end of this decade.

The HFC replacements have no ozone-depletion potential because they contain no chlorine atoms. The most promising HFC candidate is HFC-134a, which is already replacing CFC-12 in auto air conditioners and is expected to replace CFC-12 in medium-temperature range refrigeration systems. HFC's 125, 143a, and 152a also are being produced domestically, but in much smaller quantities. These four HFC's hold potential for use by themselves or more likely as blends for specific uses. In addition, some interim replacements may be mixtures of these compounds and HCFC's.

The manufacture of aluminum fluoride for use in aluminum reduction cells was a major use of HF. In the Hall-Héroult process, alumina is dissolved in a bath of molten cryolite, aluminum fluoride, and fluorspar to allow electrolytic recovery of aluminum. An estimated 20 to 30 kilograms of fluorine was consumed for each metric ton of aluminum produced. Aluminum fluoride was used by the ceramic industry for some body and glaze mixtures and in the production of specialty refractory products. It was used in the manufacture of aluminum silicates and in the glass industry as a filler.

HF was consumed in the manufacture of uranium tetrafluoride that was used in the process of concentrating uranium isotope 235 for use as nuclear fuel and in fission explosives. It was also used in stainless steel pickling, petroleum alkylation, glass etching, oil and gas well treatment, and as a cleaner and etcher in the electronics industry. It was used as the feedstock in the manufacture of a host of fluorine chemicals used in dielectrics, metallurgy, wood preservatives, herbicides, mouthwashes, decay-preventing dentifrices, plastics, and water fluoridation.

The byproduct fluorosilicic acid was used in water fluoridation (76%), either directly or after processing to sodium silicofluoride, to make aluminum fluoride for the aluminum industry (23%) and to make ammonia and magnesium fluorosilicates (1%). *(See table 2.)*

Stocks

Consumer stocks at yearend were 75,015 tons, an increase of 4% from the revised level reported in 1992. At yearend, the National Defense Stockpile fluorspar inventory had decreased from yearend 1992 and contained about 889,000 sdt (806,000 metric tons) of acid-grade material, about 282,000 sdt (256,000 metric tons) of metallurgical-grade material, about 900 sdt (816 metric tons) of nonstockpile, acid-grade material, and about 107,000 sdt (97,000 metric tons) of nonstockpile, metallurgical-grade material. The fluorspar stockpiles are at 22 sites across the country. The largest acid-grade stockpiles are in Wilmington, DE; Memphis, TN; and North Gate, CO. The largest metallurgical-grade stockpiles are in Large, PA; Warren, OH; and Pine Bluff, AR.

Prices

According to prices published by Industrial Minerals (Metal Bulletin PLC), no domestic price for fluorspar was available for 1993. Published yearend producer prices for Mexico decreased for both acid grade and metallurgical grade. South African prices for acid grade also decreased. Although no list prices for Chinese fluorspar were available, based on U.S. trade data, the prices for acid grade and metallurgical grade both decreased in 1993. *(See table 3.)*

Yearend price quotations from the Chemical Marketing Reporter (CMR) were unchanged at $0.6875 per pound for anhydrous HF and were unchanged at $52.00 per 100 pounds for aqueous HF, 70%, in tanks. These quotations were equivalent to about $1.52 per kilogram for anhydrous HF and $114.64 per 100 kilograms for aqueous HF, 70%, in tanks. The CMR yearend price quotation for hydrofluosilicic acid (fluorosilicic acid), 23% basis, in tanks, Midwest & East Coast terminals, was $165 per short ton (about $182 per metric ton). Prices of fluorosilicic acid were up in 1993, because several producers have either closed or ceased production. This tightened supplies and forced buyers to turn to higher cost producers. Rising rail and truck freight rates also caused upward pressure on prices.

Foreign Trade

According to the Bureau of the Census, U.S. exports of fluorspar decreased by about 7%. Because Ozark-Mahoning reported no foreign sales, all U.S. exports were reexports of material imported into the United States. *(See table 4.)*

Imports for consumption of fluorspar remained essentially unchanged when compared with those of the previous year, according to Bureau of the Census data and revisions made to 1992 data. In 1993, China was once again the largest supplier of fluorspar to the United States, followed by, in descending order, the Republic of South Africa and Mexico. China accounted for nearly 59% of U.S. fluorspar imports. The average c.i.f. unit value, in dollars per metric ton, was about $102 for acid grade and about $73 for subacid grade. *(See table 5.)*

The 13.5% ad valorem tariff on subacid-grade fluorspar imports went back into effect on January 1, 1993, and applied to both most-favored-nation (MFN) and non-MFN countries. The tariff on acid grade for MFN countries is $2.10 per long ton ($2.07 per metric ton) and for non-MFN countries $5.60 per long ton ($5.51 per metric ton).

Congress ratified the North American Free Trade Agreement (NAFTA) in November 1993 and the President signed the implementation bill in December 1993. NAFTA required the elimination of the 13.5% ad valorem tariff on subacid-grade imports from Mexico effective January 1, 1994. Under the Generalized System of Preferences, acid-grade imports from Mexico were already exempt from duty upon entering the United States, and under NAFTA, acid-grade imports will continue to receive duty-free treatment.

Imports for consumption of HF decreased by 6% to a quantity equivalent to approximately 94,000 tons of fluorspar. Imports of synthetic and natural cryolite decreased 7% to a quantity equivalent to approximately 4,540 tons of fluorspar. Imports of aluminum fluoride increased by 22% to a quantity equivalent to approximately 59,100 tons of fluorspar. *(See tables 6, 7, and 8.)*

World Review

World fluorspar consumption and production remained essentially unchanged compared with 1992 levels. In order of rank, China, Mexico, the Republic of South Africa, and Mongolia were the major producers. The international fluorspar industry experienced the continuing effects of major changes in the traditional markets of fluorochemicals, steel, and aluminum.

Brazil.[11]—The Brazilian mining company Paranapanema announced plans to move ahead with the development of a cryolite deposit in the State of Amazonas. Pending approval of necessary environmental permits, development would take place over a 2-year period and cost $20 million. The cryolite deposit was discovered in 1991 in the Pitinga tin mine belonging to Paranapanema. The mine is near the town of Joao Figueiredo. Reserves are estimated at 3 million tons and occur at a depth of 150 meters, below the cassiterite ore body. The project is expected to produce 25,000 tons per year of 99% purity concentrates for the domestic aluminum industry.

European Union.[12]—China's pricing practices continued to cause difficulties for other fluorspar producers. As a result, on September 1, 1993, the Commission of the European Communities imposed a provisional antidumping duty on imports of fluorspar originating in China. The duty was imposed on imports of fluorspar presented in filter cake form or in powder form, containing more than 97% calcium fluoride falling within harmonized code 2529.22.0000 or containing less than 97% calcium fluoride falling within harmonized code 2529.21.0000, originating in China. The duty was equal to the difference between a minimum price of ECU 93.40 per ton (dry net weight) and the net free at Community frontier price before customs clearance. The duty was to apply for a period of 4 months, unless the Council adopted definitive measures before the expiration of that period. This meant that acid-grade and ceramic-grade imports into the European Community from China were to be assessed a duty based on a minimum price of about $104 per ton.

Mexico.—Production figures for 1989-91 were revised in the world production table to reflect acidspar production incorrectly listed as submetallurgical grade.

Fluorita de Mexico S.A. had financial difficulties but continued production of acidspar. Applied Industrial Minerals Corp. (AIMCOR) announced plans to sell its Metals/Minerals, which included a 49% stake in Fluorita de Mexico. The stake in Fluorita de Mexico was included in the metals side of the group owing to AIMCOR's fluorspar marketing arrangements. Talks with prospective buyers were further advanced for the sale of the minerals side of the group.[13]

Mexico's largest fluorspar producer, Cia. Minera Las Cuevas S.A. de C.V., received ISO 9002 accreditation from the Bureau Veritas Quality International. The quality assurance approval applies to extraction, processing, and marketing of both acidspar and metspar.[14]

Grupo Industrial Camesa sold its chemical division, Fluorex S.A., to Norfluor U.S.A. Fluorex produced and marketed HF and inorganic fluorides from its 25,000-ton-per-year HF plant in Ciudad Juárez, Chihuahua.[15]

Namibia.[16]—Okorusu Fluorspar Ltd. received a loan from the European Union through the Namibian Government for $47 million. The loan is repayable at 6% per annum over 13 years. The company plans to use the money to continue its current program to expand and develop its processing plant in anticipation of recovery of fluorspar markets. Okorusu ships most of its product to Germany or the United States, although import data do not necessarily agree with the company's sales figures. One possible explanation is that, because ships carrying Kenyan and South African fluorspar stop at Namibia's Walvis Bay to load Okorusu's material, the trade importing country's statistics may confuse the origin of the shipments. For example, total U.S. imports from Namibia amounted to only 4,229 tons in 1990 and 4,614 tons in 1992.

Russia.[17]—Kirovo-Chepetsk Chemical Enterprise (KCCE) of Kirovskaya Oblast, Russia, and Du Pont formed a joint venture to market fluoropolymers worldwide. The new venture will be primarily targeting business opportunities in the former U.S.S.R., but also will export polytetrafluoroethylene to other countries. KCCE is the largest producer of fluoropolymers, fluoroelastomers, refrigerants, and fluorinated fluids in the former U.S.S.R.

United Kingdom.—In December 1993, Swan Industrial Minerals Ltd. went into receivership. Swan had acquired the Derbyshire mineral rights of fluorspar producer Deepwood Mining Co. Ltd. They also had acquired Matlock Barytes and Horace Taylor Minerals Ltd., the latter a grinding and concentrating facility. The company had refurbished and upgraded the processing facility, expecting an upturn in European metspar demand that never materialized. The processing plant was shut down indefinitely, but production and sales of raw materials were expected to continue, at least for a time, into 1994.[18]

British Nuclear Fuels (BNFL), a long-time producer of elemental fluorine for the production of uranium hexafluoride, has during the past 2 years expanded into the fluorochemicals business. In 1992, BNFL Fluorochemicals was set up to produce and market high value added fluorochemicals and shortly thereafter acquired Fluorochem Ltd., a supplier of fluorine compounds, mostly in research and development quantities. They extended their product line later in the year by acquiring the assets of Shell jv Yarsley Fluorochemicals Ltd. In 1993, the company acquired Rhône Poulenc's Flutec business, which produces fully saturated perfluorocarbons, containing only carbon and fluorine. BNFL Fluorochemicals also has an agreement with a Russian fluorochemical supplier for large quantities to develop their bulk and semibulk business.[19] *(See table 9.)*

Current Research

The 3M Specialty Chemicals Co., at the request of Magma Copper Co., developed a fluorochemical surfactant designed to improve acid/ore contact. Personnel at Magma Copper theorized that they could increase the rate of copper recovery by improved wetting of the ore with the acidic leach solution. The new product, called Fluorad FC-1129, improves the coverage and wetting action of the acid without affecting the subsequent solvent extraction process. Magma Copper reported a 5% increase in recovery through the addition of the new surfactant.[20]

Realizing the need to develop HFC replacements for HCFC compounds, Allied-Signal Inc. has identified four HFC compounds to possibly replace HCFC-141b for polyurethane foam-blowing applications. The four compounds are HFC-245ca, HFC-245eb, HFC-245fa, and HFC-356. A short-term toxicity testing protocol was begun to determine which compounds will require long-term testing. Short-term testing was expected to be completed by the first quarter of 1994.[21]

OUTLOOK

Consumption of metspar by the U.S. steel industry decreased again in 1993, despite a gain in raw steel production. The decreasing level of consumption is mainly a result of continuing changes in technology, improvements in efficiencies, and tighter raw material specifications. These factors indicate that U.S. consumption of metallurgical-grade fluorspar will continue to decrease through the 1990's.

The international market for metspar is still huge. Worldwide, the steel industry is still the largest consumer of fluorspar. However, with the spread of more efficient steelmaking processes, the unit consumption of fluorspar is expected to fall. This will probably offset overall gains in steel production, primarily in developing countries.

The aluminum industry consumes fluorine from different sources and in different forms. Although some acidspar is consumed directly, fluorine is also consumed in the form of synthetic or natural cryolite, but mainly as aluminum fluoride. Aluminum fluoride is manufactured either directly from acidspar, HF, or fluorosilicic acid.

U.S. consumption by primary aluminum producers is down owing to cutbacks in aluminum production necessitated by world oversupply. Aluminum Co. of America Inc., which manufactures aluminum fluoride from acidspar, cut capacity in 1993 and is expected to make additional capacity cuts in 1994. Demand for aluminum is expected to grow, on average, by only 2% per year over the rest of this decade. Consumption of fluorspar and fluorspar equivalent is expected to track aluminum demand.

Consumption of acidspar by the chemical industry for the production of HF is the largest market for fluorspar. The largest use of HF is in the manufacture of fluorocarbons (CFC's, HCFC's, and HFC's). The fluorocarbon market accounts for about 63% of HF demand and is thus the driving force in HF demand. Demand for fluorocarbons is expected to remain essentially unchanged in 1994 and then increase by 5% to 6% per year during the next 3 to 5 years. No significant growth is expected long term in the other smaller HF markets.

Prices are expected to move upward as a result of pressures on Chinese producers. In recent years, Chinese producers have closed mines, sold off inventories built up over a 2-year period, experienced rising production costs, and faced increasing inflation pressures.

TABLE 1
SALIENT FLUORSPAR STATISTICS[1]

		1989	1990	1991	1992	1993
United States:						
Production:						
Finished (shipments)[e]	metric tons	66,000	63,500	58,000	[2]51,000	[3]60,000
Value f.o.b. mine	thousands	W	W	W	W	W
Exports	metric tons	5,134	14,921	73,943	13,646	12,739
Value	thousands	$694	$1,891	$16,424	$1,983	$2,126
Imports for consumption	metric tons	655,590	513,921	437,027	[r]407,239	398,322
Value[4]	thousands	$79,897	$65,938	$54,549	[r]$42,505	$38,761
Consumption (reported)	metric tons	641,882	564,545	483,589	485,442	447,392
Consumption (apparent)[5]	do.	698,255	581,806	500,720	[6]480,376	455,261
Stocks, Dec. 31:						
Domestic mines:						
Finished	do.	W	W	W	W	W
Consumer	do.	79,347	74,692	68,999	[r]71,954	75,015
World: Production	do.	[r]5,557,424	[r]5,123,772	[r]4,221,508	[r]4,053,955	[e]4,030,852

[e]Estimated. [r]Revised. W Withheld to avoid disclosing company proprietary data.

[1] Does not include fluorosilicic acid (H_2SiF_6) or imports of hydrofluoric acid (HF) and cryolite.

[2] Includes 2,700 tons of nonstockpile-grade metspar from the National Defense Stockpile beneficiated by Ozark Mahoning Co.

[3] Includes fluorspar from the National Defense Stockpile beneficiated by Ozark-Mahoning Co., Illinois, and Mexican fluorspar processed by Production Minerals, Inc., Texas, totaling 21,775 tons.

[4] C.i.f. value at U.S. port.

[5] U.S. primary and secondary production plus imports plus adjustments for Government and industry stock changes.

[6] Includes 907 tons of nonstockpile-grade metspar from the National Defense Stockpile.

TABLE 2
U.S. CONSUMPTION (REPORTED) OF FLUORSPAR, BY END USE

(Metric tons)

End use or product	Containing more than 97% calcium fluoride (CaF_2)		Containing not more than 97% calcium fluoride (CaF_2)		Total	
	1992	1993	1992	1993	1992	1993
Hydrofluoric acid (HF)	347,367	320,706	—	—	347,367	320,706
Basic oxygen furnaces	—	—	33,204	26,877	33,204	26,877
Electric furnaces	2,229	1,319	20,733	20,159	22,962	21,478
Iron and steel foundries	W	—	W	1,367	W	1,367
Other[1]	W	W	W	W	81,909	76,964
Total	W	W	W	W	485,442	447,392
Stocks, Dec. 31 (consumer)	[r]69,959	72,987	1,995	2,399	[r]71,954	75,015

[r]Revised. W Withheld to avoid disclosing company proprietary data; included in "Total."

[1] Includes aluminum fluoride, enamel, glass and fiberglass, open-hearth furnaces, primary aluminum, primary magnesium, and welding rod coatings.

[e] Estimated. [r] Revised.

[1] Table includes data available through June 3, 1994.

[2] In addition to the countries listed, Bulgaria is believed to have produced fluorspar in the past, but production is not officially reported, and available information is inadequate for the formulation of reliable estimates of output levels.

[3] An effort has been made to subdivide production of all countries by grade (acid, ceramic, and metallurgical). Where this information is not available in official reports of the subject country, the data have been entered without qualifying notes.

[4] Formerly part of Czechoslovakia; data were not reported separately until 1993.

[5] Dissolved Dec. 31, 1992.

[6] Year beginning Mar. 21 of that stated.

[7] Formerly part of the U.S.S.R.

[8] Data for 1989-91 are reported by Consejo de Recursos Minerales; but the production of submetallurgical grade and acid grade have been redistributed by the author based on industry data. Data for 1992 and 1993 are from an industry source.

[9] Principally submetallurgical-grade material.

[10] Reported figure.

[11] Data show estimated proportions of acid-grade, ceramic-grade, and metallurgical-grade fluorspar within the reported totals. Data may not add to totals shown because of rounded estimates.

[12] Dissolved in Dec. 1991.

GEMSTONES

By Gordon T. Austin

Mr. Austin, a physical scientist with more than 30 years of industry and Government experience, has been the gemstones commodity specialist since 1986. Ms. Kelly Dorney of the Branch of Data Collection and Coordination prepared the domestic production survey data.

Webster's dictionary defines a gem "as any jewel, whether stone, pearl or the like, having value and beauty that are intrinsic and not derived from its setting; a precious or, sometimes, a semiprecious stone cut and polished for ornament. A stone of value because it is carved or engraved, as a cameo or intaglio." Additionally, the dictionary states that gemstone or gem material is a stone or material from which a gem may be cut. So a gem, gemstone, or gem material may be described as inorganic or organic minerals used for personal adornment, display, or to manufacture objects of art because they possess beauty, rarity, and durability.

In 1993, the value of natural gemstones from deposits in the United States was $57.7 million, a decrease of 13% compared with that of 1992. Production of gemstones included faceting rough, lapidary rough, carving material, specimen material, natural and cultured freshwater pearls, mother of pearl, shell, fossil ivory, amber, and coral.

Laboratory grown synthetic gemstones have essentially the same appearance and optical, physical, and chemical properties as the natural material that they represent. Synthetic gemstones produced in the United States include alexandrite, coral, diamond, emerald, garnet, lapis lazuli, quartz, ruby, sapphire, spinel, and turquoise. Laboratory grown simulants have an appearance similar to that of a natural gem material but have different optical, physical, and chemical properties. The gemstone simulants produced in the United States include coral, cubic zirconia, lapis lazuli, malachite, and turquoise. Additionally, certain colors of synthetic sapphire and spinel, used to represent other gemstones, would be classed as simulants. Colored and colorless varieties of cubic zirconia are the major simulants produced. In 1993, the reported value of production of U.S. synthetic and simulant materials was $17.9 million, about a 5% decrease from that of 1992.

Wholesale and retail stores, gem and mineral shops, gem and mineral dealers, cutting factories, and jewelry manufacturers were the major purchasers of domestic gem materials.

DOMESTIC DATA COVERAGE

The U.S. Bureau of Mines (USBM) estimates U.S. production from the "Natural and Synthetic Gem Material Survey," a voluntary survey of U.S. operations, and from USBM estimates of unreported production. Of the 387 operations surveyed, 84% responded, 84% of the natural gemstone producers and 95% of the synthetic and simulant producers.

The number of operations surveyed in 1993 was 3% less than the number surveyed in 1992. The response rate was about the same. The USBM estimated the production by nonresponding operations, by professional collectors, and by amateur or hobbyist collectors. The basis for these estimates was information from published data, conversations with gem and mineral dealers, analyses of gem and mineral shows and sales statistics, and from information informally supplied by collectors.

BACKGROUND

The history of production and preparation of gemstones begins with the wearing of items for personal adornment in prehistoric times; this preceded even the wearing of clothes. Amber was mined in the Baltic countries for use as a gem material before 25000 B.C. Later, the Phoenicians in their writings described their trade routes to the Baltic for amber and to areas in Asia and Africa for other gemstones. The voyages of Columbus brought increased interest in gemstone deposits, especially emerald, in South America. The discovery of diamond in Africa in 1859 focused major interest on Africa. More recently, the discovery of diamond in Western Australia in 1967 resulted in the development of the largest known diamond deposit in the world.

Commercial mining of gemstones is extensive in the United States but not as large-scale operations. More than 60 different gemstones have been produced commercially from small domestic sources. Often, production rests in the hands of hobbyists and members of mineralogical and lapidary clubs. The Crater of Diamonds State Park near Murfreesboro, AR, is open to the public on a fee-per-day basis, as are many gemstone deposits throughout the United States. Each year many gem-quality stones are found at these locations.

Definitions, Grades, and Specifications

The gemstones data include information on select rocks, certain varieties of mineral specimens, and some organic materials, such as pearl, amber, jet, and coral. Customarily, diamond, ruby, sapphire, and emerald are the major gems.

The most important qualities of gemstones are beauty, durability, uniqueness, and rarity. Beauty, indicated as splendor, purity, or attractiveness, is according to the taste of the beholder and includes such appearances as luster, transparency, brilliance, and color. Luster of a mineral or stone is independent of color and is the surface appearance in reflected light. Apart from materials that have a metallic luster, the chief contributors to luster are transparency and refractive index. In cut gems, the perfection of the polish enhances the luster. Visible imperfections impair the luster of transparent stones. Yet, defects, described as "jardens" or "inclusions," may enhance the beauty and value of natural rubies, emeralds, and other gemstones. Sometimes these inclusions may be used to identify the country and even the mine from which the stone came. Durability is the resistance of a stone to abrasion, pitting, chipping, or splitting. Resistance to abrasion is correlated with relative hardness, but intrinsic brittleness and toughness suggest resistance to wear in other aspects. Rarity is an essential qualification and is more important for some stones in determining their value than their physical characteristics.

Of the approximate 2,900 mineral species, only about 100 possess all the attributes required of a gem. Collectors of gems may not require that a gem be durable because the stone is for display and is not to be worn. Therefore, the number of species of gemstones may be greater than the 100 that meet all the requirements.

Silicates furnish the greatest number, including such minerals as beryl, topaz, tourmaline, and feldspar. Oxides such as corundum (ruby and sapphire) and quartz (amethyst, agate, etc.) comprise the second largest group. Sulfides, carbonates, and sulfates are of small importance; the phosphates yield primarily turquoise and variscite. An exception is pearl, essentially calcium carbonate, which ranks high as a gem. Diamond, the best known gem, is an isometric crystalline form of the element carbon.

Gemstones are classified the same as minerals; that is, into group, species, and variety. Group refers to two or more gem materials that are similar in crystal structure and physical properties but have different chemical properties. Each member of the group is a species. Varieties of species have similar crystal structure and chemical characteristics but differ in color. An example of this would be the hessonite variety of grossular species of the garnet group.

Products for Trade and Industry

Cutting of gems from gemstones is to obtain the most effective display of the material. No significant change is made in the fundamental properties, and the preparation is to enhance the desirable characteristics that are present initially. Gemstones are cut into gems in three main styles: faceted, cabochons, and baroque.

Facet cutting usually is on transparent gemstones to increase brilliancy and appearance. Often it is confined to the harder materials. Softer materials may be faceted, but extreme care must be exercised in cutting and polishing the stones and in their use in jewelry. Often the softer gems are only for display and not for making jewelry. The "round brilliant" cut, most commonly used in faceting, has 58 facets, 33 above the circle "girdle" and 25 below it, arranged in eightfold symmetry. The "round brilliant" and other common cuts are illustrated in figure 1. *(See figure 1.)*

Cabochons are cut in four operations: sawing, grinding, sanding, and polishing. Sawing, the first step in cutting, customarily is done with a diamond saw to obtain a slab or slice of the desired size and thickness from the rough gemstone. The cabochon outline is scribed onto a flat surface, using a template for making a standard size for jewelry mountings. Rough grinding of the stone may be by metal-bond diamond, electroplated diamond, silicon carbide, or aluminum oxide wheels or coated abrasive disks. In grinding, the hardness of the gemstone determines the grit and hardness of the abrasive used. Multiple grinding steps starting with 80- to 100-mesh (grit) through 600-mesh abrasives are used. The scratches left by grinding are removed by progressively finer grinding and sanding. Disk or belt sanders use abrasives bonded to cloth, waterproof reinforced paper abrasives, or cloth charged with abrasive pastes. The final polish is on hard felt, wood, or leather laps, with various polishing agents such as fine diamond compound, tin oxide, tripoli, chromium oxide, cerium oxide, alumina, or rouge.

Polished irregular shapes are baroque gems. An inexpensive method of polishing baroque gems is to tumble them in rubber-lined drums, using a grinding and polishing medium with or without water.

Industry Structure

The Central Sales Organization (CSO), the marketing arm of De Beers Centenary AG, highly controls the world market for rough diamonds. It is by far the most controlled of the world's commodity markets. The CSO markets about 80% of the world's gem and natural industrial diamond. The marketing through the CSO is by the Diamond Trading Co. Ltd. and Industrial Distributors Ltd. The CSO sells uncut gem diamonds for De Beers and most other major producers at sights (approved bidder viewings) in London, England, and Lucerne, Switzerland. There are 10 such sights each year.

Diamonds reach the CSO sights through three channels—De Beers owned and operated mines, contracts sales by mine owner and operators, and open-market competitive sales.

The distribution of rough diamonds in the Republic of South Africa is by the South Africa Diamond Board. A new agreement was reached between De Beers Consolidated Mines Ltd., its customers, and the Government of South Africa on the method of domestic rough diamond distribution. In the past, all categories of rough diamonds that could be processed economically in South Africa must first be offered to local manufacturers. Rough could be exported duty free only if it had first been offered to the local market, otherwise a 15% duty was charged. Now, all rough will be shipped to London and mixed with diamonds from the other producers. Rough for South African cutters is then drawn from the world rough supply.

The CSO has been extremely successful at maintaining the rough diamond market for more than 50 years. In modern times there has never been a decrease in CSO's price of rough diamonds. *(See tables 1 and 2.)* The compounded effect over 44 years of these increases is a price increase of about 1,800%. Thus, a piece of rough that sold for $100 in August 1949 would sell for about $1,830 in February 1993.

For more than 30 years, the major diamond cutting and polishing centers of the world were in Belgium and Israel, with a certain amount of the larger stones being cut in the United States. In the early 1980's, the development of a large cottage industry in India—today there are more than 500,000 cutters—made a major impact on world diamond trade. India consumes most of the world's small-gem, cheap-gem, and near-gem rough material in the manufacture of small stones, which resulted in annual cut-stone exports worth billions of dollars. These small stones averaged less than one-fifth of a carat (0.20 carat). The availability of small inexpensive stones resulted in substantial changes in the design of jewelry. The utilization of small cut diamond stones (usually 0.07 to 0.14 carats each, called melee) to create a pavé effect (set close together to conceal the metal base) is but one example.

Estimates are that Russia's diamond cutting industry employs about 16,000 workers. The eight Krystall factories at Moscow, Smolensk, Kiev, Barnaul, Vinnitsa, Yerevan, Kusa, and Gomel employ fewer than 8,000, with the Moscow plant having about 900 workers. The workers at the various factories may be paid by different methods.

The workers at the Moscow plant are paid by the piece according to its size and difficulty of the cut. At Kiev, those workers whose work is not subject to inspection receive a 50% higher salary. Some Krystall factories have an incentive program for workers producing stones of 0.3 carat and larger. The incentive is a bonus of 5% of the added value that is paid to each 20-worker team and is shared by the team.

The diamond cutting and polishing factory at Nur Adjen, Armenia, produced about $60 million of income per year. The factory works at full capacity even in the winter because of its priority for electricity and heat. The factory's 1,800 workers are not allowed to drink at lunch (unlike Russian and Ukrainian diamond factory workers), have high morale, and comparatively high salaries; these factors resulted in high-quality production.

Annual cut diamond production depends on the number of workers in the industry and their productivity. If it is assumed that the industry has a production rate of 20 carats of finished goods per month per worker and that polished yields are less than 40%, then the industry's consumption of rough and yield of finished goods can be estimated. It is estimated that during a year, the Russian diamond cutting industry processes about 3.8 million carats of rough that yields about 1.6 million carats of polished goods. The polished goods would be worth between $500 million and $550 million on the world market.

During 1991, Leo and Schachter & Co. opened the newest, largest, and most modern U.S. diamond polishing factory in New York. The factory is computerized to track every diamond from rough to finished stone. The computer predicts the cash return from each piece of rough based on estimates of the rough's color, clarity, yield, and make; estimates are reported to be within 2% of actuals. The factory employs 40 polishers.

Cutting and polishing of colored, synthetic, and simulant gemstones are centered in, listed according to importance, Thailand, India, Hong Kong, Republic of Korea, China, and Brazil, where cheap labor and favorable export laws ensure the lowest total costs for finished gems.

Geology-Resources

Gemstones form in a large variety of igneous, metamorphic, and sedimentary deposits, usually as a small fraction of the total deposit. The origins are as varied as the deposits. Gemstones form primarily by precipitation from watery solutions, by crystallization from molten rock, and by metamorphic processes. Approximately one-third of gemstones is silicate minerals, about one-fifth alumina-silicates, and almost one-seventh oxides. The remaining compositional groups include the sulfides, phosphates, borosilicates, carbonates, and, in the single case of diamond, an element. The composition of selected gem materials is one line item in table 3. *(See table 3.)*

There are no large resources of major gem materials defined in the United States. North Carolina has emerald, ruby, and sapphire deposits. Historically, sapphires have been mined in Montana, and commercial mining is underway again. Many other domestic deposits of gemstones are known and have been mined for many years. Still, there are no systematic evaluations of the magnitude of these deposits, and no statements can be made about their reserve or the size of the resource.

Occasional finds of diamond have been made, but no great diamond pipes or alluvial deposits similar to those of Africa have been reported. Diamond exploration is underway by several companies in the Colorado-Wyoming State line area, and in Michigan, Minnesota, Wisconsin, and Arkansas. Diamond-bearing kimberlites have been located and bulk samples have been processed for diamond recovery.

World resources of gemstones are nearly all unevaluated. However, world gem diamond reserves are estimated to be about 300 million carats, including near-gem and cheap-gem qualities. Nearly all the reserves are in, listed in order of size, Australia, Africa and Russia. The estimates for diamond reserves are of limited value because data needed for reliable estimates are not available from the producers. Reserve data on other gemstones are even less available than for diamond.

Technology

Synthetic Gems.—Synthetic gemstone producers use many different methods, but they can be grouped into one of three types of processes: melt growth, solution growth, or extremely high-temperature, high-pressure growth.

The year 1902 saw the first production of synthetic ruby using the Verneuil flame-fusion process. Later, sapphire, spinel, rutile, and strontium titanate were grown with this technique. In this process, a single crystal, called a boule, forms in the flame of a simple, downward-impinging oxygen-hydrogen blowtorch. Pure oxides of aluminum (in the cases of ruby, sapphire, and spinel) or titanium (rutile and strontium titanate) are poured into the top of a small furnace and melted. Other oxides are added as needed for process control and to obtain the specific color desired. The melted material solidifies as a boule on a rotating fire-clay peg as the peg is slowly withdrawn.

A boule has a very characteristic shape, with a rounded end, a long, cylindrical body, and a tapering end. It is usually about 13 to 25 millimeters in diameter, 50 to 100 millimeters long, and weighs 75 to 250 carats (a carat is 200 milligrams). Under controlled conditions, a boule about 5 millimeters in diameter and more than 890 millimeters long can be produced for the manufacturing of jewel bearings.

Another melt technique is the Bridgman-Stockbarge solidification method, named for an American, P.W. Bridgman, and a German, D.C. Stockbarge, who, aided by three Russians, J. Obreimov, G. Tammann, and L. Shubnikov, discovered and perfected the process between 1924 and 1936. Currently, the method is used primarily for growing nongem halide, sulfide, and various metallic oxide crystals, one of the metallic oxides being aluminum oxide or sapphire.

The Bridgman-Stockbarge process uses a specially shaped crucible, which is a cylindrical tube open at one end and capped at the other by a small, pointed cone. The crucible is filled with the powdered chemicals necessary to grow a specific crystal and is lowered slowly through a furnace. The small, pointed end of the cone cools first because it is the first part of the crucible that moves from the hottest part of the furnace into cooler regions and it is the first part to emerge from the furnace. As the crucible cools, the molten materials solidify, hopefully in a single crystal, in the point of the crucible. The crystal then acts as a seed around which the remainder of the molten material solidifies until the entire melt has frozen, filling the container with a single crystal.

This process is simple, and crystals of various sizes can be grown. The crystals are typically about 51 millimeters in diameter and 15 millimeters in length, but large ones exceeding 890 millimeters in diameter and weighing more than 1 metric ton have been grown. The crystals have the same shape as the crucible.

The Czochralshi pulled-growth method is used for ruby, sapphire, spinel, yttrium-aluminum-garnet (YAG), gadolinium-gallium-garnet (GGG), and alexandrite. Czochralshi developed his method about 1917 while working with crystals of metallic nutrients.

In the Czochralshi method, ingredient powders—nutrients—are melted in a platinum, iridium, graphite, or ceramic crucible. A seed crystal is attached to one end of a rotating rod, the rod is lowered into the crucible until the seed just touches the melt, and then the rod is slowly withdrawn. The crystal grows as the seed pulls materials from the melt, and the material cools and solidifies. Yet, because of surface tension of the melt, the growing crystal stays in contact with the molten material and continues to grow until the melt is depleted.

Typically, the seed is pulled from the melt at a rate of 1 to 100 millimeters per hour. Crystals grown using this method can be very large, more than 51 millimeters in diameter and 1 meter in length, and of very high purity. Each year this method grows millions of carats of crystals for use as gems, laser rods, windows for special scientific or technical applications, and for other industrial applications.

Certain gemstones pose unique problems when attempting to grow them. The problems arise because certain materials are either so reactive that they cannot be melted even in unreactive platinum and iridium crucibles or they melt at higher temperatures than the crucible materials can endure. Therefore, another melting system must be used, called the skull melting system. Cubic zirconia, because of its high melting point (2,700 ° C) must be grown using the skull melting method.

The "skull" is a hollow-walled copper cup. Water is circulated through the hollow walls to cool the inside wall of the skull. The cup is filled with powdered ingredients and heated by radio frequency induction until the powders melt. Because the water cools the walls of the skull, the powdered materials next to the walls do not melt, and the molten material is contained within a shell of unmelted material. Therefore, the reactive or high-temperature melt is contained within itself. When the heat source is removed and the system is allowed to cool, crystals form by nucleation and grow until the entire melt solidifies. Crystals grown using this system vary in size, depending on the number of nucleations. In growing cubic zirconia, a single skull yields about 1 kilogram of material per cycle.

Solution techniques for making synthetic gems include flux methods for emerald, ruby, sapphire, spinel, YAG, GGG, and alexandrite. The other solution method is the hydrothermal method, often used for growing beryl (emerald, aquamarine, and morganite) and quartz.

Quartz crystals are grown in a hydrothermal solution in large pressure vessels known as autoclaves. Careful control of temperature and pressure in the different areas of the autoclave result in the feed material, known as lascas, dissolving in the hotter portion. The material redeposits on seed crystals, located in the cooler portion, forming synthetic quartz crystals. The process usually takes 30 to 60 days for the crystals to reach the desired size. The process can produce rock crystal, amethyst, or citrine.

The same system is used to grow beryl crystals. Beryl seed crystals are suspended in the cooler upper portion of an autoclave. Nutrient materials dissolve in the hotter, lower portion of the autoclave and, because of the temperature and pressure gradients, migrate to the cooler seeds and are deposited.

Other techniques involve solid- or liquid-state reactions and phase transformations for jade and lapis lazuli; vapor phase deposition for ruby and sapphire; ceramics for turquoise, lapis lazuli, and coral; and others for opal, glass, and plastics.

The Verneuil, Czochralshi, and scull melting processes are the melt techniques most often used for gem materials. *(See table 4.)*

Enhancement of Gemstones.—Enhancement of gemstones through chemical and physical means has become much more commonplace in the past few years and includes a wider variety of materials. Irradiation by electromagnetic spectrum (X-rays, gamma rays, etc.) and by energetic particles (neutrons, electrons, alphas, etc.) is used to enhance or change the color of diamonds, topaz, tourmaline, quartz, beryl, sapphire, zircon, scapolite, and pearls. Nearly all blue topaz is irradiated, but this does not imply that these gem materials are irradiated regularly.[1]

Many gemstones can be enhanced by chemical treatment or impregnations. The treatments may alter the bulk of the gem material or only penetrate the surface. This includes bleaching, oiling, waxing, plastic impregnations, color impregnations, and dyeing. The treatments that alter only the surface of the material include surface coatings of various types, interference filters, foil backings, surface decoration, and inscribing. Chemical treatment is more widespread than just the common dyeing of quartz, treatment of turquoise, and oiling of emeralds. Chemical treatment and impregnations have been used to enhance amber, beryl, chalcedony, coral, diamonds, emerald, ivory, jade, lapis lazuli, opal, pearl, quartz, ruby, sapphire, tiger's eye, and turquoise.[2]

In recent years the bleaching and impregnating of jadeite jade have become much more common. Investigators at gem laboratories estimate that as much as 90% of the jadeite sold in Taiwan is bleached; this includes both high- and low-quality material. The treatment is a two-step process where the jadeite is first chemically bleached using hydrochloric acid, nitric acid, or sodium compounds. The bleaching can take several hours to several weeks. The jadeite is then impregnated with a polymer, wax, or resin.[3]

Since about 1987, fractures, cleavages, and other void-type imperfections that reach the surface in diamonds have been filled using a process developed by Mr. Zvi Yehuda, of Ramat Gan, Israel. This treatment can enhance that apparent clarity of treated faceted diamonds; examples are available that show SI stones enhanced to VS and I_1 improved to SI_2. Yehuda also had developed a similar treatment for emeralds.

The oldest and most common method of gemstone enhancement is heat treating. Heat treatment of gem materials was used in Greece and Rome well before the Christian Era. Heat treatment can cause color change, structural change, and improve clarity. In the past, heat treatment was common for quartz and gem corundum. Today, materials that are heat treated to enhance their appearance include amber, beryl, diamond, quartz, ruby, sapphire, topaz, tourmaline, zircon, and zoisite.[4]

An additional type of treatment for sapphire and ruby is diffusion treatment, a chemical-heat treatment. In this process a thin layer of color is diffused into the surface of the gem. The color may be diffused as little as 0.1 millimeter or as much as 0.4 millimeter into the gem. The treatment is a long process of heat treatment in a bath of chemicals containing the proper proportions of titanium and iron. The American Gem Trade Association (AGTA) adopted a policy for the disclosure of diffusion treated gems. The policy is "If the color of a gemstone is confined to an area near the surface so that the color of the stone would be visibly affected by recutting or repolishing then the following statement must also appear: Although the color induced in the diffusion treated gems is permanent, it remains confined to a shallow surface layer." Therefore, recutting or repolishing is not recommended.[5]

Exploration.—Gemstone exploration should be undertaken in much the same manner as any other mineral exploration program. Historically, this has not been the case, except for diamond exploration. Exploration for diamonds starts with an area analysis to determine favorable geologic settings. The analysis is followed by on-the-ground regional reconnaissance and mapping. Airborne geophysical surveys may be completed before or after the regional reconnaissance work. Followup geologic work on the ground is used to determine the presence of kimberlite or lamproite host rock. If a host rock is present, then drilling and sampling determine if diamonds are present and in what quantity and quality.

Historically, most gemstone deposits have been found by following float material to the source or by alluvial sample collected while searching for some other mineral, usually gold. One of the largest Maine tourmaline deposits was found when tourmaline crystal were found in the roots of an overturned tree. In the future, gemstone exploration will be conducted in a more businesslike and scientific manner. Successful exploration for gemstone deposits begins with the selection of target areas based on the presence of known favorable host rocks. Geologic studies and maps, topographic maps, and aerial photographs are used to identify favorable metamorphic, igneous, alluvial, or eolian geological formations.

The second step is field examination of the selected targets. This may include geologic mapping and limited sampling, but in many cases reconnaissance studies are sufficient. The next step, if warranted, is to sample the deposit in detail to measure the physical parameters of the deposit, specifically its grade and size.

The method of sampling used depends upon the type of deposit. Hard-rock deposits, igneous or metamorphic, are sampled differently than alluvial or eolian deposits.

Hard-rock deposits can be either diamond core drilled or trenched. Trenches should be oriented perpendicular to the strike of the formation and can be dug by hand, with a dozer, or with a backhoe.

Placer deposits can be sampled by drilling, trenching, or by excavating pits or shafts. The physical nature of the deposit; its thickness, hardness, and grain size; and whether it is above or below the water table influence the method of sampling chosen. For shallow deposits, hand augers or power augers can be used to drill sample holes. In deposits that are too hard to hand auger because of the presence of clay, iron oxide cement, or mild calcium carbonate cement, two-person motor-driven augers or vehicle-mounted augers (such as post hole diggers or telephone pole hole diggers) work well. However, augering does not always provide uncontaminated samples and is not effective below the water table.

Truck-mounted water-jet drills and rotary hammer drills are used to test thick deposits and deposits that are too hard to drill with other methods. A water-jet drill uses flush-jointed drill pipe with perforations near the bit to direct jets of water forward and downward from the bit. A hammer advances the drill bit and casing at the same time. Water from the jets flushes out the hole and returns cuttings to the surface in the annulus between the drill pipe and casing. Also, truck-mounted rotary drills equipped with double-pipe drill string and downhole hydraulic hammers can be used. Compressed air is forced down the inner pipe and returns samples to the surface in the annulus between the inner pipe and outer casing. Bits are selected depending on the type of material to be drilled.

Trenching can be carried out using either a dozer or a backhoe, depending on the size and depth of the deposit. In unconsolidated sediments it is difficult to maintain the stability of the walls of trenches, and samples can be contaminated by material sloughing from above. Bulk samples can be collected from 1-cubic-meter pits or shafts. However, again, wall stability can be a problem unless some form of shoring is used.

Mining.—Gemstone mining operations can range from the most primitive to the most sophisticated. In hard rock, at shallow depths, an operation by one, two, or three persons may be mined by prybar, pick, shovel, and buckets or baskets for carrying material; drilling and blasting may be employed. A larger operation includes drilling, blasting, and minimum timbering. Mechanized hauling and hoisting is done only at the larger mines.

Diamond mining in the kimberlite pipes of Africa and Russia and the lamproite pipes of Australia represent the ultimate in that huge quantities of ore must be mined to extract small quantities of diamond (as few as 20 to 30 carats per 100 tons of ore) produced at as low a cost as possible.

Placer mining for gemstones ranges from small-scale, simple procedures to huge, complicated operations. In some areas, digging is by hand, and sorting and recovery is by panning, screening, or sluicing. Diamond miners in the larger placer operations use bucket dredges and heavy-duty excavating equipment, as, for example, in Australia, Brazil, Namibia, the Republic of South Africa, and Russia.

Processing.—Most gemstone ores are broken or crushed where necessary and concentrated by various combinations of hand picking, washing, screening, or jigging. In large-scale operations, mineral beneficiation methods are mechanized and employ the latest technology in each step from primary crushing and screening to the final recovery processes. Diamond recovery, in particular, makes use of standard gravity methods, grease belts, electrostatic separation, skin-flotation, magnetic separation, separation by X-ray luminescence, and separation by optical sorting.

ANNUAL REVIEW

Production

In 1993, all 50 States produced at least $1,000 worth of gem materials. Ten States accounted for 93% of the total value of production of natural gemstones. The States, in order of declining value of production, were Tennessee, Maine, Arizona, Arkansas, Alabama, Kentucky, Oregon, Utah, California, and Nevada. These States accounted for about 93% of the total value of U.S. production of natural gemstones. Certain States were known best for the production of a single gem material (i.e., Tennessee for freshwater pearls and Arkansas for quartz). Other States produced a variety of gemstones. Tennessee, Arkansas, Alabama, and Kentucky, in declining order of value of production, were the major producers of freshwater mussel shell and pearl. Arizona produced the greatest variety. Production included agate, amethyst, antlerite, azurite, chrysocolla, fire agate, garnets, jade, malachite, obsidian, onyx, peridot, petrified wood, precious opal, shattuchite, smithsonite, and turquoise. California, Idaho, Montana, and North Carolina also produced a variety of gemstones. Historically, North Carolina is the only State to have produced all four of the major gems: diamond, emerald, ruby, and sapphire.

The reported value of synthetic and simulant gemstone production was $17.9 million in 1993, a decrease of 5% over that of 1992. Fourteen firms, four in California; four in Arizona; and one each in Massachusetts, Michigan, New Jersey, North Carolina, Ohio, and Washington, produced synthetic and simulant gem material. Production during 1993 included the manufacture of amethyst, azurite/malachite, cubic zirconia, emerald, lapis, ruby, sapphire, and turquoise. The materials were made by

10 plants operating in 8 States. The States, in descending order of value of production, were California, Massachusetts, New Jersey, Washington, Arizona, Michigan, New Mexico, and Ohio.

Arizona is known for its variety of gemstones that include agate, amethyst, antlerite, azurite, chrysocolla, fire agate, fluorite, garnet, jade, jasper, malachite, obsidian (Apache tears), onyx, peridot, petrified wood, precious opal, shattuchite, smithsonite, and turquoise. Yet, turquoise, peridot, petrified wood, and azurite-malachite accounted for more than 90% of the total value of gem material produced. Arizona was the largest domestic producer of azurite, fire agate, peridot, petrified wood, and turquoise. Also, it is estimated that Arizona was the world's largest producer of peridot, turquoise, and petrified wood and a significant producer of pyrope garnet. Many gem and mineral dealers believe that the value of mineral specimens produced from Arizona deposits is equal to, if not greater than, the value of gemstone produced. The USBM does not survey the production of mineral specimens, but its gemstones survey does capture data on that portion of the mineral specimens that are gemstones. The mineral specimen information collected is for gemstones that are used as specimen, because the value of the specimen is in the total value of production of the individual gemstone. This is particularly true for the production of Arizona's petrified wood. Additionally, four manufacturers of synthetic or simulant gem materials in Arizona produced about $0.3 million worth of material.

Arkansas continued to be the State with the greatest value of quartz production. At least four firms produced significant amounts of gem and specimen rock crystal from deposits in the areas around Hot Springs, Mt. Ida, and Jessieville. As stated earlier, the rivers, lakes, and reservoirs of Arkansas continued as the second largest source of U.S. freshwater mussel shell and pearl. Arkansas also produces several different mineral specimens other than rock crystals, but only the rock crystal specimen production is in the gemstone production numbers.

During 1993 at Crater of Diamonds State Park, Murfreesboro, AR, visitors reported finding 800 diamonds that totaled 144.44 carats. Crater of Diamonds State Park is the only location in the United States to have reported sustained production of diamonds for any appreciable length of time. Diamonds are found by visitors to the State park who pay a daily fee to hunt for diamonds using only handtools. It is possible that 1993 could be the last year that Arkansas has the only operating diamond mine. Mining tests were underway during late 1993 and early 1994 on two diamond properties in the Colorado-Wyoming Stateline Mining District. Since 1972, hobbyists have found from 300 to 1,500 diamonds per year at the Crater of Diamonds State Park. From 1906 to the present, it is estimated that production from the deposit is 100,000 to 150,000 carats; this amount of diamond production is insufficient to classify the United States as a diamond-producing country. Still, the potential to become a diamond producer may be there, and efforts were underway to evaluate this potential more fully.

Gemstone production from California includes a variety of materials almost a large as Arizona's. Tourmaline production from the State is significant, and California has the only producer of benitoite. Additionally, deposits in the State produce agate, alabaster, beryl, dumortierite, fire agate, garnet, gem feldspar, jade, jasper, kunzite, lepidolite, obsidian, quartz, rhodonite, topaz, and turquoise. Yet, even with this long list of gemstones, most people think of California in terms of its State gem benitoite, its high-quality tourmalines, and its fine orange spessartine garnets.

The State also has a freshwater culture pearl farm at Marysville, but it did not harvest shell or pearls during 1993. The farm uses animals imported from Tennessee and other southeastern States. Production includes pearls, shell, and finished nucleus for cultured pearl implants.

California also has four manufacturers of synthetic or simulant gemstones. The value of production from the State is the largest of any State for synthetics and simulants.

Colorado is not known as a gemstone-producing State, but it does hold some gemstone honors. It has the only commercially mined deposit of lapis lazuli in the United States and one of the few fee-for-dig topaz deposits currently operating. Additionally, the State was the first to produce turquoise commercially, and it still has commercial turquoise mines. It also produced the United States' finest gem-quality rhodochrosite and a quantity of high-quality rhodonite.

During 1993, two diamond deposits in the Colorado-Wyoming State Line diamond district were tested by bulk sampling. Reports in the International California Mining Journal, February 1994, issue indicated that the Kelsey Lake project of Colorado Diamond Corp., project manager for Redaurum Red Lake Mines Ltd., collected several bulk samples from the alluvial deposits associated with the Kelsey Lake kimberlites. A 6.2-carat, gem-quality diamond was recovered from one sample and a 1.1-carat stone from another. To date, sampling of the Kelsey Lake projects has yielded 268 stones larger than 2 millimeters, of which 60% was gem quality and 25% was more than 1 carat. Plans have been completed and activities are underway for a 100,000-ton test mining program. On May 31, 1994, the Denver Post reported the underground mining test by Royal Star Resources Ltd., a Canadian company, of the Sloan Ranch kimberlite deposit 40 kilometers northwest of the town of Fort Collins. Samples totaling 1,200 tons were processed and yielded more than 3,500 diamonds, the largest a 5.51-carat stone. Additional kimberlite will be mined and processed before a decision can be made about the economic feasibility of mining diamonds from the Sloan Ranch kimberlite.

Many locations in the State produce small quantities of aquamarine, the Colorado State gemstone. The best locations and the locations with the longest history of continued production (since about 1884) are Mount Antero and White Mountain in Chaffee County. Mount Antero, at 4,349 meters, may be the highest gemstone location in the United States. White Mountain, separated from Antero by a small saddle, is only slightly lower at 4,237 meters.

Star garnet, the Idaho State gemstone, and other gem-quality garnet lead the list of gemstones produced in the State. Idaho is one of two places that produce significant amounts of star garnet; India is the other. These almandite garnets are translucent, purplish-red stones that show four- or six-ray stars when cabochon cut or are transparent deep red stones that can be faceted. The primary sources of Idaho star garnet are the placer deposits on the East Fork of Emerald Creek and its tributary gulches in Benewah County. Additionally, the placers of Purdue Creek in Latah County yield star garnets. Currently, garnets that do not cut stars are mined commercially from areas in Clearwater County. These garnets range from purplish rose-red to a highly prized "special pink." Gem-quality garnets are found at several other locations in Idaho and are mined periodically by hobbyists or professional collectors for the gemstone market.

Opal is the second largest contributor to the total value of gemstone production in Idaho. The varieties produced include precious, yellow, blue, pink, and common. The Spencer opal mine is the largest producer. At the Spencer Mine, precious opal occurs as one or more thin layers within common opal that have partially filled gas cavities within a rhyolite-obsidian flow. About 10% of the material is thick enough to cut into solid gems; the remainder is suitable for making doublets and triplets. The Spencer Mine is also the source of the pink opal, which occurs as either pink common opal or pink-bodied precious opal.

Maine and tourmaline are almost synonymous in the gemstone industry. In 1822, Maine's Mount Mica was the site of the first gemstone production in the United States. In 1993, Plumbago Mining Corp. was actively mining the Mount Mica pegmatite for gem material and mineral specimens. Over the years, production from Mount Mica has included hundreds of kilograms of fine-quality gem and mineral specimen tourmaline. At least two deposits in the State produced significant quantities of tourmaline during the year.

Mount Mica is not the only large producer of high-quality tourmalines. Dunton Mine of Newry Hill is the most prolific gem tourmaline producer in Maine. Since its discovery in 1898, the mine has produced tons of gem- and specimen-grade tourmaline. Other mines and quarries in a three-county area produce gem- and mineral specimen-grade tourmalines. These include the Bennett, BB #7, Emmons, Harvard, Tomminen, Waisenen, Black Mountain and Red Hill Quarries, and Nevel Mine in Oxford County. It also includes the Mount Apatite Quarries in Androscoggin County and the Fisher and Porcupine Hill Quarries in Sagadahoc County.

Production from Maine deposits also includes fine-quality beryls—aquamarine, heliodor, and morganite. Pegmatites in Oxford, Androscoggin, and Sagadahoc Counties regularly produce fine-quality blue and blue-green aquamarine, rich yellow- and gold-colored heliodor, and rose- and peach-colored morganite.

A new discovery of amethyst in an old producing area resulted in the production of a significant amount of faceting- and specimen-grade amethyst in 1993.

Montana produces many different gemstones, some suited for faceting, while others are suited for the cutting of cabochons, carvings, or objects-of-art. Montana is noted for the production of sapphires, Montana moss agate, and Dryhead agates. Yet, deposits in the State also produced amethyst, amazonite, azurite, covellite, cuprite, garnet, onyx, opal, petrified wood, rhodochrosite, rhodonite, smokey quartz, sphalerite, and wonderstone (banded rhyolite) for use as gemstones.

Sapphires have been produced from Montana deposits since 1865. In recent years, Montana sapphire has gained in popularity, and because of the improved popularity, production has increased significantly. Currently, commercial sapphire production is from deposits on the Missouri River in Lewis and Clark County, the Rock Creek area in Granite County, and from the Yogo Gulch area in Judith Basin County. Additionally, there are fee-for-dig sapphire operations on the Missouri River, Dry Cottonwood Creek, and Rock Creek.

Nevada has been a major producer of turquoise since the 1930's, and until the early 1980's, the State was the largest turquoise producer in the United States. Estimates show that over the years, 75 to 100 different mines or prospects produced sizable quantities of turquoise. The value of production varied from a few thousand dollars at some properties to more than $1 million at others. Estimates of total production to date are between $40 to $50 million.

Precious opal production from deposits in the Virgin Valley area began in about 1906. The opal from Virgin Valley is comparable to any in the world for its vivid play of color and is unsurpassed in terms of the size of material available. The material varies in color from deep pure black to brown to yellowish-white to white to colorless. The play of color includes all the colors common to precious opal—red, blue, green, yellow, orange, and so on. The opal forms primarily as replacement of wood, or sometimes, the replacement of cones of conifer trees. A severe crazing problem restricts the use of the opal. Currently, two mines in Virgin Valley are open on a fee-to-dig basis during the summer months. The operators of these mines also mine the deposits for their inventories.

North Carolina is the only State in the United States where all four major gem materials, diamond, ruby, sapphire, and emerald, have been found. During 1988 was the last time all four major gemstones were found in the same year. The diamond was from a gold placer mine, the rubies and sapphires were from the Cowee Valley, and the emeralds were from near Hiddenite and Little Switzerland.

Production of ruby and sapphire from deposits along the Cowee Valley in

Macon County began in 1895 when the American Prospecting and Mining Co. systematically mined and washed the gravels of Cowee Creek. Today ruby, sapphire, and fee-for-dig operations are in the Cowee Valley. Many people pay to dig or purchase buckets of gravel to wash to recover gem corundum, garnets, and other gemstones. During 1993, deposits in North Carolina also produced gem-quality garnets, kyanite, emerald, and aquamarine.

Historically, Oregon has been known for the production of various picture and scenic jaspers, agates, thundereggs, petrified wood, and to a certain degree, gem labradorite. Oregon's State rock, the "thunderegg," may be the best known gem material from Oregon. Graveyard Point, Priday, and Polka Dot are names that are associated uniquely with beautiful Oregon agates. The same is true for the relationships between the names Biggs, Deschutes, and Sucker Creek and picture or scenic jasper. Yet, gem labradorite (sunstone) is currently the largest single contributor to the value of annual gemstone production in Oregon. At least seven firms or individuals currently are producing sunstone from three different geographic areas.

The other gemstone to contribute significantly to the value of production from Oregon is opal. During 1988, the first significant, commercial mining and marketing of very fine-quality opals from Opal Butte began. The varieties include hyalite, rainbow, contra luz, hydrophane, crystal, fire, blue, and dendritic. Exquisite stones as large as 315 carats have been cut from contra luz rough from this deposit and the fire opal is as fine as the best from Mexico.

Tennessee has the largest U.S. production of freshwater mussel shells and pearls of the 11 producing States. There has been an established U.S. freshwater mussel fishing industry since the mid-1850's. The mussels are from the family Unioidae, of which about 20 different species are harvested commercially. During 1993, the value of U.S. mussel shell exports was more than $32 million.

Historically, freshwater pearls from the United States were a byproduct of the shell industry. With the coming of the freshwater cultured pearl farms in Tennessee and the increasing popularity of freshwater pearl jewelry with the U.S. consumer, this has changed. Since the technology for culturing freshwater pearls was proven in the late 1970's, six freshwater pearl farms have been established. These farms are the beginning and heart of the U.S. pearl industry.

In Wisconsin and Michigan, 12 kimberlite pipes have been identified on exploration holdings, 7 have yielded microdiamonds, and 3 have not been tested. Ashton Mining of Canada, Inc. announced that its Great Lakes project found a small kimberlite body in the Crystal Falls area of Michigan. The company also reported the possibility of additional kimberlite bodies in the Upper Peninsula of Michigan.

Utah topaz is not well suited for use as a gem, but it does make a fine mineral specimen. Topaz crystals have been collected from certain rhyolite flows in the Thomas Mountains and the Wah Wah Mountains. The crystals from the Thomas Mountains are predominately small, 10 to 20 millimeters long and 4 to 6 millimeters across, and crystals from the Wah Wah Mountains are even smaller. Occasionally, large gem-quality crystals are found. The color of the topaz varies from colorless, to light yellow, sherry brown, rose, or light pink. The light yellow to sherry brown color fades to colorless if exposed to sunlight or heat and rose or light pink colored crystals are rare. Because of the size of the crystals and problem with color fading, the material yields only small to very small colorless stones.

Another Utah gemstone is variscite, first produced in about 1893 near Fairfield. The latest recorded commercial production was from near Lucin during the summer of 1992. Variscite forms as fracture fillings or as nodules. The nodules may be solid, almost geode in nature, or fractured solid nodules that have undergone alteration. The color of the variscite varies from a shade of light to dark yellow-green, but can be a dark, nearly jade green and so pale as to appear almost white. It also can have black and brown spiderwebbing.

Another material from Utah is snowflake obsidian. Snowflake obsidian (also known as flower obsidian) earns its name from the bluish-white or grayish-white patterns of cristobalite included into the normally black obsidian. During 1992, two different firms produced this material commercially.

The red beryl from the Wah Wah Mountains is the most remarkable and desirable of Utah's gemstones. Bixbite, the variety name for red beryl, is found in rhyolites at several locations in the Thomas and Wah Wah Ranges. The beryl varies in color from a pink to bright red, with the bright red being what could be called strong raspberry-red. The material from most of the locations is not as spectacular, either in crystal size or color, as the crystals from the Violet claims in the Wah Wah's.

The Violet claims in the Wah Wah's are the only known location for commercial production of red beryl. In recent years, the claims have furnished a small but steady supply of materials for both mineral specimens and a few fine-quality gems. The crystals average about 10 millimeters in length, and most are flawed. Because of the size of the crystals and flaws, finished stones only average about 0.40 carat with few more than 1 carat. The largest finished stone to date is about 10 carats. The material is expensive, but justifiably so, because of its beauty and rarity.

Certain other States produce a single gem material of note, they are: Alaska with its two jade mines; Florida's agatized coral; New York reported significant quartz production (herkimer diamonds) from the Herkimer-Middleville area and a small amount of almandite garnet production from the North Creek area; New Mexico reported production of agate, turquoise, copper minerals, and gem feldspar; both Alaska and Hawaii reported the production of gem-quality coral; Minnesota reported production of thomsonite and agate; Ohio reported production of flint; and South Dakota produced rose quartz.

The value of 1993 production by individual gemstone can be reported for those materials that have three or more producers and if one producer does not account for more than 75% of the total or if two do not account for 95% or more of the production. *(See table 5.)*

Consumption and Uses

Consumption of domestic gemstones was in the manufacture of jewelry; for exhibit in gem and mineral collections; for decorative purposes in statuettes, vases, and other art objects; and for certain industrial applications.

Frequently, tourmaline is used as a standard for calibrating piezoelectric manometers and testing devices. It is also a control substance in boron experiments because it is itself an inert boron-containing compound. Tourmaline is the standard used in tests to check possible effects of water-soluble boron in fertilizers.

Many scientific and industrial instruments use tourmaline. One such use is tourmaline tongs, a simple laboratory instrument that shows the polarization of light. Because tourmaline is both pyroeletric and piezoelectric, meaning it generates electricity when heated or compressed, it is a component of instruments for measuring high pressures and fluid compressibility. Thermal dosimeters, which were early instruments that measured the intensity of radium emanations, depended upon tourmaline's pyroelectric properties.

Once the mark of a top-rated watch or timepiece was that it was Swissmade and had 18 or 21 ruby or sapphire jewel bearings. Originally, these jewel bearings were made from natural ruby and sapphire. Later, the availability of inexpensive synthetic gemstones allowed the natural materials to be replaced in the manufacture of jewel bearings.

Why are ruby and sapphire used as bearings? Because ruby and sapphire, color variations of the mineral corundum, are second only to diamond in hardness; they have no cleavage (cleavage being the tendency for a crystallized mineral to break in certain definite directions, showing a minimum value of cohesion in the direction of easy fracture) and thus they are very durable; they have a very low coefficient of friction when highly polished; they are chemically inert; and they can be cut and polished without great difficulty.

Watches were not the only instruments in which sapphire and ruby bearings were used. Most precision gauges in aircraft and boats depend upon jewel bearings, as do many gauges, meters, and other instruments in manufacturing and chemical plants. The military is still highly dependent on jewel bearings for many of its high-tech weapons systems. Another use for one type of jewel bearing is as connectors for optical fibers.

In recent years, technological advances allowed the growth of large, high-quality synthetic ruby crystals, called laser ruby, for the manufacture of laser rods. Several other synthetic gemstones also are produced for lasers, including chromium-doped chrysoberyl (dope being an element added to the crystal growing nutrients to get a particular color), synthetic alexandrite, and varieties of doped YAG.

Lasers require high-purity, optically perfect crystals. The crystal must be large enough so that a laser rod can be cut from the raw crystal, and the mineral or material must have the correct physical properties to allow light amplification without the necessity of excessive energy. Synthetic ruby, sapphire, and YAG have these characteristics.

Over the years, both natural and synthetic corundum have been ground and graded as an abrasive. Corundum was the major compound used in the polishing of eyeglass lenses. Although industrial diamond has replaced much of the corundum used in the lens-polishing industry, some still use corundum for specialized lenses.

Other gem materials have enjoyed limited uses in nongem applications. The abrasive and ceramic industries use topaz as a raw material because of its hardness and chemical features. Once, lenses for eyeglasses were made from gem-quality beryl—if the morganite variety of beryl was used, one would truly be looking at the world through rose-colored glasses. Mortar and pestle sets, knife edges for balances, textile rollers, and spatulas are some nongem uses of agate.

Some industrial applications requiring clean homogeneous stones used low-quality gem diamond. The quantity of natural and synthetic industrial-grade diamonds used in the United States each year is 12 to 15 times greater than the amount of diamonds consumed by the jewelry industry.

The 1993 estimated value of U.S. apparent consumption of gems and gemstones was $4,266 million, up about 24% from that of 1992. In 1993, the value of U.S. estimated apparent consumption of diamonds increased about 29% to $3.6 billion. The 1993 estimated apparent consumption of colored stones, led by emerald, ruby, and sapphire, was valued at $517 million, an increase of 30%. The estimated apparent consumption of pearls—natural, cultured, and imitations—was $18 million, a 6% decrease. Estimated apparent consumption of synthetic and imitation gemstones decreased about 13% to $102.3 million.

Prices

Demand, beauty, durability, rarity, freedom from defects, and perfection of cutting decide the value of a gem. In establishing the price of gem diamond, the CSO's control over output and prices of diamond rough also is a major factor.

The average U.S. wholesale asking price of the top 25 grades (D through H color and IF through VS_2 clarity) of a 1-carat diamond fluctuated between $7,200 and $7,300, and was about $7,300 at yearend. The average value per carat of all grades, sizes, and types of gem-quality diamond imports was $444, essentially the same as that of 1992. The average yearend wholesale purchase price of a fine-quality 1-carat ruby, paid by retail jewelers on a per stone or memo basis, was $3,900, the same as that of 1992. The average value of ruby imports decreased 15% to $25.14 per carat.

The average yearend wholesale purchase price of a fine-quality 1-carat sapphire, paid by retail jewelers on a per stone or memo basis, was $1,400, the same as that of 1992. The average value of sapphire imports decreased 5% to $15.46 per carat.

The average yearend wholesale purchase price of a fine-quality 1-carat emerald, paid by retail jewelers on a per stone or memo basis, was $2,750, the same as for 1992. The average value of emerald imports decreased 38% to $44.83 per carat. *(See tables 6 and 7.)*

Foreign Trade

The value of all diamond exports plus reexports increased 10% to $1.50 billion. The quantity of cut diamonds exported and reexported decreased 10% to 911,419 carats, and the value of diamond exported and reexported increased 9% to $1.44 billion.

The value of other precious stones, cut but unset or rough other than diamonds, pearls, and synthetics, exported and reexported decreased from $241.2 million to $103.1 million. The value of synthetic gemstone exports plus reexports decreased from $21.2 million to $19.3 million.

The value of natural, cultured, and imitation pearls, not set or strung, exports and reexports of pearls increased from $6.7 million to more than $7.3 million.

The value of gems and gemstones imported increased 18% to a record high $5,850.9 million. The value of imported gem diamonds accounted for about 86% of the total.

The value of imported gem diamonds increased 23% to a record high $5,096.3 million. The imports of cut diamonds increased 26% in quantity and 23% in value to 9.7 million carats and $4,486.3 million, respectively.

The value of imports of other gem and gemstones, led by emerald, ruby, and sapphires, was $754.5 million. Emerald imports increased 14% to $244.4 million. The value of ruby imports increased 16% to $90.6 million, but was less than the record-high value for the past 10 years of $98.4 million in 1990. The value of sapphire imports was $79.3 milion, an increase of 6% compared to that of 1992.

The value of imported gem materials other than diamond, emerald, ruby, and sapphire increased 35% to $327.7 million. *(See tables 8, 9, 10, 11, and 12.)*

World Review

Diamond sales by De Beers Centenary AG was $4.4 billion in 1993, an increase of 28% compared with 1992 sales of $3.4 billion. Sales during the first half of 1993 were $2.5 billion, 42% more than the $1.8 billion for the first half of 1992. Sales during the second half of 1992 were only $1.8 billion, but still 12% more than the $1.6 billion sales for the second half of 1992. A De Beers official stated that there were sharp sales gains in the Indian-type cheaper rough, but larger rough, more than 3 carats, was sold sparingly. De Beers controls about 80% of the rough, uncut diamonds sold in the world. Sales of colored stones remained strong. In February, De Beers increased the price of rough diamonds by an average of 1.5%. Not all prices went up 1.5%—some were unchanged while others increased as much as 8%.

Natural diamond production occurs in Africa, Asia, Australia, and South America. The principal producing localities are as follows: in Africa—Angola, Botswana, Namibia, the Republic of South Africa, and Zaire; in Asia—Russia (northeastern Siberia and in the Yakutia); in Australia; and in South America—Venezuela and Brazil. *(See table 13.)*

Foreign countries in which major gemstone deposits (other than diamond) occur are Afghanistan (beryl, kunzite, ruby, tourmaline); Australia (beryl, opal, sapphire); Brazil (agate, amethyst, beryl, kunzite, ruby, sapphire, tourmaline, topaz); Burma (beryl, jade, ruby, sapphire, topaz); Colombia (beryl, sapphire); Kenya (beryl, garnet, sapphire); Madagascar (beryl, rose quartz, sapphire, tourmaline); Mexico (agate, opal, topaz); Sri Lanka (beryl, ruby, sapphire, topaz); Tanzania (tanzanite, garnet, ruby, sapphire, tourmaline); and Zambia (amethyst, beryl).

Angola.—Odebrecht, a Brazilian company, purchased modular diamond recovery plants from Van Eck & Lurie for use on its diamond projects in Angola. Odebrecht is undertaking projects in Quango Province for Endiama, the Angolan state mining corporation.

Australia.—Argyle's diamond production of 42 million carats was another record year for the mine. Since the start of mining in 1983, more than 304 million carats of diamonds has been recovered from the AK-1 pipe and alluvial operations. Argyle's annual pink diamond sale saw a single buyer, a Geneva-based jeweler, buy the entire 46-stone, 41.48-carat offering for $2.25 million.

The Philips Range Joint Venture, a venture between Triad Minerals NL and Black Hill Minerals Ltd., both Australian companies, and the Canadian firm Cliff Resources Corp., has completed a drilling project on the Aries kimberlite pipe and has started a 100,000-ton bulk sampling of the overburden. The venture has processed 1,700 tons of overburden through its 100-tons-per-hour plant and recovered 69 diamonds that weighed 26.7 carats with five stones greater than 1 carat.[6] Ashton Mining Ltd. continued to explore the Merlin and adjacent Excalibur prospects in the Northern Territory. A 70-ton sample from Merlin produced 20 commercial-size stones; 20% were gem quality, 20% were near-gem, and the largest stone was 2.44 carats. On the Excalibur, a 60-kilogram sample produced 7 macrodiamonds and 92 microdiamonds. Many drill holes on the prospect have intercepted kimberlite down to 111 meters.

Botswana.—The largest diamond ever found in Botswana, 446 carats, was recovered at the Jwaneng Mine. The stone is currently being evaluated and no value has been set.

Preliminary exploration work is underway on the Gemsbok project to evaluate five diamond prospecting licenses. The licenses cover about 4,800 square kilometers. The project is a 50-50 joint venture between Scintilore Explorations and Fancamp Resources.

The $3 million diamond cutting and polishing factory jointly owned by Lazare Kaplan Botswana, a subsidiary of the U.S. firm Lazare Kaplan International, and the Government of Botswana is the newest cutting factory in Botswana. The factory was subsidized to train local cutters under Botswana's financial assistance policy for foreign investors. The factory will purchase rough from De Beers' CSO.

Brazil.—Southwestern Gold Corp. and Hillsborough Resources have had encouraging results from their joint-venture exploration on the 592,000-hectare Canabrava project in Minas Gerais. Sampling discovered kimberlite indicator minerals and stream samples contained diamonds. Diamonds from the stream samples contained one pink diamond.[7]

The KWG Resources and Diamond Co. Ltda. Charneca diamond property joint venture in Minas Gerais began production with a 750-cubic-meter-per-day washing plan and plans to add a second 300-cubic-meter-per-day plant. KWG, the operating partner, reported the recovery of 31 gem-quality diamonds weighing 79 carats during the first 19-days of operation. The joint venture controls two additional concessions in Minas Gerais—the Santo Antonio and Grupiaria.[8]

Burma (Myanmar).—The Burmese 30th Annual Gems, Jade, and Pearl Emporium attracted 654 buyers from 16 countries and accounted for a near record $14.7 million. Jade sales were $11.5 million; pearls, $0.6 million; and gems, $1 million. The gem sales were mostly cut rubies and sapphires. Some rough was offered as well as cut peridot, spinel, green tourmaline, danburite, almandine garnet, aquamarine, diopside, enstatite, zircon, colorless topaz, and scapolite. For the first time heat-treated rubies were offered for sale. The heat-treated material was all from the new Monghsu Mine.[9]

Canada.—Broken Hill Proprietary Co., an Australian company, and its Canadian partner Dia Met Minerals, Ltd. announced the start of work on the first diamond mine in Canada with their presentation of their mining plan to environmental authorities. The mine and other facilities would cost about $375 million and would be in full operation by 1997.

During 1993, diamond exploration activities were too extensive to be summarized in this limited space. It is recommended that interested individuals obtain copies of "Diamond in Canada: An Over View of Current Developments" by R. Irvine and M. Boucher, Industrial Minerals Division, Mineral Metal Commodities Branch Mineral Policy Sector, Energy, Mines and Resources Canada, Ottawa, Ontario; or "Mineral Exploration in Canada: Recent Developments and the Diamond Story" by J. M. Duke and B. A. Kjarsgaard, Geological Survey of Canada, Ottawa, Ontario.

China.—The New China News Agency announced a De Beers Chinese joint venture that includes equipment and technology for exploration and processing of diamond ore, assistance in training personnel, and the opening of a diamond cutting factory. The new factory will be in Shanghai, one of two major cities targeted by De Beers' recently announced $1.2 million marketing campaign to increase China's consumption of cut diamonds.

Ghana.—The Government of Ghana has agreed to sell 80% of the Government-owned Ghana Consolidated Diamond Mines, Ltd., 40% each to De Beers and Lazare Kaplan International. A new company, Birim River Diamonds Ltd., will operate the diamond mines with De Beers as the managing partner. Plans are for production to be increased to 0.4 million carats per year in 3 years; eventually production will increase to 1 million carats per year.

Greece.—In February, a new synthetic ruby, grown by a flux process, was announced to the industry at the Athens Jewelry Fair by J. and A. Douras, its producers. The material is grown in a plant in Piraeus. The Douros method grows crystals that are 20 to 50 grams and smaller that are almost identical in appearance to Ramaura material. The refractive indices, density, absorption spectrum, fluorescence, and dichroism of the new synthetic are the same as for natural ruby.

India.—India processed about 65% of the carats of the world's rough diamonds, accounting for a 45% share of the world trade in finished goods. While most of the finished goods were less than 20 points in size, the industry is increasing the amount of larger goods cut. The 11 million carats of cut diamonds exported accounted for 17% of the value of total exports from India.

Mali.—Mink Minerals Resources Inc., a Canadian firm, agreed to acquire 65% of Syndicat Diamat—the Mali diamond exploration and development company owned by the Governments of Mali and France—by spending more than $6 million over 3 years and additional amounts over 3 additional years. The Syndicat Kenieba district concession has 21 identified kimberlite pipes, 8 of which contain diamonds. Sampling of paleo placer deposits within the concession yielded more than 70 gem-quality diamond, many larger than 1 carat.

Namibia.—Namibian Minerals Corp. (Namco), a firm just listed on the Vancouver Stock Exchange, is undertaking a program to evaluate and develop two Namibian marine concessions covering 920 square kilometers. Detailed geophysical surveys and sampling are planned with the start of mining scheduled for early 1995. The concessions are off the coast for the port of Luderirz and Hottentots Bay in water 200 meters or more in depth. According to Namco, the concessions may contain as many as 27 million carats, and projections of production are 150,000 to 250,000 carats per year.

Russia.—The Russian diamond mining industry, with about 95% of production coming from five mines in Sakha—Udachny, Aikhal, Mir, International, and Sytykanskaya—is undergoing much change. Construction is underway on the Jubilee Mine that will begin production in 1994. Two deep vertical shafts have been completed at the International Mine, and plans are underway to convert the Mir from an open pit to underground mine. Additionally, efforts are underway to bring the five kimberlite pipes north of Archangel into production.

Current diamond exploration includes Ashton Mining's work in the Karelia area, work near Krasnovishersk in the Pern district, Kondor and Imperial, Inc. are exploring known pipes in Archangel, Gorizont Co. is exploring additional areas in Archangel, and geologists have discovered diamonds in the Khanka depression close to the city of Lesozavadsk near the Sino-Russian border.

Mr. Thomas Chatham, president of U.S.-based Chatham Created Gems, Inc., announced the formation of Chatham-Siberian Gem Co., based in Moscow. The company will grow and market synthetic white, yellow, and blue diamonds. The diamonds will be made using the high-temperature, high-pressure process. The new company plans to begin marketing about 100 carats of finished goods per month at a price that is 10% of that of equivalent natural diamonds.

In Moscow, J.V. Intertrade, a joint venture between the Moscow Municipality, the Russian Committee for Precious Stones and Metals, and Kaszirer Diamond and Oltusky—both Belgian firms—opened a diamond cutting factory. The Municipality provided land and construction. The committee is expected to insure a supply of rough, and the Belgians invested $6 to $7 million in funds. Ruisdiamond, an Israeli-Russian joint venture, also opened a new cutting factory in Moscow. It will use laser technology on types of rough that are difficult to cut. The newest cutting factory in Yakutia is in the city of Namtsy: It is the sixth factory to open in Yakutia during 1993, and an additional seven cutting factories have been announced.

Mr. Valerie Rudakov, president of Almazy Rossi-Sakha, the firm responsible for mining, sorting, pricing, and selling Russia's rough diamonds, announced the opening of an internal Russian Diamond Selling Center. Operating much like the CSO, the Selling Center will allocate diamonds to Russian cutting factories as if they were CSO sightholders. Almazy Rossi-Sakha is a joint stock company in which 32% is controlled by the governments of Russia and Sakha each, 8% by the eight regions of Sakha, 5% by the Guarantee Fund, and 23% by employees. The company's goals are to supply adequate rough diamonds at "world prices" to Russian cutting factories and to ensure the continued well being and growth of the Russian cutting industry.

South Africa, Republic of.—Diamond Field Resources (DFR), a Canadian company, purchased the Loxton Dan and Frank Smith diamond mines in the Kimberley area. The company reports that the mines have reserves sufficient for an additional 20 years of operation even at the increased rate plan. DFR plans to increase production from the mines to 100,000 carats per year. DFR also has a marine diamond concession off the coast of Luderitz in Namibia.

Tanzania.—During 1993, the Government of Tanzania lifted the restrictions on diamond sales and exploration to foreign investors. Because of these changes Dual Resources and Pue Gold Resources, both Canadian firms, each purchased 20% of Tanzania Diamond Mines' (TDM) diamondiferous kimberite project, two contiguous diamond lining leases, and three exploration licenses. East Africa Diamond Exploration, a wholly owned subsidiary of TDM, will manage the joint-venture project.[10]

European Ventures acquired a 50% interest in Tan Range Exploration Corp.'s 60-square-kilometer diamond concession; both firms are Canadian. European agreed to spend $300,000 on exploration over the next 2 years, and issued Tan Range 100,000 shares of European's common stock.[11]

Uruguay.—It is estimated that annual exports of amethyst are about 80 tons valued at more than $500,000. The amethyst is for mineral specimens, decorator pieces, and as gemstones.

Zaire.—Sediza, De Beers' Zairian diamond purchasing company, purchased a +770-carat top-colored, gem-quality rough diamond. It is reported that the firm paid an artisanal miner $7 million for the stone and paid the Government of Zaire a 10% fee to export it. Because of its shape, the rough will be sawed or cleaved into two pieces for cutting.

Zimbabwe.—The River Ranch Mine, operated by Auridiam Zimbabwe Ltd., a joint venture between the Canadian firm Cornerstone Investments Ltd. and Auridiam Consolidated NL of Australia, is expanding production from its current 50,000 carats per year to 130,000 carats per year and plan to produce 330,000 carats per year by 1995. Gem-quality stones account for about 60% of the production, and many of the stones are larger than 8 carats. During 1993, the mine produced two large fine stones—one was 29.6 carats and the other was 17 carats. Recovered fragments totaling 356.2 carats from one broken stone and 33.4 carats from another single stone suggest the presence of very large stones.

The joint venture between Reunion Mining and Argosy Mining Corp. has confirmed the discovery of a second kimberlite pipe on its Hwange project in western Zimbabwe. The pipe is about 10 kilometers from an earlier discovered pipe. The joint venture announced that additional exploration permits have been added to the venture to increase the Hwange project area.

OUTLOOK

World demand for gem diamond can be expected to rise because of increasing effective personal incomes and the populations of the United States and other industrialized countries. Also, demand will increase because of highly effective promotional efforts. These promotions are changing social customs in many eastern countries, particularly the use of diamond engagement rings. The changes are resulting in significant growth in the diamond market. Demand for other precious gems will continue to grow as diamonds become more expensive and the popularity and acceptance of colored gemstones increase. Demand for synthetic and simulant gemstones for both personal and industrial consumption is expected to increase. The diversity of sizes, types, uses, and values of gems and gemstones precludes any meaningful forecasting of future demand.

TABLE 3

GUIDE TO SELECTED GEMSTONES AND GEM MATERIALS USED IN JEWELRY

Name	Composition	Color	Practical size[1]	Cost[2]	Mohs	Specific gravity	Refraction	Refractive index	May be confused with	Recognition characters
Amber	Hydrocarbon	Yellow, red, green, blue	Any	Low to medium	2.0-2.5	1.0-1.1	Single	1.54	Synthetic or pressed, plastics	Fossil resin, soft.
Beryl:										
Aquamarine	Beryllium aluminum silicate	Blue-green to light blue	Any	Medium to high	7.5-8.0	2.63-2.80	Double	1.58	Synthetic spinel, blue topaz	Double refraction, refractive index.
Bixbite	do.	do.	Small	Very high	7.5-8.0	2.63-2.80	do.	1.58	Pressed plastics, tourmaline	Refractive index.
Emerald	do.	Green	Medium	do.	7.5	2.63-2.80	do.	1.58	Fused emerald, glass, tourmaline, peridot, green garnet, doublets	Emerald filter, dichroism refractive index.
Emerald, synthetic	do.	do.	Small	High	7.5-8.0	2.63-2.80	do.	1.58	Genuine emerald	Flaws, brilliant, fluorescence in ultra-violent light.
Golden (heliodor)	do.	Yellow to golden	Any	Low to medium	7.5-8.0	2.63-2.80	do.	1.58	Citrine, topaz, glass, doublets	
Goshenite	do.	do.	Any	Low	7.5-8.0	2.63-2.80	do.	1.58	Quartz, glass, white sapphire, white topaz	Refractive index.
Morganite	do.	Pink to rose	Any	Low	7.5-8.0	2.63-2.80	Low	1.58	Kunzite, tourmaline, pink sapphire	Refractive index.
Calcite:										
Marble	Calcium carbonate	White, pink, red, blue, green or brown	Any	Low	3.0	2.72	Double (strong)	1.49-1.66	Silicates, banded agate, alabaster gypsum	Translucent.
Mexican onyx	do.	do.	Any	Low	3.0	2.72	do.	1.6	do.	Banded, translucent.
Chrysoberyl:										
Alexandrite	Beryllium aluminate	Green by day, red by artificial light	Russia (small), Sri Lanka (medium)	High	8.5	3.50-3.84	Double	1.75	Synthetic	Dichroism, inclusions in synthetic sapphire.
Catseye	do.	Greenish to brownish	Small to large	do.	8.5	3.50-3.84	do.	1.75	Synthetic, shell	Gravity and translucence.
Chrysolte	do.	Yellow, green, and/or brown	Medium	Medium	8.5	3.50-3.84	do.	1.75	Tourmaline, peridot	Refractive index, silky.
Coral	Calcium carbonate	Orange, red, white, black, or green	Branching, medium	Low	3.5-4.0	2.6-2.7	do.	1.49-1.66	False coral	Dull translucent.

See footnotes at end of table.

TABLE 3—Continued

GUIDE TO SELECTED GEMSTONES AND GEM MATERIALS USED IN JEWELRY

Name	Composition	Color	Practical size[1]	Cost[2]	Mohs	Specific gravity	Refraction	Refractive index	May be confused with	Recognition characters
Corundum:										
Ruby	Aluminum oxide	Rose to deep purplish red	Small	Very high	9.0	3.95-4.10	Double	1.78	Synthetics, including spinel	Inclusions, fluorescence.
Sapphire	do.	Blue	Medium	High	9.0	3.95-4.10	do.	1.78	do.	Inclusions, double refraction, dichroism.
Sapphire, fancy	do.	Yellow, pink, white, orange, green, or violet	Medium to large	Medium	9.0	3.95-4.10	do.	1.78	Synthetics, glass and doublets	Inclusions, double refraction, refractive index.
Sapphire and ruby stars	do.	Red, pink, violet blue, or gray	do.	High to low	9.0	3.95-4.10	do.	1.78	Star quartz, synthetic stars	Shows asterism, color on side view.
Sapphire or ruby synthetic	do.	Yellow, pink, or blue	Up to 20 carats	Low	9.0	3.95-4.10	do.	1.78	Synthetic spinel, glass	Curved strae, bubble inclusions.
Diamond	Carbon	White, blue-white, yellow, brown, green, pink, blue	Any	Very high	10.0	3.516-3.525	Single	2.42	Zircon, titania, cubic zirconia	High index, dispersion, single refraction, hardness, cut, luster.
Feldspar:										
Amazonite	Alkali aluminum-silicate	Green	Large	Low	6.0-6.5	2.56	—	1.52	Jade	Cleavage, sheen, vitreous to pearly opaque, grid.
Labradorite	do.	Gray with blue and bronze sheen color play	do.	Low	6.0-6.5	2.56	—	1.56	do.	Cleavage, sheen, vitreous to pearly opaque, grid.
Moonstone	do.	White	do.	Low	6.0-6.5	2.77	—	1.52-1.54	Glass or white onyx	Blue sheen, opalescent.
Garnet	Complex silicate	Brown, black, yellow, green, ruby red, or orange	Small to medium	Low to high	6.5-7.5	3.15-4.30	Single strained	1.79-1.98	Synthetics, spinel, glass	Single refraction, anomalous strain.
Jade:										
Jadeite	do.	Green, yellow, black, white, or mauve	Large	Low to very high	6.5-7.0	3.3-3.5	Crypto-crystalline	1.65-1.68	Onyx, bowenite, vesu-vianite, grossularite	Luster, spectrum, translucent to opaque.
Nephrite	Complex hydrous silicate	do.	do.	do.	6.0-6.5	2.96-3.10	do.	1.61-1.63	do.	Do.
Opal	Hydrous silica	Colors flash in white, gray, black, red, or yellow	Large	Low to high	5.5-6.5	1.9-2.3	Isotropic	1.45	Glass, synthetics, triplets	Play of color.
Pearl	Calcium carbonate	White, pink, or black	Small	do.	2.5-4.0	2.6-2.85	—	—	Cultured and imitation	Luster, structure, X-ray.
Peridot	Iron magnesium silicate	Yellow and/or green	Any	Medium	6.5-7.0	3.27-3.37	Double (strong)	1.65-1.69	Tourmaline chrysoberyl	Strong double refracation, low dichroism.

See footnotes at end of table.

TABLE 3—Continued

GUIDE TO SELECTED GEMSTONES AND GEM MATERIALS USED IN JEWELRY

Name	Composition	Color	Practical size[1]	Cost[2]	Mohs	Specific gravity	Refraction	Refractive index	May be confused with	Recognition characters
Quartz:										
Agate	Silica	Any color	Large	Low	7.0	2.58-2.64	—	—	Glass, plastic, Mexican onyx	Cryptocrystalline, irregularly banded, dendritic inclusions.
Amethyst	do.	Purple	do.	Medium	7.0	2.65-2.66	Double	1.55	do.	Refractive index, double refraction, transparent.
Cairngorm	do.	Smoky	do.	Low	7.0	2.65-2.66	do.	1.55	do.	Do.
Citrine	do.	Yellow	do.	Low	7.0	2.65-2.66	do.	1.55	do.	Do.
Crystal, rock	do.	Colorless	do.	Low	7.0	2.65-2.66	do.	1.55	do.	Do.
Jasper	do.	Uniform or spotted red, yellow, or green	do.	Low	7.0	2.58-2.66	—	—	do.	Opaque, vitreous.
Onyx	do.	Many colors	do.	Low	7.0	2.58-2.64	—	—	do.	Uniformly banded.
Rose	do.	Pink, rose red	do.	Low	7.0	2.65-2.66	do.	1.55	do.	Refractive index, double refration, translucent.
Spinel	Magnesium aluminum oxide	Any	Small to medium	Medium	8.0	3.5-3.7	Single	1.72	Synthetic, garnet	Refractive index, single refraction, inclusions.
Spinel, synthetic	do.	Any	Up to 40 carats	Low	8.0	3.5-3.7	Double	1.73	Spinel, corundum, beryl, topaz, alexandrite	Weak double refraction, curved striae, bubles.
Spodumene:										
Kunzite	Lithium aluminum silicate	Pink to lilac	Medium	Medium	6.5-7.0	3.13-3.20	Double	1.66	Amethyst, morganite	Refractive index.
Hiddenite	do.	Yellow to green	do.	do.	6.5-7.0	3.13-3.20	do.	1.66	Synthetic spinel	Do.
Tanzanite	Complex silicate	Blue	Small	High	6.0-7.0	3.30	do.	1.69	Sapphire, synthetics.	Strong trichroism.
Topaz	do.	White, blue, green	Medium	Low to medium	8.0	3.4-3.6	do.	1.62	Beryl, quartz	Refractive index.
Tourmaline	do.	All, including mixed	do.	do.	7.0-7.5	2.98-3.20	do.	1.63	Peridot, beryl, corundum, glass	Double refraction, refractive index.
Turquoise	Copper aluminum phosphate	Blue to green	Large	Low	6.0	2.60-2.83	do.	1.63	Glass, plastics	Difficult if matrix not present, matrix usually limonitic.
Zircon	Zirconium silicate	White, blue, or brown, yellow, or green	Small to medium	Low to medium	6.0-7.5	4.0-4.8	Double (strong)	1.79-1.98	Diamond, synthetics, topaz, aquamarine	Double refraction, strongly dichroic, wear on facet edges.

[1] Small—up to 5 carats; medium—up to 50 carats; large—more than 50 carats.

[2] Low—up to $25 per carat; medium—up to $200 per carat; high—more than $200 per carat.

TABLE 4
SYNTHETIC GEMSTONE PRODUCTION METHODS

Gemstone	Production methods	Company	Date of first production
Ruby	Flux	Chatham	1950's
Do.	do.	Kashan	1960's
Do.	do.	Knischka	1980's

TABLE 13—Continued

DIAMOND: WORLD PRODUCTION, BY TYPE AND COUNTRY[1]

(Thousand carats)

Country	1992				1993[e]			
	Natural			Synthetic[4]	Natural			Synthetic[4]
	Gem[2]	Industrial	Total[3]		Gem[2]	Industrial	Total[3]	
Zaire	[r] [7]8,934	[r] [7]4,567	[r]13,501	—	9,500	5,500	15,000	—
Total	[r]56,757	[r]48,773	[r]105,521	[r]419,250	57,205	50,390	107,620	456,000

[e]Estimated. [r]Revised. W Withheld to avoid disclosing company proprietary data.

[1] Table includes data available through June 8, 1994. Total natural diamond output (gem plus industrial) for each country actually is reported, except where indicated by a footnote to be estimated. In contrast, the detailed separate production data for gem diamond and industrial diamond are U.S. Bureau of Mines estimates except Brazil (1989-90), and the Central African Republic (1989-90), for which source publications give details on grade as well as totals. The estimated distribution of total output between gem and industrial diamond is conjectural, and for most countries, is based on the best available data at time of publication.

[2] Includes near-gem and cheap-gem qualities.

[3] Natural gem and industrial data may not add to totals shown because of independent rounding.

[4] Includes all synthetic diamond production.

[5] Figures do not include smuggled artisanal production.

[6] Figures are estimates based on reported exports and do not include smuggled diamonds.

[7] Reported figure.

[8] Formerly part of Czechoslovakia.

[9] Dissolved on Dec. 31, 1992.

[10] "Gem" vs. "Industrial" diamond breakdown has been revised to reflect the value of near-gem material, classified as industrial prior to 1991, but which was ultimately being sold for well above industrial prices.

[11] Data for 1989 do not include smuggled production. Data for 1990-92 are estimates of artisanal production, likely smuggled out of Liberia, but which are comparable to that hitherto reported to the Government.

[12] Formerly part of Yugoslavia.

[13] Other De Beers' Group output from the Republic of South Africa includes Kimberley Mines, Koffiefontein Mine, and Namaqualand Mines.

[14] Dissolved in Dec. 1991.

[15] Dissolved in Apr. 1992.

GOLD

By John M. Lucas

Mr. Lucas, a geologist with more than 30 years of experience in the mining industry, has been the U.S. Bureau of Mines commodity specialist for gold since 1980. While with private industry, Mr. Lucas was involved in exploring for a wide variety of commodities, including gold, in the United States as well as Australia, Brazil, and Canada. Domestic survey data were prepared by Dwayne E. Penn, and Lisa P. Conley, statistical assistants. International data tables were prepared by Audrey D. Wilkes, international data coordinator.

Domestic gold mines continued to produce at record levels in 1993, thereby maintaining the United States' position as the world's second largest gold-producing nation after the Republic of South Africa. Domestic production continued to be dominated by Nevada and California, where combined mine output accounted for nearly 75% of the U.S. total. Gold was produced at about 200 lode mines, nearly all in western States; a dozen or more large placer mines, nearly all in Alaska; and numerous small placer mines, mostly in Alaska and western States. About 14,700 people were employed in gold mines and mills. A small amount of domestic gold was recovered as a byproduct of processing base metals, chiefly copper. Twenty-five mines yielded 80% of the gold produced. The value of 1993 mine production was more than $3.8 billion.

Environmental pollution abatement continued to be of concern to domestic gold producers, especially in Alaska, where there are many small placer mines. Provisions for reclamation of mined land was an integral part of an increasing number of gold mine plans.

The trend in gold exploration activity, which peaked about 1988, continued to decline in 1993 as North American exploration companies sought unexplored territory and improved business and regulatory climates elsewhere. The principal focus remained on several Latin American nations where favorable geology, combined with recently liberalized mining regulations, held the promise of greater long-term success and reduced risk to limited investment capital.

Conversion of gold scrap to refined gold provided nearly 66 metric tons (2.1 million troy ounces[1]) of metal to the market, a quantity equivalent to about 70% of domestic gold consumption. The balance of secondary production, 85 tons, was from prompt industrial scrap, partly toll refined.

Commercial-grade refined gold came from about two dozen producers. A few dozen companies, out of several thousand companies and artisans, dominated the fabrication of gold into useful products. Nearly all jewelry manufacturing was centered in the New York, NY, and Providence, RI, areas. Estimated uses in 1993 were as follows; jewelry and arts, 71%; industrial (mainly electronic), 22%; and dental, 7%.

The Engelhard Industries/London daily price of gold ranged from a low of $327 per troy ounce on March 10, to a high of $407 on August 2. The average for the year was $361.

Gold was mined in nearly 80 countries, of which the top 5 accounted for about two-thirds of the world total of more than 2,330 tons (74.9 million ounces). The Republic of South Africa was the largest producer, with 27% of the world total, followed by the United States (14%), Australia (11%), Canada (7%), and China (7%).

Identified world gold resources at yearend 1993 were estimated by the U.S. Geological Survey at 75,000 tons, of which 15% to 20% was byproduct resources. The reserve base was estimated by the U.S. Bureau of Mines (USBM) at 57,000 tons and reserves at 42,000 tons. The Republic of South Africa had about one-half of the resources and reserve base and 43% of the reserves. The United States had about 12% of world resources, 9% of the reserve base, and 11% of the reserves.

Of an estimated 114,000 tons of gold mined in historical times through 1993, about 15% is believed to have been lost, used in dissipative ways, or otherwise unrecoverable or unaccounted for. Of the remaining 97,000 tons, an estimated 35,000 tons is official stocks held by central banks and about 62,000 tons is privately held as coin, bullion, and jewelry.

DOMESTIC DATA COVERAGE

Domestic mine production data for gold are developed by the USBM from two separate, voluntary surveys of U.S. operations. One of these surveys is the lode-mine production survey of copper, gold, lead, silver, and zinc mines. Of the lode gold producers in operation to which a survey request was sent, 216 responded, representing 98% of the total lode-mine production of gold shown in tables 4 and 5. Production for the nonrespondents was estimated using reported prior-year production levels, adjusted by trends in employment, and other guidelines such as company annual reports, the news media, and State agency reports.

ANNUAL REVIEW

Production

The individual company production

and performance data in this report were derived from published sources such as company annual reports.

Alaska.—According to a summary of 1993 Alaskan mining activity prepared by the Alaska State Division of Geology and Geophysical Surveys (DGGS),[2] production data collected by the DGGS indicated a substantial decline in gold production from that of the previous year. Gold production amounting to about 2,777 kilograms (kg) (89,283 ounces) was reported to the USBM. However, the annual survey conducted informally by the DGGS suggests that a total of about 5,946 kg (191,200 ounces) of both lode and placer gold was produced during the year; the comparable total for the previous year was 8,163 kg (262,530 ounces). Despite the sharp decline in overall production, which, to a large extent reflects the early 1993 closure of Greens Creek Mining Co.'s Greens Creek underground polymetallic mine on Admiralty Island, Alaska's approximately 198 placer mines benefitted from improved gold prices and a long, warmer-than-average mining season.

Alaska Gold Co., a subsidiary of Mueller Industries Inc., continued to operate its two Yuba class bucketline stacker-dredges on its properties in the Nome area and along the Hogatza River.

Production at Alaska's largest placer mine, Cambior Alaska Inc.'s Valdez Creek Mine, was 1,106 kg (35,560 ounces) of gold compared with more than 2,676 kg (86,052 ounces) recovered during 1992.

In addition to Cambior Alaska, Greens Creek, and Alaska Gold, the State's top 10 gold producers, according to the DGGS, included Polar Mining Inc. near Fairbanks, Alaska Placer Development near Livengood, Thurmond Oil and Mining in the Eureka District, GHD Resources in the Tofty District, Cooks Mining east of Fairbanks, Green Mining and Exploration near Ruby, and Paul and Co. in the Circle district. In the State's northern region, Silverado Mines Ltd. reported year-round production at its Nolan gold mine, inside the Arctic Circle 288 kilometers (km) (180 miles) north of Fairbanks.

Gold mines undergoing exploration and development during the year included Echo Bay Mines Ltd.'s Alaska Juneau (AJ) Mine, a large former producing mine on the edge of Alaska's capital city of Juneau, and its Kensington joint-venture project, 115 km (72 miles) north of Juneau.

Amax Gold Inc.,'s 96%-owned operating subsidiary, Fairbanks Gold Inc., continued development work on its Fort Knox Project 24 km (15 miles) northeast of Fairbanks.

Arizona.—Economic ore reserves at Cyprus Gold Co's. Copperstone Mine, in LaPaz County, were exhausted and mining ceased in late 1992. Milling and processing of stockpiled low-grade material at the plant site was completed during the second quarter of 1993. The cessation of production at Copperstone was reflected in a sharp 29% decline in 1993 Arizona gold production from that recorded during 1992 when the Copperstone operation was the State's largest gold-producing property. Most of the gold production reported during 1993 was derived as a byproduct of Arizona's numerous copper mines.

California.—The State of California was again the Nation's second largest gold-producing State during 1993, a position held since 1987.

In mid-1993, the Mesquite Mine in Imperial County was acquired by Santa Fe Pacific Gold Corp. (SFPG) as part of an asset swap between SFPG and Hanson Natural Resources Co. Homestake Mining Co.'s McLaughlin Mine, near Lower Lake, processed oxide and sulfide ore mined by open pit methods to recover a record 9.5 tons (305,312 ounces) of gold during 1993. Near Ogilby, in Imperial County, the American Girl Mine, operated by the American Girl Mining Joint Venture, produced nearly 2,200 kg (69,200 ounces) of gold. In eastern Imperial County, Glamis Gold Ltd. produced gold at its open pit and heap-leaching Picacho Mine. Production also continued at the company's two Kern County mines.

Viceroy Gold Corp. completed its first full year of metal production in February at its new Castle Mountain Mine, in eastern San Bernardino County. The mine produced an estimated 4,000 kg (128,000 ounces) of gold during the year. Nearby, Lac Minerals Ltd. recovered 843 kg (27,131 ounces) of residual gold from its recently depleted Colosseum Mine. Reclamation of the site was nearly completed by yearend.

In the Mother Lode country of Tuolumne County, Sonora Mining Corp. continued mining operations at its Jamestown Mine. During 1993 the mine owners celebrated the recovery of the 500,000th ounce (15.6 tons) of production. On December 26, 1992, a large pocket of gold was discovered at workings on the mine's Crystalline-Alabama claims. Color photographs of the more spectacular specimens were published in California Geology.[3]

In Calaveras County, 65 km (40 miles) east of Stockton, FMC Gold Co. produced about 1,710 kg (55,000 ounces) at its Royal Mountain King Mine.

In June, following 1 year of operation, Lassen Gold Mining Inc., a subsidiary of Amax Gold Inc., placed the mill at its Hayden Hill Mine on standby and temporarily stopped production. The Lassen County operation was later reconfigured to heap leaching only.

Colorado.—The State's largest gold mine, Battle Mountain Gold Co.'s (BMG's) San Luis Mine in Costilla County, increased production by about 31% over production achieved during the previous year. The increased production largely reflects the resolution of operational problems encountered during the mine's startup in 1991 and later in 1992. In Teller County, the Cripple Creek and Victor Gold Mining Co. (CC&VGMC) produced about 1,533 kg (49,310 ounces) of gold, an increase of about 16% over 1992 production.

Other Colorado operations reportedly producing gold during the year included Solution Gold Ltd.'s reclamation mining and leaching project in Gilpin County; Franklin Consolidated Mining Co.'s

Franklin Mine near Idaho Springs, in Clear Creek County; and ASARCO Incorporated's Black Cloud Mine southeast of Leadville, in Lake County, where gold is recovered as a byproduct of lead mining operations.

Idaho.—In January, Pegasus Gold Inc. completed its first full year of metal production at its Black Pine Mine near Bridge, 40 km (25 miles) north of the Idaho-Utah border. The mine was Idaho's largest gold producer in 1993.

Production at the open pit DeLamar Mine in Owyhee County amounted to a record 1,340 kg (43,094 ounces). The DeLamar's new owners moved toward a mid-1995 startup at the Stone Cabin property, 8 km (5 miles) from the DeLamar site.

Idaho Gold Corp. reportedly conducted secondary leaching of low-grade ore at its Champagne Mine 32 km (20 miles) east of Arco in Butte County. Reclamation was underway near yearend at the site, where mining was completed in 1992.

Seasonal mining and heap-leach operations continued at the Stibnite Mine near Yellow Pine in Valley County. The mine is wholly owned by MinVen Corp., which changed its name in September to Dakota Mining Corp. Also in Valley County, USMX acquired an interest in the Dewey-Sunnyside Mine properties.

On Jordan Creek in Custer County, Hecla Mining Co. moved forward with plans to develop its Grouse Creek property in the Yankee Fork Basin. In Lemhi County, Meridian Gold Co., a subsidiary of FMC Gold Co., continued to defer development at its fully permitted Beartrack property, 18 km (11 miles) northwest of Salmon.

Montana.—Mining and mineral developments in Montana during 1993 were summarized in a report prepared by the Montana Bureau of Mines and Geology (MBMG).[4] With four separate open pit gold mines, Pegasus Gold Inc. was again Montana's leading gold producer in 1993. Pegasus' Basin Creek Mine, placed on care and maintenance in 1991, produced residual gold from existing test heaps at the Lewis and Clark County mine site. The company's Zortman-Landusky Mine, in Phillips County, the State's largest gold mine, yielded nearly 3,400 kg (108,500 ounces), or 4% less than in the previous year. The decline was attributed to an extremely wet summer. Gold was recovered at Pegasus' Montana Tunnels Mine, a gold, lead, silver, and zinc mine in Jefferson County. Despite a wet operating season, production at the company's Beal Mountain Mine increased. Pegasus also began mining at its newly permitted south Beal property in late 1993.

Open pit mining operations at Placer Dome's wholly owned Golden Sunlight Mine near Whitehall in Jefferson County yielded 2,818 kg (90,612 ounces) in 1993. At Jardine, in Park County, TVX Gold Inc. produced about 1,350 kg (43,300 ounces) of gold at its underground Mineral Hill Mine. Permitting work was continued by Crown Butte Resources Ltd. at its New World gold, copper, and silver project near Cooke City in eastern Park County. Plans call for processing not involving heap leaching or the use of cyanide.

Gold production at Canyon Resources Corp.'s open pit Kendall Mine near Lewiston amounted to nearly 1,700 kg (54,203 ounces) during 1993. Canyon continued exploration at the McDonald gold deposit, the smaller Seven-Up Pete deposit, and the nearby Keep Cool mineralized area in Lewis and Clark County.

Exploration activity in Montana continued to decline, and many companies closed their exploration offices. The MBMG estimated that the quantity of gold recovered at the State's numerous small placer mining operations was impacted severely by the extremely wet operating season.

Nevada.—Gold production in Nevada, the Nation's dominant gold-producing State, increased for the 14th consecutive year. Output during 1993 represented a 27-fold increase over production achieved in 1979.

Newmont Gold Co. (NGC), with gold mining operations generally centered in Eureka and Elko Countries, was again Nevada's and the Nation's largest gold producer. NGC's operations consisted of five active surface mines, five mills, and three heap-leaching facilities. Total production during 1993 amounted to 51.8 tons (1.67 million ounces). As an extension of its current leaching operations, NGC conducted successful field tests confirming the commercial viability of a patented bioleaching process to recover gold from low-grade sulfide-bearing materials that previously could not be treated economically.

Trailing behind NGC, Barrick Goldstrike Mines Inc., a wholly owned subsidiary of American Barrick Resources Corp., recovered 44.8 tons (1.4 million ounces) of gold from its Betze-Post Mine in Eureka County. The Betze-Post operation is part of the company's Goldstrike property. Development work at the company's underground Miekle Mine, north of the Betze-Post Mine, continued during the year. Production was expected to begin at the Miekle property in late 1996.

At the Jerritt Canyon Mine, northwest of Elko, Independence Mining Co. and FMC Gold Co. produced about 11.2 tons (360,000 ounces) of gold, an increase of about 13% over production achieved during the previous year. Plans were to shift the mine's operations from surface mining to underground mining—the New Deep Mine. Independence also continued gold mining operations at its nearby Big Springs open pit.

In eastern Humboldt County, Santa Fe Pacific Gold Corp. (SFPG), through an exchange of mineral assets with Gold Fields Operating Co., acquired Gold Fields' Chimney Creek Mine. Following the exchange, mining operations at Chimney Creek and Rabbit Creek were combined to form a single operation renamed the Twin Creeks Mine. SFPG's other Humboldt County gold mine, the Lone Tree Mine, located near Valmy, produced nearly 5 tons (160,000 ounces) of gold by heap leaching during the year. Nearby FirstMiss Gold Inc. began underground development at its open pit Getchell Mine where the company first began heap leaching in 1985 and expanded to include milling and autoclave pressure oxidation in 1988. Cumulative production near yearend amounted to almost 1 million ounces (31 tons). Other operating gold mines in Humboldt County included the Crowfoot/Lewis Mine, Marigold Mine, Pinson Mine, and Sleeper Mine.

Mining operations at the Battle Mountain Complex, in Nye County, were cut back in early 1993 following depletion of the high-grade ore at Battle Mountain Gold Co.'s Fortitide deposit. The company continued to move forward with the design and permitting of its new 1,560-kg-per-year (50,000-ounce-per-year) Reona heap-leach project. Work was continued at its recently discovered Phoenix mining project.

South of Battle Mountain's operations, the McCoy/Cove gold and silver property of Echo Bay Mines Ltd. achieved another year of record production for both metals. Gold production rose 31% to 12.3 tons (395,608 ounces). Exploration during the year replaced 86% of the reserves that had been mined during the year.

Along the Lander County/Eureka County line southeast of McCoy/Cove, the Cortez Gold Mine Joint Venture produced about 2,080 kg (66,852 ounces) of gold at its Cortez Mine. The partners also completed a feasibility study of the Pipeline gold deposit and continued exploration at the nearby South Pipeline project. Discovery of the Pipeline deposit sparked a flurry of exploration and claim staking in the Crescent Valley area.

At Round Mountain in north-central Nye County, Round Mountain Gold Corp. produced nearly 11.7 tons (374,696 ounces) of gold at its open pit and heap-leaching operations. A small amount of gold, about 0.5% of the total, was recovered at the Manhattan mine and mill site at the nearby town of Manhattan.

At Lac Minerals Ltd.'s wholly owned Bullfrog Mine near Beatty in southern Nye County, 11 tons (354,887 ounces) of gold was mined during 1993, a nearly 10% increase over that of the previous year. Bullfrog's new underground mine reached full production in early 1993.

In Mineral County, mining was completed at Corona Gold Inc.'s Santa Fe Mine. Limited residual metal production from the heap leach was expected in 1994 and reclamation was expected to be completed in 1996. Nearby, Kennecott Rawhide Mining recovered about 3,300 kg (105,000 ounces) of gold at its Denton Rawhide Mine. Other Mineral County gold mines include Nevada Goldfields Inc.'s Aurora Mine and Minerex Resources Ltd.'s Aurora Partnership Mine. Respective production at these two operations amounted to about 270 kg (8,600 ounces) and 940 kg (30,120 ounces) in 1993.

South Carolina.—Three out of four gold mines brought into production in South Carolina over the past decade produced gold during 1993. Two mines recovered gold from ore mined during the year, and the third, the Brewer Mine in Chesterfield County, produced some residual gold from ore mined prior to the suspension of mining operations in late 1992. Operations at the State's fourth gold mine, the Haile Mine in Lancaster County, were suspended in mid-1991 to allow time to develop a new mine plan.

South Carolina's largest gold mine in 1993 was Kennecott Ridgeway Mining Co.'s Ridgeway Mine, an open pit and milling operation in Fairfield County. Ridgeway mined 4,260 kg (137,000 ounces) of gold during 1993. At the Barite Hill Mine in McCormick County, surface mining and heap-leaching operations recovered nearly 30% more gold than during the previous year. The mine, owned and operated by Consolidated Nevada Goldfields Corp., yielded 623 kg (20,044 ounces) of gold during the company's fiscal year ending June 30. The company estimated that the property will be mined out during fiscal year 1995. Plans for a safe and effective site decommissioning had begun.

Exploration was continued at the Haile Mine. During the year, the Haile Mining Venture conducted drilling, engineering, and environmental studies. Gold mining has been conducted intermittently on the Haile property since 1829.

South Dakota.—The Nation's largest underground mine was the Homestake Mine at Lead, SD. During the year, this 116-year-old operation produced nearly 14 tons (447,593 ounces) of gold, a 13% increase over 1992 production. According to Homestake Mining Co., the increase was due primarily to higher grades of ore mined and by employing selective mining techniques. Homestake also began expanded and accelerated stripping operations at its Open Cut surface mine to provide its uninterrupted feed to the mill. The Open Cut is a pit developed on the site of the original 1876 Homestake gold strike.

Wharf Resources Ltd. operates South Dakota's second largest gold mine, the Wharf Mine, west of Lead. This wholly owned operation produced a record 3,200 kg (102,381 ounces) of gold during 1993. Regulatory approvals were received in early 1993 to increase the mine's annual open pit mining rate to about 4.1 million tons. The company's 60%-held Gold Reward open pit mine adjacent to the Wharf Mine produced about 1,100 kg (35,549 ounces) of gold. Dakota Gold Mining Inc. a subsidiary of Dakota Mining Corp., (formerly MinVen Gold) holds the remaining 40% interest in the Golden Reward property.

At Dakota Mining's Gilt Edge Mine, open pit mining of permitted oxide ore reserves was completed; leaching of ore already on the pad continued through the year, yielding nearly 300 kg (9,423 ounces) of gold.

At the Richmond Hill Mine, Lac Minerals Ltd. continued leaching ore mined prior to a State Department of Environment and Resources-mandated cessation of mining in July 1992. The termination of mining coincided approximately with the depletion of minable ore reserves, and leaching operations ceased permanently in December. Total gold production for the year amounted to about 330 kg (10,716 ounces).

Utah.—Kennecott Corp.'s Bingham

Canyon Mine, where gold is produced as a byproduct of copper mining operations, has long been Utah's largest gold producer as well as one of the Nation's leading gold-producing mines. During 1993, Kennecott mined 16 tons (516,000 ounces) of gold from Bingham Canyon. Kennecott also operated the nearby Barneys Canyon Mine, in Salt Lake County, where production during the year amounted to about 3,330 kg (107,000 ounces) of gold.

Utah's largest primary gold mine, American Barrick's Mercur Mine in Tooele County, produced about 3,570 kg (114,761 ounces) during the year, a decline of about 5% from that of the previous year. Other producing gold mines in Utah during 1993 included USMX's Goldstrike Mine in Washington County where, despite severe winter conditions, about 990 kg (31,984 ounces) of gold was recovered, and North Lily Mining Co.'s Silver City Joint Venture, a heap-leaching operation in Juab County.

Washington.—In terms of value and the number of people employed, gold was Washington State's most important metallic mineral commodity. USBM data of gold production in the State as well as the Washington State Division of Geology and Earth Resources (DGER), in its annual review of Washington's mineral industry,[5] indicated that combined gold production by Washington's three major gold mining operations—the Cannon Mine, the Kettle River Project, and the Republic Unit—amounted to about 7,100 kg (228,509 ounces) during 1993. When compared with similar data for 1992, a decline of nearly 20% was indicated.

The Cannon Mine in Chelan County was again the State's largest gold producer. According to the DGER, this underground facility, at Wenatchee, produced 3,280 kg (105,477 ounces) of gold during 1993.

At Hecla Mining Co.'s Republic Unit near Republic in Ferry County, gold production for the year amounted to about 1,543 kg (49,601 ounces). Most of the production came from the Mine's Golden Promise deposit, which is scheduled for depletion in early 1995 unless more ore is discovered. The Republic Unit, formerly known as the Knob Hill Mine, has been producing gold and silver for nearly 60 years.

Also in Ferry County, Echo Bay produced about 2,280 kg (73,431 ounces) of gold at it wholly owned Kettle River Project. The property was developed around five separate deposits, four of which have been mined to date, with one, the Overlook deposit, scheduled for further work in 1994. The Key East and Key West deposits were mined out in 1993 as planned, and land reclamation programs were under way at both by yearend. A fifth deposit, the Lamefoot, was being developed for production in 1994 together with a small area of high-grade ore discovered near the Key West pit.

In Okanogan County, near Chelan, Battle Mountain Gold, the operator, and Crown Resources Group continued development at their Crown Jewel property.

Wisconsin.—Kennecott Corp., through its wholly owned subsidiary Flambeau Mining Co., opened its new Flambeau Mine near Ladysmith in Rusk County, WI. The new copper mine will produce gold and silver as byproducts. All metal values were recovered from concentrates processed in Canada.

World Review

World gold mine output continued to increase, with 1993 marking the 15th consecutive year of growth. Gold Fields Mineral Services Ltd. (GFMS),[6] in its latest annual statistical review of world gold supply and demand, noted that the 1993 increase in Western World mine production represented the lowest rate of increase since production started to rise in 1980. The report revealed that the strongest rate of production growth was seen shifting toward nations in the developing world, especially Asia and Latin America where modernization of mining codes, the greater availability of relatively unexplored land, and increasingly attractive investment climates have enticed increased funds for exploration and development. Data on other components of supply, including old gold scrap and net sales of gold to the market from Western World central banks, also registered increases, with improved, albeit volatile, metal prices after the first quarter of the year as the principal stimulant. Despite a substantial increase in gold demand for investment purposes, GFMS data indicated a 7% overall decline in gold used in fabricating jewelry products, the first decline since 1986. Moderate increases of 9% and 11%, respectively, were registered for the use of gold in electronics and for other industrial or decorative uses, including the increased use of gold in official coins, where a 34% increase was largely attributed to a special issue in Japan of 2 million gold coins commemorating the wedding of the Crown Prince.

Australia.—For the second consecutive year, Australia was the world's third largest gold-producing nation behind the Republic of South Africa and the United States. Australia's largest gold-producing State was Western Australia, where numerous gold mines, generally situated within three principal goldfields developed around and west of Kalgoorlie, produced about 183 tons (5.9 million ounces) of gold during 1993.

In midyear, the 7th Australian Gold Mining Conference was held at the Kalgoorlie School of Mines, in Kalgoorlie. The conference celebrated the July 1893 discovery of gold in Western Australia. The Super Pit at Kalgoorlie, Australia's largest gold mine, incorporates the workings of several previously separate mines into one large operation.

Other Australian gold-producing States and Territories, in descending order of output, were Queensland, the Northern Territory, New South Wales, Victoria, Tasmania, and South Australia. During 1993 several new gold mines reportedly began production, including the Kanowna Belle Mine near Kalgoorlie, Zapopan N.L.'s Mount Todd Mine, 290 km (180 miles) south of Darwin in the Northern Territory, and Reynolds Metals Co.'s new underground mine at its Boddington operations southeast of Perth, Western Australia.

Canada.—A review of Canadian gold developments was prepared by the Canadian Department of Energy, Mines and Resources (EMR).[7] There were about 50 primary gold mines in Canada at the end of 1993, and these mines, along with placer operations, accounted for 89% of the gold produced. The remaining 11% of production was gold derived from base metal mines. Six gold mines began or resumed operations during the year, including the Keystone Mine in the Province of Manitoba and the following five mines in the Province of Quebec: Astoria, Casa Berardi Est, Granada, Portage, and Rand. Two gold mines in Quebec were closed during the year owing to exhaustion of reserves.

Canada's dominant gold-producing jurisdiction was again the Province of Ontario, which produced about 28% of the nearly 153 tons (4.9 million ounces) of total Canadian production. Three large underground mines in the Hemlo area accounted for nearly 50% of the Ontario total. Other Canadian Provinces and Territories producing gold in 1993 were, in decending order of output, Quebec, British Columbia, Northwest Territories, Yukon, Manitoba, New Brunswick, and Alberta. Gold also was produced in Newfoundland and Saskatchewan; however, data on production in these Provinces were withheld to avoid disclosing company proprietary data.

Latin America.—Over the past 4 or 5 years there has been an increasing level of interest in Latin American and Caribbean nations. In many Latin America countries, the recent ongoing liberalization of mining codes and the lowering or removal of political and economic barriers have increasingly served to attract foreign mining interests. Many of the companies involved in the exploration, acquisition, and development of Latin American and Caribbean gold projects, or seeking opportunities there, are based in North America. Two studies released during the year examined the reasons behind this recent surge in activity as well as various factors leading to the successful entry of foreign corporations into the region.[8]

Areas of Latin American receiving much of the attention in recent years have been Chile, Mexico, Peru, and the Guyanan Shield area of Guyana and Venezuela, especially around the "Kilometer 88" area of eastern Venezuela. In Esequibo County in western Guyana, commercial production was begun at Cambior Inc.'s 60%-held Omai Mine. Annual production at the new open pit operation is expected to be about 8.7 tons (280,000 ounces) of gold.

In May, the President of Argentina signed that nation's new Federal Mining Agreement. North American companies initiating gold exploration or mine development projects in Argentina during the year included Crown Resources Corp., of Golden, CO; San Francisco-based American Resources Corp.; and International Musto Exploration Ltd. of Toronto, Canada.

Brazil is Latin America's largest gold-producing nation. Reflecting the apparent exhaustion of easily worked surface and placer gold by independent gold miners, or "garimpeiros," production declined in 1993.

In Bolivia's Altiplano, southwest of La Paz, Empresa Mineral Inti Rami began production at its newly expanded Kori Kolo Mine. Annual gold production is expected to be about 7.6 tons (245,000 ounces).

Gold production in the Caribbean area was limited to that produced by Rosario Dominicana S.A. at its Pueblo Viejo Mine in the Dominican Republic. Exploration for gold in the Caribbean region in 1993 was conducted largely in the Republic of Cuba, the Dominican Republic, Jamaica, and the Commonwealth of Puerto Rico. Various nations in Central America continued to produce small amounts of gold, and exploration and mine development activities continued to be pursued, particularly in Costa Rica and Panama.

Gold production in Chile increased for the sixth consecutive year. In early 1993, Amax Gold Inc. began production at its newly expanded Guanaco Mine. Commercial production at the expanded operation was expected to yield up to 2,500 kg (80,000 ounces) per year. El Indio, Chile's largest gold mine, 83%-owned by Lac Minerals Ltd., produced about 6,232 kg (200,355 ounces) of gold during the year.

In early 1993, a landslide struck the remote gold rush town of Nambija, in the Loja Province of Ecuador, killing or injuring many of the residents. An estimated 2,000 to 3,000 unregulated gold miners operate mines at the remote site, about 390 km (240 miles) south of Ecuador's capital city of Quito.

In Mexico, at least two new gold mines were opened and two more reached the final stages of development. In late 1993, Exall Resources Ltd. reportedly began placer gold mining operations on its Rio Yaqui projects on the Yaqui River in the State of Sonora. Later, Australian-based Walhalla Mining Co. dedicated its new Amelia Mine, an open pit and heap-leaching operation, also in Sonora. Construction at two other open pit and heap-leaching mines in Sonora, Eldorado Corp. Ltd.'s La Colorada Mine and Hecla Mining Co.'s La Choya Mine, was nearly complete at yearend.

Estimated gold production in Peru, as shown in table 11, was revised substantially to reflect more reliable information on the performance of the formal and informal mining sectors. In late 1993, Newmont Mining Corp.'s Minera Yanacocha Mine near Caja Marca began production at a rate of about 6,842 kg (220,000 ounces) annually. Yanacocha was Peru's second largest gold-producing mine during 1993. Peruvian Government efforts to attract foreign investment in mining as well as privatization of Government-owned mining interests accelerated during the year.

Production was begun at American Resources Corp.'s Mahoma gold mine and milling operation in Uruguay. The new open pit operation, about 100 km (62 miles) northwest of Montevideo, is expected to recover about 1,244 kg (40,000 ounces) of gold per year.

Oceania.—Following three successive years of increased gold production, Papua New Guinea's 1993 production declined 15% from production achieved during the previous year. Sharp declines in production, apparently a reflection of lower grades of ore processed, were registered at Placer Pacific Ltd.'s Porgera Mine in Enga Province and its Misima Mine in Milne Bay Province. Production increased at the Ok Tedi copper-gold mine and at the Mount Kare alluvial mine, both in Enga Province. Development of the large Lihir Island project off the east coast of New Ireland continued, while exploration moved ahead at various exploration projects such as Tolukuma, Woodlark Tabar Island, Wild Dog, and others. The giant Bougainville copper and gold mine on Bougainville Island remains closed. Law and order problems continued to plague some remote exploration projects.

In West Irian, on the Indonesian side of the island of New Guinea, Freeport Indonesia, Inc. recovered 24.5 tons (786,700 ounces) of byproduct gold at its large Grasberg/Ertsberg copper and gold deposit, an increase of 23% over that of the previous year. Ongoing exploration and project expansion continued to enhance prospects for increased production. In the Province of East Kalimantan, PT Kelian Equatorial Mining's Kelian open pit mine completed its first full year of production and recovered about 14.4 tons (464,000 ounces) of gold. Newmont Indonesia continued exploration projects on the Island of Sulawesi and on the Island of Sumbawa. Raw gold as well as gold jewelry fabricated by a growing domestic manufacturing sector continued to be important Indonesian export products.

In addition to three large New Zealand gold mines—the Golden Cross and Waihi Mines on North Island and the largest mine, the Macraes Mine on South Island—a new placer mine, the Island Block Mine, began production in late 1993 in the central Otago region of South Island.

Other Asia.—Gold production in the Philippines declined 36% from that of the previous year. The Philippine's oldest company, the Benguet Corp., following suspension of operations at its Paracale gold operations in southern Luzon, began a previously announced phased shutdown of its underground Acupan and Balatoc Mines in northern Luzon. Atlas Consolidated Mining and Development Co. ceased operations at its Masbate Mine on Masbate Island. Philex Mining Corp. continued development at its Bulawan gold project on Negros Island where production is set to begin in early 1995.

Interest in gold in China continued to increase during the year. New laws were prepared to encourage participation by foreign companies. Twice during the year the Chinese Government increased the official price paid to Chinese gold miners for their product. The increases were reportedly aimed at helping mines meet rising production costs and to discourage smuggling and sale of gold outside official channels. There are reportedly about 500 gold mines in China. Shandong Province is the largest gold producer, accounting for about 25% of current production.

The emergence of China as a large gold-consuming nation increasingly favors the development of a domestic jewelry industry where Chinese mined products such as gold, diamonds, and colored stones plus a skilled work force and low wage rates have been combined to produce products for domestic and international consumption. An overview of the Chinese jewelry industry focusing on the potentials and pitfalls of foreign participation was published in 1993.[9]

To encourage local jewelry production, Malaysia abolished its 5% import duty on gold bullion and coins.

Gold exploration activity continued to expand throughout much of Asia during 1993 and included reports of activity in the nations aforementioned as well as other nations such as Burma, Japan, and Laos.

Russia and the Former U.S.S.R.—At least seven independent countries resulting from the dissolution of the U.S.S.R. in late 1991 were gold producers in 1993. Russia continues to be the dominant gold-producing country in the former U.S.S.R., with much of the gold production originating from mines in Magadan-Chukotski Peninsula region of eastern Russia. According to Gold Fields,[10] despite an increase during 1993 in the official price paid for domestic production, extended delays in payment by the state resulted in greater quantities of gold being sold outside of state-administered markets.

A report documenting the significant mineral deposits of the Russian Northeast and their relationship to similar deposits to the east in Alaska was released in 1993.[11] Foreign corporate mining interest in exploring and developing gold properties in the former U.S.S.R. continues to build. In late 1993, the Zarafshan-Newmont Joint Venture broke ground at its new gold recovery project in the Republic of Uzbekistan. In early 1993, MK Gold Co. formed a joint venture with the Republic of Kyrgystan to develop the Jerooy Gold Project in the Talas region of the republic. Later, Cyprus Amax Minerals Co. formed a joint venture with Russian partners to develop the Kubaka gold field in the Magadan region of eastern Russia.

South Africa, Republic of.—Despite earlier predictions of declining South African gold mine performance, production increased for the third consecutive year. The increase, albeit marginal at about 1%, again was attributed to an improvement in the average recovery grade of ore mined from 5.37 grams per ton (0.157 ounce per short ton) in 1992 to 5.56 grams per ton (0.162 ounce per short ton) during 1993. The tonnage of ore milled by the nearly three dozen mines representing the membership of the Chamber of Mines of South Africa declined about 3% during 1993 to about 103 million tons. This was the fourth consecutive year in which a decline in the volume of ore milled was registered.

The South Africa gold mining industry is dominated by six major corporate groups or "houses." Listed on the basis of 1993 production they were as follows: the Anglo American Corp. of South Africa Ltd. (AAC), Gold Fields of South Africa Ltd., Gencor Ltd., Johannesburg Consolidated Investment Co. Ltd., Anglovaal Ltd., and Rand Mines Ltd. Anglo American, the largest of the corporate groups, produced 267 tons (8.6 million ounces) of gold from seven separate mining operations, including its large Freegold Mine, South Africa's largest gold mine, which produced about 122 tons (nearly 4 million ounces) of gold and the nation's second largest gold mine, AAC'S Vaal Reefs Mine, where 80 tons (2.6 million ounces) of gold was recovered during 1993. During the year, underground mining operations were terminated at Gencor's Bracken Mine in the Evander area of the Orange Free State.

The number of workers employed at South African gold mines continued to decline during the year, reportedly reaching 360,000 by yearend. The work force numbered about 535,000 in 1986.

Current Research

The USBM maintained nine research centers throughout the Nation, and most conducted research into various aspects of mining and extractive metallurgy that may be directly or indirectly beneficial to the gold mining industry.[12] Because gold mining is pursued in many nations, the results of the ongoing work may, like the USBM's earlier work in heap leaching, ultimately benefit a broad segment of the industry worldwide. In recent years, the USBM's research relating to gold mining has generally focused on advanced mining techniques and the use of cyanide in the recovery process. The USBM addressed several questions regarding the use of cyanide, including such topics as the mass balance of cyanide in the leaching process, the mobility of metals in the heap during heap leaching, the persistence of cyanide in the environment, alternatives to cyanide, and reclamation of mining sites where cyanide had been employed. The USBM also was investigating the leaching of metals from very low-grade ores with the aid of biotechnology. Bioleaching research for precious metals focused on a preleach treatment of precious-metal-bearing sulfide ores.

OUTLOOK

If the final outcomes of the current debate over the proposed revision to the General Mining Law are deemed to be acceptable and affordable by domestic gold producers and encourage continued exploration for new domestic gold deposits, domestic gold reserves production should continue to increase, albeit at a much lower rate than the explosive growth in gold production and reserves seen during the decade of the 1980's. If, on the other hand, the new law places unacceptable burdens on producers and reduces the incentive to explore, production could decline substantially as existing deposits are high graded wherever possible, or reclassified as uneconomic, and both producers and explorationists move to pursue opportunities in more hospitable environments elsewhere. According to data prepared by the Gold Institute, world gold production is projected to increase at a rate of about 1.6% annually through 1997.[13]

Total[3]	265,731	294,189	[r]294,062	[r]330,212	331,013

[r] Revised. W Withheld to avoid disclosing company proprietary data; included in "Total."

[1] These figures, reported to the U.S. Bureau of Mines, probably understate production. Data collected by the State indicate production to have been as follows, in kilograms: 1989—8,852; 1990—7,206; 1991—7,585; 1992—8,163; and 1993—5,946.

[2] In addition to reported data shown in the table, placer production was estimated by the State to have been as follows, in kilograms: 1992—84; and 1993—6.

[3] Includes, for at least some of the years 1989-93, Michigan, Oregon, Utah, and Wisconsin.

TABLE 3
TWENTY-FIVE LEADING GOLD-PRODUCING MINES IN THE UNITED STATES IN 1993, IN ORDER OF OUTPUT

Rank	Mine	County and State	Operator	Source of gold

[r] Revised. W Withheld to avoid disclosing company proprietary data; included in "Total," where applicable.

[1] Includes metal recovered by gravity methods.

[2] Includes old tailings and some nongold-bearing ores not separable, in amounts ranging from 0.15% to 0.25% of the totals for the year listed.

[3] Includes some placer production to avoid disclosing company proprietary data.

TABLE 6
GOLD PRODUCED IN THE UNITED STATES BY CYANIDATION[1]

Year	Extraction in vats, tanks, and closed containers		Leaching in open heaps or dumps[2]	
	Ore treated (metric tons)	Gold recovered[3] (kilograms)	Ore treated (metric tons)	Gold recovered[4] (kilograms)
1989	42,464,260	121,716	129,830,246	106,324
1990	47,614,538	135,764	149,968,960	128,730
1991	[r]45,606,862	[r]160,379	[r]174,452,362	[r]103,775

1993	54,698,929	176,684	184,007,813	128,367

[r] Revised.

[1] May include small quantities recovered by leaching with noncyanide solutions and by proprietary processes.

[2] May include tailings and waste ore dumps.

[3] May include small quantities recovered by gravity methods.

[4] May include metal recovered by leaching of previously mined ore at some inactive mines.

TABLE 7
U.S. REFINERY PRODUCTION OF GOLD

(Kilograms)

Raw material	1989	1990	1991	1992	1993

[1] Bullion also moves in both directions between U.S. markets and foreign stocks on deposit in the Federal Reserve Bank. Monetary gold excluded.

[2] Includes gold content of base metal ores, concentrates, and matte destined for refining.

[3] Data may not add to totals shown because of independent rounding.

[4] Verification of Bureau of the Census export quantities was not possible for some months of 1993. Quantities shown are rounded estimates derived by dividing dollar values, which are believed to be accurate, by an estimated value for waste and scrap of $9,400/kg.

[5] Less than 1/2 unit.

Source: Bureau of the Census.

[e]Estimated. [r]Revised.

[1] Table contains data available through Aug. 9, 1994.

[2] Gold is also produced in Bulgaria, Burma, Cuba, Czech Republic, Norway, Senegal, Serbia and Montenegro, Slovakia, Thailand, and several other countries. However, available data are insufficient to make reliable output estimates.

[3] Reported figure.

[4] Reported as bullion historically including an estimated 2% silver.

[5] Officially reported figures are as follows, in kilograms: Major companies: 1989—22,849; 1990—30,098; 1991—34,053 (revised); 1992—39,044 (revised); and 1993—40,000 (estimated). Garimpos 1989—29,678; 1990—71,815; 1991—55,525; 1992—46,818 (revised); and 1993—45,000 (estimated).

[6] Gold purchases by Banco Central from placer deposits and mines; actual production estimated to be at least twice this amount.

[7] Year ending June 30 of year stated.

[8] Does not include undocumented production from small artisanal production.

[9] Figures include reported SAG mine production of, in kilograms: 1989—1,202; 1990—1,745; 1991—1,453; 1992—1,113; and 1993—500 (estimated). Remainder represents approximate reported sales to Government, of artisanal production. Figures do not include artisanal production smuggled out of the country.

[10] Refinery output.

[11] Excludes production from so-called people's mines, which may be as much as 18,000 kilograms per year, but includes gold recovered as byproduct of copper mining.

[12] These figures are based on gold taxed for export and include gold entering Liberia undocumented from Guinea and Sierra Leone.

[13] Includes estimates (Government estimate 1989) of artisanal production and may include some gold smuggled into Mali. The Kalana Mine accounted for about 13% in 1989; 8% in 1990; about 2% in 1991; less than 1% in 1992; and none in 1993. The Syama Mine began gold production in 1990 and accounted for about 42% of the total output that year, 49% in 1991; 57% in 1992; and 56% in 1993.

[14] Data are based on official exports and do not reflect gold moved through undocumented channels.

[15] Indicates byproduct of base metals.

[16] Dissolved in Dec. 1991.

[17] Dissolved in Apr. 1992; however, information is inadequate to formulate reliable estimates for individual countries.

[18] Year beginning Apr. 1 of year listed.

GRAPHITE

By Harold A. Taylor, Jr.

Mr. Taylor, a physical scientist with 27 years of industry, Federal Government, and U.S. Bureau of Mines experience, has been the commodity specialist for graphite since 1980. Domestic survey data were prepared by William Field, statistical assistant; and international data tables were prepared by Amy Durham, international data coordinator.

Amorphous graphite was not mined domestically in 1993. Graphite supplies again exceeded industrial demand. Most prices of the major kinds of graphite dropped somewhat or remained unchanged from those of 1992. Quoted prices mostly reflected the existing oversupply. Production of manufactured graphite and graphite fibers decreased slightly and increased 21%, respectively.

DOMESTIC DATA COVERAGE

Domestic production data for synthetic graphite are developed by the U.S. Bureau of Mines from a voluntary survey of domestic producers. Of the 29 operations polled, 100% responded. This represented 100% of the total production data shown in table 4. *(See table 1.)*

BACKGROUND

Definitions, Grades, and Specifications

Graphite, a soft crystalline form of carbon, has been called plumbago and black lead. It crystallizes in a lamellar hexagonal system, has a gray to black metallic luster, and is greasy to the feel. It is anisotropic in its physical properties and has a weak plane of cleavage parallel to the lamellae.

The term "amorphous" when applied to graphite is a misnomer. The term "microcrystalline" is more descriptive. The definition of amorphous, as applied to graphite, has been complicated further by longstanding industrial application of the term to very fine particles of crystalline flake graphite that can be sold only for low-value use such as foundry facings. Fine-grained varieties of lump graphite that are easily reduced to fine particle size by grinding are called amorphous lump to distinguish them from the tough, platy and acicular varieties, known as crystalline lump, that can be reduced in particle size only with extreme difficulty.

Crystalline flake graphite is well defined in paragraph 214 of the Tariff Act of 1930 as follows:

"The term crystalline flake means graphite, or plumbago, which occurs disseminated as a relatively thin flake throughout its containing rock, decomposed or not, and which may or has been separated therefrom by ordinary crushing, pulverizing, screening, or mechanical concentration process, such flake being made up of a number of parallel laminae, which may be separated by mechanical means."

Under the foregoing definition, finely divided particles of crystalline flake graphite would be classified as crystalline graphite. The Court of Customs Appeals, however, has held that commercial designations and not scientific terms must govern classification, and when a commercial meaning differs from the technical meaning, the commercial designation must govern. Therefore, quantities of fine crystalline flake graphite are imported under the amorphous classification.

Sri Lankan lump graphite is classified as amorphous or crystalline. Each type is divided into a number of grades, depending on the size (such as lump, ranging from the size of walnuts to that of peas; chip, from that of peas to about that of wheat grains; and dust, finer than 60 mesh), graphitic carbon content, and degree of consolidation.

Amorphous graphite is graded primarily on graphitic carbon content. Commercial ore contains about 75% to 93% carbon, depending on the source.

Crystalline flake graphite from Madagascar is divided into two main grades, "flake" (coarse flake) and "fines" (fine flake). Madagascan crucible flake must have a minimum of 85% graphitic carbon and be essentially all minus 20 plus 80 mesh in particle size. Other crystalline flake graphites are also graded according to graphitic carbon content and particle size.

Natural graphite is marketed in the form of crystalline graphite as flake, lump, chip, and dust and in the form of amorphous graphite in sizes from fine powder to lumps up to the size of walnuts. It is common practice to blend different graphite to obtain a product having certain desired physical and chemical properties. In many instances, the composition of these blends is retained as a trade secret.

Geology-Resources

The three principal types of natural graphite—lump, amorphous, and crystalline flake—are based on physical characteristics that are the result of major differences in geologic origin and occurrence. A variety of silicate minerals are generally associated with graphite in the ore.

Lump graphite occurs as fissure-filled veins. It is typically massive, ranging in particle size from extremely fine grains (amorphous) to coarse, platy intergrowths of fibrous to acicular aggregates (crystalline). The origin of vein-type graphite deposits is believed to be hydrothermal.

Amorphous graphite is formed by metamorphism of coalbeds by nearby intrusives. Its purity depends on the purity of the original coalbeds. Amorphous graphite usually is associated with sandstones, shales, slates, and limestones.

Flake graphite commonly occurs disseminated in regionally metamorphosed sedimentary rocks, such as gneisses, schists, and marbles. It is believed that the graphite was formed under the same conditions that caused the metamorphism of the rocks—from carbon deposited with the sediments.

Although the flake graphite deposits of certain countries conform to this description, most of the commercial deposits that are exploited are the result of weathering of these metamorphic rocks, with the graphite being found in lateritic clays that have accumulated at the surface. Graphite, quartz, and other resistant minerals have been freed by weathering of the feldspars, thus lessening the amount of crushing necessary before beneficiation.

World graphite reserves totaled 21 million metric tons. Detailed breakouts are given in the 1988 Minerals Yearbook chapter. All tonnages are reported in metric tons, unless otherwise noted.

Technology

Mining.—In Sri Lanka, lump graphite is mined underground from narrow, steeply dipping veins. The ore is mined principally by overhand stoping and filling, using temporary stulls when necessary to support the walls. Hand drilling is used in most stoping to achieve selective mining and to avoid unwanted fines and product contamination. Drills are used in developing headings. The ore is hauled by truck to the sorting and classification yard.

Amorphous graphite beds are usually mined underground. However, the beds are much thicker than those of amorphous lump and crystalline lump. The ore is drilled, blasted, hand-loaded into cars, and hauled to the surface by conventional methods.

Flake graphite deposits have been mined by underground and surface methods. Underground deposits are usually unweathered and require drilling and blasting. Most surface mining is confined to the weathered part of the deposit, and normal excavating equipment such as power shovels, bulldozers, and rippers is used with a minimum of drilling and blasting. The ore is usually trucked to the mill.

Milling.—Sri Lankan amorphous lump graphite and crystalline lump graphite are refined by hand cobbing and hand sorting and wiping lumps on wet burlap to remove fines. Light hand sorting and cleaning operations are done by women, while the heavier duties are performed by men.

Most amorphous graphite that requires beneficiation is not worth mining. Preparation for most uses requires grinding only, and coarse impurities are removed by screening or air separation methods.

Flake graphite from disseminated deposits must be concentrated to meet market requirements. Virtually every known concentrating device and combination of separating principles have been tried. The mineral has gained a reputation of being difficult to concentrate, and probably in no other industry has such a large proportion of the mills failed to make commercial recoveries. Graphite actually is one of the easiest minerals to segregate into a rough concentrate, but one of the most difficult to refine.

Because of the premium placed on the mesh size of flake graphite, the problem in milling is one of grinding to free the graphite without reducing the flake size excessively. This is difficult because, during grinding, the graphite flakes are cut by quartz and other angular gangue minerals, thus reducing flake size rapidly. However, if most of the quartz and other angular minerals are removed, subsequent grinding will usually reduce the size of the remaining gangue, with little further reduction in the size of the flake.

Because graphite floats readily and does not require a collector froth, flotation has become the accepted method for beneficiating disseminated ores. The chief problem lies with depressing the gangue minerals. Relatively pure grains of quartz, mica, and other gangue minerals inadvertently become smeared with the soft, fine graphite, making them floatable and resulting in the necessity for repeated cleaning of the concentrates to attain high-grade products.

Substitutes

Some interchange of the various types and grades of natural graphite and between manufactured and natural graphite takes place, but the degree is difficult to determine. Manufactured graphite does not compete with natural graphite in most uses because of its greater cost. Manufactured graphite is not substitutable for natural flake graphite in clay-bonded graphite crucibles, although some crucibles are machined from manufactured graphite for special uses. Calcined coke and other carbons are satisfactory substitutes for graphite for certain foundry core and mold washes and are used when they can compete in terms of price and supply. Other carbons with high purity can be used in batteries.

Economic Factors

The price structure of graphite is quite complex because of the wide variety of products and the lack of standard market quotations. Prices quoted in trade journals are only a range negotiated between buyer and seller and sometimes do not reflect the real market. Quotations are available in Industrial Minerals and the U.S. Bureau of Mines Annual Report. However, average declared import values per ton for amorphous and crystalline graphite have been available for years from U.S. Bureau of the Census data.

The cost for domestically produced graphite from new mines would be much higher than that for graphite from the major foreign sources for the same type and purity. The high cost of production results from high labor costs and the low graphite content of the ore.

Taxes.—Graphite producers are granted a 22% depletion allowance for tax purposes on domestic lump and amorphous and 14% on domestic flake and on foreign operations.

Tariffs.—Duties on graphite items imported from most favored nations (MFN) are minimal. Graphite from a few former Soviet republics (not Ukraine or Russia) and certain other nations are subject to a higher duty.

Operating Factors

Environmental Issues.—Because there was no mining of graphite this year, there were no environment-related issues. Future mining of graphite is highly improbable; there are no domestic reserves and resources are low grade and expensive to recover. Natural graphite is an inert nontoxic substance, and environmental requirements are limited to dust control and certain organic vapors arising from ingredients blended with it to manufacture products.

Postconsumer waste mostly returns to the environment in simple and nonpolluting ways. Graphite products that have contact with molten iron and steel slowly dissolve in it during use. This applies to refractories crucibles, foundry facings, and electrodes, plus a few less important uses, which combine to account for about 75% of total usage. Other important products such as pencils and brake linings slowly dissipate as they are used, almost on an atom-by-atom basis.

Employment.—Production and marketable natural graphite requires little hand labor, except for the graphite mined in Sri Lanka. Even in areas of low-cost labor, mechanical methods are used to mine and concentrate flake graphite.

Because of the very small size of the domestic natural graphite industry, no publishable employment data are available. Because there is only one small mine open intermittently and the product is beneficiated and processed to a minimal extent, employment probably does not exceed 50. Much of the imported graphite requires grinding, perhaps further refining, mixing with other grades to meet consumer specifications, bagging, and shipping. The total number of persons engaged in these operation, including marketing, probably does not exceed 500.

ANNUAL REVIEW

Legislation and Government Programs

No acquisitions of graphite for the strategic and critical materials stockpile occurred in 1993. *(See table 2.)*

Production

United Minerals Co. continued its suspension of production of its amorphous graphitic material from its Montana mine in 1993. Output of manufactured graphite decreased slightly to about 241,000 tons, at 29 plants, with a likelihood of some unreported production for in-house use. Production of all kinds of graphite fiber and cloth increased 13% to 4,080 tons. *(See tables 3 and 4.)*

Consumption and Uses

Reported consumption of natural graphite decreased slightly to about 40,865 tons, according to a survey of more than 230 users. The three major uses of natural graphite were refractories, brake linings, and in packings, which together accounted for 53% of reported consumption. *(See table 5.)*

Nonclay refractories are represented by two important use categories of graphite. Standard refractory products, particularly gunning and ramming mixes, accounted for a sizable part of the demand in the past 5 years, mainly as amorphous graphite. Crucibles, shrouds, nozzles, stopper heads, and retorts, used in hot-metal processing operations such as the continuous casting of steel, use significant amounts of crystalline flake. Coarse flake graphite is preferred for crucibles and refractory associated items, but generally it is mixed with some fine crystalline material of lower value. The newest important refractory use for graphite in steelmaking is in carbon magnesite brick, where large amounts of crystalline flake are now used.

Graphite is used in brake and clutch linings. More graphite is being used as brake and clutch producers change over from asbestos. The graphite lubricates, transfers the heat of friction away from the part, and leads to a lower rate of wear. Graphite is more commonly used in heavier duty nonautomobile lining. Low-quality crystalline flake and amorphous graphite are suitable for foundry facing use. The graphite is mixed with a small amount of clay, suspended in an adhesive material, and applied as a thin coating to mold surfaces to provide for clean and easy mold release of the metal castings.

Graphite is important as a lubricant; when used as a lubricant, it can be a dry powder or mixed with oil or water. It is used with materials that must withstand extreme conditions, such as very high temperatures. Material for this use must be free of abrasive-type impurities.

Graphite is used in packings, which includes expanded graphite and graphite foil. While this category includes uses in ammunition and seed coatings, in addition to packings, most of the tonnage was used to make expanded graphite and graphite foil and final products resulting from them.

Prices

Natural graphite prices are often negotiated between the buyer and seller and are based on purity and other criteria. Therefore, published price quotations such as those in Industrial Minerals are given as a range of prices. Another source of information for graphite prices is the average customs value per ton of the different imported classes. These mainly represent shipments of unprocessed graphite. A third source for natural graphite prices is the amount paid per ton at the point of consumption.

The price for crystalline graphite at the point of consumption—mostly crystalline flake, some crystalline dust, and a little lump graphite—dropped slightly to $1,469 per ton from $1,481. The price for amorphous graphite (including small amounts of amorphous-synthetic graphite mixtures) rose slightly to $683 per ton from $677.

The index of unit value for high-modulus fiber produced in the United States (1973=100) was 42 in 1993, compared with 44 the previous year. *(See table 6.)*

Foreign Trade

Total exports of natural graphite decreased 4%. Exports of graphite electrodes totaled 86,369 tons valued at $178.8 million, of which 49,244 tons ($93.3 million) went to Canada, 3,394 tons ($8.5 million) to Venezuela, 6,613 tons ($10.0 million) to Brazil, 3,469 tons ($11.1 million) to Japan, and the balance to other destinations.

Imports of natural graphite increased 5% from those of 1992. *(See tables 7, 8, and 9.)*

World Review

The world graphite market moved a little closer to balance in supply and demand in 1993. This was observed mostly on the supply side, in the form of drops in production in Madagascar and Romania, or in the form of small increases in production in Canada instead of the large increases that might have been expected. Projects in Namibia and Australia (Munglinup) were dropped. Sales of Malagasy crystalline flake from the U.S. stockpile continued at a moderate rate. Commercial production of crystalline flake graphite from graphite-containing kish waste is not imminent, although progress was made at the kish pilot plant in Chicago. While U.S. apparent consumption of graphite increased moderately, the U.S. price of crystalline flake was unchanged and the price of lump decreased. The market could have been a bit worse, as it was in 1991-92.

Early this year, Industrial Minerals published a major examination of graphite supply-demand. This study delineated the overcapacity and oversupply of the past few years and indicated that any significant improvement would not occur before midyear 1993. It discussed new and proposed projects in detail, such as the coming on-stream of the Uley graphite deposit in Australia at a rate of 5,000 to 10,000 tons of product per year. Demand for ordinary grades of graphite dropped as graphite consumers, particularly the makers of brake linings and expandable graphite, insisted on graphite that is 94% carbon or above. The most damage to demand from the recession occurred in the refractories industry. It concluded that the new projects nearing production face unpleasant prospects.[1]

Brazil.—Nacional de Grafite will bring a new mine and pilot plant on-stream in March 1994, at Salto da Divisa, about 250 kilometers from its major mine at Pedra Azul, and very near the Bahia-Minas Gerais State line. The firm has stated that this crystalline flake graphite deposit is the largest in the world, has more than 100 years of ore supply averaging 5% to 6% graphite at the desired production level, and is capable of producing 40,000 tons per year of 95% graphite product. This production level will hopefully be reached in two years after a $20 million investment. The product is expected to be entirely exported, with the other two mines maintaining their current domestic or export markets. (The Pedra Azul expansion has been suspended.)

Vesuvius Co. has brought a new refractories plant on-stream in Rio de Janeiro among whose products will be some alumina graphite items.

Canada.—Quinto Mining Corp. previously announced the discovery of a large deposit containing graphite, probably amorphous, near Lumby, British Columbia. The graphite would be a byproduct of a sericitic gold ore and is low grade and widely disseminated. Laboratory work has shown it will be difficult to separate the graphite from the mica (sericite) because they are so fine grained. The firm hopes to avoid the problem by selling a mica-graphite final product.

Stratmin Inc. has signed an agreement with St. Genevieve Resources Co. to allow it to use a newly developed method for purifying graphite and use a new method to produce flexible laminated graphite sheets.

China.—According to official trade statistics, China exported a total of 145,000 tons of natural graphite in 1993, 155,000 tons in 1992, 150,000 tons in 1991, and 140,000 tons in 1990. Official statistics indicate that 40,000 tons of natural graphite was added to stocks in 1991. Probably a similar amount was added to stocks in 1992 and a much larger amount in 1990. Domestic consumption of natural graphite is believed to be very large, much larger than Japanese consumption, because of waste during consumption and much shorter product life than is common in industrially advanced countries.

France.—Pechiney signed a letter of intent to merge its synthetic graphite operations in Belgium, France, and Spain into Sigri Great Lakes Carbon Corp. in return for a 10% to 12% stock interest in the new enlarged firm, second largest in the world. Pechiney had only about 4% of the currently oversupplied world market.

Mozambique.—Kenmare Resources PLC completed the financing for its large-flake crystalline flake graphite project at Ancuabe, 100 kilometers from the port of Pemba. The financing is by the Commonwealth Development Corp. and the European Investment Bank. The deposit will be mined by open pit, and the firm stated proven reserves were 1 million tons averaging 11% graphite. Pilot plant testwork has been completed, and the final design specifies a modular flotation plant with a 5,000-ton-per-year capacity for concentrate. The engineering design has been sent out for tender. The plant may be on-stream about yearend.

Sweden.—Norbotten Grus och Grafit AB (NGG) has acquired state-owned graphite claims in the north. The two most promising deposits are at Raitajaervi and Lehtoselkae with ores running 10% to 22% carbon and 19% to 23% carbon, respectively.

Anro Graphite AB expects to have its Kringelgruvan Mine on-stream by early 1995. *(See table 10.)*

Current Research and Technology

The U.S. Bureau of Mines kish process moved closer to implementation. The small pilot plant run by Inland Steel produced about 10 tons of product in 1993 and is expected to produce about 20 tons in 1994. The product almost always has been well received where it has been used, although the price has been 5% to 10% above that for crucible-grade crystalline flake. Some drying equipment still has to be installed in the plant, and other equipment has been modified to make it work better.

Natural fullerenes have been discovered in carbon-containing lightning-seared rocks (fulgurites) from Colorado. The fullerenes are complex configurations of approximately 60 or more carbon atoms, the best known configurations being shaped like a soccer ball. Evidently these fullerenes must have originated under conditions radically different from the natural fullerenes found in coal-like shungite, discovered last year.

The following applications for fullerenes in medicine were discovered this past year: A water-soluble fullerene has been found to block an enzyme the AIDS virus uses to cut up proteins. Fullerenes also can ferry electrons across cell membranes even more efficiently than natural porphyrins can.

Fullerene microtubes now can be filled with lead or other metals to form microscopically thin wires. The fullerene microtubes have natural caps that are destroyed by heating in air, which then allows molten lead to be drawn inside by strong capillary forces. The material inside the microtube may or may not be pure lead.

Other notable applications for fullerenes also were discovered. Coating superconducting metal-containing fullerenes with polystyrene preserved them from decomposition by moisture, which allows them to be used as room-temperature superconductors. Fullerene films will polymerize when exposed to visible or ultraviolet light, the fullerene molecules directly linking together without a bridge.

OUTLOOK

Projected demand for crystalline flake graphite totaled 30,000 tons for 1995 and 35,000 tons for the year 2000. Demand for other graphite, mostly amorphous, totaled 15,000 tons for 1995 and 13,000 tons for the year 2000. This very slow growth rate reflects the maturity of the market, mostly in refractories, and particularly in carbon-magnesite brick. Production capacity is unlikely to increase from the present level while the overcapacity exists.

Total	23,303	34,237	17,562	11,994	40,865	46,231

W Withheld to avoid disclosing company proprietary data; included with "Withheld uses" and "Total" where applicable.

[1] Includes mixtures of natural and manufactured graphite.

[2] Data do not add to total shown because of independent rounding.

[3] Includes bearings and carbon brushes.

[4] Includes foundries (other) and foundry facings.

[5] Includes packings; ammunition; and seed coating.

[6] Includes paint and polishes; small packages; antiknock and other compounds; soldering/welding; mechanical products; electrical/electronic devices; industrial diamonds; drilling mud; magnetic tape; and other end-use categories.

TABLE 6

REPRESENTATIVE YEAREND GRAPHITE PRICES

(Per metric ton)

	1992	1993
Industrial minerals:[1] [2]		
Crystalline large flake, 85% to 90% carbon	$400- $800	$400- $600
Crystalline medium flake, 85% to 90% carbon	350- 750	300- 500
Crystalline small flake, 80% to 90% carbon	300- 550	250- 500
Amorphous powder, 80% to 85% carbon	220- 440	220- 440
Custom value, at foreign ports:[3]		
Flake	[r]708	710
Lump and chip, Sri Lankan	1,073	789
Amorphous, Mexican	125	127

[r] Revised.

[e] Estimated. [r] Revised. W Withheld to avoid disclosing company proprietary data.

[1] Table includes data available through May 31, 1994.

[2] Reported figure.

[3] Does not include the following quantities sold directly without beneficiation, in metric tons: 1989—13,005 (revised); 1990—8,400 (revised); 1991—7,298 (revised); 1992—8,957 (revised); and 1993—9,000 (estimated).

[4] Data are for fiscal years beginning Apr. 1 of that stated.

[5] Formerly part of Czechoslovakia.

[6] Dissolved Dec. 31, 1992. All production in Czechoslovakia from 1989-92 came from what is now the Czech Republic.

[7] Indian marketable production is 10% to 20% of mine production.

[8] Turkish marketable production averages approximately 5% of run-of-mine production. Almost all is for domestic consumption.

[9] Dissolved in Dec. 1991.

GYPSUM

By Lawrence L. Davis

Mr. Davis, a physical scientist with 38 years of industry and U.S. Bureau of Mines experience, has been the commodity specialist for gypsum since 1985. Domestic survey data were prepared by Virginia Harper, statistical assistant; and international data tables were prepared by Jeremy Tidwell, Section of International Data.

Public Law 100-418 requires U.S. Government agencies to implement the use of metric units in their business activities. The U.S. Bureau of Mines (USBM), to be in compliance with the law, has developed a schedule for making an orderly transition from English to metric units when reporting gypsum statistics in the Annual Report.

For the 1993 Annual Report, all weight data will be reported in metric units. Additional lines in appropriate tables will show total weights in English units. All other data will continue to be in English units.

For the 1994 Annual Report, weight data will be reported in metric units only. All other data; e.g., wallboard area; will continue to be reported in English units.

For the 1995 Annual Report, all data will be reported in metric units.

Demand for gypsum products increased in 1993, a result of increased construction activity, especially in new housing starts that increased 7% to 1.3 million units. The quantity of crude gypsum mined, calcined gypsum produced, and wallboard products shipped was greater than that in 1992.

Sales of gypsum products increased 9% to 24 million metric tons, and value increased 32% to $1.8 billion. Increased demand caused higher prices for gypsum products. Imports for consumption of crude gypsum increased 3% to about 7.4 million tons. Total value of gypsum product exports decreased 20% to $78 million.

DOMESTIC DATA COVERAGE

Domestic production data for gypsum are developed by the USBM from a survey of U.S. gypsum operations. Of the 117 operations to which the annual survey request was sent, 100 responded, representing 85% of the total crude gypsum production shown in tables 1 and 2. Nonrespondents were estimated from monthly and quarterly canvasses or from previous years' data. *(See table 1.)*

BACKGROUND

Definitions, Grades, and Specifications

Gypsum has a composition of 79% calcium sulfate and 21% water, $CaSO_4 \cdot 2H_2O$, and is used as a commercial and generic term for all calcium sulfate materials. The well-formed transparent crystalline variety is called selenite. The massive variety is called alabaster and can be easily carved. The fibrous, silky variety is called satin spar. Gypsite is a mixture of clay and gypsum crystals.

Anhydrite is calcium sulfate, $CaSO_4$, with no water of crystallization. It is a naturally occurring mineral commonly associated with gypsum. When gypsum is calcined at high temperatures, it is converted to anhydrite.

Commercially calcined gypsum, $CaSO_4 \cdot 1/2H_2O$, is a manufactured hemihydrate product produced by partial calcination of gypsum. It is produced by heating gypsum at temperatures to 350° F. The hemihydrate product, commonly called plaster of paris, is called stucco by the wallboard manufacturers. When water is added to form a paste, the calcined material reabsorbs water and it quickly sets and hardens to form gypsum again.

Byproduct gypsum is a chemical product of manufacturing processes such as phosphoric acid, hydrofluoric acid, citric acid, and titanium dioxide from ilmenite, consisting essentially of $CaSO_4 \cdot 2H_2O$. The sludge produced from scrubbers in the desulfurization of stack gas in thermal powerplants is also byproduct gypsum.

Keene's cement is anhydrous gypsum plaster with certain accelerator additives. It is produced by special high-temperature calcining. All of these minerals and materials, including the articles molded from the plaster, are commonly called gypsum or plaster.

Industry Structure

The domestic gypsum industry is large and is dominated by a few large vertically integrated companies that mine and calcine gypsum and manufacture plaster and wallboard products. These companies also sell crude gypsum for use in cement and agriculture. The large wallboard producers, through foreign subsidiaries, produce most of the crude gypsum that is imported to feed coastal wallboard plants. Plants on the east coast import mostly from Canada's Maritime Provinces, while plants on the west coast import gypsum from Mexico. Crude gypsum from Spain, the other major source of U.S. imports, is used mainly by cement plants.

Gypsum production is worldwide, with at least 80 countries known to produce. Because of its wide distribution and plentiful supply, most of the world's production is consumed domestically.

Exceptions include Canada and Mexico, which export significant portions of their production to the United States; Thailand and Australia, which export to much of the Southeast Asia market; and Spain, which exports to the United States, Scandinavia, and other countries. In the United States and other industrialized nations, the major use of gypsum is in the manufacture of gypsum wallboard products. Most crude gypsum is mined in rural areas and shipped to urban areas for manufacture into wallboard and ultimate consumption. In developing countries, most gypsum is consumed by local cement plants.

Geology-Resources

Gypsum deposits may be found in any geologic era, but they are most common in the Permian. They are commonly found in association with the source rocks for petroleum. Most massive gypsum and anhydrite deposits occur as large, lenticular, stratified bodies that were formed by evaporation of seawater in basins that have one or more restricted openings to the sea. The basins range in diameter from a few miles to many hundreds of miles.

Classic evaporite formation involves the deposition of anhydrite, with later hydration of the anhydrite by meteoric waters to gypsum at depths ranging from zero to 1,000 feet. The depth of hydration is generally related to topography, structure, and climate because these factors affect the depth of ground water and surface water penetration.

Technology

Gypsum deposits are explored to determine their physical and chemical properties and to determine a minable thickness and the ratio of gypsum to anhydrite. The depth of hydration is important in mining because the presence of only a few percent anhydrite is sufficient to render gypsum unusable for making plaster. Adequate samples may be obtained from outcrops or drill cores.

Deposits near the surface are developed by stripping the overburden, developing either single- or multiple-bench open pits, and constructing access and transportation routes. Underground ore bodies are developed by sinking shafts or driving adits, with mining development and production by the room-and-pillar system.

Most domestic gypsum is produced from surface mines using standard open pit mining methods. In a typical domestic mine, the gypsum is drilled and blasted as needed, usually every week or two. Broken gypsum rock, loaded with hydraulic shovel or front-end loader, is hauled to the primary crusher by a fleet of three or four 35-ton haultrucks. All material removed from the mines is crude gypsum. All waste is left in the mine.

The processing of crude gypsum depends on the end use. Gypsum for use in cement is crushed to minus 1 1/2 inch plus 3/8 inch. For agricultural or filler use, the gypsum is pulverized to 100 mesh or finer.

To produce plaster and wallboard products, minus-100-mesh gypsum is heated in batch kettles to remove three-quarters of the water of crystallization, converting gypsum, $CaSO_4 \bullet 2H_2O$, to the hemihydrate product, $CaSO_4 \bullet 1/2H_2O$. A few rotary kilns also are used, in which case a coarse feed with fines removed is calcined. During the commercial calcining process, gypsum is heated to 250° F for about 2 hours, then the temperature rapidly rises to 300° to 350° F, at which time the calcine, called stucco, is dumped into a hot pit. The calcine is then mixed with various additives, including a retarder or accelerator, and manufactured into prefabricated wallboard products and other plaster and cement products.

Plaster is generally reground calcine, modified with retarders or accelerators and containing various binders such as hair, sisal, fiberglass, aggregates, or colored pigments. Retarders, usually glue, starch, or slaughterhouse byproducts, can increase the setting time to as much as 6 hours. Accelerators, such as metal salts, set plaster, or anhydrite, can reduce the setting time to less than 5 minutes. The plaster is packed in bags and sold under various trade names.

Prefabricated products include lath, veneer base, sheathing, and wallboard. These board products are manufactured by continuous methods on automatic machines that can be adjusted to any of the standard products. A slurry of wet plaster with additives and an accelerator is spread between two moving sheets of paper. Moving through the shaping rolls, the edges are molded and sealed. The green board is run out on a traveling belt until the plaster has set. The board is then cut with a revolving knife into appropriate lengths and slowly passed through a drying kiln.

ANNUAL REVIEW

Production

The United States remained the world's leading producer of gypsum, accounting for 15% of the total world output. Crude gypsum was mined by 31 companies at 58 mines in 19 States. Production increased 7%. Leading producing States, in descending order, were Oklahoma, Iowa, Texas, Michigan, Nevada, California, and Indiana. These seven States produced more than 1 million tons each and together accounted for 76% of total domestic production.

Leading companies were USG Corp., 11 mines; National Gypsum Co., 7 mines; Georgia-Pacific Corp., 7 mines; Harrison Gypsum Inc., 2 mines; and Temple-Inland Forest Products Corp., 1 mine. These 5 companies, operating 28 mines, produced 67% of the total crude gypsum.

Leading individual mines, in descending order of production, were USG's Plaster City Mine, Imperial County, CA; USG's Sweetwater Mine, Nolan County, TX; USG's Sperry Mine, Des Moines County, IA; USG's Shoals Mine, Martin County, IN; Temple-Inland's Fletcher Mine, Comanche County, OK; National's Tawas Mine, Iosco County, MI; USG's Alabaster Mine, Iosco County, MI; Briar's Briar Mine, Howard County, AR; Harrison's Cement Mine, Caddo County, OK; and

National's Sun City Mine, Barber County, KS. These 10 mines accounted for 40% of the national total. Average output for the 58 active mines increased 7% to 273,000 tons.

Gypsum was calcined by 13 companies at 70 plants in 28 States, principally for the manufacture of gypsum wallboard and plaster. Calcined output increased slightly in tonnage and 9% in value. Leading States, in descending order, were California, Iowa, Texas, Florida, Nevada, and New York. These 6 States, with 27 plants, accounted for 48% of the national output.

Leading companies were USG, 20 plants; National Gypsum, 18 plants; Georgia-Pacific, 10 plants; Domtar, 7 plants; and Celotex, 4 plants. These 5 companies, operating 59 plants, accounted for 83% of the national output.

Leading individual plants were, in descending order of production, USG's Jacksonville plant, Duval County, FL; USG's Plaster City plant, Imperial County, CA; USG's Sweetwater plant, Nolan County, TX; USG's Sperry plant, Des Moines County, IA; USG's Shoals plant, Martin County, IN; USG's Baltimore plant, Baltimore County, MD; National's Tampa plant, Hillsborough County, FL; USG's Stony Point plant, Rockland County, NY; Temple-Inlands Fletcher plant, Comanche County, OK; and Centex's Bernalillo plant, Sandoval County, NM. These 10 plants counted for 29% of the national production. Average calcine production for the 70 U.S. plants was 218,000 tons, slightly more than that in 1992.

A total of 846,000 tons of byproduct gypsum, valued at $3.4 million, was used, principally in agriculture but some for gypsum wallboard manufacturing. Approximately 89% was of nonphosphogypsum origin compared with 90% in 1992.

According to the Gypsum Association, yearend gypsum wallboard plant capacity for producing 1/2-inch regular wallboard increased slightly to 24.64 billion square feet per year. Total wallboard shipments were 21.4 billion square feet, 87% of capacity. Domtar's plants at Florence, CO, and at Sweetwater, TX, remained closed throughout the year. *(See tables 2 and 3 and figure 1.)*

Consumption and Uses

Apparent consumption, defined as production plus net imports plus industry stock changes, of crude gypsum, including byproduct gypsum, increased 8% to 24 million tons. Net imports provided 31% of the crude gypsum consumed. Apparent consumption of calcined gypsum increased slightly to 15.1 million tons.

Yearend stocks of crude gypsum at mines and calcining plants were 2.3 million tons. Of this, 40% was at calcining plants in coastal States.

Of the total gypsum products sold or used, about 23% was uncalcined. Uncalcined gypsum, crushed and screened to specifications, is marketed for use in portland cement manufacture, agriculture, and fillers. The cement industry uses gypsum to retard the setting time of concrete.

Finely ground gypsum rock is used in agriculture to neutralize alkaline and saline soils, improve the permeability of argillaceous materials, and provide sulfur and catalytic support for maximum fertilizer utilization and leguminous productivity. Small amounts of very pure gypsum are used as fillers and in glassmaking, papermaking, and pharmaceutical applications. In 1993, 59% of the uncalcined gypsum was used in portland cement and the remainder was used mainly for agricultural purposes.

Of the total calcined gypsum products, most went into prefabricated products. A small percentage was used in industrial and building plasters. Of the prefabricated products, based on surface square feet, 65% was regular wallboard; 23% was fire-resistant type X wallboard; 5% was 5/16-inch mobile home board; and 3% was water- and/or moisture-resistant board. Lath, veneer base, sheathing, predecorated, and other types made up the balance. Of the regular wallboard, 81% was 1/2-inch and 11% was 5/8-inch.

In descending order, the leading sales regions for prefabricated products were the South Atlantic, East North Central, Pacific, and West South Central. Together these regions accounted for 62% of the total. *(See tables 4 and 5 and figure 2.)*

Markets and Prices

On an average value-per-ton basis, f.o.b. mine or plant, crude gypsum decreased slightly to $6.74, calcined gypsum increased 8% to $17.88, and byproduct gypsum decreased 39% to $4.03. Prefabricated products were valued at $89.75 per ton, plasters at $130.22 per ton, and uncalcined products at $12.99 per ton.

Quoted prices for gypsum wallboard products were published monthly in Engineering News Record. Spot prices in December, based on truck lots delivered to the job, showed a wide range. Regular 1/2-inch wallboard prices ranged from $93 per thousand square feet at Cincinnati to $170 at New York. The average price in December for 20 cities was $130 per thousand square feet, with some minor discounts for prompt payment. This represented a 5% increase compared with that of December 1992.[1]

With increased demand for gypsum products and improving prices, the industry reported improved earnings. National Gypsum emerged from chapter 11 bankruptcy protection in July. The company also received a $75 million credit line from General Electric.[2] Later in the year, National sold a 20% interest to Lafarge Copee.[3] USG went into chapter 11 bankruptcy in March and emerged in May.[4]

Foreign Trade

Imports for consumption of crude gypsum increased 3% to 7.4 million tons. Net imports represented 31% of apparent consumption. Crude gypsum from Canada and Mexico was used mainly to feed wallboard plants in coastal cities. Imports from Spain, the other major source of imported gypsum, were used mostly for portland cement manufacture. Gypsum wallboard imports, principally from Canada, increased 102% to 268 million square feet. *(See tables 6 and 7.)*

World Review

Estimated world production of crude gypsum increased slightly to 103 million tons. Total world production figures are probably low because, in some countries, significant production was consumed captively and not reported. Also, production from small deposits in developing countries was intermittent and often unreported. The United States remained the world's largest producer of crude gypsum with 15% of the world total. *(See table 8.)*

Canada.—The gypsum wallboard plant in McAdam, New Brunswick, formerly owned by Eastern Gypsum Inc. and closed since 1991, was reopened under new ownership by Nova Gypsum Co.

The Gypsum Association in the United States, of which all Canadian wallboard producers were members, reported that yearend capacity for 1/2-inch regular wallboard in Canada was 3.48 billion square feet, slightly more than the 1992 yearend capacity.

Germany.—The Fraunhofer Institute of Structural Physics developed a gypsum foam using flue gas desulfurization gypsum. The foam, made by mixing gypsum, water, and an isocyanate prepolymer, was reported to provide very good sound insulation.[5]

Oman.—Large deposits of gypsum were found in Shuwaymiyah. The reserves, estimated to be more than 100 million tons, are the largest in Oman.[6]

Taiwan.—Universal Cement Corp. purchased property in Taoyuan, where it plans to build a new wallboard plant. The plant, the company's second, was scheduled to be completed in 1995.[7]

United Kingdom.—British Gypsum Ltd. took delivery of byproduct gypsum from the newly commissioned flue gas desulfurization units at National Power's Drax powerplant in North Yorkshire. The first shipment of synthetic gypsum from the Ratcliffe-on-Soar powerplant were expected to begin in 1994.[8]

Lafarge Plasterboard Ltd. awarded a contract for the design and construction of a specialty plaster production plant. The facility will be built at Lafarge's plasterboard plant at Portbury, near Bristol.[9]

OUTLOOK

More than 90% of the gypsum consumed annually in the United States is used in construction, mainly in gypsum wallboard products, building plasters, and the manufacture of portland cement. The decline in construction activity that depressed demand for gypsum products over the past several years appears to have ended. Gypsum product demand recovered in 1992 and 1993, although not to the record highs of 1989. A slow but steady recovery is expected to continue over the next few years.

[e]Estimated. [r]Revised.

[1]Table includes data available through Aug. 3, 1994.

[2]Includes anhydrite.

[3]Less than 1/2 unit.

[4]Formerly part of the U.S.S.R.; data were not reported separately until 1992.

[5]Data are for years beginning Apr. 1 of that stated.

[6]Reported figure.

[7]Formerly part of Czechoslovakia; data were not reported separately until 1993.

[8]Dissolved Dec. 31, 1992. All production in Czechoslovakia from 1989-92 came from the Czech Republic and Slovakia.

[9]Data are for years ending July 7 of that stated. Reported in cubic meters and estimated at mean weight of 1.8 tons per cubic meter.

[10]Probably does not include production for cement manufacture (normally 3% to 5% of finished cement, equivalent of an additional 12,000 to 15,000 metric tons per year).

[11]Data are for years beginning Mar. 21 of that stated.

[12]For cement production only. Information is insufficient to formulate reliable estimates for output for other uses (plaster, mortar, etc.).

[13]Data are for years beginning on Mar. 1 of that stated.

[14]Dissolved in Dec. 1991.

[15]Excludes byproduct gypsum.

[16]Dissolved in Apr. 1992.

[17]Data may not add to totals shown because of independent rounding.

HELIUM

By William D. Leachman

Mr. Leachman, a chemical engineer with 40 years of U.S. Bureau of Mines experience, has been the commodity specialist for helium since 1983. He also prepared the domestic survey and international data tables.

Grade-A helium (99.995% or better) sales volume in the United States by private industry and the U.S. Bureau of Mines (USBM) was 67.6 million cubic meters [2,437 million cubic feet (MMcf)] in 1993.[1] Grade-A helium exports by private producers were 28.0 million cubic meters (1,008 MMcf), for total sales of 95.6 million cubic meters (3,445 MMcf) of U.S. helium. The USBM price for Grade-A helium, f.o.b. plant, was $1.983 per cubic meter [$55 per thousand cubic feet (Mcf)] and bulk liquid helium was $2.379 per cubic meter ($66 per Mcf) on January 1, 1993, with additional costs for container services and rent. On October 1, 1993, the bulk liquid helium price was raised to $2.524 per cubic meter ($70 per Mcf). Private industry also increased its helium prices last year, but they are lower than the USBM's.

DOMESTIC DATA COVERAGE

Domestic production data for helium are developed by the USBM from records of its own operations as well as the High Purity Helium Survey, a single, voluntary canvass of private U.S. operations. Of the seven operations to which a survey request was sent, 100% responded, and those data plus data from USBM operations represent 100% of the total helium sales and recovery shown in table 2.

BACKGROUND

The USBM role in helium matters dates back to the First World War when the Army and Navy became interested in using helium as an inert lifting gas and contacted the USBM for assistance because of its natural gas expertise. In 1925, the Government's Helium Program was officially placed under USBM control by Congress (Helium Act of 1925). In 1929, the USBM Amarillo, TX, large-scale helium extraction and purification facility was built and began operation. During World War II, demand increased significantly, and four more small Government helium plants were built.

New technology increased helium demand in the 1950's and led to the construction of the Keyes, OK, plant in 1959. Dwindling Hugoton-Panhandle Field natural gas supplies aroused concerns that no economic source of helium would exist by the turn of the century.

In 1960, Congress replaced the 1925 act with new legislation (Helium Act Amendments of 1960). The purposes of the act were to provide for conservation of helium for essential Government activities and to supply the current and foreseeable future helium needs of Federal agencies. The act directed the Secretary of the Interior to purchase and store helium for future Government use and to operate and maintain helium production and purification plants and related helium storage, transmission, and shipping facilities.

Purchases for helium conservation were made under 22-year contracts with private natural gas companies, which added crude helium extraction capabilities to their existing gas processing facilities. Four companies built five crude helium plants. The USBM constructed a high-pressure pipeline to transport the helium from Bushton, KS, and intermediate points to the USBM-owned Cliffside Field near Amarillo, TX, for storage.

Helium needs of Federal agencies, particularly the U.S. Department of Defense (DOD), the National Aeronautics and Space Administration (NASA), and the U.S. Department of Energy (DOE), have been met, and there is enough helium in storage to meet their foreseeable needs. The present Federal helium demand is supplied solely by the USBM's Exell Helium Plant, 56 kilometers (35 miles) north of Amarillo.

In the mid-1970's, the USBM began accepting privately owned crude helium for storage in Cliffside under long-term contracts. Private industry currently has a 9-month supply of helium in Government storage, assuming all private market requirements would be supplied from storage.

Geology-Resources

Domestic measured and indicated helium resources as of January 1, 1993, the latest figures available, are estimated to be 13 billion cubic meters [467 billion cubic feet (Bcf)]. The resources include measured reserves and indicated resources estimated at 6.9 billion cubic meters (248 Bcf) and 0.9 billion cubic meters (33 Bcf), respectively, in natural gas with a minimum helium content of 0.3%. A slight increase in the measured reserves of helium is reported due to ongoing evaluations of the Nation's depleting helium resources. The measured reserves included 1 billion cubic meters (35 Bcf) stored by the USBM in the helium conservation storage system. Measured helium resources in natural gas with a helium content of less than 0.3% are estimated to be 1.2 billion cubic meters (44 Bcf). Indicated helium resources in natural gas with a helium content of less than 0.3% are estimated to be 4 billion cubic meters (143 Bcf). Approximately 4.5 billion cubic meters (163 Bcf) or 91% of the domestic helium resources under Federal ownership are in the Riley Ridge area and the Church Buttes Field in Wyoming and in the Cliffside Field in Texas.

Most of the domestic helium resources are in the midcontinent and Rocky Mountain regions of the United States. The measured helium reserves are in approximately 98 gasfields in 11 States. About 83% of these reserves is contained in the Hugoton Field in Kansas, Oklahoma, and Texas; the Keyes Field in Oklahoma; the Panhandle and Cliffside Fields in Texas; and the Riley Ridge area in Wyoming. The USBM analyzed a total of 220 natural gas samples from 19 States and 2 foreign countries during 1993 in conjunction with its program to survey and identify possible new sources of helium.

Technology

Technology that uses liquid helium to produce superconducting temperatures continues to be developed and utilized. Liquid helium continues to be used at Fermi National Accelerator Laboratory for Tevatron/Tevatron 1, which was the world's first superconducting particle accelerator. The liquid helium-cooled superconducting magnets used in this accelerator provide an intense and extremely steady magnetic field using only a fraction of the energy required by conventional electromagnets. The Tevatron is presently the second most energetic particle accelerator in the world (1.6 trillion electron volts). In 1993, the Superconducting Supercollider (SSC) project, which would have used liquid helium-cooled superconducting magnets, was terminated by Congress.

Argonne National Laboratory is developing a marine magnetohydrodynamic (MHD) propulsion system for military and commercial use. This system has no moving parts, but uses magnetic fields and electricity to pump water through a tube. This method of propulsion was illustrated in the film "Hunt for Red October." Researchers at Argonne used the world's largest liquid-helium-cooled superconducting dipole magnet to study this propulsion system. Development of this technology could lead to a new generation of water transportation vessels that would travel more quickly, quietly, and efficiently than present ships.

Liquid helium use in magnetic resonance imaging (MRI) continues to increase as the medical profession accepts and develops new uses for this equipment. MRI equipment is providing accurate diagnoses of medical problems where exploratory surgery was previously required. Another medical application being developed uses MRI to determine through blood analysis if a patient has any form of cancer. Most researchers seem to think it will be at least 4 to 8 years before uses of the new high-temperature (about -184 °C or -300 °F) superconducting materials affect liquid helium demand.

Lifting gas applications are increasing. The U.S. Navy and U.S. Air Force are investigating the use of airships to provide early warning systems to detect low-flying cruise missiles. The Drug Enforcement Administration has installed six tethered radar blimps along the southern border of the United States to detect drug smugglers. In addition, NASA is now using helium-filled balloons to sample the atmosphere in Antarctica to determine what is depleting the ozone layer that protects the Earth from harmful ultraviolet radiation. A helium-filled balloon also will lift the solar observatory to the edge of space from Antarctica to study sunspots. The project originally was planned to be launched from the space shuttle, but about $400 million will be saved by using helium to lift the 2-ton observatory. A stealth blimp is being tested by the Army's Intelligence and Electronic Warfare Center in New Jersey. In the commercial market, several companies in addition to Goodyear are now using "blimps" for advertising.

The development of Strategic Defense Initiative (SDI) weapons such as the antisatellite (ASAT) rocket, chemical laser, and rail gun has slowed with the decline of the "cold war." The ASAT rocket uses liquid helium-cooled infrared sensors for target location and guidance. Gaseous helium is used in the lasing gas mixture of the chemical laser, and liquid helium is used to cool the tracking telescope used to locate the target and aim the laser beam. High-pressure gaseous helium provides the initial push that inserts the projectile into the bore of the rail gun at a velocity of about 1,770 kilometers per hour (1,100 miles per hour). Electromagnetic energy applied along the bore accelerates the projectile to a final velocity of about 14,500 kilometers per hour (9,000 miles per hour). Superconducting magnetic energy storage (SMES) also is being investigated to provide power for DOD laser systems and electric power peak shaving in commercial applications. SMES allows the accumulation and storage of electrical energy over the long term (hours) when excess capacity is available and discharges it in minutes or as needed to provide for peak demands. Some small commercial units are already in service.

Other evolving technologies that require the unique properties of helium are (1) metastable helium for energy storage, which involves raising helium electrons to an excited energy state and then stabilizing the atom there; (2) fiber-optic production, where an ultrapure inert atmosphere is required; (3) helium-filled plastic pillows, where helium's low density is required to simulate a precursor wave from a nuclear blast; (4) helium ion tumor treatment, where large inert particles are required; (5) liquid helium-cooled superconducting microswitches, called Josephson junctions, which are much faster than conventional semiconductors and use less power; (6) "Aneutronic" nuclear fusion, where nuclear energy is produced by fusion of deuterium and helium-3, results in few or no neutrons; (7) helium-hydrogen breathing mixtures that enable deep-sea divers to reach depths below 580 meters (1,700 feet); and (8) an 11% oxygen-in-helium mixture is being used at NASA's Ames Research Center in its combustion-driven Shock Tunnel Facility. This facility is similar to a wind tunnel but provides much higher pressures and velocities needed to test space plane models at Mach 16.

ANNUAL REVIEW

Legislation and Government Programs

The Federal Helium Program is designed to provide all Federal agencies with their current and foreseeable future helium needs to carry out other Government programs authorized and funded by Congress. The USBM's major helium customers are DOD, NASA, and DOE.

In the Vice President's National Performance Review, it was determined that the Federal Government needed to reexamine its role in the Federal Helium Program. The report states that the program can be run more efficiently, reducing outlays by Federal helium customers and increasing revenue. Suggestions were made to cancel the helium debt, reduce the selling price for USBM helium, discontinue nonrevenue-producing functions, increase efficiencies of helium operations, and begin sales of crude helium as market conditions permit. The USBM is implementing these suggestions into the operation of the Helium Program.

Production

In 1993, 16 privately owned domestic helium plants were operated by 12 companies. Eleven of the privately owned plants and the USBM plant extracted helium from natural gas. All extraction plants except one use cryogenic extraction processes. The volume of helium recovered from natural gas increased 8%, while sales only increased about 1% in 1993. A shortage of private helium production was prevented by purifying crude helium that had been stored in the USBM's Cliffside Field. All natural gas processed for helium recovery came from gasfields in Colorado, Kansas, Oklahoma, Texas, and Wyoming. Seven private plants and the USBM's plant purified helium this year. Pressure-swing adsorption is used for helium purification at all seven of the private helium plants and at the USBM's plant. The USBM also uses cryogenic purification for backup. The USBM and six private plants that produce Grade-A helium also liquefy helium. The plant operators and locations are Air Products and Chemicals Inc., Hansford County, TX, and Liberal, KS; Exxon Co., U.S.A., Shute Creek, WY; Kansas Refined Helium Co., Otis, KS; and Praxair, Inc., Bushton and Ulysses, KS. Nitrotec's helium plant near Burlington, CO, produces Grade-A helium but does not liquefy it. *(See tables 1, 2, and 3, and figures 1 and 2.)*

Consumption and Uses

The major domestic end uses of helium were cryogenics, welding, and pressurizing and purging. Minor uses included synthetic breathing mixtures, chromatography, leak detection, lifting gas, heat transfer, and controlled atmospheres. *(See figure 3.)* The Pacific and Gulf Coast States were the principal areas of helium consumption.

USBM's sales to Federal agencies and their contractors totaled 7.933 million cubic meters (286 MMcf) in 1993, a decrease of about 8% when compared with last year's sales. This decrease was due largely to slowdowns in DOD programs as the cold war eased and budget restraints imposed on NASA and DOE by Congress.

The Federal agencies purchase their major helium requirements from the USBM. Direct helium purchases by DOD, NASA, DOE, and the National Weather Service constituted most of the USBM's Grade-A helium sales. Most remaining helium sales to Federal agencies were made through USBM contract distributors, who purchased equivalent volumes of USBM helium under contracts described in the Code of Federal Regulations (30 CFR 602). Some of the contract distributors also have General Services Administration helium supply contracts. These contracts make relatively small volumes of helium readily available to Federal installations at lower freight charges by using the contractors' existing distribution systems.

Stocks

The volume of helium stored in the USBM helium conservation storage system, including the conservation pipeline network and Cliffside Field, totaled 0.95 billion cubic meters (34.3 Bcf) at yearend. The storage system contains crude helium purchased under contract by the USBM from 1962 to 1973 and privately owned helium stored under contract. Excess private helium is extracted from natural gas supplying fuel markets in the winter and stored by the USBM under contract. This privately owned crude helium is returned to the owners as needed for purification to supply private demand. During 1993, 29.6 million cubic meters (1,069 MMcf) of private helium was delivered to the USBM's helium conservation storage system and 17 million cubic meters (613 MMcf) was withdrawn for a net increase of 12.6 million cubic meters (456 MMcf) of private helium in storage. *(See table 4.)*

Transportation

All Grade-A gaseous helium sold by the USBM was shipped in cylinders, modules (large gas cylinders), special railway tankcars, or highway tube semitrailers. Small gas cylinders are filled at the Amarillo plant, and railway tankcars are filled at the Exell plant. Other shipping containers for gaseous helium can be filled at either plant. The USBM's liquid helium was shipped in dewars and semitrailers from the Exell plant. Private producers and/or distributors shipped helium predominantly as a liquid in semitrailers. These semitrailers delivered the liquid helium to distribution centers where some of it was gasified and compressed into trailers and small cylinders for delivery to the end user. The remaining liquid helium was sold as bulk liquid or repackaged in dewars of various sizes for delivery.

Prices

The USBM price for Grade-A helium, f.o.b. plant, was $1.983 per cubic meter ($55 per Mcf) and bulk liquid helium was

$2.379 per cubic meter ($66 per Mcf) on January 1, 1993, with additional costs for container services and rent. On November 1, 1993, the bulk liquid helium price was raised to $2.524 per cubic meter ($70 per Mcf). Private industry also increased its helium prices last year, but lagged behind the USBM's price.

Foreign Trade

Exports of Grade-A helium, all by private industry, decreased by 9% in 1993 to 28 million cubic meters (1,008 MMcf). *(See table 3.)* About 45% of the exported helium was shipped to Europe. Belgium-Luxembourg, France, and the United Kingdom, collectively, received about 88% of the European exports. About 36% of the U.S. helium exports went to Asia, with Japan receiving about 84%. Other exports were as follows: about 8% to North America; about 4% to Australia-New Zealand, 3% to the Middle East; 2% to South America; 1% to Central America; and less than 1% each to Africa and the Caribbean. The shipments of large volumes of helium to Western Europe were attributed to helium uses in cryogenic research and superconducting applications. Significant volumes also were used in breathing mixtures for diving, welding, and as a lifting gas. Although no helium was imported by the United States in 1993, import tariffs on helium remained at the 3.7% rate for most favored nations established on January 1, 1987. The non-most-favored-nation tariff also remained unchanged at 25%. No changes in import tariffs are scheduled at this time.

World Review

World production of helium, excluding the United States, was estimated to be 11 billion cubic meters (400 MMcf), most of which was extracted in Poland and Russia. The remainder was produced in small plants in China and India. *(See table 5.)*

OUTLOOK

Until recently, all superconductors required liquid helium (-269°C or -452°F) to reach superconducting temperatures. Current research on superconductors has resulted in the discovery of superconducting materials that operate above liquid nitrogen temperatures (-196° C or -320°F). These new superconductors have physical limitations, such as brittleness and poor current-carrying capacities, which have precluded their use in most superconducting applications. As these physical problems are solved, the new materials will replace liquid helium-cooled superconductors.

Since 1989, the market for U.S.-produced helium has grown at an average annual rate of 4.6%. Private industry's market has been growing at 5.7% per year, while the Federal market has dropped 18% since 1989. In 1993, private industry supplied about 88% of the domestic demand while the USBM supplied the remaining 12%. Private industry supplies all of the U.S. helium exports. The foreign market decreased this year, accounting for only 29.3% of U.S. helium sales, but it has grown at an average rate of almost 6% per year since 1989.

The outlook for helium is slowing in the Federal sector with cutbacks and elimination of programs that use large volumes of helium. High-temperature superconductors are beginning to be used in commercial applications, but an adverse impact is not expected in the near future.

---

[1] All metric helium volumes herein reported are at 101.325 kilopascals absolute (14.696 psia) and 15 °C (59 °F). Helium volumes, reported in parentheses following metric units, are measured in cubic feet at 14.7 psia and 70 °F. One thousand cubic feet (1 Mcf) at 14.7 psia and 70 °F = 27.737 cubic meters at 101.325 kilopascals absolute and 15 °C. One cubic meter at 101.325 kilopascals and 15 °C = 36.053 ft^3 at 14.7 psia and 70 °F.

IODINE

By Phyllis A. Lyday

Mrs. Lyday, a physical scientist with the U.S. Bureau of Mines, has been the commodity specialist for iodine for 15 years. Domestic survey data were prepared by Gail Mason, statistical assistant; and international data tables were prepared by Amy Durham, international data coordinator.

Three producers of crude iodine supplied approximately 55% of domestic demand; the remainder was imported. Because some exports and imports are in product categories rather than crude products, net imports are not clearly developed. The major world producer, Japan, produced iodine from brines associated with gas production. The second largest producer, Chile, produced iodine as a coproduct of sodium nitrate.

DOMESTIC DATA COVERAGE

Domestic production data for iodine are developed by the U.S. Bureau of Mines from a voluntary survey of U.S. operations. Of the four operations to which a survey request was sent, four responded, representing an estimated 100% of the total production shown in tables 1 and 6. *(See tables 1 and 6.)*

BACKGROUND

Definitions, Grades, and Specifications

Commercial crude iodine normally has a minimum purity of 99.5%. Resublimed iodine is usually 99.9% pure. Most iodine is converted for industrial use to potassium iodide, sodium iodide, and other inorganic compounds, as well as numerous organic compounds.

Geology-Resources

Iodine occurs in rocks and soils, surface and underground brines, and caliche ores. Michigan brines contain about 30 parts per million (ppm) of iodine in the Sylvania Formation of Devonian age. California brines contain 30 to 70 ppm of iodine in brines associated with oilfields in the middle Miocene age, Monterey Formation, and the lower Pliocene age Repetto Formation. Louisiana brines contain about 35 ppm of iodine. In Oklahoma, iodine concentrations associated with oil and gas range between 150 and 1,200 ppm. In Woodward County, OK, iodine occurs in the Morrowan Formation of Pennsylvania age. The iodine concentration averages about 300 to 350 milligrams per liter; 22 barrels of brines are required for each kilogram of iodine.

Extensive iodine-bearing nitrate ores occur in caliche deposits in a belt several hundred kilometers long in the Atacama Desert of northern Chile. The ore layers are 1 to 3 meters thick, usually flat or gently dipping and near the surface. Evaporate minerals such as lautarite (CaI_2O_6) and dietzeite ($2CaO{\cdot}I_2O_5{\cdot}CrO_3$) occur as cementing material in unconsolidated surface material or as veins and impregnations in bedrock.

Japanese brines contain 50 to 135 ppm of iodine in the Kiwada, Otadai, and Umegase Formations of the Kazusa Group of Pliocene age. The major iodine-producing area was the southern Kanto Gasfield, which extends over Chiba, Tokyo, and Kanagawa Prefectures. Iodine was produced in the Niigata and Nakojo Gasfields in Niigata Prefecture, on the Sea of Japan side of central Japan, and the Sadowara Gasfield in Miyazaki Prefecture, southern Kyushu.

In Indonesia, iodine occurs with trace amounts of bromine in brines associated with oil. The most important iodine-producing area is the Gujangon anticline of sandstone and diatomaceous marls of the Upper Pliocene, Kailiberg Formation.

On Okinawa, iodine occurs in concentrations of about 85 ppm in the Tomigusuku Formation of the Shimajiri Group of late Miocene-early Pleistocene age.

Technology

Processing.—In Japan and the United States, iodine is removed from brines by processes that separate the brines from any associated hydrocarbons. In the blowing-out process, brine is acidified and iodine is liberated by reducing the pH to about 3. A countercurrent stream of air transports the liberated iodine to a second tower where the iodine is absorbed by a solution of hydriodic acid. The iodine settles, is filtered, and is melted under concentrated acid. Brine stripped of iodine is treated and then injected into its subsurface formation of origin.

In the absorption process, brine is passed through an absorber, and the waste brine is neutralized and sent to a disposal well. The absorbent laden with iodine is treated with an alkaline solution to regenerate the absorbent and eludes iodine as sodium iodide. Iodide is precipitated under acid.

Japanese plants also use an ion-exchange resin. Upon saturation, the iodine is eluted using a caustic solution that regenerates the resin. Iodine is then processed with a sodium chloride solution and melted under acid.

Chilean caliche deposits are mined by open pit methods. The ore is leached with an alkaline solution to dissolve the iodine as sodium iodate, which is converted to sodium iodide. Iodine is precipitated by reacting with additional alkaline solution. The precipitated iodine is filtered in bag filters, and the iodine free-leach solution is returned to the nitrate-leaching cycle.

Recycling.—The removal of ionic silver from photographic processing solutions, such as developer, fixer, bleach fixers, and wash waters, can be accomplished with halogens such as iodine and an adsorbent. Photographic silver is commonly recovered by electrolytic methods if the concentration is greater than 500 ppm. Adsorbents such as natural and synthetic zeolites, activated alumina, activated silica, Fuller's earth, and ion exchange resins are used to recover low concentrations of silver from a stream.

Economic Factors

Prices.—Changes in the official price of crude iodine have in the past been initiated during shortages. Because iodine cannot be substituted readily in radiopaque media, animal feeds, catalysts, and stabilizers shortages tend to cause the accumulation of inventories to ensure an adequate supply. An adequate supply tends to lower and stabilize the price.

Costs.—One typical iodine brine well costs about $2 million to complete and is between 1,800 and 3,000 meters deep. Electrical costs for maintaining the pumps to bring the brine to the surface, for air-blowing the iodine, and for injecting the brine are major components of maintenance costs. Capital costs have been estimated at $20 per pound of annual iodine production. These costs include high-quality stainless steels because iodine is highly corrosive. In addition, the brine must be leased from private landowners over large acreage for many years. The principal material cost is for chlorine because 1 pound is required for every 1.4 to 1.8 pounds of iodine produced.

Tariffs.—Crude and resublimed iodine enters the United States duty free. Calcium and cuprous iodine has a 25% ad valorem duty for non-most-favored-nation (MFN) status. Potassium iodide has duties of 2.8% ad valorem for MFN status and 7.5% ad valorem for non-MFN status.

Depletion Provisions.—The domestic and foreign depletion allowances for mined iodine are 14% of gross income, and they may not exceed 50% of net income without the depletion deduction. The domestic and foreign depletion allowances for minerals from brine wells are 5%. The domestic and foreign depletion allowances for solid minerals are 14%.

Operating Factors

Environmental Requirements.—The injection of waste brine is a limiting factor to the production of iodine. During 1982, the Environmental Protection Agency (EPA) reclassified disposal wells for spent brine after halogen extraction as Class 5 wells. All of the injection wells for iodine in Oklahoma were drilled for the injection of waste associated with brine production or oil and gas effluent. Woodward Iodine Corp. operated 22 production wells and injected the waste brine through 10 injections wells. Brine-production and injections wells are 2,130 to 2,290 meters deep. IoChem Corp. had nine production wells and four injection wells. North American Brine Resources operated iodine production facilities at the site of two injection wells for waste brines associated with oil production.[1]

Toxicity.—Iodine is absorbed by the body and concentrated in the thyroid. Iodine is essential to higher animals and humans. A normal person requires about 75 milligrams of iodine per year, which is usually consumed as iodized salt that contains one part sodium or potassium iodide to 100,000 parts of sodium chloride. Iodine deficiency is a major cause of goiter.

The maximum safe concentration of iodine for short-term air environment exposure of up to 1 hour is 1.0 ppm. Exposure of the lungs and eyes can be irritating at concentrations of 0.1 ppm and should be avoided. Greater exposure can cause severe irritations to the eyes and the respiratory tract and may lead to pulmonary edema.

In 1979 and 1986, nuclear accidents caused the release of radioactive iodine, I^{131}, into the atmosphere. A dosage of potassium iodide (KI) administered before or shortly after exposure to radioactive iodine can block the intake of radiation to the thyroid. The dosage must be repeated if exposure continues. Replenishing the thyroid with KI prevents the thyroid from using radioactive I^{131} for normal metabolic needs.

During the 1940's and 1950's, civilians living near the Hanford nuclear weapons plant in Washington were deliberately exposed to high levels of radiation in the form of radioactive iodine. The iodine was deposited on grass that was eaten by cows and conveyed to humans through milk. More than 800,000 people in a 194,000-square-kilometer area of eastern Washington and parts of Idaho and Oregon and some children may have been exposed to as much as 870 rads and adults may have absorbed 350 rads to their thyroid. Federal guidelines call for evacuation if the dose to the thyroid reaches between 5 and 25 rads.[2]

The Joint Food and Agriculture Organization of the United Nations/World Health Organization (FAO/WHO) Expert Committee on Food Additives and No. 832 in the WHO Technical Report Series released its 40th report. The report is an evaluation of certain veterinary drug residues in food. Closantel, an anthelmintic containing 38% iodine by weight, was one of five anthelmintics examined for acceptable daily intakes and maximum residue limits in food-producing animals. The report identifies deficiencies in the available data and specifies the further information required for reevaluation.[3]

ANNUAL REVIEW

Legislation and Government Programs

The U.S. Department of Labor, Occupational Safety and Health Administration (OSHA), proposed in the Federal Register June 12, 1992, to amend its existing air contaminant standards that set permissible exposure limits (PEL's) for the maritime, construction, and agriculture industry sectors. Only employees of farms with more than 10 employees are covered under OSHA standards. Included in the proposed PEL's are iodoform and methyl iodide.

The EPA announced that the use of Iprodione will not be used in processed foods. EPA announced that the pesticide posed only a negligible risk to public health, but was seeking to comply with a 1992 Federal court decision. The action, announced jointly with the Food and Drug Administration and the U.S. Department of Agriculture, was expected to increase the need for a workable alternative to the "Delaney clause" risk standard. The clause required the Federal Government to ban from processed foods any substance found to cause cancer in animals. Although there is a need for a standard for assessing potential harm to human health, there is little consensus on a proposal to replace the clause.[4]

Strategic Considerations

The National Defense Stockpile contained 2,631,292 kilograms of crude iodine. The stockpile goal for iodine was reduced to zero with the passage of Public Law 102-484 on October 23, 1992. A meeting for prospective offers was held on June 3 at the Defense National Stockpile Center in Arlington, VA. On May 12, a draft Invitation for Bids for Iodine was circulated. The Defense Logistics Agency (DLA) of the U.S. Department of Defense sold 45 kilograms (kg) of excess iodine valued at $275 ($2.75 per pound) during fiscal year 1993.

Production

IoChem began production in 1987, 1.2 kilometers east of Vici, Dewey County, OK, by the blowing-out process. The majority of production was shipped to Schering AG, Germany, under a long-term contract. IoChem was reported to have nine production wells and four injection wells with a total production capacity of 1,400 kg per year.

North American began operating a miniplant at Dover in Kingfisher County, OK, in 1983. Two plants are at an oilfield injection disposal site that obtains brines from about 50 wells in the Oswego Formation. Iodine concentrations ranged up to 1,200 ppm. The company closed a plant in 1992 that began operating in 1991 because of the low-market prices for iodine.

Woodward Iodine began production in 1977 and was purchased by Asahi Glass Co. of Japan in 1984. Woodward operated a plant in Woodward County that produced iodine from 22 brine production wells using the blowing-out process and injected waste through 10 injection wells.

Consumption and Uses

Iodine was used primarily in animal feed supplements, catalysts, inks and colorants, pharmaceutical, photographic equipment, sanitary and industrial disinfectants, stabilizers, and radiopaque medium. Other smaller uses included production of batteries, high-purity metals, motor fuels, iodized salt, and lubricants.

Iodine deficiency is the largest preventable cause of mental impairment in the world. Disorders stemming from a lack of iodine range from simple goiter to the severe cluster of mental and physical handicaps known as cretinism. In between are mental retardation, learning disabilities, apathy and lack of motivation in adults, and increased rates of stillbirths and miscarriages. By simply adding iodine to salt the deficiency disorders could be eradicated within a few years.[5]

Excessive levels of iodine, which may cause thyroid cancer, were found in cat foods by scientists at the University of Missouri. Iodine is an essential nutrient in the diet, so high doses were thought to be healthy.[6]

The lithium-iodine battery was the first commercially successful lithium battery and is unusual because of its in situ growth of electrolytes. Superior charge transfer is achieved using an iodine compound with powdered iodine. Layers of lithium iodide act as both electrolyte and separator and are self-sealing in the event of a crack. Thus, the batteries are intrinsically reliable and withstand abuse.

Producers sold iodophors for medical, veterinary, and food-processing applications. The two main classes of iodophors are povidone iodine, manufactured from polyvinylpyrrolidone and utilized in human skin disinfectants, and the nonionic detergent-iodine combinations, utilizing primarily nonoxynol and the poloxamers. Iodophors are highly self-stable, substantially free of the corrosive effects of noncomplexed-iodine concentrations, and relatively nonirritating to human skin. One of the world's largest producers of nonionic detergent iodines is West Agro, Inc.[7]

Tall oil was produced using iodine as a stabilizer by Arizona Chemical Co., a division of International Paper Co., Hercules, Inc., and Westvaco, Inc. Modest reductions in supply were attributed to the limited availability of wood rosin. Tall oil fatty acid inventories declined during 1993 in the United States and Europe.[8]

Eastman Chemical Co. was spun off from the Eastman Kodak Co. Eastman became one of Tennessee's leading employers and joined the ranks of a public company headquartered in Kingsport, TN. The company manufactures chemicals, fibers, and plastics.[9] Acetic anhydride manufactured uses methyl iodide as a catalyst to produce acetic acid.[10]

Kodak planned to concentrate on photography and imaging and its health sciences division. Kodak manufactures its own film and paper supports, as well as photographic-grade gelatin and processing chemicals and equipment. In the photographic business, a thin gelatin of imaging layers containing light-sensitive silver halide crystals or auxiliary layers help to regulate the photographic or physical performance.

A regenerable biocide delivery unit is an extension of technology developed by Umpqua Research Co. for the space shuttle program in the late 1970's and currently used on the shuttle to purify drinking water. Water is passed through an anion exchange bed that has been treated with iodine. An improvement in the unit regenerates the resin bed in situ using small amounts of elemental iodine. The improved unit has been licensed for water purification of between 9 to 68 liters (2 to 15 gallons) per minute of water for community applications.[11] *(See table 2.)*

Prices

The average declared c.i.f. value for imported crude iodine was $7.90 per kg ($3.58 per pound). The average declared c.i.f. value for imported crude iodine from Japan averaged $7.82 per kg ($3.55 per pound). The average declared c.i.f. value for iodine imported from Chile was $8.01 per kg ($3.63 per pound). The average producer price was $7.98 per kilogram ($3.62 per pound). Quoted yearend U.S. prices for iodine and its primary compounds are shown in table 3. *(See table 3.)*

Foreign Trade

The U.S. Government adopted the Harmonized Commodity Description and Coding System (Harmonized System) as the basis for its export and import tariff and statistical classification systems. The system is intended for multinational use as a basis for classifying commodities in international trade for tariff, statistical, and transportation purposes. The Harmonized System, as proposed, includes resublimed and crude iodine under the same code, and the duty rate is free. Values that differ significantly could be a result of items being placed in the wrong category. *(See tables 4 and 5.)*

World Review

Canada.—In 1976, research was begun to selectively leach amorphous manganese dioxide from the coatings on mineral grains to enhance geochemical anomaly in soils. In recent soil analysis studies on iodine, an anomaly with a contrast of 100-times-background was found at the Sleeper and Rabbit Creek gold mines in Nevada. Trace elements released by oxidation of sulfide-mineral deposits in the bedrock migrate up through overburden by ground water flow, capillary action, or diffusion of volatile compounds. The iodine anomaly was found at a point where the Rabbit Creek deposit was buried by 183 meters (600 feet) of basin fill.[12]

Chile.—Sociedad Química y Minera de Chile (SQM, formerly known as SOQUIMICH) was the largest producer of iodine in Chile. SQM planned to expand potash with a $57.5 million share offer in the United States. On July 8, 1993, SQM issued a prospectus that advertised American Depositary Shares, backed by Series B shares in the company. The money would enable SQM to embark on a $229.7 million expenditure between 1993 and 1997 that includes $7 million to extract nitrates and iodine from fines at the Pedro de Valdivia ore crushing facility. A supplemental amount of $7 million during 1994 and 1995 was to be spent on the construction of a new iodine facility at Lagunas, northern Chile.[13]

Cominac S.A., a subsidiary of Inversiones Errazuriz S.A. Enterprises, began production at two of three reserve areas of the Pozo Almonte Project. The site is in a valley where the natural gravity flow is utilized to collect the iodine-rich solutions. A third reserve area was undergoing a third step in a civil process to determine ownership. The two areas under development are not involved in the civil processing and are under development by a subsidiary company, Compania de Salitre y Yodo de Chile (Cosayach). Cosayach has a plant to recover 600 tons of iodine per year by heap leaching. Plans to expand capacity were being developed.

ACF Minera Ltda. is a Chilean company with a 50% joint venture with DSM N.V. of the Netherlands. The company maintains three production facilities that have a nameplate capacity of 1,200 tons that are in the first region of Chile at La Granja, Lagunas, and Iris. The facilities are about 161 kilometers (100 miles) southeast of the port city of Iquique. The production capacity was reported to be 810 tons of 99.5% to 100.5% iodine, with mineral reserves of 48,000 tons of iodine in situ. The company also owns mineral rights at other locations in the first and second regions of Chile.

Mineral Yolanda, Yumbres, Chile, planned to produce 1.7 million tons per year of nitrate ore that includes iodine with a $78 million investment. The project is wholly owned by Kap Resources Ltd., Vancouver, Canada. The mineral salts or caliche will be leached with seawater to dissolve the salts. The solution will be processed to extract the iodine. The remaining solution will be evaporated in solar ponds to concentrate the nitrate salts.[14]

Indonesia.—The only producer of crude iodine was the state-owned pharmaceutical firm, P. T. Kimia Farma, that operated a plant at Watudakon near Mojokerto, East Java.

Japan.—Japan was the world's leading producer of iodine in 1993. Six companies operated 17 plants with a total production capacity of 9 million kg per year. Plans were announced to close two small plants by midyear 1994. Production of iodine was from underground brines associated with natural gas.

Russia.—Authorities in the Tyumen region will hold open bidding to extract iodine from a deposit near the city of Tobolsk. The Tyumen region was reported to contain one-half of Russia's known iodine reserves. The iodine deposit was discovered in the 1960's but remained unexploited because of the region's oil boom. Preliminary studies indicate that the deposit could produce from 1,000 to 2,000 tons of iodine annually. Russia consumes 1,600 tons of iodine per year and imports 85% of that amount.[15] *(See table 6.)*

Switzerland.—The Nuclear Medicine division of Mallinckrodt Medical Inc. acquired Oryx Pharmaceutica AG, Zurich, Switzerland. Oryx, which sells more than one-half of the radiopharmaceuticals in Switzerland, had distributed nuclear medicine products manufactured by Mallinckrodt since the 1970's.[16]

Current Research

Trifluoromethyl iodide (CF_3I), an FIC, can replace the common CFC's used in household refrigerants. An FIC is a molecule that contains fluorine, iodine, and carbon and in some cases hydrogen. FIC's have advantages as CFC replacements because they are about the same cost as the replacements now used, HFC-134a, have low toxicity, and do not damage the ozone layer. FIC's break down rapidly on exposure to sunlight; therefore, they have an ozone depletion potential of about zero. FIC's are nonflammable and noncorrosive. FIC's will have higher refrigeration capacities and energy efficiencies will be essentially unchanged. The U.S. Air Force began testing the toxicity of CF_3I as a potential substitute for Halon 1301.[17] Scientists at E.I. du Pont de Nemours & Co. Inc. have produced nonprotonated material by heating C_{60} and excessive trifluoromethyl iodide. The compounds are more volatile but display surface properties of perfluoroalkylated materials, such as Teflon.[18]

Pennsylvania State University studied new methods of producing acetic acid from methane using rhodium trichloride as a catalyst. The yield of acetic acid was increased by adding a source of iodine ions. The new process is similar to the Monsanto process used commercially for carbonylation of methanol to acetic acid using a rhodium-base catalyst. In the new method the methane is hydrolyzed to acetic acid. This reduces the steps from three to one, thereby making the process more economical.[19]

Chemists at the University of Salford and the ICI Runcorn Technical Center prepared thermoplastic hydrogels from linear copolymers of vinyl pyrrolidone and methyl methacrylate. The hydrogels demonstrated favorable properties such as film-forming capacity, melt processability, fluid retention, and biocompatability.[20]

OUTLOOK

Iodine production capacity in the United States and Chile has doubled during the past decade, ensuring an adequate world supply. Uses for iodine in specialty chemicals have remained stable. Recent developments in digital images using computers can produce electronic prints and overhead transparencies without using processing. Using a digital camera or scanning the film and converting to digital, the images are produced and stored on hard drives, disks, tape, or optical storage.

The trend to digital imaging is used for recording most sporting events, game shows, and some situation comedies for broadcasts. However, 75% to 85% of all televised shows seen during prime time are recorded on 35-millimeter (mm) motion picture film and then transferred to videotape or laser disc for display. Furthermore, just about all feature films for movie theater presentation are shot and printed on film. The main reason is the image quality. A frame of 35-mm color negative film contains about 6.6 million pixels or about 15 times that of the best current high-definition television system and 4 times that of the digital systems now in development. Most popular home video rentals have been box office movie hits. Future use of iodine in films and processing could be limited to specialty imaging in the next decade.[21]

New uses of IFC's as halogen replacements could cause an increased demand for iodine. More tests need to be completed on the IFC's before they are acceptable, but preliminary tests are promising.

IRON ORE

By William S. Kirk

Mr. Kirk became the commodity specialist for iron ore in 1992 and was previously responsible for cobalt, depleted uranium, hafnium, nickel, radium, thorium, and zirconium. The domestic survey data were compiled by Debra A. Nolan, statistical assistant, Branch of Data Collection and Coordination. The world production table was prepared by Amy D. Durham and Ronald H. Hatch, International Data Section.

Iron ore is essential to the economy and national security of the United States. As the basic raw material from which iron and steel is made, its supply is critical to any industrial country. Scrap is used as a supplement in steelmaking, but is limited as a major feed material because there is a limited quantity of high-quality scrap.

Nineteen-ninety-three was a year of recovery for the domestic iron ore industry as consumption rose by 2.3%. Production and shipments also rose slightly from 1992 levels. The increases were attributed to a 6.9% increase in raw steel production.

Production in the United States posted a moderate gain, while production in China rose by 19%. Australia and Brazil continued to be the leading exporters of iron ore with a combined total of close to 60% of the world total.

DOMESTIC DATA COVERAGE

U.S. production data for iron ore are developed by the U.S. Bureau of Mines (USBM) from two separate, voluntary surveys of domestic operations. The annual "Iron Ore" survey (1066-A) provides the basic data used in this report. Of 39 addressees to whom the 1066-A form was sent, 31 responded, representing 100% of total production shown in tables 1 through 4. In past years, production for nonrespondents to the annual survey was estimated from monthly surveys (1066-M), from railroad reports, or from reported production levels in prior years. This information may be supplemented by employment data, mine inspection reports, and information from consumers.

Data on consumption and stocks of iron ore and agglomerates at iron and steel plants were provided by the American Iron Ore Association (AIOA). AIOA also provided data on ore shipments from loading docks on the upper Great Lakes as well as receipts at transfer docks and furnace yards nationwide. The dock and steel plant data were compiled jointly by AIOA and the American Iron and Steel Institute (AISI). Data on consumption of iron ore for nonsteel end uses were compiled from information gathered from other USBM surveys.

BACKGROUND

Economic Factors

The United States has exhausted the reserves of high-grade direct-shipping ore it once had in Michigan and Minnesota. Almost all of the ore being mined now is low-grade taconite, which requires costly beneficiation and pelletizing. Moreover, the taconite mining and pelletizing complexes are deep in the interior of the country, far from any saltwater harbor. Because of the advantages of Great Lakes shipping, U.S. pellets are currently competitive at Gary, Cleveland, and Detroit. However, high rail costs put U.S. pellets at a disadvantage in the mid-Atlantic States and Alabama. Imported ores and agglomerates from Brazil, Canada, and Venezuela constitute the bulk of the iron units consumed at these coastal steelworks.

The St. Lawrence Seaway is a mixed blessing for the mining industry, being a bottleneck for ore carriers as well as an inexpensive means of transport in the Great Lakes region. The eight locks in the Welland Canal and the seven locks in the St. Lawrence River are all similar in size and have a gate-to-gate length of 262 meters (m). The relatively short length of each lock prevents oceangoing ore carriers longer than 222 m from entering the Great Lakes. At the same time, domestic "1,000 footers" cannot leave the Lakes. Foreign ore bound for Indiana or Ohio either has to be offloaded onto smaller vessels in the gulf of the St. Lawrence or transferred to rail cars at Baltimore or Philadelphia. In some cases, ore is barged from the Port of New Orleans up the Mississippi River to steelworks in the Ohio River Valley and western Pennsylvania. The high rail costs that keep domestic ores from going to the coastal steelworks also keep foreign ores out of the inland steelmaking regions.

Operating Factors

Statistics on employment and productivity in the U.S. iron ore industry in 1993, shown in table 2, were derived from quarterly employment data supplied by the Mine Safety and Health Administration (MSHA) and from production data derived from USBM surveys. Both sets of data were obtained from producers' reports.

The statistics include production workers employed at mines, concentrators, and pelletizing plants and in repair and maintenance shops, but do not include 844 persons engaged in management, research, or office work at mines and plants. Employees engaged in ore preparation, such as sintering, at blast furnace sites are not included.

Because employment data reported to MSHA are primarily for safety analysis, hours spent by salaried employees in mines or plants may be included by operators in the total number of hours worked at individual mines or plants. This has resulted in understatement of calculated productivity by 10% to 25% for some operations, but its affect on others is not known. If company reporting practice is consistent, however, comparison of productivity from one year to the next should be reasonably valid.

ANNUAL REVIEW

Legislation and Government Programs

Voluntary Restraint Agreements (VRA's) on steel imports expired on March 31, 1992. Under the VRA's, steel-producing nations had agreed to limit steel exports to the United States in return for withdrawal of charges by U.S steel companies that the imports were a cause of injury to the U.S. steel industry. In June 1992, U.S. steelmakers filed new complaints with the International Trade Commission (ITC) against 21 nations, alleging injury to the U.S. industry as a result of illegal subsidies and sales at less than face value. The ITC issued an initial decision affirming the claims of injury against a number of these nations. Effective December 7, 1992, importers were required to provide funds or bonds to cover countervailing duties, pending a final decision in 1993.

The ITC announced its final determination on the question of injury on July 27, 1993. The result was mixed for the U.S. steel industry. The Commission found that the U.S. industry was being harmed by virtue of imports of plate products from Belgium, Brazil, Canada, Finland, Germany, Mexico, Poland, Romania, Spain, Sweden, and the United Kingdom, and corrosion-resistant (galvanized) product from Australia, Canada, France, Germany, Japan, and the Republic of Korea. In the case of cold-rolled steel products, injury to the U.S. industry was found only as a result of imports from Germany, the Netherlands, and the Republic of Korea; imports from 10 other countries that had been determined to be either illegally subsidizing or unfairly pricing their products were determined to be causing no injury to U.S. industry. For a more extensive treatment of this subject, refer to the Iron and Steel chapter.

Production

There was movement among domestic producers toward installing direct-reduced iron (DRI) capacity. Cyprus Northshore Mining Co., Silver Bay, MN, made a significant move toward that goal, when the Minnesota Pollution Control Agency board voted 8 to 0 to accept a recommendation that the project did not need a time-consuming environmental impact study before a construction permit was approved. Cleveland-Cliffs Inc. (CCI) was considering the idled Republic Mine near Palmer, MI, as a site for the construction of a DRI plant.

Strikes closed four mines in Minnesota and Michigan during the year. Hibbing Taconite Co. and National Steel Pellet Co. on the Mesabi iron range of Minnesota and the Empire Iron Mining Partnership and the Tilden Mine on the Marquette iron range of Michigan were closed on August 1 after their contracts expired on the 31st of July. Although the contract between Eveleth Mines and the United Steelworkers also expired on July 31, production continued through yearend. Labor agreements were reached with employees at Hibbing, Empire, and Tilden, while National was still idle at yearend.

In 1993, iron ore was produced by 16 companies operating 17 mines, 12 concentration plants, and 10 pelletizing plants. The mines included 16 open pits and 1 underground operation. Virtually all ore was concentrated before shipment, and 97.9% was pelletized.

Combined United States and Canadian production represented only about 11% of the world output of usable ore in 1993. At least 57 other countries mined crude ore during the year. The leading producer was Brazil, which accounted for 20.7% of world output in terms of metal content, followed by Australia and China, each with 15.5%. Trends in world mine production since 1989 are shown on a country basis in table 19.

Domestic iron ore production, at 55.7 million metric tons (Mmt), was little changed from that of the previous year. Productivity for usable ore in the Lake Superior District rose slightly. Iron ore was produced by 16 open pit mines and 1 underground mine. Eleven mines produced ore for the iron and steel industry, while the remainder shipped ore mainly to cement plants. Installed domestic production capacity for usable ore on December 31, 1993, was estimated at 82 million metric tons per year (Mmt/yr), of which 81 Mmt was pellets. Total output of usable ore was equivalent to about 68% of installed production capacity. An average of 3.3 tons of crude ore was mined in 1993 for each ton of usable ore produced. This ratio does not take into account the tonnage of waste rock or overburden removed. The ratio of total materials mined to usable ore produced was probably greater than 5:1. Low-grade ores of the taconite type mined in Michigan and Minnesota accounted for 99% of total crude ore production. U.S. production of pellets totaled 54.5 Mmt, 98% of usable ore output. The average iron content of usable ore produced was 63.1%. Shipments from U.S. loading docks on the upper Great Lakes totaled 59.5 Mmt in 1993 compared with 58.3 Mmt in 1992.

Michigan.—Michigan accounted for 23% of the national output of usable ore in 1993. One hundred percent of the State's production consisted of pellets produced at the Empire and Tilden Mines near Ishpeming in Marquette County. Both mining ventures are managed by CCI's Cleveland-Cliffs Iron subsidiary. Empire shipped 6.7 Mmt of pellets produced from magnetite concentrate. Tilden shipped 1.5 Mmt of magnetite pellets and 4 Mmt of hematite pellets, for a total of 5.1 Mmt. Production of usable ore was down 8.4% from the 1992 figure of 13.9 Mmt. Production of pellets totaled 12.8 Mmt, of which 7.3 Mmt was made at Tilden.

Minnesota.—Minnesota produced 75.5% of the national output of usable ore in 1993. All of the State's production came from open pit mines on the Mesabi Range. Production of pellets totaled 41.7 Mmt, equivalent to 86.4% of installed production capacity of the State's seven taconite plants.

Inland Steel Mining Co., Virginia, MN, closed its Minorca Pit in September after its reserves were depleted. Inland had produced 120 Mmt of ore from the pit since it opened in 1976. The company continued to mine the Laurentian Pit.

Eveleth Mines reopened its pellet plant on March 9. Mining had resumed about 2 weeks earlier. The facility closed in November 1992 after Armco Steel Co. LP, part owner of the mine, determined that the mine's costs were too high. LTV Steel Co. closed its Northwest Ore division as of August 1, after close to 100 years of natural ore production on the Mesabi range. Natural ore, as opposed to taconite, is a friable, medium- to high-grade ore needing minimal beneficiation.

Missouri.—The Pea Ridge Iron Ore Co. produced iron oxide powder at its mining complex near Sullivan, MO. The company has the only active underground iron mine in the country. In January 1991, the company ceased pellet production and began concentrating on specialty iron oxide products, which had formerly been coproducts.

Utah.—Geneva Steel of Utah operated two open pit mines.

Consumption and Uses

Although crude steel production rose 6.9% and net shipments of semifinished steel rose by 8.3% in 1993 and capability utilization rose from 82.2% in 1992 to 89.1%, these increases were not matched by increases in iron ore consumption. Iron ore consumption rose by only 2.3% and pig iron production, an excellent indicator of iron ore consumption, increased by 2.6%.

This apparent paradox can be explained by examining the source of some of the shipments of steel and how most of the steel was made. As to the source, imports of semifinished steel rose markedly. For the 5 years prior to 1993 these imports ranged from 2 to 2.6 Mmt and averaged 2.2 Mmt. Imports in 1993 were 4.5 Mmt. Net imports of semifinished steel in 1993 were up 130.8%. To meet the higher demand, integrated producers sharply increased imports of semifinished steel.

In 1993, 83.9% of steel produced in the United States was continuous cast compared with 78.9% in 1992. Continuous casting reduces consumption of iron ore because it results in the generation of less home scrap. Basic oxygen furnaces, used by all integrated producers, can use no more than about 28% scrap. Because producers have less home scrap to remelt, they can use more purchased scrap. Thus, they obtain additional iron units from scrap rather than ore.

Another factor affecting the consumption of iron ore is that electric arc furnaces, used in steelmaking primarily by minimills, do not use iron ore. Electric arc furnace steelmaking accounted for 39.4% of total steelmaking in 1993. This was the largest ever share for electric arc furnace steelmaking for the United States.

Consumption of iron ore for ironmaking and steelmaking totaled 71.5 Mmt. Monthly consumption of pellets, direct-shipping ore, and merchant sinter by the industry averaged 5.82 Mmt compared with 5.71 Mmt in 1992. Reported consumption of iron ore for manufacture of cement, heavy-medium materials, animal feed, ballast, ferrites, pigments, and other nonsteel products was 1.1 Mmt.

U.S. production of hot metal and pig iron totaled 48.2 Mmt, a 1.6% increase from that of 1992. During 1993, the number of blast furnaces in operation ranged from 40 to 42.

Consumption of iron ore and all types of agglomerates reported to the AISI by integrated producers of iron and steel totaled 75.2 Mmt. This included 60.8 Mmt of pellets; 12.5 Mmt of sinter, briquettes, etc.; and 2 Mmt of natural coarse ore. Of the primary ore consumed, 79% was of domestic origin, 9% came from Canada, and 12% came from other countries. Other materials consumed in sintering plants included mill scale, flue dust, limestone and dolomite, slag and slag scrap, and coke breeze. Other iron-bearing materials charged to blast furnaces included steel furnace slag, mill scale, and slag scrap.

The U.S. steel industry accounted for 98.4% of domestic iron ore consumption in 1993.

Stocks

Stocks declined by 6.6% to 21.5 Mmt as the result of strikes at four iron ore production plants.

Transportation

After years of debate, representatives of the U.S. Army Corps of Engineers, the Michigan Department of Natural Resources, the U.S. Coast Guard, and the U.S. Fish and Wildlife Service signed a memorandum of agreement that set the navigation season for the Soo Locks at March 25-January 15.

The Mackinaw, the largest icebreaker on the Great Lakes, received a reprieve. During the year, the U.S. Coast Guard convinced Congress that it was time to decommission the ship. The severe winter of 1993-94 prompted the Lake Carriers' Association and other groups to lobby for retaining the ship. Congress agreed to fund the Mackinaw through fiscal year 1995.

Prices

As in 1992, iron ore producers were forced to accept price reductions. The 2 consecutive years of price reductions offset 3 consecutive years (1989-91) of gains.

Most iron ore prices are negotiated between buyer and seller. About 80% of domestic ore is produced by captive mines (mines producing for company smelters) and therefore does not reach the open market. The average f.o.b. mine value of usable ore shipped in 1993 was $29.21 per ton, 6.3% higher than that of 1992. This average value was based primarily on producers' statements and should approximate the average commercial selling price less the cost of mine-to-market transportation.

Foreign Trade

U.S. exports of iron ore were less than 1% higher than those of 1992. Virtually all exports consisted of pellets and concentrates shipped via the Great Lakes to Canadian steel companies that are partners in U.S. taconite projects in Michigan and Minnesota. U.S. imports of iron ore rose 12.7% to 14.1 Mmt.

Net imports averaged 11.5 Mmt from 1989 through 1992; 1993 net imports were 9 Mmt, equivalent to 14.3% of U.S. ore consumption, down from 15.3% in 1992. Canada's share of net imports was 53% and Brazil's was 20%.

World Review

At least 59 countries mined iron ore during the year, producing a total of 988.8 Mmt. China was the largest producer, with an output of 234.7 Mmt.

For the third consecutive year, Australia was the leading exporter of iron ore, shipping 116.4 Mmt to world markets, followed closely by Brazil, which exported 111.9 Mmt. Together, the two countries accounted for 57.7% of export in 1993. The next largest exporter was India, at 8%. Total exports were 395.7 Mmt, up from 367.3 Mmt in 1992. Australia's principal customer, Japan, accounted for about one-half of its exports. Brazil's primary customers were the European Community (EC) and Japan.

Integrated iron ore operations have become extremely complex and are so large as to resemble medium-sized towns in some cases. The production capacity of an operation of this magnitude is determined by equipment limitations at several stages of recovery. To simplify analysis and make comparisons of individual mines easier, data were collected that represent the rated or design capacity at three key points in the recovery process: crusher-screen output, concentrator output, and pelletizing furnace output. These three points were chosen because they serve to readily separate the mining, beneficiating, and agglomerating stages of the operation. At the first two points, the iron ore is already in a marketable form and can be diverted for sale or tolling if bottlenecks occur either downstream at the operation or upstream at competitors' facilities.

Changes in the economics of the process also could make diversion feasible. Table 21 shows world pelletizing capability at the close of 1993. The data represent the rated capacities of 82 plants in 26 countries. A significant part of the data was published by the Trust Fund Project on Iron Ore Information in 1993. The table excludes plants that have not produced since 1982. Four of these idled plants are identified in the table footnotes because they could be reactivated in some realistic scenarios. Table 21 also excludes sintering plants.

Australia.—The country continued to be the world's leading exporter of ore in 1993. BHP Iron Ore Ltd. developed the Yarrie Mine in Western Australia. The first full trainload of ore left the mine on December 1. The new operation was to replace the Goldsworthy Mine. Reserves at the deposit were estimated at 35 Mmt. The production rate was 5 Mmt/yr. Construction involved the extension of rail and power lines from Shay Gap and installation of a crushing plant, stockpiling and train loading facilities, an accommodation village, offices, and workshops.

BHP also increased the production capacity at its Yandi Mine in Western Australia to meet increased future demand. Opened in 1992, the Yandi began producing at a rate of 10 Mmt/yr.

Robe River Mining Co. completed the development of its Mesa J deposit, which was begun in 1992.

Brazil.—Cia. Vale do Rio Doce expanded its Ponta de Madeira port at Sao Luis by adding a second loading pier. This increased the loading capacity at the port from 35 to 50 Mmt/yr.

China.—Anshan Iron & Steel Corp. began expanding the Qidashan iron mine and beneficiation plant. Construction was to be completed by July 1, 1995. The expansion was expected to double the facility's iron ore capacity to 16 Mmt/yr.

India.—A pelletizing plant was being built for a subsidiary of Essar Gujarat, which produced 60% of India's DRI from its new hot-briqueted iron (HBI) plant. The plant, being built in Visakhapatnam, on the east coast, was to have a production capacity of 3 Mmt/yr. Of that, 2.2 Mmt/yr was to be shipped to the State of Gujarat on the west coast to feed Essar's three 440,000-metric-ton-per-year (mt/yr) DRI modules. Ispat was building a 1-Mmt/yr DRI plant at Alibagh near Bombay.

Essar Gujarat signed a memorandum of understanding with Met-Chem, of Canada, to develop a new iron mine in the Bailadilla mining district of eastern India. The deposit would be leased from the National Mineral Development Corp. (NMDC), which operated export mines in the district. The mine was to be open pit and have a primary crushing/screening plant for sized lump ore. Production was expected to be 6 Mmt/yr of run-of-mine ore, yielding 2.4 to 3 Mmt/yr of lump ore and about 2.7 Mmt/yr of fines.

Japan.—On March 19, the Kamaishi iron mine closed, bringing to an end 150 years of operations. The mine, in Iwate, in northeastern Honshu, was the last operational Japanese iron mine. Discovered in 1727, the deposit played a major role in the development of Japan's modern steelmaking industry in the 1850's. At its peak in 1934, annual production was 1.4 Mmt and once employed more than 3,000 people. The mine closed because it could not compete with cheaper, higher grade imported ore.

Libya.—Libyan Iron and Steel Co. (LISCO) was planning to add a third Midrex DRI module to its Misurata steel complex. The module was to be situated adjacent to the existing two-module Midrex DRI plant, which completed its second full year of operation in 1992. The new module, which was scheduled to begin operation in 1996, would increase total DRI capacity to 1.75 Mmt/yr.

Peru.—Production at the Marcona Mine, which was sold to Capital Steel (Shougang) Corp., China, rose from 3 Mmt in 1992 to 5.5 Mmt in 1993.

Technology

Joint-venture partners, CRA, Ltd. Australia, and Midrex Direct Reduction Corp., U.S.A., dedicated their HIsmelt Research and Development Facility (HDRF) in November. The $140 million project, in Kwinana, 40 kilometers (25 miles) south of Perth, Western Australia, embarked on a year long study to determine the technical and economic parameters for the scale-up and commercialization of the HIsmelt Direct Iron Ore Smelting Process. If the process could be successfully commercialized, it would serve as an alternative to the traditional blast furnace route and would compete against the Corex process owned by Vöest-Alpine Industrieanlagenbau AG of Austria. Like the Corex process, it would eliminate the need for coke ovens, blast furnaces, and sinter plants, thereby bypassing many of the environmental problems associated with cokemaking and sintering. It also used relatively cheap energy coal rather than higher quality coking coal.

The heart of the new complex was a prototype smelt reduction vessel (SRV), which had a production capacity of 0.1 Mmt/yr. The capacity of a commercial-sized plant was considered to be 0.5 to 1 Mmt/yr. The process was a single-stage process that involved the direct smelting of iron ore in a closed molten bath reactor. Coal was injected into the iron bath to maximize recovery of the carbon and to generate bath turbulence. The ore was preheated and prereduced in a circulating fluidized bed prior to injection into the horizontal SRV. Hot air was supplied to the top of the SRV to postcombust the generated CO. The hot metal and slag tapped from the SRV were transported to the pig caster and the slag pens.

The USBM published a report (RI 9473) entitled "Use of Oxygen Enriched Gas for the Oxidation of Acid and Fluxed Taconite Pellets." The USBM, in cooperation with CCI (Hibbing, MN), investigated ways of enhancing the quality (compressive strength and reducibility) of domestic acid and fluxed magnetic pellets by modifying the oxygen content during the preheat and induration periods of the firing operation.

OUTLOOK

At present consumption rates, known world iron reserves are sufficient to meet cumulative world demand well beyond the 21st century.

The domestic iron ore industry is totally dependent on the steel industry for sales. This dependence is not expected to change in the near future. Because of this relationship, the reader is referred to the outlook section in the "Iron and Steel" chapter. Only 8% of the iron ore produced from 1989 through 1993 was exported, with virtually all of it being pellets going to steelworks in Ontario. It is difficult for the United States to compete in the world iron ore market because of the country's declining ore grades, the inland location of its mines, and high labor and fuel costs.

For the near term, growth of the U.S. iron ore industry is tied to the growth of the integrated steelworks along the Great Lakes. The U.S. steel industry is concentrating on making high-value, quality steels, not increasing output. Domestic blast furnace production in the year 2000 is expected to be no more than 50 Mmt. The U.S. iron ore industry has no choice but to focus on making higher quality agglomerates, such as fluxed pellets, that meet much tighter chemical and physical specifications than have been required in the past. The hope for the domestic iron ore industry is that one or more of the new direct processes, COREX, DIOS, AISI, HIsmelt, carbide, etc., will prove to be economic for lake producers.

Electric arc furnaces currently account for more than one-third of total crude steel production. Because of advances in steelmaking, steel products now require lower residual alloy content than can be readily achieved with scrap. This indicates a role for imported DRI in the coastal regions of the United States. The growth of gas-based DRI production capacity outside North America has been spectacular in recent years. Although a large part of this growth has occurred in Venezuela, the bulk of the construction has been spread evenly through a variety of countries that have surplus natural gas. It is too early to tell whether coal-based DRI production will be economically feasible in the United States. No matter how spectacular DRI growth is over the next decade, it will not be able to replace more than a fraction of the world's blast furnace production because of technological restrictions. The blast furnace is expected to remain the mainstay of the iron and steel industries in most developed countries over the next 25 years.

In contrast to the United States, demand for iron ore in the Pacific Rim is expected to increase, particularly in China. Steelworks in the EC have become more competitive in recent years and should benefit from the growth in steel consumption that is forecasted to occur in Western Europe after the single market takes effect and internal trade barriers are removed.

The increase in consumption in Asia is expected to benefit Australia, primarily. Australia and Brazil are the two leading exporters of iron ore; each accounts for about 30% of the world total, while the next closest exporter accounts for less than 10% of the world total. Of the two, Australia seems to be better placed to take advantage of growth of iron ore consumption in Asia because of Australia's proximity and the consequent lower freight rates.

There is a large potential market for

steel used as framing in the construction industry. There were 1.3 million homes started in the United States in 1993. According to the AISI, 15,000 of the houses were steel framed, up from 500 in 1992. The AISI predicts that 75,000 will be built in 1994. If that growth rate continues, it could have a positive effect on iron ore consumption.

TABLE 1
SALIENT IRON ORE STATISTICS

(Thousand metric tons and thousand dollars unless otherwise specified)

	1989	1990	1991	1992	1993
United States:					
Iron ore (usable,[1] less than 5% manganese):					
Production	59,032	56,408	56,761	55,593	55,661
Shipments	58,299	57,010	56,775	55,569	56,251
Value	$1,939,873	$1,740,925	$1,674,100	$1,732,416	$1,642,841
Average value at mines, dollars per ton	33.27	30.54	29.49	31.18	29.21
Exports	5,365	3,199	4,045	5,055	5,061
Value	$192,796	$124,076	$156,242	$186,864	$166,904
Imports for consumption	19,596	18,054	13,335	12,504	14,097
Value	$522,262	$559,525	$436,777	$395,791	$420,799
Consumption (iron ore and agglomerates)	80,447	76,855	66,366	75,067	76,793
Stocks, Dec. 31:					
At mines, plants and loading docks[2]	[r]4,575	[r]4,795	[r]4,853	[r]3,783	2,504
At receiving docks[3]	15,730	[r]15,911	[r]17,612	[r]16,093	16,548
At consuming plants	2,171	[r]2,273	[r]2,981	[r]2,981	2,288
Total	[r]22,476	[r]22,979	[r]25,446	[r]22,857	21,340
World: Production	[r]1,013,383	[r]984,048	[r]955,552	[r]963,159	[e]988,797

[e]Estimated. [r]Revised.
[1]Direct-shipping ore, concentrates, agglomerates, and byproduct ore.
[2]Excludes byproduct ore.
[3]Transfer and/or receiving docks of Lower Lake ports.

TABLE 2
EMPLOYMENT AT IRON ORE MINES AND BENEFICIATING PLANTS, QUANTITY AND TENOR OF ORE PRODUCED, AND AVERAGE OUTPUT PER WORKER-HOUR IN THE UNITED STATES IN 1993, BY DISTRICT AND STATE

District and State	Average number of employees	Worker-hours (thousands)	Production (thousand metric tons)				Average per worker-hour (metric tons)		
			Crude ore	Usable ore	Iron contained (in usable ore)	Iron content, natural (percent)	Crude ore	Usable ore	Iron contained
Lake Superior:									
Michigan	2,067	3,878	38,810	12,780	8,659	62.3	10.01	3.30	2.23
Minnesota	5,055	10,401	141,453	42,033	26,264	63.5	13.60	4.04	2.53
Total or average[1]	7,122	14,279	180,263	54,814	34,923	63.2	12.62	3.84	2.45
Other States[2]	92	196	643	848	322	59.1	3.27	4.32	1.64
Grand total or average[1]	7,214	14,475	180,906	55,661	35,245	63.1	12.50	3.85	2.43

[1] Data may not add to totals shown because of independent rounding.

[2] Includes California, Missouri, Montana, New Mexico, South Dakota, Texas, and Utah.

TABLE 3
CRUDE IRON ORE[1] MINED IN THE UNITED STATES IN 1993, BY DISTRICT, STATE, AND MINING METHOD

(Thousand metric tons unless otherwise specified and exclusive of ore containing 5% or more manganese)

District and State	Number of mines	Open pit	Underground	Total quantity
Lake Superior:				
Michigan	2	38,810	—	38,810
Minnesota	9	141,453	—	141,453
Total	11	180,263	—	180,263
Other States:				
Missouri	1	—	414	414
Other[2]	4	229	—	229
Total	5	229	414	643
Grand total	16	180,492	414	180,906

[1] Excludes byproduct ore.

[2] Includes California, Montana, New Mexico, South Dakota, Texas, and Utah.

TABLE 4

USABLE IRON ORE PRODUCED IN THE UNITED STATES IN 1993, BY DISTRICT, STATE, AND TYPE OF PRODUCT

(Thousand metric tons and exclusive of ore containing 5% or more manganese)

District and State	Direct-shipping ore	Concentrates	Agglomerates[1]	Total quantity[2]

[1] Less than 1/2 unit.

[2] Sinter made from raw materials supplied by Australia, Brazil, and other countries.

[3] Excludes 12 metric tons of iron oxide-based coloring preparations valued at $7,542, originally reported as fine ores from China. The 1 ton of material from Namibia that was reported in October was part of a meteorite and was valued at $10,881.

[4] Data may not add to totals shown because of independent rounding.

^{e}Estimated. ^{r}Revised.

[1] Table includes data available through Aug. 8, 1994.

[2] In addition to the countries listed, Cuba and Vietnam may also produce iron ore, but definitive information on output levels, if any, is not available.

[3] Insofar as availability of sources permits, gross weight data in this table represent the nonduplicative sum of marketable direct-shipping iron ores, iron ore concentrates, and iron ore agglomerates produced by each of the listed countries. Concentrates and agglomerates produced from imported iron ores have been excluded under the assumption that the ore from which such materials are produced has been credited as marketable ore in the country where it was mined.

[4] Data represent actual reported weight of contained metal or are calculated from reported metal content. Estimated figures are based on latest available iron content reported, except for the following countries for which grades are U.S. Bureau of Mines estimates: Albania and North Korea.

[5] Nickeliferous iron ore.

[6] Reported figure.

[7] Series represent gross weight and metal content of usable iron ore (including byproduct ore) actually produced, natural weight.

[8] Formerly part of Czechoslovakia; data were not reported separately until 1993.

[9] Dissolved Dec. 31, 1992.

[10] Data are for year beginning Mar. 21 of that stated.

[11] Gross weight calculated from reported iron content based on grade of 66% Fe.

[12] Concentrates from titaniferous magnetite beach sands.

[13] Less than 1/2 unit.

[14] Includes manganiferous iron ore.

[15] Includes magnetite ore as follows, in thousand metric tons: 1989—6,594; 1990—5,613; 1991—5,658; 1992—4,647; 1993—4,338.

[16] Includes byproduct ore.

[17] Entry discontinued in 1993. Iron ore used for mineral processing only.

[1] Staged additions are treated at some mining complexes as if they were separate plants. Site data exclude plants that have had no production since 1982. Plants that produce after 1979, but have been continuously idle since 1982, are cited in the footnotes because they could be reactivated at some reasonable cost.

[2] The total for the United States includes the newer part of the E. W. Davis Works at Silver Bay, MN, but not the idled plant owned by Cleveland-Cliffs Inc. at Republic, MI. Cyprus Minerals Co. acquired the cannibalized Silver Bay facility in Aug. 1989 and resumed production in Jan. 1990. Cleveland-Cliffs has been considering reopening its 1.3-million-metric-ton-per-year (Mmt/yr) Republic plant, which has been on care and maintenance since 1981.

[3] Pellets produced from imported direct-shipping ores and/or concentrates.

[4] The older of the two plants operated by A/S Sydvaranger at Kirkenes has been idle since 1986. In addition, 0.50-Mmt/yr plant operated by Norsk Jernverk at Mo-i-Rana was shut down in Jan. 1987 for an indefinite period, leaving only one plant in Norway on-line.

[5] In early 1988, the capacity of the Svappavaara plant was upgraded from 2.8 to 3.5 Mmt/yr. The 0.3-Mmt/yr steel belt plant at Malmberget is used for both research and development purposes as well as ordinary production.

[6] Dissolved in Dec. 1991; however, information is inadequate to formulate reliable estimates for individual countries.

[7] The Skopje plant operated by Rudnici i Zelezara was recently idled.

[8] Excludes the No. 1 pelletizing plant (capacity of 2.4 Mmt/yr) of the Bong Mining Co. The No. 1 plant has been idle since 1980.

[9] The Nador plant operated by Société d'Exploitation des Mines du Rif (SEFERIF) has been idle for several years.

[10] Based on incomplete information.

[11] There is an additional plant with a capacity of 1.8 Mmt/yr at Mandovi in Goa, but it has been closed since 1982. The owner was planning to reopen the facility using high-grade blue dust from the Bellary Hospet area of Karnataka as feed.

[12] There is an additional plant with a capacity of 3 Mmt/yr at Dampier in Western Australia, but it has been closed since 1980.

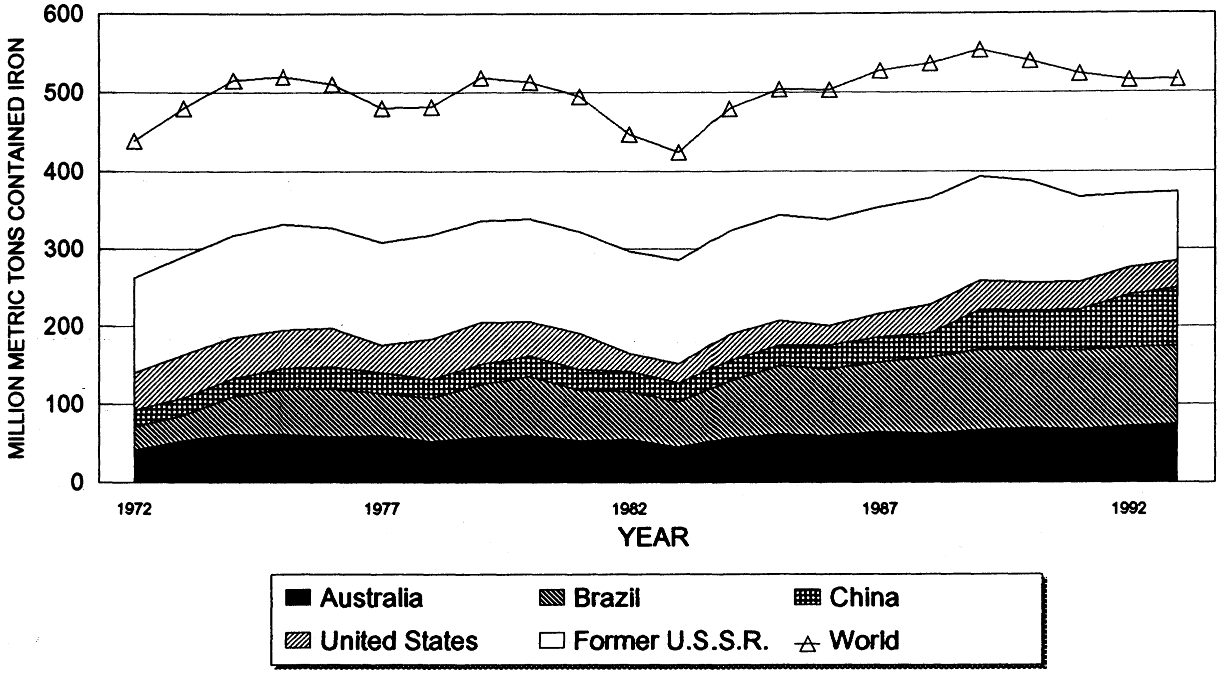
COMPARISON OF U.S. IRON ORE PRODUCTION WITH TOTAL PRODUCTION FOR THE WORLD



IRON AND STEEL

By Gerald W. Houck

Mr. Houck, a physical scientist with 37 years of industry and U.S. Bureau of Mines experience, is the commodity specialist for iron and steel. International data tables were prepared by Harold Willis, international data analyst, and Ted Spittal, international data coordinator. Ferroalloys survey data were prepared by Jo-Ann Sterling, statistical assistant, and David Kulha, management analyst.

Iron and steel are vital to the United States for both national security and economic well-being. They are the basic metals of an industrial society. Although there are many acceptable substitutes for many of their uses, in the short term, there are no practical substitutes on a large scale because of the cost and lack of availability of alternative materials.

Data tables on ferroalloys production and consumption are contained in this chapter. Ferroalloys are alloys of iron that contain a sufficient amount of one or more other chemical elements to be useful as an agent to introduce these other elements into a molten metal, usually steel. The reader is referred to the Annual Reports dealing with specific elements, especially those for chromium, manganese, and silicon, for analysis and detail with respect to the ferroalloys industry.

Consistent with international usage, the U.S. Bureau of Mines is reporting all data on iron and steel in metric units, unless otherwise noted.

This was another poor year for the U.S. steel industry. Despite strong increases in both production and shipments of steel, the industry reported an aggregate loss at the operating income level. Production of raw steel in the United States increased 5.3%, to 88.8 million metric tons, from 84.3 million tons produced in 1992. Net shipments of steel mill products by U.S. companies increased more than 8%, to 80.8 million tons, from 74.6 million tons in 1992.

Imports of steel mill products increased about 14%, to 17.7 million tons, from 15.5 million tons in 1992. Imports captured 18.7% of the apparent consumption of steel mill products, up from 18.0% in 1992. Imports of fabricated steel products, such as fasteners, wire, and fabricated structural steel, totaled 2.1 million tons, representing another 2% of the U.S. steel market.

Exports of steel mill products declined to 3.6 million tons from 3.9 million tons in 1992.

Prices of steel mill products increased slightly in 1993, after declining for the three previous years. The Bureau of Labor Statistics' Producer Price Index for steel mill products increased about 2% to 108.2 (1982 base=100.0).

World production of raw steel in 1993 was 725 million tons, up less than one-half percent from that of 1992. Production in the former U.S.S.R. continued to decline—almost 19% in 1993 alone and over 40% from production levels prior to 1990. Production in Japan was down more than 10%, and production in Western Europe declined about 4%. In China and in the other developing nations of Asia, Africa, and the Middle East, however, growth continued at a vigorous pace; production in China increased 13%.

DOMESTIC DATA COVERAGE

Data regarding U.S. production of iron and steel, and shipments of steel mill products are those reported by the American Iron and Steel Institute (AISI). These data can be regarded as representing 100% of the raw steel producers in the United States.

BACKGROUND

Definitions, Grades, and Specifications

Iron is the most useful and most abundant, as well as the cheapest of the metallic elements. It is also the most versatile and most widely studied and understood. Its many uses are based on the properties of its alloys; iron is never used by itself. Some of its useful alloys include the word "iron;" viz., pig iron, wrought iron, gray iron, malleable iron, ductile iron; others are known as "steel." The term "steel" was originally applied to an alloy of iron that would become very hard if cooled rapidly from a high temperature. Early steelmakers did not know that a carbon content from about 0.3% to about 1% is required for producing these properties, but by trial and error they developed empirical methods to produce metals of the proper carbon content.

Today, iron refers to alloys that contain too much carbon to be formable by forging or rolling. "Pig iron" contains about 4.5% carbon and is useful only for steelmaking or for remelting into cast iron products. Gray iron, malleable iron, and ductile iron are categories of cast iron and are produced by the foundry industry.

In modern terminology, steel refers to an alloy of iron that is malleable at some temperature and contains carbon, manganese, and often other alloying elements. Steel containing only carbon and manganese is called "carbon steel;" steel containing metallic elements such as chromium, molybdenum, or nickel is termed "alloy steel;" steel containing sufficient chromium to confer a superior corrosion resistance is called "stainless steel." Hundreds of individual alloy specifications have been developed to produce combinations of strength, ductility, hardness, toughness, magnetic permeability, and corrosion resistance to meet the needs of modern consumers. These alloy specifications are called "grades."

The malleability property of steel allows it to be produced by rolling or forging into a variety of product forms. Examples of forms include structural shapes (such as beams and angles), rails (such as railroad rails), round bars, wire, various types of pipe and tubular products, and flat-rolled products. In every case, the product is produced on specialized equipment in a range of sizes to suit intended applications.

For some products, metallic or nonmetallic coatings are applied to the product by the steel producer. Additionally, various thermal treatments may be used to meet the customer's requirements.

"Steel mill products" refers to products produced by a steel mill, either by forging or rolling, in the form normally delivered for fabrication or use. Some companies purchase semifinished steel mill products from other steel companies and use these semifinished products to produce steel mill products. To avoid double counting steel mill product shipments under these circumstances, steel mills identify any shipments of steel mill products to other companies that are reporters of steel mill product shipments. The accumulated shipments of all companies, less the shipments to other reporting companies, are identified as "net" shipments.

Regarding the reporting of imports and exports, "fabricated steel products" are products produced from steel mill products, but not including products that incorporate steel products along with other materials. Examples of fabricated steel products are fabricated structural steel and steel fasteners. "Other iron and steel products" refers to products that are not produced from steel mill products. Examples of other iron and steel products include iron or steel castings and direct-reduced iron (DRI).

Industry Structure

Integrated Steel Producers.— Integrated steel producers are those that smelt iron ores to crude liquid iron in blast furnaces and refine the iron, with some scrap, in basic oxygen furnaces, producing liquid steel. The liquid steel is mostly cast into semifinished products in continuous casting machines, although 14% of U.S. production in 1993 was cast in ingot form and subsequently rolled into semifinished form. The integrated steel industry in the United States in 1993 consisted of 15 companies operating ironmaking and steelmaking facilities at 22 locations. Several of these companies also operated nonintegrated plants and/or other steelmaking facilities at the same locations.

The product mix of the integrated producers consists predominantly of flat products: sheet and strip, some of which is galvanized or tin-plated. Some integrated producers made structural shapes and bar products as well, but, for the most part, these products are produced by nonintegrated mills.

Nonintegrated Steel Producers.— Nonintegrated steel producers melt raw materials, primarily scrap, in electric furnaces. Broadly speaking, there are two subcategories of nonintegrated mills: minimills and specialty mills. "Minimills" is a term used to describe steel producers that utilize modern technology in a plant built to produce a limited product line with maximum efficiency. These plants always incorporate electric melting of low-cost raw materials, continuous casting, and a hot-rolling mill, often closely coupled to the casting operation. It was once accepted that minimills produced only simple bar products such as reinforcing bars, wire rods, and small structural shapes. Today, however, minimills have become dominant in all long products, including special quality bars and large structural shapes. In recent years, the minimill concept has been successfully applied to the production of flat-rolled steel with the development of thin-slab (50-mm), continuous casting machines, closely coupled to a hot-strip mill to produce commercial quality hot bands. In the United States, two flat-roll minimill plants utilizing the thin slab casting technology were in operation, and a third plant was under construction. Plans to construct at least four additional similar plants in the United States had been announced.

The largest of the minimill plants have steelmaking capacity greater than that of the smallest of the integrated plants, and at least one of the minimill companies operated multiple minimills with cumulative steelmaking capability exceeding that of all but the largest of the integrated mills.

The second category of nonintegrated mills, specialty mills, is less well defined. Specialty mills definitely include the producers of stainless steel, alloy electrical steel, tool steel, and high-temperature alloys. In addition, this category includes producers of forging ingots and a variety of steel plants that, although not producing a large quantity of steel, are a significant part of what is called "the steel industry."

Overall, the nonintegrated sector of the industry consisted of about 65 companies with 94 raw-steelmaking locations.

Substitutes

Iron, as steel or cast iron, is the most widely used metal in the world because of its high strength-to-cost ratio. In applications where strength is not the major requirement, iron competes with less expensive nonmetallic materials or more expensive materials having some property advantage. Where weight reduction is required, aluminum, plastics, and occasionally magnesium or titanium may be substituted; motor vehicles and airplanes are obvious examples. In construction, concrete, usually reinforced with steel, and wood are frequently substituted for steel. In packaging, steel cans, pails, and household goods were largely replaced with aluminum, glass, plastics, and paper, but drums and other containers used for more severe applications are almost invariably made of steel.

ANNUAL REVIEW

Legislation and Government Programs

Trade Agreements.—From October 1, 1984, until March 31, 1992, the import of steel products into the United States was limited by a program of "Voluntary Restraint Agreements (VRA's)," which were negotiated following an investigation conducted by the U.S. International Trade Commission (ITC) in which imports of certain steel products were found to be a substantial cause of serious injury, or threat thereof, to certain domestic industries. The President determined that imposing countervailing duties under the Trade Act of 1974 was not in the national economic interest and directed the U.S. Trade Representative to negotiate VRA's with countries whose exports to the United States had increased significantly in previous years due to an unfair surge in imports.

Agreements were negotiated with the European Community (EC) and 16 individual nations. Although the structure of the agreements varied from one country to another, each involved an agreement by the foreign Government to limit exports of certain steel products to the United States. To bring the agreements into effect, U.S. steel producers withdrew pending unfair trade petitions, and the U.S. Government suspended antidumping and countervailing duties that were in effect on the products covered by the agreements. The VRA's initially covered a 5-year period ending September 30, 1989. In July 1989, the President announced a "Steel Trade Liberalization Program" extending the VRA program for 2½ years, to terminate March 31, 1992. Negotiations resulted in new agreements with the EC and the 16 other countries.

Anticipating the expiration of the VRA's, the United States, along with more than 30 other countries, has negotiated in an effort to reach a "Multilateral Steel Agreement." The principal U.S. objectives for a multilateral agreement include prohibitions against most subsidies, the elimination of tariff and nontariff barriers to trade, and the establishment of an effective mechanism to resolve disputes. Agreement on the Multilateral Steel Agreement was not reached before the expiration of the VRA's on March 31, 1992.

Following the expiration of the VRA's, some U.S. steel companies filed new countervailing duty and antidumping suits, claiming injury to the domestic steel industry as a result of government-subsidized or unfairly traded steel imported into the United States from numerous countries, including those that have been the source of most of the imported steel in the U.S. market. The most important of these suits were filed on June 30, 1992, dealing with hot-rolled, cold-rolled, and galvanized carbon steel sheets and hot-rolled carbon steel plates. Claims of subsidization were made against imported steel from 13 countries, and claims of unfair trade were made against 20 countries. The countries against whom the charges were filed had exported to the United States more than 5.8 million tons of the covered products during 1991. The products involved are the most important products of the integrated steel companies and account for more than half of all steel products shipped in this country.

To dispose of unfair trade cases such as these, the U.S. Department of Commerce (DOC) is responsible for determining whether there was subsidization or unfair trade, and if so, the value of it in relation to the value of the products imported. This determination establishes the percentage amount of a countervailing duty or antidumping duty that may be assessed. The ITC is responsible for determining whether the subsidization or unfair trade resulted in injury to the U.S. industry.

In these cases, the DOC made preliminary determinations that there was indeed illegal subsidization and unfair trade, and the ITC determined preliminarily that there was injury to the U.S. industry in most of the cases. As a result, effective December 7, 1992, in the subsidy cases, and effective February 6, 1993, in the antidumping cases, importers of the covered products were required to make cash deposits or to post bond equal to the amount of the estimated dumping margins. Recovery of the deposit or bond is subject to final calculation of the duties and to a final determination of injury by the ITC. The duties are determined and applied on a company-specific basis and differ widely. For example, the duties for hot-rolled plate range from 1.47% to 109.22%.

The International Trade Commission announced its final determination on the question of injury on July 27, 1993. The result was mixed. The Commission found that the U.S. industry was being harmed by virtue of imports of plate products from Belgium, Brazil, Canada, Finland, Germany, Mexico, Poland, Romania, Spain, Sweden and the United Kingdom, and corrosion-resistant (galvanized) product from Australia, Canada, France, Germany, Japan, and the Republic of Korea. In the case of cold-rolled steel products, injury to the U.S. industry was found only as a result of imports from Germany, the Republic of Korea, and the Netherlands; imports from 10 other countries that had been determined to be either illegally subsidizing or unfairly pricing their products were determined to be causing no injury to U.S. industry.

The most disappointing decision for the U.S. steel companies was the Commission's decision that there was no injury in any of the cases involving hot-rolled carbon steel flat products, the highest volume category under investigation. The commission decided that the total U.S. market for hot-rolled products includes hot-rolled steel used internally by steel companies to produce cold-rolled, corrosion-resistant, and other coated steel products. The steel companies had argued that the market for hot-rolled steel includes only product sold as hot-rolled to unrelated customers. By the Commissioners' reasoning, the market was much larger; as a result, the impact of the unfairly traded product was deemed insufficient to injure the domestic industry.

In the cases for which injury was affirmed by the Commission, the duties were effective for imports on or after December 7, 1992, in the countervailing duty cases and February 4, 1993 in the unfair pricing cases. Imports of the products under investigation were unusually high during the period immediately preceding February 4, as importers had rushed as much material as possible into the country to avoid the threatened duties. From February 4 until the date of the decision, exports of the products under investigation from the countries charged with unfair pricing or countervailable subsidies essentially stopped; however imports of the same products from other nations not charged in the suits began to increase.

Following the decisions, imports commenced again, but at a more moderate level, because of the risk that the Commission's decisions would be overturned on appeal to the U.S. Court of International Trade. Imports continued from the non-traditional supplier nations. Overall, imports of finished steel products in 1993 were about the same as during 1992.

Research Programs.—The U.S. Department of Energy continued its research and development efforts under the Steel and Aluminum Energy Conservation and Technology Competitiveness Act of 1988, commonly known as the Metals Initiative. Work continued on six projects in steel processing carried over from prior years, and a seventh project was selected for inclusion in the program. A requirement of the program is that industry sponsors provide cost-sharing contributions equal to a minimum of 30% of the total cost of any project.

The most notable of the steel projects was the Direct Steelmaking Project, managed and jointly sponsored by AISI. The objective of the project was to develop a coal-based, energy efficient, economically competitive direct steelmaking process. The advantages of such a process would be: (1) more effective use of domestic raw materials; (2) continuous, rather than batch operations; (3) elimination of coke and the environmental impacts related to coke; (4) ease of startup and shutdown; and (5) facilitation of incremental capacity increases and adaptation to market conditions by modular design.

The process being investigated was an in-bath smelting process, coupled to continuous refining. Coal is injected into a molten bath of partially reduced iron ore, and the key to the success of the process is the efficient use of the energy of the gases generated. The carbon in the coal is a reductant for the iron ore and a source of thermal energy. Carbon monoxide is released, which must be partially combusted within the vessel to provide heat for the process. The partially combusted smelter off-gas also serves as the fuel and the reductant for a prereduction furnace to produce hot wustite pellets from hematite. During fiscal year 1993, a pressurized pilot smelting vessel with offgas treatment and dust recycling facilities was installed in place of the original horizontal smelter. Initial operation showed promise by achieving the expected efficiency improvement. Based on the success of the research to date, a steel company has submitted a proposal to construct such a plant.

The Direct Steelmaking Project has many features in common with other processes under investigation in other countries. See discussion under Technology in this report.

The Department of Energy agreed to support a new project at the pilot smelter plant, also with joint sponsorship from AISI. It is entitled Steel Plant Waste Oxide Recycling and Resource Recovery by Smelting. This project is aimed at developing a process to recover the more than 3 million tons of blast furnace and basic oxygen furnace dusts and the 0.5 million tons of rolling mill sludge that the steel industry generates each year. The project is scheduled to be completed in fiscal year 1995.

Other steel-related projects that were studied within the Metals Initiative included (1) Development of Superplastic Steel Processing to enable complex parts to be forged from a single large piece of metal. This project is managed by Lawrence Livermore National Laboratory, with cost-sharing by Caterpillar, Inc. and North Star Steel Co.; (2) Electrochemical Dezincing of Steel Scrap, by Argonne National Laboratory with cost-sharing by Metal Recovery Industries (U.S.), Inc. In fiscal 1993, a pilot plant in East Chicago, IN, was used to dezinc more than 600 tons of automotive stamping plant galvanized steel scrap, with more than 90 percent effectiveness in removing zinc. (3) Direct Strip Casting, under investigation by Armco Inc. with additional sponsorship by Westinghouse Electric Corp. and North American Refractories. During 1993, modifications were made to the caster which resulted in greater strip thickness and improved quality. Nonetheless, Armco withdrew from the project and the research is being brought to an orderly conclusion. (4) Rapid Analysis of Molten Metal Using Laser Produced Plasma, at Lehigh University, with sponsorship by AISI, the Electric Power Research Institutes (EPRI), and an industrial consortium of nine companies. The objective this program was to develop a probe that can be immersed in molten steel to produce an elemental analysis in less than one minute. Current practice requires removal of a molten sample, which must be frozen and analyzed in a laboratory, a sequence that requires a minimum of 4 to 8 minutes. (5) The final project, named Advance Process Control for the Steel Industry, is to develop sensor and control system technology to improve quality, reduce energy consumption, and reduce costs of steel production. The program, cosponsored by AISI, comprises six separate projects, conducted collaboratively by national laboratories, universities and private companies. The six projects address various steelmaking phases from primary steelmaking through finish processing.

The Department of Energy announced that it had selected for funding under its Clean Coal Technology Program a project to demonstrate a new process to produce both electric power and pig iron from a range of U.S. coals and iron ores. The

Clean Coal Technology Program provides funding to demonstrate new technologies for the environmentally sound and efficient use of coal. The project, proposed by Centerior Energy Corporation, would demonstrate the COREX direct ironmaking process, developed by Deutsche Voest-Alpine Industrieanlagenbau GMBH (DVAI,) and the production of power from a combined cycle powerplant fueled by the export gas from the COREX process. Other sponsors of the proposed project were the LTV Steel Company, at whose plant the demonstration project would be built; DVAI; Air Products and Chemicals, Inc.; and EPRI. The total estimated project cost was $825 million, with DOE to provide $150 million and the corporate sponsors $675 million. The proposed plant would produce 2,900 metric tons per day of pig iron plus 150 megawatts of electric power.

Production

Production of raw steel in the United States increased 5.3%, to 88.8 million metric tons, from 84.3 million tons produced in 1992. Raw steel production capability was estimated by AISI as 99.7 million tons, down from 102.6 million tons in 1992. Production in 1993 represented 89.1% of estimated capability, compared with 82.2% in 1991.

Net shipments of steel mill products by U.S. companies increased about 8%, to 80.8 million tons, from 74.6 million tons in 1992.

Electric arc furnace steelmaking was utilized for 34.9 million tons, 39.4% of total steelmaking in 1993. Basic oxygen steelmaking was utilized for 53.8 million tons, 60.6% of raw steel production, compared with 52.3 million tons and 61.6% of production in 1992.

The trend toward the use of continuous casting continued. Continuous casting production was 76.1 million tons, 85.7% of production, compared with 66.9 million tons, 79.3% in 1992.

Consumption and Uses

Shipments of steel mill products by U.S. companies were up 8.2%, to 80.8 million tons, but export shipments continued to drop; exports were down 20% from those of 1992. Shipments to domestic customers were up more than 9%. Shipments to the largest single end-use market—the automotive market—were up 15%, appliances were up 6%, service centers and distributors increased 11%, and construction products rose about 10%.

Shipments of steel for containers, packaging, and shipping materials increased 10%, reversing a two-year decline in shipments to this market area.

Shipments for oil and gas drilling, mining, quarrying, and lumbering were about the same as the 1992 level, as were shipments for industrial and agricultural machinery, equipment, and tools.

Markets and Prices

Prices for steel mill products, which had declined for 3½ years, reached a nadir in December 1992 and increased steadily through 1993. On a year-to-year average basis, the Bureau of Labor Statistics' Producer Price Index for steel mill products was up by only 2% in 1993 at 108.2 (1982 base=100), but the increase during the year, from the low of 105.1 in December 1992 through 111.1 in December 1993, was 5.7%. Additional price increases were announced, effective in January 1994, and the outlook was for further price increases in 1994.

Foreign Trade

Exports of steel mill products declined to 3.6 million tons, from 3.9 million tons in 1992. Canada was again the nation receiving the largest amount of U.S. exported steel, 1.5 million tons, with Mexico again in second place, receiving 0.9 million tons. Exports to Mexico were down from 1.3 million tons in 1992; the decline in exports to Mexico exceeded the overall decline in exports.

Imports of steel mill products increased to 17.7 million tons from 15.5 million tons in 1992, an increase of about 14%. Brazil, Canada, the European Union (EU), and Japan were major sources for steel mill product imports. Increased imports from the EU accounted for almost all of the year-to-year increase. Imports from Japan and the Republic of Korea actually decreased, with imports from Japan dropping 33 percent to the lowest level in 30 years.

An important development in 1993 was a marked increase in the tonnage of imported semifinished steel. During the period 1985 through 1992, imports of semifinished steel had been about 2 million metric tons per year. This steel, primarily in the form of slabs suitable for rolling into sheet or plate mill products, was imported and utilized mostly by companies that lack their own steelmaking facilities. In 1993, imports of semifinished steel increased to 4.5 million tons, but almost all of the increased tonnage is believed to have been imported by companies within the steel industry itself to supplement their steelmaking capacity. Excluding this major increase in imports of semifinished steel, steel mill product imports in 1993 were 13.2 million tons, slightly less than in 1992.

The increase in imports of semifinished steel by steel companies must be taken into consideration in evaluating total consumption of steel mill products in the United States and the share of the market represented by imported steel. To avoid counting both the imported semi-finished steel and the products produced from it, it is necessary to subtract from domestic consumption the amount of semifinished steel consumed by companies that also produce raw steel. For 1993, this amount is estimated to have been 2.5 million tons. For years prior to 1993, the amount was less than 0.5 million tons per year. Therefore, the share of the U.S. steel market represented by imported steel was 19% in 1993.

World Review

World production of pig iron and DRI in 1993 totaled 527.9 million tons, an increase of 2% compared with that of 1992. Production increased about 1% in Japan and was down about 1% in the EU. In the eastern European states that were formerly part of the communist bloc, excluding those that were part of the former U.S.S.R., production was about the same as in 1992, ending the 40% slide in production that began in 1990. The steel—producing countries of this region are Bulgaria, the Czech Republic, Hungary, Poland, Romania, and Slovakia.

In the countries that were formerly part of the U.S.S.R., however, the decline in steel production continued and also represented about a 40% drop from production prior to 1990. Kazakhstan, Russia, and Ukraine account for almost all the steel production in this region.

Production of pig iron in China increased about 21% to an estimated 87.3 million tons. This year, China stands as the top pig iron-producing nation in the world. The Republic of Korea and Taiwan are other major iron-producing nations that achieved double-digit growth in 1993. Australia and India showed continued growth.

Direct-Reduced Iron.—World production of DRI increased to almost 24 million tons in 1993, with a 14% increase in the latest year and 65% during the past 5 years. Direct reduction of iron ore has proved to be a cost-effective way for developing countries, especially those with an abundance of natural gas, to encourage economic growth.

World capacity for DRI production was estimated to be 37 million tons, with an additional 3 million tons under construction. In India, one gas-based plant and several small coal-based DRI plants were started up, bringing India's capacity for DRI to 3.6 million tons. An additional 1.8 million tons of capacity is under construction in India, with completion planned for 1994 and 1995.

In Iran, about 1.7 million tons of capacity was started up in 1992; an additional 1 million tons was added in 1993, and 1.8 million tons is scheduled for 1994, which would bring Iran's total capacity for DRI to 5.8 million tons.

Gas-based plants were started up in Malaysia (1.2 million tons) and Indonesia (0.6 million tons.)

A United States minimill company began construction of a gas-based direct-reduction plant in Trinidad. The plant will utilize a technology never before used in a production scale operation, and produce a unique form of DRI in which all of the reduced iron (excluding about 7% or 8% of the iron that remains in oxide form in all DRI products) will be in the form of iron carbide (Fe_3C), rather than in elemental form. The resultant product, which will be called "iron carbide," will be imported to the United States to serve as a high-quality charge material for the production of flat-rolled products in the minimills operated by the company.

Steel.—World production of steel was 725.1 million tons, up slightly from that of 1992. The world picture, however, was mixed, with strong growth in the Pacific rim nations of Australia, China, India, the Republic of Korea, and Taiwan and moderate growth in Latin America and North America, offset by continued collapse in the newly independent states of the former U.S.S.R. The 12 newly independent states had combined steel production of 96 million tons, down 19% from that of 1992. As recently as 1989, the U.S.S.R. had produced more than 160 million tons of raw steel.

In the former Soviet satellite states of Eastern Europe, the slump in steel production was arrested, with 1993 production of 29 million tons, about equal to that of 1992. The six nations of this region—Bulgaria, Czech Republic, Hungary, Poland, Romania and Slovakia—had produced about 52 million tons of raw steel in 1989.

The most interesting development has been the explosive growth in steel demand and production in China. In 1993, raw steel production increased almost 10% to 88.7 million tons. China, during this decade, has achieved the status of one of the world's largest producers of steel, with tonnage output rivaling that of the United States and Japan. Moreover, the expansion of China's steel industry has been based on internal demand; in addition to its own output, China imported over 30 million tons of steel mill products in 1993.

Production of steel continued to increase in the Republic of Korea. This nation is also experiencing high internal growth, but in contrast to China, much of Korea's steel output is exported.

OUTLOOK

The outlook for 1994 is for further declines in pig iron and steel production in the newly independent states of the former U.S.S.R. Strong growth is expected to continue in China, the Republic of Korea, the Far East, and the Middle East. The major economies of the EU are recovering from a recession, and European steel production is likely to increase. In Japan, production should recover from the depressed levels of 1993.

For the long term, little growth of steel consumption is expected in the United States or countries with highly developed economies. Steel consumption tends to expand much more slowly than overall economic growth and to contract when economic growth is weak. The outlook for the U.S. steel industry is more uncertain. Imports have tended to capture an increasing share of the U.S. market, except when restrained by such devices as VRA's. Even though U.S. companies have made great progress in modernizing their mills, adopting efficient technology, and reducing their costs, they have been unable to achieve profitability due to persistently low prices caused by intense competition by foreign and domestic producers.

An important part of the competition to the integrated U.S. steel industry is that posed by minimills producing flat-rolled steel. As described earlier, one steel company, Nucor Corp., has demonstrated that flat-rolled steel can be produced in a minimill at lower cost than that attainable by the integrated process.

Buoyed by the success of its first plant, in Crawfordsville, IN, Nucor started up a second flat-roll minimill, in Hickman, AR, in 1992. Based on further success with the new processes, Nucor has doubled the capacity of the two plants, to a total of 4 million tons, and announced the intention to build two more plants, either alone or in joint venture with others, increasing its capacity to 8 million tons. Other companies, noting Nucor's success and optimism about the possibilities of minimill production of flat-rolled steel, have announced similar intentions.

Some observers of the industry predict that as much as 20 million tons of capacity will be built by about the year 2000. With little or no growth in the market, any new capacity will have to displace either imports or integrated production from the U.S. market.

The supply of raw material for increased minimill production may become a problem in the United States. Although the United States traditionally has an excess supply of scrap and is a net exporter of about 9 million tons per year, the supply of low-residual scrap necessary to produce flat-rolled steel and some other products may not be adequate. As noted in the section on DRI, imports of DRI are increasing. In early 1993, Nucor announced that it will construct a plant in Trinidad to produce iron carbide, a form of DRI, for use in its U.S. plants. The plant will have a capacity of about 300,000 tons per year. Other minimill operators and iron ore producers are reported to be considering direct-reduction plants to provide the necessary supply of low-residual raw materials for the growing flat-roll minimill sector of the industry.

Pig iron	489	314	—	—	—
Direct-reduced iron	2,773	[r]3,085	4,050	4,300	4,800
Yugoslavia[12]	2,899	2,313	[e]1,600	—	—
Zimbabwe[e]	[r]525	521	[r]535	[r]507	500
Grand total	[r]561,762	[r]550,077	[r]525,741	[r]517,278	527,907
Of which:					
Pig iron	[r]545,207	[r]531,917	[r]506,328	[r]496,395	504,091
Direct-reduced iron	16,555	[r]18,160	19,413	[r]20,883	23,816

[e]Estimated. [r]Revised.

[1] Production is pig iron unless otherwise specified.

[2] Direct-reduced iron is obtained from ore by reduction of oxides to metal without melting.

[3] Table excludes ferroalloy production except where otherwise noted. Table includes data available through July 21, 1994.

[4] In addition to the countries listed, Vietnam has facilities to produce pig iron and may have produced limited quantities during 1989-93, but output is not reported and available information is inadequate to make reliable estimates of output levels.

[5] Less than 500 tons.

[6] Reported figure.

[7] Formerly part of Czechoslovakia; data were not reported separately until 1993.

[8] Dissolved Dec. 31, 1992.

[9] Includes blast furnace ferroalloys.

[10] All production in the U.S.S.R. from 1989-91 came from Russia.

[11] Dissolved in Dec. 1991.

[12] Dissolved in Apr. 1992.

TABLE 12—Continued

RAW STEEL:[1] WORLD PRODUCTION, BY COUNTRY[2]

(Thousand metric tons)

Country[3]	1989	1990	1991	1992	1993[e]
Venezuela	2,941	3,176	3,119	3,200	3,250
Vietnam	[r]84	[r]102	[r]142	[r]175	190
Yugoslavia[10]	[r]4,383	[r]3,835	[r]2,139	—	—
Zimbabwe	650	580	[r]581	[r]547	400
Total	[r]784,092	[r]771,373	[r]736,424	[r]722,384	725,129

[e]Estimated. [r]Revised.

[1] Steel formed in first solid state after melting, suitable for further processing or sale; for some countries, includes material reported as "liquid steel," presumably measured in the molten state prior to cooling in any specific form.

[2] Table includes data available through July 21, 1994.

[3] In addition to the countries listed, Burma, Ghana, and Mozambique are known to have steelmaking plants, but available information is inadequate to make reliable estimates of output levels.

[4] Data are for year ending June 30 of that stated.

[5] Excludes castings.

[6] Reported figure.

[7] Formerly part of Czechoslovakia; data not reported separately until 1993.

[8] Dissolved on Dec. 31, 1992. Production in Czechoslovakia from 1989-92 came from the Czech Republic and Slovakia.

[9] Dissolved in Dec. 1991.

[10] Dissolved in Apr. 1992.

TABLE 13

GOVERNMENT INVENTORY OF FERROALLOYS, DECEMBER 31, 1993

(Metric tons of alloy, unless otherwise stated)

Alloy	Stockpile grade	Nonstock pile grade	Total
Ferrochromium:			
High-carbon	739,526	621	740,147
Low-carbon	273,945	11,560	285,505
Ferrochromium-silicon	51,699	1,242	52,941
Ferrocolumbium (kilograms contained columbium)	271,434	150,820	422,254
Ferromanganese:			
High-carbon	986,351	—	986,351
Medium-carbon	23,617	—	23,617
Ferrotungsten (kilograms contained tungsten)	385,404	532,732	918,136
Silicomanganese	209	—	209

TABLE 14
PRODUCERS OF FERROALLOYS IN THE UNITED STATES IN 1993

Producer	Plant location	Products[1]	Type of furnace
FERROALLOYS (except ferrophosphorus)			
AMAX Inc., Climax Molybdenum Co. Div.	Langeloth, PA	FeMo	Metallothermic.
American Alloys, Inc.	New Haven, WV	FeSi, Si	Electric.
Applied Industrial Minerals Corp. (AIMCOR)	Bridgeport, AL	FeSi	Do.
Astech Corp.	Wenatchee, WA	Si	Do.
Bear Metallurgical Inc.	Butler, PA	FeMo, FeV	Metallothermic.
Cabot Corp.	Revere, PA	FeCb, NiCb	Do.
Cyprus Minerals Co.	Green Valley, AZ	FeMo	Do.
Elkem A/S, Elkem Metals Co.	Alloy, WV, Ashtabula, OH, Marietta, OH, Niagara Falls, NY	FeB, FeCr, FeMn, FeSi, Mn, Si, SiMn, other[2]	Electric and electrolytic.
Galt Alloys Inc.	Canton, OH	FeTi, FeAl	Electric.
Glenbrook Nickel Co.	Riddle, OR	FeNi	Do.
Globe Metallurgical Inc.	Beverly, OH, Selma, AL, Springfield, OR	FeSi, Si	Do.
HTP Co.	Sharon, PA	FeTi	Metallothermic.
Keokuk Ferro-Sil Inc.	Keokuk, IA	FeSi, silvery pig iron	Electric.
Kerr-McGee Chemical Corp.	Hamilton (Aberdeen), MS	Mn	Electrolytic.
Macalloy Corp.	Charleston, SC	FeCr	Electric.
Metallurg Inc., Shieldalloy Metallurgical Corp.	Cambridge, OH, Newfield, NJ	Cr, FeAl, FeB, FeCb, FeTi, FeV, other[2]	Electric and metallothermic.
Reading Alloys Inc.	Robesonia, PA	FeCb	Metallothermic.
Satra Concentrates	Steubenville, OH	FeCr, FeCrSi	Slag conversion.
Simetco	Montgomery, AL	Si	Electric.
SKW Alloys Inc.	Calvert City, KY, Niagara Falls, NY	FeCr, FeCrSi, FeSi, Si	Do.
Strategic Minerals Corp. (STRATCOR), U.S. Vanadium Corp.	Niagara Falls, NY	FeV	Do.
Teledyne Inc., Teledyne Wah Chang, Albany Div.	Albany, OR	FeCb	Metallothermic.
FERROPHOSPHORUS			
FMC Corp., Industrial Chemical Div.	Pocatello, ID	FeP	Electric.
Monsanto Co., Monsanto Industrial Chemicals Co.	Soda Springs, ID	do.	Do.
Occidental Petroleum Corp.	Columbia, TN	do.	Do.

[1] Cr, chromium metal; FeAl, ferroaluminum; FeB, ferroboron; FeCb, ferrocolumbium; FeCr, ferrochromium; FeCrSi, ferrochromium-silicon; FeMn, ferromanganese; FeMo, ferromolybdenum; FeNi, ferronickel; FeP, ferrophosphorus; FeSi, ferrosilicon; FeTi, ferrotitanium; FeV, ferrovanadium; FeW, ferrotungsten; FeZr, ferrozirconium; Mn, manganese metal; NiCb, nickelcolumbium; Si, silicon metal; SiMn, silicomanganese.

[2] Includes specialty silicon alloys, zirconium alloys, and miscellaneous ferroalloys.

TABLE 15
U.S. FERROALLOY PRODUCTION[1] AND SHIPMENTS[2] IN 1993

(Metric tons, gross weight, unless otherwise specified)

	1993		
	Net production	Net shipments	Stocks, December 31
Ferrophosphorus	17,795	35,565	8,088
Ferrosilicon[3]	323,351	329,635	75,719
Silicon metal	158,570	164,400	6,630
Other[4]	215,716	213,818	54,978
Total	715,432	743,418	145,415

[1] Does not include alloys produced for consumption in the making of other ferroalloys.
[2] Gross sales (including exports) minus purchases.
[3] Includes all regular and specialty grades of ferrosilicon, excluding silvery pig iron.
[4] Includes ferroaluminum, ferroboron and other complex boron additive alloys, all chromium-containing ferroalloys and chromium metal, ferrocolumbium, all manganese-containing ferroalloys and manganese metal, ferromolybdenum, ferronickel, ferrotitanium, ferrovanadium, and silvery pig iron.

TABLE 16
REPORTED U.S. CONSUMPTION OF FERROALLOYS AS ADDITIVES IN 1993, BY END USE[1]

(Metric tons of alloys unless otherwise specified)

End use	FeMn	SiMn	FeSi	FeTi	FeP	FeB

TABLE 21—Continued
FERROALLOYS: WORLD PRODUCTION, BY COUNTRY, FURNACE TYPE, AND ALLOY TYPE[1]

(Metric tons)

---

[e] Estimated. [r] Revised. W Withheld to avoid disclosing company proprietary data; included with "Other."

[1] Table includes data available through Aug. 15, 1994.

[2] To the extent possible, ferroalloy production of each country has been separated according to the furnace type from which production is obtained; production derived from metallothermic operations is included with electric furnace production.

[3] To the extent possible, ferroalloy production of each country has been separated so as to show individually the following major types of ferroalloys: spiegeleisen, ferromanganese, silicomanganese, ferrosilicon, silicon metal, ferrochromium, ferrochromium-silicon, and ferronickel. Ferroalloys other than those listed that have been identified specifically in sources, as well as those ferroalloys not identified specifically but which definitely exclude those listed previously in this footnote have been reported as "Other." Where one or more of the individual ferroalloys listed separately in this footnote have been inseparable from other ferroalloys, owing to a nation's reporting system, deviations are indicated by individual footnotes.

[4] Reported figure.

[5] Includes silicomanganese.

[6] Included with other.

[7] Formerly part of Czechoslovakia; data were not reported separately until 1993.

[8] Includes ferrochromium-silicon and ferronickel, if any was produced.

[9] Includes silicospiegeleisen.

[10] Includes ferronickel if any was produced.

[11] Hungary is believed to produce some blast furnace ferromanganese.

[12] Series excludes calcium silicide.

[13] Includes ferrochromium-silicon.

[14] Includes calcium-silicon, ferrocolumbium, ferromolybdenum, ferrotungsten, ferrovanadium, and other ferroalloys.

[15] Imports of ferronickel originating in Macedonia were reported in 1992 and 93, but information on the output of the Kavadarci operation was not available.

[16] Estimated figures based on reported exports and an allowance for domestic use.

[17] May include ferrosilicon-chromium and ferronickel, if any was produced.

[18] Includes production from Bophuthatswana. Includes net production of ferrochromium-silicon, if there was any.

[19] Dissolved in Dec. 1991.

[20] Soviet production of electric furnace ferroalloys is not reported; estimates provided are based on crude source material production and availability for consumption (including estimates) and upon reported ferroalloy trade, including data from trading partner countries.

[21] U.S. output of ferrochromium includes high- and low-carbon ferrochromium, ferochromium-silicon, chromium metal, and other chromium materials.

[22] U.S. output of ferromanganese includes silicomanganese and manganese metal.

[23] Dissolved in Apr. 1992.

[24] Spiegeleisen for the western states of Germany is included with blast furnace ferromanganese.

[25] Ferromanganese includes silicomanganese (if any was produced) for countries carrying footnote 6 on "Ferromanganese" data line.

[26] U.S. production under "Other" for 1989-93.

[27] Includes silicospiegeleisen for France.

[28] Ferrochromium includes ferrochromium-silicon (if any was produced) for Japan, the Republic of South Africa, and the United States.

LEAD

By Gerald R. Smith

Mr. Smith, a physical scientist with 30 years of research and commodity experience with the U.S. Bureau of Mines, has been the acting commodity specialist for lead since March 1994. Domestic survey data were prepared by Fred Zeleznik and Lisa Conley, statistical assistants; and international data were prepared by Virginia Woodson, international data coordinator.

Domestic lead mine production declined by about 11% in 1993, continuing a 3-year decline in production. Missouri remained the dominant producing State with a 78% share, and Alaska, Idaho, and Montana contributed an additional 20%. Lead was produced at about 20 mines, employing approximately 1,500 people. The value of domestic mine production was approximately $250 million. Primary lead was processed at two smelter-refineries in Missouri, a smelter in Montana, and a refinery in Nebraska. About 82% of secondary lead was produced at 29 plants with annual capacities of 6,000 tons or more.

Legislation that would affect both primary and secondary lead producers was reintroduced in the U.S. House of Representatives in 1993. The legislation, entitled "The Lead-Based Paint Hazard Trust Fund Act of 1993," essentially a revamping of a 1992 bill, proposed a unitary tax of 45 cents per pound on all primary and secondary lead produced domestically and imported. The intent of this legislation was to provide a dedicated revenue of $1 billion per year for use in protecting against lead-based paint hazards in accordance with Title 10 of the Housing and Community Development Act of 1992. By yearend 1993, no significant advancement of this bill had occurred.

Lead was consumed in about 200 plants in the manufacture of end-use products, including batteries, ammunition, covering for power and communication cable, building construction materials, and solders for motor vehicles, metal containers, and electrical and electronic components and accessories.

Lead-acid batteries continued to be the overwhelmingly dominant use of lead, accounting for about 83% of reported lead consumption in 1993. The Battery Council International (BCI) reported a 1993 starting-lighting-ignition (SLI) battery production of 86.0 million units. This total includes both original equipment market and replacement market automotive-type batteries. An estimated 815,000 tons of lead were consumed in SLI batteries in 1993.

Disposals of lead from the National Defense Stockpile (NDS) took place for the first time since 1975, following passage of the FY 1993 Defense Authorization Bill (Public Law 102-484) in October 1992. The Bill provided for the eventual disposal of all the approximately 545,000 metric tons of refined lead now held in the NDS. Total sales of lead from the NDS during 1993, after sales were begun in June, amounted to about 35,000 metric tons.

London Metal Exchange (LME) and North American producer average prices in December 1993 were $0.003 per pound and $0.013 per pound, respectively, above those in the final month of 1992. A modest increase in prices occurred in the last half of the year, but the average LME and North American producer prices for 1993 were down by $0.036 and $0.034 per pound, respectively, compared with those of 1992.

Lead was mined in 51 countries, of which the top five accounted for 56% of the world total of 2,926 million tons. Australia was the largest producer, with 17% of the world total, followed by China (14%), the United States (12%), Peru (7%), and Canada (6%).

The world reserve base for lead was estimated by the U.S. Bureau of Mines at 130 million tons, and the world reserves at 63 million tons. Australia had about 27% of the reserve base and 16% of the reserves. The United States had about 17% of the reserve base and 16% of the reserves.

DOMESTIC DATA COVERAGE

Domestic data for lead are developed by the U.S. Bureau of Mines from five voluntary surveys. Typical of these are the combined secondary producer and consumer surveys, both monthly and annual. Of the 191 consuming companies to which a survey request was sent, 143 responded, representing 82% of the total U.S. lead consumption shown in tables 1, 6, 7, and 8. Of the 38 companies producing secondary lead, exclusive of copper base, to which a survey request was sent, 26 responded, representing 80% of the total refinery production of secondary lead, shown in tables 1, 5, and 9. Production and consumption for the nonrespondents were estimated using prior-year levels adjusted for general industry trends. *(See table 1.)*

BACKGROUND

Lead is a soft, heavy metal, the most corrosion resistant of the common metals, and one of the oldest metals used by man. Among the nonferrous metals, in terms of tonnage, demand for lead is surpassed only by demand for aluminum, copper, and zinc. Some historians have theorized that the downfall of the Roman Empire was expedited by the debilitating effects on its citizens of drinking water carried in lead pipes. Buildings built in Europe four centuries ago still stand under their original lead roofs. Today's major use of lead is in lead-acid storage batteries. The electrical systems of vehicles, ships, and aircraft depend on such batteries for startup, and in some cases, batteries provide the actual motive power. Other batteries provide standby electrical power for emergencies, and very large lead-acid systems are designed to provide "peaking" power in such applications as commercial power networks and subway systems. An increasing use is in the uninterruptible power supply systems necessary for voltage control and emergency power in critical computer storage systems. Lead in gasoline, once the second largest use of lead in the United States, has been phased out to eliminate the health hazard it was found to present. Some nontransportation applications of lead include increasing use for soundproofing in office buildings, schools, and hotels and earthquake shock dampening in building foundations. It is widely used in hospitals to block X-ray and gamma radiation and is employed to shield against nuclear radiation both in permanent installations and when radioactive source material is being stored and/or transported.

ANNUAL REVIEW

Legislation and Government Programs

Authorization providing for the disposal of the entire 601,162 short tons (st) (545,365 metric tons (mt)) of refined lead held in the National Defense Stockpile (NDS) was included in the FY 1993 Defense Authorization Bill passed on October 23, 1992. Subsequently, the Annual Materials Plan (AMP) for FY 1993, submitted to the Congress by the Department of Defense (DoD), proposed the sale of 52,000 st (47,174 mt) of lead. Actual sales of lead from the NDS were begun in June 1993. By the end of FY 1993, September 30, 1993, the quantity of refined lead sold from the NDS was 22,174 st (20,116 mt). For FY 1994, beginning October 1, 1993, the DoD proposed the sale of an additional 35,000 st (31,751 mt) of lead. Further sales of lead in the first three months of FY 1994 amounted to 16,338 st (14,822 mt), leaving about 562,000 st (510,000 mt) of lead in the NDS by yearend 1993.

Pending completion of rulemaking pertaining to the use of lead solder in food cans, the Food and Drug Administration (FDA) announced emergency action on April 1, 1994, to limit lead levels in the food packaged in such cans. Specifically, the FDA action set permissible levels of 80 parts per billion (ppb) for lead in fruit beverages, such as juices, nectars, and drinks packed in lead-soldered cans, and 250 ppb for all other foods packed in lead-soldered cans.

Subsequent to the emergency action relating to lead-soldered food cans, the FDA issued its proposed rulemaking on the use of lead-soldered food cans on June 21, 1993. In that rule, the FDA proposed to prohibit the use of lead solder in cans that contained food, applying the rule to both domestic and imported foods. The FDA tentatively concluded that available toxicological and lead exposure data demonstrated that this use of lead may be injurious to human health. Furthermore, the FDA proposed to revoke any "prior sanction" that may exist for the use of lead in metal food packaging. FDA defined "prior sanction" as an "explicit approval granted with respect to use of a substance in food prior to September 6, 1958," the date of enactment of the Food Additives Amendment. Before that date, the FDA had approved specific uses of various food-contact materials or food ingredients by issuing letters and statements indicating that, in FDA's view, these substances "were not considered unsafe," "did not present a hazard," or "were not objected to for use."

In related action on lead in food packaging, the FDA withdrew its earlier published rulemaking proposals to establish tolerance levels (December 6, 1974) and action levels (August 31, 1979) for lead in evaporated milk products. FDA's action, published on June 21, 1993, was prompted by the fact that the evaporated milk industry had not only improved its product handling during the last decade to limit lead contamination in these products, but also had converted its production facilities from the use of lead-soldered venthole cans to the use of lead-free welded cans in 1986.

On June 22, 1993, revised legislation pertaining to the "Lead-Based Paint Hazard Abatement Trust Fund" was introduced in the U.S. House of Representatives. The revised legislation proposed a unitary tax of 45 cents per pound on all primary and secondary lead produced domestically and imported, whereas prior "Trust Fund" legislation introduced in 1991 had proposed the imposition of a 75 cents per pound tax on all primary lead and a 37 cents per pound tax on all secondary lead. The original legislation was restructured because of concerns that were raised by the Joint Tax Committee and witnesses during hearings held in 1992, pertaining to the effects such taxation would have on the domestic lead industry. The intent of this legislation was to provide a dedicated revenue, estimated at $1 billion per year, for exclusive use in protecting against lead-based paint hazards in accordance with Title 10 of the Housing and Community Development Act of 1992. By yearend 1993, no significant advancement of this legislation had occurred.

On May 4, 1993, the Occupational Safety and Health Administration (OSHA) issued its interim final rule on "Lead Exposure in Construction." This rule amended OSHA standards for occupational health and environmental controls by adding specific employee protection requirements for workers exposed to lead. The added standard reduced the permitted level of exposure to lead for construction workers from 200 micrograms to 50 micrograms per cubic meter of air as an 8-hour time-weighted average (TWA). The standard also included requirements addressing exposure assessment, methods of compliance, respiratory protection, hygiene facilities and practices, medical surveillance and removal protection, recordkeeping, and employee information and training. A lead level of 30 micrograms per cubic meter of air as an 8-hour TWA was established as the level at which employers must initiate certain compliance activities. This interim rule became effective on June 3, 1993, and was mandated by and issued under the Housing and Community Development Act of 1992.

Issues

Congressional discussions during 1993 on an economic stimulus package related to improving the highway infrastructure raised concerns about worker protection against exposure to lead hazards. Specifically, concerns were expressed at a hearing of the U.S. House of Representatives Energy and Commerce Committee's Subcommittee on Health and the Environment that the stimulus package would increase lead poisoning among workers involved in activities to remove lead-based paint from bridges, if such activities were implemented before the Environmental Protection Agency (EPA) was able to establish accredited worker and contractor training requirements. Similar concern was expressed for other economic stimulus packages, such as Farmers Home Administration grants for low-income housing, the National Trust for Historic Preservation, the Museum Properties deferred maintenance projects, and the Federal Building Energy Efficiency projects, all of which will involve construction workers in the disturbance of lead-based paint. EPA was scheduled to set training and certification standards for workers and contractors, including those engaged in paint removal and demolition activities, by April 1994. The standards were required to be provided by EPA as mandated in the Residential Lead-Based Hazard Reduction Act passed in 1992.

During 1993, the Organization for Economic Cooperation and Development (OECD) continued its discussions on means whereby lead hazard risk might be reduced within its member countries. The OECD Chemicals Group, operating under a 1990 agreement to proceed with a pilot risk reduction program for lead and five other chemicals, published a monograph on lead risk reduction in May 1993. According to information in the monograph, several OECD member countries had either begun efforts or had expanded present programs to reduce lead risks.

Consistent with the OECD Chemicals Group efforts, the OECD Secretariat initiated a second phase of risk reduction activity. The aim of this phase was to identify possible further national and/or collective international risk reduction activities for lead. OECD member delegates, meeting in May 1993, subsequently requested that the OECD Secretariat, in consultation with OECD member countries, work toward developing a binding form of OECD lead risk reduction for its member countries. An OECD Working Group emerged at the May 1993 meeting to draft an initial outline of the general scope and content of a possible binding lead risk reduction action. The Working Group met again in November 1993 to consider proposals for inclusion in any such action. The proposals addressed risk reduction as it applied to lead products, recycling, new and existing uses, point source controls, abatement and clean-up programs, technology transfer, reporting requirements, and monitoring and assessment programs. Further OECD discussions on the matter of a binding lead risk reduction action were planned for 1994.

Production

Primary.—In 1993, domestic mine production of lead decreased by about 42,000 metric tons, or 11%, from the 1992 level, continuing a 3-year decline in domestic production. The further decline in production was attributed to the closure of Kennecott Mining Co.'s Greens Creek Mine in southeastern Alaska, as well as to cutbacks at Cominco American Inc.'s Magmont Mine in Bixby, MO, and The Doe Run Co.'s Buick Mine in Iron, MO. Countering these declines was an increase in production at Cominco Alaska Inc.'s Red Dog Mine in the northwest arctic region of Alaska. Missouri's share of the total mined lead production was 78%, about 4% higher than in 1992. Production in Alaska, Idaho and Montana accounted for an additional 20% of U.S. mine output. The top 12 mines listed in table 3 produced more than 98% of the total, and Asarco Incorporated, Doe Run, and Cominco (American/Alaska) accounted for slightly more than 91% of the domestic mine production of lead in 1993. *(See tables 2 and 3.)*

Fluor Corp., Irvine, CA, formally announced at the end of 1993 plans to sell its Doe Run subsidiary based in St. Louis, MO. Doe Run, the Nation's only fully integrated primary lead producer, had assets that include six mines and four mills in southeast Missouri, estimated by industry analysts to be valued at approximately $225 million. The plans to sell Doe Run's assets followed a late 1992 action by Fluor Corp. to classify Doe Run as a "discontinued operation" for tax purposes. Several sales options reportedly were being considered, including employee buyout, spin off as a separate company to Fluor Corp. shareholders with a public offering of Doe Run shares, and direct sale to a third party. By yearend 1993, no third-party buyer had been found.

Asarco Inc. operated two mines in southern Missouri that produced more than 90% of the concentrate feed for its nearby Glover, MO, smelter and refinery. Record production of 123,000 metric tons of contained lead was achieved at the mines during 1993, exceeding 1992 production by 16%, according to the company's annual report to stockholders. Refinery production at the Glover facility declined by about 5% to 124,000 tons in 1993, owing to equipment failures early in the year. Asarco's Omaha, NE, refinery, which received the bullion output from its East Helena, MT, custom smelter, produced 73,500 tons of lead in 1993, down 2% from production in 1992, owing to interruptions in deliveries of concentrate from its South American source, the Quiruvilca Mine in Peru. Asarco's East Helena and Omaha processing circuit also was supplied with concentrate from the company's Leadville, CO, mine. At yearend, Asarco reported reserves in

Missouri of 19.7 million tons grading 4.83% lead at Sweetwater and 6.4 million tons grading 5.72% lead at West Fork. *(See table 4.)*

Production from the Magmont Mine at Bixby, MO, a 50-50 joint-venture of Cominco American Inc., the operator, and Dresser Industries Inc., continued to decline in 1993 in preparation for the planned closing of the mine in 1994. According to the Annual Report of the parent company, Cominco Ltd. (Canada), orebody depletion had resulted in a 17% decrease in production from that of 1992 and had reduced the workforce at the mine to a minimum. Prolonged low market prices for lead also had caused the mine to be operated at a net loss for the year. Pillar and sill recovery at the mine accounted for the bulk of the year's production. Fifty percent of the lead concentrate produced was sold in Missouri, with most of the remainder being stockpiled, although a small portion was sold to foreign smelters. In 1993, Magmont milled 631,000 tons of ore grading 7.0% lead, which yielded 56,000 tons of concentrate. Cominco Ltd.'s wholly owned subsidiary, Cominco Alaska Inc., made operational changes in the grinding circuit at its Red Dog Mine, near Kotzebue in northwest Alaska, to improve overall metal production. As a result, annual throughput was increased to about 1.7 million tons in 1993 from 1.44 million tons in 1993, yielding 44,200 tons of lead concentrate in 1993 compared with 25,400 tons in 1992. At yearend, published ore reserves (measured and indicated) at Magmont were 2.5 million tons grading 8.3% lead, and at Red Dog were 56.8 million tons grading 5.5% lead.

In mid-1993, Kennecott Mining Co, announced the indefinite closure of its 54%-owned Greens Creek zinc/lead/silver mine in southeastern Alaska, owing to low prices. During the closure, all operating and environmental permits were to be maintained and mine development work and engineering studies were to continue, pending improvement in prices.

Secondary.—Domestic secondary production in 1993 was estimated to have declined by about 1.5% from a near-record high in 1992. Secondary lead accounted for 73% of domestic lead production in 1993, reflecting a continued high level of lead-acid battery recycling. Battery Council International statistics indicated that the recycling rate for lead-acid batteries was 94.4%, according to data available for 1992.

A significant portion of the decline in secondary production during 1993 was in the recovery of lead by nonbattery recyclers. These recyclers, who mainly produced specialty alloys for such uses as solders, brass or bronze ingots, and bearing metals, continued to experience higher costs and lower profit margins in their operations.

In late 1993, RSR Corp., Dallas, TX, announced plans to build a new $60 million auto and industrial lead-acid battery recycling plant in Aiken County, SC. The facility was to be the first greenfield lead-acid battery recycling operation in the southeastern United States and was to be capable of processing 6 million batteries annually. Company plans called for the facility to have an electric arc furnace, a reverberatory furnace, and a refinery. Desulfurization and crystallization techniques will be used to convert the battery acid into sodium sulfate salts for use in the paper, glass, and detergent production industries. The source of obsolete batteries is expected to come from an 8-state area in the southern United States through existing conversion agreements with battery scrap dealers. By yearend, RSR was awaiting permitting approval from the South Carolina Department of Health and Environmental Control. RSR expected permitting and construction time for the new facility to take from 3 to 5 years.

GNB Battery Technologies Inc., Atlanta, GA, announced in late 1993 that it was suspending indefinitely plans for a proposed greenfield secondary lead smelter in Waynesboro, GA. The decision coincided with a fine that had been levied by EPA on GNB's facility in Columbus, GA. In a subsequent agreement with EPA, the company planned to begin installation of new pollution control equipment at the Columbus facility.

Refined Metals Corp., Longview, TX, closed indefinitely its secondary smelters in Memphis, TN, and Beech Grove, IN, at the beginning of the year. The combined capacity of the two smelter operations was about 50,000 tons per year. *(See table 5.)*

Consumption and Uses

Reported consumption of lead increased by 9% in 1993 compared with that of 1992. This increase was due mainly to a nearly 6% increase in demand for original equipment starting-lighting-ignition (SLI) batteries, and replacement SLI batteries. The latter increase was attributed to abnormally low winter and high summer temperatures. Other increases in demand occurred in the end-use sectors that included ammunition, bearings for electrical and electronic equipment, cable covering for power and communication, sheet lead for medical radiation shielding, and solder for motor vehicles, containers, and electronic components.

The Battery Council International (BCI) reported a 1993 SLI battery production of 86.0 million units, compared with 81.1 million units in 1992 and 77.8 million units in 1991. The total includes both original equipment market (OEM) and replacement market automotive-type batteries. Using the BCI estimate of 20.9 pounds per unit, the SLI offtake for 1993 was about 815,300 tons of lead. SLI batteries include those used for buses and trucks, tractors, marine, golf carts, motorcycles, aircraft, mine equipment, floor care, and military equipment. Lead consumption in lead-acid batteries for uses other than SLI, such as for stationary, industrial, and motive power applications, was 211,000 tons in 1993, compared with 145,000 tons in 1992, and 184,000 tons in 1991. *(See tables 6, 7, 8, 9, and 12, 13, 14, 15.*

World Review

Statistics published by the International

Lead and Zinc Study Group (ILZSG) suggest that world production and consumption of refined lead remained essentially unchanged at approximately 5.4 million tons and 5.1 million tons, respectively, in 1993. As a result of the continued excess production, however, commercial stocks of refined lead reached 0.79 million tons, equivalent to 8 weeks of world consumption, at the end of 1993. This compared with 0.74 million tons, or 7 weeks of consumption, at the end of 1992, and 0.54 million tons, or 5 weeks of consumption, at the end of 1990.[1] Stagnant consumption, coupled with rising commercial stocks, were indicative of the continuing world recession in 1993. Lead prices thus continued to decline through the first half of the year. A modest increase in prices occurred in the last half of the year, but the average annual LME and North American producer prices were down by $0.036 and $0.034 per pound, respectively, compared with prices in 1992.

During 1993, numerous lead producing mines, smelters and refineries either were closed for part of the year or were forced to operate below capacity, owing principally to a drop in demand and declining prices in the early part of the year. In Canada, Cominco Ltd. closed its Trail, British Columbia, smelter for 2 months, and curtailed operations at its Sullivan Mine, also in British Columbia, for about 3 months. Noranda Ltd. implemented a summer shutdown of its Brunswick Mine, in New Brunswick, and indefinite closure of its Heath Steele Mine, also in New Brunswick, subsequently closing its Belledune, New Brunswick, smelter-refinery for 6 weeks. Belledune derived about 80% of its concentrates from these two mines. The Faro and Sa Dena Has Mines, Yukon, operated by Curragh, Ltd., remained closed throughout the year and were placed in control of an interim receiver in September. Canada's Cominco Ltd. and Teck Corp. subsequently agreed to purchase a 50% interest in the Sa Dena Mine, but there were no immediate plans to reopen the mine. Curragh's Faro assets remained in receivership status at the end of the year. French-based Metaleurop closed its refineries at Noyelles-Godault, France, and Nordenheim, Germany for 2 months, and reduced output at its Oker, Germany, secondary lead smelter by nearly 50%. Germany's Metallgesellschaft closed its primary and secondary smelter unit at Stolberg for 3 months because of technical difficulties, but was operating near capacity at yearend. After an extended closure in early 1993, Italy's Porto Vesme primary lead smelter was reopened in October by its operator, Nuovo Samin, a part of ENI, an Italian Government-owned holding company. In a further response to low lead prices and high operating costs, Mexico's Empresa Frisco temporarily closed three of the four mines at its San Francisco de Oro mining and milling complex in Chihuahua State in early 1993. Also in Mexico, Minera Real Des Angeles closed its mine in Zacatecas for 5 months, then reopened at a reduced rate of production in the last quarter of the year. In Sweden, Boliden Mineral reduced production at its primary lead smelter in Ronnskar by about 20%. Boliden also was forced to suspend operations at its Aznalcollar Mine in Spain as a result of a prolonged drought in the southern Iberian Peninsula.

Mine Capacity.—During 1993, a decline in mine capacity resulted from the closure of two Italian mines. In February, Italy's ENI announced the closing of its Monteponi/Masua Mines in Sardinia. Production at these mines totaled about 16,000 tons of lead in concentrate in 1992.

Counter to these closings, Japan's Nippon Mining and Metals announced in late 1993 that the proposed Japanese-Australian project for development of the McArthur River zinc-lead property in Australia's Northern Territory was set to proceed. Planned production capacity was to be about 45,000 tons of lead in concentrate annually, with startup expected to occur in 1995. *(See table 10.)*

Metal Capacity.—Industrial Minera Mexico SA closed its 60,000-ton-per-year capacity primary lead refinery in Monterrey at the end of 1993. Reasons cited for the permanent closing of the facility were environmental pressures, diminishing raw material supplies, low lead prices, and the age of the facility.

In Japan, partners in the proposed Hachinohe lead-zinc smelter announced postponement of construction because of low prices and other economic factors. This Imperial Smelting Process plant had been scheduled to begin operation in late 1994 with a production capacity of 60,000 tons of lead annually. Feed material for the operation was to be derived from a variety of concentrate and scrap sources. *(See table 11.)*

Reserves.—Worldwide reserves of lead contained in demonstrated resources from both producing and nonproducing deposits believed to be economically viable at yearend were estimated at 63 million tons by the U.S. Bureau of Mines. Reserves for the two largest producers in the Western world, Australia and the United States, were about 10 million tons each. Canada, the fifth largest producer in the world in 1993, had reserves of 6 million tons. China, the second leading producer in 1993, had reserves of 7 million tons. The reserve base (reserves plus marginal economic deposits, measured and indicated) for Australia and the United States was 35 million tons and 22 million tons, respectively. In Canada, the reserve base was 13 million tons and in China, 11 million tons. Total world reserve base at the end of 1993 was estimated to be 130 million tons.

Current Research

According to information provided by the International Lead-Zinc Research Organization (ILZRO), Research Triangle Park, NC, lead-acid batteries appear to have a clear edge to become the main energy source for electric vehicles now under development by the three major domestic car makers. The development of these vehicles is in response to State legislation aimed at lowering air pollution resulting from existing vehicles powered by internal combustion engines. Factors such as cost considerations, the availability of battery components, and already established distribution and recycling procedures for lead in batteries, give lead-acid batteries an advantage over other more recently developed batteries. These include batteries such as nickel hydride, sodium sulfur, zinc air, and zinc bromine. California has emerged as the most aggressive State in the legislative drive to reach zero emissions, and has stipulated that 2% of total car sales in the State be pollution-free vehicles by 1998, increasing to 12% of total car sales by 2001.

The U.S. Naval Facilities Engineering Service Center, Port Hueneme, CA, and the U.S. Bureau of Mines (USBM) Salt Lake City, UT, Research Laboratory began collaborating on an effort to remove the lead hazard resulting from accumulation of spent bullets on military firing ranges. More than 300 such Navy and Marine Corps ranges exist where the soil is contaminated with lead in bullet fragments, down to ultrafine particle size. To remove this lead, USBM scientists have employed an approach that combines two basic mineral-processing procedures. First, gravity separation of the larger lead fragments and particles captures up to 99% of the lead in the soil. Next, leaching with acetic acid dissolves the remaining lead, leaving the soil suitable for reuse. By yearend, the U.S. Navy was focusing initially on a few of its most contaminated ranges as candidates for this cleanup process.

OUTLOOK

While overall economic growth was somewhat slower than anticipated in 1993, those sectors of the economy that were of particular importance to the demand for lead remained strong and were expected to continue as such in 1994. Specifically, although overall personal consumption was anticipated to increase by about 3% in 1994, consumption of durable goods, such as automobiles and appliances, was projected to rise nearly 7% in 1994. Total vehicle production in the United States rose by more than 10% to about 10.8 million units in 1993, and was forecast to increase by 5% in 1994. An anticipated growth of 4% in residential construction during 1994 also was expected to increase the demand for lead.

It was anticipated that the U.S. lead market would tighten during 1994 as consumption was expected to rise by about 8% compared with 1993, while mine production should remain static and total metal production from primary and secondary sources should increase by only 6%. The tightening physical market was forecast to continue pushing prices higher on both the U.S. and European markets during 1994. Contributing to the tightening market would be factors such as the strengthening demand in all regional markets, declining exports from Eastern bloc countries, and decreasing producer stocks in the Western world. Although secondary production of lead was expected to increase in 1994, as higher prices encourage more recycling, this was expected to be more than offset by a decline in primary production and total refined lead production in the world.

Total[10]	[r]3,286.7	[r]3,352.2	[r]3,314.0	[r]3,109.4	2,926.3

[e] Estimated. [r] Revised.

[1] Table includes data available through Aug. 4, 1994.

[2] In addition to the countries listed, Uganda may produce lead, but available information is inadequate to make reliable estimates of output levels.

[3] Reported figure.

[4] Formerly part of Czechoslovakia; data were not reported separately until 1993.

[5] Dissolved Dec. 31, 1992. Production from 1989-92 came from the Czech Republic and Slovakia.

[6] Year beginning Mar. 21 of that stated.

[7] Dissolved in Dec. 1991.

[8] Dissolved in Apr. 1992.

[9] Pb content of ore milled in year beginning Apr. 1 of that stated.

[10] Data may not add to totals shown because of independent rounding.

[e] Estimated. [r] Revised.

[1] Table includes data available through Aug. 4, 1994. Data included represent the total output of refined lead by each country, whether derived from ores and concentrates (primary) or scrap (secondary), and include the lead content of antimonial lead, but exclude, to the extent possible, simple remelting of scrap.

[2] Data may not add to totals shown because of independent rounding.

[3] Reported figure.

[4] Formerly part of Czechoslovakia; data were not reported separately until 1993.

[5] Dissolved Dec. 31, 1992. All production in Czechoslovakia from 1989-92 came from the Czech Republic.

[6] Less than 1/2 unit.

[7] Estimate based on a distribution of estimated secondary production in the former U.S.S.R.

[8] Dissolved in Dec. 1991.

[9] Dissolved in Apr. 1992.

[10] Data are for fiscal year beginning Apr. 1 of that stated.

LIME

By M. Michael Miller

Mr. Miller, a physical scientist with 16 years of minerals experience with the U.S. Department of the Interior, has been the commodity specialist for lime since 1989. Domestic survey data were prepared by Kelly Dorney, statistical assistant; and the world production table was prepared by Amy Burk, international data coordinator.

Lime is an important chemical with hundreds of chemical, industrial, and environmental uses in the United States. Its history probably dates back at least 4,000 to 6,000 years. The ancient Egyptians utilized lime as an ingredient in mortar and plaster. The Greeks, Romans, and Chinese utilized lime for construction, agriculture, bleaching, and tanning. Its uses began expanding with the advent of the industrial revolution, but it remained primarily a construction commodity until the rapid growth of the chemical process industries at the beginning of the 20th century. At the turn of the century, more than 80% of lime consumed in the United States went for construction uses, but now more than 90% of lime is consumed for chemical and industry uses.

Lime is a basic chemical that ranked fifth in total production in the United States in 1993. It is produced in 33 States and Puerto Rico, and its major uses are in steelmaking; pulp and paper manufacturing; construction; and the treatment of water, sewage, and smokestack emissions.

Total lime sold or used by domestic producers, excluding that from Puerto Rico, increased by about 733,000 metric tons (808,000 short tons) to 16.9 million tons (18.7 million short tons) in 1993. Production included the commercial sale or captive production of quicklime, hydrated lime, and dead-burned refractory dolomite. These products were valued at more than $977 million. Commercial sales increased by 795,000 tons (876,000 short tons) to a record high of 15.1 million tons (16.6 million short tons), while captive production decreased by 62,000 tons (68,000 short tons) from 1992 levels. *(See table 1.)*

DOMESTIC DATA COVERAGE

To comply with Federal law and Executive Order 12770, the U.S. Bureau of Mines (USBM) has decided on the following transition plan for the mandated conversion of the remaining commodity publications not currently being reported in metric units. For the 1993 Commodity Annual Reports and 1994 Mineral Industry Surveys, all data will be published in metric units with an additional total line showing traditional English units. Beginning with the 1994 Commodity Annual Reports and the 1995 Mineral Industry Surveys, all data will be published in metric units only.

Domestic production data for lime are developed by the USBM from two separate, voluntary surveys of U.S. operations. The survey used to prepare this report is the annual "Lime" survey. Of the 118 operations to which the annual survey request was sent, 105 responded, representing 89% of the total sold or used by producers shown in table 2. Production for eight nonrespondents was provided based on the monthly survey. Production for five nonrespondents was estimated using reported prior-year production figures.

BACKGROUND

Definitions and Specifications[1]

Lime is a manufactured product made by calcining limestone (calcium carbonate or a combination of calcium and magnesium carbonate) or other calcium carbonate materials at temperatures ranging from 980° C to 1,300° C (1,800° F to 2,400° F). It is never found in a natural state. The calcination process drives off the carbon dioxide, forming calcium oxide (quicklime). The subsequent addition of water creates calcium hydroxide (hydrated or slaked lime). The term "lime" is a general term that includes the various chemical and physical forms of quicklime and hydrated lime. It may be high calcium, magnesian, or dolomitic. Quicklime is calcium oxide (CaO) with no water of crystallization. Hydrate is hydrated calcium oxide, or calcium hydroxide [$Ca(OH)_2$], and contains 24% combined water. Dead-burned refractory dolomite is dolomite that has been calcined at 1,540° C to 1,730° C (2,800° F to 3,150° F). All of these products are called lime.

Quicklime is commercially available by the carload, in bulk, or in paper bags, in the following standard sizes:

1. *Lump Lime*—the product exceeds 6.4 centimeters (2.5 inches) in diameter. Although sizes can vary, the typical size is 13 by 20 centimeters (5 by 8 inches). This largest size of quicklime is strictly a product of vertical kilns.

2. *Crushed or Pebble Lime*—the product ranges in size from 0.64 centimeter to 5.72 centimeters (0.25 inch to 2.25 inches), but the specific product size is more precise. This size has traditionally been a product of rotary kilns, but is now available from vertical kilns as either a primary product or as a result of crushing lump lime.

3. *Ground Lime*—the product is generally ground from larger size material. A typical product size passes nearly 100% through a No. 8 sieve and 40% to 60% through a No. 100 sieve.

4. *Pulverized Lime*—the product is the result of further grinding. A typical product size passes nearly 100% through a No. 20 sieve and 85% to 95% through a No. 100 sieve. This is usually a secondary product and is produced by intense grinding and classification.

5. *Pelletized Lime*—the pellets or briquets are of uniform 2.5-centimeter (1-inch) size, molded from quicklime fines. Hydrated lime is shipped in bulk tank trucks, rail cars, and in 23-kilogram (50-pound) paper bags. As a result of the hydration process, it is of fine particle size. A typical product size passes 85% or more through a No. 200 sieve, and a few special applications may require a product passing 95% to 98% through a No. 325 sieve.

Because of the differences in limestones, a rigid standardization of lime material specifications is impossible. Few plants manufacture lime with exactly the same properties; as a result, lime specifications are by necessity quite general in their provisions.

Technology[2]

Lime manufacture involves three main processes: stone preparation, calcination, and hydration. Stone preparation involves quarrying or mining (including drilling, blasting, and conveying broken stone), crushing, and screening to provide the proper size kiln feed. Care is taken to avoid contamination with undesirable impurities, such as iron oxide, silica, and alumina. Although most lime manufacturers produce their own stone, some purchase the stone for kiln feed from commercial limestone producers.

Calcination is a simple chemical reaction. It is the addition of heat to limestone to cause thermal decomposition in which the coproducts of CaO (quicklime) and CO_2 (carbon dioxide) are formed. This process is performed in a kiln, of which there are a wide variety of systems in use. The two basic kiln designs are rotary and vertical (or shaft). There are a few other miscellaneous designs, but the majority of commercial kilns are of rotary or vertical design. A rotary kiln is a long cylindrical kiln with a refractory lining, inclined at a slight angle, rotated at a slow speed, and fired by fuel at the lower end. The calcareous raw material (kiln feed) is fed into the upper end and calcined at about 1,100° C (2,000° F) during its travel through the kiln to form quicklime, which is discharged at the lower end. The calcination temperature depends on size and composition of kiln feed and the type of desired product. The carbon dioxide is driven off as a gas and normally exits the system with the stack gas.

Vertical kilns are short, wide, vertical cylinders lined with refractory materials. They are usually circular in cross section, typically with a diameter of 3 to 4 meters (9 to 14 feet) and a height of 15 to 21 meters (50 to 70 feet). They are the most widely employed type in the world, especially in Europe. A vertical kiln is divided into four distinct zones where specific parts of the manufacturing process take place. They are, from top to bottom: (1) stone storage zone, (2) preheating zone, (3) calcining zone, and (4) cooling and discharge zone.

Examples of other kiln designs are the rotary hearth kiln and the fluosolids kiln. The rotary hearth design consists of a preheater, circular hearth, and cooler, all refractory lined. Stone is placed on the hearth and rotated through a heating chamber. In the fluosolids kiln, fine-sized stone is densely suspended by air and hot gases in the preheating and calcining zone of a vertical heated chamber. It can be operated at lower temperatures because of the fine stone size. The quicklime product is the most highly reactive of any commercial lime.

Byproducts and Coproducts

Most lime companies mine their own limestone or dolomite for kiln feed. Some companies also produce as a separate coproduct crushed and pulverized stone. If practical and if markets exist, byproduct fines from the kiln feed preparation process and fugitive lime dust from different stages of the lime production process also may be marketed. Precipitated calcium carbonate (PCC) is produced as a coproduct at three commercial lime plants by combining quicklime with byproduct carbon dioxide recovered from the kiln. Byproduct carbon dioxide is recovered for use in the carbonation step of sugar refining.

Substitutes

Limestone is a low-cost substitute for lime for many uses such as agriculture, fluxing, and flue gas desulfurization (FGD). Limestone contains less reactive material, is slower to react, and may have other disadvantages compared to lime, depending on the use. Calcined gypsum is an alternative material in industrial plasters and mortars. Cement, lime kiln dust, and fly ash are potential resources as substitutes for some construction uses of lime. Alkalis such as caustic soda, soda ash, sodium bicarbonate, sodium sulfate, and magnesium hydroxide are substitutes used in the neutralization stage of water treatment.

Economic Factors

Prices.—Traditionally, lime has been a low-priced commodity. Its average value, as reported to the USBM on an f.o.b. plant basis, ranged from $4 to $15 per short ton from 1910 to 1970. It was only in the 1970's, when energy prices escalated, that lime values showed a progressive and dramatic increase. This steady increase continued into the 1980's, although at a slower pace. In 1987, lime decreased in value for the first time since 1968. When comparing values since 1973, based on constant 1993 dollars, two trends become evident. From 1973 to 1979, values increased every year and were up a total of 49%. From 1979 to 1991, values decreased every year and were down a total of 30%.

Average values for quicklime sold are only available for the past 9 years. During that period the average actual value has been reasonably stable, ranging from $51.10 to $55.48 per ton ($46.36 to $50.33 per short ton). During the past 4 years, the values have been essentially flat.

The average values for hydrated lime sold for the same period have been less stable. The average actual value has ranged from $63.65 to $82.62 per ton ($57.74 to $74.95 per short ton). During the past 5 years, however, the values have been relatively stable. *(See figures 1, 2, 3, and 4.)*

Costs.—Production costs in lime manufacture can be divided, in descending order, into the following categories: energy (mainly fuel costs), kiln feed, dust collection, depreciation, direct labor, and miscellaneous. The ranking may differ from plant to plant, and most of the categories display a great range in costs from one plant to another. The difference in ranking and the range in costs are accounted for by such variables as distance from fuel sources; thermal efficiency of individual kilns; whether kiln feed is quarried, mined underground, or purchased; electrical energy rates; and age of the plant.[3]

Tariffs.—In the Harmonized Tariff Schedule of the United States, quicklime, slaked lime (hydrate), and hydraulic lime are listed under 2522.10, 2522.20, and 2522.30, respectively. Imports are free from countries with most-favored-nation (MFN) status, Mexico, and Canada. Non-MFN countries have tariffs of 0.2¢ per kilogram (about $2.20 per short ton) for quicklime, 0.3¢ per kilogram (about $3.31 per short ton) for slaked lime, and 0.2¢ per kilogram (about $2.20 per short ton) for hydraulic lime.

ANNUAL REVIEW

Legislation and Government Programs

Under authority of the Clean Water Act, as amended, the Environmental Protection Agency (EPA) released its final regulations establishing standards for the use of disposal of sewage sludge. The regulations provide requirements for sewage sludge applied to the land for a beneficial purpose, for sewage sludge disposed of on surface disposal sites, and for sewage sludge when incinerated. In section 503.32 of the Clean Water Act, an acceptable alternative for reduction of pathogens in sewage sludge is to raise the pH of the sewage sludge to above 12 for 72 hours. In appendix B to part 503—Pathogen Treatment Processes, lime stabilization is mentioned under Processes To Significantly Reduce Pathogens, where it states that "Sufficient lime is added to the sewage sludge to raise the pH of the sewage sludge to 12 after 2 hours of contact."[4]

The EPA finalized all or portions of five core regulations for the Acid Rain Program of title IV of the Clean Air Act, as amended. The regulations addressed General Provisions and Permits, the Allowance System, Continuous Emissions Monitoring, Excess Emissions, and Administrative Appeals. "Title IV of the Act requires EPA to establish an Acid Rain Program and a national emissions cap of 8.11 million metric tons (8.95 million short tons) per year on electric utility SO_2 emissions to be implemented in two phases. Phase I (beginning in 1995) requires the 110 highest-emitting utility plants to meet an intermediate SO_2 emissions limitation. By the year 2000 (in which Phase II begins) virtually all other utility units with output capacity greater than 25 megawatts and all new utility units will be required to meet emissions limitations as well. Total annual SO_2 emissions will be reduced by 9.1 million metric tons (10 million tons) below 1980 levels beginning in the year 2000, a reduction of total SO_2 emissions of approximately 40%."[5]

Phase I requirements have already translated into increased lime demand for flue gas desulfurization. In 1993, lime consumption for this use increased by 16% when compared with 1992 levels and 18% when compared with 1990 levels. The large increase in 1993 is probably explained by the lag time between passage of the Clean Air Act and installation of new SO_2 scrubbers at utility powerplants seeking to comply with Phase I.

Production

The term "lime," as used throughout this chapter, refers primarily to six chemicals produced by the calcination of high-purity calcitic or dolomitic limestone followed by hydration where necessary. They are (1) quicklime, calcium oxide (CaO); (2) hydrated lime, calcium hydroxide [$Ca(OH)_2$]; (3) dolomitic quicklime ($CaO \cdot MgO$); two types of dolomitic hydrate, (4) type N [$Ca(OH)_2 \cdot MgO$] and (5) type S [$Ca(OH)_2 \cdot Mg(OH)_2$]; and (6) dead-burned dolomite. Nondolomitic quicklime and hydrated lime may be called high-calcium lime. Lime can be produced from a variety of calcareous materials such as aragonite, chalk, coral, marble, and shell. Lime also is regenerated; that is, produced as a byproduct, by paper mills, carbide plants, and water-treatment plants; however, regenerated lime is beyond the scope of this report.

Total U.S. lime production from limestone, including that of Puerto Rico, increased by 4.5% compared to that of 1992. Commercial lime sold by producers increased by 5.5%, and captive lime used by producers decreased by 3.3%.

In 1993, 69 companies produced lime. Leading producing companies, in descending order, were Dravo Lime Co., with two plants in Kentucky and one plant in Alabama; Mississippi Lime Co. in Missouri; Marblehead Lime Co., with two plants in Illinois and one each in Indiana and Michigan; Chemstar Inc., with two plants each in Arizona, California, and Nevada and one each in Idaho and Utah; Continental Lime Inc., with one plant each in Montana, Nevada, Utah, and Washington; Allied Lime Co., with two plants in Alabama; Martin Marietta Magnesia Specialties in Ohio; APG Lime Co., with one plant each in Texas and Virginia; Texas Lime Co., with two plants in Texas; and Chemical Lime Inc., with two plants in Texas. These 10 companies operated 28 plants and accounted for 58% of total lime production. *(See tables 2 and 3.)*

Continued changes in the industry were

reflected by announcements of restructuring, name changes, sales, closures, plant openings, construction plans, and large utility FGD contracts. Mississippi Lime Co. restructured itself and formed North American Lime Co., which includes Mississippi Co. (Ste. Genevieve, MO), Bluff City Minerals Co. LP (Alton, IL), Eastern Ridge Lime Co. LP (Ripplemead, VA), and Prairie du Rocher Lime Co. LP (Prairie du Rocher, IL).[6] Prairie du Rocher Lime Co. LP is a new lime plant under construction in Illinois about 13 kilometers (8 miles) north of Mississippi Lime's Ste. Genevieve operations. Effective October 1, 1993, Ohio Lime Co. changed its name to Redland Ohio Inc. to reflect the acquisition of its parent Steetley PLC by Redland PLC in 1992.[7] Tenn Luttrell Co., Luttrell, TN, was sold by Penn Virginia Corp. to Global Stone Corp., Vancouver, British Columbia, Canada, for a reported $24.15 million. Subsequent to the sale, Tenn Luttrell announced plans to install two 300-ton-per-day (330-short-ton) Cimprogetti vertical kilns, one due on-stream in mid-1995 and the second in mid-1997.[8] Warner Co., a long-established producer of dolomitic lime products in southeastern Pennsylvania, closed and was put up for sale by its parent company Chemical Waste Management.[9] Early in the year, Wyoming Lime Producers started up its lime plant at Frannie, WY, and began producing from its 363-ton-per-day (400 short tons) Kennedy Van Saun preheater rotary. Wyoming Lime Producers is a part of Dakota Coal Co., which is in turn a subsidiary of Basin Electric Power Cooperative.[10] Western Lime & Cement Co. completed installation of a second preheater rotary kiln at its lime plant in Green Bay, WI. The new kiln went on-line in early summer 1993.[11] Dravo Lime Co. was awarded the contract to supply lime for FGD to the General James M. Gavin power station in southeastern Ohio. The 15-year contract will require about 408,000 tons per year (450,000 short tons) of magnesium-enhanced lime beginning in 1995. To meet the demand, Dravo plans to expand production capacity at its Maysville and Black River Divisions in Kentucky.[12] *(See table 4.)*

Consumption and Uses

Lime was consumed in every State. The breakdown of consumption by major end uses was as follows: 64% for chemical and industrial uses, 25% for environmental uses, 10% for construction uses, and 2% for refractory dolomite. Captive lime was used mainly in sugar refining and in the production of steel in basic oxygen furnaces.

In steel refining, quicklime was used as a flux to remove impurities such as phosphorus, silica, and sulfur. Dolomitic lime was substituted for a fraction of the high-calcium lime to extend refractory life. Dead-burned dolomite, also called refractory lime, was used as a component in tar-bonded refractory brick used in basic oxygen furnaces. Lime consumption by the steel industry increased by nearly 3% to 5.1 million tons (5.6 million short tons) and accounted for about 30% of all lime consumed in the United States.

In nonferrous metallurgy, lime was used in the beneficiation of copper ores to neutralize the acidic effects of pyrite and other iron sulfides and maintain the proper pH in the flotation process. It was used to process alumina and magnesia, to extract uranium from gold slimes, and in the recovery of nickel by precipitation. It was used in gold and silver recovery operations to control the pH of the sodium cyanide solution used to leach the gold and silver from the ore. Such leaching processes are called dump leaching when large pieces of ore are involved, heap leaching when small pieces of ore are involved, and carbon-in-pulp cyanidation when the ore is leached in agitated tanks. Dump and heap leaching involve crushing the ore, mixing it with lime for pH control and agglomeration, and stacking the ore in heaps for treatment with cyanide solution. Lime is used to maintain the pH of the cyanide solution at a pH level between 10 and 11 to maximize precious-metals recovery and to prevent the creation of dangerous hydrogen cyanide gas.

In the environmental sector, lime was used in the softening and clarification of municipal potable water. In sewage treatment, lime was used to control pH in the sludge digester, which removes dissolved and suspended solids that contain phosphates and nitrogen compounds. It also aided clarification and killing of bacteria. Lime was used to neutralize acid mine and industrial discharges. In FGD systems serving utility and industrial plants, lime was used to react with sulfur oxides in the flue gas. Lime was used to stabilize sludge from desulfurization plants before disposal.

The paper industry used lime as a coagulant aid in the clarification of plant process water. It was used, generally in conjunction with soda ash, for softening plant process water. This is a precipitation process to remove bivalent soluble calcium and magnesium cations (and to a lesser extent manganese, ferrous iron, zinc, and strontium), which contribute to the hardness of water. This process also reduces carbonate alkalinity and dissolved solids content.

In the basic Kraft pulping process, wood chips and an aqueous solution (called liquor) of sodium hydroxide and sodium sulfide are heated in a digester. The cooked wood chips (pulp) are discharged under pressure along with the spent liquor. The pulp is screened, washed, and sent directly to the paper machine or for bleaching. Lime is sometimes used to produce calcium hypochlorite bleach for bleaching the paper pulp. The spent liquor is processed through a recovery furnace where dissolved organics are burned to recover waste heat and where sodium sulfide and sodium carbonate are recovered. The recovered sodium sulfide and sodium carbonate are diluted with water and then treated with slaked lime to recausticize the sodium carbonate into sodium hydroxide (caustic soda) for reuse.

Lime was used to make precipitated calcium carbonate (PCC), a specialty pigment used in premium-quality coated and uncoated papers. The most common PCC production process used in the United States is the carbonation process.

Carbon dioxide is bubbled through milk-of-lime to form a precipitate of calcium carbonate and water. The reaction conditions determine the size and shape of the resulting PCC crystals.

The chemical industry used lime in the manufacture of alkalies. Quicklime was combined with coke to produce calcium carbide, which was used to make acetylene and calcium cyanide. Lime was used to make calcium hypochlorite, citric acid, petrochemicals, and other chemicals.

In sugar refining, milk-of-lime, a suspension of hydrated lime in water, was used to raise the pH of the product stream, precipitating colloidal impurities. The lime itself was then removed by reaction with carbon dioxide to precipitate calcium carbonate. The carbon dioxide was obtained as a byproduct of lime production.

Dolomitic quicklime was used as a flux in the manufacture of glass. Quicklime was used to make calcium silicate building products such as sand-lime brick; hydrated lime was used to produce silica refractory brick.

In construction, lime was used for soil stabilization to upgrade clay soils into satisfactory base and subbase materials. Common applications included the construction of roads, airfields, building foundations, earthen dams, and parking areas. Hydrated lime was used with fly ash to make a base material, in asphalt mixes to act as an antistripping agent, and in plaster, stucco, and mortar to improve durability.

Begun in 1992, a tour demonstrating the manufacture and use of autoclaved cellular concrete (ACC) blocks continued in 1993. ACC or autoclaved aerated concrete is a common concrete building material in Europe and other parts of the world. The tour planned to visit eight utility companies to demonstrate the production of ACC blocks using fly ash and to show how the blocks can be used. The demonstrations were aimed at builders, architects, building inspector, masons, developers, and others. The raw material mix in this ACC product contained 20% lime, although other autoclaved aerated concretes may utilize portland cement instead.

Specific patented manufacturing processes differ, but the process involved in the demonstration tour used sand or fly ash, lime, portland cement, aluminum powder, and water. These raw materials were mixed together and the resulting slurry poured into molds. This slurry expands and hardens, at which point it is cut into blocks or panels and then autoclaved for 12 hours. The resulting materials are lightweight, fire resistant, provide good thermal and sound insulation, and have good structural properties.[13] *(See table 5.)*

Prices

The average value of lime sold or used by producers, as reported to the USBM on an f.o.b. plant basis, decreased in 1993 to $57.83 per ton ($52.46 per short ton). Average values per ton were $56.11 ($50.90 per short ton) for chemical and industrial lime, $58.15 ($52.75 per short ton) for environmental lime, $63.34 ($57.46 per short ton) for construction lime, $73.42 ($66.61 per short ton) for agricultural lime, and $83.17 ($75.45 per short ton) for refractory dolomite.

The average value of quicklime sold decreased to $55.02 per ton ($49.91 per short ton). Average values per ton were $54.32 ($49.28 per short ton) for chemical and industrial lime, $55.54 ($50.39) for environmental lime, $54.74 ($49.66 per short ton) for construction lime, $111.40 ($101.06 per short ton) for agricultural lime, and $81.18 ($73.65 per short ton) for refractory dead-burned dolomite.

The average value of hydrated lime sold decreased to $67.84 per ton ($61.54 per short ton). Average values per ton were $64.28 ($58.31 per short ton) for chemical lime, $70.63 ($64.07 per short ton) for environmental lime, $67.52 ($61.25 per short ton) for construction lime, and $72.55 ($65.82 per short ton) for agricultural lime.

Transportation

The following is a clarification of the Department of Transportation regulations covering the transportation of hazardous materials (HRM-181), 49 CFR 171-180. The regulations refer only to lime (calcium oxide) shipped by air. The listing "UN 1910, Quicklime, Calcium Oxide" is to be used only on air shipments. For standard truck, rail, or barge shipments, the term "Quicklime, Calcium Oxide" is proper.[14]

Foreign Trade

According to the Bureau of the Census, exports of lime increased by 18% to 69,045 tons (76,109 short tons). Imports of lime increased by 4% to 200,587 tons (221,109 short tons). Most U.S. trade was with Canada and Mexico, which together accounted for nearly 100% of the U.S. exports and imports of lime. Canada was the major trading partner, receiving 74% of U.S. exports and shipping 95% of U.S. imports. *(See tables 6 and 7.)*

World Review

Canada.—Preliminary figures for 1993 put Canada's production at 2.45 million tons (2.70 million short tons) at a value of $201 million. This consisted of 2.26 million tons (2.49 million short tons) of quicklime valued at $181 million and 0.186 million tons (0.205 million short tons) of hydrated lime valued at $19.3 million.

European Union.[15]—The overall economy has depressed lime demand in most traditional markets, such as steel and construction. There was some variation in individual country markets. Eastern Germany's construction boom has increased demand for lime, mainly for production of sand-lime brick and aerated concrete products. Road and rail construction projects in France and Germany have increased demand for lime for soil stabilization. Lime demand for PCC production has grown in Scandinavia.

As environmental regulations have grown more stringent, the demand for lime has increased for various environmental uses. Lime usage has encountered difficulties in water treatment owing to sludge disposal restrictions that increase total treatment costs. The utility FGD market has grown some, but most FGD systems are limestone based. In addition, nuclear power and natural gas play a more significant role in Europe's current and future power generation plans. Some growth potential is seen in FGD treatment of incinerator gases.

Germany.—German consumption has been increasing in recent years but production has remained relatively flat. The increased demand has been met primarily by imports from the Czech Republic, Slovak Republic, and the former U.S.S.R.[16]

In 1993, Rheinisch-Westfälische Kalkwerke AG (RWK) transferred its business operations to a newly formed company called RWK Kalk AG. RWK Kalk AG was merged with Belgium's Lhoist Group's French and Czech operations to form Chaufourneries de Hergenrath SA. The new company will operate six plants in Germany, five in France, and one in the Czech Republic.[17]

United Kingdom.[18]—The lime industry continued to be impacted by the European recession, with both capacity utilization and profits at low levels. Buxton Lime Industries Ltd. is the largest producer, operating lime plants at Hindlow and Tundstead. Other United Kingdom producers included Singleton Birch Ltd., Tilcon Ltd., and British Steel PLC. Totternhoe Lime & Stone Co. Ltd. discontinued quicklime production in early 1993 and now purchases quicklime and hydrates it for regional customers. Owing to poor market conditions, the joint venture between Tilcon Ltd. and the Calcitherm-Carmeuse Group of Belgium has been put on hold. The two companies had announced in 1991 plans to construct lime production facilities and to market quicklime and hydrated lime in the United Kingdom. *(See table 8.)*

Current Research

Research by a group at the University of Western Australia has demonstrated a process for destroying polychlorinated biphenyls (PCB's) and other toxic organic compounds utilizing a conventional ball mill and quicklime. The organic compound is fed along with quicklime into a mill containing 12-millimeter-diameter (0.5-inch-diameter) steel balls. The milling process converts almost all of the organic material into carbon, calcium chloride, and calcium hydroxide. In laboratory tests, a pure sample of PCB mixed with quicklime was milled for 12 hours and produced a mixture containing only 5 parts per million of PCB. The codeveloper, Australian mining company CRA Ltd., will commercialize the process.[19]

In Germany, Solvay Umweltchemie GmbH has run pilot plant tests on a process to dispose of asbestos fibers by dissolving ground asbestos in a 40% solution of hydrofluoric acid. When the reaction is complete, the solution is neutralized by adding 20% hydrated lime. The estimated disposal costs in a commercial plant are expected to be competitive with current techniques that require cement fixing before final disposal.[20]

In Canada, research funded by the Ministère de l'Environment du Quebéc, Environment Canada-St. Lawrence Centre, and Groupe Olymel, was conducted on the use of lime to treat slaughterhouse sludge wastes for land application. The slaughterhouses produce a sludge waste generated by the use of a dissolved air flotation process for pretreatment of their wastewater. This sludge contains pathogens (bacteria, viruses, protozoa, and parasitic worms), heavy metals, and other contaminants. In a bench experiment, lime was applied to samples of the sludge at various concentrations, with the best results coming from the application of 150 kilograms (331 pounds) of calcium oxide equivalent per ton dry weight of sludge. This allows the maintenance of a pH of 12 or greater for several weeks. The experiment resulted in a major reduction of pathogens, heavy-metal content, and offensive odors. The resulting product was deemed suitable for application to agricultural land.[21]

OUTLOOK

Lime has dozens of end uses in the chemical, industrial, and construction industries. Steelmaking is still the largest single end use for lime, accounting for 30% of consumption. The steel industry's consumption of lime increased by nearly 3% when compared with 1992 levels. Steel output increased by more than 5% in 1993 and should continue to increase modestly in the short term as economic growth continues. Integrated steel mills operated at 96% of capacity in 1993 and are forecast to operate at 97% of capacity in 1994 and 98% of capacity in 1995. Consumption of lime by the steel industry has been relatively flat in the recent past, but the growing economy should translate into increased lime consumption for the next few years.

Construction markets, primarily for the soil stabilization, grew by about 25% in 1993. Barring long periods of bad weather, the construction markets should continue a strong showing. Soil stabilization and asphalt paving should be the driving forces in the construction markets.

The FGD market showed a dramatic increase in 1993 and is expected to show even greater growth in next few years. The deadline for Phase I compliance with the Clean Air Act Amendments is January 1, 1995, which means utility companies will have to have their compliance strategies in place by the end of 1994. Three midwestern powerplants have announced their plans to use lime in newly installed scrubbers beginning in 1995. These plants alone will consume about 725,000 to 815,000 tons (800,000 to 900,000 short tons) per year. This will mean an increase of 40% to 45% above current FGD consumption levels. Additional growth is expected from the utility industry, and longer term increases could materialize from the use of lime in dry scrubbers used with small nonutility boilers. Consumption of lime for FGD will likely top 3 million tons (3.3 million short tons) in the next 3 to 5 years, and increase even more when Phase II of the Clean Air Act Amendments goes into effect.

Other environmental markets as a whole were up nearly 4%, spurred by acid-water neutralization's surprising 35% increase. The sewage treatment market grew by nearly 6%, which probably reflects the expected growth in the sewage sludge stabilization market. The only significant environmental market that exhibited a drop was the water purification market, which decreased by 3%. Despite occasional variations in yearly consumption patterns, the individual environmental markets should remain strong, with the greatest potential for growth in sewage sludge stabilization.

Both the traditional pulp and paper market and precipitated calcium carbonate increased in 1993. In pulp mills, lime is used for water treatment and to causticize waste sodium carbonate solution to regenerate sodium hydroxide (caustic soda). Paper industry analysts project a 2.7% increase in paper production and a 3.2% increase in paperboard production in 1994. Demand for paper depends on the health of the economy and the strength of the U.S. dollar against foreign currencies. The weakening of the U.S. dollar against foreign currencies may slow imports and increase exports of paper products, increasing production even more. Increased consumption of paper products, driven by a stronger U.S. economy, should translate into greater consumption of lime for precipitated calcium carbonate production.

Lime consumption by the gold industry decreased significantly in 1993. Gold production is forecasted to remain flat over the next 2 to 3 years and then increase by about 5%. The gold boom may be over owing to the changed political climate and growing antimining sentiments, but current mining and mines in development should continue to provide a solid regional market.

The three chemical caustic soda plants constructed in recent years have been shut down owing to low prices. When operating, one plant purchases 100% of required lime and the other two regenerate lime, needing only to purchase makeup lime. Some forecasts now call for caustic soda supplies to tighten and for prices to climb back to the $250 to $300 level. As a result, the chemical caustic plants may reopen in late 1994 or in 1995. In addition to the three companies with idle plants, other companies have been considering building chemical caustic plants. The chemical caustic industry could still develop into a regional market for lime, but it will depend entirely on the price of caustic.

A couple of years ago, a major manufacturer of propylene oxide had proposed replacing caustic soda with hydrated lime in the dehydrochlorination stage of the production process. The company shelved the proposal with the precipitous drop in caustic soda prices. With the expected rise in caustic soda prices, the proposal may be dusted off and reconsidered. If the company proceeded with the substitution, it would require about 450,000 tons (500,000 short tons) of hydrated lime per year.

A small boost to the Mississippi River region market is expected by the end of 1994 when Vicksburg Chemical Co. begins production of potassium carbonate (K_2CO_3) at its new plant at Vicksburg, MS. The plant will utilize a patented ion-exchange process where potassium chloride, quicklime, and carbon dioxide will be used to produce K_2CO_3 and calcium chloride. The plant will require about 10,000 tons (11,000 short tons) of lime per year.

[r] Revised. W Withheld to avoid disclosing company proprietary data; included with "Other." XX Not applicable.

[1] Excludes regenerated lime. Includes Puerto Rico.

[2] To convert metric tons to short tons multiply metric tons by 1.10231 or divide metric tons by 0.907185.

[3] Data may not add to totals shown because of independent rounding.

[4] Includes Arkansas, Louisiana, Massachusetts, Minnesota, Oklahoma, and data indicated by the symbol W.

TABLE 3
LIME SOLD OR USED BY PRODUCERS IN THE UNITED STATES,[1] BY RANGE OF PRODUCTION

Range of production	1992			1993		
	Plants	Quantity[2] (thousand metric tons)	Percent of total	Plants	Quantity[2] (thousand metric tons)	Percent of total
Less than 10,000 tons	11	[r]74	(3)	10	70	(3)
10,000 to 25,000 tons	21	351	2	20	330	2

[e]Estimated. [r]Revised.

[1] Table includes data available through July 12, 1994.

[2] Lime is produced in many other countries besides those listed. Argentina, Iraq, Pakistan, and Syria are among the more important countries for which official data are not available.

[3] Reported figure.

[4] Less than 1/2 unit.

[5] Formerly part of Czechoslovakia; data were not reported separately until 1993.

[6] Dissolved Dec. 31, 1992.

[7] Includes hydraulic lime.

[8] Data are lime produced for steel production and do not include the widespread artisanal production of lime for whitewash and sanitation purposes.

[9] Dissolved in Dec. 1991.

[10] Total production of the former U.S.S.R. Production data for the 15 new countries are not yet reported separately.

[11] Dissolved in Apr. 1992.

[12] Data may not add to totals shown because of independent rounding.

LITHIUM

By Joyce A. Ober

Mrs. Ober, a physical scientist with 16 years industry and U.S. Bureau of Mines experience, has been the commodity specialist for lithium since 1986. Domestic survey data were prepared by Pamela G. Shorter, statistical assistant; and the world table was prepared by Amy Durham, international data coordinator.

The United States has been the largest producer and consumer of lithium, and the two U.S. companies that produced lithium have been leading lithium carbonate producers in the world for many years. One U.S. company, with operations in the United States and Chile, merged with another major U.S. mineral producer. The other U.S. company was exploring the possibility of developing a brine deposit in South America. Chile has become an increasingly important player in the lithium industry, and with the expected development of a second lithium operation in that country, it may become the world lithium leader by the end of this century.

Because lithium is electrochemically reactive and has other unique properties, there are many commercial lithium products. Producers sold lithium as mineral concentrate, brine, compound, or metal depending on the end use. Most lithium compounds were consumed in the production of ceramics, glass, and primary aluminum.

DOMESTIC DATA COVERAGE

The U.S. Bureau of Mines collects domestic production data for lithium from a voluntary survey of U.S. operations. The two U.S. companies responded to the survey, representing 100% of total production. Production and stock data were withheld from publication to avoid disclosing company proprietary data. *(See table 1.)*

ANNUAL REVIEW

Legislation and Government Programs

During 1993, the Department of Energy (DOE) offered for sale approximately 14 million kilograms of its 36-million-kilogram stock of lithium hydroxide monohydrate. Bids ranging from $1.32 to $1.54 per kilogram were accepted for the sale of about 13,600 kilograms of the material; bids for about 1 million kilograms were rejected because the prices offered were unacceptably low. DOE was pursuing the possibility of negotiating future sales because sales resulting from the first offering were less than had been desired.

DOE had planned to offer the lithium hydroxide in 1989, but delayed the disposal until an environmental impact study was complete. The stocks were excess from a weapons program that used the lithium to make tritium, a compound necessary for nuclear fission reactions. The stockpile originally contained about 42,000 metric tons of material, from which about 75% of the lithium 6 isotope had been removed. This material possibly contained 8 to 9 parts per million of mercury, which could present an environmental hazard.

Production

The two companies that produced lithium in the United States in 1993 did so from two different types of deposits. Both firms mined spodumene (a lithium-aluminum-silicate mineral) from large hard-rock deposits in North Carolina using open pit methods. Lithium was recovered from geothermal brine deposits in Nevada. Spodumene is the most common form of lithium ore, but petalite and lepidolite are other types of lithium ores that are mined in different parts of the world. These three types of ore are beneficiated to produce lithium ore concentrates that can be consumed directly in certain applications. Spodumene and brines are converted to lithium carbonate and then other compounds for consumption in other end uses.

Lithium carbonate is the most important lithium compound produced from brine and ore deposits. Spodumene was a major raw material for the production of lithium carbonate in North Carolina, and small amounts of spodumene concentrate were produced for sale. Extracting lithium from spodumene entails an energy-intensive chemical recovery process.

After mining, spodumene is crushed and undergoes a flotation beneficiation process to produce concentrate. Concentrate is heated to 1,075° C to 1,100° C, changing the molecular structure of the mineral, making it more reactive to sulfuric acid. A mixture of finely ground converted spodumene and sulfuric acid is heated to 250° C, forming lithium sulfate. Water is added to the mixture to dissolve the lithium sulfate. Insoluble portions of ore are then removed by filtration. The purified lithium sulfate solution is treated with soda ash, forming insoluble lithium carbonate that precipitates from solution. The carbonate is separated and dried for sale or use by the producer as feedstock in the production of other lithium compounds.

Production of lithium carbonate from

brine in Nevada is much less energy intensive than production from the spodumene. Brines enriched in lithium chloride—averaging about 300 parts per million when operation began in 1966—are pumped from the ground and progress through a series of evaporation ponds. Over the course of a year to 18 months, concentration of the brine increases to 6,000 parts per million of lithium through solar evaporation. When the lithium chloride reaches optimum concentration, the liquid is pumped to a recovery plant and treated with soda ash, precipitating lithium carbonate. The carbonate is then removed through filtration, dried, and shipped.

Cyprus Foote Mineral Co., a subsidiary of Cyprus Minerals Co., produced lithium carbonate from its brine deposit in Silver Peak, NV, and spodumene concentrate at its mine in Kings Mountain, NC. Cyprus Foote operated processing facilities for downstream lithium products and metal in Kings Mountain; Sunbright, VA; and New Johnsonville, TN. The company continued to maintain its lithium carbonate plant at Kings Mountain on a care-and-maintenance status as it had since mid-1986. In 1993, Cyprus Minerals merged with Amax Inc. to form Cyprus Amax Minerals Co. The merger had little impact on the lithium operations during the year.

FMC Corp., Lithium Div., formerly Lithium Corp. of America (Lithco), mined spodumene from pegmatite dikes near Bessemer City, NC. The company produced lithium carbonate and a full range of downstream compounds, including lithium metal and some organic lithium compounds, at a chemical plant near the mine. The company also operated a butyllithium plant in Bayport, TX.

Consumption and Uses

Ceramics and glass production and aluminum smelters were the largest consumers of lithium carbonate and lithium concentrates in the United States, comprising an estimated 20% and 18% of the lithium market, respectively. Other consuming industries were synthetic rubber and pharmaceuticals, 13%; chemical manufacturing, 13%; miscellaneous chemicals, 12%; lubricants, 11%; batteries, 7%; and air treatment, 4%.[1] Estimated domestic consumption was unchanged from that of 1992.

Lithium carbonate and mineral concentrate additions in ceramics and glass manufacturing processes lower process melting points, reduce the coefficient of thermal expansion and the viscosity, and eliminate the use of more toxic chemicals. The manufacture of thermal-shock-resistant cookware (pyroceramics) consumed the majority of lithium used in the ceramics and glass industry domestically. The manufacture of black and white television picture tubes consumed significant amounts of lithium concentrates overseas. Low-iron spodumene and petalite were a source of lithium used to improve the physical properties of container and bottle glass and as a source of alumina, another important component of the glass. Glass manufacturers used lithium in container and bottle glass, enabling them to produce lighter weight, thinner walled products.

Aluminum producers added lithium carbonate to cryolite baths in aluminum potlines. The chemistry of the potline converts it to lithium fluoride, lowering the melting point of the bath, allowing a lower operating temperature for the potline, and increasing the electrical conductivity of the bath. Operators used these factors to increase production or reduce power consumption.

The third largest end use for lithium compounds is as catalysts in the production of synthetic rubbers and plastics and pharmaceuticals. N-butyllithium initiates the reactions between styrene and butadiene that form abrasion-resistant synthetic rubber and thermoplastic rubbers that require no vulcanization. Other organic lithium compounds are important in the production of polyolefins such as polyethylene, a low-cost, high-strength plastic. Lithium metal and compounds also are used by drug manufacturers in the production of a number of drugs, including Vitamin A, some steroids, an anticholesterol drug, an analgesic, antihistamines, tranquilizers, sleep inducers, and contraceptives. Pharmaceutical-grade lithium carbonate is approved directly for the treatment for manic-depressive psychosis. This is the only treatment approved by the U.S. Food and Drug Administration in which lithium is consumed by the patient.

The multipurpose grease industry was another of the important end uses for lithium in 1991. Lithium hydroxide monohydrate was the compound used for the production of lithium lubricants. Lithium-base greases are favored for their retention of lubricating properties over a wide temperature range; good resistance to water, oxidation, and hardening; and formation of a stable grease on cooling after melting. These greases continued to be utilized in military, industrial, automotive, aircraft, and marine applications.

Almost all major battery manufacturers marketed some type of lithium batteries, and research and development continued for further substitution in applications that implement more conventional alkaline batteries. These batteries represent a growth area for lithium consumption, and new battery configurations continue to be developed. Continued interest in electrically powered vehicles spurred additional interest in battery research. New, more efficient types of rechargeable (secondary) lithium batteries have been developed and improved to meet the needs for this market and for electronic equipment, such as portable telephones and video cameras. Work continued on lithium polymer and lithium ion batteries. These batteries are of particular interest because they take advantage of large power capacity available from lithium batteries without the safety problems encountered when these batteries contain lithium metal, a very reactive and volatile material when exposed to air and moisture.

Nonrechargeable (primary) lithium batteries offer improved performance over alkaline batteries at a slightly higher cost and have been commercially available for more than 10 years. They were used in watches, microcomputers, and cameras, and, more recently, in small appliances, electronic games, and toys. The military purchased large and small lithium batteries for a variety of applications. The *Galileo* spacecraft, launched in October 1989 for its 6-year trip to explore the atmosphere of Jupiter, contained lithium sulfur dioxide batteries to power its scientific instruments when it reaches its destination. Recent modifications to the lithium sulfur dioxide battery have extended the life of the batteries to at least 10 years with little or no reduction of performance.

Aircraft manufacturers in several countries have designed new aircraft using aluminum-lithium alloys for wing and fuselage skin or structural members. Use of aluminum-lithium alloys can reduce the weight of the aircraft by more than 10%, allowing significant fuel savings during the life of the aircraft. The alloys, which are 2% to 3% lithium by weight, are attractive to the aircraft and aerospace industry because of their reduced density and superior corrosion resistance compared to those of conventional aluminum alloys. These alloys face direct competition, however, from composite materials consisting of boron, graphite, or aramid fibers imbedded in polymers.

Small quantities of other lithium compounds were important to many industries. Lithium chloride and lithium bromide were used in industrial air-conditioning systems, commercial dehumidification systems, and in the production of sophisticated textiles. Sanitizers for swimming pools, commercial glassware, and public restrooms contained lithium hypochlorite, as did dry bleach for commercial laundries. Lithium metal was used as a scavenger to remove impurities from copper and bronze, and anhydrous lithium chloride was used as a component in fluxes for hard-to-weld metals, such as steel alloys and aluminum.

Prices

The price for lithium carbonate, the largest volume lithium compound, decreased 2.6% in 1993. Lithium chloride and lithium hydroxide monohydrate increased 3%, and standard-grade lithium metal increased 3.5%. Prices for other lithium products were unchanged from those of 1992. *(See table 2.)*

Foreign Trade

Total U.S. exports of lithium compounds were about 16% lower in 1993 than they were in 1992. The majority of U.S. exports of lithium compounds were to Germany, Japan, and the United Kingdom. Data reported by the Bureau of the Census indicated that exports of U.S. pharmacopoeia (U.S.P.-grade) lithium carbonate in 1993 were less than 1% of the exports reported in 1992; however, calculations of unit value for this category of exports indicate that the majority of this material in previous years was probably technical-grade material that was mistakenly reported as U.S.P.-grade. Technical-grade is much lower in value than U.S.P.-grade lithium carbonate, and the unit value for both grades were very similar in 1992. Unit value for U.S.P.-grade in 1993 was nearly five times that of the technical-grade.

Imports of lithium compounds increased 5%. Cyprus Foote Mineral Co. owns a lithium brine operation in Chile; 97% of all lithium carbonate imports was from this source. Lithium ore concentrates from Australia, Canada, and Zimbabwe were consumed in the United States, but no import statistics were available. *(See tables 3 and 4.)*

World Review

A small number of countries throughout the world produced lithium ore and brine. The United States and Chile were the leading producers of lithium carbonate; significant quantities of lithium compounds and ore concentrates also were produced in Australia, Canada, Chile, China, Portugal, Russia, and Zimbabwe. Argentina, Brazil, and Namibia produced smaller quantities; production primarily consisted of concentrates. Rwanda, the Republic of South Africa, and Zaire are past producers of concentrates. Pegmatites containing lithium minerals have been identified in Austria, France, India, Ireland, Mozambique, Spain, and Sweden, but economic conditions have not favored development of the deposits. Lithium has been identified in subsurface brines in Argentina, Bolivia, China, and Israel. Companies in France, Germany, Japan, and the United Kingdom produced downstream lithium compounds from imported lithium carbonate.

Capacity.—The data in table 5 are rated capacity for mines and refineries as of December 31, 1993. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable long-term operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgement of the author, can be brought into production within a short period of time with minimum capital expenditure. Any restrictions to capacity utilization related to legal, political, or environmental restraints have been footnoted.

Lithium presented special problems during compilation of production capacities for different operations. Ore concentrate products are not comparable to lithium carbonate. Lithium carbonate was the primary compound produced at lithium chemical plants and the compound from which all other lithium chemicals were produced. Because even high-grade ore products usually contained less than 4% lithium and lithium carbonate contains almost 20% lithium, production capacities reported in tons per year represent large differences in the actual lithium content of the product. For that reason, capacities were reported based on the lithium content of the products. *(See* *table 5.)*

Argentina.—FMC began construction of two evaporation ponds to test evaporation rates prior to full-scale development of the Salar de Hombre Muerto. Testing evaporation rates at Hombre Muerto is essential because its altitude of 4,000 meters may impede evaporation, making development of the deposit less attractive. FMC signed an agreement with the Argentine Government in 1986 to explore this salar in Catamarca Province but intensified its test program in 1990. The Argentine brines may become more attractive for development since the Argentine Government began considering revisions of its mining laws to attract more foreign investment.[2] Estimates of geologic resources have been reported at 130,000 tons of lithium contained in brine ranging from 0.22 to 1.08 grams per liter. The Salar del Rincon also was identified as a lithium resource in the Salta Province. Lithium pegmatites are mined in Argentina. Small annual production occurred from pegmatite deposits in the Catamarca and San Luis Provinces. Spodumene reserves are estimated at 140,000 tons of 0.7% lithium.[3]

Australia.—Gwalia Consolidated mined high-grade, low-iron spodumene at its mine in Greenbushes, Western Australia. Gwalia produced two spodumene concentrate products through a flotation process for sale to the ceramics and glass industry. The majority of the company's spodumene concentrate was used in the manufacture of black and white television picture tube glass and pyroceramics in the Pacific rim countries and Europe. Glass-grade concentrate with lower lithium content was marketed in the same countries for consumption in container glass.

During the year, Gwalia announced an agreement with the China National Nonferrous Metals Import and Export Corp. to supply 60,000 tons of spodumene concentrates to China during the next 3 years. The company was considering entrance into the lithium carbonate market also. Technical problems that discouraged construction of a lithium carbonate plant several years ago have been solved, and Gwalia was studying the possibility once again.[4]

Bolivia.—A lithium brine deposit identified in Bolivia may be the world's largest salt flat. Preliminary studies of the Salar de Uyuni, which is more than 3,600 meters above sea level, indicated resources of 5.5 million tons of lithium, 110 million tons of potassium, and 3.2 million tons of boron.[5]

FMC had been negotiating for 4 years with the Government of Bolivia for the rights to develop a joint-venture operation in the Salar de Uyuni, a lithium brine deposit considered to be a national asset. FMC's plans included an exploration program and a plant for the recovery of lithium carbonate from the evaporated brines. Extreme political pressures in 1990 delayed the ratification of the contract that defined FMC's development of the project to produce 10,000 tons per year of lithium carbonate over 40 years at an investment of at least $92 million.[6] After FMC signed the contract, the Bolivian Congress changed four major conditions of the contract, including raising the value added tax rate. FMC informed the Government of Bolivia that the company could not accept the changes to the contract and canceled the contract in January 1993.[7]

Development of Uyuni is still a possibility, but not in the near future. Representatives from Cyprus Foote visited Bolivia after the FMC deal fell through to explore the possibility of their company developing the deposit if and when the lithium market improves.[8]

Brazil.—Brazil has produced small quantities of lithium minerals for almost 30 years. Companhia Brasileira de Litio built a plant in Aquas Verhelhas, Minas Gerais, to produce 1,000 tons of lithium hydroxide and 200 tons of lithium carbonate.

Canada.—During the year, Cabot Corp. became 100% owner of Tantalum Mining Corp. of Canada (Tanco), the sole producer of lithium minerals in Canada, acquiring the 62.5% of Tanco owned by Hudson Bay Mining and Smelting Co. Ltd. and Manitoba Mineral Resources Ltd.[9] Since production of spodumene concentrate began at its mine near Bernic Lake in southeastern Manitoba in 1984, Tanco has grown to become the largest supplier of lithium concentrates to the U.S. ceramics and glass industry. The Canadian spodumene was similar to the material mined in Australia (high-grade spodumene with very low iron content), making the concentrates ideal for direct application in the ceramics and glass industry.

A number of other lithium deposits have been identified throughout Canada. A pegmatite deposit was operated in Quebec for about 10 years starting in 1955, but there has been no production since then. The largest demonstrated resources occur in the Yellowknife deposits in the Northwest Territories.[10] Although large, the location is too remote for production to be feasible in the foreseeable future.

Chile.—Cyprus Foote Mineral Co. is the sole owner of its lithium brine operation at the Salar de Atacama, Sociedad Chilena de Litio Ltd., having bought the remaining interest from the Chilean Government in 1989. Cyprus Foote produced lithium carbonate from the brines at this Salar, which has been worked since 1984. The project originated as a joint venture between Cyprus Foote and Corporación de Fomento de la Producción (CORFO), a Chilean Government agency. Production capacity for lithium carbonate increased steadily from a 6,300-ton-per-year capacity to reach the current level of almost 12,000 tons per year.

The possibility of a second lithium operation at the Salar de Atacama has been under investigation. Minera Salar de Atacama Ltda. (MINSAL), the consortium formed by AMAX Exploration Inc. (United States), CORFO, and Molibdenos y Metales S.A. (Chile), completed studying the feasibility of developing another lithium operation on the Salar in 1988. Evaluations of the results were analyzed, and AMAX announced its decision to sell its portion of the project in 1990.[11]

Sociedad Quimica y Minera de Chile (SQM) bought AMAX's interest in the project in the second half of 1992. SQM is a Chilean fertilizer producer and its interest in the MINSAL project is for the potash that would be produced as a raw material for its potassium nitrate plant. Production of lithium carbonate is important to the economics of the project. Production of 9,000 tons per year of lithium carbonate, the second stage of the project, should begin by the end of the century.[12] SQM had been negotiating with FMC to develop the lithium portion of the project, but FMC withdrew from discussions.[13]

China.—Lithium pegmatite and brine deposits are worked in China, but specific information about any of the deposits is not available. Lithium carbonate and hydroxide from China has been marketed in Germany, Japan, and the Netherlands.

France.—Lithium metal is produced by Metaux Speciaux SA in Plombieres St. Marcel, Savoie. The plant has the capacity to produce 25 tons per year of very high-purity metal for use in aluminum-lithium alloys. The company is a subsidiary of Pechiney.[14]

Germany.—Germany has been a major producer of lithium compounds, although no lithium ore is mined there. Chemetall GmbH, a member of the Metallgesellschaft Group AG, produced downstream lithium compounds and metal from lithium carbonate imported from the United States and other countries. The company's lithium operations are in Langelsheim.

Japan.—Japan is a major consumer of lithium compounds, some of which it produces from imported lithium carbonate. FMC and the Honjo Chemical Co. have a joint venture, Asia Lithium Corp., to market FMC's lithium products in Japan. Asia Lithium operated a 100-ton-per-year battery-grade lithium metal operation in Kagawa to meet the demands of the large lithium battery industry in Japan. Yahagi Iron Co. also produced lithium metal in Nagoya.

Namibia.—Southwest Africa (SWA) Lithium Mines produced petalite concentrate at its Rubicon Mine near Karibib. Low-grade ores were beneficiated through a flotation process, while high-grade ores were hand picked. Small amounts of two other lithium minerals, lepidolite (lithia mica) and amblygonite (lithia alumina phosphate), were other products. The Federal Republic of Germany imported most of these concentrates. High-grade lepidolite was hand picked at the company's Helicon Mine for export to Western Europe and Japan.[15]

Portugal.—Lithium has been produced inconsistently in Portugal. Recent reports indicate that production has gone up significantly in recent years, but details on the operations and markets are not available. Past lithium production had been lepidolite.

United Kingdom.—Lithium Corp. of Europe operates a facility in Bromborough, Mersyside, for the production of lithium metal and butyllithium. Lithium carbonate and lithium chloride are imported from its parent company, FMC.

Former U.S.S.R.—Lithium ores, compounds, and metal were produced in the former U.S.S.R., but no details were available. The majority of lithium production is believed to be from the Kola Peninsula in Russia.

Zimbabwe.—Bikita Minerals Ltd. mined petalite, another lithium mineral, near Masvingos. Although the ore reserves were becoming depleted, installation of a dense-media separator made it possible to recover lithium in the form of petalite averaging about 4.4% lithium oxide from a stockpile of previously rejected material. This extended the estimated mine life 30 years. Hand sorting, the method used since the mining began in 1916, amassed a stockpile of more than 1 million tons that could be recovered with a significant savings in mining costs after installation of the new device. Hand sorting continued to be used only for special small orders of minerals other than petalite.[16] *(See table 6.)*

OUTLOOK

The health of the lithium industry is closely tied to the performance of the primary aluminum industry. Reduced consumption of lithium in the aluminum industry has once again had a negative effect on lithium consumption. Demand for lithium compounds and minerals in the ceramics and glass industry continues to grow modestly. Similar increases are expected for the near future.

Demand for butyllithium is expected to continue to increase, and both domestic producers have increased production capacity to meet that demand. Demand for lithium metal for batteries and to some extent for alloys should increase, but total consumption of metal will remain small in comparison to the demand lithium compounds for the short term. The fate of the lithium battery market will be largely dependent on the success of electric vehicles and whether the best type of battery for powering them finally is determined to be some form of lithium battery.

Other markets should remain relatively stable with slight growth. Lithium demand could increase dramatically if any of the new technology areas such as nuclear fusion were perfected. This is not expected to occur within the remainder of this century and probably not within the next 25 years.

The United States should remain the largest producer of lithium carbonate until production of lithium carbonate from SQM project in Chile. At that time, Chile should become the leading producer of lithium compounds in the world.

[e]Estimated. [r]Revised. W Withheld to avoid disclosing company proprietary data.

[1] Table includes data available through Apr. 13, 1994.

[2] In addition to the countries listed, other nations may produce small quantities of lithium minerals, but output is not reported and no valid basis is available for estimating production levels.

[3] Data are for year ending June 30 of that stated.

[4] Based on all of Canada's spodumene concentrates (Tantalum Mining Corp. of Canada Ltd.'s Tanco property).

[5] These estimates denote only an approximate order of magnitude; no basis for more exact estimates is available.

[6] All production in the U.S.S.R. from 1989 through 1991 came from Russia.

[7] Dissolved in Dec. 1991.

MAGNESIUM AND MAGNESIUM COMPOUNDS

By Deborah A. Kramer

Ms. Kramer is a physical scientist with the Branch of Industrial Minerals. She has covered magnesium and magnesium compounds for 10 years. Domestic survey data were prepared by Wannette Davis, statistical assistant; and international data tables were prepared by Amy Durham and Dave Mann, international data coordinators.

U.S. primary magnesium metal production declined slightly in 1993 and imports, primarily from Russia and Ukraine, provided an increased percentage of domestic demand. In addition, inventories of magnesium increased significantly from the low level at the end of 1992. These increases in inventories and imports prompted two of the three U.S. producers to announce cutbacks in production rates near the end of 1993. This oversupply situation was reflected in free market prices for primary magnesium during the year. Prices dropped steadily through the first three quarters of 1993 before rebounding slightly during the last 3 months.

In the past few years, automobile manufacturers have begun designing magnesium alloy diecastings into future car models. Many of these new components have been introduced in the 1994 model year and as a result, consumption of primary magnesium for diecastings has increased significantly. This is expected to increase as magnesium continues to be specified by designers for more components.

In Europe, a producers' association filed an antidumping complaint alleging dumping of magnesium on the European market by the former U.S.S.R. Other countries, including Japan and India, also have suggested that magnesium exports from the former U.S.S.R. have adversely affected their magnesium production. Several magnesium production facilities in Japan and Europe were either shut down completely or closed for a short period during 1993. At the same time, construction of new facilities in Australia and Israel was proceeding on schedule.

U.S. production of magnesium compounds from all sources (magnesite, dolomite, seawater, brines, and olivine) continued to decline as it has each year since 1988. Domestic demand, however, increased by nearly 8%. The increase in demand was met primarily by increased imports, particularly caustic-calcined and dead-burned magnesia from China. U.S. producers were concentrating on increasing production of magnesium compounds for use in environmental applications such as acid neutralization.

DOMESTIC DATA COVERAGE

Data for magnesium metal are collected from two voluntary surveys of U.S. operations. Of the 113 companies canvassed for magnesium consumption data, 73% responded, representing 46% of the primary magnesium consumption shown in tables 4 and 6. Data for the 30 nonrespondents were estimated based on prior-year consumption levels and other factors.

Data for magnesium compounds were collected from one voluntary survey of U.S. operations. Of the 19 operations canvassed, 84% responded, representing 75% of the magnesium compounds shipped and used shown in table 13. Data for the three nonrespondents were estimated based on prior-year consumption levels and other factors.

BACKGROUND

Definitions, Grades, and Specifications

Primary magnesium metal contains a minimum of 99.8% magnesium. Magnesium-base alloys are named by the composition of the two chief alloying elements, each designated by a letter, and the approximate percentage of each alloying element. For example, AZ91 contains about 9% aluminum (A) and 1% zinc (Z), and HK31 contains about 3% thorium (H) and 1% zirconium (K). Other letters used in specifying magnesium alloys are E for rare-earth metals and M for manganese.

Magnesite, or magnesium carbonate ($MgCO_3$), has a theoretical magnesium content of 47.6%. Dolomite is a calcium carbonate-magnesium carbonate mineral ($CaCO_3 \bullet MgCO_3$) that has a theoretical magnesium content of 22%. Brucite, magnesium hydroxide [$Mg(OH)_2$], contains up to 69% magnesium, and olivine ($Mg_2Fe_2SiO_4$) contains up to 19% magnesium. Of these minerals, magnesite and dolomite are the largest sources of magnesium and magnesium compounds.

Seawater, brines, and bitterns represent vast sources of magnesium and magnesium compounds. In the United States, more than 60% of the magnesium compounds produced annually is recovered from seawater and brines, and 80% of the magnesium metal production capacity uses seawater or brines as a raw material.

Various magnesia products are made by calcining magnesium carbonate or magnesium hydroxide at different temperatures. Caustic-calcined magnesia, which is readily reactive with water, is calcined at temperatures up to 890° C. Dead-burned magnesia, also called refractory or sintered magnesia, is calcined at temperatures up to 1,450° C and is unreactive with water. Fused magnesia is produced at temperatures greater than 3,000° C. Magnesia produced from magnesite is generally called natural magnesia, and magnesia produced from seawater or brines is called synthetic magnesia.

Standards for magnesia, including chemical composition, bulk density, and particle size, generally are set by the consumer for a specific application. Refractory magnesia composition depends on the area of the furnace in which the material is to be used. Magnesia produced from magnesite can contain between 88% and 98% magnesia, with varying quantities of alumina, calcium, iron, and silica impurities. Synthetic magnesia normally is purer than natural magnesia, containing between 92% and 99.5% magnesia, with smaller quantities of the same impurities found in natural magnesia. Most fused magnesia contains greater than 94% magnesia.

Products for Trade and Industry

The principal use for magnesium metal, averaging greater than 50% of U.S. consumption annually, is as an alloying addition to aluminum. Magnesium improves the hardness and corrosion resistance of pure aluminum. Aluminum-magnesium alloys are used in a variety of applications, including automobiles, trucks, aircraft, appliances, and home siding. Two-piece beverage cans, containing about 2% magnesium, are the largest single use for these aluminum-magnesium alloys.

Magnesium and its alloys are used as structural components on automobiles, trucks, aircraft, computers, and power tools. Many of these applications use magnesium because of its light weight and ease of machinability. Magnesium is used in the iron and steel industry for external hot-metal desulfurization and in the production of nodular iron. Production of the nonferrous metals, beryllium, hafnium, titanium, uranium, and zirconium, involves the use of magnesium as a reducing agent. Anodes of magnesium are used for cathodic protection of underground pipe and water tanks. Small quantities of magnesium are used as a catalyst in producing organic compounds, as photoengraving plates, and in alloys other than aluminum.

Refractory magnesia represents the largest use of magnesium in compounds. Refractory magnesia is manufactured into bricks and other shapes, principally for linings in furnaces and auxiliary equipment used to produce iron and steel. Magnesia-base refractories also are used in furnaces in the cement, glass, and nonferrous metals industries.

Caustic-calcined magnesia is used in a variety of applications in the agricultural, chemical, construction, and manufacturing industries. Caustic-calcined magnesia is an important component of animal feed and fertilizer, providing essential nutrients for livestock and plant growth. In construction, caustic-calcined magnesia is used in special cements for industrial flooring and in lightweight insulating wallboard. In the chemical industry, it is used as a starting point for the manufacture of other magnesium salts. Special grades of caustic-calcined magnesia are used for pharmaceuticals, including antacids, toothpaste, milk of magnesia, and cosmetics. Magnesia is used to remove sulfur from flue gases and boiler fuels and is used for acid neutralization in process wastewater and in lubricating oils. Caustic-calcined magnesia is also important in manufacturing paper, rayon, and rubber.[1]

Other magnesium compounds are used in place of, or in addition to, caustic-calcined magnesia in many of the above applications. Magnesium hydroxide is used in the pulp and paper industry; magnesium sulfate is used for pharmaceuticals, animal feed, and fertilizers; and magnesium carbonate is used in the chemical, pharmaceutical, and rubber industries. Fused magnesia is used primarily for electrical insulation.

The principal use for olivine is as a foundry sand used in casting iron and steel components and some nonferrous metals. Olivine is used in smaller quantities for refractories, slag control in blast furnaces, and abrasives.[2]

Industry Structure

U.S. producers of magnesium and magnesium compounds are shown in tables 1 and 2. Two companies in the United States produce olivine—Applied Industrial Materials Corp. (AIMCOR) and Olivine Corp. AIMCOR operates two mines in North Carolina and Washington, and processing plants in Indiana, North Carolina, and Washington; Olivine operates one mine and one processing plant in Washington.

Electrolytic plants in Canada, Kazakhstan, Norway, Russia, Ukraine, and the United States represent 67% of the world magnesium metal production capacity (excluding the capacity in Kazakhstan, Russia, and Ukraine that is used exclusively for titanium metal production). Smaller thermal plants are in Brazil, Canada, China, France, India, Italy, Japan, Serbia and Montenegro, and the United States.

The largest magnesite production facilities in the world are in China, North Korea, and Russia. Together, these three countries account for 60% of the world magnesite production capacity. Japan and the United States account for 61% of the world's magnesium compounds production capacity from seawater or brines. Fused magnesia is produced in Australia, Canada, France, Israel, Japan, Mexico, the United Kingdom, and the United States.

Norway is the world's principal producer of olivine, and in addition to supplying its domestic needs, Norway is a major world supplier of olivine. Countries with smaller output include Austria, Italy, Japan, Mexico, Spain, Sweden, and the United States. *(See tables 1 and 2.)*

Geology

Magnesium is the eighth most abundant element and constitutes about

2% of the Earth's crust. It is the third most plentiful element dissolved in seawater, with a concentration averaging 0.13%. Although many minerals contain magnesium, magnesite, dolomite, brucite, and olivine are the only minerals from which magnesium compounds are recovered commercially.

Dolomite is a sedimentary rock commonly interbedded with limestone, which extends over large areas of the United States and is widespread throughout the rest of the world. Most dolomite occurrences are likely the result of replacement of calcium by magnesium in preexisting limestone beds. Magnesite primarily is found in four types of deposits—sedimentary beds, alterations of serpentine, vein fillings, and replacements of limestone and dolomite. Brucite is found in crystalline limestone and as a decomposition product of magnesium silicates associated with serpentine, dolomite, magnesite, and chromite. Olivine generally occurs as granular masses or disseminated grains or crystals and is a common constituent of basic igneous rocks such as basalt and gabbro. Dunite is an olivine-rich rock.[3]

Technology

***Processing.*—Metal.**—Two thermal processes currently are in use to recover magnesium metal from dolomite—the Pidgeon process and the Magnetherm process. Both use the same basic chemistry, but the Pidgeon process uses an external heat source, and the Magnetherm process uses heat generated by the electrical resistance of the reactants. In the Pidgeon process, dolomite and ferrosilicon are formed into briquettes and heated in a retort under a vacuum. Magnesium oxide in the dolomite reacts with the ferrosilicon to produce magnesium vapor, which is cooled and condensed in a separate section of the retort. Plants in Canada, Italy, and Japan use this process to recover magnesium.

In the Magnetherm process, calcined dolomite, ferrosilicon, and alumina are heated under a vacuum. Alumina reduces the melting point of the slag produced by the dolomite-ferrosilicon reaction to make resistance heating practical. Magnesium vapor is cooled and condensed in a condensing chamber. The Magnetherm process is used in plants in Brazil, France, Japan, Serbia and Montenegro, and the United States.

Electrolytic recovery of magnesium requires a magnesium chloride feedstock that normally is prepared from seawater or brines. Two types of magnesium chloride can be made—hydrous and anhydrous. In the preparation of hydrous magnesium chloride, used by Dow Chemical Co., magnesium hydroxide is precipitated from seawater by the addition of dolomitic limestone. Adding hydrochloric acid to the magnesium hydroxide produces a neutralized magnesium chloride solution. This solution is dehydrated until it contains about 25% water and then is fed directly to electrolytic cells.

Magnesium Corp. of America (MagCorp) and Norsk Hydro A/S of Norway use an anhydrous magnesium chloride feed for their electrolytic cells. MagCorp uses solar evaporation initially to concentrate magnesium chloride brines from the Great Salt Lake. After adding calcium chloride to precipitate sulfate impurities and removing boron by solvent extraction, the brine is concentrated further and dehydrated in a spray dryer. The resulting powder is purified, concentrated, prilled, and dehydrated to produce anhydrous magnesium chloride.[4] Norsk Hydro starts with concentrated magnesium chloride brine. The brine is purified, concentrated, prilled, and dehydrated to produce anhydrous magnesium chloride.

Electrolytic cells used to recover magnesium from either hydrous or anhydrous magnesium chloride differ from company to company, and most information about cell design and operating conditions usually is not disclosed. Essentially, magnesium chloride fed to an electrolytic cell is broken down into magnesium metal and chlorine gas by direct current at 700° C. Magnesium is removed from the cell and cast into ingots, and the chlorine gas is recycled or sold.

Magnesium International Corp. developed a one-step process for producing anhydrous magnesium chloride that was demonstrated at Magnesium Co. of Canada Ltd.'s (MagCan) plant, which opened in 1990 and closed in 1991. Reacting magnesite with chlorine gas in the presence of carbon monoxide in a packed-bed reactor at 900° C produces magnesium chloride and carbon dioxide. Liquid magnesium chloride collects at the bottom of the reactor and is tapped periodically for transfer to electrolytic cells.[5] This process was not proven on a commercial scale.

Nonmetal.—Preparing either caustic-calcined or dead-burned magnesia from magnesite involves crushing the magnesite to various sizes, depending on the type of material to be produced. After crushing, magnesite is beneficiated; the degree of beneficiation depends on the quality of the ore and its ultimate end use. Lower quality ore often requires heavy-media separation, magnetic separation, and flotation to remove impurities. High-quality ore may require only screening and hand sorting to produce a material of acceptable quality. Caustic-calcined magnesia is produced in shaft kilns, multiple-hearth furnaces, or rotary kilns. Dead-burned magnesia is produced in rotary or shaft kilns.

In producing synthetic magnesia, seawater or brines are treated either with a small quantity of lime or sulfuric acid to remove dissolved carbon dioxide. Then calcium hydroxide, in the form of lime or dolime, is added to precipitate the dissolved magnesium as magnesium hydroxide. The resulting slurry is thickened and vacuum-filtered to yield a filter cake containing about 50% magnesium hydroxide. The filter cake can be directly calcined to produce caustic-calcined or dead-burned magnesia, or it can be calcined and pelletized before dead-burning to give specific size and density characteristics.

Fused magnesia is produced by fusion of high-grade magnesite or caustic-calcined synthetic magnesia in an electric arc furnace. After fusion, the material is crushed, inspected to remove any unfused magnesia, and crushed further in a ball mill.

Recycling.—Magnesium scrap is in forms similar to those of other nonferrous metals. New scrap comes in forms such as castings, drippings, drosses, gates, runners, and turnings. Old scrap primarily comes from old aircraft parts and discarded consumer products, such as lawnmower decks, chainsaw housings, and hand tools. The diecasting industry traditionally is the largest source of scrap magnesium.

Sorted scrap is charged into a steel crucible, which is heated to 675° C. As the scrap at the bottom begins to melt, more scrap is added. The liquid magnesium on the bottom is covered with a flux to inhibit surface burning. After any alloying elements are added and melting is complete, molten magnesium is transferred to ingot molds by either hand ladling, pumping, or tilt pouring.[6]

Economic Factors

Costs to produce magnesium metal vary greatly, depending upon the feed material and the process used. Operating costs for magnesium production range from $309 to $2,283 per ton, with energy costs as the largest component of the total operating cost. A weighted average operating cost was estimated to be $1,122 per ton. Total production costs from seawater sources were lower than from brines or dolomite sources. Magnesium compound operating costs also vary depending upon source material and processing techniques. Operating costs range from $24 to $425 per ton for magnesium compound production, with seawater as the most costly source. The weighted average operating cost for magnesium compounds production from all sources was $288 per ton. Energy costs also represent the largest component of total operating costs.[7]

Analysts at Commodities Research Unit (CRU) evaluated the direct operating costs of magnesium plants that operated during 1991. The operating cost curve showed that about one-half of the producers had direct operating costs less than $1.00 per pound of magnesium, and about 20% of the production was at direct operating costs above $1.25 per pound. In their cost estimates, CRU evaluated capital and operating costs for a 60,000-ton-per-year greenfield magnesium plant constructed in Australia. Capital costs were estimated at $470 million, with a 20% rate of return on investment over a 10-year life of the loan. In addition, operating costs were estimated to be $1.76 per pound in constant 1990 dollars, with most of the costs being capital charges resulting from the rate of return on investment and loan life. If the rate of return was lowered to 10% and the life of the loan was extended to 20 years, capital change would drop by one-half.[8]

Tariffs for magnesium and magnesium compounds are shown in table 3. Depletion allowance for magnesium chloride from domestic or foreign sources is 5%. Magnesium carbonate and dolomite have depletion allowances of 14% from domestic and foreign ores. Depletion allowances for other ores are brucite, 10% (domestic and foreign), and olivine, 22% domestic and 14% foreign. *(See table 3.)*

ANNUAL REVIEW

Magnesium

Legislation and Government Programs.—On August 16, the United States-Canada Binational Secretariat upheld findings by the Department of Commerce that Norsk Hydro Canada Inc. was dumping magnesium on the U.S. market. The panel, established by the United States-Canada Free Trade Agreement, also affirmed the countervailing duty determinations, except on two issues. The panel was unclear on why Commerce conducted a disproportionality analysis on an enterprise-by-enterprise basis rather than on an industry-by-industry basis. The panel also stated that Commerce's appropriate allocation period for grants to Norsk Hydro for pollution control equipment must be explained to be consistent with preceding binational panel cases. Commerce explanations of the two issues were due within 30 days of the findings.[9] After remanding the final antidumping duty determination to Commerce on August 16, the United States-Canada Binational Secretariat affirmed Commerce's redetermination on October 6. As a result, the antidumping duty on pure magnesium from Canada was reduced from 31.33% ad valorem to 21% ad valorem. This reduction makes the total antidumping and countervailing duties on pure magnesium 28.65%.[10]

Because of responses received in response to a request for administrative review, the Department of Commerce was initiating administrative reviews of antidumping and countervailing duty determinations made against Norsk Hydro Canada Inc. For antidumping duties assessed on pure magnesium, the review will cover the period from November 20, 1991, through July 31, 1993. For countervailing duties, the review period for pure and alloy magnesium is from December 6, 1991, to December 31, 1992. Commerce intended to issue the final results of these reviews by August 31, 1994.[11]

On October 16, Russia was added to the list of countries that can export their goods into the United States under the Generalized System of Preferences (GSP). Counties that are designated GSP countries can export goods either free of tariffs or at substantially reduced rates. For magnesium, Russia's exports into the United States became duty free with GSP status.

Production.—U.S. primary magnesium production in 1993 declined by 4% from the 1992 level. In contrast, producer stocks of magnesium metal increased significantly from the low level at yearend 1992 as imports supplied a greater share of domestic demand.

In September, Northwest Alloys Inc. announced that it would idle two of its primary magnesium furnaces at its plant in Addy, WA, for retrofitting. The furnaces were expected to be down for about 3 months, and according to industry estimates, production will be reduced by about 2,700 to 2,800 tons. Northwest Alloys reportedly has built up inventories and can satisfy existing contracts.[12] At the beginning of October, Dow Magnesium announced a magnesium production cutback of about 30%. The cutback was expected to take place in two phases; the first would occur before the end of 1993, and the second would occur in January 1994. Fourth quarter 1993 production losses were estimated to be about 3,000 to 4,000 tons. Approximately 20% of the company's work force will be affected by the closure. Dow cited the entrance of countries from the former U.S.S.R. into the world market as the principal reason for the closure.[13] *(See table 4.)*

Consumption and Uses.—Dow Magnesium announced that its direct-chill continuous magnesium caster came on-stream in November and that it was supplying T-bars to large aluminum customers on a trial basis. Although the caster was not intended to increase Dow's production levels, it was expected to eliminate some production bottlenecks. Dow initially will offer the T-bars in three sizes—250-pound, 500-pound, and 1,000-pound, and the company plans eventually to offer 500-pound and 750-pound round billets. A second caster was expected to be operational in January 1994. Dow is the only U.S. producer of the direct-chill-cast T-bars, which the company claims have a smoother surface and a lower likelihood of pockets than conventionally cast magnesium ingots.[14]

The automotive industry continued to be a main target area for increasing magnesium usage resulting in announcements of new magnesium alloy components and increases in diecasting capacity to meet the growing demand. Port City Diecasting in Muskegon, MI, planned to complete construction on a 1,200-square-meter magnesium diecasting facility in the summer. The company, which has been casting aluminum and zinc, is installing two 600-ton cold-chamber diecasting machines dedicated to magnesium. About one-half of Port City's current customers are with the automotive industry, and the company expects to have the same product mix with magnesium.[15]

Magnesium Products of America Inc., a subsidiary of Canada's Meridian Technologies Inc., plans to install three 3,000-ton magnesium diecasting machines in its new facility in Eaton Rapids, MI; the total number of high-pressure casting machines was scheduled to be 12 or 13, ranging in size from 800 tons to 3,000 tons. This new plant was expected to be in operation in September.[16]

Because of increased demand for large die-cast magnesium components, Lunt Manufacturing planned to begin construction of a second 6,000-square-meter magnesium casting facility near Chicago, IL, in 1993. The company currently operates an 8,000-square-meter facility with 12 diecasting machines.

Borg-Warner Corp. plans to increase its production of magnesium alloy four-wheel-drive transfer cases by more than 100%, to a level of more than 500,000 units annually, within 3 years. Production of the additional cases will require nearly 3,000 tons of magnesium annually. The transfer cases are among the largest automotive parts made of magnesium, and Borg-Warner expected to shift to a production ratio of 90% magnesium-10% aluminum within 3 years.[17]

Chrysler Corp. announced that it would incorporate magnesium steering wheel armatures on its new economy car models, which were scheduled to be introduced early in 1994. It is estimated that this application will consume about 200 to 250 tons of magnesium annually. Chrysler's components will be manufactured by Gibbs Die Casting Corp., Henderson, KY, the same company that manufactures steering wheel diecastings for Ford Motor Co.[18] Ford also is investigating the potential for magnesium steering wheels for the 1996 models of another of its product lines. Ford currently uses magnesium steering wheels on several platforms. This application was estimated to represent 800 to 900 tons of magnesium alloy consumption per year.

Chrysler also reportedly finalized plans to use magnesium steering columns and mounting brackets in its minivans beginning in 1996. Total annual magnesium requirements for these parts were estimated to be about 1,000 tons annually. Suppliers for the die-cast parts were Magnesium Products Ltd. in Canada and U.S. manufacturer Diemakers Inc.[19]

Ford and General Motors Corp. (GM) were investigating the use of magnesium alloy seat risers in place of conventional steel units in two truck lines for the 1996 model year. These applications could consume more than 3,000 tons of magnesium alloy annually. Replacement of the steel part with magnesium alloy diecasting is projected to reduce the part weight from 3.6 to 4.5 kilograms to 0.9 to 1.1 kilograms.[20]

GM reportedly was completing plans for instrument panel support beam applications that could require about 5,000 tons of magnesium per year. The new components, which were scheduled to be introduced over a 2-year period beginning in late 1995, were expected to replace steel stampings in three vehicle lines. With a weight of 15 kilograms, the magnesium components were estimated to replace more than 17,000 tons of steel in GM's midsize and standard-size vans and C-body luxury cars.[21]

U.S.-based Rossborough Manufacturing was finalizing a joint venture with the East Slovak Steel Co. to construct a blending plant to produce magnesium-base desulfurization powders in Slovakia. Rossborough planned to expand the plant as demand for desulfurization increases in Eastern Europe.[22]

Dynacast Inc. reportedly acquired the assets of Lone Star Die Casting Corp., New Braunfels, TX, a major supplier of aluminum and magnesium diecastings for garden tools.[23]

IBM Corp. announced that it was producing a small pen-base notebook computer with magnesium cases. Because of magnesium's light weight, the material was chosen to reduce the case mass and make the computer easier to carry.[24]

A review of structural magnesium applications highlighted changes in the past 30 years. In 1966, more than 50 applications for magnesium were cited in 13 areas; by 1988, only 23 applications in 7 areas were cited. Reductions in the number of applications occurred in aerospace and nonindustrial machinery in particular. However, automotive and sporting good applications have increased.[25] *(See tables 5 and 6.)*

Stocks.—Producers' stocks of primary magnesium at yearend 1993 increased to 17,827 tons, more than three times the level at yearend 1992 of 5,863 tons. Stocks of magnesium metal and alloy held by consumers increased to 7,772 tons at yearend 1993 from 7,274 tons at yearend 1992. Consumer stocks of secondary magnesium also increased to 388 tons at yearend 1993 from 356 tons at yearend 1992.

Markets and Prices.—Magnesium prices quoted in trade journals generally decreased steadily through the first three quarters of 1993 before beginning to rise again. The Metals Week U.S. transaction price quotation declined from a range of $1.46 to $1.53 per pound at the beginning of the year to $1.36 to $1.46 by the end of the second quarter. Beginning in July, Metals Week began publishing two primary magnesium prices—the U.S. spot Western price and the U.S. spot dealer import price. The spot Western price would only reflect North American producer-consumer transactions, while the spot dealer import would reflect the price of imported magnesium, delivered, duty paid. These two quotations would replace the U.S. transaction price, which was a weighted average of all transactions.

The Metals Week U.S. spot dealer import price range was quoted at $1.22 to $1.48 per pound at the beginning of the third quarter, and this range dropped steadily to a low of $1.13 to $1.18 per pound by mid-September. By yearend, this price range had increased slightly to $1.17 to $1.21 per pound.

The Metals Week U.S. spot Western price was estimated at $1.45 to $1.46 from the beginning of July through mid-November. From that point, the range widened to $1.43 to $1.46 and remained at that level until yearend.

At the beginning of 1993, Metals Week's quoted European free market price range was $2,400 to $2,500 per ton. The range declined to reach a low for the year of $1,975 to $2,050 by the beginning of September and rose to $2,250 to $2,325 per ton by the end of the year.

Metal Bulletin's free market price quotation also trended downward through the first three quarters of 1993. At the beginning of 1993, the price range was quoted at $2,500 to $2,550 per ton. By mid-September, the quoted range had decreased to $1,950 to $2,050 per ton. This range rose to reach $2,220 to $2,300 per ton by the end of the year.

Foreign Trade.—Exports of magnesium in 1993 declined by 25% from the 1992 level. Canada, Japan, and the Netherlands were the principal destinations. Imports of magnesium increased significantly, with imports from Canada, Russia, and Ukraine making up the bulk of the total. *(See tables 7 and 8.)*

World Review.—In early September, Euroalliages, a European producer association, filed an antidumping suit against magnesium imports from the former U.S.S.R. The European Commission accepted the complaint in October, which alleged that magnesium from the Commonwealth of Independent States was dumped at a margin of 123%. Russian producers stated that the low prices of the magnesium appearing on the European market were from illegal exports and did not correspond to producer prices. Other countries, including Japan and India, also claimed that exports from the former U.S.S.R. were having an adverse effect on their magnesium production.[26]

According to the International Magnesium Association (IMA), world magnesium inventories at the end of 1993 were 42,400 tons, a 44% increase from the yearend 1992 level of 29,500 tons. *(See tables 9, 10, and 11.)*

Australia.—The Australian Federal and Queensland State Governments were jointly funding a feasibility study to construct a magnesium diecasting facility in Gladstone, near Queensland Metals Corp.'s (QMC) proposed magnesium plant. The study represented a strategy for adding value to QMC's magnesite deposit.

Canada.—Meridian Technologies, a Canadian-based magnesium diecaster, reportedly completed two agreements to expand its market into Europe. The company announced an agreement in principle with Stahlschmidt & Maiworm Technics GmbH to develop, produce, and sell magnesium wheels in Germany. Meridian Technologies also signed a Heads of Agreement with Italy's Teksid, with the objective of setting up a European diecasting operation. Teksid, which produces iron and aluminum castings, would provide European contacts and market knowledge to Meridian Technologies.[27]

Magnesium Products installed two 800-ton cold-chamber diecasting machines at its Strathroy, Ontario, facility and began operating a 2,200-ton caster to bring the total casting capacity at the plant to 7,000 tons per year. The company also completed construction at its Eaton Rapids, MI, plant and was planning a June 1994 startup.[28]

France.—Because of high inventory levels, Pechiney announced that it would close two-thirds of its 17,000-ton-per-year primary magnesium production capacity in November 1993, earlier than the company's normal winter closure. Pechiney originally was scheduled to shut down production completely between Christmas and the beginning of March. With the high inventory levels, the company could supply its customers' needs despite the closure. Closure of the plant during the winter, which was initiated last year and occurred during January and February only, was originally intended to reduce electric power costs.[29]

Israel.—At the end of June, Israel's Dead Sea Works (DSW), a subsidiary of Israel Chemicals Ltd. (ICL), announced that it had signed a $9 million contract with a consortium of companies and research institutes in the Commonwealth of Independent States to purchase electrolytic cell technology using carnallite as a feed material. In March, ICL's board of directors had approved a $366 million investment for the plant and a new 110-megawatt power station. The new plant will be at the southern tip of the Dead Sea in the town of Sdom. By mid-July, two Israeli engineering firms had begun work on the engineering, construction, procurement, and management for the planned 25,000-ton-per-year magnesium plant, scheduled to be completed in 1995. If expansion is warranted, construction of a second 25,000-ton-per-year phase is scheduled for 1998. A foundation stone-laying ceremony was held on October 19.[30]

Japan.—Japanese magnesium producer Ube Industries Ltd. reportedly signed a formal agreement with an unidentified partner in China to take dolomite feedstock under a long-term agreement. Previously, Ube Industries had long-term agreements with suppliers in the Republic of Korea and Taiwan and made spot purchases from China. Ube Industries was estimated to require between 80,000 and 100,000 tons of dolomite per year.[31]

Japan Metal & Chemicals (JMC) reportedly liquidated its 5,000-ton-per-year primary magnesium plant in December, after it had been idle for more than 1 year. The plant was originally opened in 1987 and has been closed since mid-1992. Furnace problems were cited as the original reason for closure, but because of increased imports from China and the former U.S.S.R. and appreciation of the yen, the plant has remained closed. JMC announced that it would continue to market magnesium through remelting ingot consigned from Northwest Alloys Inc.[32]

Kawasaki Steel Corp. in Japan announced that it is testing a desulfurization process using magnesium; this company would be the first Japanese steel producer to use magnesium. This could increase the world magnesium desulfurization market significantly.[33]

Japan's Kobe Steel finished installing production equipment at its new aluminum and magnesium alloy casting plant in Daian. The casting shop was expected to be completely operational by December.[34]

Norway.—Hydro Magnesium reportedly was conducting a preliminary study to build a magnesium recycling plant near Herøya, Norway. The proposed plant would have a capacity of 10,000 tons per year and would be the first magnesium recycling plant in Norway. To encourage European automakers to use magnesium, the plant would melt scrap returned from diecasters and return it in ingot form. Completion of the study was scheduled for the second or third quarter of 1993.[35]

Saudi Arabia.—A feasibility study conducted for the Gulf Organization for Industrial Consultancy, an offshoot of the Gulf Corporation Council (GCC), suggested constructing a 10,000-ton-per-year primary magnesium plant in the Persian Gulf area. (The six Arab nations that form the GCC are Bahrain, Kuwait, Oman, Qatar, Saudi Arabia, and the United Arab Emirates.) The study said that Saudi Arabia would be a likely location for the new plant, but both Oman and Qatar could be possible locations. Annual magnesium demand in the six nations was estimated to be 3,000 tons, but was expected to increase to 10,000 tons by 2000. Cost for building the new magnesium plant was calculated to be $85 million, and because of inexpensive fuel costs in the area, the consultancy estimated that the cost of producing 1 ton of magnesium would be $2,880.[36]

Ukraine.—In Ukraine, the Government introduced export duties on a variety of metals and raw materials. Included in these materials is magnesium, which has an export duty of 30% of the sale price, effective June 1, 1993. Previously, the country had no export duty on magnesium.[37] In May, Alusuisse-Lonza Trading Group reportedly signed an agreement with Kemo Komplex in Ukraine to market its Kalusch 99.9% magnesium in most areas of the world. Kemo Komplex was expected to continue to market magnesium in Europe, and its agreement with Alusuisse-Lonza would improve its marketing, transportation, and storage arrangements.[38]

Current Research.—Researchers at the U.S. Bureau of Mines have developed a process to vacuum distill magnesium and zinc from aluminum alloys as an alternative to chlorination. Distillation is considered more environmentally benign than chlorination, and the metals are produced as byproducts that can be recycled. Bench-scale tests have shown lower than expected distillation rates at 850° C, but commercial operations could use induction heating at higher temperatures to improve distillation rates.[39]

The International Magnesium Association's annual magnesium conference highlighted developments in several areas of magnesium and magnesium alloy technology. Topics covered in papers presented at the 1993 conference included advancements in magnesium alloy diecasting technology, alloy development and improvements, desulfurization advances, and magnesium alloy recycling.[40]

Researchers at the Universidad Nacional Autonoma de Mexico studied the effects of microstructure and alloying elements on the efficiency of sacrificial magnesium anodes. From the results of their investigations, the researchers found that by controlling the quantity of second-phase, iron-rich particles at grain boundaries, anode efficiency was improved.[41]

As part of a broad research program aimed at the characterization and development of magnesium and magnesium alloy composites, researchers at Laval University investigated different methods of producing magnesium and magnesium alloy composites reinforced with silicon carbide. Two methods of powder metallurgy processing and one method of ingot metallurgy processing were investigated. In the first powder metallurgy method, mechanical alloying using a low-energy ball mill to form composite particles is followed by hot pressing and hot extrusion. The second powder metallurgy method used simple dry mixing of the particles, followed by hot pressing and hot extrusion. In ingot metallurgy, a fluxless melting technology is used. The researchers found that the best combination of properties, including crack initiation and propagation behavior, was achieved with the low-energy mechanical alloying.[42]

Magnesium Compounds

Production.—Because of decreases in the demand for domestically produced refractory magnesia, production of dead-burned magnesia and magnesium hydroxide declined in 1993. Other magnesium compound production increased slightly.

Dow announced that it had expanded the magnesium hydroxide production capacity at its Ludington, MI, plant to 125,000 tons per year, an increase of 30,000 tons from the prior capacity level. This increase in capacity was driven by anticipated growth in acid neutralization applications for magnesium hydroxide.[43] Martin Marietta Magnesia Specialties reportedly completed a new facility at its Manistee, MI, location for producing FlowMag® slurry products use in wastewater neutralization applications. The company also received a patent on its FlowMag granular product, used to remove heavy metals from industrial-process effluent. To reduce costs and to broaden its product line, Martin Marietta began importing magnesite from China in 1993.[44] *(See table 12.)*

AIMCOR announced that it planned to sell its Metals/Minerals Group, including its olivine operations. The company has hired investment bankers Bowles Hollowell Connor & Co. to find a buyer for the group as a whole or separate buyers for the minerals division and the metals division.[45]

Consumption and Uses.—Dead-burned magnesia refractories for use in metal, cement, and glass production furnaces continued to be the primary application for magnesium compounds in the United States, representing about 66% of the total U.S. demand for magnesium compounds.

In 1993, agricultural applications (animal feed and fertilizer) were the dominant use for caustic-calcined magnesia, accounting for 35% of U.S. shipments. Chemical processing was the next largest segment, with 18% of total shipments. The following categories, with the individual components in parentheses in declining order, were the other end-use sectors for caustic-calcined magnesia: metallurgical (refractories, water treatment, electrical, and stack-gas scrubbing), 16%; manufacturing (rayon, rubber, fuel additives, and pulp and paper), 13%; construction (oxychloride and oxysulfate cements and general construction), 5%; pharmaceuticals and nutrition (medicinal and pharmaceutical, sugar, and candy), 4%; and unspecified uses, 9%.

Magnesium carbonate was used principally as a chemical intermediate and in medicines and pharmaceuticals. Magnesium hydroxide was used mainly in the chemical industries, water treatment, and pulp and paper. Magnesium sulfate was used mostly in pharmaceuticals and animal feed.

Magnesium chloride was used mainly in oxychloride cements. Magnesium chloride brines were used principally for road dust and ice control.

Foundry uses were the largest application for olivine in the United States, accounting for 60% of consumption of domestically produced material. Refractory applications consumed 26% of U.S. olivine shipments, sand blasting and other abrasive applications accounted for 7%, and slag control accounted for the remaining 7% of U.S. olivine consumption. *(See table 13.)*

Markets and Prices.—Most quoted magnesium compound prices at yearend 1993 were significantly higher than prices at the end of 1992. Magnesium hydroxide prices in particular increased almost 25%, which was mainly a result of the increased interest in the material in environmental applications.

U.S. olivine prices, quoted in Industrial Minerals, were $62 to $109 per ton for foundry grade and $50 to $79 per ton for aggregate material. All prices were quoted f.o.b. mine or plant. *(See table 14.)*

Foreign Trade.—Trade data for olivine are not reported separately by the Bureau of the Census. Some data on olivine are available from a computer service, the Port Import/Export Reporting Service (PIERS). PIERS reports data on materials that are transported by ship. According to this source, the United States imported 136,478 tons of olivine from Norway in 1993. Exports of olivine from the United States totaled 1,859 tons. Peru, with 43% and Chile, with 33% of the total, were the principal recipients. Australia, Italy, the Republic of Korea, New Zealand, and Taiwan were the other destinations. *(See tables 15, 16, 17, and 18.)*

World Review.—In Europe, the refractory magnesia market has undergone significant changes in the past few years. Western Europe has been a large producer and significant exporter of dead-burned magnesia, but recently imports have supplied up to 35% of the area's needs. For first-grade refractory magnesia, domestic sources in Greece, Ireland, Italy, the Netherlands, and the United Kingdom traditionally supplied most of western Europe's requirements, but closures in Greece, Italy, and the United Kingdom changed this. With the opening of the Qmag plant in Australia, this country is emerging as a major supplier to western Europe.[46]

Australia.—Queensland Metals Corp. (QMC) and ICI Australia Ltd. reportedly signed an agreement that formally establishes the Enviromag joint venture in May. The 50-50 joint venture was incorporated as Enviromag (Marketing) Pty. Ltd. The company planned to market magnesium hydroxide for environmental markets throughout the world.[47] QMC also reached an agreement in principle with a European group to join the 50-50 Flamemag joint venture, for which the primary objective is to identify to lowest cost process capable of producing a wide range of magnesium hydroxides from magnesite. QMC planned to construct a large pilot plant in Europe, to be operational by the second half of 1994.

China.—At the Liaoning Magnesite Refractory Co., a two-stage froth flotation process was developed to eliminate talc and other minerals from magnesite. By using this process, the magnesite concentrate may be upgraded to contain less than 1.5% silica. A two-stage calcining process also was developed to produce high-purity dead-burned magnesite. By using the high-purity raw material, the company has produced magnesia-carbon, magdol-carbon, direct-bonded magnesite-chrome, and magnesite-alumina refractory bricks. With the process improvements, these refractories have shown improved service performance in several iron and steel- and cement-making applications.[48]

Greece.—To improve the quality of both caustic-calcined and dead-burned magnesite, Grecian Magnesite S.A. commissioned a new petroleum coke facility and a new research and development laboratory. The company also was involved with several outside partners in developing new dead-burned refractory materials. The other magnesite producer, Magnomin Gemco S.A., switched from producing only caustic-calcined magnesite to a 50-50 mix of caustic-calcined and dead-burned magnesite over the past few years. Magnomin was involved in improving product quality through its research and development program, which involved evaluation of the effects of particle size of dead-burned magnesite and assessing the advantages of vertical shaft kilns.[49]

To make itself more attractive to potential buyers, Fimisco reportedly restarted magnesia refractories production in late 1993 from stockpiles of raw materials that the company had on hand. The company was put under Alpha Finance A.E. and was being privatized during 1993, although there were no offers for Fimisco during the first round of privatization. Mining, Trading & Manufacturing Ltd. (MTM), a Greek magnesite producer whose operations have been closed since 1988, also was undergoing privatization under the auspices of Alpha Finance. MTM's operations consisted of an open pit and underground mine, prebeneficiation and beneficiation facilities, and two shaft kilns.[50]

India.—India Rayon announced that it was beginning a project to produce 50,000 tons per year of high-purity refractory magnesia from seawater. This plant will be India's first seawater magnesia plant. Commercial production was expected to begin in early 1995. Refractories Consulting and Engineering, an Austrian firm, was providing technology for the project, and India Rayon was planning to import a part of the plant and equipment required for the project.[51]

In June, Dalmia Magnesite Corp. announced that it was closing its mines in Tamil Nadu for at least 2 months. Before the closure, the company had been working at reduced levels because of poor market conditions. Because of reduced import duties for magnesite, implemented in February, less costly imports from Australia, Brazil, China, North Korea, and Turkey have increased to supply a greater share of the country's demand.[52]

Khaitan Hostombe Spinels reportedly was constructing a $100 million plant in Salem, Tamil Nadu, to produce sintered magnesia and magnesia-chrome clinker. The new 34,000-ton-per-year plant, scheduled to be completed by the third quarter of 1994, will supply domestic consumers, substituting for material that previously was imported.[53]

Israel.—In October, the new 13,000-ton-per-year fused magnesia plant at Mishor Rotem was inaugurated. This $23 million plant is operated by Tateho Dead Sea Fused Magnesia Co., a joint venture between Japan's Tateho Chemical Industries Co. Ltd. and Israel's Dead Sea Periclase Ltd. Preliminary product specifications indicated that the fused magnesia contained 99.5% MgO and 0.5% CaO, with a specific gravity greater that 3.5 grams per cubic centimeter. Initial plant operations will focus on fine tuning process parameters and determining if more than one grade of fused magnesia will be produced.[54]

Jordan.—The Arab Potash Co. Ltd. (APC) planned to build a 3.6-ton-per-day pilot magnesia plant at Safi, the company's existing site. Refractories Consulting & Engineering will supply the equipment and technology for the $1 million plant, which was scheduled to be completed by the beginning of 1994. Magnesium chloride for the plant will be extracted from the brines that APC already uses as a source of potassium chloride. Depending on the results of the pilot tests, APC may decide to construct a 100,000-ton-per-year plant at the same site.[55]

Netherlands.—Billiton Refractories BV was put up for sale by its parent company Royal Dutch/Shell Group after negotiations between Gencor Ltd. and the Shell Group fell through because Billiton did not fit into Gencor's activities. Although many companies were rumored as possible buyers for Billiton, negotiations were not expected to be completed by yearend. Billiton Refractories operates a 100,000-ton-per-year dead-burned magnesia plant in Veendam.[56]

Turkey.—To reform its large state-owned enterprises, Turkey targeted some of its operations for closure and some for privatization. Two of the country's largest magnesite operations—Kümas Kütahya Manyezit and Konya Krom Manyezit—were scheduled for privatization. Kümas was separated from its parent, Çitosan, in 1992, was offered for sale in March 1993, and the bidding was closed in May. One of Turkey's private-sector magnesite companies, Magnesit AS, was one of two companies that bid on Kümas. Konya remained under the umbrella of Çitosan, but was undergoing a major modernization and automation program scheduled to be finished by the end of 1994.[57]

Magnesit began recovering crude magnesite from waste dumps at its mines in June after extensive design studies and testing. The recovery was initiated in 1992 and uses magnetic separation rather than heavy-media separation to recover the magnesite. Original estimates of output were 85,000 tons of crude magnesite per year.[58]

United Kingdom.—U.S.-based J. E. Baker Co. announced an agreement with Redland PLC to acquire the manufacturing plants of Steetly Refractories Ltd. in January. Steetly has two facilities in Worksop and Dudley. The acquisition of the magnesia refractories operations will complement J. E. Baker's dolomite refractories operations in the United States and will enhance the company's international position. *(See tables 19, 20, and 21.)*

Current Research.—Science Ventures Inc. announced that it had developed a leaching process to remove unwanted magnesium from dolomitic phosphate ores as marketable magnesium oxide. In the process, called the P^3 process, sulfuric acid is added to the ore to maintain a pH range of 4.0 to 4.4 and carbon dioxide is continuously removed by boiling the solution. In a second step, lime is added to the solution to precipitate magnesium hydroxide. The process was developed because the magnesium content of dolomitic phosphate ores increases solution viscosity and precipitates on equipment used in the manufacture of phosphoric acid.[59]

OUTLOOK

Magnesium producers throughout the world, but especially in the United States, have targeted the automotive industry as a potential growth market for magnesium. Within the past 15 years, through the introduction of high-purity diecasting alloys, the average magnesium content of a North American automobile has increased from 0.5 kilogram to 2.3 kilograms. As a result, production of magnesium diecasting has increased significantly. Steady growth in this area is likely, as automobile manufacturers continue to announce new applications for magnesium diecastings in future car, truck, and van models.

Other large applications for magnesium, aluminum alloying and iron and steel desulfurization, are likely to be areas of slow growth for magnesium consumption. These markets are fairly mature in the United States. In aluminum alloying, most of the magnesium is used for beverage cans, which generally grow only with increases in population. Although iron and steel desulfurization has had a large growth rate in the past decade, most of the U.S. market already has been captured from calcium carbide. Growth in the desulfurization market only will come as additional metal requires desulfurization, not as a result of substitution done in the past.

The most important influence on world supply of magnesium has been exports from Kazakhstan, Russia, and Ukraine appearing on the world market. In 1993, Russia and Ukraine were responsible for a 470% increase in U.S. primary magnesium imports from the 1992 figure. The IMA also reported that there was a significant increase in imports from the former U.S.S.R. to Europe and Japan. Most of this material was used for aluminum alloying and desulfurization. The European producers already have filed an antidumping suit against these magnesium imports, and press reports indicated that antidumping suits may be filed in the United States and Japan. U.S. producers have cited these increased imports as reasons for closing parts of their plants. World inventories also have shown a significant increase from 1992 levels. The outcome of the European antidumping suit and resolution of potential antidumping actions in the rest of the world will have a significant impact on the world supply of magnesium.

Production and demand for magnesium compounds in the United States were expected to remain relatively stable over the new few years, but the proportion of magnesia used as refractories was expected to continue to decrease. Technological changes in steel production have had a deleterious effect on the consumption of specific refractories. Open-hearth furnaces have been replaced by electric arc furnaces and basic-oxygen steelmaking. Although the trend to electric arc furnaces has reduced the overall demand for refractories, high-quality basic refractories (including magnesia-base refractories) are needed for the body of the furnace. At the same time, improvements in refractories technology resulted in increased longevity. There will still be a demand for magnesia refractories, but producers will continue to work to produce higher quality material that is needed by their customers.

Although refractories are the principal use for magnesia, environmental applications, such as flue gas desulfurization and water treatment, are being investigated as growth areas for magnesia and other magnesium compounds. Any increase in demand for other magnesium compounds is expected to be offset by the decline in refractories demand, leading to a stagnant demand for magnesium compounds in the United States.

TABLE 2
U.S. MAGNESIUM COMPOUND PRODUCERS, BY RAW MATERIAL SOURCE, LOCATION, AND PRODUCTION CAPACITY, IN 1993

Raw material source and producing company	Location	Capacity (metric tons of MgO equivalent)	Products
Magnesite: Premier Services Inc.	Gabbs, NV	100,000	Caustic-calcined and dead-burned magnesia.
Lake brines:			
Great Salt Lake Minerals Corp.	Ogden, UT	90,000	Magnesium chloride and magnesium chloride brines.
Reilly Industries Inc.	Wendover, UT	45,000	Magnesium chloride brines.
Well brines:			
The Dow Chemical Co.	Ludington, MI	214,000	Magnesium hydroxide.
Martin Marietta Magnesia Specialties Inc.	Manistee, MI	275,000	Caustic-calcined and dead-burned magnesia.
Morton International	do.	10,000	Magnesium carbonate, magnesium hydroxide, and caustic-calcined magnesia.
Seawater:			
Barcroft Co.	Lewes, DE	5,000	Magnesium hydroxide.
The Dow Chemical Co.	Freeport, TX	20,000	Magnesium chloride.
Marine Magnesium Co.	South San Francisco, CA	15,000	Magnesium carbonate, magnesium hydroxide, and caustic-calcined magnesia.
National Refractories & Minerals Corp.	Moss Landing, CA	165,000	Magnesium hydroxide and caustic-calcined and dead-burned magnesia.
Premier Services Inc.	Port St. Joe, FL	50,000	Caustic-calcined and dead-burned magnesia.
Total		989,000	

TABLE 3
U.S. IMPORT DUTIES

Item	HTS No.	Most favored nation (MFN)	Non-MFN
		Jan. 1, 1993	Jan. 1, 1993
Magnesium:			
Unwrought magnesium	8104.11.0000	8.0% ad valorem	100% ad valorem.
Unwrought magnesium alloys	8104.19.0000	6.5% ad valorem	60.5% ad valorem.
Magnesium waste and scrap	8104.20.0000	Free	Free.
Wrought magnesium	8104.90.0000	14.8 cents per kilograms on Mg content + 3.5% ad valorem	88 cents per kilogram on Mg content + 20.0% ad valorem.
Magnesium compounds:			
Crude magnesite	2519.10.0000	Free	$10.33 per ton.
Dead-burned and fused magnesia	2519.90.1000	0.4 cent per kilogram	1.7 cents per kilogram.
Caustic-calcined magnesia	2519.90.2000	$2.07 per ton	$20.70 per ton.
Other magnesia	2519.90.5000	Free	15.4 cents per kilogram.
Calcined dolomite	2518.20.0000	6% ad valorem	30% ad valorem.
Kieserite, natural	2530.20.1000	Free	Free.
Epsom salts, natural	2530.20.2000	3.7% ad valorem	20% ad valorem.
Magnesium hydroxide and peroxide	2816.10.0000	3.1% ad valorem	25% ad valorem.
Magnesium chloride	2827.31.0000	1.5% ad valorem	5% ad valorem.
Magnesium sulfate	2833.21.0000	3.7% ad valorem	20% ad valorem.

TABLE 5

MAGNESIUM RECOVERED FROM SCRAP PROCESSED IN THE UNITED STATES, BY KIND OF SCRAP AND FORM OF RECOVERY

(Metric tons)

	1989	1990	1991	1992	1993
KIND OF SCRAP					
New scrap:					
Magnesium-base	3,951	3,992	4,867	4,539	3,221
Aluminum-base	19,278	19,432	18,192	21,652	25,092
Total	23,229	23,424	23,059	26,191	28,313
Old scrap:					
Magnesium-base	4,269	4,277	4,443	4,220	4,323
Aluminum-base	23,702	27,107	23,041	26,634	26,254
Total	27,971	31,384	27,484	30,854	30,577
Grand total	51,200	54,808	50,543	57,045	58,890
FORM OF RECOVERY					
Magnesium alloy ingot[1]	4,494	4,290	4,604	W	W
Magnesium alloy castings	795	857	1,043	923	1,091
Magnesium alloy shapes	635	301	158	329	413
Aluminum alloys	43,125	46,807	41,606	48,619	51,587
Zinc and other alloys	W	W	3	3	2
Other[2]	2,151	2,553	3,129	7,171	5,797
Total	51,200	54,808	50,543	57,045	58,890

W Withheld to avoid disclosing company proprietary data; included in "Other."

[1]Includes secondary magnesium content of both secondary and primary alloy ingot.

[2]Includes chemical and other dissipative uses and cathodic protection, as well as data indicated by symbol "W."

TABLE 6

U.S. CONSUMPTION OF PRIMARY MAGNESIUM, BY USE

(Metric tons)

Use	1989	1990	1991	1992	1993
For structural products:					
Castings:					
Die	5,627	7,479	7,532	8,920	10,949
Permanent mold	811	875	750	853	746
Sand	1,017	724	575	450	397
Wrought products:					
Extrusions	6,712	7,848	6,387	6,435	7,433
Other[1]	2,941	3,096	2,415	2,408	2,438
Total	17,108	20,022	17,659	19,066	21,963
For distributive or sacrificial purposes:					
Alloys:					
Aluminum	53,821	45,060	45,809	41,003	46,498
Other	9	8	9	10	10
Cathodic protection (anodes)	5,474	5,421	4,976	4,852	4,723
Chemicals	594	800	695	739	653
Iron and steel desulfurization	10,463	9,853	10,895	13,611	12,525
Nodular iron	1,635	1,424	1,074	W	W
Reducing agent for titanium, zirconium, hafnium, uranium, beryllium	10,798	8,989	6,071	8,209	9,092
Other[2]	5,324	4,531	4,684	6,337	5,107
Total	88,118	76,086	74,213	74,761	78,608
Grand total	105,226	96,108	91,872	93,827	100,571

W Withheld to avoid disclosing company proprietary data; included in "Other."

[1] Includes sheet and plate and forgings.

[2] Includes scavenger, deoxidizer, and powder.

TABLE 9
WORLD ANNUAL PRIMARY MAGNESIUM PRODUCTION CAPACITY,[1] DECEMBER 31, 1993, BY CONTINENT AND COUNTRY

(Metric tons)

Continent and country	Capacity
North America:	
Canada	49,000
United States	160,000
Total	209,000
South America: Brazil	10,600
Europe:	
France	17,000
Italy	[2]10,000
Kazakhstan	[3]65,000
Norway	41,000
Russia	[3]95,000
Serbia and Montenegro	[2]7,000
Ukraine	[3]54,000
Total	289,000
Asia:	
China	10,000
India	1,500
Japan	8,300
Total	19,800
World total	528,400

[1] Includes capacity at operating plants as well as at plants on standby basis.

[2] Standby capacity only.

[3] Includes magnesium production capacity that is used exclusively for titanium production as follows: Kazakhstan, 40,000 metric tons; Russia, 35,000 metric tons; and Ukraine, 15,000 metric tons.

TABLE 10

MAGNESIUM: WORLD PRIMARY PRODUCTION, BY COUNTRY[1]

(Metric tons)

Country	1989	1990	1991	1992	1993[e]
Brazil[e]	6,200	[r]8,700	7,800	7,300	9,700

China[e]	[r]3,500	[r]5,900	[r]8,600	[r]10,000	12,000
France	14,600	[r] [e]14,000	[e]14,000	[r]13,700	13,000
Italy	[r]5,768	5,725	[r]3,919	[r]1,211	—
Japan	8,381	12,843	11,559	[r]7,119	7,500
Kazakhstan[e]	—	—	—	20,000	20,000
Norway	49,827	48,222	44,322	30,404	27,300
Russia[e] [2]	—	—	—	40,000	30,000
Serbia and Montenegro[3]	—	—	—	[e]4,000	—
Ukraine[e]	—	—	—	10,000	9,000
U.S.S.R.[e] [4]	91,000	88,000	80,000	—	—
United States	152,066	139,333	131,288	136,947	[5]132,144
Yugoslavia[3] [6]	6,105	5,788	[e]4,000	—	—
Total	[r]344,447	[r]355,237	[r]341,000	[r]306,381	283,944

[e] Estimated. [r] Revised.

[1] Table includes data available through July 14, 1994.

[2] Includes secondary.

[3] All production in Yugoslavia 1989-91 came from Serbia and Montenegro.

[4] Dissolved in Dec. 1991.

[5] Reported figure.

[6] Dissolved in Apr. 1992.

TABLE 11

MAGNESIUM: WORLD SECONDARY PRODUCTION, BY COUNTRY[1]

(Metric tons)

Country	1989	1990	1991	1992	1993[e]
Brazil[e]	1,500	1,600	1,600	1,600	1,600
Japan	20,270	23,308	17,158	12,978	[2]13,215

United Kingdom[e] [4]	1,000	[r]900	[r]800	800	500
United States	51,200	[r]54,808	50,543	57,045	[2]58,890
Total	81,970	[r]88,116	[r]77,101	78,923	80,205

[e] Estimated. [r] Revised.

[1] Table includes data available through July 14, 1994.

[2] Reported figure.

[3] Dissolved in Dec. 1991; however, information is inadequate to formulate reliable estimates for individual countries.

[4] Includes alloys.

TABLE 12
SALIENT MAGNESIUM COMPOUND STATISTICS

(Thousand metric tons and thousand dollars)

	1989	1990	1991	1992	1993
United States:					
Caustic-calcined and specified magnesias:[1]					
Shipped by producers:[2]					
Quantity	135	135	154	130	131
Value	$39,529	$37,850	$48,074	[r]$36,781	$39,476
Exports, value[3]	$2,263	$1,406	$2,289	$2,404	$2,459
Imports for consumption, value[3]	$13,657	$13,957	$15,891	$12,309	$15,709
Refractory magnesia:					
Shipped by producers:[2]					
Quantity	348	335	296	291	268
Value	$97,673	$94,962	$85,292	$80,756	$77,716
Exports, value	$10,685	$19,709	$25,038	$22,257	$21,807
Imports for consumption, value	$38,555	$32,858	$30,209	$37,928	$48,673
Dead-burned dolomite:					
Sold and used by producers:					
Quantity	365	342	308	[r]302	315
Value	$28,294	$26,988	$25,736	$25,230	$26,218
World production (magnesite)	[r]11,953	[r]10,481	[r]9,813	[r]10,501	[e]10,136

[e] Estimated. [r] Revised.

[1] Excludes caustic-calcined magnesia used in the production of refractory magnesia.

[2] Includes magnesia used by producers.

[3] Caustic-calcined magnesia only.

TABLE 13
U.S. MAGNESIUM COMPOUNDS SHIPPED AND USED

	1992		1993	
	Quantity (metric tons)	Value (thousands)	Quantity (metric tons)	Value (thousands)
Caustic-calcined[1] and specified (USP and technical) magnesias	130,118	[r]$36,781	131,207	$39,476
Magnesium hydroxide [100% $Mg(OH)_2$][1]	267,087	[r]64,445	252,471	61,585
Magnesium sulfate (anhydrous and hydrous)	37,889	13,919	42,687	13,974
Precipitated magnesium carbonate[1]	2,162	547	3,005	672
Refractory magnesia	290,558	80,756	268,275	77,716

[r] Revised.

[1] Excludes material produced as an intermediate step in the manufacture of other magnesium compounds.

TABLE 14
YEAREND MAGNESIUM COMPOUND PRICES

Material		Price
Magnesia, natural, technical, heavy, 85%, f.o.b. Nevada	per short ton	$232- $265
Magnesia, natural, technical, heavy, 90%, f.o.b. Nevada	do.	265
Magnesia, dead-burned	do.	330
Magnesia, synthetic technical	do.	366
Magnesium chloride, hydrous, 99%, flake	do.	290
Magnesium carbonate, light, technical (freight equalized)	per pound	$0.73- 0.78
Magnesium hydroxide, National Formulary, powder (freight equalized)	do.	.95- 1.05
Magnesium sulfate, technical (epsom salts)	do.	.16

[e] Estimated. [r] Revised. W Withheld to avoid disclosing company proprietary data; not included in "Total."

[1] Figures represent crude salable magnesite. In addition to the countries listed, Bulgaria produced magnesite, but output is not reported quantitatively, and available general information is inadequate for formulation of reliable estimates of output levels. Table includes data available through June 1, 1994.

[2] Series reflects output of marketable concentrates. Production of crude ore was as follows, in metric tons: 1989—1,385,565; 1990—1,432,741; 1991—879,477 (revised); 1992—880,000 (estimated); and 1993—880,000 (estimated).

[3] Magnesitic dolomite and brucite. Figures are estimated on the basis of reported tonnage dollar value.

[4] All production in Czechoslovakia from 1989-92 came from Slovakia.

[5] Dissolved on Dec. 31, 1992.

[6] Year beginning Mar. 21 of that stated. Figures for 1989 and 1990 are for magnesite; figures for 1991 and 1992 include 3,336 tons and 220 tons of huntite ($Mg_3Ca(CO_3)_4$), respectively.

[7] Reported figure.

[8] All production in U.S.S.R. from 1989-91 came from Russia.

[9] All production in Yugoslavia from 1989-91 came from Serbia and Montenegro.

[10] Formerly part of Czechoslovakia.

[11] Dissolved in Dec. 1991.

[12] Dissolved in Apr. 1992.

MANGANESE

By Thomas S. Jones

Dr. Jones, a physical scientist with more than 30 years industry and U.S. Bureau of Mines experience, has been the commodity specialist for manganese since 1982. Domestic survey data were prepared by Glenn Wallace, statistical assistant; and the international data tables were prepared under the direction of Ivette Torres, Chief, Section of International Data.

Manganese (Mn) is essential to iron and steel production by virtue of its sulfur-fixing, deoxidizing, and alloying properties. Currently, no practical approaches exist for replacing it by other materials or for obtaining the bulk of U.S. requirements from domestic sources. The steel industries and economies of Japan and Western Europe are in much the same position relative to manganese as are those of the United States.

In the United States in 1993, ironmaking and steelmaking continued to account for most domestic manganese demand, in the range of 85% to 90% of the total. The overall level and nature of manganese use in the United States is expected to remain much the same in the near and medium terms. Reported data indicated that the overall rate of usage of manganese in ironmaking and steelmaking decreased in 1993 compared to that in 1992. A slight decline of 3% in overall unit consumption of ferroalloys and metal was again because of a lower usage rate for ferromanganese. In ironmaking, the usage rate of manganese as ore dropped sharply, by about two-thirds.

U.S. imports rose to record levels for silicomanganese and manganese dioxide. Volume was up about one-fourth for silicomanganese, with major increases for receipts from China and Ukraine. The domestic industry petitioned the Government late in the year for tariff protection against imports of silicomanganese from four countries because of alleged sales at less than fair value. Renewed record imports of manganese dioxide signified continuing strong growth in demand for manganese in dry cell batteries. To help meet demand, domestic producers were making significant increases in their dioxide production capacity.

Disposals of manganese materials from Government stockpiles progressed at an increasing rate, including the making of 5-year sales contracts for metallurgical ore. At yearend, the Government inventory of manganese, all forms, was still equivalent to more than 2 years of apparent consumption.

Prices continued to trend downward, particularly for ore. The price decline for metallurgical-grade manganese ore delivered to U.S. customers was assessed at about one-fifth. Decreases in year-average prices for manganese ferroalloys in the U.S. market for high-carbon ferromanganese and silicomanganese were about 5% and 2%, respectively.

World production of manganese ore as listed in table 1 was estimated to have totaled nearly the same as that in 1992, with declines in areas of the former U.S.S.R. being offset by increases in Australia and elsewhere. In keeping with continuing trends, use of the blast furnace for producing ferromanganese was ended in Germany and the United Kingdom, and further international relationships were formed bearing on supply of ore to smelting operations.

DOMESTIC DATA COVERAGE

Data on domestic consumption of manganese ore, exclusive of that consumed within the steel industry, are collected by means of the "Manganese Ore and Products" survey. By means of this survey, approximately 15 firms were canvassed that process ore by such methods as grinding and roasting or consume it in the manufacture of manganese ferroalloys, metal, and chemicals. Their collective consumption is believed to represent that of the United States except for negligible quantities consumed by other firms, if any. In 1993, responses were obtained from all but one firm canvassed. Data for the missing respondent, which were estimated based on information received from them in prior years and data trends of other firms having similar business activities, were assessed as less than 2% of total consumption. The aggregated consumption data so obtained were incorporated into table 4 but only displayed within totals to avoid disclosing proprietary data.

BACKGROUND

Definitions, Grades, and Specifications

Ore.—The U.S. Bureau of Mines has compiled statistics on manganese-bearing ores, concentrates, nodules, and sinter, all referred to simply as "ore," by manganese content as follows: **manganese ore**, 35% or more manganese; **manganiferous ore**, less than 35% but not less than 5% manganese; and within the latter **ferruginous manganese ore**, 10% to 35% manganese; and **manganiferous iron ore**, 5% to 10% manganese.

Manganese ore may be considered as metallurgical, chemical, or battery grade. Metallurgical-grade material has an approximate manganese content range of 38% to 55% and may differ from chemical-grade ore only in physical form. Chemical- and battery-grade ores are often categorized by manganese dioxide

(MnO_2) content, which typically is in the range of 70% to 85% (44% to 54% Mn). The U.S. Government maintains specifications for metallurgical, chemical, and battery grades of ore for stockpile purposes; industry has no corresponding standards.

Ferroalloys and Metal.—Ferromanganese is a manganese-iron-carbon alloy classified according to decreasing carbon content into standard or high-carbon grades, medium-carbon grades, and low-carbon grades. Silicon is also specified in silicomanganese (such as 18%) and ferromanganese-silicon (about 30%). For U.S. tariff purposes, ferroalloys are required to have an iron content of 4% or greater; a manganese material with less iron would be treated as manganese metal. The specifications the U.S. industry generally follows for manganese ferroalloys and metal are those of the American Society for Testing and Materials. Those for metal call for a minimum total manganese content of 99.5%, of which a minimum of 99.9% is metallic.

Products for Trade and Industry

Metallurgical-grade ore is used primarily in making ferroalloys, pig iron, and steel. Such ore is used mostly to make ferroalloys, for which it is particularly desirable that the ore has a relatively high manganese and low phosphorus content.

The sulfur-fixing, deoxidizing, and alloying attributes of manganese, whose atomic weight is 54.94, are obtained mostly through use of intermediate forms such as ferromanganese. Manganese ferroalloys for use in steelmaking are selected on the basis of cost per manganese unit, allowable steel carbon and silicon specifications, and steelmaking practice. For 1993, with the cost of manganese in metallurgical ore taken as 1.0, the corresponding approximate costs per manganese unit were 2.4 for high-carbon ferromanganese, 2.1 for silicomanganese, 4.2 for medium-carbon ferromanganese, and 8.9 for manganese metal. Metallic manganese is used little per se because it is typically brittle and unworkable.

Manganese is added to aluminum principally by use of briquets that typically contain 75% Mn and 25% Al and that are made by compacting manganese and aluminum powders. Electrolytic manganese metal and aluminum-manganese master alloys that typically contain 25% Mn also are used for this purpose.

Various manganese dioxide-types of material, possibly ground, are used for batteries and other applications. These include natural mineral product (NMD) and synthetic dioxide produced either electrolytically (EMD) or chemically (CMD). If pure, these dioxides would contain 63.2% Mn.

Other manganese materials and some of their uses include manganese sulfate ($MnSO_4$) and manganous oxide (MnO) for animal feed and soil conditioners, ground manganese ore for brick coloring, and potassium permanganate ($KMnO_4$) for water treatment.

Industry Structure

Makeup of the world's manganese ore producers has been chiefly as follows: Australia, Groote Eylandt Mining Co. Pty. Ltd. (GEMCO) and, recently, Portman Mining Ltd.; Brazil, Cia. Vale do Rio Doce (CVRD) (including Urucum Mineração S.A.) and Indústria e Comércia de Minérios S.A. (ICOMI), plus a number of relatively small mines; China, apparently small- to moderate-size operations mostly in the southeastern Provinces; Gabon, Compagnie Minière de l'Ogooué S.A. (COMILOG); Georgia, mining of the Chiatura Basin; Ghana, Ghana National Manganese Corp.; India, about 200 mines, with Manganese Ore India Ltd. the most prominent company; Mexico, Cía. Minera Autlán de C.V. (Autlán); Republic of South Africa, The Associated Manganese Mines of South Africa Ltd. (AMMOSAL) and Samancor Ltd.; and Ukraine, mining of the Nikopol' Basin. Most ore produced goes into metallurgical applications.[1] Ore for nonmetallurgical uses generally is supplied by the large-scale producers mentioned and smaller ones elsewhere.[2]

In recent years, the international ore market mainly has been supplied by a group of countries consisting of Australia (GEMCO), Brazil (ICOMI and CVRD), Gabon (COMILOG), and the Republic of South Africa (AMMOSAL and Samancor) acting in the manner of an oligopoly. In addition, Georgia and Ukraine in the former U.S.S.R. together had been supplying more than 1 million metric tons[3] of ore annually to Eastern Europe. However, the total of such exports was not much more than 700,000 tons in 1987 and dropped precipitously to average about 150,000 tons in 1990-91. The radical political changes that have taken place in Eastern Europe and the former U.S.S.R. have made the future pattern and magnitude of manganese ore exports and imports in this region considerably uncertain.

Smelting of ore into manganese ferroalloys is more diversified geographically than ore production, but is becoming more integrated with ore production through international alliances. Leading ferroalloy producers are as follows: Brazil, Cia. Paulista de Ferro-Ligas (Paulista; a number of plants); China, about 10 main plants; France, Société du Ferromanganèse de Paris-Outreau (SFPO); Germany, Thyssen Stahl AG (until late 1993); Japan, Japan Metals & Chemicals Co. Ltd. and Mizushima Ferroalloy Co. Ltd.; Mexico, Autlán; Norway, Elkem A/S; Republic of South Africa, Metalloys Ltd., a subsidiary of Samancor; and Ukraine, Nikopol' Ferroalloy Works. As with ore production, the output of Georgia combined with the much larger production from Ukraine had made the former U.S.S.R. by far the world's largest producer of manganese ferroalloys.

Four market economy countries (MEC's) currently produce metal, all electrolytically, listed in decreasing order of capacity: the Republic of South Africa, the United States, Japan, and, beginning in 1989, Brazil. China, Georgia, and Ukraine produced metal, including that obtained metallothermically in the former U.S.S.R. World productive capacity for metal was given as 76,000 tons annually as of 1985[4] and would be approximately the same in 1993.

Annual world capacity for EMD was assessed as 198,000 tons in 1989, including capacities of 71,000 tons for Japan and 36,000 tons for the United States.[5] The main changes since have been the establishment of a plant in Australia with an annual capacity of about 18,000 tons and increases in U.S. annual capacity projected to total almost 12,000 tons by mid-1994. The principal producer of CMD is Belgium's Sedema S.A., with an annual capacity of about 36,000 tons.

Geology-Resources

The world's major land-based economic resources of manganese are of two principal types: marine chemical sediments and secondary enrichment deposits.[6] Marine chemical deposits represent a majority of known resources. In 1985, the Manganese Centre (name changed in 1989 to International Manganese Institute) estimated that known relatively high-grade deposits (those with a manganese content of at least 44%) contained about 330 million tons of manganese.[7] As given in the World Review section of this chapter, the reserve base for manganese can be considered more than 10 times this size. In a recent study, the world total for manganese in land-based resources was assessed as about 9 billion tons each in actually minable manganese deposits and in potentially minable accumulations.[8] The world's potential supply of manganese also includes extensive marine accumulations, such as oxide nodules on deep ocean floors and oxide crusts on midocean ridges, whose commercial future is indeterminate.

Among the more common minerals occurring in manganese ores are oxides including pyrolusite, a mineral form of manganese dioxide; the oxysilicate braunite; and rhodochrosite, a mineral manganese carbonate.

Technology

Exploration.—Highly selective methods of locating land manganese deposits do not exist, but interpretation of geologic environments can assist prospecting.[9]

Mining.—Most manganese ore is produced by mechanized operations. Standard earth-moving equipment is used in surface mining. Underground mining generally is by room-and-pillar techniques. Selective mining may be practiced in producing battery- and chemical-grade ores from a deposit being worked principally for metallurgical-grade ore.

Beneficiation.—Crushing, screening, washing, jigging, and tabling as well as flotation, heavy-medium, and high-intensity magnetic separation are being or have been used to upgrade raw manganese ore into usable concentrates. Carbonate ore may be calcined. Ore fines are sintered into bulkier shapes at some ferroalloy plants, a practice employed also by certain ore producers.

Processing.—Electrothermy is the predominant method of manufacturing manganese ferroalloys, as by the submerged-arc-furnace process.[10] Blast furnace-type operations are used in decreasingly fewer foreign countries to make still significant quantities of high-carbon ferromanganese. Recovery of metallics other than iron from manganese-bearing ore is rare.

Manganese metal and EMD commonly are produced by electrolyzing a solution of manganese sulfate prepared from ore that has been reduction roasted. Control of minor ore impurities and production technology is especially important in the manufacture of high-quality dioxide.[11] CMD can be prepared by precipitating manganese carbonate from a sulfate solution and decomposing the carbonate to oxide.[12]

Recycling.—Scrap recovery specifically for manganese is insignificant. Considerable manganese reenters processing as a minor component of steel scrap, steel slag, and nonferrous scrap. Such recycling of manganese tends not to lead to a progressive buildup in steelmaking but it does in aluminum processing.

Economic Factors

A study by the Minerals Availability Program (MAP) of the U.S. Bureau of Mines has identified transportation as the most significant cost element in the production of manganese concentrates.[13] In a later MAP assessment of costs for most major mines in MEC's, transportation was found to account for about two-thirds of concentrate cost.[14] Transportation costs were about equally divided between transportation to the port and transportation to the market. Also according to this assessment, the major mines for metallurgical-grade ore of the MEC's are quite competitive as to ore production cost. Of the considerable resources evaluated, more than 80% had estimated production costs within 20% of the lowest cost.

Operating Factors

Manganese is an essential element for people, animals, and plants.[15] For adults, a daily dietary intake in the range of 2 to 5 milligrams of manganese has been recommended, and it seems that normal diets satisfactorily meet human requirements.[16] In excess, manganese can be harmful to the respiratory and nervous systems.[17] Thus, manganese can be an industrial poison, but normally is not a hazard. According to a review published in 1991, no environmental damage was known to be caused by manganese nor did manganese exposure pose a general risk to the environment.[18]

In 1988, the U.S. Environmental Protection Agency (EPA) imposed an annual requirement of reporting releases to the environment of manganese chemical compounds and metal (40 CFR 372). This initially applied to operations classifiable within Standard Industrial Classification codes 20 to 39 that annually manufacture or process at least 75,000 pounds of these materials, subject to a minimum concentration limitation. This threshold decreased to 25,000 pounds for 1989 and beyond. Also, a reporting threshold of 10,000 pounds was established for annual use of these materials other than in their manufacturing and processing.

Environmental concerns associated with dry cell batteries have led to minimization of their content of certain materials, particularly mercury, and development of methods for recycling their constituents.

ANNUAL REVIEW

Legislation and Government Programs

On November 30, EPA announced it had reached agreement with Ethyl Corp. to extend by 180 days the deadline for EPA to take final action on Ethyl's July 12, 1991, request for a waiver to permit use of methylcyclopentadienyl manganese tricarbonyl (MMT, "HiTEC 3000") as an octane-enhancing additive in unleaded gasoline (58 FR 64761). In doing so, EPA stated that Ethyl had satisfactorily demonstrated for purposes of the Clean Air Act that use of MMT at concentrations of up to 1/32d gram of manganese per gallon of gasoline would not cause or contribute to the failure of emissions equipment to achieve compliance with emission standards. The agreement between EPA and Ethyl to extend the deadline until May 29, 1994, was made to give EPA additional time to consider potential public health effects that might result from use of MMT.

Strategic Considerations

Security of Supply.—Manganese, for which there is no economical substitute, is essential to steelmaking. Steel producers in Japan, the United States, and Western Europe have shared a common concern about the lack of economically minable domestic manganese deposits. Also, the ore supply of these countries has come from relatively few sources, chiefly Australia, Brazil, Gabon, India, Mexico, and the Republic of South Africa, and from just one or two major ore mining companies in each of these countries. The United States additionally has been concerned about supply of manganese ferroalloys. The domestic manganese ferroalloy industry has declined well below self-sufficiency. For several years, the only domestic production of manganese ferroalloys has been by Elkem Metals Co. at its Marietta, OH, plant. One of the principal activities of this plant in recent years has been the upgrading for the Government's National Defense Stockpile of metallurgical-grade ore into high-carbon ferromanganese under a 10-year program scheduled to end by December 31, 1994.

Stockpile.—In line with an expanded program for disposing of excess materials from the stockpile, the U.S. Department of Defense's March 22 submission to Congress of its Strategic and Critical Materials Report for fiscal year 1992 reduced to zero the goals for all but two manganese materials, effective 30 legislative days later. The two non-zero goals then remaining were 189,669 tons for the manganese ferroalloy group and 12,857 tons for electrolytic manganese metal. The goal for metal effectively was eliminated November 30 when the President approved the National Defense Authorization Act for Fiscal Year 1994, Public Law 103-160. This act authorized disposal of all 12,857 tons of metal in inventory.

On June 2, the Defense Logistics Agency (DLA) released the Fiscal Year 1994 Annual Materials Plan, which specified maximum amounts of materials available for sale but not necessarily to be offered for sale in fiscal year 1994. For manganese materials, the quantities were, in tons, natural battery-grade ore, 54,431; chemical-grade ore, 45,359; metallurgical-grade ore, 226,796; and high-carbon ferromanganese, 43,359.

DLA's offerings for sale (Solicitation of Offers) of stockpile manganese materials during 1993 included ORES-021 and ORES-031 for ore and ORES-024 for synthetic manganese dioxide. ORES-021 was issued March 15 and originally offered, in tons, 63,485 metallurgical grade, 36,287 chemical grade, and 13,608 natural battery grade, portions of all of which were sold. On October 26, DLA modified and extended ORES-021 until the end of fiscal year 1994. ORES-031 was issued August 6 and offered a minimum of 72,575 tons up to a maximum of 145,150 tons of metallurgical-grade ore during each of the 5 fiscal years 1994 through 1998. The base price for the fiscal year 1994 quantity was set at $2 per short ton unit of manganese, and this was to be adjusted in subsequent quarters of the 5-year period on the basis of the price of high-carbon ferromanganese. Deadline for offers under ORES-031 was September 8. In October, DLA announced that 5-year contracts had been awarded to Elkem Metals, Pittsburgh, PA, and Metals Refining Co., Orem, UT, for which the fiscal year 1994 quantities were 74,769 and 145,046 tons, respectively. DLA received no offers for synthetic manganese dioxide, although as of April 16 the entire stockpile inventory had been made available for sale during fiscal year 1993.

Disposals of manganese materials in 1993 are estimated to have decreased the total stockpile inventory of manganese units by more than twice as much as in 1992; the percentage decline was estimated as more than 7%. Disposals reported by DLA consisted, in tons, 9,072 natural battery ore, 2,903 chemical ore, 270,359 metallurgical ore, 59,760 high-carbon ferromanganese, and 11,757 silicomanganese. Basis of the disposals was cash for the various kinds of ore and payment-in-kind for the ferroalloys. At yearend, the 1.6-million-ton reserve of contained manganese being held by the Government, which is detailed in table 2, was still comfortably more than twice current national apparent consumption. However, almost one-tenth of this reserve was in the form of nonstockpile-grade metallurgical ore.

Issues

The United States has been lacking in reserves and significant production of manganese almost since the start of domestic steel production. Extensive efforts to discover worthwhile ore deposits or effective methods of using low-grade resources, including steel slags, have resulted in little commercial promise. In a 1985 report, the U.S. Congressional Office of Technology Assessment (OTA) concluded that improvements in steel production technology offered the best prospect for reducing U.S. manganese import vulnerability.[19] In so doing, OTA discounted ocean mining for the present, a view also reached in a recent assessment of the prospects for commercialization of deep seabed mining.[20]

The setting up and maintenance of a large stockpile have been the most tangible aspect of Government manganese programs. Management of the makeup, size, and disposition of this stockpile has been a key part of Government policy. Current law limits use of the stockpile to emergency situations, but its mere presence has had economic implications. Political developments during recent years and reappraisal of stockpile needs have led to the view that the size of the stockpile can be considerably reduced. DLA has signaled its intention to dispose of the large majority of the manganese items in the stockpile over a period of possibly a decade or more and has been making offerings and sales or disposals accordingly.

Production

Ore and Concentrate.—Production and shipments continued to consist only of a small amount of manganiferous material for use in coloring brick. This material was mined in Cherokee County, SC, and had a natural manganese content in the range of 5% to 15%. Shipments data were not published to avoid disclosing proprietary data.

Ferroalloys, Metal, and Synthetic Dioxide.—Production statistics for these materials were not published to avoid disclosing proprietary data; plant sites and products are given in table 3. At its Marietta, OH, plant, Elkem Metals, the only domestic producer of manganese ferroalloys, was beginning the transition from conversion of stockpile ore to sales to external markets. During the past decade, Elkem Metals has been converting stockpile manganese ore into ferromanganese for the Government. Emphasis on Government contracts was anticipated to end by the latter part of 1994. The Marietta plant was not included in Elkem Mangan KS, the holding company formed to operate the Norwegian manganese smelters of Elkem Metals' parent company, under the terms of an alliance between Broken Hill Pty. Co. Ltd. (BHP) and Elkem, as discussed more fully under Australia in the world review section of this report.

Domestic annual capacity for EMD was being raised to about 46,000 tons by expansions at New Johnsonville, TN, by Chemetals Inc. and at Henderson, NV, by Kerr-McGee Chemical Corp. Chemetals' expansion in annual capacity of 4,500 tons to more than 16,000 tons was completed on schedule as of July 1993, or approximately 1 year after having been announced. Kerr-McGee's expansion in annual capacity, announced in May 1993, was for a 50% increase, from about 14,500 to 21,800 tons, and similarly was scheduled to be completed about 1 year later.

Consumption, Uses, and Stocks

Metallurgical applications accounted for most manganese consumption, 85% to 90% of which has been for steelmaking. This can be deduced from the data relating to manganese end use that form the basis of tables 4 and 5 plus certain other information. Industry averages are presented in table 6 for kilograms of manganese used in ironmaking and steelmaking (including for castings) per ton of raw steel produced, on the basis of the reported data in tables 4 and 5. Unit consumption of manganese in ironmaking decreased significantly to one-third that in 1992. Overall manganese unit consumption in steelmaking declined further, by 3%, again because of a drop in the rate of usage of ferromanganese. Relatively small quantities of manganese were used for alloying with nonferrous metals, chiefly as manganese-aluminum briquets for alloying with aluminum.

Nonmetallurgical applications for manganese included animal feed, brick coloring, dry cell batteries, manganese chemicals, and plant fertilizers.[21] American Minerals Inc., headquartered at Wayne, PA; Chemetals Inc., headquartered at Baltimore, MD; and Prince Manufacturing Co., headquartered at Quincy, IL, supplied ore that they had ground and/or roasted or otherwise processed for nonmetallurgical uses. In its plant at La Salle, IL, Carus Chemical Co. was the sole domestic producer of potassium permanganate. Chemetals produced a variety of manganese chemicals at its Baltimore, MD, facility. Producers of manganese sulfate formulations included AlliedSignal Chemical Corp. at Pittsburg, KS (plant purchased from Koch Chemical Co. in January 1993); American MicroTrace Corp. at Fairbury, NE; and Frit Industries Inc. at Walnut Ridge, AR.

In the dry cell battery industry, Duracell International Inc. and the Eveready Battery Co. subsidiary of Ralston Purina Co. reported for their fiscal year 1993 operations a growth worldwide in excess of 10% for unit volume of alkaline batteries, which are based on use of synthetic manganese dioxide. Studies of U.S. battery markets have indicated an annual growth rate during 1988-93 of nearly 7% for primary general cells of the alkaline type and have projected that this growth rate will continue through 1996.

In the fall of 1993, a new version of rechargeable alkaline battery was introduced to the U.S. market by the Rayovac Corp., which, with emphasis on the concept of reusability, had begun mass production of popular sizes of such batteries in June. The technology being used by Rayovac was licensed from Battery Technologies Inc. (BTI) of

Ontario, Canada. BTI also had licensed its technology to Phoenix Energy Corp. of Buffalo, NY, as well as to firms elsewhere in the world. Mercury content of cells based on the BTI technology was initially 0.025% with the goal that it be reduced to zero in 1994. Rayovac's initiative was the second for marketing a rechargeable alkaline cell in the United States, as during about 1965-76 Eveready had attempted to commercialize its version of such a battery.

Use of mercury as an ingredient in primary alkaline dry cells, where the mercury content previously had been lowered to the 0.025% level, was ended completely. At least in Japan, manufacturers of alkaline batteries for the consumer market were eliminating lead as well, in this case as a component of the zinc anode, such as by replacing lead with bismuth. Alternative methods for recycling the ingredients of dry cell batteries continued to be developed.

Markets and Prices

Manganese Ore.—The price of metallurgical manganese ore declined for the third successive year. The percentage decrease was roughly twice as great as that in 1992. For the benchmark of high-grade lumpy ore containing 48% manganese, Australia's BHP agreed toward the end of April to an f.o.b. price for deliveries during the Japanese 1993 fiscal year of $2.25 per metric ton unit (mtu), a decrease of 23.7% from the prior year's contract price of $2.95 per mtu. Within a few weeks, South Africa's Samancor also agreed to a 70 cent reduction in f.o.b. price, to $2.15 from $2.85 per mtu for similar ore, a decrease of 24.6%. Shortly after BHP's settlement, Portman Mining in Western Australia had agreed to a price of $2.25 per mtu for its lumpy ore with a nominal manganese content of 45%, a decrease of 55 cents or 18.5% from the 1992 price. BHP attributed the price cut to large inventories of ore and ferroalloys, slow recovery in steel production, and financial problems in Japan's ferroalloy industry.

Metals Week and Metal Bulletin (London) both changed from a c.i.f. to an f.o.b. basis for their price quotes for manganese ore. In May, Metal Bulletin's quote for the price range per mtu for European deliveries went from $2.75-$2.95 c.i.f. to $2.15-$2.25 f.o.b. In late July, Metals Week began publishing a range per long ton unit of $2.48-$2.59 c.i.f. but in late August changed to a range per mtu of $2.15-$2.25 f.o.b.

The prevailing basis for ore purchases by U.S. consumers remained c.i.f. Although, as just noted above, published figures for a U.S. c.i.f. price were not available, an approximate c.i.f. price can be obtained by adding to the published f.o.b. price the differential between these two prices. This differential can be estimated to have been about 40 cents per mtu by averaging data of the Bureau of the Census as to Customs value and c.i.f. value of ore imports. Using this approach, the average price, c.i.f. U.S. ports, for metallurgical ore containing 48% manganese was assessed as $2.60 per mtu, which signifies a decline of 20%. It is to be recognized not only that higher prices pertained during the first quarter of 1993 but also that lower grade ore was sold at lower prices.

Because the metric ton unit is 1% of a metric ton; i.e., 10 kilograms of contained manganese, the price of manganese in ore in 1993 and 1992 can be expressed in cents per kilogram as 26.0 and 32.5, respectively. The price of a metric ton of ore is obtained by multiplying the mtu price by the percentage manganese content of the ore.

The ore market consists of a number of submarkets because of differences between ores according to the various end uses such as ferroalloy production, blast furnace ironmaking, and battery manufacture. The price trend for metallurgical ore during the past two decades is given in table 7, in which constant dollar prices were calculated using Implicit Price Deflators for Gross Domestic Product.

Manganese Ferroalloys.—Overall changes in the price of manganese ferroalloys in the United States, as given by quotations for imports, were generally less than plus or minus 5% except for the price increase during the year for silicomanganese. The year-average price versus that for 1992 declined about 5% for high-carbon ferromanganese and about 2% for silicomanganese. For these two principal manganese ferroalloys, prices at yearend versus those at the beginning of the year were higher by about 2% for high-carbon ferromanganese and 14% for silicomanganese. The larger increase for silicomanganese presumably was linked to an increase in the price of silicon in ferroalloys, which increased by more than 23% during 1993, on the basis of the price for imported 75% ferrosilicon. English units continued to be used for price quotes in the United States as given in sources such as Metals Week.

The price range for high-carbon ferromanganese containing 78% manganese, f.o.b. Pittsburgh or Chicago warehouse, was $485-$490 at the start of 1993 and broadened to $480-$500 later in January. A slight declining trend that led to lows of $475-$485 in April was followed beginning in late June by a slight firming trend that early in November gave a range of $490-$500, which remained to the end of the year.

The pattern of price variation of imported silicomanganese with 2% carbon was similar to that of high-carbon ferromanganese except that the extents of decline and subsequent increase were greater. At the start of the year, the range was 23-23.25 cents per pound of alloy, f.o.b. Pittsburgh or Chicago warehouse. A low of 19.75-20.5 was reached by early April, shortly after which a rising trend developed that produced as of early December the year's highest and also closing level of 26-26.5 cents per pound. Trade journal reports indicated that the increasing presence of Ukrainian ferroalloy in the U.S. silicomanganese market led to two-tiered pricing during part of 1993. Factors differentiating Ukrainian silicomanganese from material from most other sources were, as an advantage, its higher manganese content of 74% versus 66% typically, and, as a disadvantage, its higher phosphorus content of more than 0.3% versus 0.2% or less.

Manganese Metal.—Trade journal listings gave no indication of any price developments for the metal and continued to remain the same throughout the year as those already published effective mid-November 1990: a price range of $1.04-$1.05 per pound according to Metals Week and $1.05 per pound according to American Metal Market. These were for bulk shipments of domestic material, f.o.b. shipping point.

Foreign Trade[22]

For most materials, the volume of exports and imports was greater in 1993 than that in 1992. In terms of estimated total manganese content, the increase in number of manganese units traded was about 14% for exports and 13% for imports. For imports, the ratio of the sum of ferroalloy plus metal to the sum of ore plus dioxide was 3.8, the highest such ratio since 1982.

Among exports, the quantity of ore, although increased, was still unusually low in comparison with quantities exported during at least the past two decades. Ore reexports were 191 tons, all to Canada. Exports of ferromanganese overall increased by more than one-third, principally because of the increase from 4,637 tons to 8,172 tons in exports of material with a carbon content of more than 2%. Exports of silicomanganese, like ferromanganese principally to Canada, rose slightly to set another new record for quantity. Reexports of ferromanganese and silicomanganese, all to Canada but for 15 tons of ferromanganese, consisted of 2,418 tons of ferromanganese and 4,214 tons of silicomanganese. Those of ferromanganese were again about equally divided between higher and lower carbon grades. Reported exports of spiegeleisen were 42 tons, all to Mexico.

For imports, the average manganese content in a 6% lesser volume of ore was 49.9%, the third highest average value of the past decade. Average manganese content for all ferromanganese imports was 78.0%, the least average value since 1989.

Among imports of ferroalloys, those of ferromanganese increased about 14% overall. Imports of low- and medium-carbon ferromanganese each decreased about one-seventh, but this was compensated for by an increase of about one-fourth in imports of the high-carbon grade. Within imports of high-carbon ferromanganese, those from Brazil were the largest yet, those from the Republic of South Africa were up more than 60%, and those from Russia were the first since 1950 from an area of the former U.S.S.R. For imports of silicomanganese, an increase in volume that approached one-fourth easily produced a new record for quantity. Among the larger source countries, imports from Brazil increased to a new record quantity for the third successive year and those from China and Ukraine were 4.5 and 4.7 times as great, respectively, as those in 1992. Reported imports of spiegeleisen remained about the same, 237 tons, mostly from Germany at a high unit value.

The combined volume of imports of the two categories of metal exclusive of waste and scrap was about 8% larger. Growing since 1989 to a total of 2,721 tons, imports from China accounted for nearly one-fifth of the total. Formerly, the Republic of South Africa was practically the only source of imports of unwrought metal.

Among imports of manganese chemicals, those of manganese dioxide continued to resurge and slightly surpassed the previous record for quantity set in 1985. Significantly increased receipts from Australia and Ireland led to an overall advance of about one-eighth. All dioxide imports appeared to be synthetic material. Imports of potassium permanganate, the most since the 1989 record year, were nearly double those in 1992 because of a renewed influx of material from China. Of imports under the classification "Other sulfates," which includes manganese sulfate, those from Mexico decreased about 7% to 11,567 tons at a value of $6.1 million but rose for those from China about 44% to 5,168 tons at a value of $1.3 million.

The schedule of tariffs that applied during 1993 to U.S. imports of selected manganese materials is given in table 10.

The reduction or removal of tariff barriers to the importing of materials from republics of the former U.S.S.R. that began in 1992 continued with the granting of most-favored-nation (MFN) trade status to Kazakhstan and duty-free treatment under the Generalized System of Preferences (GSP) to Russia. MFN status for Kazakhstan was effective February 18 (58 FR 11647) and GSP status for Russia was effective October 16 (58 FR 51561). The GSP program itself was extended in August until September 30, 1994, after technically having been allowed to lapse for about 1 month.

On November 12, Elkem Metals and the Oil, Chemical and Atomic Workers, Local 3-639, Belpre, OH, filed petitions with the International Trade Administration (ITA) of the U.S. Department of Commerce and the U.S. International Trade Commission (ITC) alleging that imports of silicomanganese from Brazil, China, Ukraine, and Venezuela were being sold in the United States at less than fair value and thereby materially injuring or threatening to materially injure a domestic industry. On December 20, the ITC announced its unanimous affirmative determination that a reasonable indication existed that the allegation was true. Consequently, the ITA continued its investigation of the matter with a due date for its preliminary determination of on or about April 21, 1994. The ITA had initially evaluated the alleged dumping margins as 17.6% for Brazil, 150.0% for China, 125.3% for Ukraine, and 37.2% to 55.4% for Venezuela (58 FR 64553).

In December, Congress approved extension of the North American Free Trade Agreement to include Mexico, which had the effect of decreasing tariffs on imports from Mexico beginning January 1, 1994, and eliminating them altogether in most cases by 2003.

World Review[23]

Capacity.—The rated capacity data in table 11 are as of December 31, 1993. The major difference from the listing of the previous year is that the capabilities of the producing areas of the former U.S.S.R. have been disaggregated by respective republic. The data correspond to the manganese contents of ore and/or concentrates capable of being utilized, as in feed to a smelter. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable, long-term operating rate.

Reserves.—Only a few of the world's many manganese concentrations have enough economic significance to be classed as reserves;[24] no domestic deposits qualify.[25] World reserves of manganese, generally on the same basis as capacity, are given in table 12 with no distinction between ore type or application. The data in table 12 are exclusive of perhaps 1% to 2% of total known reserves. These are in nonlisted countries having a similar proportion of world production, as can be seen from table 13. Russia, whose reserve base can be estimated as intermediate between that of Georgia and Kazakhstan, is not listed in table 12 because no manganese ore was produced there for an extended period prior to dissolution of the former U.S.S.R.

Australia.—Manganese ore output rose by nearly two-thirds to the highest level since 1990 at operations of the Groote Eylandt Mine (Northern Territory) of the GEMCO subsidiary of BHP. The total of GEMCO's shipments to foreign and domestic destinations during calendar 1993 were reported to have increased to 1,590,000 tons for an advance comparable to that of mine production.[26]

In September, BHP Minerals and Norway's Elkem announced, following approvals by the Australian and Norwegian Governments, that a strategic business alliance had been made between GEMCO and Elkem's manganese smelting operations. The two parties had signed a letter of intent in July 1992 and a contractual agreement in April 1993. Under the agreement, Groote Eylandt Manganese Sales Pty. Ltd. (GEMS) would supply ore from GEMCO to Elkem's two Norwegian manganese smelters and to the Marietta, OH, plant of Elkem Metals. Ownership of GEMS was 51% by BHP and 49% by Elkem. The two Norwegian smelters, Elkem PEA and Elkem Sauda, were transferred to a new holding company, Elkem Mangan KS, whose ownership became 51% by Elkem and 49% by BHP.

In March, BHP's manganese smelting subsidiary, Tasmanian Electro Metallurgical Co. Pty. Ltd. (TEMCO), completed conversion of its ferrosilicon furnace to production of silicomanganese. BHP stated that this raised annual capacity for manganese ferroalloys of its Bell Bay plant in northern Tasmania to 261,000 tons (ferromanganese equivalent), an increase of 81,000 tons. Part of the increased capability was oriented toward marketing of silicomanganese in Japan, to which BHP traditionally has shipped only ore.

Annual production of manganese ore in Western Australia continued to be at the level of 300,000 tons. Portman Mining began development of the Green Snake deposit at its operations in the Woodie Woodie area of the Pilbara Manganese Province. Production of relatively high-grade ore with low silica and phosphorus contents from this newly discovered deposit was to supplant that from the Cracker deposit.

Brazil.—Shipments of manganese ore by ICOMI from operations at Serra do Navio, Amapá Territory, through Porto de Santana on the Amazon River rose slightly to 502,500 tons. Of this total, 297,200 tons was shipped to European countries and 205,300 tons to South American destinations, including Brazilian consumers.[27] ICOMI's shipments advanced for the third successive year to reach the highest total since 1990.

The Paulista group of companies, which collectively is among the world's largest producers of manganese ferroalloys, expanded its manganese ferroalloy production capabilities but ran into financial difficulties. Two new electric furnaces were brought on-stream late in the year at Eletrosiderúgica Brasileira S.A. (Sibra), which was acquired by Paulista in 1988. This was reported to have raised Sibra's annual capacity for manganese ferroalloys to more than 200,000 tons and that of the Paulista group to more than 400,000 tons. However, in December, both Paulista and Sibra applied to the courts for protection under Brazilian bankruptcy law.

Brazil's production of manganese ferroalloys in 1992 surpassed previous record levels set in 1991 for total quantity and quantity of silicomanganese produced, 479,000 and 300,000 tons, respectively. The corresponding percentage increases were about 9% and 10%. Production of high-carbon ferromanganese was 152,000 tons. At 26,700 tons, production of medium- and low-carbon ferromanganese also set a record slightly above the 1989 production and showed an increase of nearly 40% above the 1991 production. These data were not available when the Manganese Annual Report for 1992 was prepared. They are now included in a new feature that has been added to this annual report, a table of world production of manganese ferroalloys, table 14.

Burkina Faso.—The Tambao Mine was inaugurated in May, following which trial shipments of about 5,000-ton lots were made to test commercial viability of this high-grade resource. The deposit, in northeastern Burkina Faso near its borders with Mali and Niger, has been known for more than three decades but left undeveloped because of the lack of transport infrastructure. Initial output was being trucked about 250 kilometers to the nearest railhead at Kaya, which is intermediate between the mine and Ouagadougou, and then railed more than an additional 1,100 kilometers to the Côte d'Ivoire port of Abidjan. InterStar Mining Group Inc. of Canada, the operator, targeted production to begin at the annual rate of about 100,000 tons. Rated reserves reportedly were about 15 million tons of metallurgical-grade ore containing more than 51% manganese. An advantage of the Tambao ore is its relatively high manganese content. A disadvantage is its relatively high phosphorus content of about 0.15%, which has raised the possibility that the ore would be marketed for blending.

China.—Imports of 570,000 tons of manganese ore decreased about one-tenth from the 635,000 tons imported in 1992. Included in the reported ore imports for 1992 was 236,000 tons from Myanmar, which is not known to produce such quantities of manganese ore. Shipments from Myanmar to China have been categorized as small-lot boundary trade.[28]

China has become a significant factor in international marketing of manganese ferroalloys and metal. Chinese statistics indicated that Indonesia, Japan, and the Republic of South Korea were among the larger recipients of ferromanganese and silicomanganese from China in 1992. The volume of silicomanganese being exported from China to Japan led the Japanese Government to impose antidumping duties on silicomanganese from China beginning February 3, 1993. China's exports of manganese metal have been at the level of roughly 30,000 tons annually in recent years. The majority of those in 1992 were to Japan and the Netherlands.

France.—Pechiney ended its production of manganese ferroalloys in France. As of yearend, the furnaces at its Le Giffre plant in southeastern France that were being used to produce specialty manganese alloys had been shut down.

Gabon.—Production of metallurgical-grade ore from COMILOG's Moanda Mine decreased by 4%. An ownership link developed between COMILOG and South Africa's Samancor with purchase by Gencor Ltd., the major shareholder in Samancor, of the 15.1% shareholding in COMILOG formerly held by the U.S.'s USX Corp.

Germany.—In October, at the end of a production campaign, Thyssen terminated production of ferromanganese from its plants in the Duisburg area. Thyssen had been producing high- and medium-carbon ferromanganese on an intermittent basis. High-carbon ferromanganese was produced at the Hamborn plant via a blast furnace having an annual capacity of about 240,000 tons. The company stated that conditions in the markets for ferromanganese would not justify the cost of relining this furnace, due to be done in 1994. Thyssen's technology for converting high-carbon into medium-carbon ferromanganese was the subject of a recent report, which particularly focussed on attainment of low carbon and silicon contents.[29]

Ghana.—Exports of ore from the Nsuta Mine of Ghana National Manganese Corp. (GNMC) through the Port of Takoradi were 306,000 tons. Twenty-seven shipments were made to Japan and Europe (the Czech and Slovak Republics, Finland, Ireland, Norway, Romania, and Spain).[30] The level of shipments in 1993 was roughly the same as that maintained during the past 3 years.

GNMC, the subject of a recent brief review,[31] was among state-owned properties scheduled for privatization. Australia's BHP Minerals, which was among those reported to be interested in acquiring at least part ownership of GNMC, established a manganese exploration program in Ghana.

Indonesia.—P.T. Interferro Mangando (IM) initiated domestic production of manganese ferroalloys at Tangerang, near Jakarta in northwestern Java, with a ferromanganese-silicomanganese plant reported to have an annual capacity of about 40,000 tons. Production of high-carbon ferromanganese was begun in the first part of the year and later was broadened to include silicomanganese. Output was well below capacity in 1993, most of which was marketed domestically. IM was a joint venture between Taiwanese (55%), Indonesian (35%), and Hong Kong (10%) interests.

Japan.—Imports of metallurgical-grade manganese ore totaled 1,204,000 tons, an increase of slightly more than one-fourth over the relatively low 1992 quantity of 958,000 tons. As generally has been the pattern in recent years, the leading sources of ore containing more than 39% manganese were Australia and the Republic of South Africa, and for ore containing no more than 39% manganese Ghana and the Republic of South Africa. Imports of ferruginous manganese ore, almost all from India and the Republic of South Africa, totaled 140,000 tons, an increase of about one-half above that of 92,000 tons in 1992.

Production of manganese ferroalloys totaled 448,000 tons, again the least since 1987. Production of high-carbon ferromanganese remained virtually unchanged at 294,000 tons. Production of low-carbon ferromanganese increased by about one-third to 89,000 tons while that of silicomanganese decreased by about one-third to 65,000 tons.

Imports of manganese ferroalloys rose overall by about one-fifth to 266,000 tons. Imports of 211,000 tons of silicomanganese were about 9% greater than those in 1992; leading sources were China, the Republic of South Africa, and Ukraine. Imports of high-carbon ferromanganese more than doubled to 52,900 tons while those of low-carbon ferromanganese decreased about one-sixth to 2,500 tons.

After 14 months of investigation and deliberation, the Japanese Government reached a decision near the end of January to impose antidumping duties on imports of silicomanganese from China but not those from Norway and the Republic of South Africa. For the 1-year period beginning February 3, a basic duty rate of 27.2% was imposed on silicomanganese from China except that for specific exporters the rates ranged from 4.5% to 19.1%. This was the first instance of levying of antidumping duties by the Japanese Government.

Rising trends for increases in imports and relative cost of domestic production helped raise questions as to how far in the future Japan would continue to be a producer of manganese ferroalloys.[32] Nevertheless, exports of manganese ferroalloys increased overall by more than one-third to 11,500 tons. Most of the exports were low- and medium-carbon ferromanganese, which rose by 39% to 11,000 tons. An investigation of the use of a smelting furnace with a coke packed bed and injection of oxygen-enriched air and pulverized coal indicated that this might be a more competitive way for ferromanganese to be produced in Japan as compared with use of an electric furnace.[33]

For EMD, production increased moderately, by more than 3%, to 56,100 tons while exports rose by more than one-tenth to 33,500 tons, the highest level since 1988.

For manganese metal, production dropped for the third successive year, by 15% to 3,170 tons from 3,730 tons in 1992. Imports of unwrought metal, including scrap, advanced by nearly one-fourth to 24,500 tons, with China (56%) displacing the Republic of South Africa (40%) as the leading source.

Kazakhstan.—A modest production of manganese ore was concentrated in the Dzhezkazgan region of central Kazakhstan. Concentrates that tended to be siliceous and not high grade in manganese content were obtained by processing ores produced from deposits such as Ushkatyn and Dzhezdinsky at the Zhairemsky metallurgical complex. However, the low phosphorus content of these concentrates had caused them to be under consideration for some time in the former U.S.S.R. for use as charge material for manganese smelters.

Mexico.—The Grupo Ferrominero S.A. consortium took control of most of Mexico's manganese ore production and all of its manganese ferroalloy production by purchasing Autlán and Ferroaleaciones de México, S.A. (Ferromex). The sale of Autlán was completed in July about 4 years after Nacional Financiera, a development bank of the Mexican Government, foreclosed its controlling interest in Autlán. Autlán was sold for $23 million, which reportedly was only about one-eighth the value of the assets sold. Sale of Ferromex, a producer of manganese ferroalloys, was completed several months later and about 2 years after Ferromex had ceased to operate.

Ore output from Autlán's operations in the Molango District of Hidalgo State decreased for all categories, particularly for nodules and battery ore. Production data for 1993 and percentage decreases from 1992 (in parenthesis) were carbonate ore, 515,000 tons (-2%), of which 64,500 tons (-1%) was sold without nodulizing; oxide nodules, 278,000 tons (-12%); and battery ore from the Nonoalco Mine, 20,000 tons (-23%). Autlán's production of manganese ferroalloys, based on salable production, also decreased overall by roughly 4%. Manganese ferroalloys figures formerly were stated in terms of gross production. The product mix in 1993 consisted of 40,400 tons of high-carbon ferromanganese, 29,700 tons of low- and medium-carbon ferromanganese, and 55,300 tons of silicomanganese, for which the corresponding changes from the restated 1992 data were -14%, -7%, and +8%, respectively.

Norway.—As discussed more fully under Australia, Elkem and Australia's BHP Minerals announced in September the formation of a strategic business alliance. Under the agreement, ore from GEMCO would be supplied to Elkem's two Norwegian manganese smelters, Elkem PEA and Elkem Sauda, whose ownership became 51% by Elkem and 49% by BHP. At about midyear, Elkem's manganese smelters were reported to be operating at about 70% of capacity.

In March, the Government lifted investment and trade sanctions against the Republic of South Africa. This removed any need to extend the 2-year exemption that Norway's manganese ferroalloy producers, Elkem and Tinfos Jernverk A/S, had from sanctions against importing South African manganese ore. The exemption was due to expire in July.

Philippines.—Late in the year, efforts by Australia's Portman Mining and Philippine interests to develop small-scale production of manganese ore were reported to have been suspended after about 2 years of preparatory work. Sites examined were in the north of the northern island of Luzon and in the southern island of Bohol. Annual ore output in the range of 100,000 tons had been projected for shipment to consumers in the Far East.

Russia.—At the time of dissolution of the former U.S.S.R. in 1991, Russia had not been producing manganese ore for possibly two or more decades and largely had been dependent upon sources elsewhere for meeting its manganese ferroalloy requirements, as noted in a recent review.[34] Efforts were being made to reinstitute manganese ore production within the Federation even though manganese deposits in Russia have not been competitive with those in Georgia, Kazakhstan, and Ukraine. The Rossiyskiy Marganets stock company that was formed in 1992 reportedly was exploring development of manganese ore production at locations in northwestern Russia, the Urals, and Siberia.

South Africa, Republic of.—Overall production of manganese ore, which consisted nearly all of metallurgical-grade ore, increased slightly. Production of metallurgical-grade ore rose by about 3% to total 2,440,000 tons, of which about one-half was ore with a manganese content exceeding 48%. Compared with that of 1992, production of ore containing 45% or more manganese decreased about 8% while that of ore containing 30% to 45% manganese increased 26%.

Linkages developed between the manganese mining and smelting interests of Samancor and those of COMILOG. As aforementioned under Gabon, Gencor, Samancor's major shareholder, acquired a 15.1% interest in COMILOG. Samancor was exploring with SFPO the possibility of producing medium-carbon ferromanganese at SFPO's plant at Boulogne on the northern coast of France. The medium-carbon ferromanganese would have a low phosphorus content by virtue of its having been produced from low-phosphorus feed ore supplied by Samancor. SFPO was being supplied with manganese ore by COMILOG, which was also a part owner of SFPO.

Production of manganese ferroalloys rose to near full capacity during the year, at least at the two major producers. According to trade journal reports, Samancor's Metalloys manganese ferroalloy plant at Meyerton was operating at 70% of capacity early in the year but at full capacity near the end of 1993. Similarly, production of manganese ferroalloys at AMMOSAL's Cato Ridge smelter was reported to have built up during the year to near current effective full capacity. Production of low- and medium-carbon grades of ferromanganese at Cato Ridge was under consideration.

Spain.—The two producers of manganese ferroalloys remaining after the latest consolidation held a more optimistic outlook than has characterized Spain's ferroalloy industry in recent years. Ferroatlantica SL was constituted as a major European producer of bulk ferroalloys near the end of 1992 when the Villar Mir group purchased the ferroalloys and power generation businesses of the former Soc. Espan. de Carburos Metálicos SA. Ferroatlantica produced ferromanganese and silicomanganese at its Boo and Cee plants in northern Spain. The sale of Carburos also included a 12.5% interest in Hidro Nitro Española SA, a producer of specialty manganese ferroalloys at Monzon controlled by France's Pechiney.

Ukraine.—The Ordzhonikidze and Marganets metallurgical complexes continued to account for most of Ukrainian production of manganese ore and concentrates. Efforts were being made to increase capability to beneficiate a growing volume of carbonate ore. Development of the Tavrichesky metallurgical complex for utilization of the Bol'shoy Tokmak deposit still lagged. Current and planned developments at the two electrometallurgical facilities near the mines included use at the Nikopol' plant of a two-stage process to produce silicomanganese with lowered phosphorus content, production of medium-carbon ferromanganese in the near future at either the Nikopol' or Zaporozh'ye plant, and production of manganese metal electrolytically by the year 2000 to supplement the output of metal presently being obtained electrothermically at Zaporozh'ye.

United Kingdom.—In March, British Steel Plc ended production of high-carbon ferromanganese and foundry pig iron at the Cleveland Iron component of its Teesside Works on the northeast coast of England near Middlesbrough. This facility, commissioned in 1911, was one of the few remaining blast furnace producers of ferromanganese in Western Europe. In making the decision to buy rather than to produce ferromanganese, British Steel stated that it saw world overcapacity for ferromanganese and foundry iron, with demand for foundry iron being especially weak.

Current Research

Hydrometallurgical and biohydrometallurgical extraction of manganese, particularly from low-grade resources, was investigated by a number of researchers. The U.S. Bureau of Mines reported on its development of in situ leaching technology for potential application to manganese deposits in the region of the Cuyuna Range in Minnesota[35] and on bioleaching tests of wad ore from the Three Kids district in Nevada.[36] Workers in foreign countries presented at an international symposium their findings on bioleaching of such manganese minerals as those in an Italian pyrolusite ore,[37] various oxides investigated by Ukrainian scientists,[38] and tailings from the Groote Eylandt Mine in Australia.[39]

Carbothermic reduction of oxidic manganese-bearing resources and ores was investigated in the laboratory. In a study by the U.S. Bureau of Mines, the objective was to explore the possibility of prereducing domestic lower grade resource material to yield potential smelter feed.[40] The kinetics and mechanism of reduction of ore from the Wessels Mine in South Africa was the subject of another study.[41]

Among reports given at the Electric Furnace Conference that dealt with manganese pyrometallurgy, one identified zinc in the ore feed as the cause for an eruption of a submerged arc furnace producing high-carbon ferromanganese.[42] In another, the results were presented of a study of nitriding ferromanganese (mostly compositions similar to the medium-carbon grade) and how nitriding is influenced by carbon and silicon contents.[43]

Research on the behavior of manganese in steelmaking was conducted in Japan. Methodology was developed for estimating final manganese content and improving manganese yield when, in operations involving hot metal pretreatment and low slag volumes, manganese ore rather than ferromanganese was used.[44] For this type of operation, the thermodynamics of the effect of manganese on dephosphorization was analyzed.[45]

In using manganese as an alloying ingredient in aluminum, a factor to be considered is how to introduce manganese into liquid aluminum. Results of exploring the powder injection approach were reported for (1) pilot-scale tests made in the United States of equipment and procedures and (2) in-plant tests and laboratory studies conducted in Australia of dissolution fundamentals.[46]

Assessments of the thermodynamics of metal systems having manganese as a component included one by the U.S. Bureau of Mines on the manner in which a partial substitution of manganese for chromium in iron-nickel-chromium alloys affected the activities of these main elements of the alloy.[47] Two other investigations, of iron-manganese-nitrogen and iron-chromium-manganese-nitrogen systems, related to the potential development of high-nitrogen steels and the higher nitrogen contents attainable through additions of manganese.[48]

Developments in high manganese austenitic steels were assembled into a volume containing the proceedings of conferences held by ASM International in 1987 and 1992.[49] In the 1992 conference, M. O. Speidel and P. J. Uggowitzer noted (pp. 135-142) that of all materials in the world such steels have the highest product of strength times fracture toughness. R. A. Lula reviewed (pp. 229-231) the economics of using manganese to replace nickel in austenitic stainless steels. In the Republic of Korea, laboratory investigation of high manganese austenitic steels have shown that a steel containing 25% manganese, 1% aluminum, and 0.2% carbon has good potential for use as an automotive sheet material.[50]

Recent advances in battery applications of manganese have been based largely on various modifications of manganese dioxide prepared synthetically, chiefly dioxide made electrolytically. Sulfate solutions ordinarily have been used for manufacture of EMD, but research in India has indicated that use of a chloride electrolyte appears to have certain advantages.[51] So-called "rocking-chair" battery systems involving lithium ions were being intensively investigated because of the potential for using such systems in rechargeable batteries. One possibility reviewed was the combination of a lithium-manganese oxide spinel as the positive electrode with carbon as the negative electrode.[52]

OUTLOOK

The trend of manganese demand, domestically and globally, will continue to closely follow that of steel production. Although some nonmetallurgical components of manganese demand may experience higher growth rates than for steel production, especially batteries, this will have only a minor effect on overall manganese demand.

For the past decade, U.S. apparent consumption of manganese has not varied from 635,000 tons of contained manganese by much more than plus or minus 10%, as shown in table 15. This has largely been a consequence of similar variability in domestic steel production. Manganese demand as calculated in table 15 generally has corresponded to but not traced precisely the level of activity in the steel industry. Differences in the respective year-to-year variations are believed to show the influence of unmeasured changes in stocks of manganese materials, such as those of importers, the effect of which may outweigh changes in demand by steelmakers.

The outlook for domestic steel production in 1994, as discussed in the Annual Report for Iron and Steel, includes a further improvement of perhaps 3% over that for 1993, from which a small increase in domestic manganese demand can be anticipated. Forecasts of the International Iron and Steel Institute (IISI) continue to suggest only slow growth in U.S. steel output through 2000. This indicates that U.S. apparent consumption of manganese during the balance of the 1990's is unlikely to range far from 635,000 tons of contained manganese, on the assumption of insignificant change in manganese unit consumption in steelmaking. The majority of U.S. manganese demand will be met by imports.

Global forecasts of IISI and others suggest that world manganese demand during the balance of the 1990's also should increase only slightly. A late-1993 estimate by IISI was that world steel consumption in the year 2000 would be only 105% of consumption in 1990. IISI foresaw for steel consumption a relatively static condition for industrialized countries and growth in the developing countries of the Pacific Rim and Latin America that would offset decreases expected for countries of the former U.S.S.R. and Eastern Europe. Economic transition of the steel and manganese industries of the former U.S.S.R. appears likely to affect world manganese supply and demand for some years as those industries are rationalized to a smaller scale and modern steelmaking technology that also improves manganese utilization is more fully adopted. The condition of world overcapacity during recent years for production of manganese ore and ferroalloys, which has helped foster an increasing integration of ore and ferroalloy producers, seems unlikely to disappear soon.

TABLE 1
SALIENT MANGANESE STATISTICS

(Thousand metric tons, gross weight)

	1989	1990	1991	1992	1993
United States:					
Manganese ore (35% or more Mn):					
Exports	52	70	66	13	16
Imports for consumption	580	307	234	247	232
Consumption	559	497	473	438	389
Stocks, Dec. 31: Consumers	470	379	275	276	302
Ferromanganese:					
Exports	8	7	15	13	18
Imports for consumption	432	380	320	304	347
Consumption	399	413	346	339	341
Stocks, Dec. 31: Consumers and producers	68	56	50	28	30
Consumption, apparent, manganese[1]	723	630	598	596	NA
Ore price, dollars per metric ton unit, c.i.f. U.S. ports	2.76	3.78	3.72	3.25	2.60
World:					
Production of manganese ore	[r]26,260	[r]26,108	[r]22,937	[r]21,608	[e]21,757

[e]Estimated. [r]Revised. NA Not available.

[1]Thousand metric tons, manganese content. Based on estimates of average content for all significant components except imports, for which content is reported.

TABLE 2
U.S. GOVERNMENT DISPOSAL AUTHORITIES AND YEAREND INVENTORIES FOR MANGANESE MATERIALS IN 1993

(Metric tons, gross weight)

Material	Disposal authority	Physical inventory, Dec. 31				
		Uncommitted			Sold, pending shipment	Grand total[1]
		Stockpile grade	Nonstockpile grade	Total[1]		
Natural battery ore	139,343	122,920	16,423	139,343	18,216	157,559
Synthetic manganese dioxide	2,732	2,732	—	2,732	—	2,732
Chemical ore	153,759	153,678	81	153,759	1,578	155,336
Metallurgical ore	1,206,679	831,546	375,134	1,206,679	[2]436,253	1,642,932
High-carbon ferromanganese[3]	792,799	992,655	—	992,655	[2]740	993,395
Medium-carbon ferromanganese[3]	—	24,559	—	24,559	[2]890	25,449
Silicomanganese	—	209	—	209	—	209
Electrolytic metal	12,857	12,857	—	12,857	—	12,857

[1]Data may not add to totals shown because of independent rounding.

[2]Includes quantities reserved for payment-in-kind disposal.

[3]Physical inventory as of Nov. 30.

TABLE 3
DOMESTIC PRODUCERS OF MANGANESE PRODUCTS IN 1993

Company	Plant location	Products[1]				Type of process
		FeMn	SiMn	Mn	MnO_2	
Chemetals Inc.	Baltimore, MD	—	—	—	X	Chemical.
Do.	New Johnsonville, TN	—	—	—	X	Electrolytic.
Elkem Metals Co.	Marietta, OH	X	X	X	—	Electric furnace and electrolytic.
Kerr-McGee Chemical Corp.	Hamilton, MS	—	—	X	—	Electrolytic.
Do.	Henderson, NV	—	—	—	X	Do.
Ralston Purina Co.:						
Eveready Battery Co.	Marietta, OH	—	—	—	X	Do.

[1] FeMn, ferromanganese; SiMn, silicomanganese; Mn, electrolytic manganese metal; MnO_2, synthetic manganese dioxide.

TABLE 4
U.S. CONSUMPTION AND INDUSTRY STOCKS OF MANGANESE ORE,[1] BY USE

(Metric tons, gross weight)

Use	Consumption		Stocks, Dec. 31	
	1992	1993	1992	1993
Manganese alloys and metal	W	W	W	W
Pig iron and steel	49,000	17,000	20,000	13,000
Dry cells, chemicals, miscellaneous[2]	W	W	W	W
Total	438,000	389,000	276,000	302,000

W Withheld to avoid disclosing company proprietary data; included in "Total."

[1] Containing 35% or more manganese (natural).

[2] Natural ore, including that consumed in making synthetic manganese dioxide.

TABLE 5
U.S. CONSUMPTION, BY END USE, AND INDUSTRY STOCKS OF MANGANESE FERROALLOYS AND METAL IN 1993

(Metric tons, gross weight)

End use	Ferromanganese			Silico-manganese	Manganese metal
	High carbon	Medium and low carbon	Total[1]		
Steel:					
Carbon	198,989	69,555	268,544	80,074	3,419
Stainless and heat-resisting	13,237	(2)	13,237	4,575	1,855
Full alloy	20,120	5,347	25,466	16,006	386
High-strength, low-alloy	18,876	3,178	22,054	6,022	(2)
Unspecified[3]	408	649	1,057	572	181
Total steel[1]	251,630	78,728	330,358	107,249	5,842
Cast irons	8,957	569	9,525	1,530	—
Superalloys	W	—	W	—	132
Alloys (excluding alloy steels and superalloys)	1,206	354	1,559	2,747	[4]17,384
Miscellaneous and unspecified	W	—	W	W	W
Total consumption[1]	261,792	79,651	341,443	[5]111,526	23,358
Total manganese content[6]	204,000	64,000	268,000	74,000	23,000
Stocks, Dec. 31:					
Consumers and producers	24,111	6,337	30,448	6,996	(7)

W Withheld to avoid disclosing company proprietary data; included in "Alloys (excluding alloy steels and superalloys)."

[1] Data may not add to totals shown because of independent rounding.

[2] Withheld to avoid disclosing company proprietary data; included in "Steel: Unspecified."

[3] Includes electric and tool steel, and items indicated by (2).

[4] Approximately 85% of this combined total was for consumption in aluminum alloys.

[5] Internal evaluation indicates that silicomanganese consumption is considerably understated.

[6] Estimated based on typical percent manganese content (rounded).

[7] Withheld to avoid disclosing company proprietary data.

TABLE 6

U.S. UNIT CONSUMPTION OF MANGANESE IN IRONMAKING AND STEELMAKING

(Kilograms per metric ton of raw steel unless otherwise specified)

Form used	1992	1993
IRONMAKING		
Basis: Production of raw steel, million tons[1]	84.32	88.79
Ore[2]	[r].24	.08
STEELMAKING		
Basis: (Production of raw steel and steel castings) million tons	[r]85.22	[e]89.85
Ore[2]	(3)	—
Ferromanganese	3.00	2.89
Silicomanganese	.80	.79
Manganese metal	.06	.07
Total, steelmaking	[r]3.86	[4]3.74

[e]Estimated. [r]Revised.

[1] As ingots, continuous- or pressure-cast blooms, billets, slabs, etc.

[2] Containing 35% or more manganese.

[3] Less than 1/2 unit.

[4] Data do not add to total shown because of independent rounding.

TABLE 7

TIME-PRICE RELATIONSHIPS FOR MANGANESE IN METALLURGICAL ORE

Year	Average annual U.S. price, dollars per metric ton unit, c.i.f.	
	Actual price	Based on constant 1987 dollars[1]
1973	0.64	1.55
1974	.89	1.97
1975	1.36	2.76
1976	1.43	2.73

[r] Revised. XX Not applicable.

[1] Includes U.S. Bureau of Mines revision of part of reported data.

[2] Includes U.S. Bureau of Mines conversion of part of reported data (from apparent MnO_2 content to Mn content).

[3] Data may not add to totals shown because of independent rounding.

[4] Unspecified group of countries differs from that in the 1992 Annual Report.

[5] Formerly part of Czechoslovakia; shipments prior to Jan. 1, 1993, included in Czechoslovakia.

[6] Dissolved in Dec. 1992. Includes shipments from all Republics prior to Jan. 1, 1993.

Source: Bureau of the Census, adjusted by the U.S. Bureau of Mines.

TABLE 10
U.S. IMPORT DUTIES ON MANGANESE MATERIALS[1]

Item	HTS No.	Rate of duty effective Jan. 1, 1993	
		Most favored nation (MFN)	Non-MFN
Ore and concentrate	2602.00.0040/60	Free	2.2 cents per kg Mn.
Manganese dioxide	2820.10.0000	4.7% ad valorem[2,3,4,5]	25.0% ad valorem.
Ferromanganese:			
Low-carbon	7202.19.1000	2.3% ad valorem[2,3,5]	22.0% ad valorem.
Medium-carbon, 1% to 2% carbon	7202.19.5000	1.4% ad valorem[2,3,5,6]	6.5% ad valorem.
High-carbon	7202.11.5000	1.5% ad valorem[2,5]	10.5% ad valorem.
Silicomanganese	7202.30.0000	3.9% ad valorem[2,3,5,7]	23.0% ad valorem.
Metal, unwrought	8111.00.4500	14.0% ad valorem[2,8]	20.0% ad valorem.
Metal, other	8111.00.6000	5.5% ad valorem[2,3,9]	45.0% ad valorem.

[1] All subject to (1) 0.19% ad valorem Merchandise Processing Fee except for products from beneficiary countries under the Caribbean Basin Economy Recovery Act (CBERA) and least-developed developing countries and (2) 0.125% ad valorem Harbor Maintenance Fee for cargo unloaded from waterborne vessels at U.S. ports open to public navigation.

[2] Free from beneficiary countries under CBERA, the Andean Trade Preference Act, and for products of Israel.

[3] Free from certain countries under Generalized System of Preferences.

[4] Not duty free for India.

[5] Free for products of Canada.

[6] Not duty free for Mexico.

[7] Not duty free for Brazil.

[8] 7.0% ad valorem for products of Canada.

[9] 2.7% ad valorem for products of Canada.

Source for rates of duty: U.S. International Trade Commission (Harmonized Tariff Schedule of the United States 1993).

[e] Estimated. [r] Revised. XX Not applicable.

[1] Table includes data available through July 28, 1994. Data pertain to concentrates or comparable shipping product, except that in a few instances the best data available appear to be for crude ore, possibly after some upgrading.

[2] In addition to the countries listed, Burkina Faso, Cuba, Panama, and Sudan may have produced manganese ore and/or manganiferous ore, but available information is inadequate to make reliable estimates of output levels.

[3] May be for average content of each year's production rather than for content of typical products.

[4] Metallurgical ore.

[5] Reported figure.

[6] All production in Yugoslavia from 1989-91 came from Bosnia and Herzegovina.

[7] Gross weight reported; metal content estimated. Estimated metal content figures have been revised as necessary.

[8] Production of beneficiated ore as reported in Sumário Mineral (Brasilia).

[9] Includes manganiferous ore.

[10] Calculated metal content includes allowance for assumed moisture content.

[11] Concentrate.

[12] Much of India's production grades below 35% Mn; average content was reported as 38.7% Mn in 1989.

[13] Mostly oxide nodules; may include smaller quantities of direct-shipping carbonate and oxide ores for metallurgical and battery applications.

[14] Dissolved in Dec. 1991.

[15] Dissolved in Apr. 1992.

[16] Category represents the combined totals of Argentina (low-grade ore), Bolivia, Botswana, Burma, Colombia, Egypt, Greece, Indonesia, Italy (from wastes), Japan (low-grade ore), Philippines, Thailand, Turkey, and Zambia.

[17] Data may not add to totals shown because of independent rounding.

XX Not applicable.

[1] Where available, data for manganese dioxide included beginning in 1984.

[2] Including manganiferous ore.

[3] Data may not add to totals shown because of independent rounding.

[4] New series for steel-related end uses beginning in 1989.

[5] Includes miscellaneous nonmetallurgical uses of ore beginning in 1987.

[6] Not specifically based on reported data; includes processing losses. Through 1988, the distribution within this category is approximately the same as for end uses above exclusive of batteries and chemicals. Beginning in 1989, includes nonidentified uses of steel corresponding to about one-third of total steel shipments.

MATERIALS RECYCLING

By Arnold O. Tanner

Mr. Tanner is an industrial material specialist with 15 years of experience at the U.S. Department of the Interior, the first 7 years as a geologist at the U.S. Geological Survey. Since 1986 he has served at the U.S. Bureau of Mines as a physical scientist (commodity specialist), leading to his present position specializing in materials recycling. For the past 4 years he has conducted studies concerning materials recycling and solid waste management as a member of the Branch of Materials. The section on "Design for Recycling" Programs was prepared by Mr. Robert D. Brown, Jr., a physical scientist with the Branch of Materials. Some of the data and most of the tables and graphs were prepared by Ms. Grecia Matos, an industrial material specialist with the Branch of Materials.

INTRODUCTION

The recycling of scrap and waste materials provide an alternative material source to that of virgin supplies. Fairly rapid growth has occurred in recent years in the recycling of a wide variety of physical structure materials and products that are used in people's everyday lives. If a substance can be reused or recycled for part or all of its inherent value, it is a candidate for diversion from the solid waste stream. The longer a material's useful lifetime can be extended, the less Earth's virgin resources of that material must be consumed.

The greater the economic viability of a material's overall recycling process, the greater is its potential for continued recycling. Successful recycling provides opportunities for new businesses in the economy, thereby providing materials, services, and jobs. The recycling of the aluminum used beverage can (UBC) is a prime example of a profitable secondary/used material recovery operation. The reuse of UBC's requires significantly less energy resources than the equivalent processing of virgin aluminum and reduces the quantity of waste that is overcrowding our landfills.

The shrinking availability of landfill space is a very visible and politically active issue. Along with associated water and air pollution at some existing landfills, the growing question of how best to manage our waste and other used materials is coming under increasing scrutiny. Increased interest in more efficient materials use and reduction of the impacts of waste on the environment are part of the sustainable development approach to economic activity and environmental protection. Sustainable development was defined in the Bruntland report as development that meets the needs of the present without compromising the ability of future generations to meet their own needs.[1] Materials recycling, although far from a total solution for all of society's waste ills, is one avenue for managing used, or otherwise rendered-useless, materials.

A large variety of materials are recycled by different sectors of our society. The recycling that is mainly addressed in this chapter is from waste that is generated after manufacturing and consumer use. Included is the recycling of materials that is generally more apparent to the general public: the collection, reprocessing, and remanufacture of materials into new products from post-consumer UBC's, scrap metal, glass containers, paper goods, increasingly plastics, as well as rubber tires and other used goods. On the other hand, a variety of materials are recycled within the individual operations by mineral and material processors, the chemical industry, product manufacturers, utility companies, etc. This latter solid and liquid reprocessing and recycling is done internally in many industries and is generally less visible to the general public than the recycling of materials from municipal solid waste. Recycled materials in the various industries are commonly liquid or chemical in form, but also include the clean excess scrap from metal, paper, glass, and plastic manufacturers (often called "home," runaround, or flash scrap). A significant portion of pre-consumer scrap, sometimes called new scrap, is traded to industrial consumers of scrap materials to produce new products and is included in much of the data that follow. Most of the physical structure materials that are recycled back to the consumer as new products are solid materials. Other materials, such as lubricating oils, solvents, and increasingly, household hazardous substances, such as paints, home solvents, and cleaners, are currently categorized as "solid" waste, but are not addressed in this chapter.

The U.S. Bureau of Mines (USBM) publishes several annual reports that address many of these recycled materials and products. For the most part, these publications address metals that society traditionally has recycled. This chapter attempts to cover several of the basic materials and products that are not covered in other USBM writings and yet are very basic and fundamental, as are other mineral and material commodities, to our society and our way of life. The three materials treated in depth—paper, plastic, and rubber—are diverse in their makeup. Paper is produced from the renewable resource of trees and other vegetation. Virtually all plastic is produced from nonrenewable hydrocarbon feedstocks, and rubber is produced primarily from the same nonrenewable hydrocarbons as plastics in addition to a smaller, yet very significant, portion produced from renewable, natural rubber feedstocks. Because of their diverse natures, the general title "Materials Recycling" was used. While bearing fundamental differences, one "characteristic" does tie them together (along with a variety of other basic consumer commodities): if, following their initial intended use they are not: (1) reused relatively "as-is"; (2) recycled following material reprocessing; (3) incinerated in a waste-to-energy (WTE) facility; or (4) otherwise processed into usable material, such as through composting, then they become waste and are landfilled. Society always may produce some quantity of waste products that cannot be used again and must be disposed of. The important consideration here is how much must be discarded at what rate. Solid waste management, or resource management as some professionals more positively characterize it, is the overall theme surrounding the growing efforts to reuse and recycle our used materials. Of equal importance for future generations is the conservation of our natural resources, especially nonrenewable resources. This also has been a motivational force behind recent efforts to increase the recycling of materials.

DOMESTIC DATA COVERAGE

Data in this report are derived from a variety of published and unpublished sources that are mostly external to the USBM. Much of the solid waste data and some of the recycling data come from U.S. Environmental Protection Agency (EPA) studies. The other main data sources were various industry, trade association, and independent contractor studies and journal and media reports. At this writing, limited Federal Government surveys existed concerning the quantities of post-consumer materials in the municipal solid waste stream or of those being recycled. Several agencies, in particular the USBM, the U.S. Bureau of Census in the Department of Commerce (DOC), and the EPA, have been meeting to evaluate the possible gathering of such data.

BACKGROUND

Definitions, Grades, and Specifications

Overall Solid Waste Material Flow.—Post-consumer materials become part of the solid waste stream unless otherwise diverted into secondary material use. Although commonly used by various industries to refer to pre-consumer scrap, the term secondary also can be applied to used or post-consumer waste materials that are recovered for recycling. The most publicized waste is municipal solid waste (MSW), and much of the materials recycling that has become an important public issue in the past decade comes from MSW. MSW, however, is an extremely small portion of the total solid waste stream. Estimates of solid waste from all sources vary greatly, and most are based on incomplete, mid-1980's data. But from estimates of between 11.5 and 13.5 billion metric tons[2] of legally designated "solid" waste, only about 187 million tons (preliminary estimate for the United States in 1992) is MSW, a little more than 1.5% of total solid waste, as shown in figure 1. *(See Figure 1.)* Also note that these "solid" waste streams are perhaps 80% or more liquid, a common constituent being wastewaters as well as other liquid wastes. Much of these liquid-form "solid" wastes are contained in surface impoundments for treatment, storage, or disposal. True solid wastes that are not recycled, composted, or incinerated are generally managed by way of landfills, waste piles, or in other land disposal areas. All wastes are either categorized or defined as solid (meaning nonhazardous), hazardous, or radioactive/nuclear wastes. Hence, a waste that is in liquid form, but is by appropriate definitions, concentrations, etc. judged to be nonhazardous, is legally categorized as a "solid waste."

Municipal Solid Waste Material Flow.—MSW, while being a small portion of our total solid waste stream, is mostly (about 95%) solid in nature when introduced into the wastestream. Two of the included categories of waste, yard waste and food waste, are mostly solid in form but have low to moderate liquid (commonly water-based) contents. These liquid-containing wastes contribute liquid to landfill effluent as landfill wastes degrade. Together, yard and food wastes comprise about 25% of MSW.

Solid Waste Management Options.— **The Hierarchy.**—A hierarchy of solid waste management methods has been established by the EPA. Although a strong emphasis often is placed upon its first two levels, the solid waste hierarchy is a list of "method preference" rather than a rigid set of hard and fast rules. The hierarchy includes: (1) source reduction, (2) reuse, compost, or recycle, (3) waste-to-energy incineration, and (4) landfilling.

The EPA has been conducting municipal solid waste characterization studies since 1960. Estimates of solid waste that would fall under the category of source reduction are very difficult to quantify. The problem with such numbers is as much a matter of definition as it is of presenting hard numbers. No attempt is made in this chapter to quantify these materials that, because of planning and forethought, never became waste. Nevertheless, some professionals are attempting to devise methodologies to indicate the progress made in this important aspect of resource and solid waste management. Preliminary 1992 estimates for the percentage of MSW being managed by the methods in the hierarchy follow. In 1992, approximately 18% of MSW was recovered for recycling and 3% was recovered for recycling from yard waste and other composting for a total recovery of 21%. This was up from the commonly publicized EPA 1990 total recovery estimate of 17%, which included yard waste and other composting but often was not reported in the media using a similar breakdown. MSW incinerated with energy recovery accounted for about 16% of total MSW in 1992 and that incinerated without energy recovery was about 1%, for a total of 17% MSW incinerated. This was up from the total 16% that was combusted in 1990. The remaining 62% of MSW was landfilled, down from 67% in 1990.

A balanced approach in choosing the best methods for managing wastes in each particular situation is called integrated waste management (IWM). In IWM, the different methods are intended to be utilized, as most appropriate, for the varied locales or States. Recycling is not always the answer because of such reasons as geography and sparse population, local economics, lack of accessible technology, etc. Likewise, the next preference, incineration, also in some cases may be impractical. For example, an adequate future supply of solid waste "fuel" must be confidently anticipated to justify the high capital cost of building an incinerator. Local or regional economics can restrict the use of these options, especially in sparsely populated areas. Landfilling in conjunction with minimal recycling activities may at times be the most workable and beneficial waste management choice for the solid wastes in a certain community.

Source Reduction.—The first preferred option is actually a "preoption" called source reduction, sometimes referred to as waste reduction. Solid waste source reduction is the design, manufacture, purchase, or use of materials or products in ways that directly or indirectly reduce their amount, toxicity, or other toxic effects before they are produced, thus avoiding any potential entry into the solid waste stream. Not creating the waste in the first place is better than having to deal with it later. Because source reduction efforts are intended to reduce pollution as well as conserve natural resources, such activities also should not increase the net amount or toxicity of wastes generated throughout the life of the product.[3] Reduction of the quantity of materials in a particular packaging application is one example of source reduction. Another example is the design of a product, such as the automobile or a home appliance, with its materials recycling in mind. A more easily disassembled vehicle, refrigerator, or stove made of readily recyclable materials will reduce the amount of discarded material. One related design factor, the energy necessary to reprocess the materials, may either encourage or discourage a source reduction effort. The total energy expended by recycling must be considered as well as the metals, plastics, and glass materials that may be kept out of the wastestream by the future recycling of them into new, qualitative hard goods and materials. This energy factor is very important because the energy is commonly derived from hydrocarbon resources that are as nonrenewable as many of the materials that are being reprocessed.

Recycling and Composting.—Direct reuse or the physical or chemical recycling of a product or other waste material is given second preference. The goal is to recover materials from the wastestream and thereby minimize the use of virgin resources. Recycling is not 100% effective because there is always some waste that results during the recycling process. Some portion of the material either degrades too much to be reused or is otherwise lost in the process. But, recycling, while not being a perfect solution, does extend the lifespan of a material by keeping it in use. Recycling decreases the introduction of materials into the wastestream and thereby slows the filling up of valuable landfill space.

Composting also is included in this level of preference. It involves the chemical breakdown of materials into different, usually more basic, materials or chemical compounds. This contrasts with the physical breakdown of a material into smaller pieces that are chemically the same. The recycling of paper is a physical process in which the individual paper fibers may be reduced in size but remain chemically unchanged. The composting of food and yard wastes is increasingly becoming an integral part of the solid waste management efforts of many communities, especially where laws have been passed banning the landfilling of yard wastes. Composting provides an alternative to chemical fertilizers in a variety of applications. Municipal solid waste also is compostable after the removal of metals, plastics, rubber, and glass. Three factors that tend to limit its desirability are: (1) the concentration levels of some contaminates, especially metals such as lead and cadmium; (2) small pieces of glass, metals, and plastics that remain; and (3) competition from the other waste management methods, especially the recycling of paper.

Waste-to-Energy Incineration.—The next choice in the hierarchy is MSW incineration, particularly when used in conjunction with the production of energy. Waste-to-Energy (WTE) incineration, producing energy either in the form of steam or electricity, often is a viable waste handling option that makes use of the energy values contained in MSW rather than simply burying it. Both plastic and rubber material comprise an important portion of MSW "fuel" in a WTE incinerator because they can provide higher energy values than the other components of MSW. The combustion of MSW also reduces the volume of the waste that remains to be disposed of to as little as 15% of the incinerated materials' original volume. Some components of MSW, such as plastics, are virtually reduced to zero, with only a very minute portion of char remaining. This volume reduction is especially important with regard to plastics because, when compared to other MSW materials of like weight, plastics commonly take up about twice as much landfill space. Some plastics consume considerably more; for example, polystyrene foam plastic can take up as much as seven times the space. Although volume reduction is a significant reason for incinerating landfill-bound waste, MSW incinerators without energy recovery have of late been on the decline, and those with such recovery are becoming the norm. Very few, if any, new plants without such an energy recovery capability are currently in the planning stage or under construction.

Sanitary Landfilling.—Although it is still the most common form of waste management, or as some prefer to say, used material management, landfilling is becoming the least preferred choice. Minimizing the quantity of discarded materials that are landfilled has been stressed during the past several years because of the shrinking availability, of landfill space due to physical limitations or political considerations. The diversion of materials from landfills and the overall solid waste stream is the dominant force driving current material reuse and recycling efforts.

Material Resources and Related Economic Issues.—**Collection, Utilization, and the Market.**—Supplies of materials collected for recycling are relatively large in the United States. Old newspaper, mixed paper, green glass, and some plastics are examples of materials that have been collected in quantities beyond the markets' capacity to absorb them. Causes for the oversupply of some recovered materials include: (1) lack of a recycling industry infrastructure; (2) inadequately developed markets; (3) an often uneven playing field of competition with competing virgin materials; (4) low prices for recovered materials; and (5) the recently weak, though mildly improving, state of the U.S. economy. In most cases, collection of recyclables increased in 1993, adding to some oversupplies remaining from the previous year.

On the other hand, within the oversupply, undersupplies of materials that are sufficiently clean or uncontaminated add to this problem. A load of an otherwise usable material can be rendered useless if it includes too high a level of other unlike materials. The processing of such loads can be limited for technological or economic reasons. Further development of collection practices and sorting procedures and technologies, such as those for sorting plastic containers of different types, may serve to increase supplies of more competitive, marketable materials.

Domestic Recycled Material Economics.—The U.S. economy experienced increasing, though gradual, improvement during 1993, but its effects were not strongly evident in the recycling marketplace where prices for most recycled materials either declined somewhat or were flat. Overall, 1993 was not a year of attractive prices for those involved in the selling and trading of recycled materials. Steel scrap was an exception, and less so recovered plastics (containers), which exhibited a modest average increase in prices during the year. Fluctuating prices for recovered plastic, combined with the continued low price of virgin resin, hindered a more consistent and healthy development of the commodity. In the final weeks of 1993, prices for most recycled material commodities were rebounding modestly from the lows experienced earlier in the year.[4]

Despite the economics involved, most U.S. industries recorded increases in recovered material use. Substantial increases occurred in the steel and paper industries, and a little less so in the plastics industry. Modest increases occurred in the use of recovered glass containers, aluminum scrap, and steel cans, whereas there was a modest drop in the use of aluminum cans. The decline in the consumption of used aluminum cans was somewhat of a temporary lull in the marketplace. The decline was due, in part, to large volumes of scrap cans that were withheld from the market at the end of the year in anticipation of a rebound to higher prices in 1994. Prices paid for scrap aluminum cans, both by processors and end users, dropped significantly in the last quarter of 1993. Exports of several recovered materials declined. The export of aluminum cans decreased modestly, whereas drops in the exports of aluminum scrap overall and plastic scrap were more significant.[5]

Germany's Recycling Experiment.—A foreign example of collection that exceeds secondary markets is found in Germany's Green Dot program. Green Dot is the program that resulted in response to the German Packaging Ordinance, effective January 1, 1993. It specified quotas for the collection of used packaging materials, and made the manufacturer responsible for both collecting and recycling the materials. During 1992, the nationwide recycling collection organization, Duales System Deutschland (DSD), collected more than 4.5 times as much tonnage of scrap plastic as it had initially anticipated. This 204,000 tons [about 450 million pounds (lbs)] of plastic was more than 3 times the amount that the country had the capacity to handle. One-third of the plastic was exported, and the rest was stockpiled awaiting future increases in capacity and better markets for the materials.

Part of the problem in the German system has been the success of recycling collection activities, while growth in the recycling infrastructure and the marketing of recycled products overall have not been able to keep pace. Oversupplies were felt beyond the German border. In at least one district in England, secondary raw materials from Germany could be purchased for less than it cost the district to collect its own. DSD collected almost 4.2 million tons [4.6 million short tons (st)] of these materials in 1993. But the oversupply of plastic packaging was the most difficult problem with which to deal. In 1993, DSD expected a doubling of plastics collection to about 410,000 tons (more than 900 million lbs) to be used in almost the same proportions as in 1992. Almost one-third, 135,000 tons (just under 300 million lbs), was estimated to be added to current stockpiles, and exports increased beyond the one-third proportion of 1992.

DSD, a not-for-profit consortium of nearly 600 companies, twice in 1993 came close to bankruptcy.[6] Following a management reorganization, an influx of new cash, and cost cutting measures, the program appeared to be stable. Other changes included a tightening of license fee collections and commitments from local industry to step up the development of reprocessing technology and to establish plants. Two major changes were undertaken to address the oversupply of plastics. First, a separate consortium called DEKUR Kunstoff Recycling GmbH was formed and made responsible for recycling plastics packaging in the country.[7] Second, DSD moved to a sliding fee scale, based on material types, rather than weight alone. Manufacturers were charged more for plastic and composite materials, which are more expensive and difficult to collect and reprocess than other materials, such as paperboard and glass. Although the system was very troubled and near failure during the year, source reduction was achieved in 1992 and 1993. The total amount of packaging in Germany was reported to have decreased 3.1% in 1992 and about 4% in 1993.[8] This followed packaging increases of 11.7% and 3.5% in 1990 and 1991, respectively.[9]

Economic Factors Within the Recycling Industry.—The basic economic structures for each commodity within the recycling industry are similar. Metal recycling, particularly of steel and aluminum, is the most established. The paper and glass recycled material markets also have been in place for a long time.

The market for recycled plastics is still in development and, in most cases, secondary plastic resin is more expensive than virgin material. Makers of plastic bottles sometimes buy the recycled material in spite of the price disadvantage because they have faced potential legislation or other regulations that would restrict bottle disposal in landfills. The increased use of more expensive recycled materials sometimes is economically more favorable to the industry than a ban of the material or other costly restrictions.

Plastics recycling businesses are not as vertically "integrated" as those for other materials. A significant number of small firms perform only one or a few of the various steps involved in recycling and reproducing plastic materials and manufacturing new products that go to market ("horizontal" business structure). Companies in the other, more established, marketplaces commonly undertake many or all of the steps. These businesses are vertically "integrated;" they have diversified their business into multiple stages, or steps, of the production cycle. This allows for greater efficiency and leaves the companies less vulnerable to changes in markets and prices. For example, when several companies are involved in various steps of the recycling of a material, the transportation costs alone between sites can significantly add to overall processing costs compared with a more "integrated" company handling the entire process at a single site.

Some of the more successful recyclers are vertically integrated. For example, the large North American plastics recycler Wellman, Inc.,[10] located in New Jersey, is integrated forward into the production of fibers and thermoform extruded plastic sheet, as well as backward into the waste collection process. Another approach taken by some companies is to structure their businesses in accordance with agreements or alliances with other companies in support of each other.[11] This provides more security for the company while making unnecessary the direct expansion of their business into work with which they may have little experience. In addition to being a potentially difficult transition, such expansions can be very capital intensive.

Another difficulty for materials recycling is that of classic supply and demand. Most recycled materials, with the exception of scrap metals, face similar basic economic problems: high supply, low demand, high cost, low quality (compared to virgin), and low, unsteady prices. The high supplies have been caused by somewhat enthusiastic collecting by the public that increases yearly, and in part by mandatory recycling without sufficient building of the product marketplace. Low quality, commonly due to contamination by unlike materials, such as paper mixed in with a load of post-consumer plastics, limits the use and value of the materials. Contamination results in higher processing costs, or even rejection of the otherwise good material load. Virgin material is usually less expensive and quality is far more consistent and easier to control. Oversupply and unreliability of the material quality only adds to the standard costs of recycling, which are collection, transportation, sorting, further processing, and the specific technologies involved in reproducing a useful new material and final product. The recycled material marketplace can be made more stable through: (1) continued improvements in material quality, (2) the continuous reliability of that supply, and (3) emphasis on the demand for the final product to better match increasing quantities of collected materials.

The primary sources of pricing information for most recycled material commodities have thus far been weekly and monthly trade publications, which calculate the prices by polling traders. In recognition of the often low, unstable pricing for recycled materials, the National Recycling Coalition's (NRC) Recycling Advisory Council (RAC) and the Chicago Board of Trade (CBOT), a nonprofit futures exchange market, commenced an experimental project to help develop a more secure and mature recycled materials market. The National Recycling Coalition is a nonprofit organization that unites large and small businesses, recycling and environmental groups, state and local governments, and individuals in a concerted effort to maximize recycling across the United States. The RAC was created by NRC to build consensus and provide national leadership and coordination on issues affecting recycling and resource management. The RAC meets at least three times per year to review current issues and recommend recycling initiatives to both the public and private sectors and is in part funded by the EPA.

The CBOT, in allegiance with the RAC, is creating the country's first cash exchange market for recycled materials commodities. Plans call for an electronic trading market in which sellers would list offers and buyers would post bids on a computer bulletin board. This may provide potential buyers with more accurate pricing information and, in the near future, standardized quality specifications. CBOT believes that the unregulated and volatile nature of dealing recyclables has been partially responsible for the slow development of recycled material and product markets.

Polyethylene terephthalate (PET), high-density polyethylene (HDPE), and glass were projected to be the first post-consumer materials traded because of support from those industries and interest from buyers and sellers of those post-consumer materials. Paper and metals may follow as the next traded recycled materials.[12]

The "Not-In-My-Back-Yard" Factor.—"NIMBYism," as it is often called, refers to resistance by citizens to the siting of certain nonresidential facilities near to where they live. Whether the resistance is based on legitimate concerns or is more an emotional reaction, it represents a real problem for both the solid waste and recycling industries. The siting of a needed recycling facility, incinerator, or landfill can be a very difficult process. Most people do not want one "in their back yard," but reality dictates that they must be constructed somewhere. The public must be protected from unreasonable or harmful facility sitings and at the same time be served in their needs for solid waste management and materials recycling. Various facilities are needed to recycle the different kinds of used and waste materials. Some examples of these are materials recovery facilities (MRF's), where collected materials are sorted and made ready for shipment to recycled material processors, and materials transfer stations that handle and process the materials that the public puts out at the curbside for collection. Location is not the only issue; general economic issues involved can prohibit the siting of a facility in a location even when most of the people concerned accept the site.

Legislation and Government Actions

A Presidential Directive.—In October, the President signed an Executive order to modify the Federal Government's procurement practices by significantly increasing and specifying the recycled material content required for various purchased goods and supplies. Specifically, Federal agencies were directed to purchase printing and writing paper containing a required 20% post-consumer content material by the end of 1994 and 30% content by the end of 1998. Prior to this order, Federal agencies were encouraged, but not required, to purchase paper with 50% total recycled content, only 10% of which was to be post-consumer content. In support of the new requirement and standards, a revision of the brightness specifications for paper were ordered to allow, though not require, the use of stationary produced without chlorine bleaching, which can potentially be harmful to the environment. U.S. mills use chlorine more commonly than foreign manufacturers to brighten paper to meet the specifications or desires of its customers, including the Federal Government.

The new policy also strongly encouraged agencies to use retreaded tires and re-refined motor oil. Whereas purchase of recycled paper by the Government has become increasingly common, purchase of these latter two have not been usual for a variety of reasons. Only 6,000 retread tires have been purchased in the past several years for a Federal Government fleet of 60,000 passenger cars. This is partly because the Government normally keeps its vehicles only for 3 years or 30,000 miles, and often the original equipment does not wear out in time for replacement to be necessary. Virtually no re-refined oil has been bought for passenger cars owned by the U.S. Government, in part, because of concerns surrounding the validity of a car's warranty when re-refined oil is used. Additionally, the order directed the EPA to provide a publication listing "environmentally preferable" products, such as nontoxic cleansers and less cumbersome packaging.

Increased development of the recycled material marketplace was a major reason for this action, which could have significant effects for two reasons. First of all, by itself the Federal Government buys 300 million tons of paper per year, about 2% of the national market; and overall, Federal procurement accounts for about 8% of all goods and services nationwide. Also, the Executive order was applied to Government contractors. By the end of 1994, when a company responded to a request for proposal (RFP), the RFP was to be submitted on double-sided paper with no less than the same required 20% post-consumer content.[13]

Secondly, besides the direct impact of Federal Government purchases, its actions are intended "by example" to influence State and local governments and U.S. industries, as well as the general public, both to accept and to purchase more recycled-content goods. Not uncommonly, when the Federal Government "sets a standard," it is followed, in time, by a significant number of other government entities and U.S. industries.

Two exceptions to the basic rules were included in the Presidential order. The first concerned what materials could be categorized as "recycled content." Recycled content was defined as containing post-consumer paper, that is, paper that had been used by the public, except in the case of sawdust that would otherwise be discarded in landfills. When sawdust, a virgin material byproduct at lumber mills, was to be included as part of the recycled content, the mills would be required to deliver paper with a 50% recycled content. A second provision concerned costs. Higher prices for recycled paper of 3% to 4% more than virgin paper were anticipated for the first several years while the market was growing and expanding. This would have to be absorbed by the agencies' more conservative use and reduced waste of paper. More conservative use of paper, such as through two-sided copying, would be encouraged to make up for some of this extra cost. As the exception, agencies would be exempt from buying paper with the specified recycled content if certain conditions, such as price, were deemed "unreasonable." The order did not define or quantify "unreasonable," although the EPA indicated that a price differential of up to 10% would not be unreasonable.[14]

Federal Actions.—As in 1992, efforts to fully reauthorize the Resource Conservation and Recovery Act (RCRA), last accomplished in 1984, did not succeed in 1993 and were similarly not expected to succeed in the remaining year of the 103d Congress. Reauthorization of the Comprehensive Environmental Response, Compensation and Liability Act, "Superfund," and resolution of related hazardous waste issues still had priority and yet were to be accomplished.

Issues surrounding the transportation of solid waste and hazardous waste across State lines, flow control of recyclable materials and solid waste, and the hazardous or nonhazardous characterization of MSW incinerator ash received significant attention. This occurred both in the U.S. Congress and on the Federal Court scene, but nearly all were continued over into 1994 without resolution.

State Legislation and Government Actions.—The focal point of recycling legislation on the State level has changed during the past several years. A shift has occurred from collection-oriented legislation to demand-side legislation. A variety of State recycling laws were passed, but none were comprehensive solid waste or collection laws. This was the case partly because most States already had adopted them, especially since the mid-1980's. The number of legislative bills addressing packaging issues dropped 50% from those of 1992. Additionally, efforts to institute controversial recycled content mandates on packaging were successful only in a small number of cases. Debate continued concerning what methods would better increase recycled material use while minimizing adverse effects. Altogether, State legislatures created or amended 110 recycling laws in 1993.[15]

In response to the overall weak market for recovered (post-consumer) materials, many States passed laws designed to encourage the market for recycled materials, boost local economies, and create jobs. Also supporting market development, a total of 36 States had programs by the end of 1993 aimed at creating jobs and economic development in the recycling industry. Many of the other 14 States and the District of Columbia had laws or were in some other way encouraging recycling. The EPA was distributing grants to promote jobs in the recycling industry to 13 States, at least 2 of which did not have programs of any kind.

A variety of market development tools were used by State governments. Tax incentives, such as tax credits for the purchase of recycling equipment, were used by many States as they usually require no direct funding. Eight States—Arkansas, Iowa, Maine, Montana, Nevada, North Dakota, Virginia, and West Virginia—initiated or expanded tax incentives for recycling in 1993, bringing the total to 27 States. Nevada and Iowa passed property tax exemptions for recycling enterprises. Three States passed legislation in 1993 creating task forces or councils to promote market development. Government procurement was another method used: nearly all States have some form of procurement laws that affect recycling. Fifteen States strengthened their purchasing preferences for recycled materials during the year. The State of Florida used fee legislation to encourage greater use of recycled materials. The Florida Advance Disposal Fee on packaging significantly amended the original 1988 law. The fee, 1 cent on bottles, cans, jars, and beverage containers from 5 ounces to 1 gallon in size, was collected—at the wholesale level instead of the retail level—and took effect in October 1993. It applied to packaging materials not meeting a 50% recycling rate, effectively exempting aluminum and steel.[16]

Two other approaches used to encourage increased recycling were landfill bans on certain materials and implementation of recycling and waste diversion goals. Eight State legislatures passed disposal bans to bring the total to 46 States that had materials or products banned from landfill disposal. The most common materials that have been banned from landfills to date are vehicle batteries, tires, yard trimmings, motor oil, and white goods. A total of 44 States have either legislated or otherwise announced goals for recycling or waste diversion, which range from 20% for Maryland to 70% for Rhode Island. Fifteen States have goals that are 50% or greater, including the two most populous States, New York and California. Two States set new goals in 1993. Connecticut approved some of the most significant legislation in 1993 aimed at diversion of waste from disposal facilities. The State raised its recycling and source reduction goal to 40%, from 25%. The earlier goal had a deadline of 1991; the new target gives the State until the year 2000. The State reported a recycling rate, including composting of yard trimmings, of 21% for 1993. The Governor of the State of Colorado announced a 50% waste reduction target to be achieved by the year 2000. The goal was not passed into law but government grants, a funding mechanism, and a program tracking mechanism were set in place in support of the initiative.[17]

ANNUAL REVIEW

Paper Recycling

Paper and paperboard materials initially are produced almost exclusively from wood pulp, which is wood or "cellulose" fiber mainly processed from softwood timber, and to a lesser degree, from hardwood timber. Softwood fibers impart strength and tear resistance while hardwood fibers provide density and printability. The major categories of paper products include: paperboard; kraft paper, including that used for corrugated container board; cardboard; newsprint; printing and writing paper; and various utility papers, such as for bags, plates, tissues, and towel products. These products, as well as fiberboard used in construction and paper-based insulation materials, are potential markets for both pre-consumer and post-consumer recycled paper fibers to supplement virgin fiber content and reduce the quantity of paper in the solid waste stream.

Issues.—Two issues with potential to affect increases in paper recycling are: (1) how to reduce the consistently growing quantities of paper in MSW and (2) how to best balance environmental problems and conflicts related to virgin material supply with tradeoffs related to increased substitution of recycled paper. Our society has become a heavy consumer of paper and paperboard products. The "paperless society" speculated by many in the past does not appear to be close at hand. We are using more and throwing away more with each passing year.

According to the EPA, the total generation of paper and paperboard products in MSW has grown steadily from 27 million tons in 1960 to almost 67 million tons in 1990. (More recent EPA data were not yet available for this report.) As a percentage of the total MSW generated, paper (by weight) represented about 34% in 1960. Although the percentage has varied over time, it has generally increased, to 37.5% of the total MSW generated in 1990. Much of the paper that we use comes in the form of nondurable goods with relatively short lifespans. Waste from paper packaging materials and newspapers having lifespans of less than 1 year (often only several days) have followed this same trend. When added together, they account for about 60% of total paper waste. However, the actual quantities going to landfills have shown small decreases of late. Based upon EPA data, the quantity of paper being landfilled dropped by about 5% between 1985 and 1990. During this time, paper recovery for recycling and incineration (usually involving energy recovery) has significantly increased.

Paper recycling, a common practice during the newspaper drives since the 1950's and 1960's, has greatly increased in the past two decades. The recycling of paper reduces the need for virgin wood fiber. The diversion of paper alone could significantly reduce the quantities of waste filling up our landfills.

Quantities of solid waste managed by incineration substantially declined from the mid-1970's through the mid-1980's, but rebounded to above 1970 levels by 1990. Since 1985, numerous new facilities—cleaner, more efficient, and almost exclusively with energy recovery systems—have come into operation. This includes both mass-burn and refuse-derived-fuel (RDF) plants. RDF is MSW that has had certain materials, especially metals, separated out, after which the remaining materials are processed into a fairly consistent, uniform-sized feed of combustible material.

Secondly, because paper materials are produced from wood fibers, the production of paper and paperboard products promotes significant use of timber resources. About 25% of U.S. timber production goes into the making of woodpulp, of which about 95% is used in the production of paper. Increasing attention is being paid to a variety of environmental issues. Growing controversies over various endangered species, the loss of virgin forests with relatively untouched biological diversity, and the erosional effects of the clear-cutting of forests are several issues related to the harvesting of timberland. These factors have a potential to influence the increased use of recycled paper fibers in new paper products.
