Currently at issue is the establishment of a generally acceptable standard or legal definition of "recycled paper." Much effort was put forth by Federal Government agencies and joint committees, as well as trade associations and independent materials standards organizations, to do so. But final definitions for recycled paper and related terms were still in the discussion stage at yearend. The use of pre-consumer scrap paper in paper production is a common practice of many manufacturers because it is a good alternate source of raw material. It generally yields a high-quality product more easily, and most often at a lower cost than when post-consumer paper is used. Post-consumer paper tends to be "dirtier" with more contaminants than the more consistent and controlled quality of pre-consumer scrap that often has not left the factory. The need to divert more post-consumer paper from the Nation's landfills is becoming increasingly emphasized. Settling on ways to accomplish this while continuing to encourage the recycling of pre-consumer scrap has been difficult. Proper definitions are needed for Government procurement procedures to be effective. The Federal Government is a significant potential market for recycled paper. It is not only the largest single consumer of paper, but additionally, it may serve to set an example for the voluntary efforts of other organizations. State agencies and private industry tend to follow its lead.

Annual Supply and Recycling Rates.—All recycling rates are not based on the same type of data. EPA and the American Forest and Paper Association (AFPA) report paper recycling from two different perspectives. EPA compares the total post-consumer paper recovered for recycling to the estimated total paper waste generated each year. EPA estimated that 28.6% (19 million tons) of the paper waste generated (66.5 million tons) during 1990 was recovered. This was up from the 22% and 21% rates of the early and mid-1980's, respectively.

AFPA compares the combined total of pre-consumer and post-consumer paper recovered to the total "new supply" (apparent consumption) consumed in the United States during that year. Fabrication scrap is included in its pre-consumer recycled scrap numbers as part of the recycling rate. Also, AFPA's total recovered fiber data and resulting recovery rates percentage include recovered material that is exported. In 1993, exports totaled almost 5.35 million tons (5.9 million st). This was down from 1992 when 5.85 million tons was exported (6.5 million st). But the total material recovered for recycling increased in 1993, showing a gainful trend in the allocation to domestic use of recovered paper fibers.

AFPA reported that, during 1993, almost 32.5 million tons (35.8 million st) of paper and paperboard was recovered for recycling and reuse out of a total supply of about 82.8 million tons (91.2 million st). (Total supply includes total consumption in the United States of all paper and paperboard, including construction paper and board.) Both quantities represent increases from 1992 when 30.5 million tons (33.6 million st) of paper and paperboard was recovered out of a total supply of almost 80 million tons (88.15 million st). The recovery rate for 1993 was 39.2%, slightly less than the 38.1% of 1992. As shown in figure 2, both the quantities recovered and the related recovery rates have been consistently increasing for a number of years. In the years 1985 and 1990, the respective rates were 26.8% and 33.6%. Also shown are the recovery rates for the two leading types of paper products. According to AFPA, old newspaper (ONP) recovery grew from almost 45% in 1990 to 58% in 1993 (up from 55% in 1992). Old corrugated containers (OCC's) are the highest tonnage source of recovered paper, as shown in figure 3. *(See figure 3.)* The recovery of OCC's grew from almost 55% to 62% of the total supply of new OCC paper between 1990 and 1993.

The pattern of growth in the consumption of fiber used at U.S. paper and paperboard mills between 1980 and 1993 is shown in figure 4 and table 1. *(See figure 4 and table 1.)* The quantities of primary (virgin) wood fibers have consistently grown during this time period, but its percentage of total consumption has remained relatively constant, and the use of other (virgin) plant fibers, a relatively small quantity, has dropped by 1%. The greatest growth by percent, from 22.6% to 32%, has come from the increasing use of fiber from recovered paper. Quantities of wood residues and waste, also a recovered and recycled material, have consistently been in a state of flux since 1980, reaching their highest use in the mid- to late 1980's. Current use is just minimally above 1980 levels.

Consumption and Uses.—Although more than 70 different types, or grades, of paper exist, the paper industry uses 5 basic classifications: corrugated containers, newsprint, mixed, pulp substitutes (clean converting scrap), and high-grade deinking. A summary of the quantities of recovered paper and paperboard between 1983 and 1993, as reported by AFPA, is provided by category in table 2. *(See table 2.)* These data include both post-consumer scrap and pre-consumer scrap, the latter generally being easier and more economical to recycle than post-consumer scrap. Consumption of growing supplies of collected waste paper is complicated by contamination by other waste materials, reduced secondary fiber quality (shorter fibers), and readily available markets for the secondary paper fibers that are economically viable. Though not without its own difficulties, a collection program can be set up in a relatively short period of time. But creating cost-competitive, marketable products is the greater challenge.

Kraft paper can serve as an example of a paper material with a secondary market. Kraft paper is the brown paper used to make corrugated containers and paper bags. According to EPA, it makes up about 36% of the total generation of paper waste. The previously mentioned 39.2% paper recycling rate is possible because of a specific market for recycled kraft paper fiber. The outside sheets of corrugated board, called liner paper, often need to meet rigorous specifications for resistance to bursting, puncturing, and crushing. This is especially true for paper that is to be made into boxes for shipping fragile products such as electronics, appliances, and glassware.

Recycled paper has shorter fibers than does virgin paper and consequently, it is not as strong. As the recycled content of the liner paper increases, the paper's strength decreases. This limits the potential use of recycled fibers in the liner paper of corrugated boxes. The specifications for the paper from which the inner fluting of the corrugated box is made are much less rigorous. The inner fluting is the curved middle paper material between the two paper liners that gives a box the structure and look that we think of as "corrugated." It provides the transported product protection from potential damage.

Another example where significant opportunity exists for using recycled paper in lower grade applications is that of used newsprint recycled to manufacture cellulose insulation and garden mulch. In such less demanding types of applications lie a significant potential for the use of large volumes of waste paper.

Technology.—Contamination can make the recycling of post-consumer paper very expensive, if not economically impractical. OCC's sometimes include wax coatings, plastics, food, mill wrappings, etc. The recycling of office paper is complicated by a large diversity of paper grades, as well as quantities of contained groundwood fiber, nonwater-soluble glues, paper clips, and rubberbands. Although improved cleaning equipment and technological advances are minimizing these impacts, continual improvements in collection methods and an evolving education of the public concerning the problems caused by contamination are an important part of the solutions. Probably the most significant technological progress is occurring in the deinking industry, in which new methods and technologies are being developed and many new plants have been coming on-line or are in the planning stages.

Steam explosion deinking technology is a current state-of-the-art and increasingly utilized method to deink office paper, especially the lower and mixed grades of paper. The process can be used as well to process OCC's at roughly two-thirds the cost of a similarly sized plant using conventional technology. A number of new plant projects were begun in 1992, both in the United States and in Canada. Steam explosion, a process used in the past to break apart wood chips and other biomass, deinks by "exploding" waste paper. This is accomplished by feeding the paper into a high-pressure chamber and then releasing it to atmospheric pressure. This process enables the recycling of even contaminated and low grades of waste paper. The steam explosion system results in more uniform pulp than other processing alternatives, requires no hazardous chemical deinking, and can process problem feedstocks, such as coated and waterproof stocks. Also, it requires substantially less water and energy than the more commonly used technologies. When used for newsprint and writing paper-grade sheets, some further deinking by the more common methods of flotation and washing is needed to remove small quantities of ink that remain.[18] In flotation methods, ink and other contaminants are chemically induced to be hydrophobic (water-repelling). Air is injected in the lower half of the flotation tank. Ink and contaminants attach to rising air bubbles because they are repelled by the water and the bubbles are the only way to get away from the water. Washing, the oldest deinking technology, involves chemically inducing ink particles to be hydrophilic (water-attracting) so that the ink is washed away with the water. A company in Virginia and another in Maryland were developing cogeneration plants to turn coal (VA) and natural gas (MD) into electricity and steam. New waste paper facilities were to be added, using the electricity generated to run the plants and provide the steam for the deinking processes.[19]

In late spring, International Paper Co. announced a new recycling initiative for recovering milk and juice cartons into recycled-content copier and printing papers and a variety of other recycled paper products. The company had completed a pilot project on the west coast and was planning to install a new carton processing plant in one of its existing mills in the northeast. Recovered cartons there will be used to produce copier and printing papers. The initial concern has been to establish an adequate flow of suitable materials. For this reason, the company was holding ongoing discussions with several major metropolitan areas about adding cartons to their curbside collection programs.[20]

Markets and Prices.—Markets for recovered paper and reprocessed paper pulp vary with the type and grade of paper that is collected or processed. A large variety of paper products with recycled content is produced in the United States. According to AFPA, more than 80% of all the paper recovered in the United States is recycled at domestic mills. The rest is exported or reused domestically to make other products, such as animal bedding, insulation, hydromulch, and compost. Significant quantities of scrap and discarded paper, notably newsprint, OCC's, and office paper, are exported. The third largest market for ONP in the United States is the export market. These ONP exports primarily go to Pacific Rim mills that use waste paper as a primary raw material. As for OCC's, about 2.3 million tons of the 15.1 million tons that industry reported as recycled in 1993 was exported. More than one-half of the office paper collected for recycling is generally exported, again primarily to Pacific Rim countries.[21] Quantities of recovered paper being recycled have been continually increasing in spite of market prices. Except for minor upswings in 1992, the prices paid for recovered paper products remained relatively flat during that year through early spring 1993. After that time, prices for most recovered paper began a slow decline, and only OCC began to recover and rise a little by the end of the year. Prices have been relatively low in part because of oversupplies of recovered paper in addition to the sluggish overall economy. At the same time, efforts continue to collect increasing quantities of post-consumer paper. Without significant improvements in the general economy, the stabilization of current recovered paper markets, and the creation of new markets for recovered paper and pulp fiber, prices for secondary fiber were not expected to improve greatly.

Market Development: The Great Lakes Recycle Project.—In 1992, the Council of Great Lakes Governors (CGLG), composed of the Governors of the eight U.S. States bordering the Great Lakes, determined that their States had problems related to materials recycling in the region. Post-consumer materials were piling up in warehouses and at collection sites and far too often ultimately ended up in the region's landfills. This was happening because the markets for many of these secondary materials were weak or often nonexistent.

The Governors realized that a stronger secondary materials market was needed. In response to this need, they created the Great Lakes Recycle Project to promote materials recycling by way of joint procurement of recycled products through multistate contracts. The initial product purchase was for high-speed xerographic paper with a specified secondary material content. The success of that purchase resulted in the recycling of 1,360 tons of secondary paper, a Presidential citation, and the decision to further expand multistate procurements to other products and materials. To accomplish this, a Materials Board was created. The Materials Board consisted of representatives from manufacturing industries, secondary material suppliers, and State and Federal governments.

The primary objective of the board was to promote joint State procurements of goods with recycled content within the region. With the creation of the board, the need was realized for information on where State government procurement policies could have the greatest effect in promoting secondary materials use. The Governors and the board also recognized the need to minimize any possible negative effects on virgin material producers or other industries potentially affected by their good-intentioned actions. CGLG did not want to remedy one problem while creating another. The USBM, because of its extensive experience in conducting minerals and materials flow studies, was invited to be an ex officio member of the board. Also, the USBM was deemed an appropriate partner because it is a comprehensive source of information on mineral and material production, consumption, recycling, and waste handling.

The USBM's involvement with the Great Lakes Recycle Project centered on developing an analytical framework for quantifying specific material flows in the region and identifying potential procurement opportunities for recycled materials to the Materials Board. A USBM materials study group set out to define the flow of both primary and secondary material resources within the eight-State region. The paper industry was selected for the study in the initial analytical framework development phase, in part, because the State governments already had established a successful track record in the procurement of recycled-content high-speed xerographic paper. Also, the State data on these paper procurements, together with data from the analytical framework, help provide the necessary verification of the framework prior to its implementation into other material sectors. The analytic framework was designed to be nonregion specific, and therefore a generic model, allowing it to be equally useful for assessing material flows in other areas of the country or elsewhere for replication of the Great Lakes initiative.

The paper industry was a good practical starting point for this project because of the scope of the industry and, perhaps more noteworthy, the considerable dollars expended on paper and paperboard products in the region. In 1990, the eight Great Lakes States consumed $57.7 billion dollars worth of paper and paperboard products. Of that total, State and local government purchases accounted for $5.4 billion, or almost 10%. Most recently, under a joint bid, the States purchased 12,300 tons of paper in 1992 and 9,700 tons of paper with a 50% recycled waste paper content in 1993.

The USBM materials group used the computerized, economic input-output model, Impact Planning for Analysis (IMPLAN), to determine the paper product purchases and paper material flows in the region. IMPLAN, currently maintained by the University of Minnesota, depicts dollars expended for materials by 528 domestic industry sectors based upon surveys conducted by the U.S. Bureau of Census. In the paper industry, the three basic industry sectors—pulp mills, paper mills, and paperboard mills—are the integral fiber and paper material suppliers. In addition to supplying products to final consumers, these three sectors supply feedstocks to 20 paper-intensive, manufacturing industry sectors, such as envelope producers, book publishers, and producers of periodicals, paper bags, paperboard containers, etc. The project's next phase was to convert the IMPLAN data from value terms to tonnage terms for all paper materials produced primarily from virgin sources and purchased in the Great Lakes region. To follow was identification of the region's secondary paper materials flows. Upon completion of the paper materials flow study, the same basic model may be adapted by the USBM team to materials used in highways and construction, office machinery, and plastic goods. In addition to paper, the Great Lakes Materials Board discussed possible future studies concerning re-refined oil and solvents and rubber tires for future joint procurement activities.

Plastics Recycling

Plastics are long-chain polymer and resin materials that are synthetically produced almost entirely from nonrenewable hydrocarbon resources, most notably natural gas and petroleum. During the past three decades, rapid growth has occurred in the use of plastics for a seemingly countless variety of purposes. Production in the United States has shown an average annual growth rate of 10%, with continued growth expected into the future. This growing flow of plastic materials has resulted in gradually accelerating increases in the quantity of plastic waste annually generated in the United States, as shown in figure 5. *(See figure 5.)* The increasing use of plastics in packaging accounts for much of the waste. According to the EPA's municipal solid waste characterization study, containers and packaging accounted for almost 43% of all the plastic waste generated in the United States in 1990. (More recent data are not yet available). Plastic packaging is a target for recycling because most packaging material has a relatively short period of use (less than 1 year) before discard. Packaging is usually a temporary "transportation" medium for another product and is not intended to have a long useful life. The typically more durable products it contains are generally not intended for such immediate discard, and the packaging material is quickly available for use in another product.

Other sources of waste plastic in MSW are appliances, furniture, carpets, and lead-acid battery cases, in addition to a variety of nondurable goods, such as plates and cups, trash bags, footwear, disposable diapers, and both synthetic and natural material textiles. Textiles are in an industry separate from the plastics industry and are sometimes forgotten as a source of waste resin. In 1990, approximately 62% of the fibers consumed in the U.S. textile industry was synthetic resin fibers. Textile resin fibers also become part of the municipal solid waste stream. Domestically, significant quantities of used textiles were reused for their original purposes, mainly clothing, while even larger quantities were exported for similar reuse. Domestically, reuse included old textiles materials used as wiping rags. A variety of U.S. industries used about the same quantity of "rag" material as was reused as clothing. However, only small quantities were actually recycled in the United States as of 1990. Recycled textiles mostly included textile fabric fibers that were reprocessed to make specialty papers (these require a 100% cotton textile source), carpet padding and upholstery in cars and trucks, and certain wool products (only pure wool textiles are useable). Although not included in MSW data, significant quantities of waste plastic result from the discard of automobiles and from the construction—and even more so the demolition (C&D)—of houses, buildings, and other humanmade structures.

Issues.—**Used Plastic Material Management.**—Plastic products, especially as used in packaging and containers, are a low-weight but high-volume waste material that contributes to filling up our landfills. Although being about 9% by weight of our municipal solid waste that is landfilled each year, they account for possibly 20% or more of the volume, as reported by the EPA. A recent estimate of the volume of plastics in landfills was reported by William Rathje of the University of Arizona. In archeological digs of landfills across North America, as part of his "The Garbage Project," he determined that plastics compact better in landfills than has generally been believed. In these excavations, plastics took up about 16% of the space in the landfill. Although they may take up less space than previously believed, plastics by weight still take up a significantly larger portion of landfill space than other typical MSW materials. Because they are a significant nonbiodegradable material, they are often a target for recycling or incineration. Some of the very qualities, such as durability and corrosion resistance, for which plastic materials are used are the same "qualities" for which they are criticized upon discard. The management of plastic products when they have outlived their usefulness is an ongoing issue.

Although some States and counties have attempted to restrict the entry of certain plastics into the solid waste stream by banning their use, this approach has so far only been instituted in a few cases. Two U.S. locales that have attempted plastic material bans are Suffolk County on Long Island, NY, and the town of Fairfax, CA, just north of San Francisco. Suffolk County's ban on plastic grocery bags and polystyrene and polyvinyl chloride food packaging at retail food establishments was under reevaluation. A study of the future effectiveness of the policy was performed under the direction of the Waste Management Institute at the State University of New York/Stony Brook (SUNY), by request of the county executive. Among the reasons for the study were questions as to the law's possible negative effects on the county's recycling program. The study was undertaken with respect to the original goals of the legislation, including a survey of the county's current litter situation, and how the law was likely to succeed in those intended purposes. Lawmakers met 2 months after the SUNY report was issued and, by a narrow margin, defeated a measure that would have repealed the 1988 plastics law. The ban in the town of Fairfax included polystyrene packaging for food prepared on a firm's premises. The law took effect in December, having been passed by the town's voters the previous month. Thus, little time has passed to fully address any results.[22]

Under the EPA's waste management hierarchy, recycling used or waste plastic products into new products is preferred to the incineration or landfilling of them. Plastics recycling is further encouraged by some advocates because plastic is derived from nonrenewable energy resources. But to be successful recycling must result in a product with (1) high enough quality, (2) low enough cost, and (3) be done with an efficient expenditure of energy and other natural resources. If not, incineration of waste plastic is a potentially valuable alternative. When its hydrocarbon origins are considered, plastic is, not surprisingly, a highly energy-intensive material. In the WTE incinerator, it is a very valuable component of the mixed municipal solid waste. As well as having high energy values, the heat it gives off promotes better burning of the surrounding mixed wastes. Incineration is a final one-time use of the material promoted by its advocates as more productive than simply burying it.

Biodegradability.—Although some degradable plastics have been produced and others are under design, they are only a small part of the solution to related landfill and litter problems. These materials may be useful in specific applications; for example, for 6-pack beverage container rings, packing peanuts, compost bags, and possibly disposable diapers. But they are not practical for many uses of plastic. Also, the production of truly degradable plastics in the large scales necessary would currently be technologically and economically prohibitive. The large majority of "degradable" plastics at present are more accurately labeled as "biodisintegratable" or "photodisintegratable" because the plastic itself does not truly degrade. Disintegratable plastics, such as everyday plastic grocery bags, break down into a plastic sand or dust when the starch molecules that join them together truly degrade, due either to biological agents or solar energy reactions. The polymer in these materials does not degrade—it is the same durable plastic in miniature. The environmental consequences of this plastic dust is unknown. For some applications, the desired characteristics of plastics, such as durability and corrosion resistance, would be adversely affected by formulating the plastic to be degradable. Another issue is the recyclability of other plastic materials, which for technological or economic reasons, can be limited when contaminated with quantities of biodegradable plastics.

One innovative manufacturer of biodegradable polymers, Novon Products Group, ceased operations near yearend for economic reasons. Novon products included yard waste collection (compost) bags; cutlery, medical disposables, and personal care items; and blow molded bottles for the vitamin and pharmaceutical industry. Recycled plastic materials cannot be used for pharmaceutical applications owing to U.S. Food and Drug Administration compliance issues and rules, thus limiting the use of biodegradable plastic as an appropriate alternative to virgin resin. Novon's polymers are derived from the starch of corn and potatoes, in addition to other completely biodegradable ingredients, states a company report on the process. When disposed of in a "biologically active environment," such as compost, they are designed to be broken down by microbes into water, carbon dioxide, biomass, and other trace amounts of naturally occurring minerals.[23] The company had established customers in Australia, Canada, Europe, and Japan, and the United States, where its products were being used by a wide variety of institutions, including Walt Disney World Co. The shutdown was in part the result of the restructuring and consequent downsizing of their parent company, Warner Lambert Co. The decision was deemed necessary in light of the restructuring because further development of the Novon products would take more investment and financial support than was available. Novon committed itself to indefinitely continue production of the polymers at its main manufacturing facility in Illinois to fulfill current customers' orders, while looking for suitable investors for its patented technology.[24]

An ongoing, controversial issue for many recycled plastic material and product producers is that they conduct business on an uneven, unfairly competitive playing field with virgin plastic producers, resulting in unfairly stiff competition. Recyclers contend that virgin producers have the advantage of buying their raw materials from the oil and gas industry, which receives either subsidies or tax breaks, thereby reducing the expense of their raw materials. In efforts to encourage more recycling, a number of alternative approaches to this controversial problem was under discussion in the EPA and the U.S. Congress, as well as other Government agencies and independent task forces.

The Recycling Advisory Council (RAC), formed in 1989 in part under a grant from EPA, consists of representatives from business, industry, environmental organizations, and public interest groups, as discussed earlier in this chapter. In a major effort to find ways to increase recycling in the United States, RAC's mission was to investigate the crucial issues concerning and surrounding materials recycling, not the least of which were barriers to the development of the various scrap commodity markets. From the latter part of 1992 through 1993, its market development committee conducted a study of the barriers to recycling and possible approaches to solve these problems. Results of this study were to be used in 1994 to develop a "tool box" of policy options for decisionmakers to consider when addressing the challenges facing recycled material market development. The tool box was intended to consist of information concerning the possible national frameworks or systems that had been evaluated and could be used to increase the utilization of recovered materials in the United States. Also, the options for funding the suggested recycling market development approaches would be presented. Possible national frameworks under consideration included the basing of secondary material utilization rates on waste reduction goals, targeting specific waste streams, and/or establishing commodity-specific rates. Funding options were to include: a subsidylike national secondary materials utilization "trust fund" for rebates to companies using recycled materials; a virgin material tax/recycling incentive fee; several packaging stewardship models; industry-funded price support systems, where the manufacturer of a product would be, at least in part, responsible for its recycling; and a waste utilization tax.

Annual Supply and Recycling Rates.—Most survey-based plastics recycling data came from trade groups and consulting groups that conducted studies of the relatively young plastics recycling industry. The American Plastics Council (APC), a major plastics recycling trade group, reported the results of its fifth annual post-consumer plastics recycling study, conducted by R. W. Beck and Associates. The study examined six resins commonly used in consumer packaging that also were recycled: PET, HDPE, polyvinyl chloride (PVC), low-linear low-density polyethylene (LDPE/LLDPE), polypropylene (PP), and polystyrene (PS). Various other plastics, such as polycarbonate and nylon, were included in the survey totals as they also were reported as recycled by some of the companies. For a detailed breakdown of these reported quantities of plastics recycled during 1992 and 1993 see table 3.

The annual APC survey, as well as other more limited surveys, has consistently reported increases in plastics recycling each year. Total plastics recycling during 1993, including both packaging and nonpackaging, grew 11.6% over that of 1992, while the recycling of packaging plastic, based exclusively on the APC study, grew virtually at the same rate with an 11.8% rise over that of 1992. More than 638,340 tons (1,407 million lbs) of post-consumer plastics was recycled in 1993, up from more than 572,100 tons (1,261 million lbs) in the previous year. Almost 75% of the recycled plastic was from packaging materials. The packaging component grew from about 425,020 tons to 476,270 tons. The APC/Beck annual study is a relatively new canvass study of a relatively young recycling industry. As this survey has been refined each year, not only have newly formed companies been added, but also some companies missed in a previous year were picked up and added the following year. Thus, some of the increases in recycled quantities in the past 2 years could show slightly inflated percentage increases over previous years due to the absence of these companies' data from earlier years' surveys. On the other hand, this also suggests that actual quantities recycled may have been better in earlier years than those previous surveys suggested. Nonetheless, the APC/Beck survey appears to be the most complete, physical data canvassing of companies that recycle commodity plastic materials that has been conducted for the public record to date.

PET has become the most recycled of all post-consumer plastic in the United States. Recycling of PET has grown from 3,600 tons in 1979 to nearly 228,000 tons in 1993. Just over 83% (or 189,420 tons) of the 1993 total PET recycled resulted from the recycling of soda bottles alone. This quantity was almost 41% as much as the virgin PET plastic sales for soda bottle production for the year. Almost 24,900 tons of nonpackaging PET, 11% of total recycled PET, was recycled in 1993. Total HDPE recycled in 1993 was 215,910 tons, principally from the recovery of milk and water bottles (called natural bottles), and less so from pigmented bottles and soft drink base cups. The recovery rate for the common milk jug was approaching 25%, according to the APC.

PS is used in packaging applications in the form of PS foam. Both its very high volume-to-weight ratio and its common use with food products makes collection and some associated processing more difficult than other plastics. Nevertheless, in 1993, more than 18,780 tons of PS, 11% more than the previous year, was recycled in the United States. This was a more modest increase than that of the previous year; in 1992 there was a 53% increase over that of 1991.

Going along with the slowdown in recycling growth in 1993 was that of the nonpackaging application of lead-acid vehicle battery casings made of PP plastic. Numbers revised following last year's publication showed that recycled quantities of PP from this source increased not 41% but, nevertheless, a healthy 30.1%, from 65,500 tons in 1991 to 85,411 tons in 1992. In 1993, the amount of PP battery casings recycled rose only 1.6% to 86,772 tons. One major reason for the recycling growth in 1992 was the regulations by State and local governments that required lead-acid vehicle battery retailers to return spent batteries directly back to the manufacturer for recycling purposes, and/or prohibited the flow of the same batteries into solid waste landfills. As of mid-1993, 35 States had enacted battery recycling legislation, and by the end of the year 44 States had banned the MSW disposal of lead-acid batteries.

Whereas the reported increases are an indication of positive movements in the industry, there is still a long way to go. Weak prices for many recyclable commodities in 1993 ended the year much lower than had been hoped. Based on conservative estimates of plastic waste contained in the MSW that was generated in 1993, the total plastic recycled was, at best, near 3% of the total consumed. Although small, this does show progress from the slightly less than 2% sometimes estimated for recent previous years.

Consumption and Uses.—The two major types of plastic, thermosets and thermoplastics, have significantly different limitations and challenges in recycling. Thermosets are long-chain polymers that have been "set" chemically or "cured" in a cross-linked pattern. When heated to the proper temperature, these molecules do not melt in the manner that thermoplastics do. The cross-linked bonds remain intact and the degraded or charred material cannot be formed into a new and usable shape. To date, thermosets have very limited use in recycled products. They are limited to being crushed or cut up into small pieces and used as a filler or aggregate material in certain product applications. Thermoplastics also are composed of long-chain polymers, but they have not been chemically linked together, allowing them to slide by each other when properly heated. They melt into a liquid or moldable form. When the temperature drops, they resolidify or harden into the new product form.

Recovered and reprocessed plastic is consumed by a large number of industries, consequently resulting in a wide variety of new products. Consumption by individual industry is difficult to quantify. Recycled PET plastic is used in the manufacture of carpets, industrial strapping and pallets, fiberfill for sleeping bags and ski jackets, automobiles parts, nonfood containers, plastic lumber, and a continuing variety of other products. An important market for recycled PET is the synthetic fiber (textile) industry that uses the PET for carpet backing and other fiber products. HDPE is commonly formed into bottles, industrial and consumer containers, drums and oil storage containers, fuel and other tanks, tank liners, toys, housewares, corrugated pipe, pipe for irrigation and oil, gas and mineral production, consumer bags, some food packaging, sheeting, wire, and cable. Some of the products manufactured from recycled PS are park benches, office equipment, videotape cartridges, pallets, the new compact disc "jewel" cases, and a variety of household products.

Most recycling of plastics is based on physical alteration or breakdown (crushing and shredding) and melting of the material to produce another product. As with other recycled materials, when this is accomplished with uncontaminated scrap plastic of which the composition is fully known, this is categorized as "primary recycling." The term "primary" is restricted almost exclusively to the recycling of pre-consumer (in-house) scrap because, no matter how clean some shipments of post-consumer materials are, virtually all shipments come with a measure of uncertainty. Most have some quantity, whether minute or considerable, of a variety of impurities. The recycling of post-consumer scrap—often clean, of one or a few known types, and of high quality—is called "secondary recycling" and is the bulk of the materials recycling that has generated the most controversy.

"Tertiary" plastics recycling is different and accounts for a very small portion of plastics recycling. The old material is chemically broken down into fundamental components or chemical substances. Recycling occurs when a new, "virginlike" polymer is then produced from the resin components into a new, marketable product. The technology needed to chemically break down plastics into fuels and into the basic feedstock hydrocarbons has been known for decades. But, until recently, it was used principally within manufacturing plants where it was economically beneficial to do so. In part because of the limited one-time reuse, the chemical recycling of plastics into a fuel is generally not considered recycling in EPA's solid waste hierarchy; it is in effect comparable to WTE incineration.

Since late 1990, tertiary recycling by methanolysis, glycolysis, and pyrolysis has been used by three soft drink companies to recycle PET plastic. In these processes, used PET bottles are chemically recycled back into new PET soda bottles that are usually composed of a mix of 25% of the recycled material and 75% virgin material. Bottles made of 100% chemically recycled PET are technologically possible but currently cost-prohibitive. The quantities recycled by this method are a very small portion of the PET bottle recycling data. Because of the associated economics, thus far apparently marginal at best, this practice is not flourishing. However, most, though not all, of the original projects are still ongoing. Although virgin PET supplies were sufficient, virgin PET material output was at times near capacity. This measure of uncertainty created a demand for raw materials from the tertiary recycling operations to more securely guarantee supplies of needed new bottle material.

A significantly higher portion of plastic was recovered for WTE incineration to produce energy via steam or more directly to produce electricity than was recycled. In 1993, an estimated 17% of the plastic waste portion of the generated MSW generated was combusted in WTE incineration plants. When the resin fibers in the textile portion of MSW is included, the total percent of plastic incinerated rises to about 20%.

Technology.—Possibly the greatest difficulty in processing post-consumer plastics, both technologically and more so economically, is that of sorting or separating the different types of plastics. A high-quality recycled plastic material of a particular type may be feasible, but many products demand that recovered materials be uncontaminated with glass, dirt, and other types of plastic. In some cases, minute quantities of contamination greatly or even critically reduce the quality and usability of the recycled material. A good example of this is PVC-contaminated PET soda bottle plastic. Their similar densities complicate the process of segregating the two plastics before melting, and during melting PVC, which has a sufficiently lower melting point, contaminates the PET with a detrimental char product. Some materials and products demand very pure "recyclate" material; others, such as some plastic lumber and park bench materials, are more forgiving and can accommodate a combination of plastics.

Highly reliable separation technologies that demand little to no labor and also are cost-effective are needed for the continued and accelerated growth of recycling in the plastics industry. The human sorter cannot recognize all the different variables of plastic categories and subtypes, as well as different colors, particularly at the speeds necessary to make the process economical. Numerous plastics sorting technologies have been invented and range from those achieving limited results to some very effective and sophisticated systems. Most of these are based on various spectroscopic and X-ray analyses, infrared recognition, and laser technologies. Other systems under development include a water surface tension technique, a selective "dissolution system," and a near-infrared light system that incorporates specialized "neural networks" instead of conventional computers. Because of the problem of similar densities, in particular that of PET and PVC, one company is developing a flotation-type system to separate the two by means of their differing surface tensions.

The Rensselaer Polytechnic Institute (RPI) was testing and developing a selective dissolution system to separate individual resins. In the process, all plastic resins are commingled, shredded, and subjected to several solvent baths. Each bath is heated to the precise dissolving point of a certain resin and the resulting liquid is siphoned off into a holding tank. The temperature increases with each bath until all resins are removed. According to an associated consulting company, after further processing by "flash devolitization," the remaining resin is nearly as pure as virgin plastic and may be sold at a discount of at least 2.25 cents per kilogram. To further extend testing of the technology, RPI applied to the U.S. Food and Drug Administration for approval to use food packaging material in a future pilot devolitization process.

The Sandia National Laboratories of the U.S. Department of Energy is developing a system that uses the near-infrared light/neural network system. Modeled after the assimilatory abilities of human nerve cells, these networks will be capable of "learning" the characteristics of the resins—a process less arduous and time-consuming than preprogramming. In some test runs, once the networks have been trained through trial-and-error for all types of resins, accuracy levels of 100% have been reported in the lab. A prototype was undergoing testing by a recycling equipment manufacturer.[25]

With the increasing effectiveness and sophistication of sensing systems often comes a higher cost that limits their use by many companies because of the relatively low prices for scrap plastic. But, cost factors aside, some very accurate sensing systems are still hindered by mechanical difficulties encountered in separating the material. Two problems that researchers are working on are how to provide the automated systems with single plastic bottles or pieces and how to effectively mechanically segregate the different plastics.

Because of the bailing of plastics that is necessary for economical transport, used plastics become clumped together and a foolproof method of breaking of these clumps into the individual pieces is expensive and difficult. Several new technologies have been claimed to be virtually 100% effective in sensing the different plastics, but if the plastics are still stuck together, then the sensor reads the clump as one object. If there is more than one resin or color in that clump, rather than jeopardize the rest of the stream, the system rejects the clump. The more this happens, the larger the amount of material that has to be sent through the system a second time, proportionately reducing the efficiency and increasing the costs of the sorting and processing operation. If bottles are not completely separated into individual pieces, even perfect sensing and physical sorting technologies cannot finish the job as needed. Most, if not all, "singulation" systems are having these problems. The other mechanical difficulty is that of doing the physical sorting. This is generally done by air jet nozzle systems that are becoming increasingly accurate, although not foolproof. These systems balance the sensors' recognition time with the speed of the conveyor belt to eject the different bottles via streams of air into the proper collection bins. Some systems use a negative sort in which a plastic is sorted by not being jettisoned, but by merely dropping off the belt into another bin. The greater the variety of plastics being separated, the more difficult the process is. Some of the most sophisticated systems can separate plastics into four main streams or types. One operation has combined two systems and is able to separate a mixed stream of baled or loose plastics into five categories: colored HDPE, natural HDPE, PVC, green PET, and clear PET.[26]

A major source of waste plastic is that of scrapped automobiles. Following shredding, the auto shredder residue (ASR) that remains, composed of plastics, fluids, glass, rubber, and various other mixed materials, including dirt, is most often landfilled. Plastics compose about one-third or more of the total. About 10 million automobiles are shredded each year. At an approximate average of 100 kilograms of plastic per car, this amounts to 1 million tons (1.1 million st) of plastic that could potentially be diverted from landfills annually. The Argonne National Laboratory (ANL) is one of a number of labs and companies working on technologies to process ASR. Argonne's technique uses solvents in an effort to dissolve the residue into products that could be economically substituted for, or mixed with, virgin material without reduction in final product quality. According to ANL, this process reduces the residue to 50% reusable materials and 50% residue remaining for disposal. Argonne claims to have achieved a 92% recovery of the processing solvents in its laboratory work, and expects even higher anticipated percentages of recovery possible in commercial applications. These recycled plastics potentially could be used in products such as park benches, lamp posts, traffic cones, and construction materials. Under present economic conditions, these recycled materials have limited marketability because most impurities are not removed, and the cost of making the products can be as much as if virgin materials were used.[27]

The Japan Recycle and Research Center, formed in association with the Japan Iron and Steel Scrap Association, is taking a different approach in attempting to deal with the 5 million automobiles that are annually scrapped in Japan. The Center has begun a new research program to design and construct a new type of WTE incineration plant for elimination of ASR. Remnant ashes are to be processed into concrete materials.[28]

Markets and Prices.—The marketing of recycled plastic products generally suffers because of high costs and insufficient demand for recycled materials. Materials for many products are very specialized and either need a quality that cannot be produced from recycled plastic, or when proper quality can be achieved, the cost would be noncompetitive with virgin resins. Other plastic products can be produced more easily with recycled plastic but are still simply too expensive as compared with the same product made from virgin plastic. An additional factor affecting markets and prices is growing acceptance by the public, which is becoming increasingly enthusiastic about the idea of recycling and materials conservation. Municipalities want plastic materials and goods to be diverted from the solid waste stream. But both individuals and institutions have been slow to translate these notions into expressed demand for recycled material content used in lieu of virgin materials in the products that they buy off the shelves every day. The general public often is not readily confident that recycled products may be as good as the virgin products sitting next to them on the same shelf. In addition, when the recycled products are more expensive, the incentive to purchase the recycled product is further reduced.

Thus far, PET and HDPE are the only plastics that have commanded high enough prices with sufficient demand to achieve a measure of consistency in the recycling industry. PET plastic has been the most cost-effective and consistently recycled of the two with many marketable products that can be made from clean, processed PET scrap. Its main challenge has been to be cost-competitive with virgin PET, the price of which has been relatively low during the same period. Recyclers of HDPE, while experiencing a higher percentage increase in output in 1992 than recycled PET processors, faced greater competition in the marketplace. One major processor of recycled HDPE shut down its HDPE operations altogether to concentrate its efforts in the better market opportunities of recycled PET, although it planned to restart its HDPE operations when the market showed sufficient improvement and stability. While the recycling of HDPE packaging, mostly in the form of bottles, increased by 8% in 1993 (see table 3), this is significantly down from the 50% growth spurt experienced in 1992. Competition continued to increase in 1993. One major factor was the oversupply of virgin HDPE resin, which reduced the resin price below the cost incurred by most processors of recycled HDPE producing the post-consumer resin. Another factor that affected HDPE recycling concerned typical collection practices in the United States. About one-third of the HDPE containers—in particular, injection molded tubs and other nonbottle HDPE containers—are not targeted for collection because markets for them are almost nonexistent.[29]

Rubber Recycling

Rubber recycling includes both synthetic rubber and, to a lesser degree, natural rubber. Synthetic rubber (SR) is a major member of the family of materials called the elastomers. Like plastic, it is made up of long-chain polymers that are produced from hydrocarbon feedstocks. In addition, the SR polymers have been synthesized to consistently reproduce, at ambient temperatures, natural rubber's best properties, most notably its "rubberlike" elasticity. Sources of rubber waste products are discarded clothing, footwear, rubber tires, and a variety of miscellaneous durable and nondurable goods, such as gaskets on appliances, various automobile parts, furniture, floor coverings, and hot water bottles. But rubber tires are the predominant source of rubber in MSW. As many as 250 million waste tires (about 2.3 million tons) are generated annually in the United States. Of equal concern is the backlog of tires that have accumulated across the country, especially since the end of World War II. By illegal dumping and by legal stockpiling, an EPA-estimated 2 billion to possibly as many as 3 billion "units" (tires) have been thus "disposed" of in preference to being landfilled, incinerated, or recycled.

Issues.—Tires, about 85% of which come from automobiles, are a significant portion of MSW. For decades they have been a growing problem because, landfilled or stockpiled, discarded tires can be a threat to human health and the environment. Landfills traditionally have been the method of disposal for scrap tires in the absence of a market. Today, landfill bans are restricting this practice, especially the burial of whole tires. Their composition and shape do not allow easy compaction in the landfill, and they do not decompose, thus occupying significant amounts of valuable landfill space. Additionally, whole tires trap gases due to their round and hollow shape and over time "float" to the surface, breaking the landfill cover and allowing landfill gas to escape.[30] Following exposure at the landfill's surface, they then become a breeding ground for insects, rodents, and birds.

Stockpiled tires have similar associated problems, which can be amplified because greater quantities are crowded into one place. Because of their shape, tires hold water at any angle, which makes them a very attractive breeding site for mosquitoes and other insects, some of which can carry disease. North American varieties of mosquitoes can be of concern by themselves, but in recent years other strains of insects have been "imported" from other countries. For example, in 1985 the Asian Tiger Mosquito, which is known to carry some relatively dangerous sicknesses, arrived in Houston, TX, aboard a shipload of used tires from Japan. This same mosquito has since been located in other parts of the country.

Another danger is that of fire. A tire fire is extremely difficult to extinguish and can burn for a long time. Uncontrolled tire combustion at the characteristically low temperatures at which these fires usually burn tends to release significant amounts of thick, black smoke. Both the air is fouled and the rubber melts into a toxic substance or "goo" that can adversely affect ground water. A few tire piles that have caught fire have been designated Superfund cleanup sites by the EPA.[31]

Currently, the overriding issue is of how to use or safely dispose of scrap tires and other rubber products—whether to incinerate them for their contained energy values or to stress the reuse and development of recycling uses for waste rubber and tires. Incineration of tires for their energy values is currently the leading method of use or disposal after that of landfilling or stockpiling. While markets for materials and products that include recycled rubber are increasing, the greatest potential to date is the use of ground rubber tires in the production of rubber-modified asphalt for the Nation's roads.

Annual Supply and Recycling Rates.—EPA estimated that in 1990 about 181,400 tons (200,000 st) of rubber from tires was recovered for recycling. At an average of 9 kilograms (20 lbs) per tire, the average weight of a passenger car tire, this amounts to more than 20 million tires. More recent estimates have been projected by the Scrap Tire Management Council (STMC). In 1992, the estimated annual recovery in the United States stood at 68 million tires, 58 million of which was estimated to be used as fuel by several major industries. For 1993, the council estimated the annual recovery had risen to about 80 million tires, 69 to 70 million of which was estimated to be used as fuel. Of the remaining 10 to 11 million tires, 40% to 45% was used in rubberized asphalt. The remaining tires were used in civil engineering applications and the manufacture of recycled rubber products. An increasingly smaller portion was chemically broken down to more basic chemicals and materials by the process of pyrolysis. The apparent discrepancy between the two recovery estimates (STMC's and EPA's) is not as great as it may appear because the EPA's estimate does not include tires that were combusted either as a fuel or for the production of energy.

According to an EPA study, an estimated 12 million used, commonly called "waste," tires were exported in 1990. If included with STMC's estimated 1993 recovered quantity of 80 million tires, approximately 92 million tires potentially were recovered for the production of energy, recycled products, reuse, and export for similar purposes. Thus, about 35% of all waste tires in 1993 (presuming a similar exported quantity as reported for 1990) was potentially diverted from the Nation's landfills, stockpiles, and "illegal dumps." If exports are not included, then the recovery rate was nearly one-third of total discards.

Retreaded tires usually are not included in recovery and recycling data as they are considered a reuse. But they are a valuable "recycling" of the tire body as a whole and their reuse also slows their introduction into the solid waste stream.

Consumption and Uses.—Pulp and paper mills are a major user of tires as a fuel. Tires, like coal, are used as a fuel to supplement wood chips, their traditional fuel. Consumption in this industry has remained fairly constant in the past several years. The pulp and paper industry consumed an estimated 14 to 15 million tires as a supplemental fuel in 1993. The industry has burned tire-derived fuel (TDF) since the early 1980's. TDF is tire rubber that has been chipped into pieces 2 inches or less in size, called crumb rubber, and is processed to be clean of contaminants, including the steel belts. The steel belts are sold as scrap metal. The pulp and paper industry needs this clean, uncontaminated TDF if it is to use tires as a fuel. In conjunction with this need, the industry's major constraint is the cost of competing fuels, such as wood chips, petroleum coke, and coal. Lower prices for competing fuels can limit the use of TDF. Two other limiting factors are the remote location of many mills, which results in higher transportation costs, and the reliability of TDF supply.

Tire recovery has increased substantially during the past 2 to 3 years as a fuel in electric utility boilers, cement kilns, and in new, dedicated tire-to-energy plants. In 1993, almost 18 million tires were combusted in utility company boilers or in other boiler facilities, such as agricultural product processors and chemical companies. TDF is the common rubber fuel that is used in electric power companies' utility boilers, although requirements for clean TDF sometimes are less stringent than those of the pulp and paper industry. Some systems allow for the burning of whole tires. In parts of the Midwest and the east, high-sulfur coal is burned in utility plants. At times when coal costs less than TDF, using TDF as a fuel can still be competitive because of its low sulfur content. TDF and whole tire combustion are reported to produce less ash than burning coal, emit less carbon dioxide, and produce lower sulfur dioxide emissions when replacing a high-sulfur coal.[32] Very significant growth has occurred in this sector in the past few years alone, and according to STMC, some of the major utilities are currently considering using scrap tires.

The cement industry has increased its use of waste tires from 3 million tires in 1990 to 14 million in 1992 and to as much as 21 million in 1993. Cement kilns are heavy users of coal, making the use of the cleaner burning rubber an attractive option. As with some utility users, a growing number of cement kilns are able to burn whole tires, avoiding the associated costs of buying processed TDF. Tires offer these kilns other advantages. Tires have a higher energy value than coal, and a tire's steel belts and beads can replace the iron ore needed in the cement making process, thus reducing the manufacturer's raw material costs.

Only two major tire-to-energy facilities, both built by one company, were operational in 1992, but between them they consumed about 16 million tires. The same company was in the planning stages of building two more plants. The completion of one of these units by 1997 was expected to more than double the current 15-million-unit capacity. Even though these operations have been successful, the use of this technology usually is practical only in regions with high electric rates and high solid waste tipping (disposal) fees. The capital costs per megawatt of generating capacity for these facilities is about two to seven times higher than coal-fired plants.

In 1993, between 4 and 5 million scrap tires were recycled either as asphalt binder material or as aggregate in rubber-modified asphalt (RMA). This was at the previous year's level or slightly below as a result of the debates surrounding the Intermodal Surface Transportation Efficiency Act (ISTEA) legislation regarding amounts of rubber required in new roadways. The market for scrap tires for use in RMA would significantly increase under the requirements of the originally passed ISTEA legislation. Nevertheless, its use in independent, State, and local projects has remained relatively steady, especially in the southwestern United States.

Rubberized asphalt can cost up to twice as much as conventional asphalt, but recent experience has indicated that it can be applied in thinner layers and often lasts significantly longer. A more widespread use of the basic technology and the expiration of a patent on one of the most frequently used processes should help to reduce costs of this rubber-modified product. Some questions as to the safety and durability of this product and its recyclability in the construction of future roadways have been raised, mostly due to a lack of long-term experience with it. But to date, roads made of this material appear to be more durable, longlasting, and safe to travel on. According to a recent report to Congress jointly submitted by the EPA and the Department of Transportation, the use of asphalt containing recycled rubber is not substantially different from conventional asphalt in terms of health and environmental effects, recyclability, or adequacy as a paving material.

Another 5 to 6 million tires were used mostly in civil engineering applications and, to a lesser degree, in recycled rubber products. Civil engineering applications include embankments, clean fill, leachate collection in lieu of sand or gravel, artificial reefs, breakwaters, sideslope stabilizers, crash barriers, sound barriers, and playground structures and protection. Other applications include use in products such as railroad crossing ties, dock bumpers, a variety of flooring materials and mats, carpet underlay, sound insulation in automobiles, truck and trailer liners, and drip irrigation pipes.

Less than 1 million tires were consumed by tire pyrolysis, the process of chemical and physical breakdown of the whole tire into oil, gas, and char (low-grade carbon black) byproducts, and steel from the steel belting. This use has not flourished because of inconsistent markets for the oil and many differing char byproducts. Not all char byproducts are necessarily of too low a grade. Their salability is lowered because they are not easily distinguishable, one from another. According to STMC, although there were a number of test and demonstration level projects processing tires by pyrolysis, by yearend there were no commercially viable operations in the United States.

Although making new tires out of old tires may seem to be the most obvious choice, this is not possible. Tire rubber is a thermoset or "vulcanized" material. To date, no technology has been able to reverse or "devulcanize" this process. As a result, the new, strong chemical bonds necessary for new tire production cannot be achieved. Only a very minimal and relatively inconsequential amount of rubbings—very fine crumb rubber—can be used as noncritical filler in the manufacture of some tires.

Virtually the only way that old tires are currently used in tire manufacture is as retreads. The retreading of tires is a direct reuse of the basic tire and thus is not included in reported recycling amounts and rates. The American Retreaders Association (ARA) contends that it should be considered recycling because of fine lines of difference between retreading and some other recycling uses of used tires. The life of the tire is extended and consequently the annual quantity of tire waste that must be managed is reduced. Additionally, natural resources are conserved because annual demand is reduced for new, virgin tire material.

The ARA reported that the retreading process gave new life to almost 30.25 million tires in 1993. This was down somewhat from the 31.5 million tires and 31 million tires in 1991 and 1992, respectively. Of the 1993 total, 6.6 million (22%) were passenger car tires, down from 8.5 million in 1991; 7.35 million (24%) were light-truck tires (almost even with 1991); and 15.4 million (51%) were medium truck tires, up from the 15 million 2 years before. In the smaller markets of off-the-road vehicles and specialty tires, 0.66 million and 0.22 million retreads were produced, respectively (together, 3% of the market). ARA reported that the recent drops in passenger car retread production was mostly the result of highly competitive (low) retail pricing of new tires and a gradual increase in consumer interest in expensive, high performance, and the relatively new 70,000- and 80,000-mile premium tires. Fueling lower tire prices was the increasing entrance of wholesale clubs and discount chains into a relatively flat, new tire replacement market. This market for passenger tires decreased slightly in 1993, primarily because of strong sales of new automobiles. Continuing gradual growth in the production of medium truck retreads was encouraged because of the high replacement cost that makes retreading more cost effective.[33]

Technology.—A significant, source reduction-related technology has been the longer-wearing vehicle tire. The development of the radial tire more than a decade ago increased the tread life expectancy from the range of 20,000 to 25,000 miles, for the standard bias-ply tire, to 40,000 miles and more for the then new radial-ply tire. An added advantage of the radial tire was that it delivered better fuel mileage. A trend to smaller cars began somewhat earlier, during the 1970's. Smaller cars usually use smaller tires. These factors caused a reduction in the amount of rubber used in the manufacture of tires and, consequently, in the quantities of tire waste generated. According to a World Rubber & Tire Report issued in 1992 by the Freedonia Group of Cleveland, OH, the amount of natural and synthetic rubber used in tires dropped from 45% of all rubber consumed in 1980 to 42% in 1990. The International Institute of Synthetic Rubber Producers in Houston, TX, estimated that almost 52% of all synthetic rubber currently consumed goes into tire production. Both of these percentages could change further during the next decade if the most recent advanced tire technology is significantly integrated into the tire marketplace. In 1991, the original producer of the radial tire introduced a new radial tire in the United States that it warranted for 80,000 miles. Although the new technology has not been fully revealed by the manufacturer, these tires include the use of a newly developed family of elastomers.[34]

Raw material markets are being affected by the mix of raw materials used in the radial tire. Radial tire design produces higher operating temperatures than that of other types of tires, and this affects the composition of the tire material. The higher temperatures perpetuated an increase in the percent of natural rubber needed. Synthetic rubber helps tire tread last longer, but natural rubber is less heat sensitive. Radial-ply tires are composed of about 16% natural rubber as compared to their bias-ply predecessors that used 11% natural rubber. Thus a small yet significant portion of synthetic rubber, which is manufactured from nonrenewable hydrocarbon resources, is being replaced with natural rubber, a renewable resource.

Two companies claim to have developed tire pyrolysis technologies which are economically feasible. Up to now, pyrolysis generally has not been viable. Too small a portion of the byproducts—pyrolytic oil, gas, char, and metal from the char—have been profitably marketable on a consistent basis. The gas is usually used to fuel the process, and the metal, approximately 1.1 kilograms (2.5 lbs) of the typical 9-kilogram (20-lb) tire, is clean enough to market. But the grade of pyrolytic oil and char is often below market standards. Both companies claim that their more sophisticated pyrolysis technologies produce higher quality materials. One of the proposed processes operates at a relatively low temperature, 177° to 205° C (350° to 400° F), as opposed to the traditional operations at 925° to 980° C (1,700° to 1,800° F). The char or "carbon black" is sold to manufacturers of low-grade carbon products, such as hoses and tires for lawn mowers and forklifts. Thus far, pyrolysis technologies have not been able to produce a carbon black of high enough grade to reuse in tire production.[35] But even if low-temperature methods prove to be successful, widespread commercialization of them appears likely to be several years away.

Since 1990, the STMC reports that one significant technological change has occurred in the tire-to-energy industry. In the second of the two commercial facilities in the United States, certain innovations have allowed for whole tires, as well as processed TDF, to be combusted, thereby lowering everyday operational expenses.

Markets and Prices.—Continued growth is projected for most scrap rubber markets. But the two market areas that offer the most potential are incineration as a fuel and for energy generation, and the use of crumb rubber in the maintenance and rebuilding of highways. Most of the current uses are expanding and some, such as cement kilns and utility plants, are limited principally by reliable tire supply. However, the expansion of these uses would require significant capital outlay for plant modifications needed to use TDF or whole tire fuel.

Depending on final revisions to the ISTEA legislation, originally passed in December 1991, the use for scrap tires could grow significantly through 1997 because, as originally written, the law mandated a recycled content of rubber material on federally funded State roads. Beginning in 1994, 5% of all federally funded roads paved with asphalt was to contain recycled scrap tire rubber at the approximate minimum rate of 9 kilograms of rubber per ton applied. The 5% was to increase another 5% each year through 1997, when 20% of federally funded roads thereafter would be so affected. Although rubber is likely to be the main component of the recycled materials that are mandated under the law, the use of other materials, such as glass, asphalt pavement, or plastic, could reduce the anticipated quantities of crumb tire rubber that is included in the mix. The final interpretation by the Federal Government of mandated or recommended recycled material percentages to be used in accordance with the law will determine how much is actually consumed each year following implementation. Under the ISTEA legislation STMC estimated that up to 68 million tires could have been used for this application by 1996 if the law had been implemented as originally written.

OUTLOOK

Alternative Material/Waste Management Methods

The degree to which an integrated waste management system is instituted will greatly affect the future and the effectiveness of recycling, composting, incineration, and landfilling. Since 1988, the number of recycling collection programs and yard waste composting facilities have increased considerably. Curbside collection programs have risen from little more than 1,000 in 1988 to more than 5,400 in 1992 on up to 6,678 by the end of 1993. Yard waste collection and disposal facilities during the same period have increased from 700 in 1988 to 3,014 in 1993. The number of incinerators during this period also rose, although at a slower rate, from more than 135 in 1988 to more than 171 in 1991, before dropping back to 162 units in 1993. Even with increasing quantities of MSW being landfilled, the number of landfills have dropped from nearly 10,000 in the early 1980's to about 8,000 in 1988 to nearly 5,400 in 1992 on down to 4,482 by the close of 1993. Closures of many smaller, less profitable sites and others no longer environmentally permissible accounted for the large drop.[36] Fewer in number, but much larger and better environmentally designed, new state-of-the-art sanitary landfill facilities, or expansions of existing operations, have replaced some of the reduced landfill capacity. Appropriate local ordinances, and State and Federal laws and regulations have mandated these changes, as concerns over clean, freshwater supplies and a clean natural environment have risen. Recycling, composting and probably WTE incineration is likely to increase, but landfilling will probably continue to decrease in comparison to the other alternatives in the foreseeable future.

Source reduction will continue to be stressed as the weight and size of the materials and products that we produce are lowered to levels that are still adequate for the required task. Efficiency and practicality will guide these efforts. A new material may make some forms of packaging lighter and thinner than its predecessor, but if it is not cost effective or if it uses an excessive amount of energy to produce it, then it is neither efficient nor practical. The development of longer lasting materials is likely to be the target of many future research efforts.

"Design For Recycling" Programs

A variety of products, if designed with recycling in mind, could have significant, favorable impacts by reducing the amount of solid wastes generated and increasing the amount and quality of recycled materials. Automobiles, major appliances, and some packaging applications are just a few examples. This concept is becoming an integral part of the design and research efforts of some companies in the manufacturing and service industries. "Design For Recycling" is an official program and policy of the Institute of Scrap Recycling Industries (ISRI). Through its program, ISRI is seeking a national policy to promote the design and manufacture of goods that, at the end of their useful lives, can be recycled safely and efficiently. Major thrusts of the program are to motivate and assist the manufacturing industry to make consumer products and durable goods recyclable; reduce environmental risks from consumer products; and control any related special environmental problems.

The concept of design for recycling is relatively simple. But full or significant implementation may be difficult to achieve, especially in a culture where the "disposable" product often has become preferred to a similar but reusable one. This shift has been especially evident in the past two or more decades. U.S. manufacturers currently have no legal obligation to plan ahead for the obsolescence of their products. New products are designed to meet the increasingly complex needs of modern society. The necessary materials sometimes are more complex and difficult to recycle. They may even contain toxic materials that not only have the potential to harm the environment but can pose a particular risk to recycling workers if released during the recycling process. A current example is the sodium azide capsule in automobile air bag inflation mechanisms. Being both explosive and toxic, it has complicated automobile recycling processes. An example of a product that is not dangerous but is complicated to recycle is multilayered food packaging. Although this product is highly effective in protecting food from the environment, the many layers of different materials make it difficult to recycle. The scrap recycling industry is aware of these problems, and an objective of ISRI's program is to alert manufacturers.

The Automobile.—Weight reduction and lower emissions remain important, but increasingly, U.S. automobile manufacturers are instructing designers to give recyclability high-priority consideration. Currently, about 75% of each auto is recycled in the United States, and the domestic auto industry is striving to do better. Additionally, a number of foreign manufacturers have been in the forefront of recycling-conscious automobile design. One problem that is encountered in automobile design is that, as weight reduction is achieved, the use of nonmetallic components increases. These materials comprise most of the 25% of the car that is difficult, or currently not possible, to recycle. Plastics are particularly difficult because of the many different types that are used and, generally speaking, the lack of compatibility between them.

In its first year of publishing a recycling rate for steel in old cars, the American Iron and Steel Institute announced a 94% rate for 1993. This was calculated by comparing the steel used to produce new cars in 1993 to the amount of steel scrap collected from auto shredders and dismantlers.[37]

General Motors (GM) has been using recyclable plastic for body panels on its Saturn automobile. Defective panels at the plants can be ground for immediate recycling into other molding parts. Used body panels can be recovered and recycled when Saturns are scrapped. Chrysler Corp. has developed an award-winning prototype car, the Neon, which contains recyclable interior and exterior panels, wheels made from previously recycled aluminum, and is painted with water-based paint. In an attempt to maximize recycling potential, two Chrysler vehicle lines were introduced in 1992 that were designed for 90% recyclability. Du Pont supplies the glass-reinforced, PET-based plastic for the fenders on these cars. This material can be reground, remolded, and reformed. A methanolysis process, also developed by Du Pont, can be used to return the material to its original feedstock components, which can be used again on various applications, including new fenders.

Although the phrases "design for recycling" and "design for disassembly" go hand in hand, they are different. Design for recycling aims not only at ease of disassembly but also minimum disassembly so that subassemblies may be removed and recycled without further separation. Several European automakers have taken an early lead in establishing programs in these areas. In 1991, Bayerische Motoren Werke AG (Bavarian Motor Works, BMW) and Volkswagenwerk AG (Volkswagen, VW) started pilot disassembly plants to recover metals, plastics, glass, and other materials from old cars, and BMW announced plans to build a commercial plant. The German Automobile Club (ADAC) has a research dismantling facility at which its goal is the design of a 100% recyclable automobile. The French automaker Peugeot SA (Peugeot) has entered a joint venture with a leading French scrap metals processor and a cement manufacturer to maximize recycling and to convert nonrecyclable components into fuel for the cement plants. The company planned to recycle more than 7,000 Peugeot and Citroen cars by 1994. In the United Kingdom, the Rover Group has joined with the Bird Group, a leading scrap processor in Europe. The company plans to develop rapid dismantling techniques and set up standards and procedures. In Japan, similar efforts began with Toyota's collection of used plastic bumpers. The bumpers were sold to recyclers and manufactured into products such as pallets. This program was started with 26 dealers in Tokyo and was expanded to all dealers in the Tokyo area.

The U.S. big three automakers formed a consortium in 1992 to research and promote the maximum recovery and reuse of materials from junked cars. The Vehicle Recycling Partnership also is expected to develop industry guidelines for new vehicle manufacturing in such areas as materials selection and compatibility and optimum materials and techniques for joining, coating, etc.

The Automotive Group of the Durables Committee of the Society of the Plastics Industry has established a pilot study to develop economical and environmentally sound methods of recovering and recycling post-consumer automotive plastics and an industry infrastructure to support such processes. The use of as many as 40 different types of hard-to-identify plastics in automotive applications, such as fan shrouds, fender liners, radiator end caps, windshield washer bottles, interior trim pieces, and grill panels, has made auto plastic recycling difficult. GM and Ford Motor Co. now require labels that identify the type of resin in each plastic part. Auto dismantlers, an auto shredder, a nonferrous metals separator, plastics recovery and reclamation facilities, and industry laboratories will participate in the project. The difficulties encountered and information gathered during this project will be used to advise manufacturers in their design for recycling efforts in future cars.

BMW will be cooperating in a pilot automobile recycling program with three recycling companies in California, Florida, and New York that are members of the Automotive Dismantlers and Recyclers Association (ADRA). They were chosen by meeting criteria that included outstanding adherence to the ADRA Code of Ethics and use of the ADRA Hazardous Waste Management Booklet as the basis for environmentally sound practices. Fluids will be drained and recycled and batteries will be removed and properly disposed of. If the car has air bags, they will be deployed per BMW specifications to eliminate the risk of sodium azide contamination. All economically salvagable components will be removed before the metal shell is shipped to an auto shredder. BMW will use a monetary incentive to encourage the return of old BMW cars for the project.

During 1993, Ford began a pilot project for the recycling of obsolete plastic bumpers. The material from the bumpers was used to make taillight housings for the 1993 Taurus models leased to a California company. This is the first case in North America where an automaker is using recycled plastics from its junked vehicles to make parts for new ones.[38]

Another opportunity for recycling involves used oil filters. More than 400 million used auto oil filters are available for recycling in the United States annually, but most of them are landfilled. Research conducted by USBM has shown that crushed and drained filters have a higher (better) bulk density than many standard grades of steel scrap. The analysis of the material is very low in all residual elements except tin from tinplate used in filters, and overall yields of up to 85% were achieved. A California steel company expected to recycle 18 million oil filters in 1993.[39]

White Goods.—U.S. steel producers have begun talks with scrap processors and home appliance designers to develop washing machines, refrigerators, freezers, and stoves that will result in more efficient disassembly and recycling. These discussions thus far have been bilateral rather than industrywide. Steelmakers are enthusiastic because they believe that their material has the advantages of significant recyclability and the potential for easy disassembly. Plastic materials hold the advantages of lower weight and component integration.

Carnegie-Mellon University in Pittsburgh began a 4-year study in 1993 to monitor trends in recyclability, not only in automobiles, but also in microcomputers, telephones, and other consumer goods. The purpose of the program was to monitor progress and encourage greater efforts by U.S. industry in design for recycling. The study, funded by IBM and Ford, is designed to help manufacturers anticipate shifting responsibility for disposal from consumers to themselves.[40]

[r] Revised.

[1] Based on results of a survey of post-consumer plastics processors and exporters conducted from Feb. 1993 through Mar. 1993.

[2] Based on data provided by SPI's committee on resin atatistics.

[3] Percentages shown are based on virgin sales and do not account for recycled resin used in the manufacture of the product types listed, except the PET bottle, HDPE pigmented bottle and base cup categories for calendar year 1993.

[4] Based on results of a survey of post-consumer plastics processors and exporters conducted from Feb. 1994 through Mar. 1994.

[5] Based on data provided by SPI's committee on resin statistics and the results of a survey of plastic bottle manufacturers conducted in Feb. 1994 which documented recycled resin usage for the PET custom bottle, HDPE pigmented bottle, and HDPE base cup categories.

[6] Recycling consists primarily of X-ray film.

[7] Due to this Study's focus on recycling in packaging categories specifically, recycling quantities reported for non-packaging plastics may not reflect total non-packaging plastics recycling amounts. Recycling rates and resin sales have been omitted based on this fact.

[8] Includes polyester bottle and polyethylene base cup. 1992 recycling rate could not be calculated due to significant quantities of recycled resin used in the manufacture of the polyethylene base cup.

[9] 1992 recycling rate could not be calculated due to significant quantities of recycled plastic used in manufacture.

[10] Other packaging includes tubs/containers, film packaging, and other miscellaneous packaging.

[11] Other packaging includes film and sheet packaging and other miscellaneous packaging.

[12] 1992 numbers have been adjusted based on data received after publication or changes to category definition.

[13] Other packaging includes shrink/stretch wrap, film packaging and other miscellaneous packaging.

[14] Other packaging includes tubs/containers, flexible packaging, and other miscellaneous packaging.

[15] Percent of sales recycled could not be calculated due to large quantities of recycled polypropylene used in the manufacturing of new batteries and imports of batteries that could not be estimated by SPI's committee on resin statistics.

[16] Packaging includes rigid (non-foam) packaging, rigid (foam) packaging, protective packaging, food service, and other miscellaneous packaging.

[17] Sales data are reflected in segregated rigid containers categories above.

[18] Sales data are reflected in segregated flexible categories above.

[19] Sales data are reflected in segregated packaging categories above.

[20] Category consists of polycarbonate, ABS, nylon, plastics coded #7, and other miscellaneous nonpackaging.

[21] Sales data re reflected in segregated other applications categories above.

[22] Total of bottles in all six resins categories and HDPE base cups.

[23] Packaging totals for the six resins above, the rigid commingled category, and the other miscellaneous packaging category only.

MICA

By Lawrence L. Davis

Mr. Davis, a physical scientist with 38 years of industry and U.S. Bureau of Mines experience, has been the commodity specialist for mica since 1983. Domestic survey data were prepared by Linder Roberts, statistical assistant; and international data tables were prepared by Virginia Woodson, international data coordinator.

In 1993, about 88,000 metric tons of scrap and flake mica was produced in the United States, an increase of 4% from 1992 production. Ground mica sales were 92,000 tons valued at $27 million, an increase in tonnage of about 10%.

Almost all sheet mica supply continued to be imported. Consumption of muscovite block mica decreased 4% to 5.4 tons. Consumption of mica splittings decreased slightly to 826 tons. The value of sheet mica exports increased 27% to $9.5 million. The value of imports for consumption of sheet mica increased 8% to $11.9 million. *(See table 1.)*

DOMESTIC DATA COVERAGE

Domestic production and consumption data for mica are developed by the U.S. Bureau of Mines by means of three separate, voluntary surveys and one mandatory survey. Of the 17 operations to which the crude scrap and flake mica production form was sent, 15 operations, or 88%, responded, representing 81% of the production shown in table 1. Of the 17 operations to which the ground mica form was sent, 15 responded, representing 87% of the production in table 1. Of the five canvassed operations to which the mica block and film consumption form was sent, four, or 80%, responded, representing 93% of the consumption shown in table 1. Of the nine canvassed operations to which the mica splittings consumption form was sent, six operations, or 67%, responded, representing about 72% of the splittings consumption shown in table 1. Consumption for the nonrespondents was estimated using prior-year production data.

BACKGROUND

Definitions, Grades, and Specifications

Mica is a group name for a number of complex hydrous potassium silicate minerals with differing chemical compositions and physical properties. Crystals of mica have excellent basal cleavage and split easily into tough, flexible sheets. The important mica minerals are muscovite and phlogopite.

Commercial qualities of sheet mica are relatively free of defects and tough enough to be punched or stamped into specific shapes. Sheet mica is classified as block, film, or splittings. Block mica is not less than 0.018 centimeter thick and has a minimum usable area of 6.45 square centimeters. Film mica is split to specified thicknesses ranging from 0.0030 to 0.010 centimeter. Splittings are sheets with a maximum thickness of 0.0030 centimeter and a minimum usable area of 4.84 square centimeters. Punch mica, which includes circle and washer mica, is low-quality, hand-trimmed mica up to about 5 centimeters in diameter. The American Society for Testing and Materials (ASTM) designates 13 quality groups for sheet mica, based on quantity of visible inclusions and structural imperfections, ranging from black- and red-stained to perfectly clear. ASTM also designates 12 grades based on the maximum usable rectangle. The sizes range from grade 6 (with 6.45 usable square centimeters) to grade OOEE special (with 645 usable square centimeters).[1]

Block and film mica products are small, flat pieces of uniformly thin mica cut or stamped to close tolerances into a variety of shapes and sizes, depending on the use. Shapes can vary from simple circles, squares, or rectangles to very intricate patterns. Fabricators make their own dies to be able to cut the mica into any pattern desired.

Built-up mica, or micanite, consists of partly overlapped and irregularly shaped and arranged splittings cemented together with either an organic or inorganic binder. Large sheets of built-up mica are made by alternating layers of splittings and binder. Sheets of any thickness are made by pressing the layers at high temperatures. Built-up mica is sold in large, uncut sheets or is cut or molded to any size and shape specified by the customer. It is often bonded to another material such as fiberglass cloth to form a composite sheet.

Reconstituted mica or mica paper is a paperlike material made by depositing fine flakes of scrap mica as a continuous mat, which is then dried. The mica paper is sometimes impregnated with an organic binder.

Scrap and flake mica is generally of a quality and size that is not suitable for use as sheet mica. Mine scrap varies greatly in quality but usually is a heterogeneous mixture that must be crushed, screened, and washed to yield the scrap mica in usable form. Mine scrap may be the sole product of mining a pegmatite or may be a byproduct of sheet mica production. Bench scrap or shop scrap is the mica discarded during the processing of handcobbed mica into sheet. Factory scrap is the waste that results from cutting and stamping sheet mica into pieces of definite size and shape. Factory scrap is usually the highest grade and quality material. Scrap mica that is recovered from schists and from the beneficiation of feldspar, kaolin, and lithium pegmatites is commonly referred to as flake.[2]

Industry Structure

The sheet mica industry in the United States is small, consisting of processors and fabricators of imported mica. Worldwide, India dominates the production of muscovite sheet mica. Madagascar is an important producer of phlogopite sheet mica. Sheet mica mining, trimming, and splitting are very labor intensive, and producing countries have the advantage of low wages and a large labor force that is usually trained at an early age. India's sheet mica industry is characterized by a large number of small operations, most of which sell to larger companies or the Government's Mica Trading Corp. of India Ltd. for further processing and export. India is putting more emphasis on exporting fabricated mica products. This is expected to reduce further the amount of mica that will be fabricated in the United States.

The U.S. flake mica industry ranks first in world production. Most production comes from surface mining of mica schists and as a byproduct of feldspar, kaolin, and lithium beneficiation. Nearly all flake mica is ground to final specifications depending on the use. Other countries producing significant amounts of flake mica are Canada, China, India, the Republic of Korea, and Russia. Many other countries produce small amounts.

Geology-Resources

Sheet muscovite is obtained from coarse-grained igneous rocks called pegmatites. Pegmatites also contain feldspar, quartz, and various accessory minerals. Pegmatite dikes and veins range from 1 kilometer or more long and 100 meters wide to thin veins and veinlets of approximately 2 centimeters in width.

The United States has no reserves of sheet mica. Small U.S. reserves were extensively worked in the past, and the high cost of labor has kept the mines shut down since the Government's purchase program ended in 1962. The primary sheet mica resources are in New England, the southeastern Piedmont from Virginia to Alabama, the Blue Ridge Mountains in North Carolina, the Black Hills of South Dakota, and northern New Mexico. Other States with some sheet mica resources are California, Colorado, Idaho, Montana, and Wyoming.

No formal evaluation of world resources of sheet mica has been made, mainly because of the sporadic occurrence of this mineral. The most productive sheet mica districts in the world are in the States of Bihar, Andhra Pradesh, and Rajasthan in India. India's large reserves and resources of sheet mica have been the primary world sources for many years. Large reserves of sheet mica also are found in Brazil and western Africa. In Russia, sheet mica reserves are known in the Lake Baikal and Sayan upland areas as well as in the South Eniessy Range. Smaller but substantial reserves occur in Argentina, Australia, and Zimbabwe.

Phlogopite deposits are in areas of metamorphosed sedimentary rocks intruded by masses of pegmatite-rich granitic rocks. The phlogopite is found as veins or pockets in pyroxenite interlayered with or intersecting marble or gneiss. Canada and Madagascar have the world's major reserves of phlogopite. Additional reserves are known in Mexico, Sri Lanka, and the Sludyanka River district and Alden area of Russia.

The primary domestic source of flake mica for grinding purposes is weathered alaskite bodies and pegmatites in North Carolina, where most domestic flake mica is produced. The mica is recovered as a coproduct of feldspar and kaolin beneficiation. Flake mica is also recovered from muscovite schists. These schists bodies range in size from 3 to more than 100 meters thick and several kilometers long. The mica content ranges up to 90%. Another form of flake mica is fine-grained muscovite called sericite, which is an alteration product of various aluminosilicate minerals.

World reserves and resources of scrap and flake mica are not well known but are considered to be very large. All countries with sheet mica reserves or resources have even larger quantities of scrap mica because only a small fraction of the mica present is of sheet quality. Many other countries have reserves or resources of mica that, although not of sheet quality, are suitable for grinding.

ANNUAL REVIEW

Legislation and Government Programs

The Government inventory of stockpile-grade mica decreased slightly to about 9,500 tons. The U.S. Department of Defense sold 37 tons of muscovite block, stained and better; 33 tons of muscovite film; 44 tons of muscovite splittings; and 51 tons of phlogopite splittings. *(See table 2.)*

Strategic Considerations

Sheet mica and high-quality scrap mica used for making mica paper are important in the electronic and electrical industries. The United States is not self-sufficient in these materials and imports all its supplies, mostly from India. The United States competes with the rest of the world for Indian mica, and availability is sometimes limited, particularly for high-quality mica. Long delivery times and quality inconsistency also adversely affect sheet mica availability.

In a short-supply situation during an emergency, the National Defense Stockpile would be able to meet short-term demand until substitutes could be made available. It is unlikely that domestic sheet mica production could replace or significantly reduce imports. Of the five strategic stockpile categories, only muscovite block mica has ever been produced domestically in significant quantities, and then only under the stimulus of above-market prices paid by the Government. Domestic production in this century never provided more than a small fraction of domestic requirements.

The domestic supply of flake mica is adequate. Scrap and flake mica are not considered to be strategic materials. The United States is self-sufficient in flake mica but does rely on imports of high-quality scrap for the manufacture of mica paper.

Production

Scrap and Flake Mica.—Mica was mined by 9 companies with 11 mines in 5 States. North Carolina remained the major producing State, with 58% of the total production. The remainder was produced in Georgia, New Mexico, South Carolina, and South Dakota. Most mica was recovered from mica schist, high-quality sericite schist, and as a byproduct of feldspar, kaolin, and lithium beneficiation.[3] The five largest producers were, in alphabetical order, The Feldspar Corp., Spruce Pine, NC; Franklin Mineral Products Co., Hartwell, GA; KMG Minerals Inc., Kings Mountain, NC; Lithium Corp. of America, Gastonia, NC; and MICA, Fairview, NM. These five companies produced 74% of the national total.

Low-quality sericite, used primarily in brick manufacturing, is excluded from tabulated data contained in this report. In 1993, three companies, one in North Carolina and two in South Carolina, mined low-quality sericite and reported an average value of $3.31 per ton.

Ground Mica.—Ten companies operated twelve grinding plants in 6 States. Eight plants produced dry-ground and four produced wet-ground mica. The five largest producers accounted for 82% of the total. They were, in alphabetical order, Franklin Mineral Products Co., Hartwell, GA; KMG Minerals Inc., Kings Mountain, NC; MICA, Fairview, NM; Spartan Minerals Corp., Pacolet, SC; and USG Corp., Spruce Pine, NC. *(See tables 3 and 4.)*

Consumption and Uses

Sheet Mica.—Sheet mica is used principally in the electronic and electrical industries. Its usefulness in these applications stems from its unique electrical and thermal insulating properties and its mechanical properties, which allow it to be cut, punched, or stamped to close tolerances.

The largest use of block mica is as an electrical insulator in electronic equipment. High-quality block mica also is used to line the gauge glasses of high-pressure steam boilers. Transparency, flexibility, and resistance to heat and chemical attack are the properties that make mica suitable for this use. Other uses include diaphragms for oxygen-breathing equipment, marker dials for navigation compasses, optical filters, retardation plates in helium-neon lasers, pyrometers, thermal regulators, and stove windows.

Muscovite film mica is used as a dielectric in capacitors. Only high-quality mica, at or near the top of the quality scale, is used. The highest quality goes into capacitors that are to be used as standards. The next highest qualities are used for transmitting capacitors. Receiving capacitors use slightly lower quality film.

Consumption of muscovite block (ruby and nonruby) totaled 5.4 tons, a 4% decrease from that of 1992. Stained and lower-than-stained quality remained in greatest demand, accounting for 87% of consumption. About 60% of the muscovite consumed was grade No. 4 or larger. The decrease in consumption was a continuation of a long-term decrease in block mica use. Five companies continued to consume muscovite block and film in five plants in four States: two in North Carolina and one each in New Jersey, Ohio, and Virginia.

Splittings represent the largest part of the sheet mica industry in the United States. Muscovite and phlogopite splittings are used to make built-up mica. Consumption of mica splittings decreased slightly to 826 tons. Muscovite splittings from India accounted for nearly all of the consumption. The remainder was phlogopite splittings from Madagascar. The splittings were fabricated into various built-up mica products by nine companies operating nine plants in seven States.

Built-up Mica.—The primary use of this mica-based product, made by mechanical or hand setting of overlapping splittings and alternate layers of binders and splittings, was as electrical insulation material. Principal built-up mica products are segment plate, molding plate, flexible plate, heater plate, and tape.

Segment plate acts as insulation between the copper commutator segments of direct-current universal motors and generators. Phlogopite built-up mica is preferred because it will wear at the same rate as the copper segments. Muscovite has a greater resistance to wear, causing uneven ridges that may interfere with the operation of the generator.

Molding plate is sheet from which V-rings are cut and stamped for use in insulating the copper segments from the steel shaft at the ends of a commutator. Molding plate also is fabricated into tubes and rings for insulation in transformers, armatures, and motor starters.

Flexible plate is used in electric motor and generator armatures, field coil insulation, and magnet and commutator core insulation. Heater plate is used where high-temperature insulation is required.

Some types of built-up mica have the bonded splittings reinforced with special paper, silk, linen, muslin, glass cloth, or plastic. These products are very flexible and are produced in wide, continuous sheets that either are shipped in rolls or cut into ribbons, tapes, or any desired dimensions.

Total production, sold or used, of built-up mica decreased 24% from that of 1992. Segment plates and molding plates were the major end products, accounting, respectively, for 33% and 32% of the total. Other end products included flexible plates, heater plates, and tapes.

Reconstituted Mica (Mica Paper).—Primary end uses for mica paper are the same as those for built-up mica. Three companies consumed scrap mica to produce mica paper. The principal source of this scrap mica was India.

Manufacturing companies in 1993 were Corona Films Inc., West Townsend, MA; General Electric Co., Coshocton, OH; and US Samica Corp., Rutland, VT. *(See tables 5, 6, and 7.)*

Ground Mica.—The largest domestic use of ground mica was in gypsum plasterboard joint cement. The mica acts as a filler and extender, provides a smooth consistency, improves the workability of the cement, and imparts resistance to cracking.

In the paint industry, ground mica is used as a pigment extender that also facilitates suspension, reduces checking and chalking, prevents shrinking and shearing of the paint film, increases resistance of the paint film to water penetration and weathering, and brightens the tone of colored pigments.

Ground mica is used in the well-drilling industry as an additive to drilling muds. The coarsely ground mica flakes help prevent lost circulation by sealing porous sections of the drill hole.

The rubber industry uses ground mica as an inert filler and as a mold lubricant in the manufacture of molded rubber products such as tires. The plastics industry uses ground mica as an extender and also as a reinforcing agent.

Ground mica is used in the production of rolled roofing and asphalt shingles, where it serves as an inert filler and surface coating to prevent sticking of adjacent surfaces. The coating is not absorbed by freshly made roofing because mica has a platy structure and is not affected by the acid in the asphalt or by weathering. Other uses include decorative coatings on wallpaper and on concrete, stucco, and tile surfaces; as an ingredient in some special greases; as a coating for cores and molds in metal casting; and as a flux coating on welding rods.

In 1993, the major end uses were joint cement, 53%; paints, 17%; plastics, 4%; and well-drilling muds, 4%. *(See table 4.)*

Stocks

Reported yearend consumer stocks of sheet mica decreased slightly to 463 tons; of this, mica splittings represented 92% and mica block and film represented 8%.

Markets and Prices

Prices for sheet mica vary with grade and quality and can range from less than $1 per kilogram for low-quality mica to more than $2,000 per kilogram for the highest quality. The average values of muscovite sheet mica consumed in the United States in 1993 compared with 1992 were as follows: block increased 10% to $95 per kilogram, and splittings increased slightly to $1.55 per kilogram. The average value of phlogopite block remained at $26 per kilogram, while the value of phlogopite splittings decreased slightly to $4.37 per kilogram. The changes in average value are more a reflection of the quality of mica consumed during the year than actual changes in price. The average value of crude flake mica, including high-quality sericite, was $51 per ton. The average value per ton for North Carolina flake mica, predominantly a flotation product, was $53.

Foreign Trade

The United States continued to rely on imports, mostly from India, for nearly all of its sheet mica and paper-quality scrap mica. Imports for consumption of unmanufactured block, film, and splittings were about 3,000 tons, 44% more than those in 1992. Worked mica imports were about 1,400 tons, 4% less than those in 1992. About 13,100 tons of ground mica was imported mostly from Canada, while about 4,600 tons was exported to 32 countries. The combined value of all mica imports increased 9% to $21.2 million, while the combined value of all mica exports increased 26% to $12.2 million. *(See tables 8, 9, 10, 11, 12, and 13.)*

World Review

World production of mica decreased 5% to 190,000 tons. The United States continued to lead in the production of flake mica. India continued to lead in the production of sheet mica. *(See table 14.)*

Canada.—Suzorite Mica Products Inc., currently the only active mica producer in Canada, was purchased by Zemex Corp. Zemex, headquartered in Asheville, NC, is the parent of The Feldspar Corp., a major producer of mica in the United States.[4]

Stratmin Graphite Inc. was investigating the feasibility of separating phlogopite mica at its graphite operation at Lac des Iles, Quebec.[5]

Finland.— Kemira Oy was planning to increase the capacity of its pearlescent pigment facilities in Pori. Mica production from Kemira's mine at Siilinjarvi will be increased accordingly.[6]

India.—Political changes in the former U.S.S.R. and Eastern European countries have had a serious impact on India's mica exports. Exports to those countries have dropped dramatically.[7]

OUTLOOK

Demand for sheet mica has decreased dramatically during the past 30 years. For block and film mica, the major cause of decreased demand was technological change, specifically the introduction of semiconductor technology in electronics to the detriment of vacuum tube electronics that used large quantities of mica. Although the major impact of the technology change was felt in the 1960's and 1970's, consumption of block and film mica continues to decrease, albeit more slowly. Substitute materials cause part of the decrease, and increased imports of finished electronic gear mean fewer mica parts are fabricated in the United States. Since 1979, consumption block mica has decreased at an average annual rate of about 20%. This decline is expected to continue, and, by 1995, consumption will decrease to 2,500 kilograms. Consumption of mica splittings, the major type of sheet mica consumed in the United States, also decreased sharply through the 1960's and

1970's. During the 1980's, consumption leveled off to between 900 and 1,000 tons per year. Decreases were due to the development of substitute electrical insulating materials, miniaturization of electrical equipment, and increased imports of foreign-built products. Consumption of splittings is expected to decrease very slightly in the near future, remaining between 800 and 1,000 tons through 1995.

Scrap and flake mica enters markets as ground mica, and demand tends to follow construction activity levels. With increased construction activity in 1993, ground mica consumption increased about 12%. In the near future, modest increases in construction activity are expected to continue, which will probably bring ground mica consumption to about 100,000 tons by 1995.

The major end use, as a filler in joint compounds, will continue to account for about one-half of the market. Consumption for other uses—in paints, well-drilling muds, and plastics—is expected to increase slightly by 1995.

[e]Estimated. [r]Revised.

[1] Table includes data available through July 13, 1994.

[2] In addition to the countries listed, China, Norway, Pakistan, Romania, and Sweden are known to produce mica, but available information is inadequate to make reliable estimates of output levels.

[3] Reported figure.

[4] Data are for year beginning Mar. 21 of that stated.

[5] All production in the U.S.S.R. from 1989-91 came from Russia.

[6] All production in Yugoslavia from 1989-91 came from Serbia and Montenegro.

[7] Less than 1/2 unit.

[8] Dissolved in Dec. 1991.

[9] Excludes U.S. production of low-quality sericite and sheet mica, if any.

[10] Dissolved in Apr. 1992.

MOLYBDENUM

By John W. Blossom

Mr. Blossom, a physical scientist/engineer with 46 years of industry and Government experience, has been the commodity specialist for molybdenum since 1982. Survey and trade data were prepared by Sherwood C. Jordan, statistical assistant; and the world production tables were prepared by Harold D. Willis, international data coordinator.

Molybdenum is a refractory metallic element used principally as an alloying agent in steels, cast irons, and superalloys to enhance hardenability, strength, toughness, and wear and corrosion resistance. Primarily added in the form of molybdic oxide or ferromolybdenum, it is frequently used in combination with chromium, columbium, manganese, nickel, tungsten, or other alloy metals to achieve desired metallurgical properties. The versatility of molybdenum has ensured it a significant role in contemporary technology and industry, which increasingly require materials that are serviceable under higher stresses, greater temperature ranges, and more corrosive environments. Moreover, molybdenum finds significant usage as a refractory metal in numerous chemical applications, including catalysts, lubricants, and pigments. The variety of uses for molybdenum materials, few of which afford acceptable substitutions, has resulted in a demand that is expected to grow at a greater rate than most other ferrous metals.

Distribution of molybdenum reserves and productive capacity are concentrated in a few countries of the world. World mine output was an estimated 95,000 metric tons (molybdenum contained in concentrate) in 1993, of which Canada, Chile, China, and the United States provided 82%. These four countries, led by the United States, are expected to continue as the principal mine producers for the rest of this century. These countries also possess about 90% of the estimated 12 million metric tons of molybdenum in world reserve base.

The metric system is the official system of measurement of most countries. The U.S. Bureau of Mines, in an effort to provide statistical data on molybdenum that are consistent with international usage, reports data in kilograms and metric tons.

DOMESTIC DATA COVERAGE

Domestic production data for molybdenum are developed by the U.S. Bureau of Mines by means of three separate, voluntary surveys. These surveys are Molybdenum Ore and Concentrate, Molybdenum Concentrate and Molybdenum Products, and Molybdenum Concentrates. Surveys are sent to all operations that produce molybdenum ore and products. Out of 12 operations to which surveys were sent, all responded, representing 100% of the total U.S. production shown in table 1.

BACKGROUND

From the period of the Greek and Roman civilizations to the late 18th century, terms such as "molybdous" or "molybdaena" were applied to minerals that were soft and "leadlike" in character, probably including minerals now known as galena, graphite, and molybdenite. This confusion was resolved in 1778 when the Swedish chemist, Karl Scheele, demonstrated that molybdenite, the principal molybdenum mineral, was a discrete mineral sulfide. Four years later, P. J. Hjelm of Sweden reduced the acid-forming oxide of the element by heating with charcoal, thereby producing an impure powder of the metal, which he named "molybdenum." Various properties of the element and its compounds were determined during the 19th century, and in 1893, German chemists produced a 96%-pure metal by reducing calcium molybdate. The impure metal was reported to have been used experimentally as a substitute for tungsten in tool steels.

Molybdenum-bearing armorplate was produced in France in 1894; this was the first recorded use of the metal as an alloying element in steel. Soon thereafter, Henri Mossiam, a French chemist, succeeded in producing a 99.98%-pure metal by reduction of molybdenum in an electric furnace. Mossiam then conducted studies to establish the element's atomic weight and to determine its physical and chemical properties. These studies stimulated interest in the metal and its compounds and investigations of commercial applications. By the late 1890's, molybdenum was used in certain chemicals and dyes, and in 1898, a self-hardening molybdenum tool steel was marketed.

The first mine production of molybdenite was probably from the Knaben Mine in southern Norway in the late 18th or early 19th century. Because essentially no commercial use for the metal existed, output from the mine remained insignificant until about 1880. By the end of the century, molybdenum ore was also mined intermittently in Australia and the United States. Molybdenite and wulfenite concentrates were produced from ores in Arizona and New Mexico, but U.S. output was small and ceased entirely in 1906 owing to lack of demand.

World War I generated the first appreciable utilizations of molybdenum, when it was substituted for tungsten in high-speed steels and used as an alloying element in certain steels for military armament. From 1912 to 1920, small output was recorded from several additional countries, and U.S. production was resumed. The flotation process for separating molybdenite from its ores was developed during these years. The Climax deposit in Colorado and the Questa deposit in New Mexico were initially exploited from 1917 to 1919. Development of the Climax deposit, the world's largest, later proved the viability of high-tonnage extraction of relatively low-grade ore and established the United States as the leading producer of molybdenum.

Output terminated in 1920 in the United States and most other countries because nonmilitary consumption of molybdenum was insufficient to support continued production. However, industrial efforts to develop peacetime applications, primarily as an alloy in steels and cast irons, were successful, and by the mid-1920's, demand exceeded that of the war years. Operations resumed at the Climax deposit in 1924. By 1930, world output of molybdenum totaled 4.2 million pounds, of which the United States and the Climax Mine accounted for about 89% and 73%, respectively.

In 1933, the Greene Cananea Copper Co., a Mexican subsidiary of the Anaconda Co., initiated the recovery of molybdenite as a byproduct of copper mining operations. Three years later, Kennecott Corp. began byproduct recovery at its Bingham open pit in Utah. Since that time, molybdenite recovery circuits have been installed at numerous copper concentrating plants, notably in Canada, Chile, and the United States. These sources have supplied 40% to 50% of the world molybdenum output in recent years.

Since the early 1930's, industrial research and marketing programs have considerably expanded the range of metallurgical materials in which molybdenum is a preferred or essential alloy ingredient. The use of molybdenum as a refractory metal and in a variety of chemical applications also has experienced significant growth.

Definitions, Grades, and Specifications

Molybdenum is a silver-white metallic element with an atomic number of 42, atomic weight of 95.95, and a density of 10.2 grams per cubic centimeter. The chemistry of molybdenum is complex; molybdenum exhibits oxidation states from -2 to 6, coordination numbers from 4 to 8, and forms compounds with most inorganic and organic liquids. Molybdenum is a strong carbide-forming element, and much of its alloying effect in steel is imparted through the formation of carbides. It has a melting point of about 2,610° C; among the metallic elements, only osmium, rhenium, tantalum, and tungsten have higher melting points. Other significant physical properties of molybdenum metal are good thermal conductivity (about one-half that of copper), the lowest coefficient of thermal expansion of the pure metals, high strength at elevated temperatures, and resistance to corrosion in a wide variety of mediums. Molybdenum metal is stable in air or water at moderate temperatures, but above 500° C it oxidizes readily.

Molybdenite is the principal mineral from which molybdenum is obtained. Crude ore containing molybdenite is beneficiated to produce molybdenite concentrate. The concentrate generally contains about 90% molybdenite; the grade may be somewhat lower, particularly if produced at copper byproduct concentrating plants. Technical-grade molybdic oxide is produced by the roasting of molybdenite concentrate. Typically, the oxide has a content of 85% to 90%, or a minimum of 57% contained molybdenum. Other raw materials, including ferromolybdenum, purified molybdic oxide, ammonium, and sodium molybdate, and molybdenum metal powder are produced from technical-grade oxide. The production of these materials is described in the section entitled "Products for Trade and Industry."

The American Society for Testing and Materials (ASTM) has developed standards for the chemical composition of molybdenum oxide products (Specification A 146-64, reapproved 1979) and ferromolybdenum (Specification A 132-74, reapproved 1979). These standards specify minimums for molybdenum content and maximums for impurity content as an aid to producers and purchasers. Material marketed by the major domestic producers generally meet or exceed ASTM standards.

Products for Trade and Industry

Some commercial-grade molybdenite concentrate is treated in additional grinding and flotation steps to produce lubricant-grade molybdenum disulfide. Oil and water are volatilized by passing an upgraded concentrate through an inert-gas-swept kiln. The oil-free product is about 99% molybdenum disulfide and suitable for use in lubricant applications.

Molybdenite concentrate is converted to technical-grade molybdic oxide, the major form of molybdenum used by industry and the base material for production of ferromolybdenum, chemicals, and molybdenum metal powder. The technical-grade oxide is produced by roasting molybdenite concentrate in the multiple-hearth furnace at temperatures of up to 650° C. Typically, the roasted product contains 90% molybdic oxide and a maximum of 0.1% sulfur. Technical-grade oxide is used to add molybdenum to steels, cast irons, and other alloys.

Ferromolybdenum is typically produced by reduction of technical-grade oxide and iron oxide with a conventional metallothermic process, using silicon and/or aluminum as the reductant. The molybdenum content ranges from 58% to 64%. Ferromolybdenum is used as an alternative additive in producing alloy steels, cast irons, and nonferrous alloys.

Ammonium molybdate is produced by reacting pure molybdic oxide with ammonium hydroxide and crystallizing out the pure molybdate. Sodium and calcium molybdate are made in a similar manner using sodium hydroxide and calcium chloride.

Molybdenum metal powder is manufactured by reducing pure molybdic oxide or ammonium molybdate with hydrogen. The purest metal powder (99.95% molybdenum minimum) is produced from ammonium molybdate. Metal powder is pressed and sintered into small metal ingots, which are converted into rod, wire, or sheet by hot rolling, swaging, or forging. Large ingots are produced by arc-casting powder under a vacuum or inert gas atmosphere.

Industry Structure

Four countries, Canada, Chile, China, and the United States, mine 82% of world output of molybdenum ore. Plants to convert ore concentrates to technical-grade oxide and other molybdenum products are in Chile, China, Russia, the United States, and Western Europe.

Geology-Resources

Almost all molybdenum is recovered from low-grade deposits of the mineral molybdenite. Two types of deposits, primary and byproduct porphyry copper, provided the United States and world output of molybdenite. Primary molybdenum deposits generally grade 0.2% to 0.5% molybdenite; copper ores from which byproduct molybdenum is recovered contain 0.02% to 0.08% molybdenite.

The average crustal abundance of molybdenum is 1 to 2 parts per million (ppm). The molybdenum content of igneous rocks tends to increase with increasing silica content. Molybdenum does not occur in nature in its free or native state, but is found only chemically combined with other elements. Small deposits of molybdenum-bearing minerals occur throughout the world, but the only molybdenum mineral of commercial importance is molybdenite. Wulfenite, powellite, and ferrimolybdite are common but have supplied very little molybdenum.

Molybdenite (MoS_2) is a lead-gray metallic mineral that characteristically occurs in thin, tabular, commonly hexagonal plates and also disseminated as fine specks. It has a specific gravity of 4.6 to 4.7, a hardness of 1 to 1.5, a greasy feel, and it soils the fingers. Superficially, it resembles graphite, for which it commonly has been mistaken.

Molybdenum deposits are of five geological types: (1) porphyry or disseminated deposits, including stockworks and breccia pipes in which metallic sulfides are dispersed through relatively large volumes of altered and fractured rock, (2) contact-metamorphic zones and tactite bodies of silicated limestone adjacent to intrusive granitic rocks, (3) quartz veins, (4) pegmatites and aplite dikes, and (5) bedded deposits in sedimentary rocks.

The first three genetic-type deposits are hydrothermal in origin and as such represent nearly all the known molybdenum resources currently mined in the world. The remaining types do not represent a great volume of molybdenum but are of certain economic importance only when molybdenum is associated with other minerals.

In the hydrothermal deposits, metallic minerals are precipitated from high-temperature aqueous solutions either by changes in temperature and pressure or by evaporation of the liquid. Minerals are deposited in the cavities, cracks, or interstices of the matrix rock.

Most of the porphyry coppers contain small quantities of molybdenite disseminated with the copper minerals through large bodies of granitic rock. The chief minerals are chalcopyrite and chalcocite, with pyrite and small amounts of other sulfides, including molybdenite.

Available information on world reserves and reserve base of molybdenum varies widely in reliability. For certain countries such as Canada, Chile, and the United States, company annual reports or other published materials enable inventorying minable ore reserves. For most other countries, reserves must be estimated from fragmentary or preliminary data on ore tonnage and grade of known or anticipated sources. In particular, the reserve figures for China and the former U.S.S.R. should be considered order-of-magnitude estimates.

It should be noted that the reserve data refer to molybdenum contained in ore. The recovery of molybdenum after milling approximates 75% to 90% of the in-place ore content at primary molybdenum sources. Recoveries achieved at byproduct sources vary markedly from mine to mine, but average an estimated 55% of the molybdenum in ore processed. Overall, an estimated 65% of the total world molybdenum reserves can be considered as recoverable.

Most of the world reserves of molybdenum occur in the western mountain regions of North and South America, extending from Alaska and British Columbia through the United States and Central America to the Andes Mountains of Chile. These regions, roughly bordering the eastern margin of the Pacific Basin, are also regarded as most promising for future discoveries and additions to reserves.

Technology

Exploration.—Prospecting and exploration for molybdenum is basically the same as that for deposits of other metals. Areas generally considered favorable for molybdenite mineralization are those metallogenic provinces that encompass known occurrences of molybdenum stockworked deposits and copper-molybdenum porphyry deposits. An understanding of regional geology, mineral associations, and known patterns of molybdenite mineralization is essential to identify potential sites for field investigation. Sites for detailed study may be selected on the basis of geologic mapping of rock units and structures, geochemical analyses of sediments and soils, and ground geophysical surveys. An intensive drilling and sampling program is then required to estimate the size, grade, and continuity of the discovery. Exploration drifts may be driven into the ore body to provide more specific geologic information and bulk samples for metallurgical testing.

The evaluation of a deposit may require 2 to 5 years from the time of discovery. During this time, the technical, economic, and environmental aspects of mine development must be evaluated. An additional 3 to 8 years may be required to prepare the deposit for production. Long development times are indicative of the complex planning and considerable capital needed to develop the large, low-grade stockwork and porphyry deposits that are expected to remain the significant sources of molybdenum. As a general rule, development of underground molybdenum deposits would require more time and capital than that of surface deposits.

Mining.—Molybdenum ore is mined by underground and open pit methods, the choice of method determined by the size, configuration, grade, and depth of the ore body. Underground and surface operations accounted for about 40% and 60%, respectively, of the domestic molybdenum output.

Underground deposits of molybdenum ore are mined by block or panel caving methods modified to suit the characteristics of the particular ore body being worked. In these methods, large masses of ore are undercut and blasted at the base to induce the collapse and fragmentation of the ore under its own weight. The broken ore may be drawn off from the caved mass by gravity through finger raises into slusher drifts. The ore is then scraped to draw holes where it falls into ore cars on a haulage level beneath the slusher drifts. Alternatively, the broken ore may be funneled by gravity to crosscut drifts at intervals between production drifts. Ore is moved from the ends of the crosscuts along the production drifts to ore passes where it is dumped and collected in loading pockets on a deeper main haulage level. Ore is then transported from the main haulage level to the site of the initial milling operations. Caving methods are used to mine underground deposits of molybdenum because the low grade of the ore necessitates extraction of large tonnages of rock at a minimum of cost. However, caving of the ore must be carefully controlled to avoid ore dilution and excessive ground stresses to mine openings.

In open pit mining operations, the ore is exposed by removal of waste rock. The cut in the ore takes the form of benches, which vary in height and width from mine to mine. The cycle of open pit extraction consists of drilling, blasting, loading, and haulage. Primary drilling consists of driving a vertical blasting hole into the ore. Secondary drilling and blasting may be required to break large boulders. Ore is loaded by mechanical shovels into rail cars or trucks and hauled by large trucks for short distances or by train for long distances. Skipways and belt conveyors are used at some mines for transporting ore to the mill site.

Beneficiation.—Because of their low molybdenum content, all molybdenum-bearing ores require beneficiation. After crushing and grinding to a suitable size, both primary molybdenite and copper sulfide ore containing molybdenite are beneficiated by flotation. With primary ores, a final concentrate of 90% to 95% molybdenite is produced by subjecting the ore to several stages of grinding and reflotation. Copper, iron, and lead minerals are generally the critical impurities that must be minimized in the final concentrate product. Overall recovery of molybdenite at primary-ore concentrating plants ranges from 75% to 90% of the in-place ore content.

Production of molybdenite concentrate from copper ores is more difficult, however, because molybdenite constitutes less than 0.1% of the ore. As a byproduct value, molybdenite recovery is generally given less priority than recovery of copper values. In some cases, improved molybdenite recovery may be attained only at the expense of reduced copper recovery or lower grade of copper concentrate produced.

Recovery from copper ores begins with the bulk flotation of copper minerals and molybdenite as the first separation from gangue materials. Molybdenite in the bulk flotation product is then separated from the copper minerals in a selective flotation process, which usually involves the flotation of molybdenite and depression of copper minerals. The separatory flotation requires close control of pH, reagent mix, and several flotation steps. Processing of copper-molybdenum ore varies from plant to plant depending on the grade of mineralization and impurities in the ore. Concentrate produced as a byproduct contains 70% to 90% molybdenite, although most approaches the higher end of the range in content.

Recycling.—Some secondary molybdenum is recovered in the production of alloy steels, superalloys, and the metal, but data on quantities are incomplete and inconclusive. Most of this recycled material is generated and reused directly at metal-forming or fabricating plants (runaround scrap) or shipped to plants that reclaim it (prompt industrial scrap). A small amount of molybdenum-containing obsolete scrap is processed for its molybdenum content. Although some molybdenum is recycled as a minor constituent of scrap alloy steels, the use of such scrap does not generally depend on its molybdenum content. An increasing quantity of molybdenum is being reclaimed from spent catalysts and chemical residues.

Byproducts and Coproducts

Rhenium is extracted from flue gases and dust produced during the roasting of molybdenite concentrate that has been produced as a byproduct of copper mining.

Molybdenum is recovered as a byproduct primarily from copper ores. A very small amount is obtained from tungsten and uranium ores. At the Sierrita Mine in Arizona, copper and molybdenum are considered coproduct values.

Substitutes

Historically, molybdenum has been a relatively inexpensive alloying agent used primarily in specialty steels and alloys, and in the United States, it has been readily available. As a result, metallurgical applications for molybdenum were broadened, and its utility as an alloy ingredient became well recognized. The substitution for molybdenum by other alloy metals has had little impetus.

Several factors mitigate the possible replacement of molybdenum to the degree that its overall demand would be significantly affected. First, there is no acceptable substitute in numerous metallurgical and chemical uses. Second, it is commonly added to steels and alloys to enhance several desired properties (such as hardenability, strength, corrosion resistance, etc.), often in synergistic effect with other alloy metals. In such cases, molybdenum could be replaced for particular effects, but at a sacrifice in overall performance. Moreover, the molybdenum content of alloy and specialty steels ranges from less than 1% to a few percent. Therefore, costs of molybdenum raw materials have to increase substantially to appreciably affect the cost of the finished product, thereby stimulating substitution. Finally, the United States is self-sufficient in molybdenum, a situation unlike that of many other ferrous metals. Significant replacement would entail increases in the imports of substituted metals.

Nevertheless, possible alternatives exist in most applications of molybdenum. Steels and alloys containing little or no molybdenum might be used in place of those with higher molybdenum content. In most cases, such substitution would result in lowered or unacceptable performance. Boron, chromium, and manganese can replace molybdenum in steels where hardenability is the only desired effect. In certain low-alloy steels, columbium, manganese, and vanadium act in similar fashion to molybdenum. Chromium, nickel, and tungsten are possible substitutes in steels and other alloys. Molybdenum has substantially replaced tungsten in high-speed tool steels; a return to tungsten grades is possible, but with a reduction in economy and performance. Nonmetallurgical materials, such as plastics and ceramics, can replace steels and alloys containing molybdenum in certain applications.

Tungsten and tantalum can be substituted for molybdenum in certain refractory metal uses, but as a cost disadvantage. Molybdenum can be replaced by graphite for refractory elements in electric furnaces in the range of 1,000° to 1,600° C, but at the expense of slightly greater difficulty in operation and control. Chrome orange, cadmium red, and organic orange pigments are possible substitutes for molybdenum orange. Acceptable substitutes for molybdenum are not found in most of its major catalytic applications. Graphite and other solid lubricants generally do not perform as well as molybdenum disulfide, especially under high-pressure and high-temperature conditions.

Economic Factors

The prices of molybdenum products are quoted on a contained-molybdenum basis and reflect, at least partially, the cost of conversion. Technical-grade oxide, the major form of molybdenum sold commercially, varies slightly in price depending on purity, type of packaging, and whether it is briquetted.

Price quotations generally fall under two groups, the producer-marketer and the merchant. The producer-marketer mines and concentrates the ore, converts the concentrates into consumer products, and markets these products, while a merchant buys and sells concentrates and may convert concentrates into products that are marketed. The source for the merchant to buy concentrates is the byproduct producer. The byproduct producer prices the byproduct as one that provides extra credit. Therefore, this type of a producer is not likely to hold back concentrates from sale. The producer-marketer tries to keep the market balanced by setting a price-based cost plus profit and varying the output to maintain a balance.

Operating Factors

Environmental Requirements.—The mining of molybdenum ore and disposal of ore tailings disturb land areas. Land reclamation is part of the ongoing mining operation. Development of new mining and milling complexes present local socioeconomic and land-use problems. Because new potentially economic sources are likely to be found in relatively unpopulated regions with little other industry, development of a major mine can have significant impact on established occupational patterns. Interaction between mining firms and local, State, and Federal agencies are required to ensure that mine development proceeds in as orderly and environmentally sound manner as possible. The conversion of molybdenite concentrate to technical-grade molybdic oxide involves roasting. Roasting facilities have been modified with sulfuric acid recovery equipment to reduce emissions and thereby comply with stringent environmental restrictions.

Toxicity.—Compared to other industrial metals, molybdenum exhibits very low, negligible toxicity. No significant toxic effects in human beings have been identified in mining or processing molybdenum materials. As an environmental trace element, molybdenum is an essential micronutrient. Deficiencies of molybdenum can affect the normal growth and development of plant and animal species.

Employment.—Employment in the past decade has been reduced by a factor of five with about the same tonnage of production. This improvement in productivity was due to changes in mining and milling equipment and methodologies.

ANNUAL REVIEW

Domestic and foreign molybdenum markets for concentrates did not change in 1993. Total domestic stock levels decreased 11% compared with those of 1992. U.S. mine output of molybdenum was about 40% of world production. Reported end-use consumption of molybdenum in raw materials increased about 3% from that of the previous year. Exports of all forms of molybdenum from the United States decreased, while imports of molybdenum increased. Domestic producer stocks of molybdenum products decreased about 18% from those of the previous year. Domestic mine production of molybdenum concentrate decreased to a total of 37,000 tons of contained molybdenum compared with 50,000 tons in 1992. World mine production of molybdenum concentrate also decreased from a total of 108,000 tons in 1992 to 95,000 tons in 1993. Canada, Chile, China, Russia, and the United States accounted for an estimated 87% of the molybdenum produced worldwide. *(See tables 1, 2, and 3.)*

Consumption and Uses

Consumption of molybdenum concentrate decreased 1,500 tons in 1993. Domestic mine production of molybdenum concentrate was either roasted, exported for conversion, or purified to lubrication-grade molybdenum disulfide. The consumption in 1993 of technical-grade molybdic oxide increased about 6% from that of the previous year. Oxide is the chief form of molybdenum utilized by industry, particularly in steel, cast iron, and superalloys. However, some of the material is also converted to other molybdenum products, such as ferromolybdenum, high-purity oxide, ammonium, and sodium molybdate, and metal powder. Apparent U.S. consumption (defined as U.S. primary plus secondary production plus imports minus exports plus adjustments for Government and industry stock changes) was about 13,000 tons of molybdenum. *(See table 4.)*

Stocks

Total industry stocks, which include those of producers and consumers, decreased about 2,500 tons of contained molybdenum. Inventories of molybdenum in concentrate at producer locations decreased about 1,200 tons. Producer stocks of molybdenum in consumer products, such as oxide, ferromolybdenum, molybdate, metal powders, and other types, decreased about 1,300 tons. Compared with apparent consumption, yearend producer stocks of these materials represented about a 16-month supply. Domestic consumer inventories of about 2,500 tons, the same amount as at yearend 1992, represented approximately a 2-month supply as measured by average monthly reported consumption. *(See table 5.)*

Prices

The average 1993 Metals Week Dealer (MWD) price of concentrate (per kilogram of contained molybdenum) was $3.752. The average MWD price of oxide was $5.130 and the average MWD price of ferromolybdenum was $7.092.

Foreign Trade

Exports of molybdenum in concentrate and of oxide decreased about 15% when compared with those of 1992. Molybdenum concentrate exports were about 67% of domestic mine production. Approximately 97% of reported shipments of concentrate and oxides were made to Belgium, Chile, France, Germany, Japan, the Netherlands, Sweden, and the United Kingdom. The calculated molybdenum content of all exports was about 31,000 tons in 1993. Total value of exports decreased from $165 million in 1992 to $108 million in 1993.

Approximately 7,200 tons of molybdenum in various forms was imported into the United States, about 4,200 tons more than that in 1992. Total value of all forms of molybdenum imported increased from $27 million in 1992 to $48 million in 1993. In terms of both value and quantity, the major form imported was ore and concentrates. *(See tables 6, 7, 8, and 9.)*

World Review

Capacity.—The rated capacity for mines and mills as of December 31, 1993, was 125,000 tons per year of contained metal. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable long-term operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure. Mine capacity for molybdenum is based on published reports, production statistics, and estimates.

Reserves.—The definitions of reserves and reserve base are published in U.S. Geological Survey Circular 831, "Principles of a Resource/Reserve Classification For Minerals," which is reprinted in the U.S. Bureau of Mines Mineral Commodity Summaries, 1991.

Estimated world reserves and reserve base of molybdenum appear in table 10. The United States, with a reserve base of molybdenum estimated at 11.8 million tons, has 45% of the world molybdenum reserve base. About 90% of U.S. reserves occur in large porphyry or disseminated deposits mined, or anticipated to be mined, primarily for molybdenum. These deposits are in Alaska, Colorado, Idaho, Nevada, New Mexico, and Utah. Other molybdenum sources contribute insignificantly to U.S. reserves.

Canadian reserves of primary molybdenum are in British Columbia, including 30% of the total in the Endako primary deposit. Other Canadian reserves are associated with molybdenum and copper-molybdenum porphyry deposits in British Columbia and in relatively minor sources in Quebec and New Brunswick.

Molybdenum reserves in Central and South America are mainly in large copper porphyry deposits. Of several such deposits in Chile, the Chuquicamata and El Teniente deposits are among the world's largest and account for 85% of total molybdenum reserves in Chile. Mexico and Peru have substantial reserves. The La Caridad deposit in Mexico is a large producer. Numerous other copper porphyries that may contain recoverable quantities of molybdenum have been identified in Central and South America. Many of these deposits are actively being explored and evaluated and could add substantially to reserves in the future.

Reserves of molybdenum in China and the former U.S.S.R. are estimated to be substantial, but definitive information about the current sources of supply or prospects for future development in the two countries is lacking. Copper ores are being investigated on the islands of New Guinea and Bougainville in the southwest Pacific, but it is not known whether these contain economically recoverable molybdenum.

OUTLOOK

The demand for molybdenum for alloy and stainless steel decreased in 1993 but is expected to remain level for the remainder of 1994 and into 1995. The demand for molybdenum for catalysts also will remain level during 1994, but will increase with the future increases in catalysts manufacturing capacity. The long-term demand depends on developments in the steel market and the ability to meet the needs of capital expenditures for environmental controls and to expand the manufacturing capacity.

NICKEL

By Peter H. Kuck

Dr. Kuck has been a physical scientist with the U.S. Bureau of Mines since 1979 and was previously responsible for iron ore, silicon, and vanadium. Domestic survey data were prepared by Barbara J. McNair, Ferrous Data Section. International data tables were prepared by Ivette E. Torres, Chief, Jeremy Tidwell, and Ronald L. Hatch, Section of International Data.

Nickel is vital to the stainless steel industry and has played a key role since the beginning of the 20th century in the development of the chemical and aerospace industries. The element (symbolized by Ni) is critical in a highly industrialized and technological society because of its myriad of applications. Nickel's greatest value is as an alloying agent with other metallic elements, adding strength and corrosion resistance over a wide range of temperatures.

Demand for nickel in the Western World recovered substantially in 1993 despite lingering recessionary forces in Japan, the United States, and Western Europe. Total demand for primary nickel in the West was about 685,000 metric tons—an all-time high, breaking the previous record of 673,000 tons set in 1990.[1] Much of the recovery was being driven by growing production and consumption of nickel-bearing stainless steel in the newly industrialized countries of Asia. Brazil and the Republic of South Africa also have become important producers of stainless steel since 1984.

Although nickel demand was strong in the West, world prices remained weak because of global oversupply and plummeting consumption in the Russian Federation. Because of the economic turmoil in Russia and the country's need for hard currencies to convert to a market economy, large tonnages of Russian nickel have been flooding Western markets since 1989. The bulk of the material is cathode produced from nickel-copper sulfide ores mined in the West Siberian Arctic or on the Kola Peninsula. The influx of Russian material accelerated in mid-1993, after slackening somewhat in 1992. This new surge of exports, coming on the back of a global recession, caused the London Metal Exchange (LME) cash price to drop below the $5,500-per-ton mark (about $2.50 per pound) in June 1993. At that point, North American producers began idling less profitable operations because of the poor price situation. Outokumpu Oy of Finland and Western Mining Corp., however, were more sanguine about the future of the nickel industry and proceeded to bring two new mines in Western Australia on-stream. On September 30, 1993, the LME cash price hit a 6-year low of $4,012 per ton ($1.820 per pound).

The nickel market improved considerably after September 1993, but prices continue to be kept in check by the large exports of Russian cathode and record-high stocks in the LME warehouse at Rotterdam. On December 31, 1993, the LME settlement price was still only $5,295 per ton ($2.402 per pound). At the end of 1993, recessionary forces in Japan and Western Europe began to weaken.

The United States produced 1.77 million metric tons of crude stainless steel in 1993, an amount slightly lower than that of 1992. Almost 67%, or 1.18 million tons, were nickel-bearing grades.[2] Production of austenitic stainless and other nickel-bearing grades was down 7% from the previous year, while ferritic production was up 9%. In contrast, U.S. imports of all grades of stainless steel jumped more than 50% between 1992 and 1993. Most of the increased tonnage came from Canada, Japan, Mexico, and Western Europe. Japan has been the largest stainless steel producer in the Western World for more than a decade. Japan produced 2.65 million tons of crude stainless in 1993, almost the same as in 1992.[3] Almost 71%, or 1.88 million tons, were hot-rolled, nickel-bearing grades.

Data reported to the U.S. Bureau of Mines (USBM) indicated that overall demand for nickel in the United States was little changed from that of 1992. Reported domestic consumption of nickel for all end uses was up about 4%.*(See table 1.)*

DOMESTIC DATA COVERAGE

The USBM tries to identify and canvass every nickel consumer who uses 2 tons or more per year. Most of the larger companies report on a monthly basis. Reports were received from 55 of the 64 facilities on the 1993 monthly canvass. An additional 148 facilities were canvassed at the end of the year. Of the 148 facilities, 125 responded, or about 84% of the second canvass. Estimates for nonrespondents were made by comparing data reported in prior years with current consumption trends. Reported primary consumption, based on data from monthly and annual canvass forms and estimates, was 86% of apparent primary consumption. *(See table 1.)*

BACKGROUND

Definitions, Grades, and Specifications

Primary nickel is normally marketed as either nickel metal, nickel oxide sinter, or ferronickel (FeNi). Commercial nickel metal is more than 99.5% pure and may be in the form of square plates, powder, briquets, pellets, ingots, disks, or shot. The square plates are referred to as "cathode" because they are cut from an electrolytic cathode sheet at the end of the refining process. The ferronickel produced in the United States contains 48% to 52% Ni and was being sold as shot or in 28-pound ingots; material produced in other countries may contain anywhere from 19% to 55% Ni. Several customers prefer the shot over the ingot because the shot is more amenable to computerized, bulk loading systems than the ingot. Commercial grades of nickel oxide sinter typically contain either 77% or 85%+ Ni. Almost all of the 85%+ grade imported into the United States comes from the Yabulu refinery of the Queensland Nickel Joint Venture (QNJV) in Australia. In 1992, Queensland Nickel improved its extraction process and is now making a new high purity product that assays 99.5% Ni.

Industry Structure

At least 23 countries mined some type of nickel ore in 1993. All but three of the 23 also had active smelters and/or refineries. An additional six countries (Austria, metropolitan France, Japan, the Republic of Korea, Taiwan, and the United Kingdom) had smelters and/or refineries that were totally dependent on imported feed.

In almost every case, the nickel came from either a laterite deposit or a sulfide deposit. Most producing companies tend to favor one of the two deposit types at the expense of the other because of significant differences in how the ores are processed. Inco Ltd. is an exception owing to the global nature of its operations. Because laterites are formed by surface water percolating downward through ultramafic rock, most laterite deposits are either in the tropics or in subtropical-to-temperate coastal regions that have a long geologic history of heavy rainfall. Sulfide deposits, on the other hand, can occur almost anywhere, ranging from central Africa to the high Arctic.

The nickel in laterite ores is usually processed into ferronickel for two reasons. First, the ores have a high iron content. Second, the ores are more easily smelted than concentrated. Sulfide ores are more amenable to concentration and hydrometallurgical refining. During the 5-year period from 1989 through 1993, laterite operations accounted for about 37% of world mine production, with the balance coming from sulfide operations. The Norilsk Nickel Combine of Russia is currently the largest producing company in the world, followed by Inco Ltd. of Canada. For 1989 through 1993, the six largest producing countries and their share of world mine production were as follows: the Commonwealth of Independent States, 29%; Canada, 20%; New Caledonia, 11%; Indonesia, 7%; Australia, 7%; and Cuba, 4%.

The Sudbury district of Ontario continues to be one of the principal sources of nickel for the world. Falconbridge Ltd. and Inco operate most of the mines in the Sudbury Basin. The bulk of the nickel at Sudbury is tied up in iron sulfides, which are intergrown, in turn, with copper sulfides. Other important nickel mining regions are the Norilsk district of central Siberia, the western half of the Kola Peninsula, and the Kambalda district of Western Australia. Like Sudbury, all three have numerous deposits of sulfide ores averaging more than 2% Ni and 1% copper (Cu).

Cuba and New Caledonia have the largest reserves of laterite. Laterites also are currently mined in Australia, Brazil, Colombia, the Dominican Republic, Greece, Indonesia, Macedonia, the Philippines, Russia, and Ukraine. The only U.S. producer in recent years has been the Glenbrook Nickel Co., which was forced to idle its laterite mine and ferronickel smelter at Riddle, OR, in August 1993. Some nickel is also produced in the United States as a byproduct of copper refining and recycling.

Geology-Resources

Nickel laterites are formed by the weathering of ultramafic rocks. As the rocks weather, nickel, iron, and sometimes cobalt, are taken into solution by descending meteoric water and redeposited at greater depth, producing a zone of enrichment. The water is initially acidic because of the presence of organic acids and dissolved carbon dioxide. As the metal-bearing water descends, it reacts with the bedrock and becomes more basic. The cobalt and iron tend to precipitate out first, forming a limonite zone that averages 0.8% to 1.5% Ni and is rich in nickeliferous goethite [(Fe,Ni)OOH]. Further down, a point is reached where the bulk of the nickel precipitates out, together with the accompanying magnesium and silica. This second zone of enrichment typically contains 1.8% to 3.5% Ni. Here, the principal ore mineral is garnierite [$(Mg>>Fe,Ni)_3Si_2O_5(OH)_4$].

Nickel sulfide deposits, on the other hand, are formed by some type of igneous or metamorphic activity, such as the intrusion of molten ultramafic rock or the alteration of the host rock by hydrothermal solutions. The principal ore minerals are pentlandite [$(Fe,Ni)_9S_8$] and nickeliferous pyrrhotite ($Fe_{1-x}S$). Millerite (NiS) is regarded as a secondary, supergene mineral at Sudbury, but also can occur as a primary mineral in some lower temperature types of deposits. Heazlewoodite (Ni_3S_2), niccolite/nickeline (NiAs), and the various linnaeite end members [$(Fe,Co,Ni)_3S_4$] are normally present in only minor amounts. At Sudbury, pentlandite and pyrrhotite are frequently associated with chalcopyrite ($CuFeS_2$) and, to a lesser degree, cubanite ($CuFe_2S_3$). As a result, copper is an important byproduct for both Falconbridge and Inco. Cobalt and platinum-group metals also are being recovered from the sulfide concentrate.

Recycling

The International Metals Reclamation Co., Inc. (INMETCO), a subsidiary of Inco United States Inc., has been operating a recycling plant for chromium and nickel at Ellwood City, PA, since 1978. Baghouse dust, mill scale, grinding swarf, and other particulate waste from stainless steel plants are blended, pelletized, mixed with a reductant, reduced in a rotary hearth furnace, and then smelted in an electric furnace. The nickel and chromium are recovered as a remelt alloy and sold back to the stainless producers.

The Pennsylvania plant was modified several years ago so that a wider variety of waste materials could be treated. INMETCO now accepts spent pickling solutions, pickling and wastewater treatment filter cakes, and chromium-bearing refractories. Spent nickel-cadmium (Ni-Cd) batteries are also processed on-site. Up until 1994, the cadmium had been recovered as a dust and sent for further treatment across the State to the zinc recycling plant operated by Horsehead Resource Development Co., Inc. at Palmerton, PA. In 1994, INMETCO began construction of its own cadmium recovery circuit and expects the facility to be operational by mid-1995.

A completely different type of plant is operated by the U.S. Filter Recovery Services, Inc. at Roseville, MN. The Minnesota plant uses a variety of hydrometallurgical and electrowinning processes to recover nickel, cadmium, and copper from scrap and ion exchange resins.

Economic Factors

Prices.—Nickel prices traditionally have been quite volatile. The time-price relationship for the metal over a 150-year span is given in the metal prices handbook published by the USBM in 1993.[4] The annual LME price has been extremely volatile since 1985, skyrocketing to $6.250 per pound in 1988 when demand for stainless was strong, and then collapsing to $2.401 in 1993 after large amounts of Russian cathode began appearing in Western warehouses. *(See figure 1.)*

Costs.—Several significant factors determine the cost of producing nickel. They include the type and nickel content of the ore, the mining method, transportation, infrastructure, energy prices, labor and materials, regulatory compliance, and credits from recoverable byproducts.

Generally, nickel can be recovered from sulfide ores at a lower cost than from laterite ores because sulfides are more readily concentrated using established mineral dressing methods. On the other hand, virtually all of the laterite deposits are open pit operations and, therefore, less costly to mine. Most sulfide deposits occur at considerable depth and have to be mined from underground drifts. Shaft sinking, timbering, roof bolting, lighting, ventilation, and pumping all drive up costs.

Exploration and initial development costs for the two types of deposits are also quite different. Exploring and drilling for sulfides is much more expensive than for laterites. Subsurface samples can be obtained from most laterite deposits using an auger because the rock formations are extensively weathered. Sulfide deposits occur in much harder rock and must be diamond- or rotary-drilled, a more costly and time consuming operation.

Sulfide deposits are also harder to locate, driving up drilling costs even more. The sparsity of massive, primary sulfide deposits at the surface is understandable. Many sulfide minerals readily oxidize to sulfates when exposed to air for an extended period of time. Sulfuric acid forms when copious amounts of water are present, accelerating the oxidation process. Discovery of a near-surface nickel sulfide deposit can be difficult because a subeconomic laterite deposit can be mistaken for the leached and heavily oxidized gossan capping a sulfide target. A limited outcrop of gossan created by the oxidation of sulfides can be easily mistaken for other types of gossan, and vice versa. The presence of a gossan does not necessarily mean unaltered sulfides exist at depth. Even if the gossan is correctly identified, it may only overlie a much poorer fringe of the ore body.

Energy consumption is the most significant cost in recovering nickel from laterite ores. Estimates indicate that for every $1 increase in the price of a barrel of crude oil, there is a corresponding increase of $0.05 per pound of nickel produced at operations that are dependent on oil for both drying and smelting. It does not seem to matter much whether the laterite ore is converted to ferronickel or to matte. Sulfide ores, on the other hand, do not have to be dried, and, unlike laterite ores, are more amenable to concentration.

Byproduct revenues can significantly reduce net production costs. Smelters that convert laterite ores to ferronickel produce only slag, iron, and occasionally electrical power as byproducts. The few plants that chemically leach laterite ores typically recover significant amounts of cobalt along with the nickel. In contrast, sulfide operations generate revenues not only from the recovery of byproduct cobalt, but also copper and precious metals. The Sudbury nickel deposits are an important source of both platinum and palladium. The principal platinum mineral is sperrylite, $PtAs_2$, while much of the palladium is tied up in bismuthides and bismuth tellurides. Some sulfide facilities also profit from the sale of byproduct liquid sulfur dioxide and sulfuric acid.

The costs of complying with air pollution control regulations can be significant. Dust generated in the processing of laterite ores can be controlled using relatively inexpensive equipment. In contrast, a large capital investment is required to reduce sulfur dioxide emissions from a smelter processing nickel-copper sulfide concentrates. Nickel smelters have a much higher sulfur burden than their copper and zinc counterparts. As a rule of thumb, 1 ton of sulfur is generated for each ton of copper produced. In contrast, 8 tons of sulfur is generated for each ton of nickel. During the past 10 years, Inco has allocated 12% of its total capital expenditures to attain compliance with Canadian regulations limiting sulfur dioxide emissions.

Operating Factors

Environmental Issues.—The principal environmental problem associated with nickel production is the emission of sulfur dioxide (SO_2) from smelters that process sulfide ores. The SO_2 emitted from smelter smokestacks combines with water in the atmosphere to form droplets of sulfuric acid (H_2SO_4), a major component of acid rain. In 1985, the Provincial Government of Ontario ordered Inco to reduce SO_2 emissions at its Sudbury complex from 685,000 tons per year to no more than 265,000 tons per year. Since then, the company has spent $530 million on state-of-the-art pollution control equipment to meet the new limit. The sulfur dioxide abatement project was completed in late 1993, in time to meet the Provincial Government's deadline of January 1, 1994. Inco now captures more than 90% of the sulfur in its Sudbury ores. *(See Canada section of this report.)*

The Provincial Government gave Falconbridge a similar ultimatum. Falconbridge had to reduce its SO_2 emissions from 154,000 tons per year to 100,000 tons per year by 1994. Like Inco, the company spent millions of dollars complying with the Provincial order. In 1993, Falconbridge succeeded in lowering its emission rate to 57,000 tons per year.

Recent environmental legislation and other responses to environmental concerns are expected to significantly affect future nickel consumption. In some cases, the effect will be positive; in others, negative.

In November 1990, the Congress amended the Clean Air Act (CAA), updating Federal air pollution standards for the first time since 1977 and completely overhauling the hazardous air pollutants program. The amendments (Public Law 101-549), among other things, put controls on airborne emissions of nickel metal, its compounds, and alloys. Nickel compounds were specifically included in the new list of 189 hazardous air pollutants to be regulated.

The law also directed the U.S. Environmental Protection Agency (EPA) to develop an initial list of pollution source categories that warranted regulation. Because of the magnitude and complexity of the problem, it took EPA more than 2 years to develop the list and reply to the 140 comments received from public and private interests. The list was finally published in the Federal Register on July 16, 1992.[5] A number of nickel consumers appeared on the July list, including integrated steel mills, electric arc furnace operations, iron and steel foundries, and ferroalloy production facilities. A draft schedule for promulgating emission standards for each of the initial 174 source categories was published in the Federal Register on September 24, 1992, as part of the 10-year phase-in of CAA regulations.

Because many facilities will need new pollution control equipment to comply with these standards, the enactment of the Clean Air Act Amendments is expected to increase demand for stainless steel and other alloys of nickel. Under the new law, 111 fossil fuel-fired powerplants must reduce their SO_2 emissions by 1995. This particular section of the law was enacted to help control acid rain. The 111 plants—a total of 251 generating units—were specifically targeted because each emits more than 2.5 pounds of SO_2 per million British thermal units. Some plants will be able to reduce SO_2 emissions by simply switching to fuels that contain lower levels of sulfur; others, though, will be forced to install scrubbers (flue gas desulfurization units).

Because it is far cheaper and easier to include scrubbers in the design of a new powerplant than to retrofit an existing facility, most plants in the near-future will be equipped with some type of scrubbing system. Roughly 100 tons of corrosion-resistant alloy will be required for each scrubber. Although it is not clear which alloy will be used, many of the more promising candidates contain significant amounts of nickel, which improves the resistance of the alloy to corrosion and heat. A significant amount of stainless will also go into turbines for the new powerplants.

Toxicity.—Zero exposure to nickel is impossible and undesirable. Studies have shown that nickel is an essential element in a variety of cellular organisms, animals, and plants.[6] Nickel may also be an essential element for humans, but more research is needed on the subject. Some non-prescription multivitamins contain as much as 5 micrograms of nickel per tablet. Studies to date indicate that inhalation is the most important route of nickel intake in the workplace. Dermal exposure and ingestion are also important, but of lesser concern.

The American Conference of Governmental Industrial Hygienists (ACGIH) postponed action until 1995 on a proposal to set more stringent workplace limits for nickel and its compounds. The ACGIH had proposed reducing its recommended workplace limits, or threshold limit values (TLV's), for nickel metal and all nickel compounds to 0.05 milligrams per cubic meter (mg/m^3) of air . The proposal also called for nickel metal and all inorganic nickel compounds to be designated "confirmed human carcinogens." The Nickel Producers Environmental Research Association (NiPERA), among others, had urged the ACGIH not to reduce the existing TLV's until new evidence, now being gathered, could be properly evaluated. The 8-hour TLV is currently set at 1.0 mg/m^3 for insoluble forms of nickel (e.g., NiO) and 0.1 mg/m^3 for water-soluble forms of nickel (e.g., $NiSO_4$). ACGIH guidelines are important because the U.S. Occupational Safety and Health Administration (OSHA) and regulatory agencies in other countries weigh them carefully in determining mandatory permissible exposure limits for the workplace.

OSHA has specified eight-hour Time Weighted Average Permissible Exposure Limits (PELs) for more than 400 substances, including nickel and its compounds. In March 1993, after almost 4 years of litigation that involved reviews by both the U.S. Eleventh Circuit Court of Appeals and the U.S. Supreme Court, the PEL for water-soluble nickel compounds was set at 1.0 mg Ni/m^3. Nickel metal and insoluble nickel compounds also have a PEL of 1.0 mg Ni/m^3. Nickel carbonyl was singled out because of its extreme toxicity and has a

PEL of only 0.007 mg Ni/m^3.

In 1991, the United Nations published indepth environmental health criteria for nickel, together with a companion health and safety guide on nickel metal, nickel carbonyl, and selected nickel compounds.[7] The 383-page report was prepared as part of the International Program on Chemical Safety (IPCS). The principal conclusions are summarized below:

> "Although some, and perhaps all, forms of nickel may be carcinogenic, there is little or no detectable risk in most sectors of the nickel industry at current exposure levels; this includes some processes that were associated, in the past, with very high lung and nasal cancer risks. Long-term exposure to soluble nickel at concentrations of the order of 1 mg/m^3 may cause a marked increase in the relative risk of lung cancer, but the relative risk among workers exposed to average metallic nickel levels of about 0.5 mg/m^3 is approximately 1...."

In May 1994, NiPERA and the Nickel Development Institute (NiDI) published their own health guide, entitled "Safe Use of Nickel in the Workplace."[8] The 65-page report was written primarily for plant managers and individuals in the medical community who are responsible for the health and safety of personnel exposed routinely in the workplace to nickel or nickel-containing substances. A variety of topics are covered, including pharmacokinetics, toxicity, biological monitoring, air monitoring, and control measures that can be taken to prevent overexposure. The guide also compares occupational exposure limits established by the United States with those of Canada, Germany, and the United Kingdom.

Energy Requirements.—As mentioned earlier, energy costs are much more critical for laterite operations than for sulfide operations. Laterite ores are typically smelted in direct-arc furnaces having power ratings on the order of 20 to 40 megawatts (MW). Glenbrook Nickel, for example, has four 24-MW furnaces. Power is provided by the Bonneville Power Administration, a hydroelectric-based utility.

Glenbrook has been smelting the laterite by the Ugine Process. The process is not only power intensive, but also requires the addition of ferrosilicon—a source of chemical energy. This chemical energy is transferred to the molten ferronickel when the ferrosilicon is converted to slag.

The ferrosilicon can be produced onsite in a similar submerged arc furnace by reacting lumps of quartzite with shredded steel scrap and a carbon-rich reductant, such as coke. Electrical power consumption is the principal cost in producing ferrosilicon. Ferrosilicon and silicon metal are the most power intensive of the bulk ferroalloys, requiring 8,500 to 14,000 kilowatt hours of electrical energy per ton of contained silicon.

ANNUAL REVIEW

Legislation and Government Programs

On March 24, 1993, the Defense Logistics Agency (DLA) began selling nickel from the National Defense Stockpile (NDS). The Government had 33,760 tons of nickel in inventory when the sales started. The bulk of the material was purchased during the Korean War or the 5-year period immediately following the war. All 33,760 tons was cathode except for 399 tons contained in 520 tons of oxide of Cuban origin. The cathode sheets ranged in size from 30 by 64 centimeters to 64 by 91 centimeters. The fine-grained oxide powder averaged about 76% Ni with less than 0.74% cobalt and 0.21% iron. Until the end of 1992, the Federal Government had a stockpile goal of 181,437 tons.

Legislation supporting the disposal was signed into law by the President on October 23, 1992. (Title XXXIII of Public Law 102-484: The Defense Authorization Act of 1992). The current annual materials plan allows the Defense National Stockpile Center (DNSC) to continue selling a maximum of 9,072 tons per year (10,000 short tons) of nickel through September 30, 1995. When the disposal program was presented for comment at the beginning of 1993, several nickel producers were concerned that the long-term selloff would unduly disrupt an already weakened North American market. A twice-monthly auction schedule was adopted to ease their concerns, with only about 270 tons (300 short tons) being offered at each auction. Sealed bids were being solicited on the second and fourth Thursdays of each month. The auctions are scheduled to run for at least 4 more years. All of the nickel is being sold on an as-is basis.

The DNSC sold 2,209 tons of cathode in 1993, leaving a total of 31,551 tons of nickel in inventory at yearend. An additional 4,325 tons of cathode was auctioned off during the first 9 months of 1994.

On February 8, 1994, the U.S. Department of the Treasury lifted all restrictions on the importation of unfabricated nickel and nickel-bearing materials from the former Union of Soviet Socialist Republics. The restrictions had been in effect since 1983 to prevent Cuban nickel from reaching the United States in violation of the U.S. embargo on trade with the island republic. A complete ban was originally imposed on November 23, 1983, after the U.S. Government received information indicating that nickel feedstocks of Cuban origin were being processed in the Urals together with local material and later exported as Russian metal. Enforcement of the 1983 ban was tempered in 1990 following an exchange of letters between the U.S. and Soviet Governments.

The Treasury action also terminated administrative procedures established in 1990 that permitted some nickel refined at Norilsk and Monchegorsk to enter the United States. Under the terms of the 1990 agreement, the nickel had to be produced solely from Russian ores. In addition, each shipment had to be accompanied by a special certificate of origin issued by VVO Raznoimport, the former Soviet state trading organization.[9] Importation of Cuban nickel into the United States is still prohibited under the Cuban Assets Control Regulations, 31

CFR part 515. *(See Issues section of this report.)*

For the first time, the U.S. Mint began using small quantities of recycled nickel that had been toll processed in Russia. In November 1993, the Mint bought 36 tons of the recycled metal from Sovereign Recycling International, Inc. of Bettendorf, IA, for about $167,000. The material was recovered from superalloy scrap exported from the United States earlier in the year. The scrap was shipped from Norfolk, VA, through Murmansk to the Severonikel Refinery at Monchegorsk.

Strategic Considerations

Nickel is an essential ingredient in austenitic stainless steel and superalloys. As such, its availability is important to the national security. Domestic mine capacity was less than 13% of primary apparent consumption in 1993. Canada, however, a close ally and a geographically secure source, is capable of supplying U.S. needs under normal circumstances.

Issues

The U.S. Department of the Treasury continued to ban the importation of nickel and nickel-containing materials from Cuba. The ban has been in effect since 1962. In the past, more than two-thirds of the mixed nickel-cobalt oxide sinter from the Nicaro and Punta Gorda plants was exported to Europe. The mixed nickel-cobalt sulfide precipitate from the Pedro Sotto Alta smelter at Moa was shipped directly to refineries in the Ural Mountains of the former U.S.S.R.

Since 1991, however, a significant amount of Cuban material has been going to Sherritt's refinery in Alberta, Canada. Canadian import statistics show that Sherritt received 22,366 tons (gross weight) of nickel oxide sinter from Cuba in 1993, significantly more than the 19,957 tons shipped in 1992. In recent months, the Government of Cuba has strengthened its ties with Sherritt and agreed in principle to form a joint venture with the Canadian producer. *(See Cuba section of this report.)*

In June 1993, the Government of Cuba indicated that it might consider compensating the former owners of the nickel mines and plants that were nationalized in October 1960. The Cuban proposal, if followed up, would remove a major stumbling block to improving United States-Cuban relations. The original nickel plant at Nicaro was built by the United States Government in 1943 to obtain nickel oxide for the war against Germany and Japan. The plant was upgraded by the General Services Administration in 1951-52 as part of the Korean War effort. The plant built at Moa Bay by the Freeport Nickel Co. between 1957 and 1959 also was partly financed by the U.S. Government.

Production

Glenbrook Nickel Co., the only domestic nickel producer, halted mining and smelting operations at its Riddle, OR, complex because of low nickel prices and higher operating costs. On August 10, 1993, Glenbrook shut down both its Riddle smelter and Coos Bay port facility for an indefinite period. The action was taken primarily in response to weakening ferronickel prices and large exports of cathode from Russia to the West. However, the sharp rate increase proposed by the Bonneville Power Administration also influenced the company's decision. The proposed power rate increase would have significantly raised Glenbrook's production costs. The company was hurt further by a U.S. International Trade Commission antidumping ruling in March 1993 that made the importation of ferrosilicon more expensive.

In 1992, Glenbrook upgraded the capacity of the Riddle smelter from 11,000 tons per year of contained Ni in FeNi to 16,300 tons per year. The additional feed requirements were met by importing garnierite ore averaging 2.2% to 2.4% Ni from New Caledonia. The ore was being supplied by Société Minière du Sud Pacifique, which has mines on the main island at Ouaco, Nakety, and Boakaine. Feasibility studies had shown that it was cheaper to buy and ship ore from New Caledonia than to expand the mine on Nickel Mountain. The ore from Nickel Mountain had been averaging only 1.18% Ni. A little-used dock area at Coos Bay was purchased and rehabilitated to receive and temporarily store the imported laterite before trucking it to Riddle. Ore handling facilities, a crushing plant, and a dryer were constructed at dockside to remove the bulk of the water in the crude ore prior to transshipment.

In 1993, Glenbrook mined only 187,000 tons (dry basis) of usable ore containing 2,464 tons of Ni. The ore received from New Caledonia contained an additional 2,966 tons of Ni. From the two feedstocks, the company was able to produce 4,878 tons of Ni contained in ferronickel.[10] Because new shot casting equipment was purchased when the smelter was upgraded, Glenbrook can now make 6-millimeter (1/4-inch) shot in addition to the 28-pound ingots already being produced.

More than 250 employees were affected by the August 1993 shutdown. The company had been forced to take similar action only a few months earlier, idling operations from December 20, 1992, to February 22, 1993. At that time, the LME cash price ranged between $2.60 and $2.87 per pound. When Glenbrook resumed production in March, the price was still averaging about $2.70 per pound but was under intense pressure because of the global oversupply situation. By the end of June, the price had fallen below $2.50 and was rapidly collapsing. When Glenbrook shut down, it had sufficient stocks of ferronickel on hand to meet sales commitments for the remainder of 1993.

Consumption and Uses

Demand for primary nickel in the Western World recovered substantially in 1993 and was estimated to be about 685,000 tons—an all time high. The tonnage was about 2% more than the previous record of 673,000 tons set in 1990. U.S. apparent consumption of primary nickel was 122,000 tons, or about 18% of Western demand. U.S. industry consumed an additional 55,000 tons of nickel in scrap. Both U.S. and world demand continued to be driven by the stainless steel industry, which accounted for 44% of primary nickel demand in the United States and almost 60% of equivalent world demand. *(See tables 2 through 4 and figure 2.)*

Production of raw stainless and heat-resisting steel in the United States slipped slightly to 1.77 million metric tons and was 3% less than the corresponding figure for 1992.[11] Nickel-bearing grades accounted for 67% of the production tonnage. Net shipments of all types of stainless totaled 1.391 million tons. Shipments of sheets and strip rose 3% to 981,677 tons, breaking the record of 954,483 tons just set in 1992. This category has been steadily increasing since 1989. The next largest category was plate (flat product 4.8 millimeter [3/16 inch] or more in thickness). Shipments of plate were 176,623 tons, a 12% jump from that of 1992. Together, plate and sheet accounted for 83% of total net shipments, compared with 81% in 1992.

Stainless steel sheet is used in the manufacture of a wide range of consumer products, including household appliances, kitchen facilities, machinery, and medical equipment. In the past, automotive trim was an important end use for sheet, but aluminum and plastics have captured much of that market. Plate is primarily used in the fabrication of chemical reaction vessels and similar heavy-duty industrial equipment. The chemical, food and beverage, petrochemical, pharmaceutical, pulp and paper, and textile industries are all large consumers of stainless plate.

Since 1991, major restructuring, adoption of more efficient work practices, and the introduction of new technology have improved the competitiveness of the U.S. stainless and specialty steel industry. Three key mergers of stainless steel producers occurred between early 1992 and yearend 1993. In April 1992, Armco, Inc. acquired Cyclops Industries, Inc., dramatically increasing Armco's stainless steel finishing capabilities. That same month, Lukens, Inc. bought Washington Steel Corp., a major producer of stainless steel sheet. Finally, on November 10, 1993, Allegheny Ludlum Corp. bought Athlone Industries, Inc., the parent of Jessop Steel Co., for about $107 million. Jessop Steel is an important producer of stainless and alloy plate, with sizeable facilities at Washington, PA.[12]

Armco and Cyclops consolidated their melting operations shortly after merging and made Armco's state-of-the-art shop at Butler, PA, the principal melting and casting facility for the new company. The old Armco had already spent $13 million upgrading the Butler melt shop in 1991. This allowed management to close three older melt shops: one at the Cyclops plant in Bridgeville, PA; one at Armco's Baltimore Specialty Steels Corp. in Baltimore, MD; and one at Armco's Eastern Stainless subsidiary in Baltimore.

Shortly after Lukens acquired Washington Steel, Lukens announced that it would install a vacuum oxygen decarburization (VOD) unit at its melt shop in Coatesville, PA, and begin producing stainless steel. Although Lukens, a plate producer, has had a long history of rolling and finishing stainless on a tolling basis for other companies, it has not been a melter of stainless steel.

In 1993, U.S. consumption of primary nickel in superalloys increased 2%, despite problems in the aerospace industry. Sales by the aerospace industry fell 10% to $124 billion.[13] Combined aircraft and missile purchases by the U.S. Department of Defense declined for the sixth consecutive year. Purchases of civil aircraft, engines, and parts by commercial airlines and foreign governments were down 20%. Jet engine manufacturers, significant consumers of nickel-chromium-cobalt and nickel-chromium-iron alloys, were hard pressed and working aggressively to cut costs. The Boeing Co. and McDonnell Douglas Corp. continued to work off a backlog of orders received between 1988 and 1990 for civil jet transport. However, only 236 new orders for aircraft were received in 1993, compared with 670 in 1990 and 1,015 in 1989.

In August 1993, Eveready Battery Co., the world's largest manufacturer of household batteries, purchased the nickel-based rechargeable battery operations of Gates Energy Products Inc. Terms of the sale were not disclosed. The former Gates division offered a full line of nickel-cadmium (NiCd) batteries and was expanding its rechargeable nickel-metal hydride (NiMH) production facilities. The sale included Gates' main NiCd manufacturing plant at Gainesville, FL; a battery assembly plant in Juarez, Mexico; and at least three other facilities. Eveready's new division is now called Energizer Power Systems.[14]

This was Eveready's first serious entry into the NiCd market. Until then, Eveready had focused on the alkaline, carbon zinc, and zinc air segments of the battery business. Eveready is a wholly owned subsidiary of the Ralston Purina Co. and operates 43 plants worldwide. The St. Louis, MO-based food company bought Eveready from the Union Carbide Corp. in 1986 for $1.42 billion.

Reported nickel consumption statistics were revised for 1985 through 1992. The corrected annual data for 1989 through 1992 are shown in tables 1, 3, and 4.

Stocks

The combined stocks of primary nickel maintained in the United States by foreign producers and metal-trading companies with U.S. sales offices jumped 53% during the year. At yearend, these stocks represented 46 days of apparent primary consumption. *(See table 5.)*

Markets and Prices

Nickel supply exceeded demand in 1993, depressing world prices for the metal. The average LME cash price for the year was $5,293.419 per metric ton, which equates to $2.401 per pound. In terms of current dollars, this represented a drop of 24% from the 1992 average of $7,001.227 per ton ($3.166 per pound). The principal reasons for the weakening of the nickel price were associated with the deterioration of the Russian economy. Stainless steel production in Russia and the rest of the former Soviet Union had plummeted since 1991. The drop in Russian stainless production, coupled with the collapse of the ruble, encouraged the Norilsk Nickel Combine to export the bulk of its production to the West. This, in turn, led to a large buildup of stocks of nickel cathode and powder in the LME warehouses at Rotterdam. The price collapse would have been far worse if production of stainless steel in the Western World had not reached a record high of 11.6 million tons. Brazil, Canada, the Republic of Korea, the Republic of South Africa, and several countries in Western Europe all reported record production of stainless.

LME stocks continued their precipitous climb, rising from 67,914 tons on December 21, 1992, to 124,104 tons on December 31, 1993. Stocks kept growing until April 5, 1994, when they peaked at 137,010 tons. Of the 137,010 tons, 131,622 tons or 96% were in the form of cut cathodes. The remaining 4% consisted of briquettes and a limited amount of pellets. Most of the nickel was being stored in Rotterdam, even though the LME has 18 authorized warehouse sites scattered around the world.

Nickel prices lost considerable ground between early 1989 and yearend 1993. The weekly LME cash price began 1993 at $5,815 per ton ($2.638 per pound) and stayed at that level, with only minor fluctuations, until mid-May. On May 21, however, the weekly average dropped to $5,600 per ton ($2.540 per pound) and began to slowly deteriorate. On September 30, the daily cash price hit a 6-year low of $4,012 per ton ($1.820 per pound). Market conditions improved somewhat in the fourth quarter, causing prices to partially recover. The last weekly price (for the week ending December 31) was $5,328 per ton ($2.417 per pound).

Foreign Trade

U.S. net import reliance as a percentage of apparent consumption was 63% in 1993. The figure was slightly higher than the 1992 percentage because of decreased ferronickel production in Oregon and a 7% increase in imports of cathode. Imports accounted for about 98% of primary supply in 1993 if Government stockpile sales are excluded. Canada, as usual, supplied most of the imported material. A significant part of the nickel imported from Norway, the second largest source, was also of Canadian origin.

U.S. imports of Russian cathode jumped 96% between 1992 and 1993. According to the U.S. Bureau of the Census, the United States imported 6,629 tons of cathode and 36 tons of powder and/or flake directly from Russia in 1993. Importers also brought in 21 tons of Russian nickel contained in ferronickel and 30 tons contained in primary chemicals. These figures do not include material that may have been recovered in Norway from Russian matte and later exported to the United States. No primary material was reported from the Ukraine—only stainless steel scrap.

The relatively high level of demand for primary nickel in the United States also has meant high demand for nickel-bearing scrap. U.S. exports of stainless steel scrap remained strong in spite of weakening prices. Exported stainless scrap contained an estimated 17,407 tons of Ni, an almost identical amount to that of 1992. These figures are based on the assumption that stainless scrap has been averaging 7.5% Ni since 1989, when the changeover to the Harmonized Tariff System took effect.[15] *(See tables 6 through 9 and figure 3.)*

World Review

On April 23, 1993, the International Nickel Study Group (INSG) held its third general session at The Hague, The Netherlands. The INSG has two primary functions. The first is to provide transparency to the nickel market by gathering, collating, and publishing international statistical data. The second is to provide an intergovernmental forum for discussion of issues of concern to both nickel-producing and nickel-consuming countries. In conjunction with the April meeting, the INSG published a directory of world nickel production facilities and on-going development projects. The directory proved to be popular and is currently being updated.[16] The international organization also publishes a monthly statistical bulletin, with annual data for 1983 and subsequent years appearing in the October issue.

Australia.—Western Mining Corp. Holdings Ltd. (WMC), one of the four largest nickel producers in the Western World, continued to expand production capacity. If the expansion and upgrading program stays on schedule, the company will be able to produce 90,000 tons per year of contained nickel by mid-1995. In the fiscal year ending June 30, 1993, WMC's mining operations in Western Australia produced 52,705 tons of Ni in concentrate. The Kambalda operation accounted for 32,107 tons, or 61%, of the 52,705 tons. The Kambalda concentrator treated 1.12 million tons of sulfide ore averaging 3.07% Ni, recovering about 93% of the nickel in the process. The remaining 20,598 tons of Ni came from the Leinster operation, which treated 1.06 million tons of ore averaging 2.38% Ni. The Leinster concentrator was enlarged in 1992-93 and can now handle 2 million tons of ore per year. The expansion required construction of a new primary crushing plant as well as the installation of a new grinding mill, more flotation cells, and a new flash dryer.[17]

In early 1993, WMC decided to develop the huge Mount Keith deposit by itself. On February 22, 1993, the company's board of directors announced that it was buying back the 50% interest in the Western Australian deposit held by Outokumpu. The Finnish nickel producer bought the 50% interest from WMC in June 1992, but wound up in the midst of a major restructuring and had to focus on the startup of its new Forrestania Mine, near Lake King, southwest of Kalgoorlie. Although Outokumpu decided not to participate in the A$440 million (US$320 million) project, it agreed to purchase half of Mount Keith's annual output for the first 10 years of operation. Outokumpu's share was to be about

14,000 tons per year of Ni contained in concentrate. The Finnish producer planned to use funds from the Mount Keith sale to expand and modernize its Harjavalta smelter in Turku ja Pori province.

Development of the Mount Keith Mine was expected to take about 2 years. The complex will be one of the largest metal mines in Australia. WMC plans to extract 210 million tons of low-grade sulfide ore, averaging 0.58% Ni, from the deposit over the next 20 years. Although the ore is considered low grade in terms of its Ni content, it is also low in sulfur-rich pyrrhotite. Less pyrrhotite in the concentrate translates directly into lower emissions of SO_2 at the smelter and, thus, lower smelting costs. Construction crews have been onsite since March 1993. The principal contractor is Leighton Holdings Ltd., a construction and civil engineering company based in New South Wales. About 700 workers were employed on the project in mid-1994. However, after commissioning, the mining complex will need only 250 employees to operate.

Removal of overburden began in June 1993 and was ahead of schedule. Construction of the onsite concentrator started at about the same time, with commissioning tentatively scheduled for January 1995. The concentrator will be capable of processing 18,000 tons of sulfide ore per day, or about 6.6 million tons per year. This equates to a production level of about 28,000 tons per year of Ni in concentrate. Leinster, 90 km to the southeast, was serving as a base for the operation. About 120 houses were being built at Leinster at a cost of US$14 million. Mount Keith was to have its own diesel-operated power station because of the remoteness of the site. In April 1994, the open pit was about 60 meters (m) deep, and 45% of the plant and infrastructure was in place.[18]

In November 1993, WMC completed the expansion and upgrading of its smelter at Kalgoorlie. The smelter can now treat at least 80,000 tons per year of Ni in concentrate, up from 54,000 tons per year. A new, 525-ton-per-day oxygen plant was built as part of the upgrading. Kalgoorlie has a flash furnace that has operated almost continuously since its commissioning in 1978. The smelter was shut down on September 8 for 2 months so that the furnace could be rebuilt. The facility can treat limited amounts of high-grade nickel sulfide ores in addition to conventional concentrate.

Outokumpu Metals & Resources Oy (OMR) officially commissioned its new Forrestania Mine on January 14, 1993. The A$100 million mine is about 170 km south-southeast of Southern Cross. The mine is currently producing about 8,600 tons per year of Ni in concentrates from sulfide ore that assays between 1.7% and 2.3% Ni. All of the concentrates are being shipped to OMR's Harjavalta smelter in Finland.

The Government of Western Australia approved the construction of a 1,400-km-long natural gas pipeline from the northwest coast through the Pilbara to the Goldfields region and the nickel smelter at Kalgoorlie.[19] On March 23, 1994, the Premier of Western Australia signed an agreement with the Goldfields Gas Transmission Joint Venture (GGTJV), setting conditions for non-discriminatory third-party access to the gas and establishing key design parameters. The pipeline agreement was ratified by the Western Australian parliament shortly afterward and was awaiting Royal Assent at the end of April 1994.

The joint venture was composed of WMC, Wesminco Oil Pty. Ltd. (a wholly owned WMC subsidiary), BHP Minerals Pty. Ltd., Normandy Poseidon Ltd., and Normandy Pipelines Pty. Ltd. Feasibility studies, environmental assessments, and community consultations were all underway. Construction could begin as early as 1995 if all of the studies are successful. Most of the gas would come from the offshore Griffin or North Rankin gas fields on the North West Shelf. However, some could also come from the onshore Tubridgi field.

The Government and consortium were hoping that the A$400 million pipeline would stimulate additional investment in the region's mining industry and encourage owners of existing mines along the route to build downstream processing facilities that would add value to their products. Some of the gas would be used to fuel a new power generation station near Kalgoorlie, replacing more expensive electricity currently being transmitted from Perth. Part of the remaining gas would be available for mineral extraction and processing. Cheaper energy could spur development of Bulong, Anaconda, and several other nickel laterite deposits.[20] Some of the gas could also be used for a 2-million-ton-per year direct-reduced iron plant proposed for the Pilbara.

The Queensland Nickel Joint Venture halted production at its Greenvale Mine on the eastern slope of the Great Dividing Range in October 1992 and now relies heavily on imports for its lateritic feed. The company imported 16,617 tons of Ni in lateritic ore from New Caledonia in 1993. An additional 9,776 tons of Ni in ore came from Gebe Island in Indonesia.[21] The material was being converted to nickel oxide (90%+ Ni) at the company's Yabulu hydrometallurgical refinery at Townsville. Queensland Nickel also shipped a limited amount of ore from its Brolga Mine at Yaamba, part way between Townsville and Brisbane.

Brazil.—Comphania Niquel Tocantins has doubled the capacity of its nickel-cobalt refinery at Sâo Miquel Paulista in the State of Sâo Paulo. The project had been on hold for several years. Tocantins is the only producer of electrolytic nickel in Latin America. The expansion cost $25 million and was completed at the end of 1993.[22] When all of the upgrading is finished, the plant will be able to produce 10,000 tons per year of cut cathode.

Nickel-cobalt carbonate feed for the plant comes from the company's Niquelândia mining, roasting, and ammonia leaching operations at Acampamento in the State of Goiás. In 1992, Tocantins spent about $110 million to increase the capacity of the carbonate plant from 10,000 tons per year to 20,000 tons per year. The laterite ore being mined at Niquelândia runs 1.4% Ni and 0.14% Co.

Canada.—In the fourth quarter of 1992, Inco began reducing nickel production and curtailing capital expenditures because of declining nickel prices. When prices continued to fall in early 1993, the company intensified its cost control measures. Inco kept its Canadian operations shut down for 3 weeks at the beginning of 1993 and extended its annual summer shutdown to 4 weeks. As a result of the two shutdowns, Inco's Canadian operations produced only 132,000 tons of finished nickel in 1993, down from 147,000 tons in 1992. Similar shutdowns overseas caused the company's total production of finished nickel to drop from 182,000 tons to 167,000 tons.[23] In October 1993, Inco announced that it would cut back production even further in 1994 because of the deteriorating market situation. The company made plans to reduce output by 27,000 tons of nickel over the 8-month period between December 1993 and July 1994.

The shutdowns and other measures were designed to conserve cash during a period of rising operating costs and lower realized prices for nickel. Inco's unit production costs at its Canadian operations almost doubled between 1987 and 1991 as a result of declining ore grades, higher labor costs, and the strengthening of the Canadian dollar against the U.S. dollar. The salaries of all corporate officers were cut by 10% in November 1992, and hiring had been frozen for some time. Planned capital expenditures for 1993 were reduced from $225 million to $186 million, and similar constraints were to be imposed in 1994. Technological improvements, workforce reductions, and the opening of several new mines have increased productivity by 18% since 1991, but declining ore grades remain a problem. The average ore grade for the Ontario mines declined from 1.28% to 1.23% Ni between 1992 and 1993. The ore grade for the Manitoba mines declined even more, dropping 7% from 2.62% to 2.43% Ni.[24]

Inco's Ontario Division had only 11 mines operating in 1993. The Shebandowan Mine and four others were kept on standby. The entire Ontario division had about 7,200 employees. The Manitoba Division had two underground mines and two open pits in operation, but the two open pits were almost depleted. Inco also had four mines in Manitoba on standby.

The Ontario Division began recovering ore from its new Lower Coleman Mine in early 1993. The Division also reopened the old Garson Mine at an initial capital cost of $32 million. The Garson Mine was closed in 1986 after a serious rockfall. Advanced mining methods were being used to overcome bad ground conditions that existed in parts of the mine. The Garson Mine has some of the richest nickel-copper ore in the Sudbury Basin and is scheduled to produce 1,800 tons of ore per day after it reaches full production in late 1995.

Inco also had three other mining projects under development—McCreedy East at Sudbury, and the Birchtree and Thompson 1-D in Manitoba. Future production from these projects will be needed to offset declining reserves at some of the older, higher-cost mines in the Sudbury region. Mining was recently suspended at the Levack Mine, and reserves at the McCreedy West and Frood are being rapidly depleted.[25]

Despite all of its market problems, Inco's management remained optimistic about the future. The company's $530 million sulfur dioxide abatement project at Sudbury was completed on time to meet the Provincial Government's January 1, 1994 deadline. SO_2 emissions from the smelter complex have been successfully reduced to less than 265,000 tons per year, down from 2,250,000 tons in 1965. This achievement is quite remarkable and represents the largest tonnage reduction in SO_2 emissions to date from any single source point in North America. Inco now recovers more than 90% of the sulfur in its concentrates.

Three major changes were made to the Sudbury operation. In 1991, the company increased the capacity of its Clarabelle mill and modernized the facility so that it would reject increased amounts of pyrrhotite from the concentrate prior to smelting. Then, the existing reverberatory furnaces at the Copper Cliff smelter were replaced by two oxygen flash furnaces that can smelt bulk copper-nickel concentrates. The first flash furnace was completed in October 1991; the second, in August 1993. The third change involved the development of a new copper recovery process that made smelting much simpler.[26] All of the chalcocite (Cu_2S) matte generated at the matte separation plant is now run through a newly designed "MK" reactor that converts the chalcocite to blister copper. Flash smelting of the chalcocite matte generates SO_2 gas that is then sent to either the liquid SO_2 plant or the sulfuric acid plant where it is combined with the SO_2 produced by the two oxygen flash furnaces. The two SO_2 recovery operations produced a total of 425,000 tons of sulfuric acid and liquid SO_2 in 1993.

Falconbridge operated six mines at Sudbury in 1993—the Craig, Fraser, Lindsley, Lockerby, Onaping, and Strathcona. The six underground mines hoisted a total of 2.5 million tons of ore that yielded 38,300 tons of nickel, 47,200 tons of copper, and 800 tons of cobalt in matte.[27] Because of improvements in productivity, nickel production was up 8% from 1992 even though the company shut down for a total of 8 weeks.

Like Inco, Falconbridge restructured its Sudbury Division and reduced its workforce to remain competitive in an oversupplied marketplace. The shaft-sinking project at the Craig Mine was put on hold to conserve cash. Improved flotation techniques and the installation of advanced magnetic separation equipment allowed the Strathcona mill to increase its pyrrhotite rejection rate without lowering nickel recovery. Because there was less pyrrhotite in the final concentrate, sulfur dioxide emissions decreased at the smelter, helping Falconbridge to meet its abatement goals. The smelter released 57,000 tons of SO_2 in 1993, well below the 100,000-ton limit set by the Provincial Government for 1994.

Falconbridge continued to explore for nickel and copper in the intrusive rocks that rim the Sudbury Basin. Efforts were being concentrated at the Nickel Rim prospect, 12 km north of the town of Falconbridge. Drilling to date has identified 520,000 tons of ore averaging 4.13% Ni at a depth of 2,500 to 2,700 m. The ore also contains significant copper, palladium, and platinum. Teams were also evaluating three other properties on the rim: Joe Lake; an area down-dip from the Craig and Onaping mines; and the Trill-Drury prospect near Fairbank Lake.

In 1993, Falconbridge completed its feasibility study of the Raglan deposit in northeastern Quebec. Since 1989, the company has spent more than $40 million evaluating the world-class nickel deposit. The company has begun applying for the necessary government permits to bring the property into production, but actual construction will not start until market conditions substantially improve. Exploration drilling has identified at least 18.1 million tons of ore averaging 3.13% Ni, 0.88% Cu, and 0.05% Co. Falconbridge was also evaluating properties in Manitoba, Botswana, Côte d'Ivoire, Greenland, and Zimbabwe.

In early 1994, Sherritt Inc. (formerly Sherritt Gordon Ltd.) completed the expansion and modernization of its nickel-cobalt refining complex in Fort Saskatchewan, Alberta. The new complex consisted of a nickel refinery designed to handle nickel feedstock with a high-cobalt content, a cobalt separation plant, and a cobalt reduction plant. Feed material was being supplied by Cubaniquel and Union de Empresas del Niquel under agreements concluded with the two Cuban organizations in 1991. Sherritt also was considering importing supplemental feedstocks from Australia. The Metals Division produced 18,345 tons of nickel, 10% more than in 1992. Cobalt production jumped 78% to 1,218 tons—an all-time high. The expansion will allow Sherritt to produce more than 25,000 tons per year of nickel when prices recover.[28]

Hudson Bay Mining and Smelting (HBMS) closed its Namew Lake Mine in northern Manitoba on November 5, 1993. Reserves at the underground mine, a joint venture of HBMS (60%) and Outokumpu Mines Ltd. (40%), were exhausted and efforts to find new ore bodies failed. The mine, which cost $60 million, was commissioned in November 1988. Most of the concentrates ended up at Sherritt Gordon's refinery in Fort Saskatchewan, Alta., or Inco's smelter in Thompson, Man.

China.—Jinchuan Nonferrous Metals Corp. produced 27,300 tons of cathode at its smelting and refining complex in Gansu Province. The complex accounted for 88% of China's total nickel output in 1993 and 90% of its platinum output. The ore came from four mining areas at the base of Longshou Mountain, which make up about 70% of China's nickel reserves. The ore occurs in a 6-km-long dike that cuts through all four mining areas. The principal ore minerals are pyrrhotite, pentlandite, and chalcopyrite. Different members of the cobaltite family also are present in minor amounts.

Jinchuan has been producing cathode since 1964 and recently installed a new flash furnace with the help of Outokumpu and WMC. The new furnace can smelt up to 50 tons per hour of concentrate averaging 6.8% Ni, 3.4% Cu, and 0.13% Co. When the expansion project is completed in 1995, Jinchuan will be able to produce annually 40,000 tons of nickel, 20,000 tons of copper, and 500 tons of cobalt. A new acid plant being constructed will generate 400,000 tons per year of sulfuric acid.[29]

Colombia.—The Cerro Matoso ferronickel operation in Colombia was only one of a number of mining and smelting complexes caught up in the spinoff of Billiton BV from the Royal Dutch/Shell Group (Shell). *(See Republic of South Africa section of this report.)* According to the INSG, Cerro Matoso produced 20,181 tons of nickel contained in ferronickel bars and granules. Essentially all of it went for export. Exports totaled 21,632 tons on a contained basis in 1993, 61% of which went to Europe.

Cuba.—Sherritt has been working closely with the Cuban nickel industry since 1991. Most of the nickel-cobalt sulfide precipitate produced at Moa Bay now goes to Sherritt's refinery at Fort Saskatchewan. In 1993, Cuba reportedly exported 12,116 tons of Ni in intermediate products to Canada. Before 1991, the bulk of the precipitate went to the Russian refinery at Orsk. Sherritt's oil exploration and development program in northern Matanzas Province has given the company a distinct advantage on the island over other Western nickel refiners. Sherritt has been producing oil from the Varadero and Boca de Jaruco fields east of Havana as part of a joint venture with the Government.

Sherritt also was considering a joint venture with La Compania General de Niquel S.A., the parastatal company responsible for operations at Moa Bay. The Pedro Sotto Alba plant on Moa Bay produces a mixed 50% Ni+Co sulfide precipitate from limonitic laterites. The laterites are leached under pressure with sulfuric acid at 250° C and 4,000 kiloPascals to prevent large amounts of iron from dissolving along with the nickel and cobalt. The proposed joint venture would upgrade the Moa plant and make it more energy efficient, incorporating new extractive technology developed by Sherritt. Both the Fort Saskatchewan refinery and the Moa Bay plant would become jointly-owned assets of the new venture. The proposed venture would be granted mining concessions with more than 60 million tons of nickeliferous limonite reserves, 80% of which were proven. The concessions would provide Moa Bay with enough ore to operate for 25 years. The venture would also establish a jointly-owned marketing corporation to better market the nickel and cobalt overseas.

Cuba produced 30,218 tons of nickel units in 1993. Oxide sinter (90% Ni) and different forms of the more conventional oxide (76% to 77% Ni) accounted for 16,185 tons of the nickel. This material came from the Nicaro and Punta Gorda plants, which use an ammonium carbonate leach process to recover nickel from serpentine laterites. The remaining 14,033 tons were contained in mixed precipitates from Moa Bay and other intermediate products.

Finland.—OMR moved ahead with its plans to modernize and expand the Harjavalta Works, despite weak nickel prices. The complex consists of a nickel smelter, a copper smelter, and a nickel refinery. The blister copper is shipped to Pori for electrolytic refining. The upgrading program will cost 1.8 billion Finnish markka (about US$330 million) and increase the complex's capacity to produce copper as well as nickel. Construction began in May 1993 and was scheduled to be completed in 1996.

The refined nickel capacity of Harjavalta will almost double, going from 18,000 tons per year to 32,000 tons per year of Ni. The additional 14,000 ton-per-year capacity will be used to make briquettes instead of cathode. The copper smelting capacity of the complex will jump similarly from 100,000 tons per year to 160,000 tons per year. The capacity of the copper refinery at Pori will increase from 70,000 tons per year to 125,000 tons per year. New pollution control equipment and the adoption of innovative technology should decrease sulfur dioxide emissions even though the smelter output is being raised.

More than half of the additional concentrate needed to feed the nickel smelter was coming from Outokumpu's new Forrestania Mine in Western Australia. It is the first mine outside Finland which is wholly owned, built, and operated by Outokumpu. An additional 14,000 tons per year will come from WMC's new Mount Keith Mine, which is scheduled to open in 1995. For a short period of time, Outokumpu held a 50% interest in Mount Keith but sold out to WMC. More feedstock could conceivably be obtained from the remote Keivitsa deposit recently discovered in Lapland by the Finnish Geological Survey.

In 1993, Outokumpu Harjavalta Metals Oy produced 14,800 tons of nickel cathode, 107,000 tons of blister copper, and 73,400 tons of cathode copper (a new record). Outokumpu Finnmines Oy was planning to close its Enonkoski and Vammala Mines in 1994 because of declining reserves and low nickel prices, leaving only the Hitura Mine operating.[30] The Telkälä Mine closed in 1992.

On October 20, OMR sold its 96% share in OM Group, Inc. (OMG) for $129 million. The shareholding was sold to individual and institutional investors by listing the former chemical subsidiary on the NASDAQ. OMG is now the largest producer of cobalt and nickel chemicals in the Western World. OMG produced 2,690 tons of Ni in chemicals during the first 10 months of 1993 while the company was still owned by OMR. *(See World Review section of 1992 Annual Report.)*

Indonesia.—P.T. International Nickel Indonesia (P.T. Inco) produced 34,400 tons of Ni in matte in 1993, down from a record high 36,300 tons in 1992. The matte typically contains 77% to 80% Ni and is shipped to Japan for refining, where it is admitted duty-free. The company was forced to cut back production in July 1993 when the main 65-megavolt-ampere (MVA) transformer feeding Furnace No. 2 failed. The furnace had just been rebuilt and brought back on line in May. A spare 50-MVA transformer was installed in its place, but the reduction in power capacity resulted in lower production. A new 75-MVA transformer was to be delivered in mid-1994. The furnace was one of three at the company's 45,400-ton-Ni-per-year Soroako smelting complex.[31]

P.T. Inco accelerated its revegetation of mined-out areas and has restored about 280 hectares (692 acres) to date. The Soroako area still has proven and probable reserves of 78 million tons of laterite containing 1.5 million tons of Ni. Recent reconnaissance work in the Pomalaa East area has identified a possible resource of 147 million tons. At least 55 million tons of this material runs 1.9% Ni. Construction of a 24-MW, three-unit diesel electric generating station was completed in August on schedule as budgeted. The additional power was to supplement the output of the company's existing hydroelectric facility.

P.T. Aneka Tambang also experienced furnace problems. The operation at Pomalaa produced only 5,267 tons of Ni in FeNi, down 4% from 5,507 tons in 1992. A second ferronickel plant with a capacity of 5,500 tons per year of contained Ni was under construction and scheduled to come onstream in early 1995. Production of ore for export dropped from 35,745 tons of contained Ni to 26,850 tons in 1993.

Macedonia.—The Feni-Mak mining and smelting complex at Kavadarci reportedly operated at less than 50% of capacity in 1993 and was producing only about 400 tons per month of Ni in ferronickel. The smelter is capable of producing 28,000 tons per year of ferronickel on a gross weight basis, but was unable to operate efficiently because of the civil war in Bosnia and Hercegovina, United Nations sanctions on neighboring Serbia, and related power outages and transport problems. The ferronickel had to be shipped from the Greek port of Salonika to Rotterdam, instead of being transported by rail through Belgrade to Austria and Germany.

New Caledonia.—Société Métallurgique le Nickel (SLN) shipped 36,888 tons of nickel in ferronickel, up from 32,080 tons in 1992. The company's three furnaces at Doniambo were recently upgraded and now have a combined capacity of about 53,000 tons per year of Ni in ferronickel. The ferronickel has been averaging about 29% Ni. The operation also produces matte, which is cast into ingots and sent to the Eramet-SLN refinery at Sandouville, France, for conversion to cathode. The matte operation at Doniambo operated at full capacity in 1993 and shipped 14,766 tons of matte containing 10,883 tons of Ni to Sandouville. The average grade of the matte was 73.7% Ni.[32]

Goro Nickel S.A., a French company created in 1992 to evaluate laterites at the southeastern tip of the island, shipped a bulk sample of ore to Inco's research laboratory in Mississauga, Ontario. Inco, which owns 85% of Goro, wanted to learn if new proprietary technology developed by the company could be used to economically process the high-iron, limonitic Goro ore. The Goro deposit reportedly has 150 million tons of ore averaging 1.57% Ni.

SLN's new Kopeto 2 Mine was essentially completed. Formal commissioning was scheduled for May 1994. The open pit mine is near Nepoui, about 250 km northwest of the capital of Nouméa. The mine was expected to produce 830,000 tons per year of lateritic ore during the next 15 years, and was designed to provide one-third of the feed material required by the Doniambo smelter. The garnierite-rich saprolitic ore assays about 2.1% Ni. The Nepoui area was worked during the 1970's and eventually abandoned. SLN decided to resume mining at the site when 14 untouched ore bodies of garnierite were discovered.[33]

Norway.—Productivity at Falconbridge's Nikkelverk refinery has been continuously improving during the last 10 years. In 1993, the operation recovered 56,800 tons of nickel, 37,200 tons of copper, and 2,400 tons of cobalt from matte shipped primarily from Sudbury, Botswana, and Russia. Nickel production was up 2% from that of 1992, despite a drop in employment of about 9%. The refinery currently has about 145 employees and is capable of recovering 64,000 tons of nickel, 40,000 tons of copper, and 2,600 tons of cobalt annually.

Russia.—Russian nickel production dropped significantly between 1992 and 1993. Cash flow problems, bad weather, rising costs for energy and transportation, supply shortages, equipment failures, and declining ore grades all contributed to the falloff. The Norilsk Nickel Combine produced only about 160,000 tons to 180,000 tons of refined nickel in 1993. The combine's principal mining, smelting, and refining operation is at Norilsk in north-central Siberia. The combine also has operations on the Kola Peninsula that include several mines near Nikel and Zapolyarnij, a smelter at Pechenga, and a smelting and refining complex at Monchegorsk. A large part of the production cutbacks apparently occurred at the Severonikel complex at Monchegorsk.

Significant production also came from the Yuzuralnikel Combine in the Ural Mountains. This second combine operates independently of Norilsk. In 1993, total Russian production of cathode, powders, and Ni in ferronickel was estimated to be somewhere between 175,000 tons and 195,000 tons, but official statistics still have not been released by the central government.

In recent years, production of ore and intermediate products at Norilsk proper has outpaced the capacity of the complex's processing facilities, with the excess going to either Severonikel at Monchegorsk or Pechenganikel at Nikel. Ore, concentrates, and matte destined for the Kola Peninsula are normally railed from Norilsk to the port of Dudinka, near the mouth of the Yenisey River. From Dudinka, the nickel goes by ocean vessel to Murmansk. Flooding at Dudinka in July 1993 apparently slowed shipments of these different feed materials. The transportation delays, in turn, created a shortage of feed material at Monchegorsk. Severonikel was able to offset part of the shortage by tolling material imported from the West. Because of the feed shortages, Severonikel's output of cathode and powder was significantly less than the estimated 97,000 tons to 102,000 tons produced in 1992. Finland reported shipping 2,888 tons (gross weight) of concentrates to Russia in 1993. Part of the concentrates reportedly went to Monchegorsk's nickel carbonyl plant for conversion to powder.

The July flooding was only part of the production problem. At the beginning of 1993, mining and concentrating operations at Norilsk were hampered by a period of harsh weather conditions. Air temperatures were abnormally high during the 1992-93 winter in north-central Siberia, generating very heavy snowfalls and unusually strong Arctic winds in Norilsk and the rest of the Rybnaya Valley.

In the spring of 1993, the new Russian Government put out a tender to upgrade the Pechenga smelter. The tender was eventually awarded to a Scandinavian consortium led by Elkem A/S. However, there were delays in signing the contract and a number of technical and financial matters still had to be negotiated. The consortium may have to significantly modify its proposal to bring costs down to a level more acceptable to the Russians. At least 30 Western companies initially participated in the competition, but only about 5 bids were eventually submitted.

The Pechenga smelter can produce up to 70,000 tons per year of nickel-copper matte averaging 40% to 50% Ni. The matte is shipped to Monchegorsk, where the two metals are separated from one another and cast into anodes suitable for electrolytic refining.

The Scandinavian consortium was composed of Elkem Technology (Oslo), Kvaerner Engineering (Oslo), and Boliden Contech AB (Stockholm). Elkem Technology is a major supplier of electric smelting furnaces and has considerable expertise in air pollution control technology and baghouse filter systems. The $300 million upgrading is expected to reduce sulfur dioxide emissions from the smelter more than tenfold. Some analysts believe that the upgrading of Pechenga will cost far more than $300 million and could easily exceed $800 million.

In October 1991, Outokumpu won an earlier tender to renovate Pechenga for $600 million, but a contract never materialized. Outokumpu had been considered a strong contender in the new bidding, but the Competition Commission of the Russian Federation eventually ruled in favor of the Elkem group.

The Russian Government was considering a plan to partially privatize Norilsk Nickel. Under the plan, the combine would operate somewhat like Outokumpu does currently in Finland. The combine would issue stock, with the Russian Government retaining 37% of the shares. Another 25% would be given to Norilsk's workforce free, while 10% would be held by management. The remaining 28% would be sold at public auction to Russian investors to raise cash for modernization. Foreigners would be prohibited from owning stock in the combine.

Large tonnages of Russian cathode entered LME warehouses in both 1992 and 1993, building up Western trading stocks to record high levels. Official Russian customs data on 1993 nickel exports were still being compiled at the time of publication. According to data received by the INSG from importing countries, Russia shipped a total of only 38,148 tons of unwrought nickel (in unalloyed form) to 15 countries in 1992, a significant drop from the 87,665 tons reported for 1991. The 38,148-ton figure is much lower than industry estimates of Russian exports for 1992, the difference being made up by "black" (smuggled) and "gray" (physically modified or deliberately misclassified) material. A total of 77,484 tons had been reported, as of this writing, from Russia for 1993, with the bulk going to Germany (23,501 tons), Italy (7,277 tons), the United States (6,629 tons), France (5,651 tons), and Canada (5,615 tons). Norilsk also sent significant amounts of nickel matte to Norway for refining. In 1993, Russia shipped 15,000 tons (gross weight) of matte to the Kristiansand refinery of Falconbridge Nikkelverk A/S. This was almost double the 8,500 tons shipped in 1992.

Yuzuralnikel Kombinat temporarily suspended nickel production at its Orsk smelting and refining complex in the southern Urals. The length of the shutdown was not disclosed. The State-owned complex was put in a difficult position by the ongoing economic restructuring of the Russian economy and the political situation in the Commonwealth of Independent States (CIS). The Orsk facility was set up originally to process lateritic ores from more than a dozen mines in the Orsk-Chelyabinsk-Sverdlovsk region and had satellite operations at Buruktal, Ufaley, and Rezh. Some ore apparently also came from the Aktjubinsk region of Kazakhstan. However, for more than a decade, Orsk also has been processing anodes made at Buruktal from Cuban nickel-cobalt sulfides.

The combine reportedly was forced to shut down both the Orsk and Ufaley smelters because of soaring production costs and a shortage of raw materials. Costs for electricity and fuel have risen dramatically since the elimination of many state subsidies. The combine also has had difficulty securing an adequate supply of sulfide concentrates. In 1991, the Cuban nickel industry started shipping the bulk of its mixed concentrates to Sherritt instead of to the combine. Cuban shipments to Buruktal fell off dramatically between 1991 and 1993, and are now less than 2,000 tons per year of contained Ni.

According to the INSG, the Orsk complex is capable of producing 16,000 tons per year of Ni in granules (averaging 98.6% Ni), 16,000 tons per year of Ni in refined metal, 8,000 tons per year of Ni in salts, and 2,500 tons per year of refined cobalt.

South Africa, Republic of.—Gencor Ltd. was in the process of buying Billiton BV from the Royal Dutch/Shell Group. Management teams from the two resource giants had been immersed in negotiations since late 1992 and were still working out key details of the complex transaction. *(See World Review section of 1992 Annual Report.)* Gencor would raise money for the acquisition by divesting itself of its papermaking, energy, and consumer products subsidiaries.[34]

Because many of Billiton's operations were joint ventures, the sale of individual mines and smelters depended upon whether the other shareholders choose to exercise their preemptive purchase rights. For example, Billiton owned 47% of Cerro Matoso S.A., the Colombian ferronickel producer, with the rest controlled by the Colombian Government. Gencor, on the other hand, had to deal with financing problems created by South African currency controls. The South African giant reportedly agreed to pay Shell $1.14 billion for Billiton. The long-awaited transfer of assets, scheduled to take place in September 1994, would transform Gencor from a South African mining house into an international resource group. Gencor's new subsidiary was to be called Billiton International Ltd. The South African mining company had to come up with $335 million in cash. The bulk of the remaining $809 million would be loaned to Gencor by a consortium of international banks.

Tanzania.—BHP Minerals International Exploration Inc. (BHP Minerals) was moving ahead with its $4 million drilling program in the Kagera region, southwest of Lake Victoria. The operation was part of a joint venture with Sutton Resources Ltd. of Richmond, British Columbia.[35] Exploration was continuing despite the influx of 400,000 refugees from Rwanda and Burundi into the region. BHP had three rigs drilling a series of geophysical and geochemical anomalies 70 km west of the lake. The anomalies lie along a 200-km-long belt stretching from Kabanga north to Kyaka.

According to Mine Development Engineering Ltd., a Sutton contractor, the previously identified deposit at Kabanga has 23.1 million tons of sulfide ore averaging 1.19% Ni, 0.20% Cu, and 0.10% Co, based on a 0.5% Ni cutoff. The sulfide ore is associated with a series of ultramafic intrusives, primarily peridotites and pyroxenites. In late 1993, stepout drilling 1,100 meters north of the Kabanga deposit located additional mineralization, with the highest cobalt-nickel grades found to date. Reconnaissance drilling at a second anomaly 40 km northeast of Kabanga also located nickel sulfide mineralization. *(See tables 10 and 11 for individual country data.)*

OUTLOOK

Since 1991, the supply of nickel has exceeded world demand. In recent months, this imbalance has shrunk considerably in the Western World but grown worse in the East. Consumption of nickel in the CIS has fallen faster than the dropoff in Russian production, freeing up large amounts of cathode and powder for export to the West. The bulk of the material shipped in 1992-94 went to, in decreasing order, Western Europe, North America, Japan, the Republic of Korea, and Taiwan.

The Russian push to export nickel is being driven by a combination of forces. First, the Russian nickel industry has had considerable excess capacity for more than a decade and has been a significant supplier to Western Europe and Japan since the early 1980's. Nickel production far exceeded internal needs under the former Soviet system, even when demand by the military was strong and stainless output was high.

Second, production of stainless steel within the entire former Soviet Union (FSU) has been declining since 1990 as a result of the shift from a centrally planned economy to a market economy. The FSU output of crude stainless has fallen steadily from 2,270,000 tons in 1988 to 550,000 tons in 1993. Some of the stainless allegedly was being sold in the West as scrap and remelted to make new stainless of better quality. Several CIS stainless plants were using obsolete technology or were situated in remote locations where the transportation infrastructure was limited.

Third, nickel exports have been an important source of hard currency for the FSU, and now Russia. Hard currency is vital to the new Russian economy because acceptability of the ruble in the West continues to be a problem.

Fourth, nickel consumption by the Russian defense industry has plummeted.

One of the more difficult challenges facing Western analysts will be to correctly forecast the point at which the Russian economy turns around and a rejuvenated Russian industry starts consuming more stainless and nickel.

Between 1981 and 1991, demand for nickel in the Western World grew at an average rate of almost 4% per year. However, demand began to slow in early 1991 as recessionary forces spread from North America to Western Europe and eventually to Japan. In 1991 and 1992, Western consumption of nickel actually declined, slowing the upward rate of growth. In 1993, Western nickel consumption began to pick up and is currently growing, causing the LME cash price to rise. On November 17, 1994, the LME price was $7,535 per ton ($3.418 per pound), up 45% from the $4,614 per ton ($2.093 per pound) quoted a year earlier.

If prices remain at the November level for some time, additional production will quickly come onstream to meet demand. There is already idle capacity in Oregon, Ontario, the Dominican Republic, Greece, and Macedonia, plus numerous deposits ready for development (e.g., Birchtree, Bulong, Fortaleza, Goro, Honeymoon Well, Loma de Hierro, McCreedy East, Raglan, Thompson 1-D, Victor, and Yakabindie). According to a senior company official in the nickel industry, nickel prices have to be at $6,600 per ton to $7,100 per ton (about $3.00 per pound to $3.20 per pound) for most Western nickel producers to break even.

How high the LME price will rise will depend, in part, upon the eagerness of the Norilsk Nickel Combine to earn hard currency and secure a permanent sales position in the West. Norilsk Nickel signed a cooperative agreement with Outokumpu in September 1993 and has strengthened ties to three or four Western trading companies. Norilsk also has its own sales agent in London, Normaco Ltd. Normaco is currently selling about 75,000 tons of cathode per year for the combine. Outokumpu was considering helping Norilsk upgrade some of its facilities in exchange for nickel and copper. One or two Russian-Finnish joint ventures also are possible if the Russian Government acquiesces. Long-term financing could be provided by a consortium of Scandinavian and EC investment banks.

In the second half of 1994, LME stocks climbed back and were again at record high levels. On November 10, 1994, LME warehouses held 150,498 tons of nickel metal, of which 149,802 tons, or 99.5%, were in the form of cut cathodes. At closing on the 10th, the Rotterdam depots had 140,346 tons on warrant, or 93% of total LME stocks. Two years earlier, Rotterdam only had about 56,000 tons on hand, while stocks at all of the remaining LME locations totalled less than 2,000 tons.

Austenitic stainless steel will continue to drive world nickel demand for both the short term (1995-97) and midterm (1998-2001). Japan is expected to be the dominant austenitic producer for the rest of the century and will continue to rely heavily on Australia, Indonesia, New Caledonia, and the Philippines for nickel matte and mine products. Japan is also the largest consumer of stainless of all types on a per capita basis. In recent years, Japanese stainless production has been 1.4 to 1.9 times greater than that of the United States. U.S. stainless production peaked in 1988 at 1.996 million tons and has since been averaging between 1.70 and 1.85 million tons. Nickel prices could conceivably rise to $9,900 per ton ($4.50 per pound) in mid-1995 as Japan begins to emerge from its recession and increases production of austenitic stainless.

Western demand for austenitic stainless should set a new record in 1995 despite lingering recessionary forces in Japan. The rest of East Asia will continue expanding stainless production capacity, although perhaps at a somewhat reduced pace. In recent years, there has been a significant shift in U.S. exports of stainless scrap from Japan and Western Europe to the Republic of Korea, Taiwan, and other rapidly developing Asian countries. The Republic of Korea is already making almost as much stainless as Spain and Sweden, while Taiwan is rapidly approaching Canadian production. Even Western Europe is expected to slightly increase stainless production. In 1993, Western Europe accounted for 40% of the 12.7 million tons of stainless (both austenitic and ferritic grades) produced worldwide.

The long-term forecast (2002-2005) is much more rosy. If the past is any guide to the future, world stainless steel production should grow on the average 3% to 5% per year over the next 10 years. Stainless currently accounts for almost 60% of primary nickel demand. Total nickel consumption should grow at an even faster rate because several novel, nonsteel uses are being developed for the element. The successful revitalization of

Russia and the rest of Eastern Europe, coupled with a restructuring of the Chinese economy, could generate unprecedented demand for nickel at the turn of the century.

A significant amount of nickel also goes into superalloys. In the United States, much of this material ends up either in jet turbine engines or in sophisticated chemical processing equipment, such as chemical reactors and pumps. In mid-1994, the U.S. aerospace industry was in a slump brought on by declining orders from both domestic airlines and the U.S. Dept. of Defense. Many domestic airlines were experiencing financial difficulties brought on by the recession, Government deregulation, a large debt load, new environmental controls, and escalating costs for jet fuel. However, this situation is expected to change within the next 2 or 3 years. Increased orders for civil aircraft should begin to materialize sometime after 1997 because air traffic is steadily increasing and aging fleets need to be replaced. Demand for nickel by U.S. superalloy producers will probably be flat until then.

The outlook for key segments of the chemical industry has improved substantially since mid-1993. Until recently, the sluggish U.S. economy and the slowdown in Europe and Japan discouraged chemical manufacturers from building new plants. Chemical companies around the world were forced to restructure, downsize, and make strategic alliances to penetrate previously closed markets. Orders for new chemical plants and equipment will continue to be weak through 1995. However, capacity utilization is currently quite high, with some chemical plants running at 85% to 90% of capacity. Further increases in chemical production will require the construction of new facilities, driving up demand for both stainless and superalloys. Demand should improve even more after Germany finalizes reunification and Japan escapes from recession. The long-term outlook for superalloys is optimistic.

Advanced batteries and electric vehicle technology probably will not significantly affect the nickel market before the year 2002. The nickel-metal hydride battery and the nickel-cadmium battery are both serious contenders for the power system of the futuristic automobile, but could lose out to their advanced lead-acid, sodium-sulfur, or zinc-air competitors. If a nickel battery were adopted universally, U.S. demand for the metal could easily double.

Commercial production of electric vehicles (EVs) powered by nickel batteries has been slowly moving closer to reality. On May 13, 1993, the California Air Resources Board (ARB) reaffirmed its requirement that, beginning with the 1998 model year, 2% of all vehicles sold within the State must have zero tailpipe emissions. The regulation, adopted in 1990, requires all automobile manufacturers who sell more than 35,000 cars or light trucks annually in California after 1997 to certify that at least 2% of their total sales were zero-emission vehicles (ZEVs). The sales requirement jumps to 5% in the year 2001, and then to 10% in 2003. At the present time, only electric vehicles can satisfy the zero-emission requirement. It is still unclear whether vehicles powered by certain fuel cells would be acceptable. Polymer electrolyte fuel cells running on methanol, for example, generate only water vapor and carbon dioxide—two essential ingredients for photosynthesis.

Several auto manufacturers had hoped that the ARB would delay the deadline, giving their companies more time to improve the performance of their prototype EVs. The auto manufacturers were concerned about the limitations of existing battery technology (range, speed, manufacturing cost, and so forth) and the absence of a network of recharging stations.[36] The Board, however, concerned about increasingly severe air quality problems in the Los Angeles basin, rejected the auto manufacturers' arguments. The Board then went on to adopt a report prepared by its staff which concludes that zero-emission vehicles are "technologically feasible in the timeframe provided."[37]

On February 1, 1994, the Governors of 12 northeastern States and the District of Columbia voted by a margin of 9 to 4 to follow California's lead. The Ozone Transport Commission (OTC) for the 12 coastal states, which stretch from Maine to Virginia, approved a plan that resembles the California program and calls for the introduction of zero-and low-emission vehicles into the region starting in 1999. On February 2, the OTC submitted its controversial plan to the EPA for approval. The EPA tentatively approved the controversial OTC clean air-clean car petition on December 19, 1994.

The California reaffirmation and the 12-State petition were important to nickel producers as well as battery manufacturers. During the mid-term (1998-2001), at least four nickel-based EV batteries are expected to strongly compete with the new high-performance lead-acid battery being developed in Texas and other lead-based batteries of advanced design. The four nickel-based technologies are: nickel-cadmium, nickel-iron, nickel-metal hydride, and sodium metal-nickel chloride.

A variety of advanced, affordable batteries also are being developed in Canada, Europe, and Japan. The performance of existing and prototype EVs has been reviewed on a world-wide basis in a 201-page book entitled *Electric Vehicles: Technology, Performance and Potential.* The book was published in 1993 under the auspices of the International Energy Agency (IEA) and its parent, the Organization for Economic Cooperation and Development (OECD).[38]

TABLE 2
NICKEL RECOVERED FROM PURCHASED SCRAP IN THE UNITED STATES, BY KIND OF SCRAP AND FORM OF RECOVERY[1]

(Metric tons of contained nickel)

	1989	1990	1991	1992	1993
KIND OF SCRAP					
Aluminum-base[2]	2,165	2,230	2,147	2,303	2,348
Copper-base	3,362	3,012	2,379	1,991	2,064
Ferrous-base[3]	[r]42,263	[r]48,608	[r]44,823	[r]47,735	47,247
Nickel-base	[r]4,341	[r]3,517	[r]4,172	[r]3,842	3,043
Total	[r]52,131	[r]57,367	[r]53,521	[r]55,871	54,702
FORM OF RECOVERY					
Aluminum-base alloys[4]	2,165	2,230	2,147	2,303	2,348
Copper-base alloys	[r]5,308	[r]4,769	[r]4,273	[r]4,086	3,675
Ferrous alloys	[r]42,317	[r]48,655	[r]44,871	[r]47,793	47,304
Nickel-base alloys	[r]2,336	[r]1,589	[r]2,163	[r]1,641	1,373
Miscellaneous and unspecified	[r]5	[r]124	[r]67	48	2
Total	[r]52,131	[r]57,367	[r]53,521	[r]55,871	54,702

[r] Revised.

[1] Significant changes were made to the computer program that generates data for this table. The changes were adopted after an extensive review of computational procedures and a reanalysis of industry reporting patterns. Because of these changes, consumption data for ferrous-base scrap were revised significantly upward. Some of these changes also affected data on copper-base and nickel-base scrap.

[2] Primarily used beverage cans and foundry borings and turnings.

[3] Primarily stainless and alloy steel scrap consumed at steel mills and foundries.

[4] Includes can scrap converted to ingot by toll smelters for sale on open market.

TABLE 3
REPORTED U.S. CONSUMPTION OF NICKEL, BY FORM

(Metric tons of contained nickel)

Form	1989	1990	1991	1992	1993
Primary:					
Metal	[r]80,257	[r]84,560	[r]77,053	70,006	72,281
Ferronickel	[r]14,174	[r]25,024	[r]21,690	[r]21,193	21,229
Oxide and oxide sinter[1]	5,883	5,578	3,901	4,578	4,439
Chemicals	[r]1,256	1,155	[r]1,246	[r]1,211	1,789
Other	[r]2,298	4,529	4,889	4,427	5,697
Total primary	[r]103,868	[r]120,846	[r]108,779	[r]101,415	105,435
Secondary (scrap)[2]	[r]52,131	[r]57,367	[r]53,521	[r]55,871	54,702
Grand total	[r]155,999	[r]178,213	[r]162,300	[r]157,286	160,137

[r] Revised.

[1] Includes chemical-grade oxide.

[2] Based on gross weight of purchased scrap consumed and estimated average nickel content. Data were revised for 1989 through 1992. (See footnote 1 of table 2.)

TABLE 4
U.S. CONSUMPTION OF NICKEL, BY USE

(Metric tons of contained nickel)

Use	Metal	Ferro-nickel	Oxide and oxide sinter	Chemicals	Other forms	Total primary	Secondary (scrap)	1993 grand total	1992 grand total[r]
Cast irons	220	W	W	W	36	256	1,422	1,678	1,202
Chemicals and chemical uses	W	—	W	1,385	—	1,385	—	1,385	51
Electric, magnet, expansion alloys	W	—	—	—	W	W	W	W	W
Electroplating (sales to platers)	16,309	W	W	292	10	16,611	—	16,611	16,538
Nickel-copper and copper-nickel alloys	2,990	W	W	W	W	2,990	3,088	6,078	6,313
Other nickel and nickel alloys	15,789	W	W	—	W	15,789	1,215	17,004	15,946
Steel:									
Stainless and heat-resistant	17,488	20,232	W	—	4,808	42,528	44,878	87,406	83,460

[1] Chemical-grade oxide is included with salts.

[2] For the different salts, the nickel contents are assumed to be as follows: chlorides, 25%; sulfates, 22%; other salts, 22%; and oxide, sesquioxide and hydroxide, 65%. The typical catalyst is assumed to have a nickel content of 22%.

[3] Data may not add to totals shown because of independent rounding.

[4] The nickel content of waste and scrap is assumed to be 50%, while that of stainless steel has been shown to be about 7.5%.

[e]Estimated. [r]Revised.

[1] Insofar as possible, this table represents recoverable mine production of nickel. Where actual mine output is not available, data related to a more highly processed form have been used to provide an indication of the magnitude of mine output and this is noted parenthetically or by a footnote following the country name. Finland and the United States both reported receiving ferronickel originating from Macedonia in 1992, but definitive information on the output of the Kavadarci operation was not available. Table includes data available through Aug. 1, 1994.

[2] Reported figure.

[3] This series (content of laterite ore) differs from that published previously. The earlier series shown (content of ferronickel produced) is given in table 11.

[4] All production in Yugoslavia from 1989-91 came from Serbia and Montenegro.

[5] Dissolved in Dec. 1991.

[6] Dissolved in Apr. 1992.

TABLE 11—Continued

NICKEL: WORLD PLANT PRODUCTION BY COUNTRY AND PRODUCT[1]

(Metric tons of nickel content)

Country[2] and product	1989	1990	1991	1992	1993[e]
U.S.S.R.:[e] [9]					
Ferronickel	25,000	[r]22,000	20,000	—	—
Metal	255,000	[r]240,000	[r]230,000	—	—
Oxide	15,000	[r]13,000	12,000	—	—
Total	295,000	[r]275,000	[r]262,000	—	—
United Kingdom: Metal	26,100	26,800	29,030	[e]28,000	28,000
United States: Ferronickel	347	3,701	7,065	8,962	[5]4,878
Yugoslavia:					
Ferronickel[e]	5,100	3,600	2,500	—	—
Metal	956	—	—	—	—
Total[e]	6,056	3,600	2,500	—	—
Zimbabwe: Metal[10]	11,633	11,426	11,297	[r]10,349	[5]11,097
Grand total	[r]936,947	[r]901,831	[r]916,067	[r]885,322	806,972
Of which:					
Chemicals	[r]3,333	[r]2,734	[r]3,163	[r]7,090	6,326
Ferronickel	211,075	[r]198,056	[r]214,720	[r]206,440	188,157
Metal	[r]473,044	[r]467,715	[r]463,428	[r]429,172	388,164
Oxides	[r]62,695	[r]55,626	[r]53,256	[r]57,420	51,185
Unspecified	186,800	177,700	181,500	185,200	173,140

[e] Estimated. [r] Revised.

[1] Table includes data available through Nov. 1994.

[2] In addition to the countries listed, North Korea is believed to have produced metallic nickel and/or ferronickel, but information is inadequate to make reliable estimates of output levels. Finland and the United States both reported receiving ferronickel originating from Macedonia in 1992 and 1993, but definitive information on the output of the Kavadarci operation was not available. Several countries produce nickel-containing matte, but output of nickel in such materials has been excluded from this table in order to avoid double counting. Countries producing matte include the following, with output indicated in metric tons of contained nickel: Australia (estimated): 1989—45,000; 1990—45,000; 1991—45,000; 1992—45,000; and 1993—45,000; Botswana: 1989—19,759; 1990—19,022; 1991—19,294; 1992—18,873; and 1993—21,620; Canada: 1989—44,320; 1990—43,300 (estimated); 1991—40,000 (estimated); 1992—40,000 (estimated); and 1993—40,000 (estimated); Indonesia: 1989—29,030; 1990—24,949; 1991—27,433; 1992—39,307; 1993—40,000 (estimated); New Caledonia: 1989—10,650; 1990—9,683; 1991—9,041; 1992—7,475; and 1993—10,883.

[3] Brazil is believed to also produce nickel oxide, but information is not available on which to base estimates.

[4] Nickel contained in products of smelters and refineries in forms which are ready for use by consumers.

[5] Reported figure.

[6] Cuba also produces nickel sulfide but, because it is used as feed material elsewhere, it is not included to avoid double counting. Output of processed sulfide was as follows, in metric tons: 1989—20,017; 1990—19,652; 1991—14,593; 1992—15,270; 1993—14,033.

[7] Dissolved Dec. 31, 1992.

[8] All production in Czechoslovakia from 1989-92 came from Slovakia. Production for 1993 is estimated to be zero.

[9] Includes production from sulfidized concentrates shipped from Cuba for toll refining.

[10] Excludes production from matte shipped from Botswana for toll refining.

NITROGEN

By Raymond L. Cantrell

Mr. Cantrell joined the U.S. Bureau of Mines as a physical scientist in 1988 following 25 years in the private sector. He coordinated fertilizer market research for the W. R. Grace & Co. Agricultural Chemicals Group (1972-87); conducted plastics product development for Hasbro Industries (1968-72); and fertilizer and organics research and development, Columbia Nitrogen Corp. (1964-68). Domestic survey data were prepared by Gail D. Mason, statistical assistant; and the world ammonia production table was prepared by Amy Burk, international data coordinator.

Synthetic anhydrous ammonia (NH_3) is the basic building block for a seemingly endless variety of agricultural and industrial nitrogen (N) compounds essential to life and prosperity on Earth. In agriculture, nitrogen compounds serve as fertilizers and crop protection chemicals vital to the production of enough food, fiber, and protein to sustain a global population rapidly approaching 6 billion. In industry, nitrogen compound demand ranges from relatively simple but important consumer products like ammonia cleaning agents to more advanced technical applications in the mining, polymer, and environmental remediation industries. Therefore, it is not surprising to find ammonia or downstream nitrogen compound consumption in virtually every country. Elemental nitrogen (N_2) mined from the atmosphere is used extensively by the electronics, metals, food, and aerospace industries because of its inert and cryogenic properties.

In 1993, more than 75 countries produced an estimated 111 million metric tons of anhydrous ammonia product (82.2% N) that carried a landed value of about $14 billion. World ammonia production declined for the fourth consecutive year owing to continued restructuring in the former U.S.S.R. and Eastern bloc countries, and recession in Western Europe.

U.S. ammonia plants continued to operate at near capacity, indicative of another good year for the U.S. nitrogen fertilizer and industrial sectors. Ammonia output was 15.7 million tons, or 14% of the global total, while consumption, including imports, accounted for roughly 17% of world demand. U.S. production of elemental nitrogen gas reached a record high 0.9 billion cubic feet.

Several historic events occurred in the U.S. nitrogen fertilizer industry during 1993. Record floods across several Midwestern States during the summer and early fall of 1993 damaged or destroyed significant acreages of feed grains, which reduced grain inventories to low levels, and created a more favorable outlook for 1994. At the same time, Arcadian Corp. of Memphis, TN, continued to gain a more dominant posture in the nitrogen business through plant acquisitions, including B.P. International's facility at Lima, OH, together with a large operation in Trinidad and Tobago.

In the ammonium phosphate sector of the nitrogen business, Cargill, Inc.'s purchase of Seminole Fertilizer, together with the formation of a joint venture between IMC Fertilizer and the Agrico Div. of Freeport-McMoRan, resulted in the aggregate consolidation of approximately 45% of U.S. ammonium phosphate capacity. Restructuring of this historically volatile export-oriented business was welcomed by the industry as a whole and should bring some semblance of stability to the supply side of the equation.

The Uruguay Round of General Agreement on Tariffs and Trade (GATT), under negotiation since 1986, was finally resolved in principle by yearend. A meeting was to be held in Morocco during early 1994 to negotiate the liberalization of agricultural trade policies that should enhance U.S. agricultural trade opportunities. The North American Free Trade Agreement (NAFTA) was approved by Congress late in the year and should enhance the outlook for U.S. agricultural trade with Canada and Mexico.

On July 9, 1993, the International Trade Administration (ITA), U.S. Department of Commerce, published a notice of intent in the Federal Register to revoke a urea antidumping duty order in force against countries of the former U.S.S.R. and Romania since mid-1987. On July 22, 1993, a private industry group, the AD Hoc Committee of Domestic Nitrogen Producers, objected to ITA's proposed ruling, and the order was rescinded.[1]

The metric system is the official system of measurement of most countries. The U.S. Bureau of Mines, in an effort to provide statistical data on nitrogen compounds that are in compliance with Public Law 100-418, began to report nitrogen data in metric units in 1992. *(See table 1.)*

DOMESTIC DATA COVERAGE

Industry statistics for anhydrous ammonia and derivative products were developed by the Bureau of the Census, U.S. Department of Commerce. Preliminary monthly data were published under product codes 28731, 28732, and 28742 in Current Industrial Reports (CIR), Fertilizer Materials, M28B. In 1991, the Bureau of the Census adopted a quarterly format and replaced monthly series M28B with the quarterly series

MQ28B, under the same title. Final data are subsequently published in a companion annual report MA28B. During 1993, the Bureau of the Census surveyed approximately 250 known producers of inorganic fertilizer materials. Statistics covering industrial gases were reported in the Bureau of the Census CIR publications M28C, M28QC, and MA28C, Industrial Gases.

BACKGROUND

Nitrogen chemical matter developed as part of our solar system about 5 billion years ago, according to astrophysics. Outgassing from the interior, soon after the Earth was formed, is believed to be the source of the nitrogen-rich atmosphere as we know it today. Nitrogen was discovered independently in 1772 by the Swedish druggist, Carl Scheele, and the Scottish botanist, Daniel Rutherford.[2]

Earth is enveloped by an atmosphere dominated by nitrogen (N_2), oxygen (O_2), and water vapor. The air we breathe consists of about 78% N_2 and about 21% O_2 by volume; argon makes up most of the remainder. Trace amounts of helium, hydrogen, krypton, neon, and xenon are natural atmospheric sources, together with the greenhouse gases—global warming gases—carbon dioxide (CO_2), methane (CH_4), and nitrous oxide (N_2O).

Nitrogen is an absolute requirement for all life forms on Earth. The gas cycles between its inert diatomic form (N_2) in the atmosphere and chemically fixed forms on Earth, weaving an intricate balance with the carbon cycle that is driven by the photosynthesis processes of living plants. Plants absorb carbon dioxide from the atmosphere, synthesize carbohydrates and essential amino acids and proteins (nitrogen forms), and emit oxygen. The microorganisms of the rhizosphere topsoil supply available mineral nitrogen to nonleguminous plants and biological nitrogen to leguminous (nitrogen fixing) plants for human and animal nutrition.

At the turn of the 20th century, natural sources of nitrogen chemical materials supplied virtually all of the nutrient requirements for agricultural crop production. Mineralized organic soil nitrogen, domestic animal manures and byproducts, guano, seed meals, and coke oven ammonia predominated. The mineralized occurrences of sodium nitrate found in the Atacama Desert of northern Chile also provided strategic supplies of agricultural nitrogen to the global community.

In the late 1800's, agronomists warned that a global food crisis would materialize unless supplemental nitrogen forms could be found to increase crop production for the exploding world population. Four major industrial nitrogen fixation technologies evolved between 1900 and 1920: (1) the electric arc process, developed by Birkeland and Eyde in Norway, produced nitric oxide (NO) from atmospheric nitrogen and oxygen that was used to produce nitric acid (HNO_3); (2) the cyanamide process, discovered by Frank and Caro in Germany, synthesized calcium cyanamide ($CaCN_2$) from calcium carbide (CaC_2) and N_2; (3) the cyanide process, developed by Bucher of Brown University in Rhode Island, produced sodium cyanide (NaCN) from N_2 and sodium carbonate (Na_2CO_3) as an intermediate to ammonia production; and, (4) the ammonia process, developed by Haber and Bosch in Germany, reacted N_2 and hydrogen (H_2) under high temperatures and pressures in the presence of a catalyst to form ammonia (NH_3).

The Haber-Bosch process overshadowed all other industrial methods for producing nitrogen chemical materials and fostered today's mammoth ammonia-based nitrogen fertilizer and industrial sectors. This process was ideally suited for the large-scale commercial production of ammonia (82.2% N) because of the enormous natural resources of essential chemical feedstock elements: nitrogen from the atmosphere, hydrogen from fossil fuels (natural gas, petroleum, coal), and water.

Definitions, Grades, and Specifications[3]

At ordinary ambient temperature and pressure, anhydrous ammonia is a colorless gas with a very sharp, characteristic odor. Ammonia condenses to a liquid at minus 33° C (-28° F). Anhydrous ammonia is not a poison and has no cumulative toxic effects on the human body. It, however, is corrosive and may cause lung, throat, mouth, nose, and eye irritation. When liquid anhydrous ammonia comes into direct contact with the skin, a severe burn may result. Anhydrous ammonia is not combustible except when its concentration in the air falls between 16% to 25% at temperatures in excess of 850° C (1,560° F).

Ammonia vapor becomes "life threatening" only when exposure levels reach 2,500 to 6,500 parts per million (ppm) for up to 30 minutes or "rapidly fatal" if exposure levels reach 5,000- to 10,000-ppm concentrations for up to 30 minutes. Steel is the only acceptable metal allowed in the process of transfer, storage, and transport of anhydrous ammonia.

Technology

Elemental nitrogen is mined from the air by cryogenic separation and membrane technologies. In a typical air separation plant, liquefied air is separated into its individual components by fractional distillation. The resources of nitrogen in the air are virtually unlimited and renewable because of the continuous nitrogen cycle between fixed forms on Earth and atmospheric nitrogen.

Mining.—Mineralized occurrences of sodium nitrate ($NaNO_3$) and potassium nitrate (KNO_3) are mined in significant quantities in the Atacama Desert of northern Chile. The extremely arid nature of this region, with its paucity of soil microorganisms, creates an ideal environment for preserving the nitrate deposits that formed in Miocene times. The nitrate content of the deposits range from about 6.5% to 50%, with an estimated reserve base of about 2.5 billion tons.

Product grades of sodium nitrate and sodium nitrate-potassium nitrate mixtures are obtained through selective precipitation and filtering, followed by granulation. In 1992, Sociedad Quimica y Minera de Chile S.A. (SQM) produced more than 1 million tons of granular sodium nitrate and mixed potassium products for fertilizer and industrial use.[4]

SQM's principal product line, in order of importance, included sodium nitrate (16% N) and homogeneous chemical mixtures of sodium nitrate and potassium nitrate containing 15% N and 14% potash (K_2O). Sodium nitrate was also blended with potash to produce a mixed fertilizer containing 13% N and 44% K_2O.

Processing.—Anhydrous ammonia is typically produced through a sequence of catalytically driven reactions involving the steam reforming of natural gas in the presence of air to produce hydrogen and nitrogen in the proper ratio to effect ammonia synthesis. The latest state-of-the-art plants operate at about 25 million British thermal units (Btu) per ton, resulting in an energy efficiency of more than 70%.

Modern ammonia plants employ efficient centrifugal compressors for air and synthesis gas compression. Temperatures and pressures fluctuate throughout an ammonia plant depending on the process, but typically vary between 315° C to 980° C (600° F to 1,800° F) and 350,000 to 2,110,000 kilograms per square meter (kg/m^2) or 500 to 3,000 pounds per square inch gauge (psig), respectively. A nickel catalyst is used in the reformer and associated front-end sections of the plant where nitrogen and hydrogen are manufactured from natural gas, compressed air, and steam, while an iron-promoted catalyst is used to combine nitrogen and hydrogen to synthesize ammonia.

Urea is formed when ammonia is reacted with byproduct carbon dioxide (CO_2) generated during ammonia synthesis. The materials are reacted under high pressure in a two-step process at about 200° C (400° F) to first form ammonium carbamate, which then decomposes to urea (NH_2CONH_2).

Nitric acid is formed when ammonia is passed over a platinum-rhodium catalyst at about 930° C (1,700° F) and 84,400 kg/m^2, or 120 psig. As ammonia passes over the catalyst gauze, it reacts with oxygen to form nitric oxide (NO), which is converted to nitric acid by mixing with water in a countercurrent absorption tower.

Ammonium nitrate, in turn, is formed by the simple acid-base reaction between ammonia and nitric acid, and urea and ammonium nitrate may be blended to produce the popular U.S. urea-ammonium nitrate (UAN) fertilizer solutions containing 28% to 32% N.

Economic Factors

Between 1970 and the early 1980's, natural gas prices rose dramatically, causing ammonia production costs to become much more sensitive to feedstock costs. Natural gas feedstock costs as a percentage of total production costs rose from 45% in 1970 to 75% by 1982. Natural gas prices declined after 1985, and feedstock costs in 1992 represented about 65% of total ammonia production costs. Gas prices rose in 1993 and accounted for 68% of ammonia production costs.

The U.S. ammonia industry experienced record profitability during 1974-75 because of a tight global supply-demand situation, in spite of the rising dependency on feedstock costs; a similar situation developed during 1979-81. Conversely, the U.S. ammonia industry suffered substantial losses in 1986-87 owing to a sustained period of oversupply in the world fertilizer and grain markets.

A dramatic recovery in the U.S. agricultural sector since 1987, accompanied by favorable energy prices, has led to a return to profitability in the domestic converted nitrogen industry. The profit margin for straight nitrogen compounds (urea, ammonium nitrate, and UAN solutions) has been more consistent, on average, than the more volatile, cyclical price swings experienced by the export-dependent ammonium phosphate industry.

U.S. natural gas futures have been traded on the New York Mercantile Exchange (NYMEX) since April 3, 1990. Natural gas futures trading was designed to allow suppliers, producers, and end users to shift or hedge price risks. NYMEX believed that natural gas futures contracts would provide the same liquidity, unambiguous price reference, and hedge against risk characterized by its successful petroleum contract system. NYMEX futures trading suggested that a renewed upward spiral in natural gas prices would continue into 1993.

ANNUAL REVIEW

Legislation and Government Programs

NAFTA was signed into law by the President on December 8, 1993 (Public Law 103-182).[5] The act was to liberalize agricultural and industrial trade between Canada, Mexico, and the United States designed to gradually phase out most tariff barriers.

Also, the long-awaited agreement to finalize the Uruguay Round of multilateral trade negotiations involving more than 100 nations was enhanced by the signing of Public Law 103-49 on July 2, 1993, extending "fast track" procedures to conclude the Uruguay Round of GATT trade negotiations.[6] The GATT agreement was designed to liberalize agricultural and industrial trade on a global basis. The United States and more than 100 other nations were scheduled to sign the Uruguay Round agreement in Marrakesh, Morocco, on April 15, 1994.

The Food, Agriculture, Conservation, and Trade Act of 1990, Public Law 101-624, signed on November 28, 1990,[7] introduced several creative mechanisms designed to promote environmentally sound and cost-effective agricultural management practices, with the added objective of cutting discretionary Federal spending for farm programs. The 1990 farm bill provided the U.S. farmer with planting flexibility options ("triple base flexibility"), long-term Conservation Reserve and Wetlands Reserve Programs (CRP and WRP) designed to protect the environment and control grain inventories, and an Export Enhancement Initiative that would allow U.S. grain to compete in a global marketplace laden with unfair trade practices.

Under triple base, farmers lost Government deficiency payments on 15% of their base acreage but gained the flexibility to plant virtually any crop except fruits and vegetables on this land and still receive Government price support loans. The triple base initiative provided the impetus for a $13 billion reduction in Government "entitlement" farm program spending over a 5-year period as prescribed by the Omnibus Budget Reconciliation Act of 1990 (Public Law 101-508), signed on November 5, 1990.[8]

Agricultural provisions in the 1990 act were revised by the Omnibus Budget Reconciliation Act of 1993 (Public Law 103-66), signed by the President on August 10, 1993.[9] Agricultural policy changes in the new act will produce savings of $3.2 billion over 5 years. Major spending cuts involved more stringent restrictions on farm setaside programs. Current law exempted gasoline used on the farm for farming purpose from Federal excise taxes.

Total CRP acreage was originally mandated to increase from a level of 14 million hectares (34 million acres) in 1990 to between 16 to 18 million hectares (40 to 45 million acres) by 1995. Following the 12th CRP signup in mid-1992, the U.S. Department of Agriculture (USDA) reported that total CRP acreage had increased to 14.7 million hectares (36.4 million acres). Congress, however, did not include money for the fiscal year 1993 signup, and allocations would reportedly be directed toward the WRP in the future.

Lands available for WRP include restorable farmed wetlands that were converted to cropland prior to December 23, 1985, and functionally related wetlands, uplands, and riparian areas. In fiscal 1993, USDA was expected to accept about 20,000 hectares (50,000 acres) in WRP. Also, landowners in Midwestern States flooded in 1993 were to have the opportunity to return cropland to wetlands during the second signup period for the Emergency Wetlands Reserve Program (EWRP). The first EWRP signup returned an estimated 10,000 hectares (25,000 acres) to wetlands in the Midwest. Missouri and Iowa led the list of States accepted with 5,000 hectares (12,300 acres) and 2,400 hectares (6,000 acres), respectively.

The Alternative Agricultural Research and Commercialization Center (AARC) in Washington, DC, was empowered under title XVI (subtitle G), sections 1660 and 1661, of the 1990 farm bill to create the world's most effective organization in generating new industrial (nonfood, nonfeed) market demand for U.S. farm and forestry products. AARC includes a distinguished board of directors from private industry whose mission is to apply sound business and technical practices that will facilitate the prudent development and commercialization of cost-effective, environmentally friendly renewable industrial and consumer products. The new private ventures will create jobs, enhance rural economic development, and diversify agricultural markets.

The AARC Center expects, at minimum, matching funds for projects. Successful projects are expected to repay the AARC Center Revolving Fund through negotiated arrangements. In 1993, the Center was spending $10 million on projects and $25 million came from private-sector funds. Overall, private companies, nonprofit research organizations, and universities proposed 407 projects and requested $175 million in AARC Center funds to supplement $273 million in private investments.[10]

In February 1993, the Environmental Protection Agency (EPA) issued a final ruling on Standards for the Use or Disposal of Sewage Sludge.[11] The new regulations established requirements for the final use and disposal of sludge in three circumstances: (1) land application for beneficial purposes, including sewage sludge or sewage sludge products that are sold or given away for use in home gardens; (2) sludge disposal on land for placement on surface disposal sites, including sewage sludge-only landfills; and, (3) regulatory requirements for the incineration of sludge.

EPA noted that assessing the potential for adverse effects on public health and the environment from sludge pollutants had been a major challenge, but expressed confidence that the regulations would adequately protect public health and the environment. The Agency stated that when even given very conservative assumptions that probably overstated exposure, studies revealed virtually no adverse effects from sludge disposal on the land when used as a soil conditioner or fertilizer. EPA emphasized that while public exposure to incinerator emissions would pose the greatest threat to human health, available data indicated that detrimental effects should be minimal.

The Clean Air Act of 1990 (Public Law 101-549)[12] contained 11 titles that targeted 3 principal forms of pollution: acid rain, smog, and toxic air pollutants. One of the major impacts of the new clean air bill will be the emphasis placed on clean burning alternative fuels and the use of oxygenated fuels as air pollution control strategies. This strategy will have broad implications for both the United States and the international motor fuels market. The principal fuel oxygenates are methyl tertiary butyl ether (MTBE); ethanol, a derivative of corn; ethyl tertiary butyl ether (ETBE); and tertiary amyl methyl ether (TAME).[13]

EPA's Oxygenated Fuel Program became effective November 1, 1992, requiring gasoline marketers to supply oxygenated fuels for at least 4 months out of the year having a minimum average oxygen content of 2.7% by weight in the 39 cities that do not meet Federal air quality standards for carbon monoxide (CO). The National Corn Growers Association, a trade group in St. Louis, MO, and Information Resources, Inc., a Washington, DC, consulting firm, estimated that approximately 1.1 billion gallons of ethanol (419 million bushel corn equivalent) may be required to help meet the projected U.S. oxygenated fuel demand created by the Clean Air Act in 1993 and up to 2.4 billion gallons (894 million bushel corn equivalent) by the year 2000.[14]

EPA's Reformulated Fuel Program will commence on January 1, 1995, wherein the nine worst U.S. ozone nonattainment areas (Los Angeles, New York, Greater Connecticut, Baltimore, Philadelphia, Chicago, Milwaukee, Houston, and San Diego) will be required to sell gasoline with a minimum 2% by weight oxygen, 1% maximum by volume benzene, 25% aromatics maximum by volume, and no heavy metals (e.g., lead, manganese).

EPA was expected to announce a Renewable Oxygenate Standard (ROS) in mid-1994 mandating that 30% of oxygenated fuel used to produce reformulated gasoline for the Reformulated Fuel Program be made from renewable resources such as ethanol. Although 70% of oxygenates could still be nonrenewable and although the renewable resources would replace less than 2% of gasoline, most oil companies reportedly were opposed to the EPA decision.[15]

Acid rain is caused primarily by sulfur dioxide (SO_2) and nitrogen oxide (NO_x) emissions from coal-fired electrical powerplants. Under title IV, SO_2 emissions were slated to decline 10 million tons from 1980 levels by the year 2000 and NO_x emissions were to be cut by 2 million tons.

Under title III, a list of 190 hazardous chemicals and materials was established for regulation with the requirement that maximum achievable control technology (MACT) be applied to industries emitting major sources of air pollutants. Several important industrial nitrogen-containing compounds were on the list, including acrylonitrile, aniline, caprolactam, ethyl carbamate (urethane), hydrazine, coke oven byproducts, and cyanides.

Section 313 of EPA's Emergency Planning and Community Right-to-Know Act of the Superfund Amendments and Reauthorization Act (SARA) of 1986 (Public Law 99-499) required EPA to establish a national inventory of toxic chemical emissions from certain facilities, called the Toxic Release Inventory (TRI). The 1991 TRI indicated that for 285 chemicals surveyed, a total of 3.3 million tons was released to the environment or transported to publicly owned treatment works (POTW's), of which about 1.5 million tons (45%) was released directly to the air, water, and/or injected underground.[16]

In 1991, a total of approximately 220,000 tons of ammonia was released into the environment: 39% to the air; water, 8%; injection into underground wells, 50%; and disposal in landfills, 3%. Another 53,000 tons was disposed of in POTW's. The 1991 TRI data could not be compared statistically with prior surveys because of a change in survey methodology.

Between 1987 and 1989, ammonia losses to the atmosphere declined by 18%, and discharges into rivers, lakes, streams, and other bodies of water declined 25%. Ammonia processed through municipal waste-treatment plants rose 14%, and underground injection disposal methods increased 17%. Ammonium nitrate and ammonium sulfate solutions of unknown concentration were released to the environment in an aggregate total of about 75,000 tons in 1991, about 60% of which was disposed of in POTW's.

The Energy Policy Act of 1992 (H.R. 776) was signed into law on October 24, 1992. The comprehensive energy bill contained 30 titles covering nonrenewable and renewable energy resources and was underscored by environmental and energy efficient mandates for the implementation of new technology and for long-range research and planning.

Some of the provisions that apply to agriculture and the Department of the Interior may be found in Title III—Alternative Fuels, General—the economic development of an 85% mixture of ethanol with gasoline or other nonrenewables; Title XII—Renewable Energy—biomass chemical conversion or direct combustion technology development; and Title XIII—Coal—clean coal technology that would reduce sulfur dioxide and nitrogen oxides in commercial powerplants and in nonfuel uses. The Secretary of the Interior was to provide consulting services to the Secretary of Energy for research and development of effective utilization of coal wastes and for the administration of mineral rights for coalbed methane projects on Federal lands. Title XVI—Global Climate Change—includes provisions for a 75% increase in energy derived from renewable resources over 1988 levels by the year 2005 and a reduction in the Nation's oil use from a level of approximately 40% of total energy consumption in 1990 to 35% by the year 2005.

Issues

A major issue for the fertilizer industry in coming years will be the Accidental Release Prevention program currently under development by EPA. Ammonia is the major fertilizer material targeted by EPA to be subject to program mandates. The Fertilizer Institute (TFI) of Washingston, DC, was working to assist the industry in preparing for the risk communication aspects of the program.

The U.S. ammonia industry has done a creditable job in implementing best management practices designed to significantly reduce ammonia emissions to the air and water. TFI recently conducted a survey of 28 U.S. ammonia plants representing 71% of industry capacity, and the results were impressive. In fact, TFI's study demonstrated that ammonia releases to the environment had been reduced by a significant 74% between 1987 and 1994.

Legislation involving fertilizer use taxes was introduced that would tax fertilizer production and use along with industrial and commercial water use to pay for city water and treatment facilities. The legislation as currently formulated would add approximately $14 to a ton of ammonia and would tax the release of chemicals on the TRI list at a minimum of $250 million annually.

EPA's multiyear phase 2 Drinking Water Well Survey released in late 1991 concluded that nitrate occurrence in U.S. waters is a limited, site-specific problem and cannot be generally predicted by a simple set of factors. EPA concluded that a variety of environmental conditions and human activities combine to affect the occurrence of nitrate in drinking water wells and that no one single factor can explain their presence.

TFI continued to communicate with EPA on the nitrate in drinking water issue. TFI pointed out that EPA's study had refuted the commonly held theory that a national drinking water quality problem exists and that a simple reduction in nitrogen fertilizer use would solve the problem. It was further pointed out that there were already two successful Federal programs in force establishing limits on the nitrate concentration in the Nation's water supply: the Safe Drinking Water Act and the Clean Water Act. TFI also reported that the few documented cases of "Blue Baby Syndrome" on record involved nitrate levels at several multiples of EPA's 10-ppm limit.

The large Saskferco ammonia and urea project that came on-stream in the fall of 1992 at Belle Plaine, Saskatchewan, continued to be monitored by the U.S. Ad Hoc Committee of Domestic Nitrogen Producers and the Canadian Council of Nitrogen Producers. The International Trade Commission (ITC), ITA, U.S. Department of Commerce, and the U.S. Trade Representative had been lobbied by the groups in 1991 regarding potential injury to other North American nitrogen producers and unfair subsidization of the project, a joint venture between Cargill Fertilizer of Minneapolis, MN, the Crown Corp. of Saskatchewan, and Citibank Canada.

Production

The U.S. ammonia industry operated at 99% of design capacity in 1993, indicative of a continuation of relatively balanced supply-demand conditions for ammonia and straight nitrogen conversion products. Thirty firms in twenty-three States across the country produced 15.7 million tons of anhydrous ammonia (82.2% N).

Ammonia production declined 6% owing to a combination of reduced demand for domestic product and plant closures, but capacity fell by a net of only 2% owing to a combination of debottlenecking activities in active plants and the startup of inactive units. Principal closures included Arcadian Corp's. ammonia and urea plant at Lake Charles, LA, and Nitrogen Products', Inc. ammonia and nitric acid plant at Helena, AR. Ammonia production ceased in Washington State altogether with the closure of Occidental Petroleum's small plant at Tacoma.

The gas-rich States of Louisiana, Oklahoma, and Texas, in order of importance, continued to provide about 60% of total U.S. production; the Midwest, 16%; South and Southeast, 14%; and the Western States, predominately Alaska, 9%. Natural gas feedstock costs at the well-head averaged $1.99 per million Btu, providing the industry with reasonably favorable profit margins at the wholesale level in the case of straight nitrogen fertilizers and for industrial products. The TFI annual survey of domestic ammonia producers, however, indicated that average ammonia production costs rose 15% to $117 per ton in 1993.[17] Production costs rose principally because of a runup in natural gas prices.

About 90% of the ammonia produced in U.S. plants was allocated to domestic fertilizer use and trade, and about 10% went into industrial products. Major downstream ammonia fertilizer derivatives included urea, 46% N; diammonium phosphate (DAP), 18% N; monoammonium phosphate (MAP), 11% N; ammonium nitrate (35% N); and ammonium sulfate, 21% N. Important industrial chemical derivatives and intermediates were urea, ammonium nitrate, nitric acid (22% N) and organic nitration products, acrylonitrile (26% N), caprolactam (12% N), and amine ($-NH_2$) derivatives. *(See tables 2 and 3.)*

Industry Profile.—Arcadian Partners, L.P., a master limited partnership, is a leading domestic and international producer and marketer of nitrogen fertilizers and chemicals used in agricultural and industrial applications. Arcadian's principal products are ammonia, urea, ammonium nitrate, and nitrogen solutions. Nitrogen solutions are Arcadian's most versatile fertilizer materials. Arcadian's sales mix is favorably balanced with approximately two-thirds destined for agriculture and the remainder to industrial products. With eight plants along the East Coast and Gulf Coast, the Midwest and in Trinidad, Arcadian has easy access and low transportation costs to most U.S. agricultural and industrial markets east of the Rocky Mountains. In addition, the Trinidad plant is well situated to serve Latin America and other world markets.[18]

In 1993, Arcadian made several strategic moves designed to increase market share and to improve the firm's competitive economics in the nitrogen fertilizer and industrial chemicals arena. In March, the firm purchased two adjacent fertilizer plants in the Republic of Trinidad and Tobago, an island country in the Caribbean Sea off the coast of Venezuela. The complex at Point Lisas consisted of two ammonia production units having a combined annual capacity of 700,000 tons and a granular urea production unit having a capacity of 530,000 tons.

The ammonia units had been jointly owned by Amoco Corp. of the United States and, Fertilizers of Trinidad and Tobago, Ltd. (FERTRIN), Trinidad and Tobago, while the urea plant, Trinidad & Tobago Urea Co., Ltd., was wholly owned by Trinidad and Tobago. Debottlenecking projects were to increase ammonia capacity 17%, to 820,000 annual tons, and urea capacity 21%, to 640,000 annual tons, by yearend.

In May, Arcadian acquired an integrated nitrogen fertilizer complex at Lima, OH, from BP Chemicals Inc. The plant geographics coincided with Arcadian's strategy of improving competitiveness through the acquisition of production capacity in close proximity to key market areas. Annual plant capacities at Lima were approximately 500,000 tons of ammonia, 310,000 tons of urea, and 200,000 tons of nitrogen solutions. Plans were also formulated to increase production capacity and improve the energy efficiency of nitrogen production facilities at Geismar, LA, and Memphis, TN.

Later in the year, Arcadian signed a letter of intent to purchase certain assets associated with a 350,000-ton-per-year nitric acid plant closed by E. I. Du Pont de Nemours & Co. Inc. at Gibbstown, NJ. Arcadian also leased a large subterranean ammonia storage cavern on-site. Du Pont was to continue to operate sodium nitrite facilities at Gibbstown.[19]

Arcadian's 400,000-ton-per-year ammonia plant at Lake Charles, LA, was mothballed in late July 1992 following irreversible damage to a 190,000-ton-per-year urea synthesis reactor. The ammonia plant was scheduled to be dismantled and sold to a firm in Pakistan.

In January 1993, Mississippi Chemical Corp. (MCC) started up a $32 million state-of-the-art nitric acid plant and ammonium nitrate neutralizer section at Yazoo City, MS. The new 550-ton-per-day nitric acid plant replaced two obsolete plants having a combined capacity of 330 tons per day and utilized the latest NO_x air emissions control technology. The new plants operated well above design levels in producing record levels of Amtrate solid ammonium nitrate and N-Sol UAN solution. MCC, along with Arcadian Corp. and Agricultural Minerals Corp., form the UAN Solutions Export Association operated under provisions of the Webb-Pomerene Act.

MCC officials announced the discovery of a new process for producing a unique industrial explosives-grade ammonium nitrate material possessing superior physical properties and detonation characteristics. The patented material was successfully produced in a pilot project.[20]

MCC's ammonium phosphate facility at Pascagoula, MS, Mississippi Phosphates, was brought to full capacity based on the reaction between ammonia and wet-process phosphoric acid derived from imported Moroccan phosphate rock. Atlantic Fertilizer and Chemical Corp. marketed the DAP output rated at 700,000 tons per year.

CF Industries Inc. of Long Grove, IL, a major North American cooperative, supplies nitrogen, phosphate, and potash fertilizer products to more than 1 million farmers and ranchers in 46 States and 2 Canadian Provinces. CF's ammonia, urea, and UAN Nitrogen Complex at Donaldsonville, LA, is the largest facility of its kind in the United States. CF also operates a wholly owned ammonium phosphate facility at Plant City, FL, having an annual capacity of 2 million product tons and holds a joint-venture interest in Canadian Fertilizers Ltd., a large ammonia and urea complex at Medicine Hat, Alberta.

CF's $87 million nitric acid and UAN solution expansion project at Donaldsonville, LA, was completed in mid-1993. Annual urea capacity was increased by 240,000 tons per year and UAN solution capacity by 440,000 tons per year. The new urea unit began commercial production in September, as planned.

The Donaldsonville ammonia plants were capable of operating at 1.8 million tons per year—120% of design capacity—because of revamp and retrofit initiatives that led to further improvements in the cooperative's competitive economics. CF management reported that ammonia emissions were reduced by 60% and NO_x emissions by 33% from 1987 levels. Ammonia production at the firm's Medicine Hat, Alberta, facility reached a record 1 million tons.

In 1993, two projects were completed to facilitate rail shipments from CF's ammonia terminal on Tampa Bay, acquired from Mulberry Phosphates in mid-1992. Throughput capacity is now rated at more than 800,000 tons annually. Primary assets include an ammonia terminal on the Port of Tampa having a 40,000-ton storage tank and related distribution equipment, together with the Tampa Bay Ammonia Pipeline system owned jointly with Cargill Fertilizer of Minneapolis, MN. The location of the storage facility is strategic in that only 37 rail miles are now required to deliver ammonia to CF's Plant City ammonium phosphate plant. The Tampa Bay Ammonia Pipeline system supplies ammonia to major producers of ammonium phosphates in Polk County, FL.

In mid-1993, construction was begun on the 3.5-million-ton-per-year South Pasture phosphate rock project in Hardee County, FL, following approval by the CF Board of Directors. The new state-of-the-art mine and beneficiation plant will provide CF with an independent and economic source of phosphate rock to meet demand for ammonium phosphate production at the Plant City complex for at least 20 years. The beneficiation plant from the depleted North Pasture mine was to be relocated, modified, and expanded.[21]

On May 4, 1993, Cargill purchased the phosphate production and mining assets of Seminole Fertilizer Corp., a subsidiary of Tosco Corp. of Stamford, CT. The transaction included the large ammonium phosphate complex at Bartow, FL; the Hookers Prairie phosphate rock mine in Polk County, FL; and an ammonia terminal at Port Sutton on Tampa Bay. Tosco initially retained its 50% interest in a large wet-process phosphoric acid plant at Ft. Meade, FL, owned jointly with U.S. Agri-Chem. (Sinochem) of China, but sold out to Agri-Chem. later in the year. Agri-Chem. operates a large ammonium phosphate facility at Bartow.

Cargill reportedly will have the aggregate capability of producing about 3 million tons per year of ammonium phosphates from its two large plants at Bartow and Tampa, FL, or 15% of the U.S. total. Ammonia requirements for ammonium phosphate production are sourced from the Tampa Bay Pipeline system—jointly owned by Cargill and CF Industries—and should average more than 500,000 tons per year.[22]

In mid-1993, the IMC Fertilizer Group Inc. (IMCF) of Mundelein, IL, and Freeport-McMoRan Resource Partners L.P. (FMRP) of New Orleans, LA, finalized one of the more significant consolidations in the history of the U.S. fertilizer industry. The new venture, IMC-Agrico, involved the merger of nitrogen and phosphate operations of FMRP's wholly owned Agrico Chemical Co. with IMCF, the leading producer of phosphate raw materials and finished ammonium phosphate fertilizers in the United States. According to information published by the International Fertilizer Development Center (IFDC) at Muscle Shoals, AL, the new joint-venture share of U.S. ammonium phosphate capacity approximates 30%, equating to an ammonia consumption potential of more than 1 million tons.[23] IMCF was to assume responsibility for operating the Agrico facilities.[24]

Agrico's primary nitrogen production facility—the Faustina plant—is on the Mississippi River near Donaldsonville, LA. Annual production capabilities at Faustina were 450,000 tons of ammonia, 225,000 tons urea, 2 million tons ammonium phosphates, and 500,000 tons P_2O_5 wet-process phosphoric acid. Agrico also operated a 1-million-ton-per-year ammonium phosphate plant at Taft, LA, together with wet-process phosphoric acid plants at Uncle Sam, LA, and Pierce, FL.

IMCF was operating the largest wet-process phosphoric acid and ammonium phosphate complex in the United States at New Wales, FL. IMCF had previously reached an agreement in principal to purchase the Conserv, Inc. 550,000-ton-per-year DAP plant at Nichols, FL, formerly owned by EniChem Agricoltura S.p.A. of Milan, Italy.

Farmland Industries, Inc. is a major U.S. cooperative specializing in the production of nitrogen and phosphate fertilizers. The firm ranks among the top nitrogen fertilizer producers in the United States. Farmland and J.R. Simplot have held joint-venture ownership of the former Chevron phosphate rock mine at Vernal, UT, and DAP plant at Rock Springs, WY, since early 1992. Annual DAP production capability at Rock Springs is 410,000 tons. Farmland has also moved the former Chevron Finley, WA, nitrogen solutions plant to its primary nitrogen production complex at Enid, OK.

In late 1991, Norsk Hydro became a joint-venture partner in Farmland's Green Bay, FL, phosphate operation. The Farmland Hydro Ltd. Partnership group operates from headquarters in Bartow, FL. DAP/MAP production capability approximates 1 million tons per year.

Agricultural Minerals Corp. (AMC) of Tulsa, OK, is traded publicly on the New York Stock Exchange as Agricultural Minerals Co. LP. AMC was founded in March 1990 by former Agrico executives to facilitate a leveraged buyout of the firm's nitrogen fertilizer production facilities at Verdigris, OK, and Blytheville, AR. Ammonia, urea, and UAN solutions are the primary products produced by AMC, along with the highly efficient slow-release Super N fertilizers containing dicyandiamide. AMC was among the top five U.S. nitrogen fertilizer producers. AMC is a member of the UAN Export Association.

Koch Industries, Inc. continued to operate a large ammonia complex at Sterlington, LA, acquired from IMCF in 1992. The Sterlington complex consists of two ammonia trains having a total capacity of 1 million tons per year. The acquisition provided a good fit for Koch Industries, owner of the Gulf Central Ammonia Pipeline that serves the Sterlington plant. An ammonia supply contract for a portion of IMCF's New Wales, FL, DAP-MAP complex was also negotiated.

In August, Air Products and Chemicals Inc. disclosed plans to shut down its 263,000-ton ammonia plant at New Orleans, LA, in the next 12 to 18 months. The firm was considering a plan to retrofit the plant for hydrogen production. The ammonia plant is in a large chemical complex that also produces hydrogen, oxygen, carbon dioxide, and other products. Hydrogen is a strategic product produced for the National Aeronautics and Space Administration (NASA).[25]

Air Products was completing a $1.5 million ammonium nitrate upgrade project at its Pace Junction, FL, facility in October that was to increase capacity 10% to 15%. The firm produces ammonia, ammonium nitrate, and nitrogen solutions at Pace Junction. At the same time, the firm reduced ammonia capacity by 50% to 91,000 tons per year by yearend.

Terra International, Inc. completed a 70,000-ton-per-year ammonia expansion at Port Neal, IA, in late 1992 that was to bring total annual capacity to about 270,000 tons. Emissions were also to be reduced 30%. Terra also announced a $15.5 million retrofit project that would provide for the optional production of up to 400 tons per day of methanol in the existing 1,200-ton-per-day ammonia plant at Woodward, OK, by early 1994. Ammonia capacity would reportedly be reduced by up to 20% because of the swing with methanol, but there was an upside advantage in hedging against fertilizer market seasonality. Methanol was to be sold to producers of methyl tertiary butyl ether (MTBE), the leading automotive fuel oxygenate.

In early November 1993, Cypress Chemicals began production of granular NitroS ammonium sulfate on the site of the former Nitrogen Products, Inc. plant at Helena, AR. The plant production capability was rated at 40,000 tons per year assaying 21% N and 24% sulfur (S). Cypress had earlier purchased the bankrupt facility at auction in April with the purpose of creating a regionalized granulation operation. Officials of Mulberry Phosphates, Inc. and other undisclosed parties reportedly provided financing for the new operation.[26]

Nitrogen Products' 190,000-ton-per-year ammonia plant at Helena, AR, together with an associated nitric acid plant, was closed in bankruptcy proceedings by the Dutch-owned bank NMB in late 1992 and later dismantled.

Coastal Chem, Inc's. planned 175,000-ton-per-year ammonia expansion at Cheyenne, WY, based on the reconstruction of a plant on-site, was delayed. Coastal completed a 130,000-ton-per-year nitric acid plant at Elko, NV, in 1992 to be used for the production of ammonium nitrate-based explosives.

Hydro Agri Ammonia, Inc. (HAAI), a U.S. affiliate of the Norwegian firm Norsk Hydro, continued to market ammonia from the former W.R. Grace & Co. joint-venture Tringen plants now run by Norsk and the Government of Trinidad and Tobago at Point Lisas. HAAI is headquartered in Tampa, FL, for this purpose and is staffed by key personnel from the former Grace marketing team in Memphis, TN.

Nitram, Inc. continued to produce about 300,000 tons per year of ammonium nitrate prills for the fertilizer and industrial nitrogen sectors. High-density fertilizer-grade product (34% N) averages 992 kilograms per cubic meter (kg/m^3) (62 pounds per cubic foot) and is about 1.7 millimeters, or 10 to 14 mesh. Low-density industrial explosives-grade material (33.5% N) averages 800 kg/m^3 (50 pounds per cubic foot) and is about the same screen size. Product is sold in bulk and bag through a co-op structure.

Union Chemical Co. (Unocal) permanently closed the former Chevron 130,000-ton-per-year ammonia plant at Finley, WA, purchased in 1991, but continued to use the complex for storage and distribution. Unocal was to toll ammonia from Chevron's 20,000-ton-per-year El Segundo, CA, plant. Chevron planned to continue operating a wholly owned 80,000-ton-per-year ammonia plant at St. Helens, OR, until a buyer could be found and planned to sell its 1,000-ton-per-day nitric acid plant at Riverton, KS, shuttered since 1982. *(See table 4.)*

American Cyanamid's 680-ton-per-day ammonia plant at Fortier, LA, idle since 1983, was to be converted to methanol production for MTBE synthesis. Lurgi and the U.S.-based Pritchard Corp. were contracted to execute a detailed engineering design for a 1,700-ton-per-day methanol plant to be operated as a joint venture between Cytech, the new American Cyanamid chemicals business, and the firm Methanex.

Consumption and Uses

U.S. apparent domestic consumption of ammonia was 15.3 million tons N, representing a moderate 3% decline from the 13-year record-high 15.8 million tons recorded in 1992. Fertilizer materials accounted for about 80% of domestic ammonia demand and industrial applications about 20%.

Urea and ammonium nitrate found extensive use in the fertilizer and industrial sectors in both solid and liquid form. Anhydrous ammonia continued to be the leading direct application fertilizer material in the United States, but UAN solution fertilizers that contain 28% to 32% N were growing in popularity because of their safe handling and storage characteristics and ease of application.

In the industrial sector, urea was used in the production of synthetic fibers, resins, and polymers and as a protein supplement in ruminate animal feeds. Ammonium nitrate-fuel oil explosives (ANFO) dominated the industrial explosives sector. Nitric acid was used in chemical synthesis and in metal treatment. Acrylonitrile, caprolactam, and hexamethylenediamine found respective use in the production of acrylic and nylon fibers, resins, and plastics. Toluene 2,4-diisocyanate, an ammonia derivative, is employed in polyurethane resins; whereas hexamethylenetetramine, produced from ammonia and formaldehyde, is used in the manufacture of phenolic thermosetting resins. *(See table 5.)*

Other uses for ammonia and ammonia-based compounds included consumption as ammonia refrigerant, in specialty horticultural and lawn and garden fertilizers, home and industrial cleaners, solvents, fuel ethanol derived from corn and other biomass species, and as sodium azide propellant in vehicular air bags. Ammonia and urea were also becoming popular low-cost agents that significantly reduced NO_x atmospheric emissions when injected into combustion gas streams.[27]

In 1993, ammonia and ammonia derivatives accounted for 10.3 million tons N, or 54% of the 19.0-million-ton primary fertilizer nutrient market in the United States. The ratio of nitrogen (N) nutrient consumption to phosphate (P_2O_5) and potash (K_2O) fertilizer nutrient consumption was 2.5:1 and 2.2:1, respectively, according to statistics published by the National Fertilizer and Environmental Center, Tennessee Valley Authority (TVA), at Muscle Shoals, AL.

U.S. nitrogen fertilizer consumption fell by a moderate 1% in 1993, from 10.4 million tons N in 1992. Single-nutrient compounds led by direct application ammonia, UAN solutions, urea, and ammonium nitrate, in order of importance, provided 80% of the total. A 13% decline in direct application ammonia consumption, owing to wet weather across the Midwest, was largely offset by increases in direct application solid urea, UAN solutions, and granular bulk-blend fertilizers. *(See table 6.)*

Wet weather, flooding, and lower feed grain plantings across the six key States that comprise the Midwest Corn Belt—Illinois, Indiana, Iowa, Missouri, Nebraska, Ohio—together with Minnesota, resulted in a 7% decline in nitrogen fertilizer consumption to 3.9 million tons N. In consequence, the region suffered a 3% loss in market share to 38% of the U.S. total. Nitrogen fertilizer consumption in Texas, Kansas, California, North Dakota, and Oklahoma, in order of importance, was up 9% to 2.7 million tons N, representing a 2% increase in market share to 26% of the U.S. total. This area was aided by a drop in setaside acreage for food grains and barley. The State of Texas displaced Iowa as the leading U.S. consumer of nitrogen fertilizers in 1993, with 0.85 million tons N, or 8% of total.

U.S. planted crop acreage dropped 4.5 million hectares (11 million acres) or 3% to 134 million hectares (332 million acres) in 1993, and another 24 million hectares (60 million acres) was idled by crop programs and the CRP, according to U.S. Department of Agriculture statistics. Planted acreage dropped principally because of the Secretary of Agriculture's prescribed 10% setaside on most feed grain acreage, together with widespread flooding across the Midwest that hampered planting intentions. Planted feed grain acreage declined 4 million hectares (9 million acres) or 8% to about 40 million hectares (100 million acres), while harvested acres dropped 5 million hectares (13 million acres) or 14% to 34 million hectares (83 million acres).

Harvested acres were down substantially owing to wet weather and flooding across the Midwest that damaged or destroyed crops and negatively affected yields. As a consequence, feed grain yields plunged 22% from the record yields of the previous year, and carryout inventories dropped to near-record lows established back in 1976. Carryout inventories of wheat and most other food grains ended the year at relatively low levels. U.S. net cash farm income in

1993 was estimated to approximate a record $59 billion, while net farm income was estimated at $43 billion, 12% below the record $49 billion of 1992. The Secretary of Agriculture lowered the acreage setaside (ARP) on corn and other feed grains from 10% to 0% for next year and maintained wheat at 0%.

Stocks

U.S. stocks of major nitrogen compounds declined about 9% at the producer level and ended the year at 1.6 million tons N. There was a 19% drawdown in anhydrous ammonia inventories. *(See table 7.)*

Transportation

Ammonia was transported by refrigerated barge, rail, pipeline, and truck. In late 1990, the Research and Special Programs Administration (RSPA) of the U.S. Department of Transportation (DOT) classified anhydrous ammonia as a nonflammable gas linked to a required "inhalation hazard" label. RSPA officially classified anhydrous ammonia a division 2.2 nonflammable, nonpoisonous compressed gas for domestic shipments.[28] The inhalation hazard label requirement, including nurse tanks, became effective October 1, 1992.

International shipments, however, were classified as a division 2.3 "poison gas" consistent with United Nations regulations. International shippers were originally required to comply under the new regulations on January 1, 1991. Because of the documented inhalation hazards of anhydrous ammonia when released in large quantities, RSPA was also requiring the words "INHALATION HAZARD" on packages and shipping papers, in addition to other current hazard communications information.

The Interstate Commerce Commission (ICC) replaced the Federal Energy Regulatory Commission (FERC) as the Federal agency responsible for ammonia pipeline regulation in late 1990. FERC had been responsible for ammonia pipeline regulation since 1977, when ICC transferred power of control under the Department of Energy act.

Koch Industries operated the Gulf Central Ammonia Pipeline built in 1969 that extended about 3,060 kilometers (km) (1,900 miles) from the Gulf of Mexico into the Midwest, as far north as Iowa. The annual capacity of this pipeline is about 2 million tons, and storage tanks along its path have an additional capacity of more than 1 million tons. Koch Nitrogen, a subsidiary, purchased four Midwest ammonia terminals from ConAgra Fertilizer in 1991 having a combined capacity of 150,000 tons. The pipeline was extended 24 km (15 miles) to the firm's Wood River, IL, terminal by yearend 1992.

Mapco Ammonia Pipeline Inc. operated Mapco Ammonia Pipeline and its sister company, Mid-America Pipeline, along a 1,770 km (1,098-mile) corridor that extended in a northeasterly direction from Borger, TX, in northern Texas, to Mankato, MN, in southern Minnesota. Mapco built the first leg of the pipeline in 1968-69 and, by 1978, had added six extensions. The Mapco pipeline has an annual capacity of about 1 million tons, and about 500,000 tons of ammonia storage capacity was located along the pipeline.

Mapco Ammonia Pipeline neither produced nor marketed ammonia independently, but transported ammonia on behalf of five shippers. Competition from the rail and truck transportation sectors was minimized because areas served by Mapco Ammonia Pipeline did not have river access. Mid-America Pipeline had more than 400 shippers and competed with the other transportation sectors.[29]

Between January and May 1993, Seminole Fertilizer and CF Industries were operating the Tampa Bay Pipeline system, a joint-venture ammonia pipeline that serves ammonium phosphate producers in Polk County, FL. Cargill Fertilizer, Inc. purchased Seminole on May 4, 1993, and assumed joint ownership of the pipeline with CF Industries.

Markets and Prices

Anhydrous ammonia prices continued firm at about $130 per ton, f.o.b. barge, New Orleans, through the first quarter, following a significant runup during the fall of 1992. Prices dropped thereafter, reaching lows of about $100 per ton between midyear and early September. Ammonia prices declined for a number of reasons, including lower direct application ammonia fertilizer demand during the wet spring season, a steady flow of imported ammonia and urea, and a continuing oversupply of diammonium phosphate.

Ammonia prices rose steadily during the fall as supplies tightened owing to an improvement in domestic fertilizer demand and a more optimistic outlook for ammonium phosphate markets and prices. Ammonia peaked at about $145 per ton by yearend. In mid-December, ammonia futures contracts were trading at $134 per ton on the Chicago Board of Trade (CBOT) for April 1994 delivery, f.o.b. barge, Louisiana. There was an indication that ammonia futures were experiencing upward movement because of improving prospects for a strong spring fertilizer season and improving ammonium phosphate trade.

Urea and ammonium nitrate prices were stable to firm during the first half of the year. Granular urea prices peaked at a firm $165 per ton, f.o.b. New Orleans, during the April through early June period before falling in the third quarter. Urea prices picked up during late fall and ended the year at $140 per ton. Ammonium nitrate prices declined marginally during the fall.

DAP prices, f.o.b. central Florida, continued to be depressed and fell from $124 per ton in early January to about $113 by the end of June, continuing a downward spiral that began back in the fourth quarter of 1991. The U.S. DAP industry was plagued by an inordinate supply overhang from 1992 and a significant decline in export sales to China. The market turned up during the fall and DAP product sold for more than $150 per ton by December. At yearend, June 1994 DAP futures contracts were trading on the CBOT for upward of $160 per ton, f.o.b. central Florida. *(See table 8.)*

Foreign Trade

The total U.S. nitrogen trade deficit more than doubled in 1993 and reached a level of 2.1 million tons N, or $1 billion. Approximately 70% of the increase was attributable to urea, where shipments from most traditional U.S. trading partners were up significantly, along with new entries (a trade deficit occurs when imports exceed exports).

Although Canada shipped approximately 50% of the urea import volume, where Cargill operated the new Saskferco plant in Saskatchewan, Canada, was by no means the decisive factor in the overall increase. Shipments were up substantially from Brazil, Trinidad, and Venezuela and Bulgaria in the Eastern bloc, which landed urea at $23 per ton below the $134 c.i.f. average. Nigeria was a new entry, along with Saudi Arabia and Qatar in the Persian Gulf. A shipment of 8,000 tons was even reported from Belarus, a former Soviet country still tied to an antidumping duty order of the ITC. Urea antidumping duties imposed in 1987 against the former German Democratic Republic (now Germany), Romania, and countries of the former U.S.S.R. protected U.S. producers against unfair trade practices for the most part.

In 1993, the U.S. ammonia trade deficit remained at 2.8 million product tons, or roughly $0.3 billion. Ammonia imports originated predominately from Trinidad, Canada, the former U.S.S.R., and Mexico, in order of importance. An approximate 50% drop in Mexican ammonia imports was offset by shipments from Bahrain, Quatar, and Saudi Arabia in the Middle East, Algeria, and Western Europe. U.S. ammonia imports in 1993 were valued at $415 million, representing an average landed price of $128 per ton, c.i.f., compared with $112 million in 1992. *(See tables 9 and 10.)*

Anhydrous ammonia import tonnage data from the former U.S.S.R. continued to be withheld from the public domain during 1993 because of a previous ruling by the Bureau of the Census that determined Occidental Petroleum to be the proprietary U.S. agent. Occidental's long-term trade pact with the former U.S.S.R. involving ammonia for superphosphoric acid was conceptually no longer in effect, however, owing to the dissolution of the U.S.S.R. in late 1991. Although Occidental was successful in dealing for ammonia in the recent past, the new independent republics were forced to discontinue purchases of Occidental superphosphoric acid because of a lack of hard currency. Agrovit, a subsidiary of the Russian trade agency Agrichem Export, was now handling Soviet ammonia shipments on behalf of Occidental.

Ammonia shipments from the former U.S.S.R. originated predominately from the Black Sea port at Yuzhnyy in the Ukraine with minor shipments from Latvia on the Baltic Sea. MAP shipments from Russia and the Ukraine to the United States were 132,000 tons compared with 122,000 tons the previous year in line with the global press for hard currency. MAP was landed at a value of $16.6 million, or $125 per ton c.i.f., somewhat lower than the $134 per ton, c.i.f. price of 1992.

Ammonium nitrate was also imported in significant quantities amounting to 0.5 million tons valued at $58.5 million, or roughly $120 per ton, c.i.f. About 75% of the total was Canadian product. The United States exported a modest 66,000 product tons in 1993.

U.S. ammonium phosphate exports fell 10% to 8.3 million product tons (1.4 million tons N equivalent), from 9.2 million tons in 1992. The major decline can be traced to DAP trade with China, where volume plunged 40% to 2.1 million tons compared with 3.6 million tons in 1992. MAP trade was up about 23% overall to 1.1 million tons in 1993. *(See tables 11 and 12.)*

World Review

In 1993, global ammonia production fell significantly for the fourth consecutive year to a level of 91.5 million tons N, representing a decline of 1.8 million tons or 1.9%. Production fell in virtually every region of the world except for the Middle East, where countries were recovering from the Persian Gulf Crisis, together with relatively minor increases in Asia. The former U.S.S.R., Western Europe, Latin America, North America, and the Eastern bloc experienced the brunt of the decline, in relative order of importance.

Since 1989, global ammonia production has fallen by 7.8 million tons N (8%) from a near-record level of 99.3 million tons N. During this 4-year period, production in the former U.S.S.R. has declined 5.8 million tons (-30%); Eastern bloc countries, 4.5 million tons (-48%); and Western Europe, 2.3 million tons (-18%). This 12.6-million-ton N drop has been partially offset by rising net production in other regions, especially Asia and North America.

Anhydrous ammonia was produced in about 79 countries during 1993, of which about 9 million tons N (10%) was directly traded. Ammonia was converted into about 36.1 million tons of urea N in 62 countries, of which about 9.4 million tons (26%) was traded. Total world nitrogen fertilizer consumption fell about 2% to a level of 73 million tons N, according to data available in May 1994.

While China—the world's largest urea importer—experienced a dramatic fall in urea imports, India and Vietnam continued to gain as large-volume urea importers. This, together with the increased urea import take in the United States, Latin America, and Middle East, served to maintain a relatively level global urea nitrogen materials trade balance in 1993.

Eastern Europe and the former U.S.S.R. have suffered significant losses in domestic production and consumption because of sweeping political reforms, accompanied by high inflation and foreign exchange problems. Western Europe has been impacted negatively by inflated natural gas prices, an attendant decline in competitive economics, and a downturn in domestic agriculture. Recession, the reunification of Germany, transition to the new European Community reform

(EC-92), and declining demand in Eastern Europe and the former U.S.S.R. also have been contributing factors. The Mideast downturn through 1992 was primarily a result of events surrounding the Persian Gulf Crisis and ensuing Operation Desert Storm initiatives of 1990 and 1991.

It is estimated that between 1991 and 1993, domestic nitrogen fertilizer consumption has declined 3.3 million tons N (42%) in the former U.S.S.R.; 0.3 million tons (-17%) in Eastern Europe, compared with -62% during the previous 3 years; and 1.1 million tons (-11%) in Western Europe.

The dissolution of the centrally planned economy of the U.S.S.R. commanded global attention in 1992 and resulted in the evolution of 15 independent republics. The new republics have been plagued by a combination of high inflation and drastic cuts in domestic nitrogen fertilizer production and consumption. The region continues to dominate global nitrogen trade, accounting for 3.5 million tons N, or 39% of global ammonia exports, and 2.5 million tons N, or 27% of global urea exports in 1993. The former U.S.S.R. has traditionally experienced pressures to generate hard currency and is thus motivated to be an aggressive trader. In 1993, ammonia exports were level at 4.3 million tons of product, although urea trade was off 7% to 5.5 million tons.

Ammonia was produced in 10 of the 15 new independent republics in 1993, of which Russia accounted for 60% of the 13.6-million-ton N total; the Ukraine, 24%; Uzbekistan, 8%; Belarus, 5%; Estonia, Georgia, and Lithuania, 2%; and the remainder, 1%. The ammonia plants were designed for output but not efficiency, and gas costs were reported to have risen dramatically in 1993. Natural gas costs in the Russian Republic, for example, rose from $0.08 per million Btu in March 1992 to $0.63 per million Btu in May 1994, an approximate sevenfold increase. In the Ukraine where Russian gas is used, the price jumped 35%, from $1.30 per million Btu in October 1993 to $1.75 in May-June 1994.

Gas supplies were extremely short in the Ukraine during 1993, and a substantial gas debt with Russia ultimately resulted in the disruption of Russian ammonia and urea export shipments to the Ukrainian port at Yuzhnyy on the Black Sea. The situation was reportedly resolved late in the year.

If gas were fully deregulated by the end of 1993 in Russia, as planned, which now does not seem plausible, feedstock prices may increase to roughly $60 per thousand cubic meters, or $1.70 per million Btu. This could potentially escalate ammonia production costs to about $90 per ton and urea to $100 per ton, values that may be prohibitive to export competitiveness on the U.S. gulf coast. A full-scale revamp of Russian ammonia and urea plants was needed. Russian gas was deregulated and priced at roughly $2.50 per million Btu to Europe.

All Eastern European countries are now forced to rely heavily on costly, deregulated Russian gas for ammonia and urea production and other uses. Romania, Hungary, Poland, and the former Yugoslavia, in order of importance, have sizable gas production, but still require significant imports. Bulgaria and Czechoslovakia rely almost exclusively on Russian gas imports. Romania, Poland, Bulgaria, the former Yugoslavia, Czechoslovakia, and Hungary, in respective order of importance, are all major participants in the Eastern European ammonia industry. In 1992, about 47% of the natural gas consumed in Eastern Europe was supplied from domestic production and 53% was imported from the former U.S.S.R. Escalating natural gas prices have driven ammonia and urea production costs up to near-prohibitive levels, precipitating critical shortages of nitrogen fertilizers for domestic use and export.

Operation Desert Storm resulted in severe damage to nitrogen plants in both Kuwait and Iraq during January and February 1991. Information available on the damage and destruction of nitrogen production facilities in the two countries last year indicated that nitrogen output would be restored on a more timely basis than previous estimates of approximately 5 years, but now the pendulum has swung once again to longer term prospects. Kuwait, in particular, is now planning to divert much of its scarce natural gas feedstock supplies to petrochemical and plastics synthesis.

In Kuwait, a 271,000-ton-per-year N ammonia plant and 216,000 tons per year of urea N came back into operation during 1992 at Shuaiba, but preinvasion capacity levels may now be delayed beyond 1994 as previously expected. In Iraq, the new 272,000-ton-per-year N ammonia plant at Baiji was operational in 1992, together with a 265,000-ton-per-year N urea facility. Approximately 63% of preinvasion capacity was scheduled to be restored by 1994.

Iraq and Kuwait, in combination, had represented about 1.5% of total world ammonia capacity and 2.5% of world urea capacity. In 1989, Iraq and Kuwait accounted for about 5% of total world urea and ammonia N trade. This, together with the supply potential of the other Persian Gulf countries, accounts for about 15% of world nitrogen trade in the form of ammonia and urea.

Industry Structure.—Global ammonia was produced in 79 developed and developing countries that had access to fossil fuel feedstocks, principally, natural gas, naphtha, petroleum refinery offgases and condensates, and coal and coke gases. The supply pattern, in general, followed the world population trend, with Asia and Eastern Europe, including the former U.S.S.R., accounting for more than 60% of the global ammonia supply potential and 58% of production in 1993. The developed regions—North America (United States and Canada), Western Europe, and Oceania—produced ammonia primarily for domestic use and accounted for about 25% of world supply potential and 30% of global production. The energy-rich countries of the Middle East accounted for about 4% of the world supply potential and 4% of global production in 1993 and exported significant quantities of ammonia and urea to the global community. Latin America and Africa, in order of importance, accounted for roughly 6% of global ammonia supply potential.

Capacity.—Rated capacity is defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable long-term operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure.

In 1993, there was a net gain in global ammonia capacity of about 0.6 million tons per year N (0.5%) and about 1.5 million tons per year N (3%) of urea. At yearend, world ammonia capacity stood at about 119 million tons per year N and urea at 47 million tons per year N.

New ammonia and urea capacity was brought on-stream in Asia: Bangladesh, China, Indonesia, and Pakistan; the Middle East: Kuwait (repairs), Saudi Arabia, and Turkey; and Africa: Egypt, South Africa, and Zambia; all in relative order of importance. In the Ukraine, a new 160,000-ton-per-year urea plant was coming on-stream.

A total of approximately 1.4 million tons per year of ammonia N was closed in 1993. In Western Europe, ammonia capacity declined 0.7 million tons N (5%) owing to closures in Finland, Italy, the Netherlands, and Norway. In Latin America, ammonia capacity fell 0.4 million tons per year N owing to the Petromex closure at Cosoleacaque; and, in the former U.S.S.R., ammonia capacity declined by a collective 0.3 million tons per year (1.5%) in Belarus, Russia, and Turkmenistan.

Major world ammonia and urea capacity contracted or under construction and scheduled on-stream between 1993 and 1998 is equally divided between 8 million tons per year of ammonia N and 8 million tons per year of urea N. Potentially, up to 2 million tons per year of ammonia N in the former U.S.S.R. and Western Europe, in order of importance, will close during this timeframe, resulting in a net increase of roughly 6 million tons per year.

Individual region/country ammonia and urea capacity profiles follow. New ammonia and urea capacity additions in Asia are projected to approximate 12 million tons N and to account for approximately 75% of the world total.

Asia.—**China**.—2.6 million tons ammonia N and 3.1 million tons urea N. Bangladesh—0.3 million tons ammonia N and 0.3 million tons urea. India—1.9 million tons ammonia N and 1.7 million tons urea N. Indonesia—0.9 million tons ammonia N and 0.6 million tons urea N. Pakistan—0.2 million tons ammonia N and 0.2 million tons urea N.

Africa.—**Egypt**.—0.1 million tons ammonia N. Republic of South Africa—0.1 million tons ammonia N. Nigeria—0.3 million tons ammonia N and 0.2 million tons urea N.

Eastern Europe.—**Romania**.—0.3 million tons ammonia N (restart idle plant). Former Yugoslavia—0.4 million tons ammonia N and 0.1 million tons urea N (restart idle plants).

Former U.S.S.R.—A net of approximately 1.3 million tons per year of ammonia N was planned to close—Uzbekistan (55% of the total); Russia (22%); Belarus (14%); and the Ukraine (9%). Urea capacity, however, was scheduled to increase by a total of 0.4 million tons per year N, predominately in the Ukraine, and to a lesser extent in Russia and Belarus. *(See table 13.)*

Middle East.—**Iran**.—0.3 million tons ammonia N and 0.2 million tons urea N. Iraq (reconstruction)—0.3 million tons ammonia N and 0.3 million tons urea N. Qatar—0.4 million tons ammonia N and 0.3 million tons urea N. Saudi Arabia—0.2 million tons ammonia N and 0.2 million tons urea N. Bahrain was to add 0.3 million tons per year of urea N, while Kuwait planned an indefinite hold on the reactivation of plants having annual capacities of 0.3 million tons ammonia N and 0.2 million tons urea N.

North America.—**Canada**.—Cargill was operating a new C$435 million nitrogen fertilizer complex at Belle Plaine, Saskatchewan—the Saskferco project—commissioned in the fall of 1992. The operation was structured through a corporation formed between its Canadian subsidiary, Cargill Ltd., the Crown Investments Corp. of the Province of Saskatchewan, and Citibank Canada. The plant was designed to produce 510,000 tons per year of ammonia and 680,000 tons per year of granular urea.

More than one-half of the Saskferco output was scheduled to move through Cargill retail and wholesale distribution outlets. Agreements were reportedly reached with other large retail distributors for the sale of the remaining product, including Land O'Lakes, Inc., and Farmland Industries, Inc. in the United States. Product was to be marketed in western and eastern Canada, the north-central region of the United States, and offshore.[30]

ICI Canada's nitrogen fertilizer production facility at Courtright, Ontario, was purchased by Terra International of the United States in April 1993. The plant produces ammonia, ammonium nitrate, and related products.

Current Research

During October 1993, the U.S. Bureau of Mines held a seminar on the topic: Agricultural Commodities Competing With Traditional Metals and Materials. Speakers from the AARC Board of USDA, the Institute for Local Self-Reliance, and the Novon Products Group of Warner-Lambert Co. addressed the situation and outlook for renewable materials development in the United States. There was a consensus that prospects were favorable for a continuing penetration of the nonrenewables organic sector by industrial and consumer materials derived from renewable organic materials grown on our Nation's farms and forests.

Speakers cited steady improvement in renewables technology and processing efficiency, environmentally friendly aspects, the availability of skilled labor and resources in rural America, plus the opportunity to reduce agricultural subsidies as focal points for a slow but steady revival in renewable materials. Warner-Lambert disclosed recent developments in its Novon line of biodegradable plastics materials, including garbage bags and cutlery that had been successfully composted and recycled on a commercial scale.

Tetra Technologies, Inc. of The Woodlands, TX, developed a continuous countercurrent ion exchange (CCIX) method for the removal of nitrate contaminants from mine waste streams, including residual unreacted ammonium nitrate-fuel oil explosives, and in gold mining where waste nitrates result from the nitric acid washing of activated carbon and the oxidation of cyanide during heap detoxification. The system was also reported to be effective in controlling nitrate effluent levels in dairy and other agricultural operations, according to the firm.

M. W. Kellogg of Houston, TX, continued to publicize two major advances in its ammonia process technology: the Kellogg Reforming Exchanger System (KRES) and the Kellogg Advanced Ammonia Process (KAAP), a joint technology development with British Petroleum.

Kellogg's KRES design was revolutionary in that it completely eliminated the conventional fired primary reformer from the ammonia production process. KRES is environmentally attractive because without a primary reformer, nitrogen oxide emissions are substantially reduced. The system could be easily installed in new or existing plants and would save up to 10% on capital costs.

The KAAP process employs a novel ammonia synthesis catalyst that was claimed to be the first significant breakthrough in catalyst technology since 1927. The proprietary KAAP catalyst is up to 20% more active than conventional iron catalysts. The KAAP system was to be employed in a retrofit project designed to increase production capability by 40% at Ocelot's ammonia plant in Kitimat, British Columbia.

Norton Chemical Process Products of Akron, OH, developed a novel line of NC-300 zeolite catalysts for NO_x removal utilizing the injection of ammonia. Zeolite-based NC-300 catalysts are used in Selective Catalytic Reduction (SCR), a process in which ammonia is injected into the exhaust gas ahead of the catalyst reactor. As the gas passes through the NC-300 catalyst, ammonia reacts with NO_x to produce inert nitrogen gas and water. Norton's patented SCR process catalysts can be used with gas turbines and reciprocating engine systems, industrial boilers and process heaters, electric utility boilers, waste incinerators, nitric acid plants, nuclear fuel reprocessing, and miscellaneous chemical and combustion processes, according to the firm's product literature.

Exxon Research and Engineering Co. of Florham Park, NJ, has developed a process that significantly reduces NO_x emissions by injecting ammonia into flue gas streams emanating from stationary combustion sources. The Exxon process is based on a noncatalytic gas phase homogeneous reaction between NO_x in flue gas and ammonia that produces nitrogen and water. The patented process was offered for license by Exxon Research and Engineering Co.[31]

A catalytic process (SNOX) was developed by Haldor Topsoe A/S of Denmark for the cleanup of flue gas from fossil fuel burning equipment. Nitrogen oxides and sulfur oxides emanating from industrial and utility boilers burning fossil fuels are converted to elemental nitrogen, water vapor, and sulfuric acid. The SNOX process is offered under license in North America by ABB Environmental Systems.

USDA and DOE's "memorandum of understanding" on biomass research has accelerated the development of ethanol and other alternative fuels and fuel additives from agricultural and forestry products.[32] This agreement promised significant new markets for U.S. farmers and supported DOE's National Energy Strategy that focused on a reduction in foreign energy dependency.

In September 1991, the former Solar Energy Research Institute at Golden, CO, was designated the National Renewable Energy Laboratory (NREL), reflecting a strong commitment to renewable energy technology research and development (R&D) in the United States. In April 1992, work began on the National Alcohol Fuels User Facility, including construction of a process development unit for testing new biofuel conversion technology. DOE was developing a cellulose-to-ethanol process development unit at NREL to evaluate methods for converting wood cellulose into ethanol fuels that was to serve as the centerpiece for the National Alcohol Fuels User Facility.[33]

Fuel ethanol research is receiving a boost from a cooperative R&D agreement (CRADA) between NREL and New Energy Co. of Indiana. The CRADA partners are developing a method of converting corn fiber to ethanol, a technology honored by R&D magazine as one of the top technological innovations of 1993. New Energy currently produces ethanol by the fermentation of corn starch, but starch makes up only about 72% of the corn kernel. Currently, the residual fibrous residue consisting of cellulose, hemicellulose, and lignin, along with protein and fat, is dried and sold as an animal feed known as distiller's dried grains and solubles (DDGS).[34]

New Energy will utilize novel NREL technology for converting cellulose and hemicellulose in DDGS to sugar for fermentation to ethanol. Ethanol yields are expected to increase by as much as 13% by taking advantage of the carbohydrates left in this material. Another plus will be that DDGS, with the carbohydrate fraction removed, will become a protein concentrate, reduce shipping costs, and should command a premium price. The research will utilize two 8,000-liter fermentation tanks, already completed.

According to recent DOE information, ethanol production from corn starch could probably be increased fivefold without unduly affecting grain prices. Corn cobs and stover also hold promise as lignocellulosic feedstocks for ethanol production. Beyond the corn industry, potential feedstocks are virtually unlimited, ranging from specially grown grasses or trees to wastepaper.

In the field of microbiology, NREL was conducting research that could pave the way to vast ponds of microalgae from which economic quantities of environmentally friendly biodiesel may be produced. Large coal-burning plants in the southeastern United States offer an excellent potential source of CO_2 essential to large-scale microalgae production and downstream production of biodiesel. The symbiosis between these two technologies would substantially increase the amount of energy generated per unit of greenhouse gas produced. Research is targeted at demonstrating an environmentally suitable technology converting lipid-rich microalgae to biodiesel fuel at a total cost of $0.26 per liter ($1 per gallon equivalent). Negligible CO_2 costs and a plant size of about 1,000 hectares (3.9 square miles) are believed necessary to compete with petroleum-based diesel. Biodiesel releases up to 70% less smoke than conventional diesel and emits no sulfur or aromatics.[35]

Deshen International of Newton, MA, continued to develop markets for mobile power-intensive nitrogen plants based on the electric arc nitrogen fixation process. Several electrical power utility facilities worldwide were interested in the process, which could be used to improve powerplant efficiencies during off-peak periods, according to Mr. Mosche Alamaro, president of Deshen International.

OUTLOOK

The U.S. Bureau of Mines ammonia nitrogen demand forecast was developed from World Bank-United Nations Fertilizer Working Group projections[36] taking into consideration world per capita consumption trends and geopolitical factors in the former U.S.S.R., Europe, and the Mideast. Steady-state conditions were assumed for weather. World ammonia capacity projections were provided by the International Fertilizer Industry Association Ltd. (IFA), Paris, France. *(See table 14.)*

Global ammonia demand and operating rates dropped to an exceptionally weak 77% in 1993, 1% point below the 78% operating rate estimated last year. Operating rates, for example, were 83% to 85% in 1988-89. The downturn can be traced largely to the dramatic fall in domestic demand during the past 4 years in the former U.S.S.R., Eastern Europe, and more recently in Western Europe. Global per capita nitrogen consumption has dropped 16%, from 19 kilograms in 1989, to an estimated 16 kilograms in 1993.

Conceptually, a substantial drop in per capita nitrogen consumption means that many people are not eating as well these days, and certainly this must be true, particularly in the former Eastern bloc and U.S.S.R. countries. It also should be recognized, however, that nutrient efficiency has improved dramatically in the new Soviet republics since the dissolution of the U.S.S.R. in 1991. Thus, the sizable reductions in global per capita nitrogen consumption and operating rates experienced during the past 4 years hopefully may not be quite as severe in real terms as indicated by current statistics. It is known that world grain stocks have been drawn down to quite low levels in the recent past.

The world ammonia supply-demand outlook anticipated by the U.S. Bureau of Mines suggests that soft market conditions will continue to prevail at the global level into 1994 and persist for an indefinite period because of new additions to world capacity, a protracted period of recovery anticipated in the former U.S.S.R. and Europe, and lower expectations for fertilizer demand. Recent projections by IFA indicate that growth in global nitrogen fertilizer demand will average no better than 1.3% per year between 1993 and 1998.

Ammonia production and demand are projected to decline by another 2% in 1994 owing to a continued downturn in the former U.S.S.R., especially in the Ukraine. There is also concern that China will be forced to shut down a portion of its inefficient 10-million-ton-per-year ammonium bicarbonate production capability and that India and Indonesia may be in jeopardy of running new plants at reduced rates or experiencing startup delays because of natural gas shortages. Gas shortages also have been experienced in Trinidad and Tobago, but the situation will reportedly be resolved in the near-term.

The upside to this seemingly gloomy forecast is that world supply-demand fundamentals outside the severely affected regions should continue in reasonable balance. For example, limited increases in domestic supplies from major consuming countries like China and India could provide trade opportunities for ammonia, urea, and ammonium phosphates. The combination of continuing declines in former U.S.S.R. and Eastern bloc production capabilities and rising production costs may further restrict exports from these dominant regions. Also, capacity rationalization in Western Europe and caps on subsidized acreage setasides may provide opportunities for fertilizer and grain trade from outside the region.

In the United States, the outlook for continued strength in the nitrogen fertilizer and grain sectors is anticipated. The U.S. ammonia industry is running at near capacity, grain stocks are still relatively low at the domestic and global levels, herd rebuilding is needed, and U.S. and North American ammonia capacity expansion plans are minimal. Planted acreage should be up approximately 4.9 million hectares (12 million acres) in 1994, mostly in feed grains, translating to a robust spring season for the U.S. farmers and suppliers of agricultural fertilizers and crop protection chemicals. Crop demand should be adequate to hold up planted acreage near current levels during the next 5 years. The mechanisms of CRP and WRP acreage setaside programs, together with regular farm ARP, should assist in holding U.S. crop acreage at about the current 138-million-hectare (340-million-acre) level. This, together with the Export Enhancement Initiative, should control crop inventories and provide favorable crop prices for the U.S. farmer.

The new farm bill to be enacted in

1995 was being deliberated on Capitol Hill and around the farm community in general. Of major concern was the fate of 36 million acres in the CRP, contracts on which were to begin to expire in 1995. By late 1996, about 5.7 million hectares (14 million acres) will move back into active farm program crop acreage under existing law, a total of 10.1 million hectares (25 million acres) by the end of 1997, and a grand total of 14.6 million hectares (36 million acres) by the end of 1999. Congress and the farm community face the challenge of effectively controlling planted crop acreages to avert a possible return to the excessive grain oversupply and depressed price situation of the mid-1980's.

The U.S. converted nitrogen supply-demand outlook will be critically dependent upon the following: (1) a continuation of reasonably priced natural gas for U.S. ammonia production; (2) a return to favorable supply-demand fundamentals by the ammonium phosphate industry; (3) new industrial outlets for U.S. agricultural crops, including corn-based ethanol in reformulated motor fuels under the provisions of the Clean Air Act of 1990 and USDA's new AARC initiative; (4) favorable provisions in the 1995 farm bill that will continue to strengthen agricultural economics in the United States, including sound management of CRP acreage; (5) acceptable markets for the new Saskferco ammonia and urea nitrogen complex, which came on-stream in the fall of 1992 in Saskatchewan, that would minimize the closure of U.S. nitrogen fertilizer capacity; (6) favorable implications for the recently negotiated GATT agreement that would liberalize global agricultural trade and provide opportunities for the United States to compete more effectively in world trade; (7) improved agricultural trade with Canada and Mexico under provisions of NAFTA legislation and for the granting of most-favored-nation (MFN) status to the former U.S.S.R. and other Eastern European countries; (8) a more expedient transition in democratic reforms in Eastern Europe and the former U.S.S.R.; (9) resolution of the MFN-status debate with China; and (10) a balanced approach to fertilizer nutrient management in the United States based on pending legislative amendments to the Clean Water Act of 1972.

TABLE 1
SALIENT AMMONIA STATISTICS[1]

(Thousand metric tons of contained nitrogen unless otherwise specified)

	1989	1990	1991	1992	1993[p]
United States:					
Production	12,280	12,680	[r]12,803	[r]13,643	12,865
Exports	346	482	580	354	378
Imports for consumption	2,861	2,673	2,742	2,690	2,657
Consumption, apparent[2]	14,871	14,923	[r]14,826	[r]15,856	15,348
Stocks, Dec. 31: Producers'	849	797	936	[r]1,059	855
Average annual price per ton product, f.o.b. gulf coast[3]	$104	$106	$117	$106	$121
Net import reliance[4] as a percent of apparent consumption	17	[r]15	[r]14	[r]14	16
Natural gas price: Wellhead[5]	$1.69	$1.71	$1.64	[r]$1.74	$1.99
World:					
Production	[r]99,331	[r]97,160	[r]94,472	[e]93,253	[e]91,497
Trade[6]	9,823	10,004	[r]9,587	[r]9,231	8,935

[e]Estimated. [p]Preliminary. [r]Revised.

[1] Synthetic anhydrous ammonia, calendar year data, Bureau of the Census; excludes coke oven byproduct.

[2] Calculated from production, plus imports minus exports, and industry stock changes.

[3] Green Markets, Fertilizer Market Intelligence Weekly, Pike & Fischer, Inc.

[4] Defined as imports minus exports, adjusted for industry stock changes.

[5] Monthly Energy Review, U.S. Department of Energy. Average annual cost at wellhead in dollars per thousand cubic feet.

[6] International Fertilizer Industry Association statistics—World Anhydrous Ammonia Trade.

TABLE 2
FIXED NITROGEN PRODUCTION IN THE UNITED STATES

(Thousand metric tons of contained nitrogen)

	1989	1990	1991	1992	1993[p]
Anhydrous ammonia, synthetic:[1]					
Fertilizer	11,131	11,573	[r]11,559	[r]12,294	11,226
Nonfertilizer	1,148	1,107	[r]1,244	[r]1,349	1,639
Total[2]	12,280	12,680	[r]12,803	[r]13,643	12,865
Byproduct ammonia, coke plants:[3]					
Ammonium sulfate[e]	48	47	42	41	40
Ammonia liquor[e]	5	5	4	4	4
Total[e] [2]	53	52	45	44	44
Grand total[2]	12,332	12,731	[r]12,849	[r]13,687	12,909

[e]Estimated. [p]Preliminary. [r]Revised.

[1] Current Industrial Reports, MA28B, M28B, and MQ28B, Bureau of the Census.

[2] Data may not add to totals shown because of independent rounding.

[3] Quarterly Coal Report, U.S. Department of Energy. Production estimates based on reported coke production trend.

TABLE 3

MAJOR DOWNSTREAM NITROGEN COMPOUNDS PRODUCED IN THE UNITED STATES[1]

(Thousand metric tons)

Compound	1989	1990	1991	1992	1993[p]
Urea:					
Gross weight	7,261	[r]7,454	[r]7,378	[r]8,147	7,105
Nitrogen content	3,340	[r]3,429	[r]3,394	[r]3,748	3,268
Ammonium nitrate:					
Gross weight	7,140	[r]6,998	[r]7,093	[r]7,106	7,615
Nitrogen content	2,499	2,449	[r]2,483	[r]2,487	2,665
Ammonium phosphates:[2]					
Gross weight	14,862	15,871	[r]16,431	[r]17,250	14,484
Nitrogen content	2,517	2,673	[r]2,713	[r]2,915	2,459
Ammonium sulfate:[3]					
Gross weight	2,163	2,285	2,035	[r]2,169	2,175
Nitrogen content	[r]459	[r]485	[r]432	[r]460	461
Nitric acid, direct use:[4]					
Gross weight	1,951	[r]1,684	[r]1,605	[r]1,701	1,748
Nitrogen content	434	[r]374	[r]357	[r]378	388
Acrylonitrile:					
Gross weight	1,183	1,373	1,201	1,283	1,138
Nitrogen content	312	363	318	338	300
Caprolactam:					
Gross weight	595	626	582	[r]625	616
Nitrogen content	73	78	73	78	77
Total:[5]					
Gross weight	35,155	36,291	[r]36,325	[r]38,281	34,881
Nitrogen content	[r]9,634	[r]9,851	[r]9,770	[r]10,404	9,618

[p]Preliminary. [r]Revised.

[1] Ranked in relative order of importance.

[2] Diammonium phosphate (DAP), monoammonium phosphate (MAP), and other ammonium phosphates.

[3] Excludes coke plant ammonium sulfate.

[4] Gross nitric acid production netted for use in production of ammonium nitrate.

[5] Data may not add to totals shown because of independent rounding.

Sources: Bureau of the Census and International Trade Commission.

TABLE 4
DOMESTIC PRODUCERS OF ANHYDROUS AMMONIA IN 1993

(Thousand metric tons per year of ammonia)

Company	Location	Capacity[1]
Agricultural Minerals Corp.[2]	Blytheville, AR	363
Do.	Verdigris, OK	907
Air Products and Chemicals Inc.	New Orleans, LA[3] [4]	263
Do.	Pace Junction, FL[5]	91
Allied Chemical Corp.	Hopewell, VA[3]	392
Ang Coal Gas	Beulah, ND	22
Arcadian Corp.	Augusta, GA	499
Do.	Clinton, IA	236
Do.	Geismar, LA	372
Do.	LaPlatte, NE	172
Do.	Lima, OH[3] [6]	481
Do.	Woodstock, TN	308
Borden Chemical Co.	Geismar, LA	386
Carbonaire Co. Inc.	Palmerton, PA	32
CF Industries Inc.	Donaldsonville, LA	1,633
Chevron Chemical Co.	El Segundo, CA	18
Do.	St. Helens, OR	77
Coastal Chem, Inc.	Cheyenne, WY	154
Cominco American Inc.	Borger, TX[3]	381
Cytec (American Cyanamid Co.)	Fortier, LA[3]	404
Diamond Shamrock	Dumas, TX	127
E.I. du Pont de Nemours & Co. Inc.	Beaumont, TX	445
Farmland Industries Inc.	Beatrice, NE[3]	236
Do.	Dodge City, KS[3]	218
Do.	Enid, OK[3]	880
Do.	Fort Dodge, IA	200
Do.	Hastings, NE	(7)
Do.	Lawrence, KS[3]	399
Do.	Pollock, LA[3]	440
First Mississippi Corp. (Ampro)	Donaldsonville, LA[3]	440
Green Valley Chemical Corp.	Creston, IA	32
IMC-Agrico[8]	Donaldsonville, LA	454
Koch Industries	Sterlington, LA	998
Jupiter Chemicals	West Lake, LA	27
LaRoche Industries Inc.	Cherokee, AL	159
Mississippi Chemical Corp.	Yazoo City, MS[3]	454
Monsanto Co.	Luling, LA[3]	445
Phoenix Chemical Co. (Vigoro)	East Dubuque, IL	245
PPG Industries Inc.	Natrium, WV	45
J.R. Simplot Co.	Pocatello, ID	93
Terra International, Inc.[9]	Port Neal, IA	308
Do. (Oklahoma Nitrogen)	Woodward, OK[3]	408

See footnotes at end of table.

TABLE 4—Continued

DOMESTIC PRODUCERS OF ANHYDROUS AMMONIA IN 1993

(Thousand metric tons per year of ammonia)

Company	Location	Capacity[1]
Triad Chemical Co.[10]	Donaldsonville, LA[3]	408
Union Chemical Co. (Unocal)	Kenai, AK[3]	1,134
Wil-Grow Fertilizer Co.	Pryor, OK	85
Total		15,871

[1] Engineering design capacity adjusted for 340 days per year of effective production capability.

[2] Plants purchased from Freeport-McMoRan Feb. 28, 1990.

[3] Revamp and/or retrofit.

[4] Scheduled to close in 1994.

[5] Capacity cut 50% at yearend.

[6] Purchased from B.P. Intl. Ltd. in 1993.

[7] Plant (140,000 tons per year) mothballed.

[8] Joint venture formed midyear 1993; Freeport-McMoRan owns Agrico.

[9] Expansion (60,000 tons per year) complete late 1992.

[10] Joint venture between First Mississippi Corp. and Mississippi Chemical Corp.

TABLE 5

CONSUMPTION TRENDS FOR MAJOR NITROGEN COMPOUNDS PRODUCED IN THE UNITED STATES[1]

(Thousand metric tons of contained nitrogen)

	1989	1990	1991	1992	1993[p]
Fertilzer materials:					
Urea:					
Solid	1,831	1,917	1,871	[r]1,992	1,767
Solution	1,118	1,158	1,139	[r]1,323	1,147
Total	2,949	3,075	3,010	[r]3,315	2,914
Ammonium phosphates[2]	2,517	2,673	[r]2,713	[r]2,915	2,459
Ammonium nitrate:					
Solid	719	697	696	[r]677	713
Solution	1,170	1,018	1,167	[r]1,172	1,286
Other[3]	-12	68	[r]15	[r]2	[e]—
Total	1,877	1,783	[r]1,878	[r]1,851	1,999
Ammonium sulfate:					
Synthetic and byproduct	[r]459	[r]485	[r]432	[r]460	461
Coke oven byproduct[e]	53	52	45	44	44
Total	[r]512	[r]537	[r]477	[r]504	505
Total fertilizer	[r]7,855	[r]8,068	[r]8,078	[r]8,585	7,877
Nonfertilizer materials:					
Urea:[2]					
Feed	175	82	95	[r]104	115
Industrial	217	270	[r]289	[r]329	239
Total	392	352	[r]384	[r]433	354
Ammonium nitrate[2]	621	667	605	[r]636	[e]666
Nitric acid	434	[r]374	[r]357	[r]378	388
Acrylonitrile	312	363	318	338	300
Caprolactam	73	78	73	78	77
Total nonfertilizer	1,832	[r]1,834	[r]1,737	[r]1,863	1,785
Grand total[4]	[r]9,687	[r]9,902	[r]9,815	[r]10,448	9,662

[e] Estimated. [p] Preliminary. [r] Revised.

[1] Ranked in relative order of importance.

[2] Solid and solution.

[3] Unaccounted distribution.

[4] Data may not add to totals shown because of independent rounding.

Sources: Current Industrial Reports, MA28B and MQ28B, Bureau of the Census, and International Trade Commission.

TABLE 6

U.S. NITROGEN FERTILIZER CONSUMPTION, BY PRODUCT TYPE[1]

(Thousand metric tons nitrogen)

Fertilizer material[2]	1992[r]	1993[p]
Single-nutrient:		
Anhydrous ammonia	3,723	3,248
Nitrogen solutions[3]	2,183	2,298
Urea	1,476	1,642
Ammonium nitrate	588	592
Ammonium sulfate	172	166
Aqua ammonia	62	61
Other[4]	181	200
Total	8,385	8,207
Multiple-nutrient[5]	2,029	2,107
Grand total	10,414	10,314

[p] Preliminary. [r] Revised.

[1] Fertilizer years ending June 30.

[2] Ranked in relative order of importance by product type.

[3] Principally urea-ammonium nitrate (UAN) solutions.

[4] Includes other single-nutrient nitrogen materials and all natural organics.

[5] Various combinations of nitrogen (N), phosphate (P), and potassium (K): N-P-K, N-P, and N-K.

TABLE 7

U.S. PRODUCER STOCKS OF FIXED NITROGEN COMPOUNDS AT YEAREND[1]

(Thousand metric tons nitrogen)

Material[2]	1992	1993[p]
Ammonia	[r]1,059	855
Nitrogen solutions[3]	313	305
Urea	[r]203	245
Ammonium phosphates[4]	100	85
Ammonium nitrate	[r]73	101
Ammonium sulfate	41	34
Total	[r]1,789	1,625

[p] Preliminary. [r] Revised.

[1] Calendar year ending Dec. 31.

[2] Ranked in relative order of importance.

[3] Urea-ammonium nitrate and ammoniacal solutions.

[4] Diammonium, monoammonium, and other ammonium phosphates.

Source: Current Industrial Reports, MA28B and MQ28B, Bureau of the Census.

TABLE 8

PRICE QUOTATIONS FOR MAJOR NITROGEN COMPOUNDS AT YEAREND

(Per metric ton product)

Compound	1992	1993
Ammonium nitrate: F.o.b. Corn Belt[1]	$138-$149	$138-$149
Ammonium sulfate do.	121- 132	133-147
Anhydrous ammonia:		
F.o.b Corn Belt	147- 160	157- 171
F.o.b. gulf coast[2]	129- 130	143- 146
Diammonium phosphate: F.o.b. central Florida	122- 127	152- 154
Nitrogen solutions (28% to 32%):		
F.o.b. South Central[3]	95- 103	99- 112
Urea:		
F.o.b. Corn Belt, prilled	149- 160	141- 165
F.o.b. gulf coast, granular[2]	142- 146	139- 141
F.o.b. gulf coast, prilled[2]	139- 141	128- 130

[1] Illinois, Indiana, Iowa, Missouri, Nebraska, and Ohio.

[2] Barge, New Orleans.

[3] Alabama, Arkansas, Kentucky, Louisiana, Mississippi, Tennessee, and Texas.

TABLE 11
U.S. EXPORTS OF MAJOR NITROGEN COMPOUNDS IN 1993

(Thousand metric tons)

Compound	Gross weight	Nitrogen content	Value[1] (thousands)
Fertilizer materials:			
Ammonium nitrate[2]	66	22	NA
Ammonium sulfate[2]	757	159	NA
Anhydrous ammonia	460	378	NA
Diammonium phosphate	7,238	1,303	NA
Monoammonium phosphate	1,098	121	NA
Nitrogen solutions	28	8	NA
Sodium nitrate	2	(3)	NA
Urea	659	303	NA
Mixed chemical fertilizers[4]	329	52	NA
Other ammonium phosphates[5]	69	11	NA
Other nitrogenous fertilizers[6]	171	7	NA
Total[7]	10,877	2,365	NA
Industrial chemicals:			
Ammonia, aqua (ammonia content)	20	16	$1,623
Ammonium compounds[8]	9	3	8,839
Ammonium phosphate (ortho)	(3)	(3)	152
Potassium cyanide	(3)	(3)	1,127
Sodium cyanide	62	17	50,859
Other cyanides and cyanates	1	(3)	6,261
Hydrazine, hydroxylamine and related inorganic salts	13	6	21,291
Bismuth/silver nitrates	(3)	(3)	7,231
Potassium nitrate	18	3	4,441
Other nitrates	4	1	7,851
Nitric/sulfonitric acids	15	3	5,282
Nitrates	7	1	4,120
Total[7]	149	50	119,075
Grand total[7]	11,025	2,414	119,075

NA Not available.

[1] Export values f.a.s.

[2] Includes industrial chemical products.

[3] Less than 1/2 unit.

[4] Harmonized codes 3105.10.0000 and 3105.20.0000.

[5] Codes 3105.51.0000, 3105.59.0000, and 3102.70.0000.

[6] Codes 3101.00.0000, 3102.29.0000, 3102.60.0000, and 3102.90.0000.

[7] Data may not add to totals shown because of independent rounding.

[8] Carbonates, chloride, fluorides, and tungstate.

Source: Bureau of the Census. Effective Jan. 1, 1989, U.S. exports and imports were reported under the new international Harmonized Commodity Description and Coding System (Harmonized System).

TABLE 12
U.S. IMPORTS OF MAJOR NITROGEN COMPOUNDS IN 1993

(Thousand metric tons)

Compound	Gross weight	Nitrogen content	Value[1] (thousands)
Fertilizer materials:			
Ammonium nitrate[2]	485	162	$58,476
Ammonium nitrate-limestone mixtures	12	3	1,249
Ammonium sulfate[2]	367	77	31,992
Anhydrous ammonia[3]	3,233	2,657	414,669
Calcium nitrate	(4)	(4)	11,855
Diammonium phosphate	38	7	7,096
Monoammonium phosphate	157	17	25,978
Nitrogen solutions	391	117	38,205
Potassium nitrate	28	4	8,751
Potassium nitrate-sodium nitrate mixtures	39	5	6,573
Sodium nitrate	123	20	20,915
Urea	2,964	1,363	395,979
Mixed chemical fertilizers[5]	200	24	32,246
Other ammonium phosphates[6]	92	15	10,750
Other nitrogenous fertilizers[7]	141	28	25,524
Total[8]	8,269	4,501	1,090,257
Industrial chemicals:			
Ammonia, aqua (ammonia content)	11	3	751
Ammonium compounds[9]	15	4	22,502
Calcium cyanamide	1	(4)	782
Potassium cyanide	1	(4)	1,358
Sodium cyanide	3	1	3,454
Other cyanides and cyanates[10]	4	1	4,950
Hydrazine, hydroxylamine and related salts	2	1	5,653

NONRENEWABLE ORGANIC MATERIALS

By Raymond L. Cantrell

Mr. Cantrell has served as a physical scientist in the Branch of Industrial Minerals since 1988. His 30-year career in the public and private sectors includes organic chemicals research, plastics and rubber product development, and fertilizer market research. Ms. Deborah A. Kramer, Branch of Industrial Minerals, facilitated data input and prepared graphics.

Nonrenewable organic materials refer to nonfuel derivatives of finite fossil fuel feedstocks of petroleum, natural gas and associated liquid fractions, and coal, as opposed to those derived from renewable natural organic biomass sources. All organic materials contain carbon, most commonly associated with hydrogen, oxygen, nitrogen, and sulfur, and comprise a vast number of chemical compounds.[1] Organics range from the simplest hydrocarbon compound, methane (CH_4), to high molecular weight thermoplastic and thermoset polymers, and complex biological matter associated with all life forms on Earth. The terms "plastics," "resin," and "polymers" are often used interchangeably by the synthetic organic chemicals industry.[2]

Products manufactured from nonrenewable organic materials include a variety of items such as household goods, beverage containers, food packaging, cosmetics, and sporting goods; solvents, paints and coatings, ink, pigments, and adhesives; textiles, construction materials, pipe and hose, electrical devices, and computer goods; automotive components, tires, battery casings, engine oil, grease, and asphalt; fertilizers, pesticides, pharmaceuticals, medical devices, eyewear, and a multitude of other items vital to modern society.

The U.S. nonrenewable organics industry ranks third in terms of value in the United States behind the automotive and petroleum industries, in respective order of importance. In 1993, the organics industry—including feedstocks and salable nonfuel petroleum byproducts—was valued at more than $90 billion, f.o.b. plant, according to the U.S. International Trade Commission (ITC).[3] Basic raw material feedstock costs calculated from U.S Department of Energy (DOE) information were about $12.5 billion, based on point-of-origin prices for crude petroleum, dry natural gas, and liquid fractions, plus coal and salable downstream residual byproducts.[4]

In 1993, domestic production in the large-volume polymeric resin, rubber, and fibers industries increased about 3% and domestic consumption increased 5% compared with 1992. However, the U.S. resin industry—polyethylene (PE) in particular—continued to be adversely impacted by slow economic recovery at home and a substantial capacity overhang at home and abroad, which created downward pressure on margins and prices. The situation was exacerbated by continuing recession in Europe, Japan, and the former U.S.S.R. In contrast, polyvinyl chloride (PVC), thermoplastic elastomers, thermosets, synthetic rubber, paints and coatings, and other specialty resins and organic products experienced solid growth; and the U.S. trade surplus for all organic materials held relatively constant at about $12 billion. Domestic demand for construction materials, automotive industry materials and accessories, along with durable and nondurable consumer goods improved as the economy strengthened, especially in the second half of 1993.

Organic chemicals production moved up 9% in 1993 among the top 50 chemicals in the United States, compared with overall chemicals growth of only 3%. Of particular note was the 120% increase in production of methyl tertiary butyl ether (MTBE), the leading fuel oxygenate, and a 30% and 20% increase in MTBE precursors methanol and isobutylene, respectively. Propylene glycol production increased 74%, ethylene dichloride, 18%; and perchloroethylene, 11%, relative to 1992. Sizable increases also were established for vinyl chloride, terephthalic acid, and the dimethyl ester thereof.

Major issues faced by the organics industry during 1993 included the imminent ban of 11 ozone depleting chlorofluorocarbons (CFC's) and chlorinated hydrocarbons beginning in January 1996. Producers were developing stopgap hydrogenated CFC's (HCFC's) alternatives and more desirable hydrogenated fluorocarbons (HFC's) to replace CFC refrigerants, solvents, and blowing agents. Probably one of the most critical chlorinated hydrocarbons on the list was 1,1,1-trichloroethane, the leading solvent used in vapor degreasing of electronic components and numerous other solvent applications. Consumers were slow to accept any proposed alternatives.

Perchloroethylene, the major dry cleaning solvent in the United States, was under strict regulation by the U.S. Environmental Protection Agency's (EPA) Clean Air Act provisions designed to significantly reduce volatile organic carbon materials (VOC's). In related developments, the Society of the Plastics Industry, Inc. (SPI) expressed concern over the administration's proposed chlorine ban, citing the potential threat to strategic supplies of and pesticides on EPA's toxic inventory list, many of which were destined for extinction owing to VOC and carcinogenic issues. Also, the paint industry was reformulating to more environmentally friendly water-based coatings and high-density solvent materials. Powder coating and other nonsolvent technologies also continued to be developed.

The organics industry has reacted to the downturn of the recent past by initiating significant cost-cutting measures directed at improving efficiency and competitiveness. Creative employee reduction incentive programs were prominent among the major petrochemicals producers, including E.I. du Pont de Nemours and Co. (DuPont), Exxon Corp., Occidental Petroleum Corp. (OxyChem), and Texaco, Inc., to name a few. Additionally, industry restructuring and the rationalization of obsolete capacity were underway. The U.S. industry also was continuing to become multinational in scope, as witnessed by its growing presence abroad.[5]

U.S. crude oil production in 1993 reached the lowest level since 1958, as domestic prices fell 11% to an average of about $14.20 per barrel, the lowest level in 5 years. Still, refineries ran at more than 90% of capacity as the U.S. import reliance increased from about 40% in 1992 to almost 45% in 1993. Imported crude prices also fell 11%, to an average of $15.75 per barrel, c.i.f., the lowest level in 5 years. Although there was an increase of more than 10% in natural gas prices during the year, the average annual price of about $2 per million British thermal units (Btu) was still reasonable. *(See table 1.)*

DOMESTIC DATA COVERAGE

Data were obtained from a variety of government sources, including the ITC publication Synthetic Organic Chemicals—derived from an annual canvass of the U.S. organic chemicals industry under the authority of Section 332g of the Tariff Act of 1930; the Annual Energy Review 1993, Petroleum Supply Annual 1993, and coal reports published by the Energy Information Administration (EIA); U.S. Department of Commerce reports; U.S. Bureau of Labor statistics; and the EPA.

Several private trade groups provided data on nonrenewable organic materials for use by the U.S. Bureau of Mines (USBM), including the SPI; American Plastics Council; Chemical Manufacturers Association; Federation of Societies for Coatings Technology; Fiber Economics Bureau, Inc.; American Fiber Manufacturers Association, Inc.; Rubber Manufacturers Association; the Asphalt Institute; Asphalt Roofing Manufacturers Association; The Fertilizer Institute; and the National Agricultural Chemicals Association. Information also was gathered from industry trade journals.

BACKGROUND

Organic chemical materials were first categorized as naturally occurring carbon compounds associated with human and animal life-forms, like urea excrement in urine. It was later recognized, however, that organic compounds also were associated with plant matter and could be further isolated from metamorphosed carbonaceous materials like coal and coal ignition byproducts. Later, chemists demonstrated that organic chemicals could be produced synthetically in commercial quantities through sophisticated chemical reaction mechanisms involving coal, natural gas, and petroleum derivatives.

Charles Goodyear perfected the vulcanization process for natural rubber in 1846, and in the mid-1800's, John and Isaiah Hyatt experimented with the polymer cellulose nitrate, produced from nitric acid and cellulose, in searching for a viable substitute for billiard balls made traditionally from expensive ivory. In 1872, the term "celluloid" was coined by Isaiah Hyatt for materials made from cellulose nitrate and camphor, and the Hyatt's firm, Celluloid Manufacturing Co., is known today as Hoechst Celanese Corp. Shortly after the turn of the 20th century, Leo Bakeland developed and introduced Bakelite, an industrially significant phenol-formaldehyde thermosetting heat-resistant polymeric resin.

The Petroleum Age

A major wildcat oil strike by Edwin L. Drake near Titusville, PA, on August 27, 1859, gave birth to a new technological era in the United States—the petroleum age. An abundant source of fluid organic chemical feedstock containing a multitude of carbon compounds had been found that was relatively easy to pump and process, unlike solid coal minerals. Although the first U.S. petroleum refinery was built in 1860 near the Titusville oilfield, the major contributing factor that transformed petroleum into an industrial giant was the commercial development of the internal combustion engine in the early 1900's.

The 1920's served as the major benchmark for major oil discoveries in the United States, and during the 1930's there were enormous finds in east Texas and at Prudhoe Bay, AK, by 1967. U.S. oil output exceeded 3 billion barrels in 1966 and reached a peak of more than 3.5 billion barrels in 1970. During this period, the United States was the world's leading oil producer. Today, the United States continues as the world's leading consumer of petroleum, with about 20% of world consumption, but has gradually developed a significant import dependency in the mid-40% range.

The petroleum industry developed sophisticated distillation and associated technologies for the production of gasoline and lubricants for the growing automotive industry. Heating oils, diesel fuel, asphalt for road building, and a number of consumer products also were produced. Many light fractions of petroleum manufacture such as ethane (C_2H_6), propane (C_3H_8), and butane (C_4H_{10}) were vented and flared because technology had not been developed for their use. Natural gas, or methane, along with liquid organic fractions thereof, also was found to be associated with petroleum, but much was flared as a nuisance item of crude oil production.

Petrochemicals

During World War II, important organic synthesis technology developed earlier by noted research scientists was put to practical use. Petroleum engineers learned how to recover the lighter, more reactive organic molecules and crack both small and large ones into forms that could be turned into synthetic organic chemical feedstocks and downstream polymers and other items of commerce. Nylon was developed by Wallace Carothers and DuPont between 1927 and 1940 and was used in parachutes during the war. Following the war, nylon hosiery and other nylon fabrics precipitated a major synthetic fiber revolution. Synthetic rubber (styrene-butadiene, neoprene, and butyl) was developed to augment supplies of natural rubber cut off from Indonesia, Malaysia, Singapore, and Thailand during the war. Military explosives also were involved in the organics revolution, including trinitrotoluene (TNT) and nitroglycerine (dynamite).

During the 1950's, PE, polypropylene (PP), polystyrene (PS), and other nonrenewable synthetic organic materials began to significantly displace or supplement minerals and renewable organic resources traditionally used in the manufacture of consumer goods like bottles, films, fiber, and rubber, and in automotive components. PVC materials were compounded with industrial minerals, such as calcium carbonate, clays, talc, and titanium dioxide; extruded into pipe, vinyl siding, and garden hose; or fabricated into vinyl sheet and film as a superior substitute for "linoleum" flooring and upholstery. Polyvinyl acetate and acrylic water-based emulsions were developed as a substitute for natural resins and oils in adhesives and paints. Synthetic organic urea nitrogen fertilizers replaced low-analysis fertilizers and, along with more effective organic pesticides, improved crop yields.

Polyethylene terephthalate (PET) soda bottles and the popular polyurethane (PUR) roller blades are recent successful entries in the marketplace, along with a growing repertoire of other new polymeric materials, such as aromatic copolyester and liquid crystal polymers for electrical applications introduced in 1984 and 1985, together with polymethylpentene, a high-temperature, transparent polymeric material introduced in 1988. Microcircuitry revolutionized the computer, communications, and timepiece industries; and integrated circuits and computer chips merged high-tech polymeric resins and minerals-derived materials.

Definitions, Grades, and Specifications

Petrochemical feedstocks for nonfuel organics use are obtained principally from crude oil, natural gas, and, to some extent, from coal. There are about eight primary organic chemical feedstocks needed to produce intermediate and finished petrochemical materials, as shown in figure 1. It is interesting to note that of the eight, only methane is directly available from petroleum and natural gas. The other seven feedstocks must be synthesized from crude petroleum and liquid hydrocarbon fractions of natural gas by processes such as catalytic cracking (cat cracking), reforming, and other chemical engineering processes, to obtain chemically reactive ("unsaturated") bonds between the carbon atoms.

Crude Oil.—Petroleum is a complex mixture containing thousands of different organic compounds ranging from the most simple hydrocarbon form, methane (CH_4), to very high molecular weight compounds. Most of the compounds are straight chain saturated hydrocarbons called alkanes or paraffins, which are in the family of compounds grouped with methane (CH_4). This simply means that the four available reaction sites for each carbon atom are filled. But, for C_3 saturated forms and higher, the molecules can be arranged in a ring structure as well.

Benzene is an important ring compound found in petroleum in limited amounts (0.5% to 1%), but synthesized in large quantities from petroleum feedstock. Benzene is an organic ring compound belonging to a unique family of organic compounds known as aromatics. The benzene ring (C_6H_6) contains only one-half as many hydrogen atoms as its saturated cyclic paraffin cousin cyclohexane (C_6H_{12}). This means that benzene is "unsaturated," and has three "double bonds" between the carbon atoms that can react with other elements. All aromatic organic molecules are arranged in rings and contain reactive "unsaturated" carbon bonds of a special type.

Crude oil is characterized as being "sweet" or "sour" depending upon its sulfur content and "heavy" or "light" depending upon its particular distribution of large and small organic chemical compounds, as measured by specific gravity or weight per unit volume. Oil is measured by the barrel, containing 42 gallons.

Most of the components of oil can be separated by fractional distillation, taking advantage of a wide range of boiling points. The distillate fractions that are made into reactive, unsaturated petrochemical feedstocks include the gaseous C_1 to C_4 components removed overhead, the C_5 to C_{20} naphthas and gas oil liquid fractions, the heavy residues beyond C_{20}, and the asphalt and petroleum coke residues.

Lubricating Oils.—Lubricating oils used in vehicles and in industrial machinery and processes are made from a relatively small number of crude oil-base stocks blended with several additives designed to achieve specific properties. Special additives allow for relatively constant or variable viscosity change with temperature, promote oxidation resistance, and regulate acidity and pour points.

Asphalt.—Asphalt, a product of petroleum refining, is generally the bottom product left after all other products have been taken out. It is always blended with cutter stock, similar to kerosene but with a lower flash point, into three grades: fast cure (less of the kerosene material added so that it sets up faster), medium cure, and slow cure, for use as road base at different ambient temperatures.

Not all refinery operations produce asphalt because it is a natural product only from heavy crude oils and the amount of asphalt produced will be in rough proportion to the specific gravity of the crude oil. Further processing is necessary to make the asphaltic material suitable for roofing applications.

Asphalt serves as a highly effective binder in roadway construction. Asphalt roadways typically consist of only 5% to 10% asphalt, filled with an enormous quantity of crushed stone and modified with hydrated lime to facilitate impact resistance.[6]

Petroleum Coke.—Petroleum coke is obtained by severe thermal cracking of the bottom residues remaining after petroleum refining. The feed is heated to about 560° C and charged to the bottom of a coking drum. The cracked lighter product is drawn off overhead; the heavier product remains and, because of the retained heat, cracks to coke, a solid coal-like substance. Coke yields may approximate up to 30% of the feed.

Coke comes in two principal forms—"sponge coke" and "needle coke." Sponge coke varies from a hard, porous, irregular-shaped lump to a fine powder. The main uses for sponge coke are in the manufacture of electrodes and anodes, as a carbon source for carbides, and for the manufacture of artificial graphite used for motor brushes. The strength of sponge coke is not sufficient for its use in blast furnaces for pig iron or in foundry work.

"Needle coke" derives its name from its microscopic elongated crystalline structure. Needle coke requires special coker feeds and more severe operating conditions. Its qualities make it the preferred material for graphite electrodes because of its lower electrical resistivity and lower coefficient of thermal expansion. Graphite electrodes are integral to the production of steel based on the electric arc process.

Carbon Black.—This significant carbonaceous black pigment is an extremely fine soot, primarily carbon (90% to 99% C), that contains some hydrogen and oxygen and is produced by the partial combustion or thermal decomposition of hydrocarbons in the vapor phase. Although carbon blacks are available as furnace black, thermal black, lampblack, acetylene black, and bone black, furnace black is the dominant commercial material of choice. Carbon black is one of the most important pigments in industrial use today; significant quantities are used as a reinforcing agent in tires and other rubber products and as the primary black pigment in printing inks, paints, and plastics.

Petroleum Waxes.—Waxes are also a natural product of the refining processes and are derived from the gas oil fraction in the distillation process. Waxes come out of all crude oils. If the crude oil contains a large proportion of wax, then the final "pull" becomes unsuitable for asphalt production, even if it is a heavy crude oil.

Natural Gas.—Methane (CH_4) must be separated from various components before sale as "dry gas" for fuel use and as chemical feedstock. According to recent DOE statistics, about 83% of the total process feed was recovered as dry natural gas, 2% was removed as nonhydrocarbon gases (carbon dioxide, helium, hydrogen sulfide, and nitrogen), with some of the remainder being injected for repressurizing. Substantial amounts of other natural gas liquids (ethane, propane, and butane) also may be recovered during methane processing. Natural gas is sold on a dollars per million Btu basis. Substantial amounts of elemental sulfur also may be recovered as a marketable byproduct depending on the hydrogen sulfide content of the gas.

Natural gas is used extensively in catalytic steam reforming processes to produce inorganic ammonia (NH_3) and byproduct carbon dioxide, which are subsequently used to synthesize organic urea (NH_2CONH_2) for fertilizer and industrial use. Ammonia is also integral to the production of nylons and other important polymers and synthetic organic chemicals. Methanol, or methyl alcohol (CH_3OH), also is produced from methane by a similar reforming process.

Coal.—Coal is a black or brownish-black combustible sedimentary organic rock that contains more than 50% carbonaceous organic material by weight. In popular usage, coal commonly is called a mineral because it was formed in the earth. However, the scientific use of the term "mineral" is reserved for a naturally occurring inorganic material that has a definite chemical composition and a regular internal structure. Coal has neither of these. Coal is called a fossil fuel because it is derived from plants that grew in vast swamps millions of years ago and was subsequently reworked and metamorphosed. Recoverable coal reserves in the United States are considered to be the largest in the world, and the U.S. ranks as the leading producer at about 1 billion tons per year.

Outside of fuel uses for electrical power generation, the most important use of coal is for the production of metallurgical coke from bituminous coals mined principally from the Appalachian region of the United States. Typically, a 1-ton charge of low-sulfur bituminous coal when heated in a high-temperature coking oven in the absence of air will yield about 700 kilograms of coke containing 97% carbon and a variety of organic byproducts, including about 32 liters of crude tar containing creosote, naphthalene, phenol, pitch, pyridine, and other aromatic hydrocarbons, and 10 liters of crude light oil containing benzene with smaller quantities of the aromatics toluene ($C_6H_5CH_3$), xylene ($C_6H_4(CH_3)_2$), naphtha, and related hydrocarbons.[7]

Products for Trade and Industry

Approximately 50% by weight of all U.S. polymeric materials derived from nonrenewable organics is currently fabricated into packaging and building and construction materials, while consumer and institutional products account for another 10%; transportation equipment, 5%; electrical and electronic goods, 5%; furniture and furnishings, 4%; adhesives, inks, and coatings, 3%; and other merchandise, 11%. Exports account for about 12% of the total.

Packaging materials include bottles, jars, vials, and food containers, refuse bags and film, and items such as tubes, tape, pallets, shipping crates, blister and bubble containers, buckets, and drums. Building and construction materials vary from pipe, conduit, and fittings—including drainage, irrigation, plumbing fixtures, and septic tanks—to siding, flooring, and insulation materials. Other construction materials consist of panels, doors, windows. skylights, bathroom units, gratings, and railings.

Consumer and institutional products encompass disposable food serviceware, dinnerware and kitchenware, toys and sporting goods, health care and medical products, hobby and graphic arts supplies, together with footwear, luggage, credit cards, and other items. Transportation equipment includes parts and composites for motor vehicles and bicycles, railroad equipment, travel trailers, campers, golf carts, snowmobiles, aircraft, ships, and boats.

Electrical equipment is composed of wire and cable coverings and industrial equipment, while electronic components include resistors, magnetic tape, records, and batteries. Furniture and furnishings include household and office furniture, bedding, carpets, rugs, backing, curtains, blinds, awnings, lamps, picture frames, and wall coverings. Adhesives, inks, and coatings consist of adhesives and sealants, printing ink, magnet wire enamels, core binders, foundry facings, paper coating and glazing, paints, varnishes, and enamels.

A variety of products ranging from pipe to window trim may be produced from PVC and PP resins. These rigid, high-strength polymeric products contain significant quantities of reinforcing fillers, extenders, and pigments that include varying combinations of organic pigments, titanium dioxide, calcium carbonate, talc, treated kaolin, wollastonite, mica, feldspar, alumina trihydrate, barite, silica, stearic acid, and derivatives.

Plastic coated handles on pliers, tin snips, scissors, and other items such as the coated wire trays in dishwashers, are derived from PVC dispersion resins processed into fluid plastisols or organisols that cure out or plasticize with heat. Plastisols are most commonly made by dispersing PVC resin in a suitable phthalate plasticizer. Organisols are made the same way except that an organic solvent is added to produce more solvation and fluidity.[8]

Phenolic thermosetting resins are used principally as an adhesive in pressed board products, etc. The material also is used in the production of foundry sand molds that withstand high temperatures associated with the molding of products such as engine blocks. Thermoset polymers also are used as a binder with organic and inorganic fillers in automotive brake linings, drum brake blocks, disk brake pads, clutch facings, and abrasives grinding wheels.[9] Synthetic rubber containing carbon black reinforcement pigment is used extensively in automotive components, including tires, motor mounts, nylon reinforced V-type drive belts, and high-temperature radiator, heater, and power-assist hoses. The modern-day radial tire comes equipped with steel-reinforced belts that span the tire circumference. Tire walls generally consist of tough, molded natural rubber vulcanized with sulfur and sulfur curing accelerators, while tire treads consist predominately of the more flexible molded and vulcanized styrene-butadiene synthetic rubber forms, which provide for better handling and wear characteristics.

Synthetic organic materials are integral to the construction of shingles and other roofing materials. Bitumen materials ranging from asphalt to coal tars comprise the major components of shingles, while protective roofing granules in shingles are derived from the minerals industry. "Built-up roofing" (BUR) systems are commonly employed in the industrial roofing sector. At the heart of the roofing system are two components, bitumens and felts. There are two types of roofing felts: organic and fiberglass-based. The roofing membrane is protected from solar radiation by a cap sheet of gravel embedded in bitumen.[10]

Technology

The production of petrochemical feedstocks, downstream intermediates, and end-use products encompasses an enormous array of organic chemical reactions and technologies as demonstrated by the descriptive flow diagrams contained in this report. *(See figures 1 through 9.)*

Oil Refining and Petrochemical Feedstocks.—The feedstocks for petrochemical plants are obtained from oil refineries and from light fraction hydrocarbon extracts of natural gas and from natural gas itself. Several industrial minerals and other minerals-related catalysts are used to effect the complex chemical reactions required to produce the essential petrochemical feedstocks shown in figure 1. The world's first fluid catalytic cracker using powdered catalyst came on-stream at Jersey Standards' Baton Rouge, LA, refinery in May 1942, only months after the Japanese attack at Pearl Harbor, and revolutionized the petroleum and petrochemical industries. By 1967, fluidized reactors were in commercial use for naphtha hydroforming, fluid coking, coal carbonization, coal coking, and chemicals production. Fluidization continues today as a major component of chemical engineering technology.

Cracking catalysts are used in oil refineries to facilitate the conversion of heavier molecules into lighter, more desirable products. High temperatures are needed, but pressures can be more moderate. Bentonitic clays in the form of granular pellets are typical natural cracking catalysts, while synthetic catalysts generally are silica-alumina, silica-magnesia, or silica-zirconia-alumina. One process uses a platinum catalyst to reform naphthas into petrochemical compounds. The catalytic cracking process uses operating pressures ranging from about 15 pounds per square inch (psi) to 700 psi [1 to 49 kilograms per square centimeter (kg/cm^2)] and temperatures ranging from 425° to 590° C.

Polymerization.—A number of highly complex chemical reaction mechanisms and technical processes are involved in the synthesis of polymers from petrochemical feedstocks. In 1929, W. H. Carothers subdivided polymers into two general groups, "condensation" and "addition" polymers. Polyester resins, for example, are formed by typical condensation reactions between bifunctional organic acid and alcohol monomers, with the elimination of water. Addition polymers, unlike condensation polymers, are formed by direct molecular linkup mechanisms in which no byproduct is generated. PE is an example of addition polymerization whereby ethylene molecules combine in large numbers to form continuous chains of high molecular weight polymer. The terms "step reaction" and "chain reaction" are used in deference to the more classical condensation and addition polymerization terminology whenever a more precise definition between reaction mechanisms is needed.

There are two basic types of polymers, "thermoplastic" and "thermoset." Thermoplastic polymers can be softened repeatedly at elevated temperatures and may be processed under pressure into a variety of products and recycled. PE, PVC, nylon, and PP are examples of thermoplastic resins. Thermoset resins, once processed, will not soften again as the temperature is raised, but eventually degrade or decompose at highly elevated temperatures. Phenol-formaldehyde, phenol-furfural, urea-formaldehyde, melamine, unsaturated polyesters, and epoxies are typical thermosetting resins.

Ethylene Synthesis.—Ethylene (C_2H_4) is the simplest unsaturated hydrocarbon, or "olefin," and is by far the largest of all the petrochemical feedstocks shown in figure 1 in terms of volume, sales value, and number of downstream derivatives. Figure 3 details the enormous family of downstream derivatives obtained from ethylene, the most important of which are the polyethylenes, PVC, styrene, vinyl acetate polymers, and ethylene-propylene elastomers. Other important derivatives include ethylene oxide and linear alcohols, such as ethyl alcohol (C_2H_5OH).

Thermal cracking of hydrocarbons in the presence of steam is the most widely used process for producing ethylene. Cracking is accomplished at about 1,600° C and 30 psi, followed by rapid quenching to below 1,000° C. Ethylene is recovered by low-temperature fractionation at 500 to 550 psi and purified by low-temperature (-65° C) gas-separation processes to remove hydrogen, methane, and ethane.

In the United States, hydrocarbon gases—ethane through the butanes—from natural gas condensates and petroleum refinery offgases dominate the feedstocks used to produce ethylene. With these clean feedstocks, yields may approach 80%. Liquid refinery products, such as naphthas and gas oils, also may constitute up to 25% of process feedstocks, but yields are less than 40%, and process costs are relatively higher. Ethylene also may be recovered by petroleum cat cracking, but the only practical source is from the hugh refineries in the United States owing to economies of scale.

Ethylene Polymerization.—Ethylene is a colorless gas that condenses to a liquid at -169° C. In high concentrations, it is a simple asphyxiant without other significant physiologic effects. Ethylene is commonly transported by pipeline to downstream processing facilities. About 50% of ethylene production in the United States is used to manufacture polyethylene polymers-high-density polyethylene (HDPE); low-density polyethylene (LDPE), and linear low-density polyethylene (LLDPE). LLDPE has made significant inroads relative to the other PE resins because of its unique properties derived from a number of copolymer derivatives, versatility of usage, and breakthroughs in synthesis technology. PE resin density varies between about 0.90 to 0.96 g/cm^3.

HDPE resins are produced by a variety of low-pressure processes. Since the introduction of novel LLDPE technology in the 1970's, also based on low- pressure processes, the classic process-based distinction between LDPE and HDPE has become obsolete. Many of the newer PE plants are designed with LLDPE/HDPE swing capabilities to meet changing market demands.

HDPE resins are characterized by greater toughness and by superior mechanical strength and high modulus, low gas permeability, coupled with higher service temperature limits. HDPE resins compete with PP resins in a variety of molding applications. Resin price and other factors affecting total conversion economics may favor one or the other material for a given end-use article. As a result, some back-and-forth substitution is always taking place. Most HDPE resins are converted to end products by various polymer processing technologies: blow molding, injection molding, and variations of the extrusion process.

HDPE manufacturing processes fall under three basic categories: gas-phase, fluid-bed, or stirred-bed reactor polymerization; slurry-phase polymerization using isobutane diluent or C_6 or higher diluents; and solution-phase polymerization processes using cyclohexane or a paraffinic hydrocarbon.

Major advances in polymerization technology have resulted from the introduction of innovative catalyst systems incorporating complex chromium compounds impregnated in silica or silica-alumina support or those based on complex titanium compounds chemically bound to a solid magnesium-containing support. Recently, single-site metallocene catalysts have been developed or are under development; these new catalysts allow precise control of molecular properties, enabling products to be specifically tailored to match the performance needs of a given application.

LDPE resins, conversely, are derived under high-pressure environments ranging from 15,000 to 50,000 psi using organic peroxide initiators. Two types of reactors are used: a continuous-flow stirred autoclave and tubular reactors. Autoclave reactors produce homopolymers with a high degree of long-chain branching, resulting in polymers useful for extrusion-coating markets and high-strength industrial heavy-duty film. In contrast, tubular reactors produce resins that have much lower degrees of long-chain branching. These resins are well suited for clear packaging film production.

Other commercial synthesis reactions include the palladium-catalyzed oxidation of ethylene to produce acetaldehyde (CH_3COH), or if synthetic acetic acid (CH_3COOH)—"vinegar" in nature—is used as the solvent, vinyl acetate. Chlorination and oxychlorination processes are used to make vinyl chloride monomer (CH_2CHCl), which in turn is polymerized to the industrially significant PVC and PVC copolymers like polyvinyl alcohol and polyvinyl acetate. Ethylene oxide, a ring compound containing oxygen (C_2H_4O), is produced by the silver-catalyzed oxidation of ethylene. About 50% of the ethylene oxide produced is converted to ethylene glycol ($HOCH_2CH_2OH$), most commonly sold as automotive "antifreeze" and used in the manufacture of polyester resins. Acid catalyzed hydration of ethylene produces ethanol (C_2H_5OH), ethyl alcohol, competitively priced with alcohol from traditional fermentation processes.

Methane and Propylene.—These petrochemical feedstocks are second to ethylene in terms of volume. The flow diagrams of figures 4 and 8 track the downstream synthesis products of propylene and methane, respectively. Some of the more familiar reaction products of propylene are isopropyl alcohol, used as a solvent and rubbing alcohol, acrylonitrile that goes into acrylic-based resin and fibers, and the significant polymer PP.

Methane (natural gas), as already described, is the feedstock for ammonia that is used to produce nitrogenous-based organic compounds: urea, organic nitration products such as TNT, amines ($-CNH_2$), and methanol; downstream polymers, nylon-6; urea-formaldehyde, phenolic, and melamine thermosetting resins; and many other important resin intermediates. Nickel and iron-promoted catalysts are used in the production of ammonia. Methanol is important to the synthesis of methyl methacrylate from which acrylics ("plexiglass") are made, together with polyester fibers and resins. Methanol is commonly used in automotive windshield washer and deicing fluids and in the production of the major fuel oxygenate MTBE.

Benzene.—This important petrochemical feedstock ranks fourth in terms of volume behind ethylene, methane, and propylene. Benzene is probably most notable for its use in the production of polystyrene, one of the more important resins in commercial use. It is also essential to the production of cyclohexane, cyclohexanol, and cyclohexanone, precursors of the important nylon polymers nylon-6 and nylon-6,6.

Properties of Organic Chemicals.—Organic chemicals are highly useful participants in chemical synthesis, in purification processes, and as end-use products themselves as solvents, etc., because of unique properties. Many organic synthesis processes require an aqueous-free environment and may be conducted in an organic solvent system. Organic solvents are important extractants in the purification of products owing to different affinities for contaminants and end-use synthesis materials. Some organic synthesis materials such as caprolactam, the monomer for nylon-6, may be cycled back and forth between organic and aqueous phases to effect purification.

Many separation processes use the azeotropic properties of organic compounds whereby two organic compounds boil at a constant temperature and composition, and may be removed by simple distillation. Undesirable organic carboxylic acid (-COOH) byproducts may be removed by countercurrent extraction using aqueous sodium hydroxide, and other undesirable ionic impurities may be removed by ion exchange resins—polymerized organic beads having cationic (positive charge) or anionic (negative charge) exchange properties—and new membrane technologies. Another interesting feature of organic chemicals is that separation may be more easily effected by distillation under reduced pressure, or vacuum conditions, creating a wider variation in the vapor pressures of the various organic components. Organic products may be further purified and decolorized by filtration through a medium of activated charcoal.

Materials Processing.—The processing of solid polymeric resin and rubber materials into marketable products is accomplished through a series of operations ranging from the initial compounding of ingredients to the final process steps of molding, calendaring, or extrusion. Liquid products or intermediates, such as paints and coatings, are commonly produced from an aqueous colloidal dispersion base of plastic or rubber, or organic solvent-based systems involving the incorporation of solid fillers by shear milling processes and special-high-intensity liquid mixing.

Both resins and rubber are compounded or blended with varying combinations of ingredients—fillers, extenders and pigments, processing aids, blowing agents, curing agents and accelerators, antioxidants, etc.—for processing into solid end-use products. Compounding usually is effected in high-intensity steel alloy pressure mixers containing a pair of rotating sigma, or Z-shaped, mixer arms and jacketed for temperature control. Following compounding, the formulated mixtures may be processed on an alloyed steel roller mill consisting of two horizontal rotating drums revolving at different speeds to provide shear to complete the mixing process, to sheet out the mix, and to remove moisture and other volatiles.

In rubber compounding, extra care must be taken to shear, or "break down," the elastomeric molecules into rheological forms suitable for compounding and to precisely control the mix temperature to prevent "kick-off" of sulfur and associated curing accelerators. Many rubber compounders prepare "master batches" containing premixed rubber, curing agents, and pigments that are added during the processing step to facilitate more exacting quality control.

Compounded plastics and rubber materials may be prepared for downstream processing by "dicing" or "extrusion chopping" to produce granules or pellets that provide uniform flow or by "calendaring" sheets through pairs of compression rollers that more precisely control thickness or gauge. Calendaring also may represent the final step in processing.

Extrusion, injection molding, and blow molding are the most popular methods of production of thermoplastic materials, in order of importance, while compression molding dominates the thermoset resin and rubber arena. Several important rubber items of commerce—hoses, gaskets, and pencil erasers, etc.—are extruded and cured under pressure in autoclaves.

Thermoplastic extruders are made of heavy-duty special alloy materials capable of withstanding high temperatures and pressures. The integral parts of a typical extruder consist of a feed hopper; high-alloy steel internal chamber or barrel; specialty feed/shear screw; a die of suitable geometry, together with a face plate. Plastic pellets or granules flow from the extruder hopper to the screw chamber where plasticization is effected through a combination of barrel temperature and screw shearing rheology. The plastic medium is then forced through a die, producing the desired profile. Typical marketable products range from writing elements, soda straws, plastic pipe and hose, to vinyl siding and window trim.

Coextrusion is a process in which two extruders facilitate the cojoining of materials in a mutual chamber, creating a two-component or multilayer system. The inner polymeric resin component is extruded through a die of desired shape and is then sheathed or coated by the second extruder system whose shape is determined by a mutual die exiting the mixing chamber. One unusual and commercially significant form of coextrusion involving metals and plastics is wire and cable coating, where a thermoplastic of suitable dielectric properties is extruded around a continuous feed of wire or cable that passes through an individual and common die. The coated wire is wound on drums after cooling.

In the production of wide film or sheeting, resin is extruded in the form of a tube that may be split as it comes from the die and then stretched and thinned to the desired dimensions of the finished film. An alternate method involves inflating the tubing as it comes from the die, with the degree of inflation regulating the thickness of the final film.

Injection molding is a process in which the hopper feed is pushed into a long heating chamber by a plunger, where the polymer is softened to a fluid state. The fluid resin is then forced at high pressure through a nozzle into a cold mold. As soon as the material cools to a solid state, the mold opens and the finished product is ejected from the press.

Blow molding is the most popular process for producing thermoplastic bottles. Blow molding consists of stretching and then hardening a polymeric resin against a mold. There are two general methods, direct and indirect, encompassing several variations of each. These processes basically involve the air blowing of a glob of resin or heated thermoplastic sheet into a mold or die of the desired shape.

Compression molding is simply the squeezing of a material into a desired shape by application of heat and pressure to the material in a mold. The three compression molding factors—pressure, temperature and time—vary with the design of the finished article and the material being molded.

Thermoforming of resin sheet has developed rapidly in recent years. This process consists of heating thermoplastic sheet to a formable state and then applying air and/or mechanical assists to shape it to the contours of a mold. Pressures of up to 14 psi may be obtained by evacuating the space between the sheet and the mold in a process called "vacuum forming," which is used in the majority of thermoforming applications. *(See table 2.)*

Operating Factors

Total industrial employment in the synthetic resin, fiber, and rubber sectors fell by about 4% to 166,000 workers in 1993, compared with about 173,000 workers in 1992. This was in line with cost cutting measures by major manufacturers of organic chemicals and resin materials. The average hourly workweek increased marginally, and wages of production workers fell $0.11 per hour to $15.26. Average hourly wages of employees engaged in the synthetic organic chemicals business, however, were 30% above the $11.76 per hour earned by employees in all manufacturing jobs, indicative of the high-tech skills required by employees in this industry. *(See table 3.)*

ANNUAL REVIEW

Legislation and Government Programs

The North American Free Trade Agreement (NAFTA) was signed into law by the President on December 8, 1993 (Public Law 103-182).[11] This act was designed to liberalize agricultural and industrial trade between Canada, Mexico, and the United States owing to a gradual phaseout of most tariff barriers.

Section 313 of EPA's Emergency Planning and Community Right-to-Know Act of the Superfund Amendments and Reauthorization Act (SARA) of 1986 (Public Law 99-499) required EPA to establish a national inventory of toxic chemical emissions from certain facilities, called the Toxic Release Inventory (TRI). EPA's 1992 TRI data released in April 1994[12], disclosed that organic compounds accounted for 31 of the top 50 TRI chemicals releases, led by methanol, toluene, acetone, 1,1,1-trichloroethane, and xylene. Organic compounds also predominated the reported emissions of suspected carcinogens, ozone-depleting chemicals, and bioaccumulators. EPA reported that about 17 million tons of toxic chemical waste continued to be generated by reporting facilities, about 80% of which was recycled, recovered, or treated on-site. Industrial releases to the environment were reported to have declined 6.6% from the previous year, and offsite transfers to treatment facilities, primarily for recycling, increased nearly 17%. EPA planned to double the list of TRI chemicals to about 600 compounds in 1994, including several pesticide materials.

The 1992 TRI indicated that for about 300 chemicals surveyed, a total of 3.4 million tons was released to the environment or transported to offsite facilities, including publicly owned treatment works (POTW's), of which about 1.4 million tons (42%) was released directly to the air, water, land, or injected underground. Based on available information, about 50% by weight of direct releases was attributable to organic chemicals, while organic compounds comprised about 30% of the 2 million tons transported offsite. Approximately 65% of total offsite transfers was recycled; 18%, treated; 11%, recovered as energy; and the remainder disposed of. *(See table 4.)*

TRI includes a voluntary industry toxic chemicals control program known as 33/50, implying an interim goal of reducing emissions of 17 high-priority toxic chemicals by 33% between 1988 and 1992, with an ultimate goal of 50% reduction by 1995. One of the more noteworthy findings revealed in the 1992 TRI was that emissions had declined more than 40% between 1988 and 1992, surpassing program objectives. Twelve of the seventeen high-priority toxic chemicals listed under the 33/50 program were organics: benzene, carbon tetrachloride, chloroform, cyanides, dichloromethane, methyl ethyl ketone, methyl isobutyl ketone, tetrachloroethylene, toluene, 1,1,1-trichloroethane, trichloroethylene, and xylenes.

On August 3, 1993, the President signed a new Executive order pledging the Federal Government to protect the environment by preventing pollution at the source. This executive order applies Federal Right-to-Know laws, including TRI reporting requirements, to all Federal facilities beginning in 1994.

On November 30, 1993, EPA finalized the addition of more than 30 chemicals to the TRI list. EPA added 11 hydrochlorofluorocarbons (HCFC's) because of their potential to damage the Earth's protective ozone layer, leading to adverse human health and environmental effects. EPA also added 21 chemicals and 2 chemical categories that were listed under the Resource Conservation and Recovery Act (RCRA). On January 12, 1994, EPA proposed the addition of 313 toxic chemicals to the TRI list, including hazardous air pollutants, carcinogens, ozone depleters, and pesticide active ingredients.

The Energy Policy Act of 1992 (H.R. 776) was signed into law by the President in October 1992. This comprehensive energy bill contained 30 titles covering nonrenewable and renewable energy resources and was underscored by environmental and energy efficient mandates for the implementation of new technology and for long-range research and planning. Under Title XIII—Coal—clean coal technology, the Secretary of the Interior was to provide consulting services to the Secretary of Energy for research and development of effective utilization of coal wastes and for the administration of mineral rights for coalbed methane projects on Federal lands.

Title XVI—Global Climate Change—included provisions for a 75% increase in energy derived from renewable resources over 1988 levels by the year 2005 and a reduction in the Nation's oil use from a level of approximately 40% of total energy consumption in 1990 to 35% by the year 2005.

The Clean Air Act of 1990 (Public Law 101-549) contains 11 titles that target 3 major forms of pollution: acid rain, smog, and toxic air pollutants. The most important facets of the act relative to nonrenewable, nonfuel organics deal with VOC emissions from industrial processing, industrial solvents, paints, and coatings, together with emissions from coke ovens.

Effective November 1, 1992, EPA's Oxygenated Fuel Program required gasoline marketers to commence supplying fuel oxygenates averaging 2.7% by weight oxygen during 4 inclusive winter months in 39 cities that did not meet Federal air quality standards for carbon monoxide. The major fuel oxygenates are MTBE, a nonrenewable organic material produced from the natural gas derivative methanol and isobutylene; and ethanol, a renewable organic material produced primarily through the fermentation of corn starch.

EPA's year-round reformulated fuel program will commence on January 1, 1995, wherein the nine worst U.S. ozone nonattainment areas (Los Angeles, New York, Greater Connecticut, Baltimore, Philadelphia, Chicago, Milwaukee, Houston, and San Diego) will be required to sell gasoline with a minimum 2% by weight oxygen, 1% maximum by volume benzene, 25% aromatics maximum by volume, and no heavy metals (e.g., lead, manganese). MTBE consumption in U.S. motor fuels is currently in excess of 2 billion gallons, and ethanol consumption is slightly less than 1 billion gallons.

Issues

On September 16, 1987, the United States, along with 23 other nations and the European Community (EC), signed the "Montreal Protocol on Substances That Deplete the Ozone Layer." As a result of this protocol and newer scientific evidence, Congress mandated in the Clean Air Act Amendments that the production of CFC's and halons (organic bromine/fluorine/chlorine compounds) be phased out by the year 2000. In 1991, however, the National Aeronautics and Space Administration's (NASA) conclusion that ozone depletion in the previous decade was far more severe than previously predicted, led to a new ruling banning the production of 11 organic compounds called Class I ozone depleters as of January 1, 1996.

CFC's and halons release chlorine or bromine in the stratosphere and may act as a catalyst to convert ozone to oxygen. An increase in ultraviolet radiation resulting from stratospheric ozone depletion has been linked to skin cancer, suppression of the immune system, cataracts, and respiratory damage. Interim substitutes such as HCFC's, more marginal Class II ozone depleters, must also be eventually phased out.

CFC's and halons are used widely as refrigerants in household refrigerators and freezers, cold storage warehouses, refrigerated transport systems, and air conditioning. Some CFC's are used as blowing agents in the manufacture of foam plastics, in combination with ethylene oxide to sterilize medical equipment, in pharmaceutical production, and in spice fumigation. Organic chemicals in this class also include the chlorinated hydrocarbons carbon tetrachloride and 1,1,1-trichloroethane, a significant solvent used in vapor degreasing of electronics components and precision cleaning, adhesives, inks, and coatings, including wood, metal, and aerospace.

On June 14, 1993, the President created a new White House advisory group called the President's Council on Sustainable Development. The goal of the council was to develop a national strategy for sustainable development that could be implemented by both the public and private sectors.

In late 1993, several national trade agencies expressed concern over an executive branch policy decision to develop a national strategy for substantially reducing or prohibiting the use of chlorine and chlorinated compounds, in conjunction with reauthorization of the Clean Water Act. Chlorine especially is an essential ingredient in the manufacture of PVC plastics. Products made from PVC include blood bags and many other medical device applications, plumbing, drainage pipe, and other building materials. Chlorine is also critical in the production of raw material for many other plastics, including polyurethane (PUR) insulation, compact disks, scores of automotive and electronic components, and adhesives.

On October 22, 1993, petitions were filed with the ITC by several U.S. firms, alleging that subsidized imports of phthalic anhydride (PAN) from Brazil, Israel, Mexico, and Venezuela threatened to materially injure the domestic industry. Furthermore, it was alleged that Brazil, Hungary, Israel, Mexico, and Venezuela were landing PAN at less than fair market value (LTFV).

The ITC published the results of an investigation into the matter in the Federal Register on December 16, 1993 (p. 65732), finding that there was a reasonable indication that Venezuelan imports were threatening material injury to the U.S. industry, pursuant to the Tariff Act of 1930. PAN is an aromatic synthetic organic chemical usually produced from the primary petrochemical orthoxylene, although it may also be produced from naphthalene. PAN is used predominantly in the production of plasticizers, unsaturated polyester resins, and alkyd resins, which, in turn, are generally used to produce plastics and paints.

The issue of renewables versus nonrenewables use in fuel oxygenates precipitated a major debate between the U.S. petroleum industry—proponents of nonrenewable MTBE—and the U.S. farm community—proponents of renewable ethanol and ethyl tertiary butyl ether (ETBE), a renewable/nonrenewable reaction product. The U.S. petroleum industry cited favorable production economics, ease of blending and transportation, and lower vapor pressures, especially during the summer months, as factors favoring MTBE use. The U.S. farm community countered by citing favorable environmental factors associated with the use of renewable ethanol, including the recycling of greenhouse gases; a reduction in U.S. dependency on foreign oil, methanol, MTBE, and domestic agricultural subsidies; plus the overall favorable energy balance aspects of ethanol or ETBE.[13]

Production

Organic chemicals production among the top 50 chemicals in the United States grew by 9%, to 129 million tons in 1993, compared with an overall nominal chemicals growth of 3%. MTBE production for fuel oxygenates was 12 million tons, more than double that of the previous year, making it the ninth largest volume chemical. Production of MTBE precursors methanol and isobutylene rose 30% and 20%, respectively. Methanol production was 5.3 million tons, ranking twenty-first in total volume, while isobutylene production was 0.6 million tons. Ethylene, MTBE, propylene, ethylene dichloride, urea, benzene, and ethylbenzene ranked in the top 20 volume chemicals, in respective order of importance, while cumulative output of 73 million tons accounted for 57% of subject organics production.[14]

All categories of plastics posted gains in production. Thermosets rose 8%, with the increase for individual resins varying from 5% for phenolics to 16% for melamines; thermoplastic resins were up 3%. Synthetic fibers and rubber each increased about 3%; paints and coatings, 4%; while pesticides were mixed. *(See tables 5 and 6.)*

According to the most recent ITC statistics, the United States produced 197.5 million tons of synthetic organic chemicals and related raw materials in 1992, valued at $155 billion, f.o.b. plant. Excluding raw materials, total synthetic organic chemicals production, plus coal tar and crudes, amounted to 141 million tons, valued at $137 billion, f.o.b plant. USBM estimates indicate that about 59 million tons of salable synthetic organic materials was produced at an f.o.b. plant value of $67 billion, after discounts for reaction intermediates and salable petroleum byproducts.

Plastics, resin, and plasticizer materials accounted for 55% of total tonnage; surface active agents, 5%; synthetic rubber and processing agents, 5%; pesticides, medicinal chemicals, dyes, organic pigments, flavor and perfumes, 1%; and miscellaneous organic chemicals, 34%. Although pesticides, medicinals, dyes, pigments, flavors and perfumes accounted for only 1% of salable tonnage, the products commanded premium prices amounting to 16% of the total value. *(See table 7.)*

Total U.S. nonfuel feedstock demand for nonrenewable organic chemical derivatives manufactured in 1993 was up about 1% to 123 million tons, according to DOE data. Nonrenewable organic fossil fuel feedstocks were derived primarily from crude petroleum, petroleum refinery derivatives, natural gas liquids, dry natural gas, and coal. About 60% of total nonfuel feedstocks was equally divided between synthetic resin, fiber and rubber manufacture, and numerous other organic chemical products. The remainder consisted of finished or semifinished organic materials, including lubricants and waxes, petroleum coke, asphalt, and road oil. Average feedstock values in 1993 fell about 9% to $12.5 billion, owing to a bottoming out of crude petroleum prices during the year.

A summary of producer activities and market trends occurring within the U.S. organic resins and chemicals industry during 1993 follows. *(See table 8.)*

Ethylene/Polyethylene (PE).—PE is the dominant resin produced in the United States. At yearend 1993, there were 18 U.S. producers situated primarily along the Texas and Louisiana gulf coast having a combined capacity of about 12 million tons per year. LDPE and LLDPE commanded about 62% of the market and HDPE, 38%. HDPE and LDPE producers continued to be adversely affected by overcapacity and low margins, while LLDPE supply and demand were more equally balanced. Capacity additions planned by several producers should add another 900,000 annual tons of PE, or 8%, to capacity in 1994-95.

Three major olefin steam crackers were coming on-stream shortly in the United States. Formosa Plastics was adding 700,000 annual tons of ethylene and propylene capacity at Point Comfort, TX, in late 1993 to mid-1994, split approximately 70/30% between HDPE and PP production. Dow Chemical was constructing another 700,000 annual tons of ethylene capacity at Freeport, TX, scheduled to come on-stream by early 1995. Dow had not reached a final decision on whether to shut down older units. Exxon Chemical Co. was constructing a 200,000-ton-per-year ethylene facility at Baytown, TX, scheduled to come on-stream in 1994. Exxon also completed a 75,000-ton ethylene debottlenecking project at Baton Rouge, LA, during the year.

In 1993, Union Texas Petrochemicals (UTP) of Houston, TX, contracted M.W. Kellogg to expand its 540,000-ton-per-year ethylene plant at Geismar, LA, about 4% to 561,000 annual tons. The expansion involved Kellogg's Millisecond ethylene furnace process based on ethane and propane feedstocks. Meanwhile, Hoechst Celanese was planning an ultra-high-density PE plant at its Bay City, TX, facility.

Occidental Chemical Corp. of Dallas, TX (OxyChem), discontinued HDPE production at its 120,000-ton-per-year Orange, TX, plant in late 1992, and announced its permanent closure in 1993. Oversupply and industry projections for a continued supply-demand imbalance led to the decision. The company has at least 650,000 tons per year of HDPE capacity elsewhere in Texas.

In July 1993, an agreement in principle was formulated for the purchase of Quantum Chemical—the largest U.S. PE producer—by the Hanson Group of London, England. The total transaction, including Quantum's debt, was to approximate $3.2 billion. Hanson's New York affiliate, Hanson Industries, looked for a strong recovery by Quantum owing to global economic recovery and steady absorption of capacity within the PE industry.

Polyvinyl Chloride (PVC).—PVC resin was the second leading polymeric material produced in the United States and continued to perform impressively during 1993. Output was up 3%, operating rates remained firm at about 95%, and there was upward movement in prices. There were 13 PVC producers in the United States with a combined annual capacity of about 5.2 million tons.

Because of the tight U.S. PVC market, producers were planning capacity expansions of about 13% during 1994 and 1995. Shintech, OxyChem, Formosa, Geon, Georgia-Gulf, Vista, and Vygen—in order of importance—announced about 680,000 annual tons of new capacity, in aggregate. B.F. Goodrich spun off its wholly owned 0.8-million-ton-per-year Geon Vinyl subsidiary into a new publicly owned firm called Geon Co.

Polypropylene (PP).—Propylene monomer is the second largest olefin produced in the United States, accounting for 30% to 35% of primary olefins production. At yearend 1993, there were 16 U.S. PP resin producers having a capacity of about 4.7 million tons per year. PP capacity ranks third in terms of production and capacity to PE, and is similar in volume to PVC, the second leading U.S. resin.

U.S. PP production was up only about 1% in 1993, however, and profit margins did not move to any extent. Formosa Plastic's new 210,000-ton-per-year PP plant coming on-stream in mid-1994 at Point Comfort, TX, should continue to hamper PP's performance during the next 1 to 2 years. Amoco Chemical, the second leading producer to Himont, brought a new 135,000-ton-per-year PP plant on-stream at Chocolate Bayou, TX, in 1992. Fina reportedly was planning a new 145,000 PP plant for 1995.

Huntsman Chemical contracted with the John Brown firm to carry out engineering design work for a 150,000 annual ton grassroots facility at Bayport, TX. At the same time, Huntsman was investing $30 million to debottleneck and expand its Woodbury, NJ, PP facility 18% to 180,000 tons per year by yearend 1993. In September 1993, Huntsman and a major firm in Australia acquired Texaco's worldwide petrochemicals business for $1.06 billion. The U.S. facilities purchased involved 3 plants in Texas. The Texaco Chemical facilities produced ethylene, propylene, and ethylene glycol, surfactants, and other specialty chemicals.

Polystyrene (PS).—PS was the fourth leading resin in terms of capacity and production in the United States. There were 15 U.S. producers having an aggregate capacity of about 2.9 million tons per year, including about 0.5 million tons of idle capacity.

In 1993, PS production increased about 6%, and operating rates, excluding idle capacity, were firm at 95%. There was an improvement in export markets and materials substitution markets, including engineering plastics, urethane foams, packaging and appliance, and computer disk housings. Huntsman, the leading producer of PS in the United States, planned aggregate expansions of 120,000 annual tons over the next 2 years. A retrofit project at Belpre, OH, will increase annual capacity by 20,000 tons in 1994, and a new unit for high-impact PS will be completed at Peru, IL, by late 1995. Huntsman also was planning to build a new crystal PS plant at an undisclosed location by late 1996.

Responding to growing demand in food packaging and other applications, BASF Corp. announced an expansion of low-residual, high-heat crystal PS at Joliet, IL. The expansion will raise capacity 8% to 235,000 tons, annually. Total BASF PS capacity in the United States was quoted at 300,000 tons per year, at three locations. BASF purchased the facilities from Mobil Chemical Co. in early 1992.

Chevron Chemical previously announced plans for a new $250 million benzene plant at its Pascagoula, MS, refinery in 1992 to supply feedstock to the downstream styrene market by 1994; Westlake Styrene also completed its 160,000 annual ton ethylbenzene-styrene plant at Lake Charles, LA, in 1992. Industry analysts projected PS demand growth in the United States at 3% per year.

Acrylonitrile-Butadiene-Styrene (ABS).—U.S. ABS production was up 12% in 1993, but global operating rates were only 70% and there was downward pressure on prices, with even more capacity increases slated in the Far East. General Electric Co., Monsanto Co., Dow Chemical Co., and Diamond Polymers, Inc., were the major producers of ABS resin, in order of importance. Monsanto completed a 36,000-ton-per-year ABS expansion in Addyston, OH, last year.

Basic applications in the automotive interior and business-machines housings businesses were meeting with resistance from PP and other lower priced resins. General Electric reportedly was countering automotive materials competition by installing a continuous mass capacity plant at Bay St. Louis, MS, due on-stream in 1994. The mass capacity process yields low-gloss ABS that can bypass painting in some uses, while minimizing chemical waste generation. Diamond Polymer's joint venture between Network Polymers of Akron, OH, and Marubeni and Mitsubishi Rayon of Japan planned to double its relatively minor capacity in early 1994.

Polyethylene Terephthalate (PET).—The U.S. PET bottle resin industry continued in tight supply during 1993, with overall PET resin consumption up about 6% to 0.5 million tons; the tight supply-demand situation could be alleviated somewhat in 1994 with new capacity coming on-stream. Also, rising demand in Mexico has prompted U.S. companies to construct plants there, while domestic producers anticipated increased trade with Mexico owing to NAFTA. Eastman Chemical Co. and Hoechst Celanese were planning to commence construction of PET capacity in Mexico.

As a result of the tight supply, several companies announced capacity increases. Shell Chemical Co. was adding 70,000 tons per year by early 1994 at Point Pleasant, WV, bringing nameplate capacity to 270,000 annual tons. Eastman Chemical planned to debottleneck plants at Kingsport, TN, and Columbia, SC, to increase capacity by 5%, from 410,000 tons per year to 430,000 tons per year; recycler Wellman was to bring 30,000 annual tons on-stream at Palmetto, SC, in early 1994. U.S. demand for bottle-grade resin in 1994 was expected to be about 0.7 million tons according to Eastman Chemical sources, just 10% below overall PET capacity additions in the United States. Total U.S. PET resin capacity was pegged at about 1.2 million tons per year

Toray Plastics America, a subsidiary of Japan's Toray Industries, planned to more than double its production of PET film to 20,000 tons per year at a cost of $100 million. The expanded facilities in North Kingstown, RI, were expected to begin production in March 1994 and will give the Toray group as a whole, 108,000 tons of annual capacity, making it the world's largest producer of PET film for audio and videotapes. The firm, John Brown, was awarded a contract by Goodyear for the design, engineering, and procurement of a 90,000-ton-per-year PET plant in Point Pleasant, WV. Construction commenced in late 1992, and, when completed, will increase PET capacity at the site to 295,000 tons per year.

Nylon.—U.S. production was up about 15% in 1993 and growth should continue into next year, fueled by a resurgence in the automotive and fibers industries. Industry leader DuPont reported a 30% increase in fiber production and a 40% reduction in inventories. DuPont's goal of strengthening its global presence in the nylon business was enhanced through the purchase of Imperial Chemical Industry's (ICI's) worldwide nylon fibers business for $475 million and the swap/sale of its acrylics business to ICI for $280 million. DuPont also was improving its position in Asia-Pacific. In the continuing shakeup of the worldwide nylon fibers business, AlliedSignal, Inc., and BASF Corp. agreed to combine their North American nylon carpet fibers and textile nylon businesses.

Hüls America planned to construct a multipurpose nylon polymer facility at Theodore, AL, to produce nylon-12 and copolyamide specialties. World demand for nylon-12 is estimated to be 40,000 tons per year, and it is expected to be increasingly in demand for use in pneumatic tubes for industrial robots and tubes and hoses for automobiles.

Polyurethane (PUR).—U.S. PUR production was up about 4% to 1.6 million tons, along with sales of isocyanates used in the production of PUR. Accordingly, diphenyl-methane-4,4'-diisocyanate (MDI) sales were up 11%, while toluene diisocyanate (TDI) sales increased 3%. The upturn was primarily attributable to the automotive, housing, bedding, and furniture sectors. Global operating rates for MDI and TDI were 90% and 85%, respectively. CFC's were being replaced by alternative blowing agents for PUR foam, including HCFC's and chlorine-free pentanes.

MTBE/Methanol.—At yearend 1993, DOE statistics indicated that there were 44 U.S. facilities capable of producing MTBE having a total capacity of about 200,000 barrels per day. Approximately 34,000 barrels per day, or 17% of total capacity, was idle. Large petroleum companies in Texas, Louisiana, and one location in Mississippi—in order of importance—controlled 87% of total capacity. Arco Chemical Co. was operating a swing train for MTBE/ETBE production at Corpus Christi, TX, that could produce either 12,000 barrels per day of MTBE, or 9,500 barrels per day of ETBE. Amoco Oil Co. was operating the only facility dedicated 100% to ETBE at Yorktown, VA, having a capacity of 815 barrels per day. Net imports of MTBE averaged 15,000 barrels per day, or 8% of U.S. capacity in 1993. MTBE was shipped primarily from very large plants—more than 10,000 barrels per day—in Canada, Saudi Arabia, and Venezuela. Imports came in duty free from Venezuela, while Canadian material will become duty free in January 1994 under NAFTA. All other countries except Argentina, Bahrain, Malaysia, and Trinidad, were required to pay a duty of 5.6%.

At yearend 1993, there were 13 U.S. methanol plants having a capacity of 126,000 barrels per day, or 1.8 billion gallons per year. Approximately 85% of total capacity was concentrated in Texas and Louisiana—in order of importance—and all plants were operating. Methanex of Vancouver, British Columbia, the world's largest methanol producer at more than 1.5 million tons per year, was involved in a joint-venture project to retrofit American Cyanamid's mothballed ammonia plant at Fortier, LA, while Terra Chemical was retrofitting its Woodward, OK, ammonia plant for methanol swing capacity. North American methanol supply-demand was tight in 1993 owing to an upswing in U.S. MTBE production for fuel oxygenates. Methanol growth was pegged at 6% to 7% per year for the 1991-95 period. The United States is believed to have an import dependency approximating 30% for methanol.

Other Organics.—DuPont started up the world's largest hydrofluorocarbon-134a plant at Corpus Christi, TX, during 1993, bringing total CFC substitute capacity to 50,000 tons per year, including facilities in Ponca City, OK, and Chiba, Japan. DuPont's 1993 Annual Report cited the firm as an industry leader in CFC alternatives, with a full line of refrigerant products marketed under the "Suva" trademark. These products were reported to have zero or significantly reduced ozone depletion potential.

OxyChem's new chlorinated isocyanurates business positioned the firm as the global leader in swimming pool sanitizers and a wide range of household and industrial disinfectants. Meanwhile, Elf Atochem North America was constructing a 10,000-ton-per-year liquid peroxide initiator plant at Crosby, TX, scheduled for completion by mid-1994.

Sun Co. of Philadelphia planned a 34-million-gallon-per-year cyclohexane plant at its Marcus Hook, PA, refinery, scheduled to come on-stream in late 1994. Cyclohexane will be produced as a downstream product of the firm's associated 60-million-gallon-per-year benzene project. Sun's announcement brought some relief to the tight market situation following the closure of the firm's Tulsa, OK, plant and the withdrawal of Texaco Chemical from the business. Additionally, Kerr-McGee Chemical Co. acquired a cyclohexane plant from Unocal and was relocating it from Beaumont, TX, to Corpus Christi, TX, in 1993. Meanwhile, Phillips Petroleum was expanding cyclohexane capacity by 15% to 50,000 tons per year at Guayama, Puerto Rico.

Texaco announced the shuttering of its 20,000-ton-per-year ethylenamines plant at Conroe, TX, after only 2 years of operation. The firm cited worldwide overcapacity, a 3-year downward trend in pricing, and slow acceptance of its material as reasons for the closure. Ethylene oxide feedstock complicated the process involving higher molecular weight linear material, which was new to customers. Industry leaders Union Carbide and Dow Chemical, on the other hand, have recently expanded capacity at Taft, LA, and Freeport, TX, respectively, and expect 4% market growth. Total industry capacity now stands at about 200,000 tons, annually. The strongest markets are for polyamines, used in lubricating oil and fuel additives and in specialty applications.

In early 1993, Monsanto signed a letter of intent to buy Chevron Chemical Co.'s Ortho business for about $400 million. Ortho is a leading merchandiser of more than 300 lawn and garden products, including insecticides, fungicides, herbicides, plant foods, and indoor household insecticides.

Consumption and Uses

Resins.—In 1993, U.S. plastic resin sales were up 5% to 31.2 million tons, reflecting an upturn in the domestic economy. Resins were valued at about $33 billion, f.o.b. plant. There was a general volume improvement across the board for all resins, although major thermoplastic prices did not follow suit, except for PVC. HDPE prices fell, indicative of continued oversupply, along with expanded PS bead, and downward price pressure continued to be felt in PP, ABS, and unsaturated polyester markets. Sales volume was driven primarily by improved demand for primary construction materials, automotive, and general consumer products. Within key markets, demand outperformed the average 5% growth in sales, indicating that consumers were no longer postponing the purchase of plastics-intensive products. Resin use in furniture was up 13% over 1992 levels; building materials, 12%; appliances, 10%; and marine applications, 8%. Demand and prices, in general, were perceived to turn up markedly for most commodity resins in the fourth quarter of 1993. *(See tables 9 and 10.)*

Packaging commanded about 30% of the U.S. resins market in 1993, followed by building and construction, 20%; and consumer and institutional use, 10%. The transportation and electronic industries accounted for another 10% in total; furniture and furnishings, 4%; adhesives, inks, and coatings, 3%; industrial and machinery, 1%; miscellaneous use, 10%; and exports, about 12%. *(See table 11 and figure 10.)*

Fiber.—U.S. synthetic fiber shipments were up 3% to 4 million tons in 1993, including a 2% increase in exports of 0.2 million tons. Approximately 95% of fiber shipments were noncellulosic synthetic materials, distributed to polyester, 40%; nylon, 30%; olefins (polyethylene-polypropylene), 25%; and acrylics, 5%; in respective order of volume. Cellulosics include rayon and acetates, produced by reacting cellulosic wood pulp with inorganic and organic chemicals. The majority of nylon and olefins was used for carpets, textiles, and industrial yarns and monofilament, with lesser amounts going into staple fibers and fiberfill. Polyesters were used more heavily for staple fibers, including nonwovens and fiberfill.

Approximately 1 million tons, or 25% of total fiber shipments, consisted of staple fibers, including nonwovens and fiberfill markets. Both nonwovens and fiberfill set new sales records in 1993. Nonwovens moved up 5% to 0.3 million tons, while fiberfill increased 2% to 0.2 million tons, representing about 50% of the total staples market. Olefin is the fastest growing fiber in nonwovens, and together with polyester, commands about 90% of the market. Polyesters, predominately PET, dominate the fiberfill market. The largest single market for polyester and olefin staple in 1993 was broad weaving, which absorbed 26% of total sales of the two fibers. *(See table 12.)*

Rubber.—U.S. synthetic rubber (elastomer) shipments moved up 3% to 2 million tons on the heels of surging demand for U.S. automotive products, including tire treads, hoses, belts, and other materials. Synthetic rubber was valued at about $3.7 billion, f.o.b. plant. Styrene-butadiene and polybutadiene rubbers accounted for approximately 60% of total synthetic rubber demand and were used primarily in tires. About 5% of styrene-butadiene was produced as latex for coating applications. Ethylene-propylene rubber accounted for another 10% of the total, followed by butadiene-acrylonitrile (nitrile), 3%; and silicone elastomers, 3%. Butyl rubber, polychloroprene (neoprene), polyisoprene, and miscellaneous elastomers accounted for another 15%. Thermoplastic elastomers accounted for the remaining 9% to 10%. These materials are primarily styrene-block copolymers, thermoplastic olefin elastomers, and thermoplastic polyurethane elastomers and copolyesters. *(See table 13.)*

Approximately 1 million tons of imported renewable natural rubber also was consumed in the United States during 1993 to fulfill the requirements for tire production and other demand. The United States is the leading global tire manufacturer and demand market for natural rubber. Securing a consistent supply of natural rubber for the United States has been a high priority of the rubber industry and the Federal Government because no synthetic alternative has been found to replace many of its unique physical properties. The majority of natural rubber is produced in Indonesia, Malaysia, and Thailand. Landed prices for natural rubber in the United States have ranged between $0.83 and $1.31 per kilogram during recent years.

Natural rubber is imported as latex (60% solids), sheet, or crepe, and approximately 80% is consumed in tire manufacture. The remainder is used mainly to produce footwear, gloves, contraceptives, thread, adhesives, foam, medical devices, hose and belting, and automotive goods. Many of these traditional applications for natural rubber have been replaced by synthetic rubbers and thermoplastic elastomers in recent years because synthetic materials offered a better variety of properties such as durability and chemical resistance.

The consumption of natural rubber in the rubber glove and contraceptive industries, however, has increased recently with the spread of Acquired Immune Deficiency Syndrome (AIDS). However, the overall demand for natural rubber is expected to be affected minimally by the AIDS epidemic, as gloves and contraceptives are low-volume end-use commodities, according to a recent ITC study. Thus, tire demand should continue to be the dominant driving force for natural rubber.

Solvents.—Organic solvent demand was pegged at 5.7 million tons in 1992, representing a $2.9 billion industry. Major solvent use was led by hydrocarbons (38%), followed by alcohols, esters, and ethers (33%), chlorinated solvents (11%), ketones (9%), and glycols (6%). Major end-use markets were in coatings, printing inks, and adhesives, where about 3.1 million tons, or 54% of the total, was consumed. Consumer markets accounted for 1.2 million tons (21%); manufacturing and process industries, 0.6 million tons (10%); industrial cleaning, 0.5 million tons (9%); and miscellaneous uses, 0.3 million tons (6%).

A multitude of environmental regulations ranging from the elimination of certain CFC's by January 1996 to forced reductions in VOC emissions, EPA's toxic release inventory and health concerns, are restricting growth of organic solvents. Many companies are turning to aqueous carriers or high-solid contents in paints and coatings, and to hot-melt, ultraviolet-cured, and waterborne adhesives. In the cosmetics and personal care markets, solvents have been dropped from some formulations because of concerns over VOC's; water-based hairsprays and solid deodorant sticks have captured market share.

Large-use chemicals, such as acetone, 1,1,1,-trichloroethane, and xylene, that could dissolve seemingly anything, are being replaced to an extent by myriad high-value specialty chemicals. Although 1,1,1-trichloroethane is being phased out in 1996, for example, only 20% to 30% of customers have been willing to change. Furthermore, perchloroethylene solvent used by the 25,000 dry cleaning facilities in the United States was the first to be regulated under EPA's 1990 Clean Air Act national emission standards for hazardous air pollutants (NESHAP). EPA has established a goal to reduce emissions of perchloroethylene, a suspected carcinogen and hazardous air pollutant, through a combination of tightening emissions standards in the dry cleaning industry and a gradual move to wet-based dry cleaning.[15]

Paints and Coatings.—Paints and coatings sales rose 4% to about $13 billion in 1993 and shipments climbed by more than 3% to 1.1 billion gallons, according to the U.S. Bureau of the Census. Architectural coatings led in all categories, commanding 55% of total industry volume and 43% of total industry value. Product coatings were 29% of total shipments and 35% of total value, while special-purpose coatings represented 16% of all shipments and 22% of total value. Architectural coatings include exterior and interior house paints, stains, undercoaters, primers, and sealers. Product coatings applications include appliances, automotive, electrical insulation, and factory-finished wood, marine equipment, metal containers, furniture, and pipe, in order of importance. Special-purpose coatings applications range from aerosols, arts and crafts, automotive, machinery refinishing, and bridge maintenance to multicolored, roof, swimming pool, and traffic marking, in order of importance.

Paint manufacturers are reformulating paints to reduce VOC's and hazardous air pollutants (HAP) in face of increasingly stringent air pollution regulations by EPA that will become effective in 1996. The paint industry has worked cooperatively with EPA for more than 2 years with the objective of establishing specific limits that would reduce VOC's emitted from architectural and industrial paints 25% by 1996; 30% by the year 2000; and 40% by 2004, based on 1990 emissions levels of about 0.5 million tons—an agreement had not been reached by yearend, however.

Whenever possible, industrial paint consumers have shifted to newer technologies, such as heat-curable powder coatings and radiation-curable coatings. Both of these technologies can eliminate VOC's because they are solvent free. However, these technologies are only practical on specially adapted, original equipment manufacturers' product-coating lines. Cost and practicality factors have led paint consumers to continue using newly developed low-VOC liquid coatings on their existing production lines. Some inroads have been made, for example, by replacing solvent containing urea alkyd coatings for kitchen cabinets with high-performance aqueous coatings. Waterborne systems to coat wood also are making inroads against the high-solvent nitrocellulose lacquers used widely for furniture.

Paint formulators are facing increasing regulatory pressure to reduce the use of older aromatic and aliphatic solvents—among them toluene, xylene, and mineral spirits—with oxygenated solvents such as butyl acetate and ethyl acetate; propylene glycol-based materials; and some ketone-based products and dibasic esters. In the industrial maintenance arena, formulators are shifting to higher solids, low-solvent coatings as well as waterborne coatings. Newly introduced propylene-based diether solvents have proven to be effective for use in both waterborne and solventborne urethanes.[16]

Recycling

According to the latest EPA figures, plastics account for 21.1% of the municipal wastestream by volume; paper and paperboard, 31.9%; metals, 11.1%; yard waste, 9,8%; food waste, 3.2%; and all others, 20.7%. Most municipalities in the United States have found that the only real solution to waste management is an integrated approach utilizing four basic methods: (1) source reduction, (2) recycling, (3) waste-to-energy incineration, and (4) landfilling.

On October 20, 1993, the President signed an Executive order requiring that Federal agencies purchase printing and writing paper containing 20% postconsumer material by the end of 1994. Federal agencies also are required to begin purchases of rerefined lubricating oil and retread tires by April 18, 1994. The Chief Executive's order was designed to emphasize to the Nation that recycling activities will protect the environment while providing the private sector with incentives to develop new market opportunities and technologies.

A brochure circulated by the U.S. Conference of Mayors' "Buy Recycled" Campaign, in conjunction with the Presidents new Executive order, suggested that instead of discarding used tires to waste—an estimated 3 billion tires litter the U.S. landscape—many may be retreaded. Retreading was said to require only 35% of the energy necessary to produce a new tire. It was also estimated that about 2 billion gallons of automotive lubricating oil was used in the U.S. annually, with about 10% known to be either dumped or burned. Thus, recycled oil was reported to make sense from both an environmental and nonrenewable resource conservation standpoint.

Recent data compiled by Modern Plastics on postconsumer recycling of thermoplastics indicate that recyclate volume increased by a significant 25% to 0.5 million tons between 1992 and 1993. PET and HDPE commanded equal shares of the market and, in combination, represented about 80% of total feedstock volume. LDPE held a 10% share of the market; PS foams, 5%; with PVC, PP, and other resins accounting for the remainder. Most of the recycled PET and HDPE feedstock was in the form of soda bottles and natural color bottles, respectively. PET was reclaimed predominately as fiberfill, with lesser amounts going to bottles, strapping, film, and export. HDPE was reclaimed as bottles and drainage pipe and transformed into a variety of construction and general consumer products. LDPE was reclaimed principally as film, PS as foam packaging and loosefill, and PVC as molded goods and miscellaneous items. *(See tables 14 and 15.)*

An independent study conducted for the American Plastics Council by R. W. Beck and Associates revealed that postconsumer plastics recycling increased significantly between 1991 and 1992. The recycling of plastics packaging was up 47% in 1992 to about 430,000 tons. Plastic bottles recycled in all forms increased from 14% to 19%. PET soda bottle recycling amounted to 170,000 tons, or 41% of total production between 1991 and 1992. Recycled HDPE milk, juice, water, and household chemical bottles and film bags was about 200,000 tons in 1992, up 67%, while colored HDPE bottle recycling rose dramatically to about 60,000 tons. Recycled PP was 100,000 tons, while LDPE, PS, and PVC, in combination, was about 60,000 tons.

In response to an ongoing nationwide survey conducted by the council, more than 6,850 cities and towns confirmed that plastics were being collected for recycling through either curbside, dropoff, or buyback programs during 1992.

Additional information on materials recycling is available, as noted.[17]

Transportation

Crude oil and natural gas were transported domestically through a network of major pipelines, while crude oil imports were landed at domestic ports primarily in supertankers. Newer, more modern supertankers were equipped with multiple hulls to prevent leakage in the event of accidents. In some instances, ethylene was transported through pipelines from petroleum refining and petrochemical facilities operated by major oil companies on the U.S. gulf coast. Large-volume synthetic plastic, resin, and rubber commodities were moved in bulk and bags by rail, truck, and barge. Selected synthetic fiber producers received monomers principally by rail, and subsequently polymerized and transformed the polymerized material into marketable fiber. Liquid organic chemicals and intermediates were transported principally by rail or barge.

Markets and Prices

An upturn in the U.S. economy during 1993 and improved consumer demand were the key factors leading to an approximate 3% to 4% rise in the large-volume organics commodity businesses, although margins were still negatively impacted by depressed petroleum prices and a sluggish recovery from recession.

PVC markets continued in tight supply as reflected by a steady rise in prices throughout the year. By yearend, PVC monomer prices were 18% above 1992 values and polymer prices were up 11%. Butadiene prices ended the year 22% above 1992, reflecting a tight supply-demand situation for styrene-butadine and polybutadiene synthetic rubbers. Polypropylene prices were down 8% in 1993, and HDPE declined 5%, reflecting continuing oversupply and downward price pressure. Polystyrene prices were mixed depending upon grade of resin. In general, there was dramatic improvement in HDPE, LDPE, and PS prices during the fourth quarter, but not enough to offset generally declining trends in the large-volume commodity thermoplastics during the preceding three quarters. *(See tables 16 and 17.)*

Foreign Trade

Organic chemicals are the single largest segment of U.S. chemical exports, accounting for nearly one-half of total chemical shipments to foreign markets. On a volume basis, 75% to 80% of organic chemicals are petrochemicals. The remaining 20% to 25% are pharmaceutical or drug products, which on a value basis comprise about 50% of organic chemicals. The trade surplus for U.S. nonfuel synthetic organic chemical materials derived principally from petrochemical feedstocks increased 1% to about $12 billion in 1993, according to the U.S. Department of Commerce. The trade surplus breakout includes $4 billion for organic chemical derivatives; $5 billion for plastics and resin materials; and $3 billion for synthetic fibers and rubber, in aggregate. According to the International Trade Administration (ITA), about 20% of U.S. petrochemical shipments by value in 1992 were to Canada and Mexico, 24% to the EC, 23% to the Far East, 9% to Japan, 10% to South America, and 14% to other countries.

Available data for U.S. large-volume thermoplastic resins trade in 1993 indicate that the traditional trade surplus declined 13%, from 2.4 million tons in 1992 to 2.1 million tons in 1993. Exports were flat at 3.5 million tons, while imports increased from 1.1 to 1.5 million tons. ITA estimates for 1993 indicate that the United States experienced a $4.6 billion trade surplus in plastics and resin materials, relative to $5 billion in 1992. Canada and Mexico accounted for about 30% of U.S. plastics and resin shipments by value; the EC, 23%; Asia, 21%; Japan; 6%, South America, 8%; and other countries, 12%. ITA also reported an estimated trade surplus of $0.4 billion in finished plastic goods, while a trade surplus of $2.5 billion was recorded for synthetic fibers, and $0.4 billion for synthetic rubber. *(See table 18.)*

DOE projections indicate that the U.S. MTBE trade deficit will probably increase threefold to 45,000 barrels per day in 1995, while domestic production capability will rise 48,000 barrels per day to about 250,000 barrels per day and operate at about 83%. Under NAFTA, MTBE will be allowed to come in duty free from Canada and Mexico effective January 1994, while MTBE imports from Argentina, Bahrain, Malaysia, Trinidad, and Venezuela were already duty free under existing trade agreements. All other countries must pay a duty of 5.6%. About 30% of U.S. methanol requirements were imported owing principally to a domestic capacity shortfall for the production of MTBE.

Under NAFTA, Canada and Mexico, and the United States agreed to create a free trade area under the existing General Agreement on Tariffs and Trade (GATT) provisions, designed to phaseout customs duties according to schedules established for each country. More specifically, the United States agreed to phase out existing duties on most plastics and resin materials effective January 1994. There was a provision to stage U.S. duties on LDPE from the existing 12.5% to 4% in 1994, with complete removal in 1998. Most duties were to be phased out shortly after the turn of the century. U.S. duties on petrochemical feedstocks are already free for the most part. The ramifications of the NAFTA agreement were published in five volumes and are available from the National Technical Information Service, Springfield, VA, 22161.

The ITC's recent report: "Potential Impact on the U.S. Economy and Industries of the GATT Uruguay Round Agreements;" concluded that the positive U.S. trade balance in plastics, resin, and rubber is likely to increase only marginally as a result of the Uruguay Round because U.S. rates are already low in comparison to other countries and will remain so, particularly in the developing world where future growth is anticipated. Because the U.S. industry is already multinational in flavor, ITC believes that many firms will opt to conduct business more aggressively in areas of the world where a competitive edge can be gained; GATT would not substantially alter these conditions.

The U.S. plastics and rubber industry position on GATT has generally been supportive. However, there have been concerns expressed with regard to market access in Latin American and Asian countries having relatively high tariffs and where no provisions have been reached to harmonize tariff levels to EC, Japanese, and United States levels. The U.S. industry is diverse, with some manufacturing sectors more affected than others by GATT provisions, but the general consensus has been that while exports may increase to an extent, imports probably will not be affected.

World Review

Global demand for selected synthetic resin materials in 1993 was up 1.5% to 69 million tons, largely on the strength of U.S. sales, which accounted for about 45% of the accountable total. In spite of improving conditions in the United States, recession in Europe and Japan and restructuring in the former U.S.S.R. and Eastern bloc countries continued to dampen global demand and prices. Overcapacity was the principal factor, especially in Europe and Japan, where rationalization measures were underway. Declining import demand in China further exacerbated the situation owing to inventory overhangs and economic pressures associated with currency devaluation. In the troubled global PE market, margins narrowed, overcapacity was rampant, and despite repeated attempts, price hike initiatives were unsuccessful. In Western Europe, prices also were undermined by a rise in imports from Eastern Europe and South America. Global operating rates ranged from a low of 79% to 83% for PP, HDPE, LLDPE, and PVC, in increasing order of importance, to a high of 87% for LDPE.

Industry Structure.—According to available statistics, the United States was the leading producer and distributor of global synthetic plastics resin, fiber, and rubber in 1992 and 1993, commanding more than 40% of the global resins market and about 30% of the synthetic rubber and fibers markets. Supply capability, excluding the United States, was generally concentrated in Europe, Japan, the Far East, former U.S.S.R. and Eastern bloc countries, Canada, and Latin America. *(See tables 19 through 21.)*

Capacity.—According to data reported by Chem Systems of Tarrytown, NY, world capacity for PE, PVC, and PP in 1993 increased more than 4% to about 85.5 million tons per year. Annual PVC capacity was 23 million tons, or 27% of total; PP, 20.1 million tons (24%); LDPE, 17.1 million tons (20%); HDPE, 14.9 million tons (17%); and LLDPE, 10.4 million tons (12%).

Asia and the Pacific Basin.—This region accounted for about one-third of world chemicals demand. The area's first major impact on the world chemical market was as a textile supplier, so chemical fibers were the first to undergo expansion. As a result, Taiwan and the Republic of Korea have larger polyester fiber production capacities than western Europe—each produces about 1.2 million tons per year of polyester filament yarn and staple fiber. This area has been primarily a market for Japan, which accounts for about two-thirds of the region's gross national product (GNP). Large multinational companies have been increasing their investment in the printstyle region; however, impending overcapacity has led to a slowdown in investments. China, Indonesia, and Taiwan have some room for growth. Other countries in the region are faced with overcapacity. Between 1990 and 1992, ethylene production capacity in Asia (China, Indonesia, Japan, the Republic of Korea, Malaysia, Singapore, Taiwan, and Thailand) grew from 10.6 million tons to 13.3 million tons, and in 1995 capacity is projected to reach 16 million tons. Polymeric resin production capacity growth in China from 1991 to 1995 is projected to grow by the following quantities: LDPE, 1.26 million tons; LLDPE, 330,000 tons; HDPE, 300,000 tons; PS, 300,000 tons; PP, 980,000 tons; and PVC, 480,000 tons.

Regional growth in the Far East led several companies to announce expansion plans for PVC. Tosoh Corp. (Japan) plans to expand production in Indonesia and Malaysia, while Thai Plastic & Chemicals also plans to increase its capacity in Thailand. Postwar reconstruction programs in Cambodia and Vietnam were cited as reasons for increased PVC demand.

Amoco Chemical Corp. and a local conglomerate formed a joint venture to build a 350,000-ton-per-year purified terephthalic acid (PTA) plant in West Java. Completion is slated for 1995. Amoco also formed a joint venture with several Japanese firms and completed a feasibility study for a 250,000-ton-per-year PTA plant in the Republic of Korea. The new capacity, to be completed by mid-1995, will bring the country's total capacity to nearly 900,000 tons per year, all to be used in the domestic market. The firm also was moving ahead on previously reported plans to build a wholly owned 500,000-ton-per-year PTA plant in Malaysia and is expected to invite bids in early 1994. Amoco's other regional PTA production is through joint ventures in the Republic of Korea and Taiwan; the latter is being expanded by 25%.

ICI commissioned its 350,000-ton-per-year PTA plant in Taiwan to serve the Asia-Pacific market, which accounts for about 60% of total world demand. The Far East market has been oversupplied following several startups in the past few years, and analysts do not believe this market will be able to absorb the additional capacity until 1993 or beyond. Between 1993 and 1995, at least six new PTA plants were planned in the region, increasing capacity by about 1.5 million tons per year.

In 1993, DuPont and Mitsui & Co. signed an agreement to jointly develop markets and sell DuPont's advanced composites in Asia-Pacific. Mitsui will be responsible for promotion and sales of the products, which are being targeted to replace metals in aerospace, automotive, industrial, and recreational applications. DuPont also signed a similar partnership agreement with Asahi Chemical to look for nylon synergies in Asia-Pacific. DuPont recently commenced construction of a major nylon-6,6 facility, including adipic acid, in Singapore.

China.—The Chinese Government approved construction of a 140,000-ton-per-year ethylene plant at Dongying, Shandong, and discussions began with foreign suppliers for an associated $600 million complex that also will produce 100,000 tons of PE, 60,000 tons of acrylonitrile, and 30,000 tons of acrylic fibers per year. China also started a new ethylene plant in Liaoning Province with a capacity of 120,000 tons per year. Toyo Engineering was awarded a contract to expand an ethylene plant for Yangzi Petrochemical at Nanjing. The present 300,000-ton-per-year Lummus Crest process plant, built in 1978, will be debottlenecked by 100,000 tons to 400,000 tons per year. The country plans to increase ethylene capacity from 1.8 million tons per year in 1990 to 3.7 million tons per year by 1995, and by at least another 1.5 million tons to 5.2 million tons per year by the year 2000.

The Italian firm Snamprogetti won an order to build a 120,000-ton-per-year LLDPE plant in China. The plant will form part of the Zhongyuan complex at

Puyang, Henan. Mitsui Engineering won a $35 million contract to build a 40,000-ton-per-year PP plant at the Daqing petrochemical complex in Heilongjiang Province. Chi Mei Industrial planned to build a 300,000-ton-per-year ABS plant and a 300,000-ton-per-year PS plant in China by mid-1995.

Snamprogetti won an order to build a 100,000-ton-per-year styrene monomer unit, and Mitsui Engineering won an order to build a 100,000-ton-per-year ethylene oxide/glycol unit at the Maoming petrochemical complex.

SNC-Partec was awarded a $55 million contract for a 60,000-ton-per-year styrene plant in Panjin, Liaoning Province. Two additional styrenics complexes were planned. One in Heilongjiang Province was to have annual capacities of 60,000 tons of styrene monomer, 25,000 tons of PS, and 50,000 tons of ABS. At Guangzhou, annual capacities will be 60,000 tons of styrene monomer and 50,000 tons of PS.

India.—India has experienced shortfalls in domestic capacity and production to meet petrochemical demand. With the Government's liberalization of the economy, official industry sources expected enough new petrochemical capacity to be installed to meet demand and perhaps provide some material for export. By the end of the decade, official industry sources projected an increase in ethylene capacity from 230,000 tons per year to more than 2 million tons. In 1992, production of LDPE, LLDPE, HDPE, PP, PVC, and PS was estimated to be 471,000 tons, with demand at 755,000 tons. By 1995, production is expected to be 1.1 million tons, with a demand of 1.06 million tons.

Simon-Carves of Manchester, England, was awarded a contract for the basic design and engineering of a 55,000-ton-per-year LDPE plant to be built in an undisclosed location in India. The plant was due on-stream in 1994.

Reliance Petrochemicals, based in Bombay, formed a joint venture with Mitsubishi Corp. to build a new 250,000-ton-per-year PP plant at the petrochemical complex in Hazira, Gujarat. Startup was scheduled for 1994, to coincide with the complex's 320,000-ton-per-year olefins cracker coming on-stream. Italy-based Tecnimont was awarded a contract to build a 75,000-ton-per-year PP plant for Indian Petrochemical Corp. Ltd. at Baroda, Gujarat; completion was scheduled for 1995.

ABB Lummus Crest of Bloomfield, NJ, was selected to build a 60,000-ton-per-year styrene monomer/PS complex in India. The company also will provide basic engineering and other services for a 100,000-ton-per-year ethylbenzene/styrene monomer plant. Both plants will be near Nagothane and were scheduled for completion in 1994.

Reliance Industries planned to build a 350,000-ton-per-year PTA plant at Hazira at a cost of $528 million. Also to be constructed were downstream facilities for the production of polyester filament, polyester staple, and PET, totaling 200,000 tons per year. Initial production was scheduled to begin at the end of 1993, and the complex completion date was scheduled for 1995.

Indonesia.—A new joint-venture company, PT Polytama Propindo, owned 80% by the local PT Tirtamas Majutama and 10% each by BP Chemicals (London) and Nissho Iwai (Tokyo), received permission to set up a $230 million, 100,000-ton-per-year PP Himont process plant at Balongan, Java island. The project will receive propylene feedstock from a new refinery under construction at Balongan for Pertamina and is scheduled for completion in 1995. This will be the third PP plant in Indonesia. Indonesia's existing PP plant is owned by Tripolita; the firm planned to double capacity.

P.T. Tripolita Indonesia will soon begin production of PP at its new 160,000-ton-per-year plant in Anyer, West Java. PT Styrene Monomers Indonesia completed its 100,000-ton-per-year styrene plant in West Java. Dow Chemical and the Salim Group were constructing a plant in Indonesia to produce 30,000 tons per year of styrene-butadiene latex. The plant came on-stream early in 1993.

In addition, Golden Key was building a 140,000-ton-per-year Unipol process unit at Serang, Java. Golden Key Group completed engineering for its $300 million styrenics complex at Serang. The project was expected to come on-stream in 1994 and included plants for styrene monomer, PS, high-impact PS, ABS, styrene acrylonitrile (SAN), styrene butadiene rubber, and styrene butadiene latex. BP Chemicals' PE joint venture, PT Peni, successfully started up a 200,000-ton-per-year LLDP and HDPE plant during 1993.

Indonesia has approved construction of the Chandra Asri petrochemical complex at Cilegron, West Java, as long as it is 100% foreign owned; the project was postponed in 1991. The first stage is a 450,000-ton-per-year to 500,000-ton ethylene plant, with downstream units to produce PE and PP.

Textile company P.T. Polyfin announced that it would build a complex with a capacity of 63,000 tons per year of polyester fiber to be completed by mid-1994. Total polyester filament capacity in Indonesia was 170,000 tons per year and was scheduled to double by 1993 when capacity expansions announced earlier are brought on-stream.

Japan.—Ethylene oversupply was substantial in 1993, and output was expected to drop by a further 7.9% in the first-half of 1994, to 2.7 million tons, according to a Ministry of International Trade and Industry (MITI) advisory panel. MITI projections indicated that ethylene equivalent demand was expected to decrease from those of 1992 and 1993 because of continuing declines in the automotive, construction, packaging, and electronics sectors. Several Japanese PE producers were extending shutdowns in 1993 owing to the downturn in the domestic market.

Because of the continued slump in

the Japanese petrochemical industry, where ethylene capacity currently approximates about 6.5 million tons per year, several projects were postponed or downsized. Maruzen Polymer delayed plans to build a 100,000-ton-per-year HDPE plant at Chiba, and Asahi postponed the April 1992 startup of its 40,000-ton LLDPE plant in Mizushima. Nippon Petrochemical postponed the startup of its 50,000-ton LLDPE plant from March until late 1992 to early 1993. Nippon Petrochemical postponed commissioning of its 50,000-ton-per-year LLDPE reactor until early 1993, and Showa Denko planned to cut back production of ethylene and derivatives into 1993.

Japanese manufacturers of PS were working to reduce high inventory levels, and plant operating rates decreased to less than 80%; total Japanese PS capacity was about 1.4 million tons, and 1993 demand was about 1.1 million tons. Exports for Japanese PS were not growing as expected because of competition from other producers in countries such as the Republic of Korea, where 300,000 tons per year of new styrene capacity competed in traditional Japanese markets. Several Japanese PS producers were considering closing outdated plants amid falling demand in 1993.

The Japanese styrene oversupply situation was further exacerbated by the startup of Idemitsu Petrochemical's 200,000-ton plant at Tokuyama in 1992. Sumitomo Chemical and Denki Kagaku reached an agreement to build a 250,000 annual ton $160 million styrene plant at Chiba by 1994. Nippon Polystyrene cut production of PS as a result of lower demand for electronic appliances and office equipment.

Idemetsu Petrochemical began limited production at its 80,000-ton-per-year PP plant, the output of which was destined for Malaysia; the company did not expect to start full-scale operations until the spring of 1993. Ube Polypropylene postponed startup of its new 80,000-ton PP plant from October 1992 until sometime in 1993, citing poor demand and overcapacity. An 80,000-ton-per-year PVC plant was completed at Sumitomo Chemical's Chiba complex in 1992, but startup was delayed by at least 6 months because of the depressed state of Japan's PVC market.

Tejin and DuPont reportedly reached an agreement to jointly develop polyethylene napthalate (PEN) films, an analog of PET. Tejin is currently the only commercial producer of PEN films with a plant in Japan. PEN films are stronger than PET films and are expected to see significant growth in the next few years. They are used in Japan for audiotapes and videotapes, and DuPont hopes to market PEN for thin-film capacitors and for insulating film used in motors, traditional PET markets.

Mitsubishi Kasel planned to raise its current xylenol capacity of 2.6 million annual tons, about 20% to 30% by 1994. The material is supplied to Yuka Shell Epoxy, a joint venture with Shell Oil, to produce epoxies for use in encapsulating advanced semiconductors. Mitsubishi Yuka announced the restart of a mothballed 25,000-ton-per-year acrylic acid plant at Yokkaichi, closed since March 1993, despite the local market slump. The company plans to export most of the material to the United States, under contract.

Idemitsu Kosan planned to construct a 100,000-ton-per-year MTBE plant at its Chiba refinery. Completion was scheduled for June 1993. In Japan, MTBE was approved for use in gasoline blending in 1991, which prompted several companies to build production capacity. In September 1992, Kashima Oil completed the first MTBE plant in Japan, with an annual capacity of 60,000 tons; the plant relied on imported methanol, supplied predominately by Methanex.

Korea, Republic of.—In the Republic of Korea, the Ministry of Trade and Industry banned construction of new ethylene plants and some derivatives through yearend 1994, including styrene and caprolactam. Ethylene capacity in the Republic of Korea was at about 20% above domestic demand; 2 years before, the deficit between MTBE capacity and domestic demand was about 20%; but, to meet upcoming clean air regulations, the Republic of Korea plans to increase its MTBE capacity. Sales of selected high-volume thermoplastics increased 13% in 1993.

Malaysia.—Titan Himont Polymers recently commissioned a 120,000-ton-per-year PP plant in Pasir Gudang. A 140,000-ton plant was under construction at the site and scheduled to come onstream during late 1993. Japan's Mitsui Engineering & Shipbuilding reportedly won an order to build Idemitsu's $50 million, 60,000-ton-per-year PS plant in Malaysia. This plant is a part of Idemitsu Chemicals' ethyl benzene/styrene monomer, PS, and ABS production facilities.

Singapore.—In 1993, DuPont broke ground for a new $100 million nylon-6,6 plant at Pulau Sakre. The unit, scheduled for mid-1995 completion, will form part of a major nylon complex; a $250 million adipic acid plant was under construction at the site. DuPont referenced the growing demand in Asia-Pacific for adipic acid, a key building block for nylon and polyurethanes.

Taiwan.—After a 6-year delay, Formosa Plastics, based in Taipei, received tentative approval from Taiwan's Environmental Protection Administration to begin construction of a $3.3 billion petrochemical complex. The complex will include the country's sixth ethylene plant and 24 downstream units, including styrene, MTBE, acrylonitrile, PVC, PE, polycarbonate, and ABS. Taiwan's Environmental Protection Administration mandated PS foam recycling beginning in late September 1993.

ICI formally commissioned a 350,000-ton-per-year PTA plant in Taiwan. This plant will bring the company's global PTA capacity to 872,000 tons per year. Taiwan is the second largest user of PTA, and if predicted growth rates materialize, Taiwan will be the largest user within a few years. ICI estimates demand will grow by an average of 8% per year during the 1990's, with 60% of that growth in Asia and the Far East. Prices were depressed in 1993, however.

Taiwan faces a significant oversupply of polyester filament. Demand has fallen to about 25,000 tons per month, while production is about 70,000 tons per month. Although exports fell in 1992, producers were reluctant to reduce production, resulting in a significant supply overhang in 1993.

Thailand.—Dow Chemical Co. and Siam Cement received a license to build a 75,000-ton-per-year PS plant at Map Ta Phut, at a cost of about $50 million. Completion was scheduled for mid-1995. Several other projects are underway at Map Ta Phut, including a 25,000-ton-per-year polyols plant; a 20,000-ton styrene-butadiene latex plant; and a 200,000-ton-per-year styrene plant.

Europe.—In PE, recent capacity additions in Europe have led to a significant oversupply situation for all three major product lines. In 1991, about 570,000 tons per year of HDPE capacity came on-stream and another 320,000 annual tons in 1992. New PE capacity represents a 7% to 8% increase, while the market has grown by a nominal 3%, at maximum.

In May 1992, Compagnie Industrielle des Polyethylenes de Normandie began production at its 220,000-ton-per-year LLDPE plant in France. The startup came at a time when PE markets were depressed because of overcapacity and economic recession. In October, because of the slump in Europe's PE market, the company temporarily closed its new LLDPE plant to correct "inventory imbalances." In addition, Dow Europe planned to close 55,000 tons per year of LLDPE capacity in Spain for at least 1 year and then reevaluate the market.

Shell Chemical Co. commissioned a new ethylene pipeline to feed downstream units in England. The company planned to have a 100,000-ton-per-year LDPE plant on-stream by yearend and to close 40,000 annual tons of existing capacity, leaving the company with a total of 170,000 tons per year of LDPE capacity.

PP was the healthiest of all polyolefins markets in Europe, growing by about 3% in 1993 and outperforming gross domestic product. Overcapacity, however, thwarted producers' attempts to raise prices. Even so, about one-third of producers were thought to have made a positive margin in the third-quarter of 1993, much better than the lackluster performance of the European PE industry. In fact, 1994 could prove to be a watershed for the European PP industry. Even if none of Europe's less efficient plants close next year, the forecast rate of growth should take plant operating rates from the current 85% to beyond 90%, leading to better operating efficiency and a decided reduction in capacity overhang.

Neste Corp. has been authorized to construct a $150 million PP plant in Porvoo, Finland, to be completed by 1994. The plant also will produce LLDPE and HDPE. The company may close one of the existing LDPE lines at the plant when the new capacity comes on-stream, because it is already balanced in ethylene.

Hoechst AG announced that it would close its old 135,000-ton-per-year PP plant at Kelsterbach, Germany, by early 1993. The company recently opened a 140,000-ton-per-year PP plant at Knapsack. BASF is investing $32 million in an expanded PP plant in Germany to be completed by 1994. Expanded PP will be used primarily for packaging and impact absorbing applications in the automotive industry.

In the first half of 1993, the 4.9 million annual ton European PVC market saw consumption decline 15%, mainly because of Germany's recession. European price increases were needed badly, because every PVC producer in Europe experienced losses in the third quarter principally because of high PVC production costs—according to Chem Systems in London. Solvay officials in Brussels, the world's third largest PVC producer, indicated that for the long term, the firm had no choice but to restructure to be competitive with the United States. With inventories well below normal by midyear, however, European producers could not look to North America to alleviate the shortage because of tight supplies in the United States. With U.S business tight and surplus capacity already absorbed by foreign markets, the European market has stabilized and plants were running at near capacity by yearend. Western Europe accounted for about 26% of global PVC demand in 1993.

Producer competition for European engineering polymers (EP's) share has resulted in price declines more dramatic than elsewhere. Lower car production in Western Europe, for example, led to a downturn in ABS resin demand, although polycarbonate demand was up 2% to 3%, largely because of healthy compact disk sales.

ABS prices have dropped, too, because of a large influx of imported material from the Far East and market share inroads by PP.

Eastman Chemical Co. plans to double PET capacity at its United Kingdom facility to 100,000 tons per year by early 1993. After the expansion, Eastman will share the title as the largest European producer with EniChem Elastomeri of Milan, Italy. European PET consumption is projected to increase from 465,000 tons in 1992 to 630,000 tons by 1995, and to 950,000 tons by the year 2001. Production is expected to increase as well, from 335,000 tons in 1992, to 560,000 tons in 1995, and 890,000 tons by the year 2001.

Melamine demand in Europe, which has dropped significantly in the past 3 years, has resulted in severe overcapacity in that sector. One new 50,000-ton-per-year plant in the Netherlands completed in 1991 has never come on-stream. In the past, eastern Europe was an important destination for melamine exports from western countries, but this region has severely curtailed buying because of a shortage in foreign exchange. Product also was being imported from the United States and Saudi Arabia. European melamine producers were projecting flat demand, with average annual growth rates of about 1% through 1995.

In 1993, EniChem Elastomeri started up its new $30 million neodymium polybutadiene plant for the production of a special elastomer, of which EniChem is the world's largest manufacturer, at Raveni, Italy. Product from the 30,000 annual ton plant is brand-named Europrene Neocis, and is used mainly in tires. EniChem already produces the product at Grangemouth, United Kingdom.

Following reappraisal, Statoil and Conoco will proceed with construction of an 830,000-ton-per-year methanol plant at Tjeldbergodden, Norway. Conoco will market its 18% (150,000-ton) share in the $423 million plant, scheduled to start up in late 1996, while Statoil's 680,000 tons will be targeted at European markets.

Latin America.—Petrochemicals integration and privatization in the Mercosur free trade zone linking Argentina, Brazil, Paraguay, and Uruguay were major topics addressed at the recent Asociacion Petroquimica Latinoamericana (APLA) meeting in Rio de Janeiro in late 1993. Delegates continued to express skepticism as to the feasibility of agreeing on zero tariffs in the next few months, however, because of the unbalanced economies between Brazil and Argentina. Increases in PP in South America from 1990 to the end of 1992 should allow the area to become a net exporter. Additional capacity in Brazil and Argentina, coupled with existing capacity in these countries, along with Colombia, Mexico, and Venezuela, should bring total capacity to 900,000 tons per year. Latin American PP consumption was estimated to be about 600,000 tons annually.

Argentina.—Argentina was struggling with the issues of privatization and consolidation, together with its significant cost disadvantages relative to Brazilian resins, and concomitant import reliance, especially on Brazilian HDPE. Argentina's HDPE domestic demand of 130,000 tons per year significantly outstripped the country's capacity of 85,000 tons per year.

Brazil.—Plans to privatize the Brazilian petrochemicals and resin businesses and restructure the chemical industry met with resistance in 1993 as Brazil's oil monopoly, Petrobras, was still unwilling to compromise on naphtha supplies. Petrobas officials continued to favor the importation of less expensive oil derivatives compared with the price of domestic product. Consequently, about 30% of the 6.6 million tons per year of naphtha needed for petrochemical crackers was imported in 1993.

Meanwhile, synthetic rubbermaker Petroflex was privatized successfully and given the go-ahead by the Brazilian Government to create a major styrene-butadiene rubber enterprise in South America. Petroflex was given the authority to handle details for a merger with the other Brazilian rubber producer, Coperbo.

Government-controlled styrene producer Estireno do Nordeste (EDN) halted production at its 45,000-ton-per-year PS plant at Camacari for 2 years. The company was planning to concentrate on production at its 90,000-ton-per-year plant in Sao Paulo. EDN officials reported that normal operation would continue at the company's 172,000 annual ton ethylbenzene plant and 150,000-ton styrene monomer unit at Camacari. The Sao Paulo PS unit will run at 95%, with one-half dedicated to the domestic market.

PE capacity was more than 1 million tons per year, with domestic demand estimated at less than 500,000 tons per year. Two new PE plants were added during 1992, with a total capacity of 240,000 tons per year. PP capacity was about 650,000 tons per year, and demand was estimated at 300,000 tons per year. This, together with Braspol Polimeros' recently commissioned 150,000-ton-per-year PP plant in Brazil, brings total Brazilian PP capacity to 700,000 tons per year, leaving a large surplus for export. The Brazilian PVC market performed slightly better during 1993, following a demand surge in the first half of the year. Brazilian officials estimated the market at 375,000 tons annually; imports accounted for 60,000 tons.

Mexico.—Hoechst Celanese planned to increase its PET capacity by 57,000 tons per year in Mexico in response to the country's increasing growth in the PET market. This is a part of Hoechst's plan to increase total North American capacity by nearly 227,000 tons per year by 1995.

In May 1993, Eastman Chemical of the United States confirmed plans to build a 60,000-ton-per-year PET resin plant in a joint venture with the Mexican firm Temex. The plant will be located at Temex's site in Cosoleacaque, Veracruz. Eastman will own the plant and be responsible for its operation, while Temex will supply purified terephthalic acid (PTA) feedstock. The unit will meet soaring demand for PET bottle resin in Mexico, the world's second largest soft drink market. PET refillable soft drink bottles were introduced to Mexico in 1991 and the market has enjoyed substantial growth, approximating 15% to 20% per year.

Trinidad and Tobago.—German contractor Ferrostaal and U.S. trader Helm signed a memorandum of understanding in June 1993 to build a $235 million methanol plant at Point Lisas having a capacity of 550,000 tons per year, based on ICI process technology. The two firms were expected to take a 31% stake in Trinidad and Tobago Methanol Co. (TTMC), which operates a 460,000-ton-per-year methanol plant at the site. The plant was scheduled to come on-stream in 1996. In addition, Caribbean Methanol Co. (CMC) was scheduled to bring a 500,000-ton-per-year methanol plant on-stream in late 1993 at Point Lisas. If financing is obtained for the new TTMC project, Trinidad will have 1.6 million tons per year of methanol capacity by 1996. The Canadian firm Methanex will market output from the CMC plant, while Helm was to market output from the TTMC plants.

Venezuela.—In 1992, ABB Lummus Crest was awarded a contract to build a 150,000-ton-per-year LLDPE plant in Venezuela. The plant was scheduled for completion in the first quarter of 1994.

***Mideast Region.*—Iran.**—Iran reportedly gave permission for 10 new private-sector chemical projects. These included a project to produce 30,000 tons per year of aniline; a project for 25,000 tons per year of isocyanates, 24,000 tons per year of acetic acid, and 10,000 tons per year of monochloroacetic acid; a project for 10,000 tons per year of melamine; a 70,000-ton-per-year PVC plant; a 15,000-ton-per-year ABS and styrene-acrylonitrile resins complex; a plant for 40,000 tons per year of dioctyl phthalate and 10,000 tons per year of petroleum resins; and two 10,000-ton-per-year plants for petroleum resins.

A new 1 million-ton-per-year MTBE plant was planned to be constructed in Iran by the third quarter of 1994. State-owned National Petrochemical Co. and an Iranian entrepreneur signed a letter of intent for the $300 million venture to be constructed in Bandar Imam. About 15% to 20% of the output from the plant was expected to be sold in the domestic market, with the rest to be exported.

Israel.—Israel's Carmel Olefins may begin shipments of PP to Egypt in 1994, according to senior Israeli energy ministry officials. Diplomatic negotiations between the two countries resulted in an agreement in principle whereby Egypt would provide Israel with caustic soda in exchange for PP. Carmel Olefins began PP production in the summer of 1993 at Haifa. Carmel was producing 100,000 tons per year, of which 60,000 tons was for local use.

Kuwait.—In 1992, Petrochemical Industries Co. reportedly revived plans to construct a petrochemical complex at Shuaiba that had been shelved since the war with Iraq. Along with an overseas investor, the company planned to build a 600,000-ton-per-year ethylene plant and include facilities to produce PE, PP, ethylene oxide, and glycol.

Saudi Arabia.—Dow Europe formed a joint venture in 1992 with a Saudi Arabian firm to manufacture and market styrene-butadiene latex in Saudi Arabia. The first 30,000-ton-per-year unit was due on-stream at the end of 1994, and a doubling of capacity was planned.

In 1993, a $225 million loan was extended by Mideastern banks for the construction of an oxo-alcohols plant planned by Al Jubail Fertilizer (Samad). Samad is a joint-venture between Taiwan Fertilizer and Saudi Arabian Basic Industries Corp. The Saudi plant was to produce 150,000 tons per year of 2-ethyl hexanol based on the Davy process, with the John Brown Co. serving as contractor. The loan also was to cover part of a project to produce annually 50,000 tons of dioctyl phthalate plasticizer. Both projects will require a total investment approaching $400 million.

Saudi Venture Capital Group (SVCG) confirmed that it was planning a 100,000-ton-per-year caprolactam plant at Al Jubail as a downstream unit from its recently announced aromatics joint venture with Chevron Chemical. SVCG's first project will consist of a 50-50 joint venture with Chevron to produce 420,000 tons of benzene and 270,000 tons of cyclohexane annually, using Chevron's Aromax technology. SVCG also planned to produce 50,000 tons per year of maleic anhydride, and eventually paraxylene and PTA.

United Arab Emirates.—The Abu Dhabi National Oil Co. announced plans to begin petrochemical manufacture. The first stage of the project was to include an ethylene and PE complex with an annual capacity of 300,000 to 500,000 tons. No timetable was given for construction.

North America.—Total sales of domestic Canadian resin in 1993 were about 2.3 million tons, level with 1992 values; net exports were 0.8 million tons. LDPE and HDPE accounted for 73% of sales, in order of importance. Other significant resin sales were PVC, PP, PS, and ABS, in order of importance.

Nova Corp. of Alberta acquired a 24% stake in Methanex of Vancouver, British Columbia, in exchange for its methanol assets plus $185 million. Novacor's methanol plant at Medicine Hat, Alberta, will add 370 million gallons per year to Methanex's 1.4 billion gallon per year capacity in 1994. Nova's methanol plant will provide Methanex with improved marketing and logistics flexibility. Methanex's Vancouver plant was well placed for serving the Far East and the Western United States, while Nova's Alberta site offered rail access to the Midwest and Eastern United States. Methanex is the largest global producer and distributor of methanol.

***Former U.S.S.R.*—Belarus.**—Eastman Chemicals and Pepsico International formed a joint venture with two Belarus companies to produce PET and PET bottles at Mogliev. PET resins were expected to be produced beginning in late-1992. One-half of the output will be used to produce bottles for use in the former U.S.S.R., and the remaining PET resin was destined for the western European market.

Kazakhstan.—The French company Litwin reportedly signed a contract with Shevchenkovski Zavod Plastmass to build a 370,000-ton-per-year styrene plant in Kazakhstan. The existing plant also will be modernized.

Russia.—Major Russian chemical

producers have formed a new company, A/O Neftek-Techno. This brought together some of the country's largest chemical producers, and the goal was to coordinate plans to improve earnings and profitability. For example, rather than selling excess propylene in western markets, the material was to be converted to value-added PP. Tecnimont signed a contract to supply a 100,000-ton-per-year PP complex for the Kapotnia Refinery in Moscow.

In 1993, a new company, Chem Bridge Corp. of Chicago, IL, was formed to help western companies gain access to Russian chemical science and industry. In custom products, the company will engage in complex organic, bioorganic, organometallic, and inorganic chemistry.

Ukraine.—The Chlorvinyl enterprise at Kalush, Ukraine, announced that it signed a $200 million contract with Linde (Germany) and Union Carbide Corp. of the United States, for the construction of a 100,000-ton-per-year LLDPE and an 80,000-ton-per-year PP plant. The plants could be completed as early as 1995. Uhde will expand capacity of vinyl chloride monomer and PVC in Ukraine. The monomer plant will be expanded from 250,000 tons per year, to 370,000 tons.

Current Research and Technology

In 1993, resin research was intensified in olefin polymerization technologies that would produce superior properties. Dow Chemical, for example, bypassed conventional Ziegler/Natta catalyst processes with its new Insite single-site metallocene catalyst technology to produce a new line of ethylene-based copolymers with densities as low as 0.864 grams per cubic centimeter (g/cm^3) and flexibility comparable with some rubbers. Dow's new polyolefin elastomers (POE's) incorporate 20% to 40% octene comonomer, higher than previously obtained with LLDPE, while modulus levels approximate those of ethylene-propylene-diene rubber (EDPM). Dow was targeting the new product for impact modification of PP to replace EDPM; for cross-linked, low-voltage power cable, under-the-hood automotive molding and profile, to compete with LDPE's; and textile calendared coating applications designed to compete with PVC.

In late 1993, Dow introduced its first line of metallocene catalyzed resins, containing up to 20% comonomer, and aimed primarily at film and sealant roles in packaging. The new resins were dubbed polyolefin plastomers (POP's). POP's demonstrate plastic and elastic properties, excellent for packaging, automotive, and consumer and industrial goods. Compared to polyolefins used now in these markets, POP's have lower and sharper melting points, excellent clarity, hot tack and seal properties, good recovery, and organoleptics.

Dow's Insite metallocene catalyst technology is based on group IV transition metals, like titanium, covalently bonded to a monocyclopentadienyl group bridged with a heteroatom such as nitrogen. The components are connected in such a way that a constrained cyclic structure is formed with the titanium center. Insite constrained geometry (CG) homogeneous catalysts produce highly processible polyolefins with a unique combination of narrow molecular weight distribution and long-chain branches, with useful properties across a broad range of densities and melt indexes.

Exxon Chemical Co. commercialized a new generation of metallocene-based specialty olefin elastomers for tire, automotive, pharmaceutical, and adhesive applications. Production commenced at a new plant in Baytown, TX. Additionally, seven grades of new resins based on proprietary technology were introduced. A total of 23 grades, one-half of them for the film packaging industry, have been introduced since commercial sales of these resins began in 1992.

Phillips Petroleum Co. commenced production of an ethylene-hexene-1 copolymer called low-density linear PE (LDLPE), using a new chromium-base Ziegler-Natta catalyst. The new material was said to be tougher and was designed to compete with traditional LLDPE materials in film, blow-molding, and injection-molding markets. The material has the advantages of swing production with HDPE, Phillips' major product, and direct interchange with HDPE film processing equipment. Premarketing production was being effected at Phillips' newest HDPE plant at Pasadena, TX.

Shell Chemical Co. introduced a new family of PP random copolymers that use butene as the comonomer. The firm reported that this is the first time that butene, a C_4 hydrocarbon, has been so used. Typically, suppliers offer PP copolymerized with ethylene or terpolymers employing a combination of propylene, ethylene, and butene. Shell's new products were reported to offer above-conventional levels of stiffness, clarity, and low heat-seal-initiation temperature as compared to traditional random PP copolymers. The higher heat-seal initiation properties of traditional products have been the key detriment to high line speeds. Union Carbide's gas-phase polymerization technology and Shell's 200 series super-high-activity catalyst were credited as being responsible for vast improvements in materials performance. Unipol technology allows high—up to 14%—levels of comonomer, versus conventional levels of 7% or less. The materials were also excellent for use in shrink films.

GE Plastics Co. commercialized a polybutylene terephthalate (PBT) resin grade that is designed to enhance optical fiber use in stringent aboveground environments. One resin is for use in buffer tubes, the brightly colored extrusions that jacket groups of eight optical fibers, which in turn are bundled to form a fiber optical cable. The key benefit of the new resin involves improved hydrolytic stability or the ability to retain integrity in humid, elevated temperatures. The material was reported to extend time to embrittlement by 500% over most existing PBT's at above 70° C. Projected growth of 20% per year over the next 10 years for communications technology requiring that optical fiber be employed in exterior and near-the-home uses is expected to drive demand for the new product. Additionally, a new Bell Communications Research standard (Bellcore TA20) has established generic requirements for increased hydrolytic stability. Flame-retardant and glass-filled versions designed for use in electrical connectors and plumbing were under development.

Georgia Gulf's PVC Div. entered the chlorinated PVC (CPVC) compound supply market through the launch of pipe and profile grades. The firm's new resin is a powder compound in tan and gray versions for extruded tubing and small-diameter pipe, respectively. The material combines excellent impact strength and processability, including the ability to readily utilize reworked material. The product is listed under the National Sanitation Foundation's Standard 14 code for hot and cold potable water pipe. A series of pelletized compounds offer a range of elevated heat-deflection temperatures for extruded profiles. Targeted markets include window glazing, components subjected to the "greenhouse effect"—dark-color window frames—and, construction profiles requiring high heat and chemical resistance properties, like skylights. Another CPVC grade is a pelletized injection molding grade targeted at pipe fittings and components in fire sprinkler and chemical transfer systems.

PPG Industries, Inc. is the world's leading supplier of automotive and industrial finishes and a major supplier of architectural finishes. PPG's most significant event reported during the year in terms of growth, however, was Transitions Optical, Inc., a joint venture with Essilor International of France. Transitions' new variable-tint plastic prescription lenses were well received worldwide, and sales increased dramatically throughout 1993. Transitions Optical has become the world's leading supplier of variable-tint plastic lenses for prescription eyewear, according to the firm's literature.

PPG's coatings products introduced in 1993, or that achieved broader consumer acceptance, were the environmentally compatible waterborne base coats for autos and the economical, high-quality automotive refinishes. PPG opened three new training centers for automotive refinishers during 1993. Also, a novel method involving externally coating glass bottles in lieu of blending colorants in situ was introduced at PPG's Monterrey, Mexico, plant. The external colorants and much of the coating equipment were supplied by Brandt Technologies of Windsor, NY. Coating the bottles rather than using tinted glass reduced costs and allowed for easier recycling.

In nonwovens, DuPont remained dominant worldwide in this rapidly expanding, high-technology, multi-billion dollar market. DuPont's nonwovens business was centered about spunlaced fabric, spunbonded olefins, and spunbonded PP—products designed to solve market needs in medical, apparel, construction, packaging, reinforcement, and absorbents. Spunbonded PP was the leading product growth nonwoven material in the United States and Europe for broadloom carpet backing. DuPont's new reinforced spunbonded olefins used for breathable roofliners that simplify construction techniques experienced strong growth in Europe. Spunlaced fabric maintained a strong position in the global health care industry as the preferred material for surgical gown and drapes. The material also continued to experience significant growth in diverse consumer applications, including window shades, specialty wipes, synthetic leather, and adult incontinence products.

The flame-resistant and high-strength aramid fibers businesses continued to expand, as DuPont opened new plants for each at Richmond, VA, and Asturial, Spain, respectively. A newly developed aramid fiber product provides the lightest and thinnest bullet-resistant vests currently available, while another grade provides protection against static electricity, as well as flame and thermal shock, for flight suits and in apparel for the oil, chemical, and munitions industries.

A major development in organic chemicals during the year involved the startup of DuPont's largest world-scale hydrofluorocarbon-134a plant at Corpus Christi, TX. The firm was reported to be an industry leader in CFC alternatives, with a full line of refrigerant products marketed under trademark. The new product had zero or significantly reduced ozone depletion potential. In a related development, OxyChem introduced a new product line, designed to replace certain ozone-depleting solvents widely used in the marketplace.

In other CFC-related industries, cyclopentane blowing agents were introduced as CFC substitutes for polyurethane in foam applications, particularly for refrigerator appliance insulation in Europe. In North America, pentane-blown PS foam also competed with urethanes, and high-impact PS competed with ABS for appliance liner markets.

Catalytica, of Mountain View, CA, was awarded a U.S. patent covering a direct catalytic methane-to-methanol synthesis conversion. Working with partners PetroCanada and a subsidiary of Mitsubishi Oil, Catalytica developed a low-temperature synthesis to foil one of the classic problems in direct methane oxidation—stopping the reaction at the methanol stage. Also, Pennsylvania State University (Penn State) chemists announced a novel acetic acid synthesis route based on the direct oxidation of methane, using a rhodium chloride catalyst. The reaction represents the first low-temperature catalytic oxidation of methane using oxygen, according to the Penn State chemists. Although the subject direct methane conversion efforts are currently in the early research stage, they suggest fundamentally new pathways to overcome methane's (natural gas) "notoriously fickle chemistry," according to the researchers.

Current technology involves high-temperature, energy-intensive, methane-steam-reforming-processes in which methane is oxidized to carbon dioxide, carbon monoxide, and hydrogen to form syngas for the production of ammonia, methanol, formaldehyde, and acetic acid. The new direct processes, thus, could pave the way to more economical, direct methods. If methanol could be produced more cheaply by direct routes, for example, the vast natural gas reserves of North America could potentially take their place alongside petroleum as a feedstock, and the use of C_1-C_2 feedstocks is inherently cleaner.

OUTLOOK

Steady upward growth has been generally experienced in U.S. synthetic organic chemicals and downstream products since World War II, interrupted only infrequently by disruptions in the economy or by supply-demand factors. Since 1967, the production of polymeric resins has increased at a compound annual rate of about 6% and sales and captive use by about 7.1%, although average annual growth has slowed to 4% and 5%, respectively, since the recessionary period of 1990 and 1991. Dynamic growth in the synthetic organics industry can be traced largely to increasing domestic demand for crude petroleum and the availability of petrochemical feedstocks for the production of a proliferation of synthetic organic consumer materials that have preferentially substituted for traditional materials. Other factors have involved growing consumer demand generated by technological innovations, together with international demand for U.S. basic and finished synthetic organic materials. *(See figure 11.)*

In 1993, the United States continued as the leading producer of polymeric resin materials, accounting for about 40% of global production, followed by Europe and Japan. The total U.S. synthetic organics industry was valued at more than $100 billion, including value-added products.[18] As the year progressed, there was a slow but steady recovery in the U.S. economy, as reflected by an upward movement of about 3% in the gross domestic product (GDP) and comparable growth in synthetic organic resins, fiber, and rubber products.

Although margins were less than desirable in 1993, the economic outlook for 1994 is encouraging, and nonfuel organics volume should rise at least 5% to 6%, along with a substantial rebound in prices. MTBE fuel oxygenates and associated methanol and renewable ethanol demand should continue to experience substantial growth in 1994, owing to the provisions of the Clean Air Act. Ethylene should begin to come back into balance, along with propylene and other large-volume petrochemical feedstocks and downstream commodity resins. PVC should remain in relative balance, and gradually absorb new ethylene cracker capacity coming on-stream, while demand for PET bottle resin and thermoplastic elastomers should remain firm.

The long-term outlook for the U.S. organics industry is positive, given its large-volume, competitive nature. This, in concert with projected near-term recovery in the EC and Japan, the growing multinational flavor of the industry, continuing growth potential in the developing world—especially Asia-Pacific—and favorable prospects for NAFTA further support this premise. Eastern Europe was reflecting early signs of recovery and, eventually, the former U.S.S.R. should complete the major economic restructuring necessary for recovery. Finally, the current prospects for long-term stability in both the supply and price structure of crude petroleum and natural gas are encouraging, barring any unforeseen events.

On the down side, a continuing buildup of petrochemical capacity in Asia-Pacific, the Middle East, Latin America, and in the former U.S.S.R., will probably result in declining market share in the long-term, and possibly cut into our Nation's current multi-billion dollar trade surplus for resin, rubber, fiber, and specialty organic products. In the United States, there are a variety of problems to contend with, including the elimination of CFC's and other chlorinated materials, in addition to suspected carcinogenic and VOC-emitting organic solvents widely used for specialty cleaning and in paints and coatings. Viable substitute materials and technologies will have to be developed at reasonable costs, including a large number of agricultural pesticides on EPA's toxic inventory list.

The evolving "Green Movement" in the United States and around the globe could potentially result in a significant reinvention and development of environmentally friendly renewable organic products targeted to replace or otherwise supplement nonrenewable organic materials in selected applications. Finally, prudent waste management and recycling will continue to challenge the U.S. organics industry, and support the Nation's drive toward sustainable development.

Value, dollars per metric ton[5]	$111.50	$124.01	$115.56	$110.96	$100.20
Value, millions	$11,609	$12,945	$12,951	$12,986	$11,877
Imports for consumption	11.99	12.87	12.02	11.42	12.79
Exports	6.49	7.11	5.96	7.25	7.30
Consumption:					
Quantity	109.98	110.13	116.43	122.07	123.28
Value, dollars per metric ton[5]	$112.32	$124.12	$116.38	$111.88	$101.16
Value, millions	$12,353	$13,669	$13,550	$13,657	$12,471

[p] Preliminary. [r] Revised.

[1] Feedstocks are composed of natural gas liquids and liquefied refinery gases, dry natural gas, naphthas, other petroleum oils, and still gas.

[2] Excludes dry natural gas and coal.

[3] Synthetic plastics, resins, fiber, and rubber.

[4] Pesticides, medicinals, plasticizers, solvents, dyes, pigments, other organic materials, process losses, and statistical discrepancies.

[5] Feedstock prices based on crude oil first purchase prices and natural gas at wellhead.

TABLE 4
RELEASES AND TRANSFERS FOR THE TOP 50 U.S. CHEMICALS IN 1992

(Percent of all TRI chemicals)

	Total releases[1]	Total transfers[2]	Percent of total transfers recycled
First-level derivatives:			
Benzene	0.4	0.1	6.5
Ethylene	1.2	.3	—
Propylene	.7	.1	—
Toluene	6.1	3.0	22.9
Xylene	3.5	2.6	34.9
Other organics	32.2	18.6	33.3
Inorganics	52.2	64.4	78.9
Total[3]	96.1	89.1	65.7
Total for all TRI chemicals metric tons	1,443,186	1,977,247	1,287,519

[1] Releases include fugitive or nonpoint air emissions, stack or point air emissions, surface water discharges, underground injection, and releases to land.

[2] Transfers include transfers to publically owned treatment works, transfers to treatment, transfers to disposal, transfers to energy recovery, transfers to recycling, and other offsite transfers.

[3] Total represents the percentage for all TRI chemicals.

TABLE 7

U.S. PRODUCTION AND SALES OF SYNTHETIC ORGANIC MATERIALS IN 1992[1]

(Thousand metric tons)

Material	Production	Sales[2]	
		Quantity	Value[3] (millions)
Plastics and resin	31,419	27,828	$28,210
Plasticizers	915	861	1,032
Pesticide products	492	406	4,174
Synthetic rubber	2,614	1,870	3,454
Rubber-processing chemicals	157	132	498
Surface-active agents	3,174	2,023	2,480
Medicinal chemicals	149	92	2,384
Dyes	148	137	912
Organic pigments	57	46	779
Flavor and perfume materials	101	92	882
Miscellaneous chemicals[e]	[4]19,927	[5]16,921	[6]12,518
Total[e]	59,153	50,408	57,323

[e] Estimated.

[1] Ranked in relative order of monetary significance by class.

[2] Excludes intracompany corporate transfers, shipments to wholly owned subsidiaries, resales, and toll agreements.

[3] Principally sales value f.o.b. plant or warehouse.

[4] Difference between reported primary products of petroleum, natural gas, and coal tar and crudes and finished materials.

[5] Estimated at 85% of production-basis-identified distribution.

[6] Based on average reported price of miscellaneous compounds.

TABLE 14
U.S. SOURCING PATTERNS OF POSTCONSUMER FEEDSTOCK[1]

(Thousand metric tons)

Resin and product	1992	1993
Polyethylene terephthalate (PET):		
Soft drink bottles[2]	141	163
Custom bottles	9	14
Other[3]	27	27
Total PET	177	204
High-density polyethylene (HDPE):		
Natural color bottles[4]	84	111
Pigmented bottles	41	59
Base cups	20	16
Other[5]	14	18
Total HDPE	159	204
Low-density polyethylene	34	50
Polystyrene[6]	23	27
Polyvinyl chloride	9	14
Polypropylene	2	5
Other	11	14
Grand total	415	518

[1] Excludes typical 10% losses of collected volume that occurs during cleaning and reclaim steps.
[2] Base cups included in HDPE.
[3] Mostly X-ray film.
[4] Typically, natural bottles are homopolymer for milk and water use; pigmented are copolymer for chemical and detergent use.
[5] Primarily HDPE film.
[6] Mostly polystyrene foams.

Source: Modern Plastics, Jan. 1994.

TABLE 15

U.S. POSTCONSUMER RECYCLATE PATTERN OF CONSUMPTION[1]

(Thousand metric tons)

End-use market	1992	1993
Polyethylene terephthalate (PET):		
Bottle-grade:		
Fiberfill	86	95
Food bottles[2]	16	11
Nonfood bottles	9	14
Strapping	9	11
Export	14	11
Other[3]	43	61
Total PET	177	203
High-density polyethylene (HDPE):		
Bottles	27	45
Drainage pipe	27	29
Film	11	20
Plastic lumber	11	14
Pallets	9	14
Other[4]	73	82
Total HDPE	158	204
Low-density polyethylene (LDPE):		
Film	27	41
Other	7	9
Total LDPE	34	50
Polystyrene (PS):		
Foam packaging	9	10
Loosefill	7	7
Solid moldings	5	5
Other	2	5
Total PS	23	27
Polyvinyl chloride (PVC):		
Molded goods	5	7
Other	5	5
Total PVC	10	12
Other resins	14	18
Grand total	416	514

[1] Excludes typical 10% losses of collected volume that occurs during cleaning and reclaim steps.
[2] PET bottles converted by chemical processes back to monomer for reuse in virgin soft drink bottles.
[3] Includes bottles and nonpackaging film.
[4] Includes bottles, film, and base cups.

Source: Modern Plastics, Jan. 1994.

TABLE 16

U.S. PETROCHEMICAL FEEDSTOCKS (CONTRACT PRICES)

(Cents per pound)

	1992 average	1993				
		First quarter	Second quarter	Third quarter	Fourth quarter	Average
Acrylonitrile	26.3	26.0	26.0	26.0	27.0	26.3

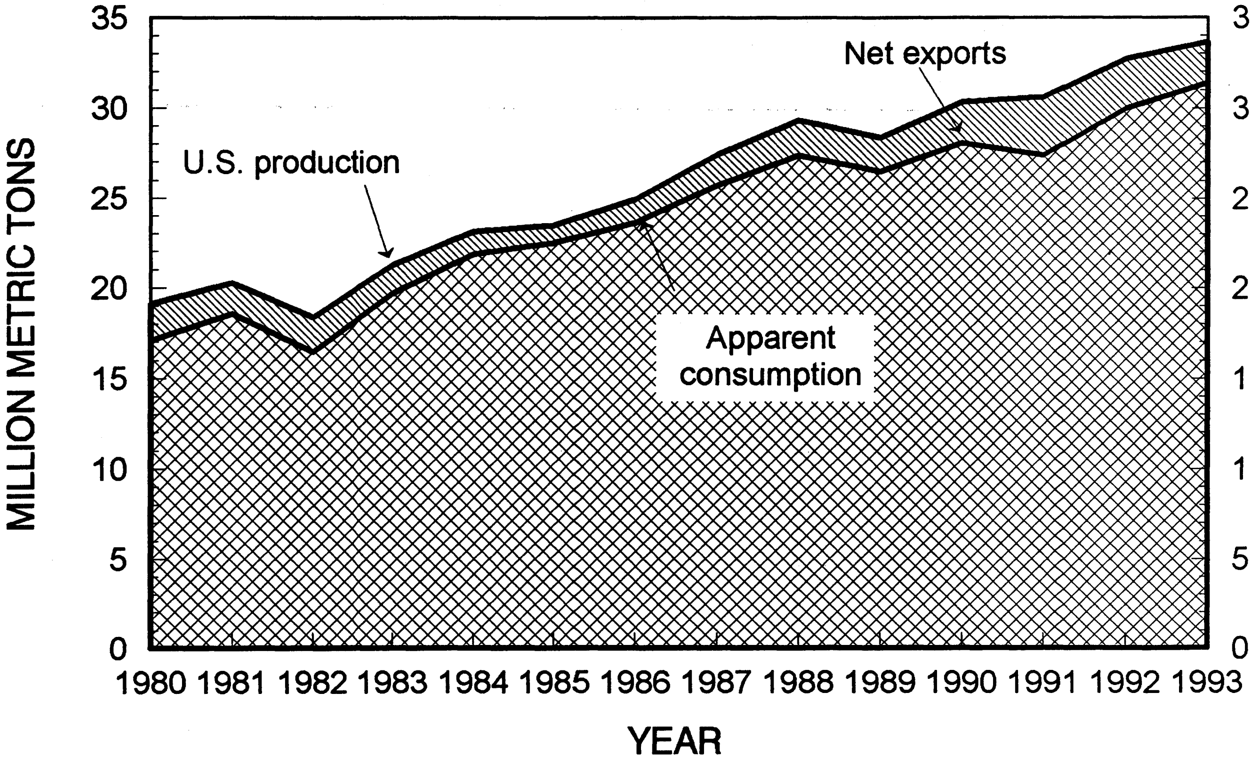
FIGURE 11
U.S. SUPPLY-DEMAND RELATIONSHIPS FOR PLASTIC RESINS AND RUBBER



PEAT

By Wallace P. Bolen

Mr. Bolen, a physical scientist with 6 years as a U.S. Bureau of Mines commodity specialist, was assigned as the Bureau peat commodity specialist in the spring of 1994. Tony Roberts, statistical assistant, monitored the survey and also prepared domestic data tables. The international data table was prepared by Amy Durham, international data coordinator.

More than 90% of Earth's 450 million hectares (ha) (1.1 billion acres) of natural organic peat and peatland resources remain untouched, forming the basis for a continuous biological procreation mechanism for biomass. It is estimated that carbon stock in peat is approximately 300 billion metric tons, representing about 13% of the total carbon resources on Earth.

Significant quantities of peat are consumed by the global horticultural and agricultural sectors for use as a plant growth medium and soil amendment. In addition to its large volume use by the home gardener and professional nursery and landscape businesses, peat also enjoys substantial use in a myriad of industrial applications and consumer products, including potting soils, turf cultivation, golf course greens construction and course maintenance, mushroom cultivation and earthworm culture, poultry litter, fertilizers, composting, seed inoculants, humic acid extracts, toxic waste filtration, oil absorption, hygienic products, and fuel for electrical power generation.

In 1993, the U.S. peat industry continued to be disrupted by regulatory constraints, the large-scale recycling of yard wastes and other natural organic materials, and record imports of Canadian sphagnum peat, peat mixtures, and other articles of peat. Accordingly, 1993 was the second year in a row Canadian peat imports surpassed U.S. domestic production.

Several entrepreneurial domestic peat firms capitalized on the abundance of recycled yard and animal wastes by selling blends of composted natural organic materials and peat. The utility of U.S. sphagnum peat in specialty value-added applications also continued to generate new demand in the areas of oil sorption products and wastewater effluent treatment. Peat-based oil sorbents were accepted as environmentally friendly substitutes for clay sorbents in industrial and emergency cleanup applications in selected northeastern States and cities where clay has been banned from landfill disposal because of bulk, undesirable disposal economics, and potential health risks associated with clay dust containing crystalline silica. Minnesota's new sphagnum peat operations optimized capacity utilization and experienced improved competitiveness and profitability.

The U.S. Bureau of Mines (USBM) annual survey of domestic peat producers in the 48 contiguous United States reflected a 3% increase in production accompanied by the closure of two U.S. peat operations in the States of Maine and Michigan and the first full year of operations at a new Minnesota peat mine. Sales volume fell 6% to just more than 0.6 million tons, although the total value of producer sales increased slightly to $16.8 million, f.o.b. plant. Idled and discontinued operations continued to liquidate stocks.

Alaskan peat production in the Fairbanks vicinity was estimated at 55,000 cubic meters (m^3) by personnel of the State Division of Geological & Geophysical Surveys, Fairbanks, AK. The Alaskan peat carried a value of about $445,000, or $8.09 per m^3, representing an increase of 8% in unit value compared to that of 1992. Peat production from the Anchorage area was not available for publication.

Canadian peat shipped predominately from the Provinces of Quebec and New Brunswick, in eastern Canada, and from Alberta, Manitoba, and Saskatchewan, in western Canada, accounted for a record 51% of the total U.S. peat supply. Canadian import volume was a record 644,696 tons and was valued at $117.8 million, equating to a new record price of $183 per ton at U.S. Customs. Another $28 million of Canadian finished peat products was declared at U.S. Customs.

The total U.S. peat supply was valued at $135 million based on f.o.b. domestic plant and U.S. import Customs values. The monetary significance of peat as a value-added product at the retail level in the United States is many times greater and is estimated to be well in excess of $1 billion.

The metric system is the official system of measurement of most countries. The USBM, in an effort to provide statistical data on peat that are in compliance with Public Law 100-418, began, with the 1992 report, publishing in both metric units (metric tons, kilograms) and English units (short tons, pounds). This year's report uses all metric units with a total line in English units. Reports covering periods after 1993 will use only metric units with an occasional English reference, particularly for volume measurements, i.e. cubic yards. *(See table 1 and figure 1.)*

DOMESTIC DATA COVERAGE

The Division of Statistics and Information Services, USBM, conducts an annual survey of domestic peat producers in the 48 contiguous United States. Information obtained from the

USBM's voluntary canvass was used to develop data tables for publication. Of the 88 peat operations surveyed in 1993, 67 were reported to be active, 19 idle, and 2 to have closed permanently. Estimates were made for active operations that did not report data, based on past trends.

Alaskan peat producers were surveyed independently by the Department of Natural Resources, Division of Geological & Geophysical Surveys, Fairbanks, AK. In 1993, operations in the Fairbanks area reported active production.

BACKGROUND

Peat is a unique natural organic material of botanical origin and commercial significance that is found deposited in abundant quantities at the Earth's surface, where it plays an active role in the dynamics of our planet's ecosystem. Peat deposits function as natural hydrological control sources for vast areas of wetlands, provide an effective natural filtration medium for waterborne contaminants, and also serve as a biomass-related carbon link between the land and air. Today, peat deposits cover about 400 million ha (1 billion acres), or 4.4% of the Earth's total land mass, of which the United States ranks third in importance, eclipsed only by the large deposits found in the former U.S.S.R. and Canada.

The U.S. peat industry developed from small "mom and pop" operations that today comprise about 70% of all active peat operations and account for about 20% of total production. They provide essential peat supplies to surrounding communities that contribute significantly to cash-flow and liquidity within local economies. About 80% of U.S. peat is produced in high-volume operations by 30% of the producers. Large operations move peat in interstate commerce owing to economies of scale.

Peat deposits developed typically through the gradual decomposition of plant matter under anaerobic conditions in shallow aquatic basins. Most of the peat deposits in existence today lie at the Earth's surface and have formed since the last ice age approximately 10,000 years ago, although much older Pleistocene peats, typical of the deposits buried beneath the sands of Trail Ridge in Bradford and Clay Counties, FL, are known. Peat is a precursor of lignite and coal.

Peatlands, or mires as they are sometimes called, are more extensive in the temperate, boreal, and subarctic zones of the Northern Hemisphere and more limited in the cool and humid zones of the Southern Hemisphere. Peat deposits may be called bogs, fens, or "poor fens"—combinations of bog, fen, or swamp formations—depending on the aquatic mechanisms of the particular setting.

Most of the world's peatlands are classified as bogs. Bog is from the Celtic word "bocc," meaning "soft," which is an apt description for these waterlogged terrains. A bog is typically an acidic peatland that depends principally on rainfall to perpetuate the waterlogged conditions necessary for its survival. Because there is less decomposition in these nutrient-poor, acidic environments, the more fibrous peats—sphagnum moss, hypnum moss, and reed-sedge—may be found as the predominant species in the upper zone of the deposit.

The term "fen," as derived from the Anglo-Saxon language, translates to "mud" in modern day English. Fens are peatlands that depend mainly on ground water sources for their formation and survival and, thus, are less dependent on rainfall. Fens, unlike bogs, are found in less acidic nutrient-rich environments. Plant matter tends to decompose more rapidly under these relatively chemically neutral conditions, leading to a less fibrous, more mineralized material that in advanced stages of decomposition is known as muck or peaty muck. The majority of fens are over sites of sand and gravel deposits that are buried within more clayey glacial materials (intertill), providing a ground water seep over which the peat forms. It, therefore, is not uncommon to find fens situated on hillsides.[1]

Definitions, Grades, and Specifications

Methods adopted by the American Society for Testing and Materials (ASTM) find widespread use for the characterization of peat matter.[2] The ASTM Classification of Peats, Mosses, Humus, and Related Products requires the use of three parameters: ash content, fiber content, and botanical composition. Earthy organic materials must have an ash content of no more than 25% by dry weight to be classified as "peat." Botanical characteristics and fiber content govern peat types. Fibrous peat is defined as material retained on an ASTM No. 100 screen; that is, material 0.15 millimeter or larger.

Sphagnum moss peats must have a fiber content greater than 66%, all of which must be derived from the genus Sphagnum, as determined by screening and botanical analysis. Hypnum moss peats must have a 33% minimum fiber content, of which at least 50% must be derived from the genus Hypnum. Reed-sedge peats must have a 33% minimum fiber content containing more than 50% reed-sedge and other nonmoss fibers.

The U.S. Department of Agriculture Soil Conservation Service subdivides peat into three general categories: (1) fibric (peat moss), which is composed of sphagnum, hypnum, and other mosses; (2) hemic (reed-sedge), which is formed from reeds, sedges, swamp plants, and trees; and (3) sapric (humus), which is composed of materials that are decomposed beyond recognition of botanical origin.[3]

Fibric peats such as sphagnum and hypnum are relatively young moss species that are light in color in comparison to other peat varieties. Fibric peats, because of the lower order of decomposition, have a relatively high water-retention capacity and, in general, are quite acidic. Fibric peats have a low bulk density that averages about 150 kilograms per cubic meter (250 pounds per cubic yard) on an air-dried basis and very little ash. These peats are not suitable for fuel owing to the low degree of decomposition.

Hemic, or reed-sedge, peats are

somewhat older and more decomposed than fibric peats and originate from reeds, sedges, and other nonmoss-type plants. Hemic peats are considered to be intermediate between fibric and sapric in degree of decomposition, bulk density, and ash content. The average density of air-dried, reed-sedge peat is about 565 kilograms per cubic meter (950 pounds per cubic yard). Reed-sedge peats are usually slightly acidic and have a high energy value owing to fixed carbon content and low ash.

Sapric, or humic, peats, are the oldest and most decomposed peats, with color ranging from dark brown to black. Normally, sapric peats are the first peats formed in the filling of basins and are the most dense and colloidal. Sapric peats, because of their colloidal nature, take on less water, but retain it more strongly than other peats. Many sapric peats are excellent energy sources and are quite acidic. Sapric, or humus, peat, has an average bulk density of about 770 kilograms per cubic meter (1,300 pounds per cubic yard).

The von Post scale was developed in Sweden as a field method, or squeeze test, for determining the degree of peat humification or breakdown and is utilized by peat enthusiasts worldwide. According to the von Post method, peats are ranked on a scale from H 1 to H 10 relative to their degree of humification. A von Post of H 1, for example, would represent undecomposed peat that ejects colorless, clear water when squeezed, with the remainder containing easily discernible plant matter. At the opposite end of the scale, at H 10, the peat would be completely decomposed, with no plant remains recognized, and, upon squeezing, the whole amount would come out between one's fingers as a homogeneous material. In general, fibric peat mosses are in the von Post range between H 1 and H 3; hemic reed-sedges, H 4 to H 6; and saphric humus peat, H 7 to H 10.[4]

A typical proximate analysis for peat would yield a moisture content of about 50%; carbon, 26%; oxygen, 16%; hydrogen, 3%; nitrogen, 1%; sulfur, 0.1%; and ash, 4%. Fuel-grade peats may vary between 1,800 British thermal units (Btu's) per kilogram to as high as 4,500 Btu's per kilogram depending on moisture content and peat type.

Geology-Resources

In the United States, peat is deposited to some extent in all 50 States. About 10 million ha (25 million acres) of peatlands has been identified in the lower 48 States, representing an estimated reserve base of 6.4 billion tons. Alaska contains an enormous peat resource estimated at 51 million ha (125 million acres). Minnesota, Florida, Michigan, Wisconsin, and Maine, in order of importance, account for the major reserves that are available for commercial harvesting in the 48 contiguous United States. Peat reserves are also found in about 10 Western States, of which active harvesting is known to occur in Colorado, Montana, North Dakota, and Washington. At current mining rates, the U.S. permitted reserve base estimate of 4.5 million tons could theoretically be depleted within the coming 20 years.

Large peat resources are protected by Federal and State agencies in a vast area known as the Great Dismal Swamp near the southeastern coast of Virginia, extending south into northeastern North Carolina. Vast peat resources are also found in the sensitive wetlands areas of North Carolina's Pamlimarle Peninsula, Pamlico River Basin, and along the South Carolina Coast. Peat resources also are found along the east coast and southern regions of Georgia and along the U.S. Gulf Coast from Alabama to Texas.

Although Florida, Maine, Minnesota, and many other States have done a credible job in estimating individual State peat reserves, there has not been a comprehensive effort to consolidate individual State reports to establish the extent of U.S. peat resources since the 1922 U.S. Geological Survey (USGS) publication, "The Occurrence and Uses of Peat in the United States."[5]

As a result of the energy crisis in the mid-1970's, the Department of Energy (DOE) initiated a Peat Resource Estimation project in several States to provide information on the extent of our Nation's availability of peat resources for energy utilization, but the results were incomplete and never fully tabulated.

In the mid-1980's, the University of North Dakota and the USGS submitted a joint proposal to the U.S. Department of the Interior designed to survey the peat resources of the United States. The principal objective of the proposal was to systematically bring together and analyze the information obtained from DOE's Peat Resource Estimation program that had been conducted by the individual States. Other non-DOE-sponsored research in other States also was to be included. To date, a Federal program has not been established to research and publish a comprehensive report of U.S. peat reserves and resources.

This posture could change given that the Secretary of the Interior is currently formulating a proposed plan to conduct an extensive biological survey across the United States. The survey, which would be run by a new organization, the National Biological Survey, would map the country's ecosystems and biological diversity. Because peatlands or bogs are extensive, unique, and by nature biological, it was expected that a comprehensive survey would provide valuable and reliable information on U.S. peat reserves, resources, and locations.[6]

Technology

Mining.—Peat is mined or harvested by numerous methods in the United States dependent upon the prevailing conditions and the type of peat involved.

Sphagnum peat is mined through a combination of milling, aeration, and vacuum harvesting. A wide variety of equipment is required, including light and heavy power equipment; ditching machines to provide drainage; stumper, wood rake, and turner-aerator equipment to clear and aerate the surface; milling machines; vacuum harvesters; and wagons or trucks for transporting the harvested peat to the processing plant.

Reed-sedge peat may be harvested with conventional agricultural disking equipment, wide track bulldozers, and front-end loaders. Alternate methods involve milling or bulldozing, followed by windrowing and product pickup with a force feed loader equipped with a side-loading attachment. Smaller operations sometimes mine humus peat with power shovels, small draglines, and front-end loaders.

Fuel-grade peat, following conventional field preparation methods, is compressed into 10-centimeter-diameter cylinders with sod harvesting equipment. The cylinders break off at lengths ranging from 20 to 30 centimeters and drop to the surface for air drying. After windrowing to effect complete drying, the cylinders are picked up by a force feed conveyor loader and discharged into trailers for transport to the powerplant.

Processing.—All peat usually requires screening to remove debris and to produce a desirable marketable product. In state-of-the-art sphagnum operations, harvested peat is fed to a radar screen for sifting and the removal of large debris. The raw product is next discharged to a double-deck vibrating screen to effect sizing and to remove the smaller debris. Product oversize passing over the primary screens is hammermilled and recycled to the screening process. Processing is effected in a closed system equipped with an overhead vacuum takeoff for fine or dusty material. The fines may be recycled or conveyed to a closed waste bin outside the plant.

Product-grade material is discharged to a surge bin from which peat is processed in a four-step automated turntable process, wherein product is gravity metered into plastic containers, compressed into bales on a 2:1 volume ratio, sealed, and conveyed to storage. Four-cubic-foot bales (0.12 m^3) are the most popular size produced, but 2-cubic-foot (0.06 m^3) and 6-cubic-foot (0.18 m^3) bales also are produced in significant quantities.

Reed-sedge and humus peats are screened, packaged in bags, or sold in bulk. The materials also may be blended with perlite, vermiculite, sand, and sphagnum moss and packaged as potting soils, or for a variety of other uses. Peat-sand mixtures are popular bulk materials that are sold to golf courses for greens construction and for top dressing greens, tees, and fairway turf.

Economic Factors

U.S. peat prices, without adjustment for inflation, have increased at an average annual rate of 5% per year over the past 24 years (1970-93). Prices expressed in terms of constant 1993 dollars, however, have declined at an average annual rate of about 2% per year over the same period. The U.S. peat industry has overcome inflationary pressures principally through the rationalization of capacity, together with a move to higher volume modern and efficient plants, the proliferation of value-added consumer products, and the importation of more peat and finished peat products from Canada.

ANNUAL REVIEW

Legislation and Government Programs

The Environmental Protection Agency (EPA) issued final rules for Hazardous Waste Management; Liquids in Landfill, 40 CFR Parts 260, 264, 265, and 271. The rule was published in the Federal Register on November 18, 1992, and became effective on May 18, 1993. EPA's ruling addressed the final of three Congressional requirements developed under the 1984 Hazardous and Solid Waste Amendments to the Resource Conservation and Recovery Act (RCRA): "landfill disposal of containerized liquids mixed with sorbents."

This rule satisfies the statutory requirement that EPA issue a rule prohibiting the disposal of liquids in "hazardous waste landfills" that have been sorbed in materials that biodegrade or that release liquids when compressed, as might occur during routine landfill operations, and is intended to ensure the stability of materials in "hazardous waste landfills."

The Assistant Surgeon General, U.S. Public Health Service, clarified several points relative to EPA's seemingly complicated ruling. It was emphasized that the rule prohibits only the "direct" landfilling in "hazardous waste" landfills of liquids that have been sorbed into "biodegradable" sorbents. Thus, the rule does not in any way prohibit or restrict the use of sorbents (organic or otherwise) to address wastes or products going to a nonhazardous waste landfill (e.g., municipal or nonhazardous waste industrial landfill). Furthermore, it does not affect the use of sorbents with hazardous waste that is not landfilled—for example, that is burned for energy recovery, incinerated, recycled, or treated through bioremediation or land treatment.

EPA, in its rulemaking, did not conduct tests on the degradation of organic sorbents in an anaerobic landfill environment. Also, EPA did not test and made no judgment on the efficacy of different sorbents, including organic sorbents, in spill situations. Factors like absorption and retention—important considerations in the performance of sorbents in responding to spills—lay outside the scope of the rulemaking.

The U.S. Fish and Wildlife Service (FWS) continued to act as custodian for the preservation of a 38,000-ha (93,000-acre) peatland on the environmentally sensitive Pamlimarle Peninsula in northeastern North Carolina. About 32 million dry tons of high-energy, fuel-grade peat was deposited to an average depth of 2 meters over 28,000 ha (70,000 acres) of the property, formerly owned by First Colony Farms.

The FWS combined these lands with its adjacent 4,000-ha (10,000-acre) Pungo National Wildlife Refuge to form Pocosin Lakes National Wildlife Refuge. The development includes fire control, maintenance of drainage canals, provision of grain for feeding, and enforcement of wild game hunting. Deer, black bear, and wood duck were native to the area.[7]

The Pamlimarle Peninsula is the site of North Carolina's largest peat reserves. The peninsula is estimated to include 93,000 ha (360 square miles) of peatlands containing about 200 million tons of peat on a moisture-free basis. Only two small peat operations are currently active on the peninsula.

Large-scale commercial composting programs, fueled by environmental regulation, continued to proliferate in both the public and private sectors during 1993 and competed with peat in selected applications. Compost could lead to further growth in mulching and soil amendment activity dependent upon economic factors and consumer acceptance. In any event, several peat-compost product blends were marketed by major U.S. peat producers in 1993, representing a new trend that will most probably continue to increase in proportion to the availability of quality compost materials.

Issues

Major issues for the peat industry are uniquely intertwined with the very nature of peatlands, namely, peatland's location in wetlands and their contained ecosystems. Currently, debate on both ecosystem preservation and wetland regulations is increasingly concerning those involved with the harvest and consumption of peat.

In an article titled "Is Peat P.C.?" in the American Horticulturist, the preservation and mining of peat bogs is discussed with emphasis on activities in Canada. Ecologists contend that peat bogs contain many rare species and also fix carbon that is removed from the atmosphere. The article discusses the relatively tiny percentage of peatlands mined in Canada and restoration of previously harvested peat bogs.[8]

Peat deposits along the U.S. Eastern Seaboard, extending from Maine to Florida, are regulated by Federal, State, and local environmental agencies owing to population density and sensitive wetlands areas; this is also true in California along the U.S. west coast, and to an extent in several Midwestern and northeastern States. Conversely, the northern tier Great Lakes States are situated, for the most part, in more environmentally friendly surroundings. This is particularly true in Minnesota, where the prudent development of the State's tremendous peat reserve base—representing about 30% of total reserves in the 48 contiguous United States—is encouraged to generate employment and contribute to economic growth.

Since 1986, U.S. domestic peat sales have declined 35%, apparent domestic consumption has fallen by 8%, and 23 U.S. peat operations have been closed. During the same period, imports of Canadian peat have increased 29% and the U.S. import reliance has risen from 41% of total domestic consumption in 1986 to 51% in 1993.

Between 1986 and 1993, about 60% of the decline in domestic peat production and sales was in the leading States of Florida and Michigan, but equally disturbing was the fact that about one-third of the loss was attributable to 5 States in mid-America (Iowa, Illinois, Indiana, Ohio, and Pennsylvania). Many small operations, including some in Maryland, New Jersey, and New York, for example, have been shut down for an indefinite period by various regulatory agencies. In 1993, certain Michigan peat producers initiated litigation proceedings against the State Department of Natural Resources owing to new regulations that restricted peat mining.

In total, about 37 U.S. peat operations have been idled or have gone out of business since 1986. Many producers and consumers felt that a more equitable balance between environmental regulation and peat mining was needed, given the importance of peat to the U.S. economy and its value to the U.S. consumer. Industry sources were becoming increasingly cognizant of the role that Minnesota's tremendous sphagnum peat reserves will play in advancing future competitiveness and growth in the U.S. peat business.

Production

Peat was harvested and processed by 67 operations in 20 States, excluding Alaska. Florida and Michigan produced about 67% of the U.S. total, followed by Minnesota with 5%. The majority of U.S. peat production, about 80%, was conducted in high-volume operations that accounted for about 30% of the total number of active facilities. Geographically, about 50% of the total U.S. peat output by weight was from the Great Lakes region; 38% from 3 southeastern States; and the remainder from New England, the Midwest, and the West. The States of California, Georgia, and Maryland did not report production in 1993. *(See tables 2 and 3).*

On a weight basis, reed-sedge peat was 66% of total U.S. production; humus, 16%; sphagnum moss, 13%; hypnum moss, 4%; and other forms, 1%. On a volume basis, the product distribution may be altered dependent upon variations in peat bulk density, from sphagnum moss at the low end of the scale having a density of about 300 kilograms per cubic meter (500 pounds per cubic yard), to humus having a bulk density of more than 600 pounds per cubic meter (1,000 pounds per ton). Thus, reed-sedge was 60% of production by volume; sphagnum moss, 24%; humus, 12%; hypnum moss, 4%; and other forms, less than 1%.

In Alaska, A&A Services, The Dirt Co., and Landscape Supply Corp. produced peat in the Anchorage area, while Great Northwest, Inc. was active near Fairbanks. Alaskan peat demand increased dramatically during the early 1980's coincident with the economic boom precipitated by the development of the Alaskan Oil Pipeline. Production peaked at 100,000 m^3 (125,000 cubic yards) in 1984 and carried a value of $859,375, or $8.59 per m^3 ($6.88 per cubic yard). The potential for future development of Alaska's tremendous peat resources will be dependent upon Alaska's economic growth, peat's emergence as an effective filtration medium for the control of toxic waste effluents in mining, and logistical factors.

Domestic Operations.—Although Florida and Michigan were by far the largest producing States, Minnesota was thought to hold much promise for future peat production. Nine producers, including one new operation, were active during the year, of which there were major sphagnum producers in Carlton County and St. Louis County and one major bulk producer of reed-sedge in Aitkin County, all near Duluth, MN. It is useful to notice that Minnesota garnered 11.5% of the value of peat sales in the United States even though, by quantity, the State represented only 5.4% of the national tonnage. Minnesota's premium peat was valued at $60 per metric ton, f.o.b. plant, more than twice the U.S. average. This is a reflection of the higher quality of peat in Minnesota compared to the average peat in the Nation. It was anticipated that because of a favorable climate for job creation via peat operations and quality resources, Minnesota would continue to experience growth in peat production, sales, and number of operations.

Davidson Peat was harvesting reed-sedge peat from a 14-ha (35-acre) bog in Rice County, MN. Raw peat was extracted with a 3-m^3 (4-cubic-yard) swinghoe power shovel and stockpiled on-site. Following windrowing to effect drying and weathering, tractor-trailer rigs transported the peat to Davidson's processing plant at Kenyon, MN, near the town of Webster. Davidson sells fine-milled bulk peat and peat-sand bulk blends. The firm was operating under county mining permits because peat harvesting permits were not available, but was working with local officials to study the feasibility of introducing peat harvesting permits.

Aitkin Agri-Peat began harvesting and selling reed-sedge at its bog in Aitkin County in 1984. The operation was improved and expanded through the lease and later purchase of specialized equipment from the Natural Resources Research Institute (NRRI) at Duluth. Aitkin also designed and constructed unique harvest machinery that provides an efficient and economical method of harvesting bulk peat. Production capacity is about 15,000 m^3 (20,000 cubic yards) annually, from 40 ha (100 acres) of the 120-ha (300-acre) deposit. Aitkin Agri-Peat markets bulk reed-sedge to general contractors and golf courses within a 400-kilometer (250-mile) radius of the harvest site near McGregor, MN.

Minnesota Sphagnum, Inc. (MSI) commenced sphagnum harvesting in 1987. The first 5 years were devoted to improvements in processing facilities and field expansion. Expansion of this operation will continue for the next 2 to 4 years. MSI currently harvests peat from 100 ha (250 acres) and markets sphagnum peat in bale and bulk in the mid- and southwestern States. The MSI organizational structure is through Hyde Park Products and Conrad Fafard, Inc.

Peatrex Ltd. began sphagnum production in 1985 near the town of Cromwell, MN, in Carlton County. The operation is of Finnish design with good drainage. The fields are profiled for fast turnaround after heavy rains. In 1989, Peatrex was purchased by Premier Enterprises of Canada, and since, has constructed a state-of-the-art sphagnum processing facility on the property. Harvested sphagnum from the 100-ha (250-acre) operation is processed into 2-, 4-, and 3/4-cubic-foot bales or sold in bulk.

Michigan Peat Co. is a major supplier of retail soil amendments and professional grower horticultural products in the north-central States, providing a wide range of peat-based products to an area containing more than 40% of the Nation's population. Peat was harvested and processed in three locations, including sphagnum moss production at Cromwell, MN, and two facilities in the "thumb" area of Michigan, near Sanilac.

Michigan Peat is headquartered in Houston, TX, from which a $15 million annual business is coordinated. The firm has the capacity to harvest 135,000 tons of reed-sedge peat and sphagnum peat moss annually, or about 20% of current U.S. production. Michigan Peat products are marketed under the BACCTO and Garden.magic labels.

Hyponex Corp. harvested and processed reed-sedge peat from facilities in five States extending from Florida to Colorado. Hyponex markets peat and peat blends throughout much of the United States. The firm operates from parent headquarters, the O. M. Scott & Sons Co., in Marysville, OH, which is a recognized leader in the lawn and garden fertilizer market.

Hyponex also was operating 12 organic composting process facilities and a like number of additional sites across the country that were open to receive yard trimmings in line with the national thrust by the EPA and municipalities to recycle waste materials that otherwise contribute significantly to the overloading of landfills. Waste collection firms contracted by various municipalities transfer natural organic yard waste materials like leaves, grass, and hedge trimmings, which in turn are recycled into marketable compost materials. The composting/recycling approach has proven to be a win-win-win situation for municipalities, taxpayers, and the environment. Consumer demand for Hyponex organic products, such as Compost plus Organic Peat, Rich Dark Top Soil, and all purpose Potting Soil, ensure a steady market for composted yard trimmings. The firm believes that enough demand could be generated for its organic products to allow for the recycle of virtually all yard trimmings generated by the major metropolitan areas of the United States.

Domestic Projects.—New horticultural peat projects were reported to be under consideration in the States of Florida, Georgia, Maine, New Mexico, North Dakota, and possibly in North Carolina.

NorthWood Organics, a new Duluth, MN, subsidiary of Faulks Brothers Construction Co., Inc. of Waupaca, WI, opened its new sphagnum peat bog in St. Louis County, MN. Bog development began in early 1993, and production was underway later in the year. Full production at the 60-ha (150-acre) site, in the Toivola bog, is expected in 1994. NorthWoods Organics will provide technical support and new product development for Faulks Brothers while producing organic products for commercial landscape, horticultural products, and construction applications.

Power-O-Peat Co., with a bog near Eveleth, MN, has been closed since 1988. The owners announced plans to reevaluate the bog with the hope of reopening the operation of the reed-sedge/humus bog in the near future. Power-O-Peat has 120 ha (300 acres) available for harvesting and interest in an additional 800 ha (2,000 acres).

Folsom Marine Service Corp. reported the sale of its Saco Heath Property to the Maine Nature Conservancy in December 1993. The property is in York County, ME.

Fuel Peat Projects.—Plans by EcoPeat Co.—a U.S. affiliate of the Finnish firm Outokumpu—to develop 360 megawatts of peat-fueled electrical powerplants in cooperation with south-central Florida utility companies were postponed indefinitely. Central Florida utilities reportedly have opted to build powerplants based on natural gas fossil fuel.

The Down East Peat LP peat-fueled powerplant at Cherryfield, ME, was purchased in early January 1993 under the provisions of a reorganization that involved the formation of Worcester Energy Co., Inc., and Worcester Peat Co., Inc. The energy company acquired the 22.8-megawatt biomass powerplant, ancillary buildings, equipment, and 8 ha (20 acres) of adjoining land. The peat company, in turn, purchased about 360 ha (900 acres) of the adjoining Denbow Heath peat bog. At full capacity, the powerplant will require about 150,000 tons of bone-dry peat annually.

Worcester Energy Co. closed the powerplant in mid-January 1993 pending negotiations of a proposed power contract with Bangor Hydro-Electric Co. in which Bangor was asked to pay 2 cents above the normal 3-cent-per-kilowatt-hour "avoided" rate. Bangor Hydro was required by law to purchase the plant's power at the avoided rate, the cheapest price that the utility would pay for additional electricity. The new firms projected a good harvest season on the bog because the powerplant was back on-line in the second half of 1993.

Down East Peat LP of St. Petersburg, FL, originally brought the $51 million peat-fueled powerplant on-stream in June 1989 under the provisions of a 20-year supply agreement with Boston Edison, but the owners were ultimately faced with the prospect of continued losses and opted to allow the utility to buy its way out of the contract in mid-1992. The plant operated on a combination of woodchips and peat depending on the availability of peat. Former Down East Peat officials reported that the project could potentially become one of the more viable sources of power in the country were enough peat acreage available, given that peat can be harvested at a fraction of the cost of wood, oil, or coal. Down East Peat also cited technology problems, high transmission costs, and an oversupply of electricity in the northeast as other factors that had been detrimental to the project's success.

Humate Production.—Humates were mined from the San Juan Basin deposits in northwest New Mexico and sold primarily for use as soil conditioners and drilling mud additives. In 1985, the last year of available data, humate production was about 18,000 m^3 (23,000 cubic yards), with an f.o.b. mine value of $404,000. Mining and processing were conducted by three companies in McKinley, Sandoval, and San Juan Counties.

Humate and weathered coal occur in the Upper Cretaceous Fruitland, Menefee, and Crevasse Canyon formations in the San Juan Basin. All of these humate deposits—high in humic acid content—represent a facies in poorly drained swamps in nearshore deltaic and fluvial sequences accumulated during marine regression in the Cretaceous. Most humate occurrences consist of carbonaceous claystones rich in organic matter, or weathered coal ("leonardite"), having a high humic acid content.[9]

Humate is commonly associated with coal and lignite. When associated with lignite, humate is called leonardite, after A. G. Leonard of the North Dakota State Geological Survey. Through use, the term leonardite has been informally expanded to include coal-derived humate. Humic acid-rich deposits also exist in Arkansas, Florida, Louisiana, New York, North Dakota, Michigan Minnesota, Texas, and Wyoming. Alpine Humate, Inc. planned to start up a new humate mine near Denison, TX.

Consumption and Uses

Sales of U.S. peat products in 1993 continued a 3-year slide as U.S. peat continued to struggle against imports of Canadian peat and peat products. In 1993, domestic sales tonnage declined 6% from 1992 levels, while sales of imported peat rose slightly and maintained 50% of the total U.S. peat market for the second year in a row.

Packaged peat as a percentage of total domestic sales volume by weight dropped from 56% in 1992 to 44% in 1993. Packaged peat was valued at a 92% premium relative to bulk forms, according to the USBM annual survey. Approximately 90% of U.S. producer sales was for general soil improvement, horticultural, and agricultural use. In horticulture, peat was used predominately for general soil improvement, as an ingredient in potting soils, and in the nursery business. In agriculture, peat was used for general soil improvement, in mixed fertilizers, as a carrier and coating agent in seed inoculants, for vegetable cultivation, and as poultry litter.

Specialty applications included peat's use in golf course greens construction and course maintenance, as an earthworm culture medium, for mushroom cultivation, oil absorption and wastewater filtration, and for use in hygienic products. Minor quantities of peat were used as fuel for electric power generation. *(See tables 4 and 5.)*

Stocks

In 1993, primary producer peat stocks did not vary significantly from prior-year levels and stood at about 0.3 million tons at yearend, according to the USBM's annual survey of domestic peat producers. Producer peat stocks in all forms were about 50% of production, typical of the industry. Reed-sedge peat accounted for about 80% of total stocks by weight. *(See table 6.)*

Transportation

Peat was moved predominately by truck in both bulk and packaged form.

Small producers were restricted to local market areas because of the sensitivity of peat prices to transportation charges. High-volume producer costs were less sensitive to transportation charges, allowing for interstate movement of peat and peat products.

Lindqvist Business Development Corp. of Minnetonka, MN, was evaluating the feasibility of the CARGO 2000, an innovative side-dumping trailer developed by BURE VERKSTADS A.B. of Sweden for tractor-trailer or rail transport of peat, woodchips, beet pulp, and other bulk materials. During unloading, the roof, floor, and one side of the trailer are raised hydraulically. The lifting action of the floor and side wall will break up the cargo as it is dumped from the trailer, allowing even frozen cargo to be safely unloaded at rates in excess of 68 m^3 (90 cubic yards) per minute.

Markets and Prices

Domestic peat prices averaged $28 per ton f.o.b. plant in 1993, a 7% increase from the prior year. Packaged peat was quoted at a premium $38 per ton compared with $20 for bulk peat, although packaged forms captured only 44% of the total sales tonnage. Sphagnum moss sold at a premium $46 per ton, about 60% more than the national average. *(See table 7.)*

Foreign Trade

The United States has shipped minor quantities of peat offshore averaging about 18,000 tons per year during the past 5 years. In 1993, exports dropped significantly, to 8,000 tons from 22,000 tons in 1992. The exported peat was valued at $0.9 million f.a.s., or about $103 per ton, and went to 18 countries. Mexico, Saudi Arabia, Bermuda, Canada, Japan, Bolivia, and Argentina accounted for 83% of the total, in order of importance.

In 1993, Canada continued to provide more than 99% of total U.S. peat imports—principally sphagnum moss—and new records again were established for both volume and value. Canadian imports reached a record 645,000 tons, about 50% of the total U.S. peat supply, and carried a U.S. Customs value of $117.8 million, equating to $183 per ton. Another $28 million in Canadian peat merchandise was recorded by U.S. Customs under the "Articles of Peat" category. Peat pots and other specialty peat-based products, including some peat mixtures, were reportedly included under this category.

Under terms of the United States-Canadian Free-Trade Agreement, the Canadian tariff on U.S. peat was removed effective January 1, 1993. Prior to 1993, Canadian peat shipments in all forms entered the United States duty free, but a tariff of 10.2% was imposed by Canada on U.S. peat. The United States exported about 700 tons of peat to Canada in 1993, valued at $59,000 or $84 per ton, according to U.S. Department of Commerce trade statistics. A Canadian duty of 3.4% is currently imposed on U.S. "Articles of Peat," down from a maximum of 6.8%. This duty is scheduled to be gradually phased out at a rate of 10% per year over the next 10 years. The USBM could not find a record for U.S. articles of peat export shipments in the U.S. Department of Commerce trade data base.

The United States accounted for roughly 90% of total Canadian export shipments in 1993. About 70% of the total was shipped from central and Atlantic Canada, and the remaining 30% from western Canada. Officials of Natural Resources Canada in Ottawa, Ontario, reported that Canada's improved performance in the United States was largely attributable to a greater visibility brought about by an intensive national promotional campaign, together with more aggressive marketing by Canadian producers.[10] Canada typically exports between 75% to 80% of its total peat shipments. *(See table 8.)*

Natural Resources Canada reported that about 67% of all Canadian shipments in 1993, domestic and export, originated from Quebec and New Brunswick in eastern Canada. Alberta and Manitoba, in western Canada, supplied about 26% of the total. The remaining 7% was reported to originate principally from Saskatchewan in western Canada, with minor contributions from the eastern Provinces of Nova Scotia, Newfoundland, and Prince Edward Island.

World Review

After peaking at 197 million tons in 1989, global production is estimated to have declined by 57 million tons to current levels, representing a drop of nearly 29%. The major decline can be traced to the former U.S.S.R. where USBM production estimates indicate that production has fallen about 53 million tons, or 30%, during the period cited.

In 1993, global peat production declined to 140 million tons, a drop of nearly 9% from that of 1992, principally because of continuing geopolitical events in the former U.S.S.R. Finland's 1993 production pace slowed from the torrid production rate of 1992. The high 1992 production levels were a reaction to a poor 1991 season, which was attributed to restrictive wet weather. Finnish peat was utilized mainly for energy production as Finland, along with Ireland, are the leading western nations in fuel peat utilization and consumption. Production in all other countries was believed to be comparable to 1992 levels. The total value of world peat production, assuming an average f.o.b. plant value of $30 per ton, was about $4.2 billion.

Ireland and Finland, in order of importance, accounted for about 60% of the estimated 17 million tons of peat produced outside the former U.S.S.R. in 1993. In Ireland, greater emphasis was being placed on fuel peat technology transfer, environmental technology, and the marketing of horticultural peat, while in Finland, plans for additional peat-fueled powerplants were under consideration. Germany (Western states) provided 16% of global production outside the former U.S.S.R.; Sweden, 10%; Canada and the United States combined for 9%; and other countries, 5%.

Although peat was known to be deposited in the United Kingdom, tropics of Africa, Argentina, Brazil, China, Indonesia, Malaysia, New Zealand, Paraguay, and Uruguay, production data were not available. *(See table 9.)*

Industry Structure.—The former U.S.S.R. was estimated to account for about 88% of global peat production in 1993, followed by Ireland, 5%; Finland, 2%; Germany (Western states), 2%; Sweden, 1%; the United States and Canada combined for 1%; and all other countries, 1%.

Canada.—Natural Resources Canada, Ottawa, Ontario, reported that the total area of peatlands in Canada is estimated at 111 million ha (275 million acres) covering approximately 12% of the country's surface. Canada produces sphagnum peat for the most part typically from May to September, primarily in the eastern and southeastern parts of the Province of Quebec, in the eastern and northeastern parts of the Province of New Brunswick, and in the western Provinces near Edmonton, Alberta; Carrot River, Saskatchewan; and Giroux and Elma, Manitoba. Some peat production is also found in the Provinces of Nova Scotia, Prince Edward Island, and Newfoundland. Canada's massive peat resources can probably be harvested for centuries.

Production from about 73 operations improved about 12% in 1993 as Canadian producers sought to replenish depleted stocks. Shipments fell even as exports rose, indicative of a decrease in domestic peat demand. Production increased in Quebec (50%), Nova Scotia and Prince Edward Island (combined for 100%), and Alberta (4%). Production was down 13% in New Brunswick, 7% in Saskatchewan, 8% in Newfoundland, and Manitoba was practically unchanged. Production figures are confidential for the Provinces of Alberta, Manitoba, Nova Scotia, and Saskatchewan.

The fortune of Canadian peat is dependent on continuing exports, especially to the United States; therefore, various Canadian companies sought to maintain their markets via processing and packaging improvements and research. These activities continued in 1993 as various groups worked to modernize operations, researched peat use in horticultural and environmental protection, and developed equipment for peat handling and packaging. Research projects continued on restoration and reclamation of peat bogs and improving knowledge of the peat bog as an ecosystem.

The United States and Japan were Canada's principal export targets, in respective order of importance. A 1990 study supported by the Canadian Embassy in France indicates that substantial quantities of peat could be sold to France and eventually to other European countries if producers took full advantage of backhauling to reduce freight costs.[11]

The Newfoundland and Labrador Peat Association, in cooperation with many other Canadian agencies, held an international peat conference, Newfoundland Peat Opportunities, in the fall of 1993. The conference examined the current situation in Newfoundland and around the world, identified barriers to development, and formulated a plan of action aimed at appropriate development of the Province's peat resources. The island of Newfoundland is blessed with more than 1 million ha (2.5 million acres) of peatlands. These deposits represent a largely untapped natural resource offering significant business development opportunities. The resources of Labrador, while yet to be quantified, are likely to offer far greater potential.

Finland.—In 1993, Finland's peat production totaled 13 million m^3 representing a decrease of 60% compared to 1992 when production ran full throttle to make up for lost production time in 1991. Milled fuel peat production was 9.7 million m^3, 75% of the total, and sod fuel peat 2.2 million m^3, or 17%, bringing total fuel peat to 92% of total production. Horticultural peat was 1.1 million m^3, or 8% of total production.[12]

Peat production in Finland was very small in 1970, but grew to about 3 million m^3 by 1975 and to a record of about 22 million m^3 by 1986.[13] The potential for utilization of fuel peat in Finland is currently about 30% above actual use and is projected to potentially more than double during the next 10 to 15 years.[14]

Former U.S.S.R.—The peat resources in the former U.S.S.R. are commonly referred to as the largest in the world, and more than 90% are found in Russia. The total area of peatland in the former U.S.S.R. is about 80 million ha, and the quantity is on the order of 200 to 250 billion tons at 40% moisture. The western Siberian plain is a vast peatland covering about 30 million ha with a resource base in excess of 100 billion tons. The world's largest deposits lie here with Vasyugaskoe alone having an area of 5 million ha (12.4 million acres) containing about 10 billion tons of peat. The resource has been extensively exploited for fuel use for more than 50 years.[15]

In the former U.S.S.R., production was confined to the Baltic Republics, the Moscow-Gor'kiy area, Belarus, and the Ukraine, although peat was known to be deposited throughout much of the country. Peat was burned in thermal powerplants in European former U.S.S.R. and also was used to fire industrial boilers and large heating plants.

The use of peat in the former U.S.S.R. was reportedly declining because of insufficient reserves in the primary consuming areas around Moscow and St. Petersburg and restricted demand in the energy and agricultural sectors owing to a radical shift in sociopolitical and socioeconomic philosophy. The chemical industry produced methanol and synthetic natural gas from peat.[16]

A Finnish publication, ENERGY in Finland 1993, reported that the Baltic countries face serious problems related to their energy costs, which often consume 50% of an individual's income. However, all three countries have abundant peat and forestry products that could be harvested to help reduce their nations' reliance on imported oil and gas. Peat reserves were estimated at 1 million ha (2.4 million acres) in Estonia, 415,000 ha (1 million acres) in Lithuania, and 120,000 ha (300,000 acres) in Latvia.

Peat traditionally has been harvested in all three countries but has dropped off in the past few years. However, potential certainly exists for fuel peat production. History records Lithuania harvested about 2 million tons of agricultural peat from 25,000 ha (62,000 acres) at peak production and both Estonia and Latvia produced 1.5 million tons, each from 18,000 ha (45,000 acres). It was noted that 2 million tons of fuel peat represents an energy production potential of 4 million megawatt hours, roughly equal to 400,000 tons of heavy fuel oil.[17]

Estonian officials reported that in 1992, a total of 6.1 million m^3 of peat was produced, of which 4.0 million m^3 (66%) was horticultural peat and 2.1 million m^3 (34%) was peat fuel. Estonia exported 111,000 tons of peat, representing a volume of about 555,000 m^3. Peat was harvested from an area of 14,000 ha (35,000 acres). Estonian peat resources were reported to cover about 1 million ha (2.5 million acres).[18]

In Ukraine, annual agricultural peat use dropped sharply between 1991 and 1992, from 18 million tons to slightly less than 5 million tons per year. Fuel use has remained level at about 2 million tons of dried peat, about 50% of which was used to produce briquettes in about 20 factories.

In Belarus, fuel peat production was reported to be about 2 million tons, almost all in the form of briquettes. Lithuania has only three small briquette plants with a total annual capacity of 20,000 tons.[19]

Ireland.—For 1993, Irish peat production for fuel use was estimated to have increased 5% to 6.5 million tons. Peat used in agricultural uses remained about 300,000 tons. Ireland has a long tradition of using peat as an energy source and has been the largest producer of fuel peat in the world.

Bord na Móna, established by the Turf Development Act of 1946 to develop Ireland's peat resources, sells milled peat to the Electricity Supply Board for use in domestic peat-burning power stations, briquettes and machine turf on the domestic fuel market, moss peat and other growing media in the garden and horticultural industries on a worldwide basis, and manufactures pollution abatement products.

A reorganization in 1988 established four core business divisions. The largest of the new divisions is the Peat Energy Division, which is responsible for milled peat operations, with sales accounting for about one-half the group's turnover. Milled peat productivity has been doubled and unit costs dramatically reduced. The Division's principal objective was to continue to improve the comparative economics of milled peat relative to oil, gas, and coal. Gains in productivity have reached a point where milled peat costs are becoming more competitive in terms of world energy prices. The Division decided to conduct a prefeasibility study for a new 125-megawatt peat-fired power station that could take advantage of recent advances in technology.

The Solid Fuels Division is responsible for the production and sales of "briquettes and machine turf." The outlook for solid fuels has been clouded by a swing in demand to natural gas by industrial users of solid fuels as an inevitable consequence of the extension of the national gas grid and a significant rise in privately produced turf in the Midlands region, a traditionally strong market area for briquettes. Production of private turf—promoted by the Turf Development Act of 1981—rose to 1.5 million tons in 1990, representing a fourfold increase over that of the last decade.

The Horticultural Products Division is a major exporter with more than 90% of production being sold abroad, mainly to markets in the European Union. A minority holding in a Dutch cooperative was established in 1990 to enhance the Division's presence in what is regarded as Europe's leading market in horticultural products. Effective January 1990, the Division established its own distribution subsidiary, Du Móna France S.A., with offices in Lyon. This strategy, together with the previous acquisition of the French horticultural peat subsidiary, Pouget Solami, should further enhance the Division's competitive advantage in the French peat market.

The United Kingdom is the largest market for the Division's exports, and much effort was spent in restructuring marketing strategy to deal with declining disposable income in the United Kingdom and an increasing awareness of environmental considerations on the part of consumers. Shamrock Horticulture, a wholly owned subsidiary, was processing peat at a new plant in Liverpool. A new composting plant was successfully commissioned at Liverpool during the year in response to a growing trend in consumer preference for blended products (fertilizer and other).

Bord na Móna reiterated its opposition to the unacceptable practice of exploiting boglands of special scientific interest and continued to transfer environmentally sensitive boglands to the Wildlife Service. Ultimately, 3,400 ha (8400 acres) of boglands will be protected in accordance with Government policy.

Netherlands.—In the 11th and 12th centuries fuel peat cutting in the bogs was practiced throughout the country, and by the 15th and 16th centuries peat production also was active in the lowmoor deposits. The landscape was changed radically and land reclamation commenced, but extensive lakes also were formed that today contribute to the beauty of the surrounding countryside. After World War II, demand for fuel peat had been reduced to the small-scale production of activated carbon.

Sphagnum peat moss began to be harvested by 1880, and many mills were founded in the east of the country and in the neighboring German peat-areas, where Dutch producers bought bogs. The peat moss industry flourished until the end of World War I, when there were large-scale exports of sphagnum peat moss litter to Belgium, England, France, and many other countries.

Peat production in the Netherlands today is essentially nonexistent. There are still a few state-owned bogs reserved for conservation and a few thousand ha of boglands is managed by environmentalists. Demand continues to grow, however, and in addition to traditional black peat imported from Germany, supplies continue to increase from Scandinavian countries, the Baltic States, Ireland, and Russia. Canada also may become a future supply source.[20]

Sweden.—In 1993, Sweden was producing about 1 million m^3 meters of horticultural peat and about 3 million m^3 of fuel-grade peat, annually. Swedish peatlands were reported to cover an area of about 6.3 million ha (15.6 million acres), or about 15% of the total land area. About 865,000 ha (2.1 million acres) of peatland was available for fuel peat production. The overall area suitable for horticultural peat production has not been surveyed yet.

Sweden currently has about 50 producers of horticultural peat, mainly in the south and middle regions. Roughly 400,000 m^3 is produced as milled peat and 600,000 m^3 as sod peat, of which 30% to 35% is exported. More than one-half of the domestic consumption is used by amateurs for home and garden applications.[21]

After reaching maximum production and sales of about 2.5 million m^3 in 1950, fuel peat declined dramatically because of its economic disadvantages to cheaply priced fuel oil. By 1970, fuel peat production in Sweden was nonexistent. There was a subsequent revival in fuel peat demand beginning in the early 1980's, however, as an aftershock of the global energy crises of the 1970's.

Unfortunately, the Government's philosophy regarding Swedish fuel peat and peatland research has changed during the past 3 years. Environmental and ecological concerns apparently have dampened further progress in fuel peat output. So far, fuel peat has been taxed based on sulfur dioxide and nitrogen oxide emissions. The Swedish Peat Producers Association's recent promotional activities again have generated moderate optimism by Government agencies.

United Kingdom.—A private consortium of peatland conservationists, called the Commission of Inquiry Into Peat and Peatlands, held three public hearings between September 29, 1991, and November 27, 1991—two at the Natural History Museum, London and another in the Council Chamber, Strathclyde Regional Council in Glasgow, Scotland. The Commission was concerned primarily with the conservation of lowland raised bogs, because this was identified as the most immediately and seriously threatened of peatland types in the United Kingdom. The Commission also expressed concern for the conservation of blanket bogs, fens, and other British peatlands, but considered this issue to merit separate consideration.

The Commission reached several important conclusions and recommendations. Current data suggested that there was 1.4 million ha (3.5 million acres) of "blanket boglands" in England, Scotland, and Wales; 10,000 ha (25,000 acres) of "intermediate bog," and 67,000 ha (165,000 acres) of "lowland raised bog." The best available scientific evidence suggested that the maximum area of natural, undamaged raised bog remaining in Great Britian was less than 6,200 ha (15,000 acres), 10,000 ha (25,000 acres) in the United Kingdom; the predominate reduction resulted from forestation and conversion of peatlands to agricultural use.

It was recommended that Country Conservation Councils: English Nature, the Countryside Council for Wales, Scottish Natural Heritage, and the Department of the Environment (Northern Ireland) should adopt a rigorous policy to protect raised bogs and rehabilitate damaged bogs where necessary. The Commission also stressed the use of alternative natural organic composts.[22]

Current Research

Peat research and development continued during 1993, as several projects were reaching commercial fruition. Commercial ventures were established to produce and market peat-based oil sorbent products in significant quantities in the United States. Consumers of the peat-based products liked the superior absorbency and environmentally friendly aspects of disposal relative to clay-based products. Peat also was shown to be an effective filtration source for the removal of toxic wastes from secondary sewage effluents, urban stormwater management control, for the elimination of offensive odors, and as a superior bulking agent in the composting of natural organic waste products.

The Louisa County (VA) Housing Foundation issued a news release announcing the dedication of the Laurel Hill Project. The dedication, on November 15, 1993, was for a $100,000 neighborhood improvement project funded by Federal, State, and local governments as well as private donations. What makes this project unique is that for the first time in the United States, a septic system using biological filter will be used to treat wastewater from five homes. This system, which uses peat imported from Ireland, is being constructed by the Louisa County Housing Foundation under permit from the State water control board.

The peat system represents a major breakthrough in wastewater treatment. It is a low cost, effective, and environmentally safe solution to providing wastewater treatment in areas where the land will not support conventional septic drainfields and commercial systems are too expensive.

The Natural Resources Research Institute (NRRI), University of Minnesota at Duluth, continued to provide technical assistance to Mat Inc., a Floodwood, MN, peat firm that produced peat sorbents for D M S & D Associates, Inc. of Ocean, NJ, and Fisher Steven Inc. NRRI researchers reported that additional sorbent products were in the development stage, including peat-based socks, booms, and wood fiber pads. Mat, Inc. was already receiving orders for the new products although NRRI had just begun to identify tooling requirements for production.

According to a recent NRRI study, sorbents manufactured from the higher density, more decomposed Minnesota peats carry an optimal unit value that gives Minnesota product more than a twofold competitive transportation cost advantage over Canadian sorbents. NRRI researchers also reported that properly dried and processed Minnesota sphagnum peat performs as well or better than Canadian peat and surpasses clay, paper, sawdust, and corn. All peats tested were reported to exceed clay-type sorbents.[23]

During 1992, a 2-year commercial-scale turkey litter waste management project was initiated between NRRI, the Agriculture Utilization Research Institute (AURI), and Langmo Farms of Litchfield, MN, in association with Minnesota Technology, Inc. and Howe Chemical.

Traditionally, farmers have tilled turkey droppings into wood shavings litter that remain in the barn with the birds throughout the year. Heavy applications of turkey manure to agricultural lands can lead to an excessive buildup of fertilizer nutrients that may lead to serious water quality problems.

A novel feature of the landmark research was to incorporate turkey-friendly and environmentally sound sphagnum peat, oat, and sunflower hulls, with the traditional wood shavings litter. Peat is used in the litter to maintain low ammonia and odor levels and to control microorganisms that can cause disease in the birds. Additionally, sphagnum peat is low in dust—beneficial to the birds' health—and provides a low pH and high nitrogen content; ideal conditions for producing high-quality compost for horticultural applications. Howe Chemical planned to collect 1,000 tons of composted turkey litter produced during the project to manufacture and test market an organic-based, premium-grade lawn and garden fertilizer and a low-grade organic agricultural fertilizer.[24]

Michigan Peat Co. of Houston, TX, developed a unique compacted peat that served as a natural potting soil additive, providing improved aeration and drainage. Michigan peat representatives said that its particle size could be tailored to individual needs, while maintaining integrity and resistance to breakdown during watering cycles.

D M S & D Associates, Inc., Ocean, NJ, developed and test marketed a unique hydrophobic sphagnum peat moss product having superior hydrocarbon sorption properties. The firm reported that 1 pound of the product would effectively sorb 1 gallon of oil typically weighing about 8.2 pounds. D M S & D personnel said that the new product represented an advanced concept in spill cleanup.

The new peat product was reported to be cost efficient and safe to use compared with traditional products. Savings per gallon for the cleanup and disposal of a 1-gallon spill were favorable to traditional clay products, corn-based materials, and paper absorbents, in respective order of importance. In addition to its unique hydrocarbon sorbent properties, the product has disposal advantages. It is biodegradable, fuel blendable, EPA qualified as an alternative fuel with a low ash content, and is vapor suppressive. Thus, the product is environmentally friendly, helping to minimize waste going into diminishing landfills. Its native population of microorganisms assist in bioremediation, and it can be recycled as an alternative fuel. When used on water, it locks in the hydrocarbons, protecting wildlife and reducing environmental impact.

State transportation agencies in the northeastern United States, where clay sorbents have been banned, found that peat sorbents represent an environmentally friendly and economically viable clay substitute. In one northeastern State where clay has been banned since 1990, it was found that the use of peat sorbents was advantageous to employee health, represented indirect cost savings via disposal and less bulk, avoided landfills, and could be consumed in industrial fuel applications.

Research continued into "beads" made of peat moss and a common polymer. Researchers at the USBM Salt Lake City Research Center developed the beads to be used to clean rivers, streams, or other contaminated waters. These beads were effective in extracting toxic metal ions from a variety of wastewaters. USBM researchers developed porous polymeric beads that were prepared by blending sphagnum peat moss or algae into a polymer solution and spraying the mixture into water.

Batch and continuous tests demonstrated that the beads removed arsenic, cadmium, lead, and other toxic metals from acid mine drainage waters collected from several sites. Selectivity for heavy and toxic metal ions over calcium and magnesium was demonstrated. The sorption process was reversible, and metal ions were eluted from the beads using dilute mineral acids. Cyclic tests indicated that the beads continued to extract metal ions after repeated loading-elution cycles.[25]

STS consultants, Ltd., Minneapolis, MN, continued to develop a unique peat/wetlands treatment approach to acidic mine drainage abatement. The firm reported that peat wetlands demonstration plots constructed and operated over 2 years had effectively removed 80% to 95% of copper and nickel emanating from acid mine drainage streams. STS was constructing the first commercial peat wetlands system in Minnesota. The system will be designed to treat a flow of approximately 40,000 liters per day, constructed for subsurface flow utilizing 0.3 meters of limestone as a substrate, covered by about 1 meter of fibrous screenings and peat mixture.[26]

The Department of Environmental Programs of the Metropolitan Washington (D.C.) Council of Governments (MWCOG) was preparing study areas to determine if using peat-sand filter (PSF) systems to process stormwater would reduce waste entering regional bodies of water. Two study areas were chosen: the River Terrace PSF Project situated on a 63-ha (155-acre) drainage area in the District of Columbia and the East Springbrook Study Area (in the Paint Branch Watershed) in Montgomery County, MD. These PSF were chosen because it was not possible to use traditional urban Best Management Practices in these areas. After an extensive literature search, the staff of the MWCOG determined that the PSF system might offer a partial solution to the acute need for end-of-pipe water quality control.[27]

MULTITEK of Prentice, WI, introduced a modular system designed to separate and pulverize peat and other natural materials to desirable marketable consistency at rates up to 150 tons per hour. The unique tumbler screen rotates the material while 32 hammers pulverize to produce unequalled productivity. The system is totally portable and is hydraulically powered, permitting variable adjustment to peak performance speeds. This machine was reported to outperform a typical vibrator screen system. A portable unit was available that could be towed at highway speeds with a 1-ton truck. In addition to peat, the system can handle top soil, sand and gravel, compost, grade rock, composted manure, clays, woodchips, bark, coal, and composted sewage sludge.

Enviro Industrial Technology Corp. (E.I.T.C.) of Alberta, Canada, developed a novel line of peat harvesting and wetlands transport equipment. The products currently developed include a Field Profiler, Root Picker, Spoon and Rotary Harrow, Chain Miller, Ditcher, Vacuum Harvester, and Transport Wagons. E.I.T.C.'s equipment was designed to meet the rigorous durability demands associated with high production rates and low maintenance costs expected by the North American peat industry.

SaskPower and a Meadow Lake company in Saskatchewan planned to build a $22 million peat-burning powerplant at Jans Bay, north of Meadow Lake. It would reportedly generate 15 megawatts, enough to heat a community of 3,000 homes.

Peat Resources was planning a $4.5 million pilot plant to produce fuel-grade peat at a prime peatland 56 kilometers northwest of Thunder Bay, Ontario, Canada. Data collected from the pilot plant operation would be used for the potential design of a $95 million commercial plant capable of producing 1 million tons per year of peat fuel. The fuel would reportedly be used as an environmentally attractive alternative energy replacement for coal in electrical power generation plants.

The pilot plant would test a process for producing high-grade industrial peat fuel with a heating value comparable to bituminous coal. In a recent test burn completed by Ontario Hydro, the experimental peat fuel produced less than 5% ash, and a mixture of coal and peat fuel reduced sulfur emissions in direct proportion to the quantity of peat blended. Peat Resources, which had been developing the peat fuel process since 1984, applied for a Canadian patent.[28]

Peat also showed promise as a biodegradable medium in disposable diapers and in food packaging.

OUTLOOK

During the past 20 years, U.S. domestic peat production has grown at an average annual rate of about 2% per year and apparent domestic consumption by about 3.5%. The most recent upturn in the U.S. peat supply-demand cycle was experienced between 1981 and 1987. Domestic peat production hit the bottom of the latest cycle in 1981 at 0.7 million tons and gradually increased to a record 1 million tons by 1987, representing an average annual growth of about 7%. Total apparent domestic consumption during the same period followed the domestic production trend and grew at an average annual rate of 7%, from 1.1 million tons in 1981 to a record 1.5 million tons in 1987.

Between 1987 and 1993, domestic peat production and total apparent domestic consumption have declined 7% and 2%, respectively, owing to a downturn in the U.S. economy. Canadian imports as a percentage of the total U.S. supply, however, increased from 35% in 1987 to a record 51% in 1993.

The USBM forecast for horticultural peat during the next 5 years is based on a gradual recovery in the economy and a resultant rebound in domestic production and total apparent domestic consumption. Domestic production of horticultural peat is forecast to grow at an average annual rate of about 2% to levels approaching 0.8 million tons by 1998.

Total apparent domestic consumption for horticultural purposes is forecast to grow at an average annual rate of about 4% per year to about 1.6 million tons by 1998. Canadian imports are forecast to rise from a current 50% of the U.S. supply to about 55% by 1998. Per capita consumption is forecast to approximate 5.6 kilograms (12.5 pounds) by 1998 and approach the 5.7-kilogram (12.7-pound) average experienced during the peak years of 1986 and 1987.

The USBM's forecast for domestic peat production and demand could be optimistic in the event that Canadian competition becomes more intense, environmental regulations inhibit growth, composting captures an increasing market share, or a continued downturn in the economy persists. However, new uses for peat as a filtration medium for the cleanup of waste streams, oil absorption, composting natural organics, and for hygienic and other purposes could potentially drive U.S. peat demand to levels higher than forecast, regardless of the supply source, domestic or Canadian.

The outlook for future growth in domestic fuel peat demand for electric power generation has been deferred beyond the forecast period because of the loss of four 80-megawatt power contracts in Florida to the competitive economics of natural gas. Natural gas is currently in oversupply, and gas prices have declined significantly in recent years. Additionally, the capital costs associated with the construction of natural gas power plants are favorable to peat-based plants.

Florida Power and Light and Florida Power Corp. had previously signed letters of intent with EcoPeat—a U.S. subsidiary of the Finnish firm, Outokumpu—to purchase peat-fueled electrical power from proposed plants adjacent to vast peat reserves to the northwest and southeast of Lake Okeechobee in south Florida.[29] The plants were to be brought into production sequentially beginning in mid-1995 and at full capacity would have required about 2.5 million tons of peat annually, representing a threefold increase in current U.S. peat production.[30]

The global outlook for peat supply-demand is shown in table 10. This year's outlook, long-range, continued to be clouded by the downward trend in former U.S.S.R. production. If the projected downturn only impacts the former U.S.S.R.'s internal supply-demand situation, then the world outside the former U.S.S.R. should still anticipate reasonably balanced conditions during the next 5 years. If the former U.S.S.R. becomes pressured to move surplus product to the international marketplace, however, a global imbalance in peat supply-demand could be precipitated for an indefinite period. *(See table 10.)*

The USBM basic forecast methodology continues to include the assumption that peat production in the former U.S.S.R. will not return to 1990 levels in the foreseeable future. Otherwise, traditional methodology gauging global demand on the historic trend in per capita consumption has not changed. The long-term trend based on the current forecast shows that, between 1994 and 1998, global peat demand is projected to grow at an average 1% per year, about one-half of the projected 2% growth in population. This forecast is consistent with historic trends.

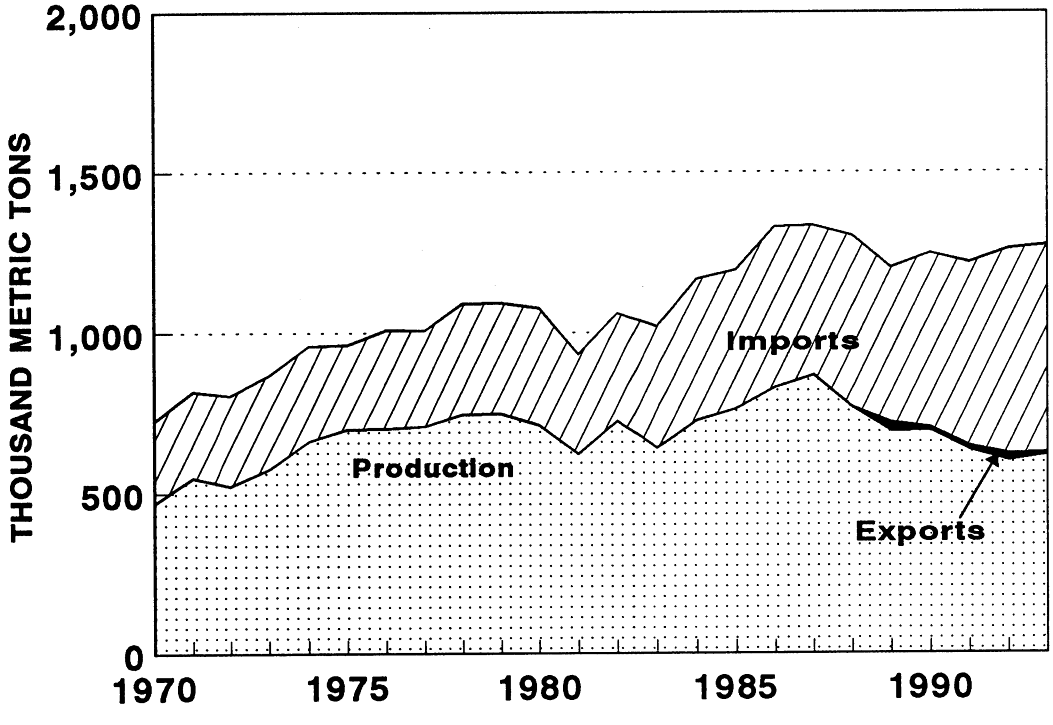
FIGURE 1
PRODUCTION AND IMPORTS OF PEAT IN THE UNITED STATES



PHOSPHATE ROCK

By Thomas O. Llewellyn

Mr. Llewellyn, a physical scientist with more than 30 years of industry and U.S. Bureau of Mines experience, has been a commodity specialist since 1987. Domestic survey data were prepared by Christopher Lindsay, statistical assistant; and the international data table was prepared by Jeremy Tidwell, international data coordinator.

Phosphate rock, the only significant commercial source of the element phosphorus, is vital to the agricultural sector worldwide. Phosphorus is a basic element that is essential to life. Phosphorus is not usually very abundant in soils because it is removed by crop and natural losses. To maintain high crop yields, fertilizers containing the major plant nutrients phosphorus, nitrogen, and potassium must be applied to the soil. The world requires that agriculture be highly productive to feed its expanding population. In the United States, nearly 90% of the phosphate rock consumed is for the production of fertilizers with the remainder consumed in a variety of phosphate chemicals used by industry and the general public.

U.S. production of phosphate rock dramatically decreased in 1993 compared with that of 1992 as sales of phosphate fertilizer products declined. The phosphate industry, faced with lower demand and prices for fertilizer products, was forced to idle and/or close some mines and fertilizer plants in an effort to control production to ensure competitive selling prices. Domestic and world production of phosphate rock decreased 24% and 10%, respectively, compared with output in 1992. Preliminary estimates showed that world phosphate rock trade decreased again in 1993 by about 7%, reaching only 27 million metric tons, from the almost 29 million tons traded in 1992; U.S. phosphate rock exports decreased from 3.7 million tons to 3.2 million tons primarily because of reduced consumption in Western Europe and the loss of exports to India.

The historical breakup of the former U.S.S.R. and the significant changes in the socioeconomic structures of countries in Eastern Europe is expected to continue affecting the demand for phosphate fertilizers in that region and across the world markets for the near future. Producers of phosphate products from the former U.S.S.R. and the Eastern Europe countries have been dumping phosphate fertilizer inventories on the world market to obtain needed hard currency.

The year 1993 produced significant changes in international trade. The North American Free Trade Agreement (NAFTA) was approved by the Governments of Canada, Mexico, and the United States. After 7 years, the Uruguay Round of multilateral trade negotiations were closer to reality. The United States intended to enter into the trade agreements by April 15, 1994. These agreements will not have domestic legal force until the U.S. Congress has approved them. *(See table 1.)*

DOMESTIC DATA COVERAGE

Domestic production data for phosphate rock were developed by the U.S. Bureau of Mines from two separate voluntary surveys of U.S. operations. Of the 14 operations to which a survey request was sent, all responded, representing 100% of the U.S. production data shown in table 1.

BACKGROUND

Phosphate rock deposits occur as marine phosphorites, apatite-rich igneous rock, and guano. Guano deposits are a result of animal waste accumulation, mainly sea birds. Current world phosphate production from guano deposits is insignificant. *(See table 20.)* All U.S. production was from marine phosphorites. The U.S. industry reports production in terms of a beneficiated phosphate rock concentrate and reserves in terms of an economically recoverable phosphate rock concentrate product. The grade of phosphate rock may be reported as percent of phosphorus pentoxide (P_2O_5) or as tricalcium phosphate, $Ca_3(PO_4)_2$, which also is referred to as percent bone phosphate of lime (BPL). Conversion factors are: $P_2O_5 = \%BPL \times 0.4576$; $\%BPL = P_2O_5 \times 2.1853$; and $P = P_2O_5 \times 0.436$. The phosphate ore bed or the zone of phosphorus-bearing material is known as matrix in Florida and North Carolina.

Marketable phosphate rock was produced by 14 companies in the United States. Six companies in Florida and one in North Carolina produced about 85% of the phosphate rock. The balance of 15% was produced in Idaho, Montana, and Utah. Approximately 82% of the phosphate rock sold or used by U.S. producers was consumed domestically to produce fertilizers and feed supplements; about 8% was exported and 10% was used to produce a variety of industrial chemicals.

Sedimentary apatite has a range of chemical compositions. The general formula for marine carbonate-apatite is $Ca_{10}(PO_4CO_3)_6F_{2-3}$. Apatite is host to many cation, anion, and anionic radical substitutions for PO_4. Accessory elements may be associated minerals or those that are chemical substitutions in the phosphate mineral.

The part of phosphate resources that can be economically recovered is called reserves. Reserves may increase as new deposits are discovered and as technology is improved. Estimates of phosphate rock reserves are made for a specific date and are subject to changing economic or environmental conditions. Operating companies and companies holding phosphate lands estimate the recoverable tonnages based on current and future economics. Estimated reserves for Florida and North Carolina deposits are about 1 billion tons for each State.

The phosphate rock bed of the Pungo River Formation in North Carolina is a primary marine phosphate 6 to 12 meters (20 to 40 feet) thick, overlain with 27 to 40 meters (90 to 130 feet) of sand, clay, and marl overburden. The underlying aquifer was depressurized by pumping water to the surface to ensure a dry pit. Currently, bucket wheel excavators have replaced dredges to strip the top 12 meters (40 feet) of overburden. Large-capacity draglines with buckets as large as 55 cubic meters (72 cubic yards) were used to strip the remaining overburden and mine the matrix. The matrix was slurried with high-pressure waterjets, pumped to the beneficiation plant, washed, and classified to produce a minus 16-mesh, plus 200-mesh flotation feed. Flotation concentrate was either calcined or dried.

Most of the phosphate mines in central Florida recover phosphate rock from the Bone Valley Formation. Overburden averages about 6 meters (20 feet). The overburden consists of a clay sand and a leach-zone material that overlays the matrix. The materials were selectively strip-mined with large electric draglines. The matrix was slurried in a sump and pumped to the washing plant. Cleaned, screened material from the washer that was plus 14 or 16 mesh was separated and may be a salable pebble product. The minus 16-mesh fraction was deslimed at a 150-mesh, and the plus 16- minus 150-mesh fraction was floated to produce a phosphate concentrate. The minus 150-mesh fraction, called slimes, is discarded by pumping into impoundment areas. Phosphate slimes contain 6% to 17% P_2O_5, which in some cases amount to almost one-third of the phosphate content in the matrix. Over the years, many unsuccessful attempts have been made to economically recover phosphate values from the slimes. Recovery of phosphate values from this waste product would lengthen the life of domestic phosphate reserves.

Improved recovery of phosphate rock concentrate from deposits in the United States was accomplished with the introduction of the flotation process in 1927 and 1928. Values in the 14 mesh by 150 mesh became recoverable, adding to the coarser plus 14-mesh pebble fraction. Conversion of phosphate rock with controlled quantities of sulfuric acid to single superphosphate, which contains about 20% P_2O_5, was the major phosphate fertilizer through the 1950's and into the 1960's. High analysis triple superphosphate, which contains more than 40% P_2O_5, is manufactured by acidulating phosphate rock with phosphoric acid. Ammonium phosphates, which contain 46% to 54% P_2O_5, are produced by reacting phosphoric acid with anhydrous ammonia. The ammonium phosphates and triple superphosphate have become the preferred fertilizers for domestic consumption and international trade. The intermediate chemical for these preferred fertilizers, phosphoric acid, is produced by acidulating phosphate rock with sulfuric acid. Phosphoric acid itself may be used as a fertilizer and is traded internationally; importers of phosphoric acid may manufacture fertilizers from the acid or use it to produce other phosphate chemicals.

In the past few years, experimental farming has determined more efficient use of mineral-based fertilizers. Farmers have learned to follow recommended application rates, timing, and use of efficient spreaders. These advances in the use of fertilizers significantly increased crop yields and decreased fertilizer consumption per planted acre.

ANNUAL REVIEW

Legislation and Government Programs

On September 30, 1993, the U.S. Department of Commerce notified the public of its determination not to revoke the antidumping duty on industrial phosphoric acid from Belgium, as was proposed the month before. Special dumping duties were established on August 20, 1987.[1] In Florida, new phosphogypsum stacks are required to be lined to prevent ground water from becoming contaminated with heavy metals. Heavy metals such as arsenic, cadmium, chromium, and phosphorus are found in waste phosphogypsum. New stacks must be constructed using a thick plastic sheet. The cost to build a 160-hectare (400 acre) lined stack site was estimated at more than $80 million.

The U.S. Environmental Protection Agency (EPA) announced the establishment of the Dialogue Committee on Phosphoric Acid Production Wastes (DCPAPW) in November 1992. The committee included the EPA, various State agencies, industry representatives, the Fertilizer Institute, and public interest groups. As required by the Federal Advisory Committee, the DCPAPW held two meetings in Arlington, VA, one in March and the other in November 1993, to continue reviewing information regarding existing or potential risks to human health or the environment from generated phosphoric acid wastes by identifying technically and economically feasible changes to the current production process of phosphoric acid.[2] The committee plans to publish a report on its findings in 1994.

The U.S. President, by Executive Order 12850 of May 28, 1993, announced the renewal of China's most-favored-nation (MFN) trading status without conditions. Each year MFN trading status for all nations expires. Therefore, the President recommended renewal of China's MFN status for an additional 12-month period beginning July 3, 1994, but future renewal would be subjected to its progress in human rights and weapons proliferation improvements.[3] U.S. exports of phosphate fertilizers are among the Nation's principal sales to China.

The North America Free Trade Agreement (NAFTA), between Canada, Mexico, and the United States, becomes effective January 1, 1994. Under this agreement most fertilizer products tariffs were eliminated, except for the following: phosphoric acid and anhydrous ammonia were assigned a 10-year phaseout and diammonium phosphate (DAP) and ammonium sulfate were assigned a 5-year phaseout.[4] The fertilizer industry is expected to benefit directly and indirectly from this agreement. The United States has no duties or tariffs on fertilizer imports. As Mexico eliminates duties under NAFTA, the U.S. industry is expected to directly benefit from an increase on fertilizer sales and, indirectly, from a potential increase in U.S. grain export.

On December 15, 1993, the President notified the U.S. House of Representatives and the U.S. Senate of his intention to enter into the trade agreement resulting from the Uruguay Round of multilateral negotiations under the auspices of the General Agreement of Tariffs and Trade (GATT). The Administration planned to enter into the GATT by April 15, 1994. Signed agreements will be submitted for congressional approval together with legislation and administrative actions required to implement the agreements in the United States. Fertilizer products are included in a chemical harmonized tariff system adopted in the market access of the GATT agreement.[5]

Issues

Phosphate rock mining and beneficiation processes require huge volumes of water. Transporting the matrix to the beneficiation plant, desliming it, and producing a high-grade phosphate concentrate by flotation consumes large volumes of water. The matrix is slurried with high-pressure hydraulic jets and pumped via a pipeline to the beneficiation plant. During beneficiation the minus 150-mesh slimes, mainly clays, are removed from the matrix by hydrocyclones and discarded by pumping into settling areas, called slime ponds. The Florida Department of Natural Resources, Bureau of Mine Reclamation, indicated that as of December 1991 there were about 40,000 hectares of active and inactive slime settling areas. Slime pond reclamation was a long-term operation requiring about 15 years for the clays to settle from an original 5% solids content to about 20% solids. Now reclamation time, after the slime pond becomes inactive, has been reduced to about 4 years by dewatering the pond using flotation tractors to dig the drainage ditches. For the past 30 years the phosphate industry, government institutions, and private research organizations have investigated methods of dewatering slimes instantaneously using flocculants. To date, an economic process to dewater slimes has not been discovered.

In the wet phosphoric acid process, phosphate rock is digested with sulfuric acid to produce dilute phosphoric acid. The process generates a solid waste of mainly calcium sulfate, called phosphogypsum. This waste also contains quartz, phosphates, fluoride, and radioactive minerals as well as minor amounts of heavy minerals, such as cadmium and cobalt. The water-slurried phosphogypsum is pumped to impoundments where the solids settle and the water is recycled to the process. The use of phosphogypsum is restricted because its radium content emits the radioactive gas radon. The National Emissions Standards for hazardous air pollutants of the Clean Air Act Amendments of March 15, 1990, requires that phosphogypsum be disposed of in stacks or mined-out areas. It is estimated that the Florida phosphate industry generates about 30 million tons of phosphogypsum per year at the present operating rates and there are about 600 million tons of this material in the existing stacks. It is technologically feasible to remove the harmful impurities from phosphogypsum, but the purified phosphogypsum is not economically competitive with natural gypsum.

Runoff from excessive application of fertilizer can contaminate ground water and receiving waters. The concern over negative environmental impacts frequently dismisses the importance of mineral fertilizers. Without providing and replenishing soil nutrients by increased use of fertilizers, production of food to satisfy an increasing world population will not be possible. The World Bank estimates that by the year 2025 the world population will reach 8.3 billion compared with the current population of about 5.4 billion, a 54% increase in a period of only 31 years.

Production

Production of marketable phosphate rock in the United States dramatically decreased from about 47 million tons in 1992 to about 35 million tons in 1993. Some mines and fertilizer plants were either closed or temporarily idled because of a low demand for phosphate rock and phosphate fertilizer products.

Florida and North Carolina.— Phosphate rock was produced in central Florida by Cargill Fertilizer, Inc. (CFI); CF Industries, Inc.; IMC-Agrico Co.; Mobil Mining and Minerals Corp.; and U.S. Agri-Chemicals Corp., owned by Sinochem (USA) Inc.

CFI closed its North Pasture Mine in June 30, 1993. CFI was buying phosphate rock from IMC-Agrico as feedstock for its phosphoric acid production through a contract expiring by the end of 1995. CFI also hired Jacobs Engineering Group Inc. to provide all engineering services related with the expansion and relocation of its beneficiation plant from the closed North Pasture Mine to a site near the new South Pasture Mine in Hardee County, FL. Startup for both the new South Pasture Mine and the expanded beneficiation plant was scheduled for late 1995.

IMC-Agrico Co. closed its Kingsford Mine in June and the Payne Creek Mine in October 1993. Both mines are in Polk County, FL. In July, the company also was forced to make additional adjustments in production of both fertilizers and phosphate rock concentrate as a result of large inventories in relation to low demand for fertilizers. DAP production was shut down at the Taft, LA, plant and production was reduced at one of the New Wales, FL, plants. To accommodate this lower fertilizer production level, the Four Corners Mine operation in Polk County, FL, was reduced from a 7-day to a 5-day week schedule. The closures and cutbacks in phosphate rock production were generally attributed to continued low prices for chemical fertilizers in the world market. The mines were expected to remain idle until market conditions improve. However, Clear Springs Mine, closed since November 1991, was reopened in October 1993. Company officials indicated that despite the sustained decline in phosphate prices the high-grade phosphate concentrate produced from Clear Springs had higher demand.

On December 2, 1993, IMC-Agrico announced the reopening of the DAP Taft fertilizer plant before the end of the month and returned the Four Corners Mine to a 7-day, three-shifts-per-day scheduled operation by January 1994, in response to the increased demand and higher prices for fertilizer products from domestic and international consumers. According to the company, this action was taken in anticipation of an expected increase in fertilizer demand for the coming spring season and to offset their lower fertilizer stocks.

Mobil Mining and Minerals Co. of Florida was told to go ahead with its projected mine development at South Fort Meade property. Mobil Corp., the parent company, agreed to fund the project cost of $200 to $300 million. Startup production of about 3 million tons per year was scheduled for 1995.

In northern Florida, Occidental Chemical Agricultural Products Inc. (Oxy) produced phosphate rock for production of phosphoric acid, superphosphoric acid, and diammonium phosphate. Oxy operated two mines north of Lake City, FL. As a result of the prevailing economic conditions affecting the phosphate fertilizer business, the company's Swift Creek phosphate mine was temporarily closed in May and remained closed through the end of 1993. In north-central Florida, low-fluorine soft phosphate rock was recovered from hard phosphate rock tailing ponds.

Texasgulf Chemical Co. (TG), a division of Texasgulf Inc., a subsidiary of Elf Aquitaine Inc., produced phosphate rock from the Aurora Mine in eastern North Carolina. TG employed bucket wheel excavating systems to remove the top 12 meters of overburden. Draglines were used to remove the remaining overburden and mine the 10 to 12 meters of matrix.

During 1993, the phosphate industry was affected by lower demand and prices for fertilizer products, and an important way to remain in business was through consolidation or joint ventures. Thus, in May 1993, Cargill Fertilizer, Inc., a subsidiary of Cargill Inc. of Minneapolis, MN, bought the assets of Seminole Fertilizer Corp., which was formerly owned by Tosco Corp. of Stanford, CT. The transaction included Seminole's Bartow phosphate fertilizer production plant, the phosphate mine Hookers Prairie, and two ammonia-storage tanks at Port Sutton, FL. Seminole's DAP plant in Fort Meade, FL, which is jointly owned (50%) by Agri-Chemicals, was not included in the deal.

On July 1, 1993, IMC Fertilizer Inc. and Freeport-McMoRan Resources Partners L.P., two of the largest domestic phosphate producers, finalized a joint agreement that combined both companies' phosphate rock mining and phosphate fertilizer businesses, as well as their uranium extraction operations. The new company name, IMC-Agrico Co., was expected to generate an overall operational cost savings of about $95 million in 1993.

Western States.—Phosphate rock was mined in Idaho by J. R. Simplot Co., Monsanto, and Rhône-Poulenc Basic Chemicals Co. Simplot produced phosphate rock from the Gay Mine on the Fort Hall Indian Reservation; however, the Gay Mine was closed in July 1993 because of phosphate rock depletion. Mainbed ore was used by Simplot to manufacture phosphoric acid, and the lower grade shale was used in FMC Corp. electric furnaces in Pocatello, ID. Simplot also produced phosphate rock from the Smoky Canyon Mine in the Caribou National Forest. The concentrate was pumped from the mine to Simplot's fertilizer plant west of Pocatello, ID. FMC produced phosphate rock from the Dry Valley facility for its Pocatello plant; Dry Valley material replaced shale from the Gay Mine, which closed during 1993. Monsanto supplied its electric furnaces in Soda Springs, ID, with phosphate rock from its Enoch Valley Mine in the Caribou National Forest. Rhône-Poulenc produced phosphate rock from the Wooley Valley Mine, Caribou National Forest, ID, and shipped to its electric furnace plant in Silver Bow, MT. Conda Partnership produced phosphate rock from the Mountain Fuel Mine and Maybe Canyon Mine, Caribou National Forest, ID. The Mountain Fuel Mine closed at the end of December 1993. The phosphate rock was shipped by rail to Conda, ID, beneficiated, calcined, and used to produce phosphoric acid. In March 1993, Cominco American closed its Warm Springs Mine near Garrison, MT. This was the only operating underground phosphate rock mine in the United States. The Cominco announcement stated that with scaled down production at its smelter complex at Trail, British Columbia, Canada, owing to environmental problems, the need for phosphate rock from the Warm Springs Mine was substantially reduced. SF Phosphates Ltd., formed in April 1992 by Simplot and Farmland Industries, produced phosphate rock from a mine near Vernal, UT. *(See tables 2 and 3.)*

Consumption and Uses

The demand pattern for phosphate rock was similar to that of 1992. In 1993, nearly 89% of the phosphate rock sold or used by U.S. producers was for the manufacture of wet-process phosphoric acid, single superphosphate, triple superphosphate, and deflourinated rock;

the balance was used to produce elemental phosphorus. Most of the phosphate rock imported was used to produce wet-process phosphoric acid. *(See tables 4 and 5.)*

Stocks

Phosphate rock stocks were maintained in wet rock piles in Florida and North Carolina and, after drying or calcining, were stored in silos. In the Western States, phosphate rock was stockpiled during the nonfreezing months of the year near electric furnaces or wet-process phosphoric acid plants to avoid railroad car or truck unloading problems in the wintertime. Phosphate rock inventory levels are of interest to analysts who follow inventory levels to indicate the strength of the demand for phosphate rock. In the United States, ending stocks in 1992 were 12.6 million tons. In 1993, phosphate rock ending stocks were 9.2 million tons, indicating a decrease of 3.4 million tons. *(See table 6.)*

Transportation

From production centers in central and north Florida, phosphate rock was moved by rail to terminals on Hillsborough Bay, FL, and Jacksonville, FL. In central Florida, CSX Transportation Railroad moved phosphate rock to terminals on Hillsborough Bay. The Rockport terminal was owned and operated by the CSX Railroad. Big Bend terminals and Port Sutton were owned and operated by IMC-Agrico Co. Eastern Associated Terminal (E.A.T.) was owned and operated by E.A.T.

In North Carolina, barges were used to transport phosphate rock from the Aurora Mine to the port at Morehead City for export. Railroad facilities were also available at the Aurora Mine to move phosphate rock to the port or domestic markets. Both railroads and trucks were used in the Western States to move phosphate rock from mines to plants. Two pipelines were used to move slurried phosphate rock from mines to plants. One pipeline was used to pump slurried concentrate from Vernal, UT, to Rock Springs, WY, and another was used to pump phosphate rock from the Smoky Canyon Mine in the Caribou National Forest to Pocatello, ID.

Markets and Prices

The price or value of phosphate rock, f.o.b. mine, was obtained from a semiannual survey of producing companies. The data from the survey were used to develop the weighted average price or value for each grade of phosphate rock sold or used in the domestic market or exported. The average annual price for phosphate rock in 1950 was $5.67 per ton and gradually increased to $7.42 per ton by 1966. In 1967, the average price started to decline progressively and, by 1972, bottomed out at $5.62 per ton. In 1973, the average price of phosphate rock followed a slight upward trend, reflecting the variation in supply and demand. In 1974, the price of phosphate rock continued a 2-year trend of sharp increases and averaged four times greater than the 1973 level, reaching the $25-per-ton mark for 1975. The dramatic increase in price was attributed to an arbitrary price increase by Morocco's Office Cherifien des Phosphate for exported phosphate rock. Although the price declined to $17.39 per ton in 1977, cost increases caused the price to level off at more than $20 per ton in 1979; the price peaked again in 1981 to $26.63 per ton, reaching a record-high level due to a strong demand. The price gradually declined to $19.37 per ton in 1987 and increased to $23.20 per ton in 1990. The price for phosphate rock followed a slight downward trend throughout 1991 and 1992 and for 1993 was $21.38 per ton. *(See tables 7, 8, and 9.)*

In 1993, prices of phosphate-based fertilizer products were low. DAP, the main phosphate fertilizer traded commodity, was selling at about $120 per ton in central Florida compared with about $150 per ton in January 1992. By mid-April, the price reached $110 per ton, the lowest in two decades. Low prices were attributed to lower demand for fertilizer products, an international market flooded with fertilizer products from the former U.S.S.R. in search of hard currency, and a compounded effect resulting from fewer fertilizer products bought by China and India.

Low prices and demand forced the phosphate industry to consolidate operations, close plants, and/or cutback on fertilizer products. Production cuts were necessary to turn depressed prices around. Since July, prices followed an upward trend, and at the end of December, DAP was quoted at more than $150 per ton in central Florida. The rise in fertilizer products prices did not trickle down to the phosphate rock prices. It usually takes more than 6 months of firm prices for the end products before the prices for raw materials gain ground.

Foreign Trade

Total exports of phosphate rock decreased about 14% from those in 1992. The major factor on exports of phosphate rock continued to be a lower demand for raw material, mainly triggered by closures of a number of phosphoric acid plants in Western Europe during 1992. These closures continued to affect the phosphate rock market in 1993. Exports of DAP, phosphoric acid, triple superphosphate, and elemental phosphorus decreased. Exports of monoammonium phosphate, however, increased by about 23% compared to those of 1992.

Imports of phosphate rock into the United States remained at about the same level in 1993 compared with those of 1992. The Bureau of the Census, however, supressed data on imports from Morocco into one U.S. customs district, which resulted in the artificially low import data shown in tables 1 and 17. The Moroccan Office Cherfien des Phospahtes reported exports of 1.46 million tons to the United States in 1993. *(See tables 10, 11, 12, 13, 14, 15, 16, and 17)*

World Review

World phosphate rock production decreased again in 1993 and was 20%

less than ouput in the peak year 1989. The decline in rock production was a consequence of lower phosphate fertilizer consumption worldwide. Morocco's phosphate rock exports were down by 8% compared to the level of 1992. However, Morocco's lower level of phosphate rock exports was probably due more to its built-up capacity for conversion of phosphate rock into other chemical products, rather than only a low international demand for raw materials. Preliminary estimated world phosphate fertilizer consumption showed a decline of about 6% in 1993 compared to that of the previous year. This was principally caused by reduced consumption in China and the former U.S.S.R. In Western Europe, during 1991, 1992, and 1993, phosphate rock imports decreased as a reflection of the closure or idling of various phosphoric acid plants with an annual capacity of more than 1.3 million tons P_2O_5. The acid plants were closed or idled for environmental and/or economic reasons. Closures of phosphoric acid plants during the previous 2 years had their final impact felt on phosphate rock production and trade in 1993.

Israel.—Fertilizers and Chemicals, a subsidiary of Israel Chemicals Ltd., formed a joint venture with Turkey's Trans Turk. The partners intended to build a plant in southern Turkey to produce liquid fertilizers. Fertilizers and Chemicals expected to have sales of more than $5 million in 1993.

Pakistan.—Fauji Fertilizer Co. (FFC), Pakistan, and Jordan Phosphate Mines Co. (JPMC), Jordan, have signed a memorandum of agreement to build a 200,000-ton-per-year phosphoric acid plant in Jordan and an ammonia, urea, and DAP facility at Port Qasim, Pakistan, with a capacity of 450,000 tons per year of DAP. The project cost was estimated at about $400 million. FFC was to own 65% of the phosphoric plant in Jordan and 75% of the facility in Pakistan, with the remaining 35% and 25%, respectively, to be owned by JPMC. The project cost was estimated at about $400 millon; plants in both countries were expected to start production by 1996.

Russia.—Phosphate concentrate production capacity of Production Association Apatit (P.O. Apatit) decreased by about 20% owing to the closure of the company's apatite-nepheline beneficiation plant No. 1, in January 1993. P.O. Apatit is Russia's largest producer of high-quality phosphate rock concentrates.

The U.S. Bureau of Mines estimates of world phosphate rock reserves and the reserve base are shown in table 19. Included are reserves and reserve base estimates with costs of less than $40 and $100 per ton, respectively. *(See tables 18, 19, and 20.)*

Current Research

The U.S. Bureau of Mines, research center in Tuscaloosa, AL, conducted research in an attempt to prevent loss of coarse phosphate in a flotation circuit. The results of this study to reexamine the conditioning of coarse Florida phosphate has determined that the mixing intensity of the conditioner affects the P_2O_5 rougher concentrate grade and recovery. The study also showed that removal of the residual clay or fine particles from the coarse flotation feed material resulted in a lower reagent consumption that could offset the added cost of scrubbing and/or elutriation. Optimizing the conditioning time, mixing intensity, and other conditioning parameters resulted in a rough phosphate concentrate grading 30% P_2O_5 with a total recovery of 95%.[6]

OUTLOOK

World production and consumption has declined steadily since 1989, primarily as a result of the sociopolitical restructuring of the economies of Eastern Europe and the former U.S.S.R. In addition, Western European imports were affected by the closure of a number of phosphoric acid plants the previous year that continued affecting the demand for phosphate rock. North American consumption of phosphate fertilizers has followed a downward trend in recent years as farmers learned to apply fertilizers following recommended procedures to optimize crop yield.

Significant dislocations worldwide have contributed to the decline in phosphate production, consumption, and trade. Despite all the negatives mentioned, the balance between supply and demand shifted in favor of the fertilizer producers during the last quarter of 1993. China resumed its levels of acquisition after almost a year of backcuts, and India, the second largest importer, increased fertilizer imports during the last part of 1993. The importance of having these two countries back into the international market cannot be ignored; these countries are recipients of about one-half the U.S. phosphate exports.

Based on the market recovery for phosphate fertilizer products that occurred during the last quarter of 1993, the outlook for domestic phosphate-based fertilizers within the next 2 to 3 years can be seen as optimistic. Farmers from the Midwestern States will need fertilizer to replace nutrients washed out by the worst flood in 100 years that took place in 1993. A modest increase in phosphate rock trade for 1994 is forecast. However, in the long term, phosphate rock trade will probably continue to decline. The continuing growth in world population will require increased use of fertilizer for food production. The long-term growth in phosphate-based fertilizers production should average between 1.5% to 2.0% annually beginning in 1996.

[e] Estimated. [r] Revised.

[1] Table includes data available through May 13, 1994. Data for major phosphate rock-producing countries derived in part from the International Fertilizer Industry Association; other figures are from official country sources where available.

[2] In addition to the countries listed, Belgium may have produced small quantities of phosphate rock and Namibia may have produced small quantities of guano, but output is not officially reported, and available information is inadequate for formulation of reliable estimates of output levels.

[3] Less than 1/2 unit.

[4] Beneficiated.

[5] Includes only output used to manufacture fertilizers.

[6] Production from Western Sahara area is included.

[7] Reported figure.

[8] Does not include aluminum phosphate production, gross weight estimated as follows in thousand metric tons: 1989—140; 1990—127; 1991—92; 1992—75 (revised); and 1993—75.

[9] Dissolved in Dec. 1991.

PLATINUM-GROUP METALS

By J. Roger Loebenstein

Mr. Loebenstein, a physical scientist with 19 years of industry and U.S. Bureau of Mines experience, has been the commodity specialist for platinum-group metals for 13 years. Domestic survey data were prepared by Evangeline Hemphill, statistical assistant; and international data tables were prepared by Harold Willis, international data coordinator.

Ore containing the platinum-group metals (PGM) was mined, concentrated, and smelted in Montana, and the resultant PGM matte was exported to Belgium for refining and separation of the individual PGM. In addition, PGM were recovered as byproducts of copper refining by two companies in Texas and Utah. Domestic mine production of PGM was valued at $47 million in 1993.

Secondary metal was refined by about 20 firms, mostly on the east and west coasts. About 4,800 kilograms (kg) of PGM was refined from scrap on a nontoll basis. The quantity of toll-refined secondary was 13 times larger, amounting to about 61,000 kg.

PGM were sold by at least 90 processors and dealers, largely in the northeast, and were used primarily in the automotive, electrical/electronic, dental/medical, chemical, jewelry, and petroleum refining industries. The automotive, chemical, and petroleum-refining industries used PGM mainly as catalysts. The other industries used them in a variety of ways that took advantage of their chemical inertness and refractory properties.

Dealer prices for iridium, rhodium, and ruthenium continued to decline in 1993, while prices for palladium and platinum increased somewhat. The annual average price for rhodium, $1,066 per troy ounce, was the lowest since 1989.

PGM were mined in at least 10 countries in 1993; production was dominated by the Republic of South Africa, which accounted for 60% of the world total, and Russia, which accounted for 30%. Platinum and palladium amounted to 49% and 42%, respectively, of all PGM mined, and the other four metals—iridium, osmium, rhodium, and ruthenium—together amounted to 9%.

Identified world PGM resources at yearend 1993 were estimated jointly by the U.S. Geological Survey and U.S. Bureau of Mines (USBM) at 100 million kg. The reserve base was estimated by the USBM at 66 million kg and reserves at 56 million kg. Of the reserve base and the reserves, the Republic of South Africa had nearly 90% of each; Russia had 9 and 11%, respectively; and the United States had 1% and 0.4%, respectively.

DOMESTIC DATA COVERAGE

Domestic production data for PGM are developed by the USBM from a voluntary survey of U.S. refiners. Of the 13 refiners to which a survey request was sent, 8 responded. These respondents represent 62% of the total refined metal production shown in tables 1 and 2. Production for nonrespondents was estimated using prior-year levels adjusted for general industry trends. *(See tables 1 and 2.)*

ANNUAL REVIEW

Strategic Considerations

Although some platinum and palladium were produced at the only PGM mine in the United States, the Stillwater Mine, the great majority of PGM consumed in the United States was imported.

Inventories of platinum, palladium, and iridium in the National Defense Stockpile remained unchanged in 1993, as shown in table 1. No purchases of rhodium or ruthenium were made, even though there are unmet stockpile goals for these two metals.

Consumption and Uses

Reported sales of PGM by refiners is shown in table 3. For comparison, the calculated apparent consumption of the individual PGM also is shown. *(See table 3.)*

Automotive demand for platinum, palladium, and rhodium was estimated on the basis of 10.4 million automobiles and light trucks produced in 1993, the quantities and proportions of the three metals differing from model to model. While the trend toward palladium-only autocatalysts—reportedly suitable only for smaller vehicles—continued, most autocatalysts still contained all three metals or a combination of platinum and rhodium.

Federal standards require that medium-duty trucks, beginning with model year 1994, be fitted with catalysts. International Catalyst Technology Inc., a joint subsidiary of Degussa (Germany) and Nippon Shokubai (Japan), started producion of diesel catalysts for the North American market in Calvert City, KY, at a rate of 3 million catalyst units per year. Engelhard Corp., in Huntsville, AL, and Johnson Matthey PLC, in Wayne, PA, also produced diesel catalysts. *(See table 4.)*

Markets and Prices

There was some tightness in the world palladium market because of greater demand by the automotive and electronics industries. The average annual dealer price for palladium rose $33, to $120 per troy ounce. In contrast, average monthly dealer prices for rhodium declined substantially, dropping below $1,000 per ounce for 7 months of the year.[1] The average annual dealer price was $1,066, thus remaining more than $1,000 per ounce for the eighth consecutive year. The world supply of rhodium exceeded demand significantly for the second consecutive year despite a 16% increase in world autocatalyst demand.[2]

Foreign Trade

U.S. imports of palladium rose 29% in 1993. U.S. exports of palladium rose 48%, spurred by higher demand for palladium for use in automobile catalysts in Europe and for dental and electrical uses in Japan. *(See tables 5 and 6.)*

World Review

North American Palladium Ltd. (formerly Madeline Mines) started up its open pit PGM mine, 81 kilometers north of Thunder Bay, Ontario, Canada. At full production in 1994, the mine was expected to yield 3,100 kg of palladium and 230 kg of platinum annually.[3]

In the Republic of South Africa, Rustenburg Platinum Mines Ltd., in response to weak platinum demand, closed its Boschfontein shaft, a move that reduced its platinum production by about 8,000 kg. The mine reportedly was a high-cost producer. Also, Rustenburg brought the open pit Potgietersrust Mine on-stream. The mine reportedly is one of the lowest cost producers in the industry. Initial annual production was projected at 5,300 kg of platinum, 5,100 kg of palladium, and 400 kg of rhodium, along with subsidiary copper, gold, and nickel. *(See table 7.)*

Current Research

A new alloy of palladium, ruthenium, and zirconium having extraordinary wear characteristics was developed at the Paffenbarger Research Center, National Institute of Standards and Technology, in Gaithersburg, MD.[4] The patent for the new alloy is held by the American Dental Association Health Foundation, sponsor of the research. The alloy has no known toxic reactions with human tissue and is strong enough to be used surgically for tooth, hip, and knee implants. It also could be used as an industrial coating for high-performance bearings and mechanical joints.

OUTLOOK

Future demand for PGM is expected to continue to grow worldwide, given the strong demand for a cleaner environment. Catalytic converters for controlling emissions from gasoline-powered automobiles are currently used in Australia, Canada, Japan, Mexico, the Republic of Korea, Taiwan, the United States, and several Western European nations. Brazil, Hong Kong, Indonesia, Malaysia, Singapore, and Thailand are expected to start using catalytic converters in the very near future. The potential market for the catalytic converter is huge—there are 500 million motor vehicles worldwide. The use of palladium is growing because the wider use of cleaner, lead-free fuels permits its use as a substitute for more expensive platinum. However, platinum will probably continue to remain the dominant metal in catalytic converters for some time in the future. The advantage in price that palladium has over platinum is somewhat negated by the necessity of using as much as three times more palladium than platinum to achieve the desired reduction in emissions.

The world market for diesel catalysts, now $30 million to $40 million per year, is expected to double by 1998.

In the United States, California has for years had the most stringent automobile emission regulations, setting the tone for Federal standards. California will require that 2% of new vehicles sold in the State in 1998 be "zero-emission" vehicles. The percentage is scheduled to increase to 5% in 2001, and to 10% in 2003. Electric vehicles are being studied as a way to meet the zero-emissions requirement.

[e] Estimated. [r] Revised. W Withheld to avoid disclosing company proprietary data.

[1] The platinum group comprises six metals: platinum, palladium, iridium, osmium, rhodium, and ruthenium.

[2] Estimates for the Stillwater Mine are from published sources. A very small quantity of byproduct platinum and palladium produced from gold-copper ores was excluded.

[3] Value based on dealer prices.

[4] Data do not add to total shown because of independent rounding.

[5] Excludes ores and scrap.

[6] Quantities for general imports and imports for consumption are identical.

[7] Includes mine production plus nontoll-refined production plus refined imports for consumption minus refined exports plus or minus changes in Government and industry stocks.

[8] Refined imports for consumption minus refined exports plus or minus changes in Government and industry stocks.

[r] Revised. W Witheld to avoid disclosing company proprietary data.

[1] Comprises primary and nontoll-refined secondary metals.

[2] Data may not add to totals shown because of independent rounding.

[3] Defined as mine production plus nontoll production of secondary metal plus refined imports minus refined exports plus beginning stocks minus ending stocks. Export data for iridium, osmium, and ruthenium are not available separately; in this calculation, the collective export figure was assigned to ruthenium.

[4] 1989-93 platinum, palladium, and rhodium sales to the automotive industry are estimated based on U.S. light truck sales and U.S. automobile production.

[5] Withheld to avoid disclosing company proprietary data; included in "Total."

TABLE 4
REFINER, IMPORTER, AND DEALER STOCKS OF REFINED PLATINUM-GROUP METALS[1] IN THE UNITED STATES, DECEMBER 31

TABLE 7—Continued

PLATINUM-GROUP METALS: WORLD PRODUCTION, BY COUNTRY[1]

(Kilograms)

Country[2]	1989	1990	1991	1992	1993[e]
Grand total[14]—continued:					
Of which:					
Platinum	122,994	128,611	[r]128,065	[r]132,296	122,141
Palladium	131,889	135,207	134,192	[r]124,835	106,170
Other	26,746	27,196	26,086	[r]24,307	22,407

[e]Estimated. [r]Revised.

[1] Table includes data available through May 25, 1994. Platinum-group metal production by Germany (Western states), Norway, and the United Kingdom is not included in this table because the production is derived wholly from imported metallurgical products and to include it would result in double counting.

[2] In addition to the countries listed, China, Indonesia, Papua New Guinea, and the Philippines are believed to produce platinum-group metals, and several other countries may also do so, but output is not reported quantitatively, and there is no reliable basis for the formulation of estimates of output levels. However, a part of this output not specifically reported by country is presumably included in this table credited to Japan. (See footnote 7).

[3] Partial figure; excludes platinum-group metals recovered in other countries from nickel ore of Australian origin; however, a part of this output may be credited to Japan. (See footnote 7).

[4] Unless otherwise indicated, data show estimated proportions of platinum, palladium, and other platinum-group metals within the reported total.

[5] Reported preliminary estimate.

[6] Data are for years ending July 7 of the years listed.

[7] Japanese figures do not refer to Japanese mine production, but rather represent Japanese smelter-refinery recovery from ores originating in a number of countries; this output cannot be credited to the country of origin because of a lack of data. Countries producing and exporting such ores to Japan include (but are not necessarily limited to) Australia, Canada, Indonesia, Papua New Guinea, and the Philippines. Output from ores of Australian, Indonesian, Papua New Guinean, and Philippine origin are not duplicative, but output from Canadian material might duplicate a part of reported Canadian production.

[8] All production in the U.S.S.R. from 1989-91 came from Russia.

[9] All production in Yugoslavia from 1989-91 came from Serbia and Montenegro.

[10] Includes osmiridium produced in gold mines.

[11] Dissolved in Dec. 1991.

[12] Estimates for the Stillwater Mine, from published sources. A very small quantity of byproduct platinum and palladium produced from gold-copper ores was excluded.

[13] Dissolved in Apr. 1992.

[14] Data may not add to totals shown because of independent rounding.

POTASH

By James P. Searls

Mr. Searls, a physical scientist and economist, has been a commodity specialist for 14 years. Domestic survey data were prepared by Kelly Dorney, statistical assistant; and international data were prepared by Theodore Spittal, international data coordinator.

Potash is the third of the three essential nutrients for plant growth, fixed nitrogen, phosphorus, and potassium. There are no substitutes for these elements in lifeforms on this Earth. As fertilizers they are essential to the intensive agriculture system, which has allowed more people to live on the production of more food from less crop area.

U.S. potash production in terms of potassium oxide (K_2O) equivalent decreased about 12% compared with that of 1992 because of the permanent closure of a Carlsbad, NM, muriate of potash mine. Apparent consumption increased about 2% in spite of the summer floods because of relatively greater autumn applications of potash. Prices increased less than 2% owing to larger amounts of sulfate of potash (SOP) and sulfate of potash magnesia being sold relative to muriate of potash sales and the much higher unit prices for SOP and sulfate of potash magnesia. Yearend producers' stocks increased about 8% in terms of tons, K_2O.

DOMESTIC DATA COVERAGE

The U.S. Bureau of Mines developed potash domestic data from voluntary semiannual surveys of U.S. operations. Of the 12 survey requests sent to operations in the first half of the year, 10 responded, and data concerning the 11th was provided by another U.S. Department of the Interior agency. In the second half of the year, the 11th company was not in production. The 12th operation was estimated in both the first and second half of the year. Responses to the U.S. Bureau of Mines surveys and data from another agency provided about 97% of total production shown in table 3.

ANNUAL REVIEW

Issues

A muriate of potash operation closed permanently in April, and a receiver occupied the premises. The receiver sold movable equipment, but not plant or real estate, by auction in December. The holder of the bond for reclamation and abandonment refused to perform under the bond at the end of the year.

The Carlsbad potash industry considered an antidumping action against the former U.S.S.R. but filed a petition to the President under Section 406(d) of the Trade Act of 1974 for consultations with Belarus, Russia, and Ukraine. The Russian Foreign Economic Relations Ministry agreed to the concept of consultations, but consultations were not held concerning potash in 1993.

The suspension of the antidumping investigation against the Canadian potash producers by the U.S. Department of Commerce, International Trade Agency, was continued for another year.

Several civil antitrust lawsuits were filled in California, Illinois, Minnesota, and New York in April. The cases were consolidated into one case in the Federal District Court in St. Paul, MN, where all information from a former employee for Potash Corp. of Saskatchewan (PCS) was considered tainting and disqualifying; all lawyers having direct or indirect contact with the former General Counsel were disqualified.

The U.S. Department of Justice, Anti-Trust Division, convened a grand jury in Cleveland, OH, to hear evidence concerning allegations of antitrust behavior by U.S. producers. Subpoenas were issued for company records concerning possible criminal activity.

Production

Domestic potash production, in terms of K_2O content, declined about 12% to 1.5 million metric tons[1] in 1993 from that in 1992. *(See tables 1 and 2.)* Of the total production for the year, 66% was standard, coarse, and granular muriate of potash (MOP), also known as potassium chloride (KCl), and 17% was SOP, also known as potassium sulfate. The remaining 17% of production included manure salts, soluble and chemical grades of muriate of potash, and sulfate of potash magnesia, also known as potassium magnesium sulfate. In muriate of potash, "standard," "coarse," and "granular" refer to their particle sizes and are known as the three muriates, a term that ignores the soluble and chemical grades. "Standard" and "soluble" grades of muriate of potash and sulfate of potash also have industrial end uses. "Manure salts" formerly referred to high-grade "run-of-mine" ore and was applied to a few crops; 25% K_2O sylvinite ore is approximately 40% KCl, which can be used on sugar beets. Currently, it refers to a mixture of white KCl and sodium chloride (NaCl or table salt) for industrial uses.

The New Mexico potash producers accounted for 81% of the total marketable potash salts production. The production of crude salts (ore) in New Mexico was 13.0 million tons, excluding Horizon Potash Corp.'s crude ore production, with an average K_2O content of 12.5%, a 2% decrease in ore grade from that of 1992. Four producers operated five mines at the end of 1993. *(See table 3.)* Horizon shut down permanently on April 23d, the day the petition for consultation with the potash producers of Belarus, Russia, and Ukraine was filed with the Office of the U.S. Trade Representative. The company cited the low price of potash in the southern United States and Latin America for its demise. About 340 employees were laid off. Other producers were Eddy Potash Inc., owned by Trans-Resources Inc.; IMC Fertilizers Inc. (IMCF); Mississippi Potash, Inc.; New Mexico Potash Corp., owned by Trans-Resources Inc.; and Western Ag-Minerals Co., owned by Rayrock Resources of Toronto, Canada. Mississippi Chemical Corp.'s potash mine became Mississippi Potash, Inc., a separate subsidiary on July 1. Mississippi Potash announced plans in August to (1) increase production by operating at full capacity rather than 10 days on and 4 days off, and (2) install a compactor bought from the closed potash refinery to increase granular MOP capacity. Mississippi Potash has more than 100 years of reserves and plans to serve some of the closed mine's former customers. *(See table 4.)*

All the New Mexico potash producers mined underground bedded ore zones and all except Western Ag-Minerals mined sylvinite ore (the mixture of sylvite and halite) from which muriate of potash originates and beneficiated the ore to 95%-pure (60% K_2O) muriate of potash. Several forms of beneficiation were used; the flotation of sylvite (potassium chloride) from halite (sodium chloride) was used at Eddy Potash and Mississippi Potash. The IMCF plant used both heavy-media separation and flotation. New Mexico Potash used hydrocyclones to wash away some of the 6% clay in the ore, leached the sylvite crystals, separated more clay in hydrocyclones and thickeners, then produced white muriate of potash in crystallizers. Western Ag-Minerals mined langbeinite ore and beneficiated the ore by dissolving the halite with water to liberate sulfate of potash magnesia (potassium magnesium sulfate). IMCF mined langbeinite ore that was beneficiated by heavy-media separation and flotation to produce sulfate of potash magnesia. With both langbeinite and sylvite products, IMCF reacted fractions of each potash product to produce sulfate of potash. Some muriate of potash from New Mexico was sold to a domestic potassium nitrate manufacturer who produced about 50,000 tons.

In Utah, Moab Salt Inc. produced muriate of potash for Texasgulf Inc., owned by Elf Aquitaine Inc., from an underground bedded sylvinite deposit by two-well solution mining and solar evaporation. The sylvinite salts from the solar ponds were beneficiated by flotation to separate sylvite from halite. Great Salt Lake Minerals Corp. (GSLMC), of Harris Chemical Group, produced sulfate of potash from the brines of the North Arm of the Great Salt Lake by solar evaporation and a proprietary process of fractional crystallization. GSLMC purchases muriate of potash from other sources for conversion to sulfate of potash owing to an excess of sulfate ions in the lake brine concentrate, but these purchases of muriate of potash were not factored into 1993 numbers owing to scheduling errors. The Reilly-Wendover operation of Reilly Industries produced muriate of potash and manure salts from near-surface brines at the west end of the Bonneville Lake.

In California, the muriate and sulfate of potash (and other products) operation at Searles Lake, owned by North American Chemical Corp. of Harris Chemical Group, continued to produce by solar evaporation and selective crystallization from the underground brines of the lake bed. This is the oldest (since 1915) inorganic potash production site in the United States.

In Michigan, Kalium Chemical Ltd. continued pilot plant efforts to develop the technology to extract and concentrate muriate of potash from a deep ore body.

Greensand, also known as glauconite, a natural silicate of aluminum, iron, magnesium, and potassium, was produced by Inversand Co., a subsidiary of Hungerford and Terry Inc., near Clayton, NJ. Production and sales information are withheld to avoid disclosing company proprietary data. Processed greensand was sold as a filter media for the removal of iron, manganese, and hydrogen sulfide from drinking water supply systems. Classified raw greensand was resold by Zook and Ranck Inc. as a soil conditioner and as a slowly released potash, with a K_2O equivalent between 5% and 10%, to the organic farmers of North America.

Consumption and Uses

According to the Potash & Phosphate Institute, shipments of agricultural potash from Canadian and United States producers increased by about 1% from 1992 to 1993. Shipments of nonagricultural potash increased 9% for a total (agricultural plus nonagricultural) increase of 2% from 1992 to 1993. The major States receiving agricultural potash from Canadian and United States producers, in decreasing order, were Illinois, Iowa, Ohio, Indiana, Minnesota, Missouri, and Wisconsin. *(See tables 5 and 6.)* These seven States received 53% of the total. Domestic producers accounted for 3% of agricultural shipments to Illinois, 4% of the agricultural shipments to Iowa, 7% of the agricultural shipments to Ohio, 5% of the agricultural shipments to Indiana, 1% of the agricultural shipments to Minnesota, 59% of the agricultural shipments to Missouri, and 1% of the agricultural shipments to Wisconsin. The major receiving States of domestically produced agricultural potash, in decreasing order, were Texas, Missouri, California, Kansas, Florida, Arkansas, and Louisiana, and these States received 63% of the total. The major States receiving domestically produced agricultural sulfates of potash (sulfate of potash and sulfate of potash magnesia) were, in decreasing order, Florida, California, Georgia, Kentucky, Ohio, and Texas. These six States accounted for 59% of the total. These figures do not account for the imports from the rest of the world. The potash import tonnage from the rest of the world is counted only at the port of entry and is not tracked to the State in which the potash is applied to the field.

The major States for shipments of nonagricultural potash from Canadian and United States producers, in decreasing order, were Alabama, Ohio, Delaware, Wisconsin, and Mississippi. These five States accounted for 75% of the total. Domestic producers supplied less than 1% of the first four States and 100% of Mississippi.

Stocks

Yearend producers' stocks increased 8% compared with those of 1992. Yearend stocks represented 20% of annual production or about 11 weeks of average production.

Prices

The average annual price, $193.06 per ton f.o.b. mine, of U.S. potash sales of all types and grades was about 2% greater than that of 1992. *(See table 7.)* The average price was $187.88 for the first half of the year and $200.91 for the second half of the year. The average annual price of the three grades of muriate was $127.84, down 6% from that of 1992. For the full calendar year standard grade averaged $130.56 per ton; coarse grade, $124.94 per ton; and granular grade, $126.95 per ton. The average annual price for all grades of sulfate of potash averaged $329.59 per ton, essentially unchanged.

Foreign Trade

Total potash exports from the United States as reported by the Bureau of the Census decreased 37% relative to those of 1992. *(See tables 8 and 9.)* Muriate of potash fell 49% and sulfate of potash fell 28%. Only sulfate of potash magnesia exports increased, about 14%. By half year, muriate of potash exports (in competition with the exports from the former U.S.S.R. states and others) to all countries decreased from 242,000 tons in the first half of 1992 to 184,000 tons in the second half of 1992, 121,000 tons in the first half of 1993, and 96,000 tons in the second half of 1993. Exports of muriate of potash to Latin America, where U.S. potash producers historically had transportation cost advantages, fell from 196,000 tons in the first half of 1992 to 148,000 tons in the second half of 1992, 100,000 tons in the first half of 1993, and finally 72,000 in the second half of 1993. Exports of muriate to Brazil declined from 106,000 tons in the first half of 1992 to 81,000 tons in the second half of 1992, 33,000 tons in the first half of 1993, and 29,000 tons in the second half of 1993. For 1993, 42% of all potash exports was muriate of potash shipments to Latin America while 17% of all potash exports was sulfate of potash shipments to the countries in and around the Pacific Ocean.

Potash imports for consumption into the United States as reported by the Bureau of the Census increased slightly relative to those of 1992. *(See tables 10 and 11.)* Imports of muriate of potash increased by less than 3% while sulfate of potash increased by nearly 29%. Potassium nitrate imports fell by 28%. Imports of muriate of potash from Canada increased to 3.84 million tons. Muriate of potash from Canada was about 90% of total potash imports and about 72% of total U.S. consumption of potash. Imports from the former U.S.S.R. (Russia, Belarus, and from those two countries passing through Latvia) rose by about 4% to 205,000 tons. These imports provided less than 5% of potash imports and less than 4% of total U.S. consumption of potash. Imports of muriate from Israel rose 94% to 142,000 tons.

World Review

World potash production was estimated to have declined about 13% from that of 1992. *(See table 12.)* Production has declined about 11 million tons in the past 5 years, a drop of 34.5% from the production level of 1988. World price, as exemplified by the per ton price of standard muriate of potash, f.o.b. Vancouver, Canada, was about $167 per ton ($100 per ton product) in January and February, jumping to about $182 per ton in March, and declining to about $177 per ton in December.[2] This price would have been lower had Canpotex Ltd. attempted to compete in the South American market where pricing was much lower.

Argentina.—Potasio Rio Colorado SA of Minera Tea has reported an ore grade of 27% to 28% K_2O. Minera Tea has written of a 150,000-ton-per-year K_2O muriate of potash for 25 years, which calculates to about a 5-million-ton reserve using solution mining technology. FMC Lithium International is investigating the Salar del Hombre Muerto for lithium production; potash may be a byproduct of the operation.

Belarus.—The potash producer in Belarus produced only 1.95 million tons from a capacity of 5.6 million tons in 1993 as it struggled with gas supply dislocations, reduced domestic consumption, and fluctuations in potash exports owing to several factors, such as loss of rail cars at new national boundaries, inability to coordinate train shipment arrivals with vessel arrivals, and transportation price increases. Domestic consumption has been suppressed partially because approximately one-quarter of the arable crop land was rendered unusable by fallout from the Chernobyl nuclear station accident in 1988. Potash was exported through the Latvian port of Ventspils. Belarus potash passed through Ventspils more easily than Russian potash. The Belarus potash producers announced their intent to jointly construct an exporting dock in Gdansk, Poland, with Gdansk port officials. Rail freight tariffs increased by 50% in October, but it is not clear how much this affected sales. Belarus sold through the export group AgroChemExport, a former state operation, through the year but the three large potash producers, including Beloruskalii, planned to form their own sales organization in 1994.

Bolivia.—FMC Lithium International has ceased consideration of the Salar de Uyuni for lithium production and the possible byproduct potash.

Brazil.—The potash mine in Sergipe Province was leased from Petrobrás S.A., the Brazilian national petroleum company, through its subsidiary Petrobrás Mineraçào S.A. (Petromisa) by Companhia Vale do Rio Doce, a state-owned mining company in January 1992. The operational branch is named Unidade Operacional do Rio Doce. The new operator planned to increase production, to a 180,000-ton-per-year rate, then up to a 300,000-ton-per-year rate. Reserves are estimated to be 12 million tons, and the ore grade was placed at 17.4% K_2O.

Canada.—From an annual capacity of 12 million tons per year, Canadian potash companies produced 6.85 million tons in response to sales of only 7 million tons and efforts to reduce relatively large end-of-year stocks. Mines at Cory and Lanigan operated at about 30% capacity, and the sum of all the Canadian potash mine temporary closures was 142 mineweeks.[3] The Canadian average unit value of muriate of potash sales was C$79 per ton of product (C$129.50 per ton K_2O), a decrease of C$6 per ton of product from that of 1992. Operations at Saskatchewan mines produced about 85% of Canada's total potash production while operations at New Brunswick mines produced the remaining 15%. The Potash Corp. of Saskatchewan (PCS), with mines in Saskatchewan and New Brunswick, operated at 40% capacity for the year to control product inventories.

Rio Algom Ltd. sold its Potash Co. of America mines to PCS in September for C$160 million plus C$30 million of working capital. The sale included the solution mine at Patience Lake in Saskatchewan, the underground Penobsquis Mine near Sussex, New Brunswick, and the warehouse and dock in St. John, New Brunswick. The PCS news release[4] mentioned that Patience Lake "...produced 300,281 tons with 89 employees" in 1992 while the New Brunswick mine's capacity was placed at 716,683 tons and produced 671,324 tons of product in 1992 with 350 employees. Production from the Patience Lake Mine continued to be exported through the Canpotex while production from the Sussex Mine continued to be exported independently. Kalium Chemical announced a 5-year, C$45 million conversion of capacity from agricultural sales to nonagricultural grades of potash. The Province of Saskatchewan sold its last shares of PCS stock in December, ending the Province's 17 years of potash involvement, just after PCS acquired more than 50% of Provincial potash capacity. Since the autumn of 1986, the Province has not been in active management and has sold off shares. Formed as a crown corporation in 1976 with the aim of acquiring one-half of the Provincial potash capacity, the firm lost C$103 million (operating loss was put at C$47 million) on sales of 3,765,000 tons of product (or about C$27.45 lost per ton) in 1986 and was quickly privatized. Big Quill Resources, the Saskatchewan potassium sulfate (SOP) producer on Big Quill Lake, announced expansion plans, from 2,000 tons per year to about 10,000 tons per year, for an investment of C$550,000. It produced SOP from MOP and Big Quill Lake water, which is rich in sulfate ions, using ion exchange technology. Entreprise Minière et Chimique reported that Potacan Mining Co.'s Clover Hill Mine in New Brunswick reached profitability in 1992, earning C$9.2 million.

In April, there were several civil antitrust suits filed against the Canadian (and most of the United States) potash producers. The suits were filed in New York and Minnesota on behalf of several small fertilizer retailers. It was consolidated into one suit, including a later California suit, in U.S. District Court in St. Paul, MN. In December, any information from a former employee of PCS who was general counsel for some period of time was disqualified by the Federal judge for violating ethical obligations, and any lawyer who received information from that lawyer was declared tainted. The remaining lawyers had the option to refile an amended complaint. In November, both the Canadian Director of Investigation and Research, under the Competition Act, and the U.S. Justice Department's Anti-Trust Division commenced investigations of their respective potash industries.

Chile.—Minera Yolanda Ltda. received $9 million ($7 million in loans and $2 million in equity financing) from the Inter-American Investment Corp. for development of surface deposits of nitrates and iodine. The property is known as the Taltal Project, and Kap Resources Ltd. of Vancouver, British Columbia, Canada, continued to develop the property. Potassium nitrate, sodium nitrate, and iodine were the projected coproducts. Sociedad Quimica y Minera S.A. (Soquimich) purchased Molibdenos y Metales' 11.25% portion of the Minsal project, giving Soquimich 75% ownership of the property.

China.—Israel and China reported studies of a sulfate of potash project in southern China. China was considering participating in a 90,000-ton-per-year potassium nitrate expansion plant at Mishor Rotem in Israel. The agreement between Israel and China concerning the Qinghai project for 480,000 tons of MOP was finalized in early October.

Eritrea.—Newly separated from Ethiopia after 30 years of civil war, Eritrea has asked any mining company for help with its economy by exploiting what few minerals it has, including potash resources in the Dallol region.

European Community.—The European Commission reopened the investigation of the prices of Russian MOP after being informed by Western European potash producers that Russian potash was suspected of being sold at prices lower than the 1992 minimum prices. The European Commission also reviewed the combination of West German and former East German potash companies. The Commission acknowledged, late in the year, the German market dominance by the combination but considered that the former East German companies could not compete very well alone or as owned by someone else. The West German and former East German potash mining companies were allowed to combine but told to discontinue cooperation with Entreprise Minière et Chimique, the French potash producer, in European sales and in exports through Kali-Export.

France.—Entreprise Minière et Chimique (EMC) reported losses of F500 million in 1992 due to former U.S.S.R. dumping, a 30% decrease in French potash consumption due to the Common Agricultural Policy, and a price drop in France. The company will continue to need subsidies from the state to provide retirement funds for the employees and operating funds until the last Alsatian mine closes in 2004. After that, the company intended to continue mining potash in New Brunswick and Manitoba, Canada. The Government of France started a divestiture program of 21 holdings, including Société Nationale Elf Aquitaine, which owns the U.S. firm Texasgulf Chemical Co., which owns a small potash mine in Utah.

Germany.—The European Commission on Monopolies allowed Kali & Salz and Mitteldeutsche Kali to form a single company, but the single company will have to compete with French potash throughout Europe. The Commission noted that German potash capacity has dropped to about 56% of the preunification total. The unification will cost DM1.5 billion, paid through Treuhandanstalt to the new company. Kali und Salz will have to withdraw from Kali Export. Only in the Potash Co. of Canada (Potacan) joint venture can Kali and Salz and EMC continue to cooperate, but potash from that mine must be marketed separately and competitively in Europe.

India.—In June, the Ministry of Agriculture announced a program for reduced subsidies for imported muriate of potash. The subsidy will be Rs1,000 per ton of MOP, reducing prices from the Rs4,600 to 4,900 range down to Rs3,600 to 3,900 range.

Israel.—Israel was considering building a potassium nitrate plant in southern China along with a potassium sulfate plant. Israel formed a joint venture with Alkim Alkali Kimya of Turkey to build a potassium sulfate plant in Turkey.

Jordan.—Arab Potash Co. Ltd. (APC) reported that potash was very important to the economy of Jordan. Potash exports accounted for 15% of total Jordan exports, and sales (all exports) were 3.3% of the Jordanian gross domestic product. APC announced plans in May to commence development of the bromine, magnesium, and sodium chloride resources of the Dead Sea. APC also has commenced studies for 75,000 tons per year of product of SOP in Safi or Aqaba and mentioned future plans for a potassium hydroxide, potassium carbonate, and potassium nitrate plant.

Russia.—The Russian agricultural economy was in turmoil as that economy continued to convert from planned production to independent production with no money and diminished state-allocated inputs. The producers of fertilizers, including potash, changed, temporarily, to exports to maintain production and cash-flow for the schools and hospitals of the mining towns. The potash production managers had to change managerial styles as they dealt with their changing cost structures and markets. Uralkalii (formerly Berezniki) and Sylvinit (formerly Solikamsk) combined produced 2.6 million tons from a capacity of 7.7 million tons.

Russian fertilizer consumption continued to decline as farmers did not receive free market prices for their production, therefore receiving little money for investment in fertilization. Russian potash shipments to Western Europe were restrained by a European Commission dumping duty. Potash exporters had to turn toward the rest of the world, especially Asia, to expand their market. India and China decreased imports in late 1992, and Russian potash exporters could only ship toward South America and Pacific Basin countries. A small but significant amount found its way into the Mississippi River Basin to add to U.S. potash producers' problems.

Some of Russia's potash exports passed through a Latvian port. Rail freight tariffs increased by 50% in October, but it is not clear how much this affected sales. Uralkali and Sylivinit sold through the export group AgroChemExport, a former state operation, throughout the year, but the three large potash producers, including Beloruskalii, planned to form their own sales organization in 1994.

Spain.—The workers of Potasas del Llobregat struck in February over plans to release 347 of the 850 miners employed. The mine is now part of Teneo, still part of Instituto Nacional de Industria (INI), the large state holding company. The Teneo group is the profitable portion of INI, and the release of 347 workers was part of the "profitablility" plan.

Turkey.—Alkim Alkali Kimya was investigating a joint project with the Dead Sea Works Ltd. of Israel. The joint venture was constructing a pilot plant to investigate the solvent extraction of SOP. For the present this would be a pilot plant effort in Turkey. If successful, the companies were considering a 75,000-ton-per-year plant.

United Kingdom.—Minorco SA of Luxembourg announced in September an asset swap with Anglo-American Corp. that would transfer ownership of Cleveland Potash Ltd. to Minorco.

OUTLOOK

The world potash industry was in a situation of overcapacity in 1993 and seemed likely to remain so for at least a decade. The United States will lose more capacity (another mine) before the year 2000, but also has a workable solution mine in central Michigan seeking a solution to an unspecified problem(s). It seems likely to start up before the year 2000 because it is extremely close to the world's largest potash-consuming area and will use a mining technology that is relatively low cost. Some cautious development in Thailand may come on-stream around the turn of the century or shortly thereafter as a Canadian developer takes an in-depth look at the Udon Thani (silvinite) concession. The ASEAN Potash Mining Co. Ltd. (carnallite) concession in Thailand has problems with the disposition of magnesium chloride brine. The Government of China signed a joint venture with Israel to further develop the closed, nonmarine Qaidam Basin that contains Lake Qarhan; production on a large scale is still problematic. The Colorado River potash property in Argentina is apparently a small but high-quality resource in an undeveloped area. It will probably be viable when the region has more infrastructure.

RARE EARTHS
THE LANTHANIDES, YTTRIUM, AND SCANDIUM

By James B. Hedrick

Mr. Hedrick is a physical scientist in the Branch of Industrial Minerals. He has been the commodity specialist for rare earths since 1981. Domestic survey data were prepared by Ms. Debra A. Nolan, management analyst, Kelly A. Dorney, management analyst, and Eraina C. Dixon, supervisory statistical assistant. The international data tables were prepared by Mr. Harold Willis, international data analyst.

The rare earths are a relatively abundant group of elements that range in crustal abundance from cerium, the 25th most abundant element of the common elements at 60 parts per million, to lutetium, the 61st most abundant element at 0.5 part per million. The rare earths were discovered in 1787 by Swedish Army Lieutenant Karl Axel Arrhenius when he collected the black mineral ytterbite (later renamed gadolinite) from a feldspar and quartz mine near the village of Ytterby, Sweden. With similar chemical structures, the rare-earth elements proved difficult to separate. It was not until 1794 that the first element, an impure yttrium oxide, was isolated from ytterbite by Finnish chemist Johann Gadolin. The rare earths are iron gray to silvery lustrous metals; typically soft, malleable, and ductile; and usually reactive, especially at elevated temperatures or when finely divided. Melting points range from 798°C for cerium, which at atmospheric pressure is denser as a liquid than as a solid, to 1,663°C for lutetium. The rare earths' unique properties are used in a wide variety of applications.

Domestic mine production of rare earths decreased in 1993. The domestic economy continued to recover slowly during the year and inflation rose a modest 2.5%. Estimated domestic apparent consumption decreased 21%; however, earnings by the major domestic processor reportedly increased amid a slight decline in sales. *(See table 1.)* Demand increased for rare earths used in petroleum fluid cracking catalysts, automotive catalytic converters, permanent magnets, and television and lighting phosphors. Demand decreased for rare earths in automotive UV glass applications.

The domestic use of scandium in 1993 remained small. Commercial demand remained extremely small, with most metal and compounds sold for research and analytical standards. Minor amounts were used in specialty lighting and semiconductors.

DOMESTIC DATA COVERAGE

Domestic mine production data for rare earths are developed by the U.S. Bureau of Mines (USBM) from the voluntary survey, "Rare Earths, Thorium, and Scandium." The two mines to which a survey form was sent responded, representing 100% of known mine production. Mine production data are withheld to avoid disclosing company proprietary data.

BACKGROUND

Definitions, Grades, and Specifications

The rare earths are defined by the USBM as a group of 17 elements composed of scandium, yttrium, and the lanthanides. Rare earths are classified chemically as members of the IIIB subgroup of the periodic table.[1]

Scandium, atomic number 21, is the lightest rare earth. It is the 31st most abundant element in the Earth's crust with an average crustal abundance of 22 parts per million. Although its occurrence in crustal rocks is greater than lead, mercury, and the precious metals, scandium occurs widely dispersed in the lithosphere and has no affinity to combine with the common ore-forming anions. It is a member of the first transition series of elements.

Yttrium, atomic number 39, is chemically similar to the lanthanides and commonly occurs in the same minerals. The average concentration of yttrium in the Earth's crust is 33 parts per million, the second most abundant rare earth in the Earth's crust. Yttrium is a member of the Second Transition Series.

The lanthanides comprise a group of 15 elements with atomic numbers 57 through 71, and include: lanthanum, cerium, praseodymium, neodymium, promethium, samarium, europium, gadolinium, terbium, dysprosium, holmium, erbium, thulium, ytterbium, and lutetium. The lanthanides are part of the Third Transition Series. Cerium, the most abundant of the group at 60 parts per million, is more abundant than copper and lead. Thulium, the least abundant of the lanthanides at 0.48 part per million, occurs in the Earth's crust in higher concentrations than bismuth, indium, selenium, and silver.

Based largely on trivalent ionic radii, the rare-earth elements are broadly classified into two groups: the light rare-earth elements (LREE) or cerium subgroup, composed of the first seven lanthanides (atomic numbers 57 through 63) and the heavy rare-earth elements (HREE) or yttrium subgroup, composed of the remaining lanthanides and yttrium (atomic numbers 64 through 71 and 39). Yttrium is classed with the heavy subgroup because of its occurrence, ionic radius, and other similar properties.

Bastnasite can theoretically contain 74.81% rare-earth oxide (REO).[2] Flotation concentrates of bastnasite average 60% REO, which can be upgraded to 70% REO by acid leaching and to 85% REO by a combination of acid leaching and calcining.

Monazite can theoretically contain 69.73% REO. Monazite concentrate usually is sold at 55% minimum REO contained plus thorium, with product grading from 55% to 65% REO. Thorium contents are variable, but typically occur in the range of 4% to 10% equivalent thorium oxide.

Xenotime can theoretically contain 61.40% yttrium oxide. However, xenotime concentrates from Southeast Asia and Australia typically contain 25% to 30% yttrium oxide. Xenotime commonly is upgraded by acid leaching to produce an yttrium concentrate grading 60% yttrium oxide and the balance comprised primarily of other rare earths.

Various metallic rare-earth products are produced. The term "mischmetal" is used to denote a mixture of rare-earth elements in metallic form. It generally has the same ratio of rare-earth elements as that found in the ore and is typically 98% to 99% pure. Recently, a high-purity "battery-grade" mischmetal was produced to supply the market for rechargeable rare-earth-nickel hydride batteries.

Ferrocerium is a pyrophoric alloy of mischmetal and iron. A typical ferrocerium alloy contains 74% mischmetal, 23% iron, 2% copper, and 1% magnesium.

Rare-earth silicide is an alloy typically containing about one-third mischmetal, one-third iron, and one-third silicon. The rare-earth content of a silicide may be as high as 50%.

The rare-earth content of master alloys range from tenths of a percent in nodularizing alloys for ductile iron to tens of a percent in inoculants for gray cast iron. Alloys containing nearly 100% rare-earth metals, such as mischmetal, are additives to certain steels.

The purity of separated rare-earth elements, produced primarily by solvent extraction or ion exchange, usually grade 96% or higher in purity. High- purity rare-earth compounds and metals are produced up to 99.99999% purity. Rare-earth products grading higher than 99.9% purity are often produced to specification. As a result of the wide range of products in which rare earths are consumed, many grades of rare-earth concentrates, compounds, alloys, and metals are produced.

Products for Trade and Industry

A wide variety of products is available for trade and industry, including concentrates, individual and mixed compounds, and pure and alloyed metals. Bastnasite concentrate produced in the United States is available in three grades, an unleached concentrate grading 60% REO, an acid-leached concentrate containing 70% REO, and a calcined concentrate upgraded to 85% REO. A mixed bastnasite-monazite concentrate (predominantly bastnasite) from China is produced in three grades, a 30% minimum REO, a 60% minimum REO, and a 71% minimum REO.

Mixed compounds derived from bastnasite include rare-earth chloride, rare-earth nitrate, lanthanum-rare-earth carbonate, lanthanum carbonate, cerium carbonate, cerium nitrate, cerium fluoride, neodymium carbonate, neodymium fluoride, praseodymium fluoride, cerium-rare-earth hydrate, and rare-earth hydrate.

Monazite is marketed as a concentrate containing 55% to 60% minimum REO plus contained thorium. Mixed compounds produced from monazite include cerium chloride, ceric ammonium nitrate, ceric sulfate, cerium carbonate, cerium hydroxide, cerium nitrate, cerium octoate, rare-earth carbonate, lanthanum carbonate, lanthanum-neodymium carbonate, lanthanum-neodymium nitrate, neodymium carbonate, neodymium nitrate, praseodymium oxalate, rare-earth octoate, and yttrium nitrate.

Xenotime concentrate with a minimum 25% yttrium oxide content is a source of yttrium. It typically is upgraded chemically to a 60% yttrium oxide product known as yttrium concentrate, the balance of the concentrate being mostly other rare earths. The primary product derived from yttrium concentrate is high-purity yttrium oxide.

Rare-earth ion adsorption ore, produced in southern China, is the principal source of yttrium. The ores vary by locality, but two principal concentrates, an yttrium concentrate and an europium concentrate, are produced. The yttrium concentrate is enriched in the heavy rare earths and has greater than 60% yttrium oxide. Although the europium concentrate grades from 0.5% to nearly 1% europium oxide and 12% yttrium oxide, it is predominantly enriched in lanthanum oxide, 33% to 43%.

Individual rare-earth oxides and other compounds, except promethium, are produced from bastnasite, monazite, xenotime, and ion adsorption ore. Purities from 96% up to 99.9999% are available for most oxides. Compounds for almost all of the rare earths are available as oxides, acetates, carbonates, chlorides, fluorides, nitrates, oxalates, and sulfates.

High-purity rare-earth metals are marketed in the form of sponge, lump, ingot, crystal, rod, wire, chips, powder, sheet, foil, plate, sputtering plates, and custom cast and machined shapes. Alloys such as mischmetal, rare-earth silicide, ferrocerium, and other rare-earth alloys are available in a variety of ingot shapes and sizes.

Rare-earth magnet alloys are produced to individual requirements. Magnet alloys are marketed in ingot form, crushed ribbon, or may be purchased as mixed oxides for powder metallurgical processes. Magnets are available in finished and semifinished shapes, bonded and unbonded, and magnetized and unmagnetized.

Scandium is marketed primarily as a high-purity oxide. Oxide purities from 98% to 99.9999% have been produced in the United States. In addition to the oxide, scandium compounds are available as the acetate, acetylacetonate, bromide, carbonate, chloride, fluoride, hydride, iodide, nitrate, oxalate, and sulfate. Scandium metal is produced in ingot, powder, lump, and foil form.

Industry Structure

Few rare-earth companies are fully integrated. Rare earths are typically mined and processed by different companies. In the United States, Molycorp, Inc. is the only fully integrated producer from its mine, mill, and refinery at Mountain Pass, CA. The other principal producer, RGC (USA) Minerals Inc., operated a mine and wet and dry concentrating plants at Green Cove Springs, FL. Except for Molycorp, all other domestic refiners have operated independently.

Rare-earth ore is beneficiated by mine producers into concentrates that are sold directly to processors or, to a lesser extent, are sold to brokers for resale.

Rare-earth concentrates undergo extensive processing to produce mixed or separated compounds. The major processes used in separating rare earths are precipitation, solvent extraction (SX), and ion exchange (IX). Processors sell refined rare-earth products directly to consumers or brokers.

The scandium industry, for the most part, is separate and distinct from the lanthanide and yttrium industry. Its high-price and very limited demand have made scandium one of the smallest commodity markets in the world. Its limited demand has supported only intermittent mine production in the United States. As with lanthanides, the scandium industry is rarely fully integrated. Byproduct mine production in 1993 is reported only from China and the former Soviet Union. Minor amounts of scandium have been separated from lanthanide and yttrium ores, most scandium is produced as a byproduct from other ores. In the United States, scandium has been recovered as a byproduct during processing of uranium at a copper mine, from tailings from a mined-out fluorite mine, and from tungsten byproduct from a molybdenum operation. Tailings and concentrates from these sites were shipped to processors for production of high-purity scandium oxide and other compounds. Most scandium is sold in oxide form. A small group of companies produce scandium metal, primarily for lighting and research purposes.

Geology-Resources

Rare-earth minerals occur in a variety of geologic environments. Concentrations exist in igneous, sedimentary, and metamorphic rocks. Rare earths are mined primarily from igneous and sedimentary deposits. The geologic age of the deposits range from Recent to Precambrian.

The rare earths are constituents in more than 100 minerals, but only a few are recovered for commercial production. Bastnasite, monazite, xenotime, and rare-earth-bearing clay are the major sources of the world's rare-earth supply. Other sources are loparite, uraniferous phosphorites, synchisite, and byproduct solutions from processing uranium.

Bastnasite.—Bastnasite, a rare-earth fluocarbonate mineral, is found in vein deposits, contact metamorphic zones, pegmatites, and carbonatites. It is typically enriched in the LREE (Bastnasite-Ce); however, a rare HREE variety (Bastnasite-Y) is known from Kazakhstan. Bastnasite forms in the trigonal crystal system and ranges in color from yellow to reddish-brown. It has the following mineralogical properties: transparent to translucent; vitreous to greasy luster; density of 4.78 to 5.2 grams per cubic centimeter; and a hardness of 4 to 4½ on the Mohs scale.[3] It forms as an igneous or hydrothermal mineral and occurs as an accessory mineral in several large deposits. Deposits containing bastnasite as a high-grade accessory mineral are at Mountain Pass, CA, United States; Bayan Obo, Nei Monggol Autonomous Region, China; Wigu Hill, Tanzania; and Karonge, Burundi.[4] Bastnasite and other independent rare-earth minerals commonly form by hydrothermal processes, although its occurrence at Mountain Pass, CA, is considered primary igneous. Concentration of the rare earths can occur as a result of coprecipitation with calcium carbonate or by precipitation in the presence of fluorine. While the Mountain Pass bastnasite is believed to have formed by the coprecipitation process, the Bayan Obo's bastnasite is hydrothermal in origin and formed by alteration of dolomite in the presence of large amounts of fluorine.[5] Most of the world's rare earths resources are recovered from bastnasite.

Monazite.—Monazite, a rare-earth phosphate, is one of the most abundant rare-earth minerals. It occurs as an accessory mineral in granitic and metamorphic rocks, pegmatites, vein deposits, as a detrital mineral in placer deposits, and as a hydrothermal and supergene mineral in carbonatites. It is classified as a LREE and is usually enriched in cerium (Monazite-Ce). Rarer monazite varieties are a lanthanum-rich monazite (Monazite-La) and a neodymium-rich monazite (Monazite-Nd) described from Italy and from Marmara, Greece.[6] Monazite, which forms as a monoclinic mineral, is found in a wide range of colors, including honey yellow, greenish brown, reddish brown, yellowish brown, brown, pink, yellow, grayish white, dark grey, and black. It has the following mineralogical properties: transparent to subtranslucent; resinous, waxy, vitreous, or subadamantine luster; density of 4.6 to 5.4 grams per cubic centimeter; and a hardness of 5 to 5½ on the Mohs scale.[7] Monazite forms primarily as an accessory mineral in igneous and metamorphic rocks, including granites, gneisses, aplites, and pegmatites, and occasionally as a vein mineral (VanRhynsdorp, Republic of South Africa).

Economic placers develop where monazite has been weathered from its original host rock and concentrated by wind and water. Placer monazite is mined as a byproduct of titanium and zirconium minerals or tin minerals. Significant placer deposits are in

Australia, Brazil, Malaysia, Thailand, and the United States.[8]

Monazite of hydrothermal and supergene origin in carbonatites also represents a large rare-earth resource. Deposits of this type occur at Araxá, Minas Gerais, Brazil; Catalao I, Goiás, Brazil; Bayan Obo, Nei Monggol Autonomous Region, China; and Mount Weld, Western Australia, Australia.[9] Although China's Bayan Obo deposit is known primarily as the world's largest bastnasite deposit, it contains substantial tonnages of monazite. Formed by hydrothermal alteration of dolomite, the Bayan Obo monazite occurs in veins and stockworks in the footwall rocks.[10] One of the richest grade deposits in the world, the Mount Weld carbonatite grades 15 million metric tons at 11.2% REO, including a 1.3-million-metric-ton zone at 23.6% REO.[11] Enriched by supergene solutions, the deposit's primary ore minerals are secondary monazite and cheralite, along with lesser amounts of monazite, rhabdophane, cerianite, florencite, and churchite.

Technology

Exploration.—Commercial exploration for rare-earth minerals (primarily thorium) began in the 1880's, for the purpose of locating thorium and cerium for incandescent gas mantles. After electric lighting came into general use about 1912, demand for gas mantles fell. Subsequently, most rare-earth deposits have been located during the search for other minerals and metals, especially gold, ilmenite, rutile, uranium, and zircon.

Exploration methods to locate rare earths include surface and air reconnaissance with magnetometric, electromagnetic, and radiometric equipment. Other techniques include satellite imagery, aerial photography, and remote sensing. The application of geologic principles to develop depositional models is also used. After identifying a match for a depositional model or an indicator from one of the other methods, a ground survey of the region is conducted. A typical ground survey would include geologic mapping; rock, soil, and gas sampling; geophysical testing; surface radiometric surveying; and geochemical testing of the water, rocks, and plants.

Following visual identification of a rare-earth mineral, a systematic subsurface drilling and sampling program is conducted to determine ore grades. Individual rare-earth contents are analyzed by various assay methods, including X-ray fluorescence, instrumental neutron activation analysis, spark source mass spectrometry, and inductively coupled plasma and direct current plasma-atomic emission spectrometry.

Because rare-earth minerals are often associated with the radioactive elements uranium and thorium, many rare-earth deposits were discovered during exploration for these elements. Prospectors searching for radioactive minerals in California discovered bastnasite, which eventually led to the discovery of the Mountain Pass deposit.

Most monazite mineral sands deposits were discovered by exploring alluvial deposits using radiometric and magnetometric equipment. Discovery of buried alluvial deposits are typically located by depositional modeling.

Mining and Beneficiation.—Bastnasite is mined domestically as a primary product from a hard-rock carbonatite. The carbonatite is mined via bench-cut, open pit methods. Ore is drilled and blasted, loaded into trucks by rubber-tired loaders, and hauled to the mill. At the mill the ore is crushed, screened, and processed by flotation to produce a bastnasite concentrate.

In China, bastnasite and lesser amounts of associated monazite, also are mined from a hard-rock deposit. The ore is recovered as a byproduct of iron ore mining by open pit methods. After primary crushing at the mine site, the ore is transported by rail 135 kilometers southeast to the mill because of the scarcity of water at the mine site. A bastnasite concentrate and a mixed bastnasite-monazite concentrate are produced as flotation byproducts during processing for the iron ore.

Heavy-mineral sands are the source of most monazite and xenotime mined in the world. Most of these minerals are recovered by surface placer methods from unconsolidated sands. Almost all mining of these sands is done by floating cutterhead or bucket wheel dredges that concentrate the heavy minerals ("heavies") onboard and discharge the unwanted tailings back into previously mined areas. An onboard wet mill separates the "heavies" (specific gravity greater than 2.9) from the lighter weight fraction through a series of wet-gravity equipment that includes screens, hydrocyclones, spirals, and cones.

Consolidated and partially consolidated sand deposits that are too difficult to mine by dredging are mined by dry methods. Ore is stripped by typical earth-moving equipment such as dozers, scrapers, shovels, and loaders. Sand recovered by these techniques is crushed and screened and then processed by wet mill methods as describe above.

Wet mill product, a mixed heavy-mineral concentrate, is sent to a dry mill to separate the individual heavy minerals and produce a concentrate. Dry mill processing includes a combination of scrubbing, drying, screening, electrostatic, electromagnetic, magnetic, and gravity processes. Monazite, in contrast to ilmenite, rutile, and several other heavy minerals, is nonconductive and can be separated, with zircon, by electrostatic methods. Monazite, which is moderately susceptible to induced magnetism and may be slightly higher in specific gravity, can be separated from zircon by electromagnets or by additional gravity methods. Xenotime, which has a specific gravity and magnetic properties similar to monazite, usually is separated from monazite by precise gravity methods. Certain deposits also require an acid-leach treatment and calcining to eliminate iron oxide or other grain coatings.

Economic Factors

Prices.—Time-price relationships for bastnasite and monazite concentrates, based on 1993 constant dollars, were calculated based on U.S. Government implicit price deflators for gross domestic product. The 1993 price for bastnasite concentrate in real dollars remained unchanged from that of the previous year. Adjusting for inflation, bastnasite's price in terms of 1993 constant dollars decreased $0.07 per kilogram of REO from the previous year, the result of a $0.025 decrease in purchasing power per dollar. The 1993 price for monazite decreased $0.02 per kilogram of REO from last year's level. Adjusting for inflation, monazite's price in terms of 1993 constant dollars decreased $0.03 per kilogram of REO, the result of a $0.025 decrease in purchasing power per dollar. *(See figures 1 and 2.)*

Concentrates of bastnasite and monazite have traditionally been low priced. Significant value is added when the concentrates are separated into the individual REO's or other compounds. Mischmetal prices also have been historically low, with kilogram prices remaining in the $7 to $13 range over the past 21 years. Individual high-purity metals have commanded the highest prices of the rare-earth products. Metal prices typically run from two to six times the separated REO price.

Initially available in 1954, bastnasite concentrate was priced at $3.31 per kilogram. By the early 1960's, the development of the first major commercial applications for the rare earths caused its price to drop to less than $0.50. Bastnasite prices have increased progressively since that time, doubling in price between 1974 and 1980 as a result of the domestic energy crisis.

Monazite's price series is more complex than bastnasite's. As a byproduct, the supply and price of monazite is partially dependent on production and demand of the primary minerals. As a result of Australia's dominant position as a monazite producer, fluctuations in monazite's domestic price also are based on United States-Australian foreign exchange rates. Monazite's historical price trend displays an overall increase in price through 1985. In the 1950's, its price was $0.33 to $0.40 per kilogram of REO, decreasing to $0.22 to $0.33 per kilogram in the early 1960's. By the mid-1960's, monazite's price began to increase steadily, with a major increase appearing in 1985, the result of a weak Australian economy and increased competition for monazite supplies. Balanced supply and demand was seen in monazite's price through 1990. In 1991, however, a decline in monazite prices signaled an oversupply, the result of the availability of low-cost separated rare earths from China, a downturn in the U.S. economy, and the decision by a major domestic consumer to switch from monazite to a thorium-free rare-earth feed material. As a result of further decreases in demand, monazite's price continued to decline in 1992 and 1993, as a major foreign consumer switched to alternative feed material.

Costs.—U.S. mine and mill operating costs to produce concentrates of bastnasite and monazite differ substantially. The cost to mine bastnasite is greater than that for monazite. Bastnasite, as a primary product, incurs all costs of production, whereas monazite, as a byproduct, accounts for only a fraction of the production costs. The cost to recover monazite is based almost entirely on the expenses made to recover the primary minerals. Mine production costs for bastnasite are also higher than monazite because of the type of deposit. Costs to mine a hard-rock deposit (bastnasite) are significantly higher than mining a placer deposit (monazite).

Because both domestic mines have been in production for several years, mining costs are related mostly to direct costs, which include labor, mining equipment (trucks, drills, loaders, dredges, pumps, etc.), supplies (explosives, drill bits, etc.), and utilities (fuel, natural gas, water, and electricity). Capital expenditures for plant expansions and other major capital improvements represent the balance of significant costs. These costs commonly are added to long-term debt, but occur intermittently and are based typically on an increase in market demand.

Costs to comply with environmental regulations continue to increase. These costs are mostly indirect operating costs which include waste treatment and disposal, water purification, systems monitoring, reclamation, administration, and legal and technical personnel.

Tariffs.—U.S. tariff rates, specific to the rare earths, including scandium and yttrium, are unchanged for 1993 and 1994, except for certain special tariff revisions for Canada and Mexico. The regular tariff rates reflect results from the 1979 Tokyo Round of Multilateral Trade Negotiations under which the tariffs on many items were reduced in several stages over the period January 1, 1980, to January 1, 1987. Revisions to rare-earth tariffs for Canada and Mexico were the result of Presidential Proclamation 6641, implementing the North American Free Trade Agreement, effective January 1, 1994. Except for certain staged reductions for Canada and Mexico, tariff rates are expected to remain at present rates until the Uruguay Round of Multilateral Trade Negotiation are completed. The Uruguay Round of negotiations is expected to be completed in 1994 with new staged rate schedules taking effect in 1995. U.S. tariff rates for rare earths are listed in the Harmonized Tariff Schedule of the United States (1993), publication 2567, and the Harmonized Tariff Schedule of the United States (1994), supplement 1, publication 2690, as compiled by the U.S. International Trade Commission.

Depletion Provisions.—Depletion is defined as the exhaustion of mineral or oil and gas reserves by mining or drilling of wells and the resulting production from these mines or wells.[12] Depletion allowance is a tax deduction that may be taken against income provided by the U.S. Internal Revenue Code to compensate mining companies in the United States for decreasing capital brought about by production. The allowance is based on gross income.

There are two ways of figuring depletion allowance: cost depletion and percentage depletion.[13] Cost depletion is calculated by dividing the adjusted basis of the mineral property by the total number of recoverable units. Percentage depletion is figured by taking a percentage, specified for certain minerals (elements), of the gross income from the mineral property during the tax year. The depletion deduction may not be more than 50% of the taxable income from the property figured without the deduction.

The depletion allowance for monazite is 22% on the thorium content and 14% on the rare-earth content when mined from domestic deposits and 14% on the thorium content and 14% on the rare-earth content from foreign deposits.[14] Bastnasite's depletion allowance is 14% on the rare-earth content on both domestic and foreign production.

Operating Factors

Toxicity.—Rare-earth toxicity may be broadly classified into two groups—nonradioactive and radioactive. The relative risk is greater from nonradioactive rare earths because there are few naturally occurring radioactive isotopes. As a group, they are classified as slightly toxic.

Nonradioactive.—Toxicity of rare earths is dependent on the chemical form, its route of administration, and the individual rare earth.[15] Only limited data are available for humans, with most research acquired from experiments on small vertebrates. Overall, the rare earths are considered only slightly toxic.[16] Orally administered lanthanides are poorly absorbed by the gastrointestinal tract and have very low toxicity. Administered at levels as high as 1 to 10 grams of lanthanide oxides and lanthanide sulfates per kilogram (kg) of body weight, the compounds were not lethal to small vertebrates.[17]

Lanthanides administered by routes other than orally are absorbed at greater rates and are thus more toxic. Intravenous injection is the most toxic method. Pharmacologic responses to intravenous-administered lanthanides were calcification, hypotension, and hypoglycemia. Intravenous injection of salts of neodymium in humans caused increased blood coagulation times with toxic manifestations.[18] Intravenous injections of lanthanum chloride solutions in humans produced abdominal cramps, chills, fever, hemoglobinemia, hemoglobinuria, and muscle pain.[19] Intravenous injections of rare-earth nitrates (Ce, Pr, Nd, Sm, and Er) in rats were highly toxic compared to other routes of administration with a general decrease in toxicity with increasing atomic weight. The LREE salts were noted to be 7 to 11 times more toxic to female rats than male rats while the HREE erbium salt was only 1.5 times more toxic.[20] The production of skin and lung granulomas (in rats and mice) after exposure to oxides, fluorides, chlorides, and metals by prolonged breathing, intradermal or intraperitoneal injection, or subcutaneous implantation requires extensive protection to prevent exposure through cuts and abrasions of the skin or through inhalation. Symptoms of toxicity observed (in mice and rats) included anorexia, writhing, ataxia (loss of voluntary muscle control), diarrhea, dyspnea (labored respiration), walking on the toes with arched back, and sedation.

Humans exposed to airborne lanthanides reported itching, insensitivity to heat, and a sharpening of the senses of taste and smell.[21] Chronic exposure to lanthanide dust can lead to *rare-earth pneumoconiosis*.[22] This condition has been noted in those exposed to lanthanide oxide-bearing fumes from carbon arc lamps.

Intratracheal injections of 50 milligrams (mg) of a mixed lanthanide oxide into rats were 100% lethal within 24 hours, the result of pulmonary edema.[23] However, a similar injection of 200 mg/kg of the rare-earth ore monazite into mice produced no ill effects.[24] Extreme care also must be taken when exposed to finely divided rare-earth metals and metallic powders to avoid burns from rapid and possibly instantaneous oxidation, especially if inhaled. Certain finely divided rare-earth metals, alloys, and metal powders also may present the additional hazard of oxidizing rapidly enough to explode.

Radioactive.—Toxicity from rare earths also may occur from radioactive lanthanides. Only neodymium, samarium, gadolinium, and lutetium have naturally occurring radioactive isotopes.

The risk of toxicity from these natural isotopes is believed to be very low due to their extremely long half-lives and low radioactivity levels. Neodymium's one radioactive isotope, Nd^{144}, represents 23.85% of the naturally occurring material and is an alpha emitter. Samarium has three alpha emitting isotopes: Sm^{147}, Sm^{148}, and Sm^{149}, which represent 14.97%, 11.24%, and 13.83% of the naturally occurring material, respectively. Gadolinium's sole alpha emitting isotope is Gd^{152}, with an abundance of only 0.2% in naturally occuring gadolinium. Lutetium also has one radioactive isotope, Lu^{176}, with an abundance of 2.59% in naturally occuring lutetium. Lutetium is the only natural lanthanide isotope that decays by negative beta emission.

Manufactured rare-earth isotopes were produced primarily for use in nuclear medicine. The relative health risks for these materials varied depending on the application and dosage.

It should be noted that the rare earths often exist in ore and concentrates in association with other elements that have vastly different properties, including varying toxicities and possibly radioactive emissions. Care should be taken to assess the health factors associated with each substance present.

Employment.—Rare-earth mine and mill employment statistics, based on the domestic quarterly average number of employees on-site, are shown in figure 3. For the second consecutive year, rare-earth mining employment in the United States dropped, falling 4.8% from the previous year's level. The 1993 decrease was the result of several plant closings initiated by Molycorp, in 1992 and the closing of Nord Ilmenite Corp's Jackson, NJ, operation at yearend 1992. Data were furnished by the U.S. Department of Labor and compiled by the USBM.

(See figure 3.)

Productivity Trends.—The 11-year trend for U.S. rare-earth mine productivity, based on capacity utilization for bastnasite concentrate and monazite concentrate, are shown in figures 4 and 5.

Bastnasite production decreased in 1993, changing its previous 11-year productivity trend from a slight increase to a slight decrease. *(See figure 4.)*

The 11-year trend for domestic monazite capacity utilization continued to decline. The decline is primarily a function of continued decreased demand for monazite and continued depressed demand for the primary products. *(See figure 5.)*

ANNUAL REVIEW

Legislation and Government Programs

The calendar year 1993 included the U.S. Government fiscal years for 1993 and 1994. Public Law 102-484, the National Defense Authorization Act for Fiscal Year 1993, covered the year 1993 through September 30, and continued specific previous authorizations for disposal of stocks in the National Defense Stockpile (NDS) classified as excess to goal. The National Defense Authorization Act for Fiscal Year 1994, Public Law 103-160, was enacted on November 30, and covered the last month of 1993. Stocks of rare earths in sodium sulfate were all classified as excess to goal at yearend 1993 and were inventoried at 457 tons. Rare earths in the NDS, which were not authorized for disposal during fiscal year 1993, received authorization for disposal in fiscal year 1994 under Public Law 103-160.

Issues

In response to environmental regulations under the Resource Conservation and Recovery Act, Molycorp is reportedly taking corrective actions at its Mountain Pass plant to comply with the law. Compliance with the regulations was not expected to have an adverse material effect on the company's operations or financial situation.[25]

Sales of rare earths by Molycorp in 1993 were slightly lower than in 1992, however, earnings reportedly increased as a result of cost-reduction measures. Molycorp's Mountain Pass, CA, mine and plant and its operations at White Plains, NY, received ISO 9002 certification by meeting or exceeding the standards for the international quality rating.

Molycorp's mine, plant, and operations continued to be for sale throughout 1993. No potential purchasers were announced during the year. The company was expected to continue to remain for sale in 1994.

Production

Two domestic mines produced rare earths in 1993. The United States was the world's second largest producer of rare earths in 1993. Producers were Molycorp, a wholly owned subsidiary of Unocal Corp., and RGC (USA). Bastnasite was mined by open pit methods by Molycorp at Mountain Pass, CA. Molycorp's mine was the leading producer of rare earths in the United States and second in the rest of the world. Mine production decreased from the previous year's level of 20,699 tons REO to 17,754 tons REO in 1993.

Monazite was produced as a byproduct of titanium and zirconium minerals production by RGC (USA). RGC (USA) operated a placer dredging operation at Green Cove Springs, FL. Production increased 6% from last year's level, primarily the result of increased demand for the primary products.

Refined lanthanides were produced by three companies. Molycorp produced refined compounds from bastnasite at its separation plant at Mountain Pass, CA. Rhône-Poulenc Basic Chemicals Co. produced lanthanide compounds from rare-earth intermediate compounds at its facility at Freeport, TX, and Davison Specialty Chemical Co. refined rare earths from rare-earth chloride at its operations in Chattanooga, TN.

Three scandium processors operated in 1993. High-purity products were available in various grades with scandium oxide produced up to 99.999% purity.

Sausville Chemical refined scandium concentrates at its facilities in Garfield, NJ, to produce scandium oxide, fluoride, nitrate, chloride, and acetate. Boulder Scientific Co. processed scandium at its Mead, CO, operations. Scandium concentrates were derived from a variety of ores. Boulder's main ore source was thortveitite-bearing tailings from the mined-out Crystal Mountain fluorite mine near Darby, MT. Scandium was also processed by APL Engineered Materials in Urbana, IL. APL produced both compounds and metal.

Reactive Metals and Alloys Corp. (REMACOR) was the principal domestic producer of mischmetal. Production of mischmetal, rare-earth silicide, and other rare-earth alloys decreased 25% in 1993, primarily the result of decreased demand in the other rare-earth alloy group. Production of high-purity metals also decreased as a result of plant closures by Molycorp.

Principal domestic producers of neodymium-iron-boron magnet alloys were the Delco Remy Div. of General Motors, Anderson, IN; Molycorp, York, PA; Neomet Corp., West Pittsburg, PA; and Rhône-Poulenc, Phoenix, AZ. Leading U.S. producers of rare-earth magnets were the Delco Remy Div. of General Motors, Anderson, IN; Hitachi Magnetics, Edmore, MI; Crucible Materials, Elizabethtown, KY; and IG Technologies, Valparaiso, IN.

Consumption and Uses

Domestic reported consumption of rare earths decreased 14% in 1993 compared with that of 1992. The producers of mischmetal, rare-earth silicide, and other rare-earth alloys consumed essentially the same amount of rare earths in 1993 than they did in 1992, despite a 25% decrease in domestic shipments. Consumption of mixed rare-earth compounds showed a 90% gain as demand increased for petroleum fluid cracking catalysts and automotive catalytic converters. Domestic shipments of mixed compounds, however, increased only 7% as adequate supplies of materials were produced. Shipments of high-purity rare-earth metals from domestic processors decreased 27% during the year amid a major decrease in production; the result of plant closures in 1992.

The approximate distribution of rare earths by use, based on information supplied by primary processors and some consumers, was as follows: catalysts in petroleum, chemical, and pollution control, 47%; metallurgical uses as iron and steel additives and as alloys, 24%; glass polishing compounds, glass additives, and ceramics, 18%; permanent magnets, 10%; lighting, phosphors, mantles, research, and miscellaneous, 2%.

Rare earths are used in hundreds of applications, ranging from 19th century traditional applications to modern high-technology uses. The applications encompass a wide range of products from mixed rare-earth compounds and alloys to ultrahigh-purity individual metals and compounds. Quantities vary by application and range from tonnage quantities to milligrams. Following are the uses, in order of increasing atomic number, of rare earths, including the metals, oxides, and both inorganic and organic compounds.

Scandium.—Metal halide lamps to improve color appearance and produce high output, lasers crystals (GSGG), high-strength aluminum alloys, anode tubes in X-ray spectrometers, semiconductors, tracer material, collimators in neutron lenses.

Yttrium.—High-temperature superconductor (YBaCuO), incandescent lamp mantle, phosphor for cathode-ray tubes (reddish orange), trichromatic fluorescent lighting phosphors (reddish orange), metal halide lamp phosphor (reddish orange), high-temperature sensing phosphor, oxygen sensor ceramic, laser crystal (YAG, YLF), gemstone simulants (CZ and YAG), microwave ferrites (YIG), cast iron alloys, magnesium castings, superalloys, dispersion strengthened nickel and titanium alloys, aromatization of n-hexane, prostheses, stabilizer for silicon nitride and zirconia ceramics, microwave filter, and semiconductors, acetylene lights, deoxidizer for vanadium and other nonferrous metals, solid oxide fuel cell electrolyte and anode, refractory crucibles and coatings, high-temperature furnace electrodes.

Lanthanum.—Petroleum fluid cracking catalyst, glass additive to increase refractive index and decrease dispersion (eyeglasses, cameras, binoculars, rifle scopes, and telescope lenses), nickel hydride rechargeable batteries, hydrogen storage alloys, optical glass, solid oxide fuel cell cathode and interconnect, trichromatic fluorescent lighting phosphor (green), X-ray intensifying screen phosphor (violet, blue, yellow-green, and blue green), low-temperature sensing phosphor, phosphor lamp coating, laser glass, calcium lighting, lighting electrode, tungsten welding electrode, cast iron alloys, steel alloys, superalloys, aromatization of n-hexane, fluoride determination, conductive ceramic heating elements (chromites), dielectric ceramic capacitors (titanates), electrooptical ceramics, oxidative dimerization of methane to ethylene, antiseptic, electronic thermoemissive cathode (boride), insulation, reducing agent to convert nitrogen oxides to nitrogen, low-temperature superconductor, cryogenic refrigerant using hydrogen ($LaNi_5$), semiconductors (LaAs, LaSb, LaP).

Cerium.—Glass, metal, and gemstone polishing, radiation shielding glass, glass colorization and decolorization, discolorization stabilizer, photochromic glass opacifier, ceramic pigment, ceramic glaze, enamel opacifier, carbon arc lighting, incandescent lamp mantle, trichromatic fluorescent lighting phosphor (yellow green), pyrophoric alloys including lighter flints, cast iron alloys, steel alloys, aluminum alloys, magnesium alloys, superalloys, automotive catalytic converter monolith, heat stabilizer in alumina catalyst, fluid cracking catalyst, hydrolysis of phosphoric acid esters, oxidation of naphthalene, polymerization catalyst for olefins, corrosion inhibitor, getter in azide manufacture, getter in vacuum tubes, developing agent for aniline black, heavy metal soaps for lubricating greases and flatting agents, waterproofing and mildewproofing, dying and printing textiles, ceramic capacitors, semiconductors, cathodes, desulfurizing catalysts, high-strength glass, catalyst for ammonia production, illuminant in photography, radiation dosimeter, diluent in plutonium nuclear fuels, fluorinating agent, oxidant for organic compounds, antiknock fuel additive, oxidizer in self-cleaning ovens, and pharmaceutical for sea sickness and morning sickness.

Praseodymium.—Ceramic pigment (yellow), glass colorization (light green), refractory ceramic heating element, laser crystal, aluminum alloys, magnesium alloys, permanent magnets, oxidative dimerization of methane to ethylene, cryogenic refrigeration ($PrNi_5$).

Neodymium.—Permanent magnets (NdFeB), glass colorization (violet), glass decolorization, dopant in laser crystals and glass, ceramic capacitors, ceramic glaze (pinkish violet), magnesium alloys, welder's protective glass, carbon arc lighting electrodes, catalyst for polymerization of olefins, fiber-optic temperature sensor.

Promethium.—Fluorescent lighting starter, coatings for self-luminous watch dials, beta particle source for thickness gauges, miniature atomic batteries, semiconductor battery, X-ray source (Pm-147), tungsten cermet for space power system.

Samarium.—Permanent magnets (SmCo), dopant in laser crystals, neutron absorber, nuclear reactor control rod, catalyst in dehydrogenation of ethyl alcohol, catalyst in oxidative dimerization of methane to ethylene, infrared absorbing glass.

Europium.—Cathode-ray tube phosphor (reddish orange), trichromatic fluorescent phosphor (reddish orange and blue), X-ray intensifying screen phosphor (violet), metal halide lamp phosphor (reddish orange), high- and low-temperature sensing phosphors, nuclear reactor neutron absorber, nuclear reactor control rods, ceramic sensor, organic shift reagent in nuclear magnetic spectroscopy, dopant in laser crystals, tagging agent in postage stamp glue.

Gadolinium.—Trichromatic fluorescent lighting phosphor (yellow green), X-ray intensifying screen phosphor (yellow green), nuclear reactor control rods, nuclear reprocessing, neutron absorbing paint, high refractive index glass, synthetic garnet for computer memory (GGG), scavenger for oxygen in titanium production, dielectric ceramics, laser crystal, cryogenic refrigeration, pharmaceutical isotope in scanning devices to detect osteoporosis (Gd-153), magneto-optical recording,

Terbium.—Trichromatic fluorescent lighting phosphor (yellow green), X-ray intensifying screen phosphors (yellow green, violet, and blue), magnetostrictive alloys for transducers (TbFeNi), dopant in laser crystals.

Dysprosium.—Permanent magnet addition (NdFeB), nuclear reactor control rods, semiconductors (DyAs, DySb, DyP), measurement of neutron flux, atomic weight determination, high-temperature sensing phosphor.

Holmium.—Dopant in laser crystal, getter in vacuum tubes, refractories.

Erbium.—Fiber-optic amplifier, glass colorizing of crystal and glassware (light pink), additive for colorization and nonreflective coating for sunglasses, infrared-absorbing glass, colorization of simulant gemstones, lasers, burnable poison in nuclear reactor, chemical catalyst for n-hexane, permanent magnet additive.

Thulium.—X-ray source (Tm-170), dopant in laser crystal, ferrites.

Ytterbium.—Portable X-ray source for blood irradiation, dielectric ceramics, carbon rods for industrial lighting, dopant in synthetic garnet, dopant in laser crystal, additive in special glass.

Lutetium.—High-temperature sensing phosphor, nuclear technology.

Stocks

U.S. Government stocks of rare earths in the NDS remained at 457 tons throughout 1993. Rare-earth stocks held in the stockpile were contained in sodium sulfate and were inventoried on a contained-REO basis. NDS stocks of rare earths were not available for sale in 1993 until the 30th of November, when Pubic Law 103-160 went into effect.

Prices

Prices for rare earths generally were unchanged in 1993. Published prices were stable for most rare earth oxides and compounds, but remained nominal and subject to change without notice. Competitive pricing policies remained in effect with prices for most rare-earth products quoted on a daily basis.

The price range of Australian monazite (minimum 55% rare-earth oxide including thoria, f.o.b./f.i.d.),[26] as quoted in Australian dollars (A$),[27] remained unchanged at A$300 to A$350 per ton at yearend 1993. Changes in the United States-Australia foreign exchange rate in 1993, resulting from a slightly weaker Australian dollar, caused the corresponding U.S. dollar to be up $0.01 against the Australian dollar at yearend. The U.S. price range, converted from Australian dollars, decreased slightly from US$207 to US$241[28] per ton in 1992 to US$204 to US$238[29] per ton in 1993. Prices for monazite remained depressed as several major world processors switched to thorium-free rare-earth feed materials.

Prices quoted by Molycorp for unleached, leached, and calcined bastnasite in standard quantities, containing 60%, 70%, and 85% REO, were $2.87, $3.20, and $3.86 per kilogram ($1.30, $1.45, and $1.75 per pound) of contained REO, respectively, at yearend 1993. Bastnasite concentrate prices increased $0.10 for the 70% grade and $0.20 for the 85% grade, the first increases since 1990.

The price of cerium concentrate was quoted by Molycorp at $5.73 per kilogram ($2.60 per pound) of contained cerium oxide at yearend 1993, unchanged from the 1992 price. The yearend price of lanthanum concentrate was also unchanged from the 1992 level of $3.08 per kilogram ($1.40 per pound) of REO contained. Prices for cerium concentrate and lanthanum concentrate are quoted for 907-kilogram minimum (2,000-pound minimum), f.o.b. shipping point. Molycorp began quoting prices for cerium carbonate on a contained REO basis. The yearend 1993 price for cerium carbonate was $21.50 per kilogram ($9.75 per pound) of contained REO.

The nominal price for basic neodymium-iron-boron alloy, compiled by the USBM, was $25.35 per kilogram ($11.50 per pound) at yearend, f.o.b. shipping point, 1,000-pound minimum. Most alloy was sold with additions of cobalt (up to 15%) or dysprosium (up to 5%). The cost of the additions was based on market pricing; with cobalt at $52.91 per kilogram ($24.00 per pound) the cost would be about $0.53 for each percent addition per kilogram ($0.24 for each percent addition per pound).

The price for standard-grade mischmetal remained unchanged from the previous year at $12.68 per kilogram.

Molycorp quoted prices for lanthanide (rare earth) and yttrium oxides, net 30 days, f.o.b. Louviers, CO, Mountain Pass, CA, or York, PA, in effect at yearend 1993, as shown in table 2. *(See table 2.)*

Molycorp also quoted prices for lanthanide (rare earth) compounds, net 30 days, f.o.b. York, PA, Louviers, CO or

Mountain Pass, CA, in effect at yearend 1993, as shown in table 3. *(See table 3.)*

Rhône-Poulenc quoted rare-earth prices, per kilogram, net 30 days, f.o.b. New Brunswick, NJ, or duty paid at point of entry, in effect at yearend 1993, as shown in table 4. *(See table 4.)*

No published prices for scandium oxide in kilogram quantities were available. Yearend 1993 nominal prices for scandium oxide per kilogram were compiled by the USBM from information from several suppliers and processors. Prices remained unchanged from the previous year for most grades and were listed as follows: 99% purity, $1,500; 99.9% purity, $3,000; 99.99% purity, $5,000; and 99.999% purity, $8,000. The price for 99.999% purity decreased $2,000 per kilogram from the previous year.

Scandium metal prices, as listed by the Johnson Matthey Aesar Group, were as follows: 99.99% purity, lump, sublimed dendritic, ampouled under argon, $312.00 per gram; 99.9% purity, 250-micron powder, ampouled under argon, $559.00 per 2 grams; and 99.9% purity, lump, vacuum remelted, ampouled under argon, $405.00 per 2 grams; 99.9% purity, foil, 0.025 millimeters (mm) thick, ampouled under argon, 25 mm by 25 mm, $117.00 per item.[30]

Scandium compounds prices, as listed by Aldrich Chemical Co., were as follows, scandium acetate hydrate 99.9% purity, $33.10 per gram; scandium chloride hydrate $99.99% purity, $44.50 per gram; scandium nitrate hydrate 99.9% purity, $47.70; and scandium sulfate hydrate 99.9% purity, $53.20 per gram. Prices for standard solutions for calibrating analytical equipment were $17.30 per 100 milliliter of scandium atomic absorption standard solution and $272.20 per 100 milliliter of scandium ICP/DCP standard solution.[31]

Prices for kilogram quantities of scandium metal in ingot form have historically averaged about twice the cost of the oxide while higher purity distilled scandium metal was approximately five times the cost.[32]

Foreign Trade

Rare-earth imports showed mixed results in 1993. Imports declined in two major categories and increased in four categories. U.S. imports of ore and compounds are shown in tables 5 and 6. As in the previous 4 years, France dominated the import market, especially for rare-earth compounds. *(See tables 5 and 6).*

U.S. imports of monazite concentrate (thorium ores and concentrates) remained at zero for the third consecutive year as a result of a major domestic processor switching to a thorium-free rare-earth feed material in 1991. Imports of cerium compounds increased 57% from the 1992 level as cerium demand increased for use in automotive exhaust catalysts, UV-absorbing glass additives, and polishing compounds. Principal sources, by quantity, were China, France, and Japan. For the first time, China became the largest source of imported cerium compounds, displacing France.

Imports of individual rare-earth compounds, other than cerium compounds, also increased in 1993. The 20% gain was mainly for feed material for permanent magnet alloys. Principal sources of these imports were France, China, and Japan.

Imports of mixed rare-earth compounds, excluding cerium compounds and mixed chlorides, decreased 15% as demand fell for plant feed materials. France, China, and Japan were the major suppliers in order of decreasing volume. U.S. imports of rare-earth metals decreased 33% during the year. Principal sources for the metals, by quantity, were China and Brazil. Decreased demand for alloy imported from Austria was responsible for most of the decrease.

Imports of mixed rare-earth chlorides gained 49%, with India remaining the principal source. China's share of the market also increased substantially. Rare-earth chloride imports were mainly used as feed material for manufacturing fluid cracking catalysts with lesser amounts consumed in producing mischmetal.

Ferrocerium imports in 1993 increased about 12%, with most material originating from France, Brazil, Austria, and Belgium. The principal sources of U.S. imports, in terms of volume of equivalent REO contained, are displayed in figure 6. *(See figure 6.)*

U.S. exports of rare earths in 1993 were diverse. Exports of cerium compounds decreased 16% from 1992's level. Principal destinations were automobile catalyst plants and glass polishing operations in Canada, Japan, Singapore, and the Republic of Korea. Exports of rare-earth compounds, excluding cerium compounds, also declined, down 17% as a result of decreased demand from Japan and Canada.

Exports of ferrocerium and other pyrophoric alloys increased 76%. A large number of countries received shipments, with the largest quantities going to Japan, Hong Kong, and Canada. U.S. exports of rare-earth metals also increased, up 343%, with principal destinations of Germany, Canada, and the United Kingdom. Domestic exports of rare earths are shown in table 7. Based on limited available U.S. Bureau of the Census data, Japan, Canada, and Hong Kong were the leading export destinations of rare earths from the United States in 1993. This was a shift from 1992 when Brazil, Japan, and Taiwan were the leaders. Principal destinations of U.S. exports are displayed in figure 7. *(See table 7 and figure 7.)*

World Review

Industry Structure.—Bastnasite was the world's principal source of rare earths. It was mined as a primary product in the United States and as a byproduct of iron ore mining in China. Minor production also was reported from Madagascar. Significant quantities of rare earths were also recovered from monazite, a byproduct of heavy-mineral sands mined for titanium and zirconium minerals or tin minerals in Australia, Brazil, China, the former U.S.S.R., India, Indonesia, Malaysia, the Republic of South Africa, Sri Lanka, Taiwan, Thailand, and the United States.

Smaller amounts of rare earths, especially yttrium, were obtained from the mineral xenotime. Xenotime was recovered primarily as a byproduct of processing for tin minerals in Indonesia, Malaysia, and Thailand, but was also produced as a byproduct of processing titanium and zirconium minerals in Australia and China.

Most yttrium produced in the world is now derived from ion-adsorption ores in China. The ore was mined and processed as a primary product for yttrium and the other rare earths at several locations in southeastern China.

Mining in Russia, Kazahkstan, Kyrgyzstan, and Ukraine produced rare earths from loparite, synchisite-(Y), and uraniferous phosphorites. Minor production was also reported from pilot-plant processing eudialyte in Russia. *(See tables 8 and 9.)*

Scandium was recovered as a byproduct of processing ore for beryllium, iron, tin, and tungsten in China, and previously was produced as a byproduct of uranium processing in the United States. In the former U.S.S.R., scandium was recovered as a byproduct of uranium.

Reserves.—World reserves of rare earths were estimated by the Bureau of Mines at 100 million metric tons of contained REO. China has the largest share of world reserves with 43%. *(See figure 8.)*

OUTLOOK

Demand for rare earths continues to shift towards higher purity mixed and separated products with applications in a wider range of products. This trend of increased demand and diversification is expected to accelerate through the year 2000. Strong growth is forecast in the areas of permanent magnets, materials for auto catalytic converters, and rechargeable batteries.

World rare-earth reserves are sufficient to meet world demand well into the 21st century. Considering the likelihood that additional deposits of rare earths will continue to be located and assuming reasonable increases in energy, transportation, processing, and environmental costs, world resources are more than adequate to fulfill demand for the foreseeable future.

Domestic companies have shifted away from radioactive-bearing rare-earth ores. This trend has had a negative impact on monazite-producing mineral sands operations worldwide. Future long-term demand for monazite, however, is expected to increase due to its abundant supply and low cost byproduct recovery. The cost to monitor and dispose of radioactive waste products in the United States is expected to continue to increase, severely limiting domestic use of monazite and other thorium-bearing ores.

Domestic and foreign demand in 1994 is expected show strong growth as the domestic economy shows signs of strengthening. Competitive world markets are expected to endure in the future, with economic restructuring in Russia and the rest of the former U.S.S.R. greatly expanding market opportunities. Future growth, however, will be greatest wherever low-radioactivity, easily beneficiable deposits are found.

The distant outlook is for an increasingly competitive and diverse group of rare-earth suppliers. The economic base of the rare-earth industry is forecast to continue to grow and broaden. Emerging applications are expected to develop faster and demand higher-purity materials at faster rates in response to rapid technological changes and increasing global competitivness. Demand is forecast to continue to grow as improved knowledge of the rare earths continues to generate new commercial applications, a trend that is expected to continue.

[r] Revised.

[1] Formerly part of the U.S.S.R.; data were not reported separately until 1992.

[2] Dissolved in Dec. 1991; however, information is not available for individual countries, other than those listed in this table.

[3] Revised to zero.

Source: Bureau of the Census.

RECYCLING IRON AND STEEL SCRAP

By Gerald W. Houck

Mr. Houck, a physical scientist with 37 years of industry and U.S. Bureau of Mines experience, is the commodity specialist for iron and steel. Domestic survey data tables were prepared by Henry F. Sattlethight and David J. Kulha, Section of Metals Data.

Iron and steel scrap is a vital raw material for the production of new steel and cast iron products. Because of the ready availability of scrap from manufacturing operations and from the recovery of steel products that have reached the end of their useful lives, the steel industry and the foundry industry in the United States have been structured efficiently to recycle scrap, and, as a result, are highly dependent upon scrap.

The recycling of steel scrap plays an important role in the conservation of energy because remelting of steel scrap requires much less energy than the production of steel or iron products from iron ore. In addition, the consumption of steel scrap by remelting reduces the burden on landfill disposal facilities and prevents the accumulation of abandoned steel products in the environment.

Brokers, dealers, and other outside sources supplied domestic consumers in 1993 with 46.3 million metric tons[1] of all types of ferrous scrap at a delivered value of approximately $5 billion, while exporting 9.8 million tons (excluding used rails for rerolling and other uses and ships, boats, and other vessels for scrapping) valued at $1.3 billion. In 1992, domestic consumers received 42.1 million tons (revised) at a delivered value of approximately $3.5 billion (revised); exports totaled 9.26 million tons valued at $1.1 billion. This represented a tonnage increase of about 10% for received quantities and a tonnage decrease of about 6% for exported quantities. The total value of these received and exported scrap grades increased about 20%.

DOMESTIC DATA COVERAGE

Domestic data for ferrous scrap were developed by the U.S. Bureau of Mines from voluntary monthly or annual surveys of U.S. scrap consuming operations. For manufacturers of pig iron and raw steel, about 90% of the known establishments responded to the surveys. Responses to surveys represented about 85% of scrap consumption. The remaining 15% of scrap consumption was estimated, based on prior reports and other information. For manufacturers of steel castings and iron foundries and miscellaneous users, about 40% of the known establishments responded to the annual survey, representing about 65% of estimated scrap consumption by these scrap consumers. Total consumption for these two classes of consumers was estimated using statistical methods.

ANNUAL REVIEW

Legislation and Government Programs

In the United States, there were four instances in 1993 where steel mills or foundries melted a radioactive source. This makes a total of 14 reported such occurrences since 1983. Twelve of the accidental meltings have involved cesium-137, a radioactive isotope commonly used, among other things, in industrial gauging devices.

When melting of a radioactive source occurs, the radioactive cesium volatilizes in the high temperature of the steelmaking furnace and is collected in the dust collection system of the furnace. The contaminated dust must be assayed for radioactivity levels, treated when necessary, and segregated either for recycling or disposal at a licensed radioactive waste disposal site. The cost to the mill has been estimated as between $5 million and $10 million.

Radioactive sources become mixed with iron and steel scrap because of improper controls and disposal of radioactive materials by persons licensed by the U.S. Nuclear Regulatory Commission (NRC) or by the States. In response to the problem of melting radioactive sources, protective measures have been mounted by NRC and by the industry. NRC publishes a warning poster to alert metal scrap industry and mill workers to the problem. In addition, NRC is considering a rulemaking to improve controls and accounting of radioactive sources by industrial gauge users. The Institute of Scrap Recycling Industries, the principal trade association of the scrap metal industry, has published an informational booklet and a Recommended Practice and Procedure for handling scrap that may be radioactive.

Increasingly, steel mills and scrap dealers are installing radiation detection devices to monitor incoming scrap for radiation. These can be effective. NRC and the Pennsylvania Department of Environmental Health have tabulated 79 instances between 1984 and June 1993, where radiation detection equipment detected a radioactive source mixed with incoming scrap. However, such equipment cannot provide 100% protection because the large volume and density of steel scrap tends to shield the radiation, sometimes to the point where even the most sophisticated radiation monitoring equipment cannot detect the source, and melting of radioactive sources has occurred at mills equipped with detection equipment.

Available Supply, Consumption, and Stocks

Raw steel production was 88.8 million tons in 1993 compared with 84.3 million tons in 1992. The shares of raw steel produced by electric and basic oxygen furnaces were, respectively, 39% and 61% in 1993 and 38% and 62% in 1991. Continuous cast steel production represented 86% of total raw steel production in 1993 compared with 79% in 1992. Raw steel production capability was 102.6 million tons in 1993 compared with 106.7 million tons in 1992. Raw steel capability utilization was 89% in 1993 and 82% in 1992.

Net shipments of all grades of steel mill products were 80.8 million tons in 1993 and 74.6 million tons in 1992. Imports of steel mill products increased from 15.5 million tons in 1992 to 17.7 million tons in 1993. Exports of steel mill products decreased from 3.89 million tons in 1992 to 3.60 million tons in 1993. The U.S. apparent supply of steel mill products increased from 86.2 million tons in 1992 to 92.0 million tons in 1993. Imports of steel mill products, as a share of the U.S. market, were 18% in 1992 and 19% in 1993. Pig iron production increased from 47.4 million tons in 1992 to 48.2 million tons in 1993.

Iron castings shipments totaled 7.9 million tons in 1993 compared with 7.4 million tons in 1992. Steel castings shipments (including investment castings) totaled 0.96 million tons in 1993 compared with 0.93 million tons in 1992.

In 1993, steel mills accounted for 81% of all scrap received from brokers, dealers, and other outside sources; steel foundries received 2%; and iron castings producers and miscellaneous users received 16%. The apparent total domestic consumption of ferrous scrap in 1993 was composed of 46.1 million tons net receipts (total receipts minus shipments) and 21.5 million tons of home scrap. Stocks were essentially unchanged. The 1993 total domestic consumption was 67.5 million tons; in 1992, the total domestic consumption was 63.2 million tons (revised).

The total market for U.S. produced scrap (net receipts plus exports minus imports) was 54.4 million tons in 1993 compared with 49.7 million tons (revised) in 1992.

Prices

The average composite delivered price per metric ton, calculated from prices per long ton published weekly and monthly by American Metal Market (AMM), for No. 1 heavy melting steel scrap was $112.44 in 1993, ranging from a low of $96.91 in January to a high of $133.26 in December. Calculated from prices per long ton published weekly by Iron Age Scrap Price Bulletin (IA), the average composite delivered price per metric ton of No. 1 heavy melting steel scrap was $109.98 in 1993, ranging from $95.79 in January to $131.22 in December. The average composite price for No. 1 heavy melting steel scrap in 1993 was higher than that in 1992, by 33% in AMM and by 31% in IA.

Based on weekly quotations by Iron Age for 18-8 (18% chromium, 8% nickel)-grade stainless steel scrap (bundles and solids) delivered to consumers in the Pittsburgh, PA, area, the average price decreased 16%, from $743 per ton in 1992 to $624 per ton in 1993.

In 1993, the average value for total ferrous scrap exports (excluding used rails for rerolling and other uses and ships, boats, and other vessels for scrapping) increased 13% to $134.23 per ton compared with that of 1992, while that of total imports increased 1% to $113.80 per ton.

Foreign Trade

Foreign trade valuation continued to be reported on f.a.s. (free alongside ship) basis for exports and on Customs value basis for imports.

The trade surplus in 1993 for all classes of ferrous scrap (including used rails for rerolling and other uses and ships, boats, and other vessels for scrapping) was $1,165 million in value and 8.5 million tons in quantity. This represented an increase of 21% in value and 5% in quantity compared with the 1992 surplus of $965 million in value and 8.1 million tons in quantity.

Total U.S. exports of ferrous scrap (excluding used rails for rerolling and other uses; ships, boats, and other vessels for scrapping; stainless steel; and alloy steel) in 1993 went to 49 countries and totaled 9,226,782 tons valued at $1,105,593,600 for an average of $119.82 per ton. Six countries received 83% of the total quantity. The largest tonnages went to the Republic of Korea, 3,436,197 tons; Turkey, 1,309,640 tons; Canada, 1,219,718 tons; Malaysia, 606,753 tons; Mexico, 592,540 tons; and Japan, 483,395 tons. The value of scrap exports to these six countries was $888,535,080, 80% of the total value.

Total U.S. exports of stainless steel scrap in 1993 went to 30 countries and consisted of 238,000 tons valued at $147,226,190 averaging $618.60 per ton. Six countries received 91% of the total quantity. The largest tonnages went to the Republic of Korea, 67,061 tons; Canada, 53,829 tons; Japan, 44,324 tons; Spain, 34,592 tons; Belgium, 8,926 tons; and Taiwan, 7,668 tons. The value of stainless steel scrap exports to these six countries was $134,622,063, 91% of the total value.

U.S. exports of alloy steel scrap (excluding stainless steel) in 1993 were shipped to 39 countries. The total comprised 340,404 tons valued at $63,284,278 for an average of $185.91 per ton. Six countries received 81% of the total quantity. The largest tonnages went to Canada, 162,763 tons; China, 46,119 tons; Singapore, 22,520 tons; Mexico, 16,693 tons; Colombia, 14,012 tons; and Italy, 12,549 tons. The value of alloy steel scrap to these six countries was $50,230,723, which was 79% of the total value.

World Review

The United States continued to be the leading exporting country of iron and steel scrap. France, Germany, Netherlands, and the United Kingdom were also major exporters of ferrous scrap. Leading importing nations included Italy, Spain, Turkey, and the developing nations of Asia: China, Indonesia, India, Republic of Korea, Taiwan, and Thailand.

Nucor, Inc., a leading U.S. steel producer, in partnership with Simitri, a Brazilian iron ore mining company began construction of a plant in Trinidad and Tobago to produce iron-carbide, a form of direct-reduced iron. Startup was anticipated in late 1994. The capacity of the new plant will be about 300,000 tons per year. Nucor plans to use the iron carbide along with steel scrap at its sheet mills in Crawfordsville, IN, and Hickman, AR, where it will enable the production of low-residual steel, increasing the range of steel products produced.

OUTLOOK

The overall outlook for U.S. ferrous scrap through 1995 is expected to be continued growth. In addition to the two flat rolled steel plants operated by Nucor, several other new electric furnace steel plants were planned in the United States, and the reopening of at least two major electric furnace operations appears likely. In addition, the replacement of ingot casting facilities with continuous casting equipment has increased the effective capacity of the few remaining integrated flat roll plants, increasing their demand for scrap. As increased demand results in sustained higher price levels for ferrous scrap, substitutes in the form of pig iron and direct-reduced iron will increase in use. The higher price of these substitutes will be more acceptable when scrap prices are high. In addition, producers of flat-rolled steel and other products requiring low levels of residual elements in the steel increasingly will turn to these iron-ore-based products to dilute the residual content that is intrinsic in scrap. However, the availability of these substitutes will not result in reduced demand for scrap; rather, it will ensure and facilitate the use of scrap.

Value	$73,184	$60,069	$75,261	$72,784	$116,736
Direct-reduced iron (all grades)	171	334	380	545	924
Value	$22,621	$40,974	$53,624	$56,445	$90,796

[r] Revised.

[1] Data are not entirely comparable due to changes in collection and estimation methods in 1993.

[2] Includes manufacturers of raw steel that also produce steel castings.

[3] Net receipts of scrap is defined as receipts from brokers, dealers, and other outside sources, plus receipts from other own-company plants, minus shipments.

[4] Home scrap production includes recirculating scrap resulting from current operations and obsolete home scrap.

[5] Some of these manufacturers produce iron castings.

[6] Data may not add to totals shown because of independent rounding.

[7] Source: Bureau of the Census. Export valuation is on a "free alongside ship" basis, and import valuation is on a customs basis.

[8] Excludes used rails for rerolling and other uses, and ships, boats and other vessels for scrapping.

TABLE 2
U.S. CONSUMER RECEIPTS, PRODUCTION, CONSUMPTION, SHIPMENTS, AND STOCKS OF IRON AND STEEL SCRAP IN 1993, BY GRADE

(Thousand metric tons)

Grade	Receipts of scrap: From brokers, dealers and other outside sources	Receipts of scrap: From other own-company plants	Production of home scrap: Recirculating scrap from current operations	Production of home scrap: Obsolete scrap[1]	Consumption of both purchased and home scrap[2]	Shipments of scrap	Ending stocks, Dec. 31
MANUFACTURERS OF PIG IRON AND RAW STEEL AND CASTINGS							
Carbon steel:							
Low-phosphorus plate and punchings	603	30	323	—	949	12	46
Cut structural and plate	2,934	25	413	192	3,446	143	261

[r] Revised.

[1] Excludes used rails for rerolling and other uses, and ships, boats, and other vessels for scrapping. Export valuation is on a "free alongside ship" (f.a.s.) basis.

[2] The U.S. exported scrap to the following number of countries: 63 in 1989; 60 in 1990; 57 in 1991; 59 in 1992; and 60 in 1993.

[3] Less than 1/2 unit.

[4] Data may not add to totals shown because of independent rounding.

[r] Revised.

[1] Excludes used rails for rerolling and other uses, and ships, boats, and other vessels for scrapping. Import valuation is on a customs basis.

[2] The U.S. imported scrap from the following number of countries: 31 in 1989; 30 in 1990; 38 in 1991; 37 in 1992; and 34 in 1993.

[3] Less than 1/2 unit.

[4] Formerly part of the U.S.S.R.; data were not reported separately until 1992.

[5] Dissolved in Dec. 1991.

[6] Data may not add to totals shown because of independent rounding.

[r] Revised.

[1] Exports for 1989-93 contain mixed (used plus new) rails: 1,191 metric tons valued at $8,664,660 in 1989; 5,979 metric tons valued at $4,439,351 in 1990; 6,828 metric tons valued at $3,963,245 in 1991; 2,376 metric tons valued at $1,783,731 in 1992; and 7,142 metric tons valued at $4,239,220 in 1993. Export valuation is on a "free alongside ship" (f.a.s.) basis.

[2] Less than 1/2 unit.

RECYCLING—NONFERROUS METALS

By James F. Carlin, Jr., Daniel Edelstein, Stephen M. Jasinski, John F. Papp, Patricia A. Plunkert, and Gerald R. Smith

Mr. Carlin, a physical scientist in the Branch of Metals, has been the tin specialist for 14 years. Mr. Edelstein is a physical scientist with 20 years of combined experience working for the U.S. Bureau of Mines (USBM) in minerals processing research, process evaluation, and mineral commodities. He has been a commodity specialist dealing with copper and its byproduct metals for 10 years. Mr. Jasinski, a physical scientist with 7 years of USBM experience has been a commodity specialist in the Branch of Metals since 1988, has been the acting specialist for zinc since August 1994. Dr. Papp, a physical scientist with 22 years of USBM experience, has been the commodity specialist for chromium since 1983 and was the coordinator for this report. Ms. Plunkert, a chemist with 25 years of USBM experience, has been the commodity specialist for aluminum since 1987. Mr. Smith, a physical scientist with 30 years of reseach and commodity experience with the USBM, has been the acting commodity specialist for lead since March 1994.

INTRODUCTION[1]

Recycling, a significant factor in the supply of many of the key metals used in our society, provides environmental benefits in terms of energy savings, reduced volumes of waste, and reduced emissions associated with the energy savings.

The estimated value of recycled nonferrous metals in 1993 was about $7.3 billion and is an increasingly important component of economic activity in the United States. Table 1 shows salient U.S. recycling statistics for selected metals. Table 2 shows salient U.S. apparent supply and recycling statistics for those same metals. Figure 1 shows a general flow scheme for recycling.

As part of its Commodities and Materials Program, the USBM provides information and analysis on more than 100 raw and/or processed minerals. Collected data are assessed by commodity specialists, and information is disseminated to government, industry, and academia through consultative services and more than 100 recurring publications. This publication examines and reports on minerals and materials trends as well as environmental aspects of the entire life cycle of minerals use.

The USBM's Research Directorate conducted research in 1993 on recycling of consumer products, advanced materials, and metallurgical residues and effluents currently discarded. The Bureau also conducted research on impurity control during recycling and design for reuse or waste minimization. To increase the efficiency of recycling, the USBM investigated the control of impurities such as magnesium, zinc, and lithium in aluminum scrap and the removal of copper from ferrous scrap. The USBM also investigated methods to remove heavy-metal contaminants from mineral processing and manufacturing waste and to stabilize those heavy metals not removed. The USBM in cooperation with the American Iron and Steel Institute initiated a research project to dewater steelmaking sludges, currently landfilled or stockpiled on site, in order to recycle the contained iron units.

Because of the increasing importance of recycling to domestic metal supply and the intense public interest, the USBM initiated this separate chapter on nonferrous metal recycling as part of its Annual Report series in 1991. A separate chapter on iron and steel scrap already had been part of this series for many years. The focus of this chapter is on aluminum, copper, lead, tin, and zinc recycling.

ALUMINUM[2]

Domestic Data Coverage

Domestic recycling data for aluminum are developed by the U.S. Bureau of Mines from a voluntary survey, "Aluminum Scrap," of U.S. operations. Of the 92 companies and/or plants to which monthly or annual survey requests were sent, 85 responded, representing 94% of the total scrap consumed shown in table 5.

Annual Review

The U.S. Bureau of Mines estimated that more than 2.9 million metric tons (Mt) of metal was recovered from purchased aluminum scrap in 1993. Forty-five percent of this recovered metal came from new (manufacturing) scrap and 55% from old scrap (discarded aluminum products). The metal recovered from old scrap satisfied 25% of the total domestic aluminum metal demand for the year. The predominant type of purchased scrap was aluminum used beverage can (UBC) scrap, accounting for approximately one-half of the old scrap consumed.

According to a survey conducted by the Aluminum Association Inc., the Institute of Scrap Recycling Industries, and the Can Manufacturers Institute, 59.5 billion aluminum UBC's were recycled in 1993, equivalent to a recycling rate of 63.1%. This was the fifth consecutive year that the recycling rate for aluminum UBC's exceeded 60%.

The London Metal Exchange (LME) reported that aluminum alloy ingot held at its U.S. warehouses at yearend 1993 decreased to 980 tons, a mere fraction of the 10,120 tons of alloy held at yearend 1992. Increased demand by the domestic automotive diecasting industry reportedly contributed to this significant decrease in LME alloy inventories. *(See tables 3, 4, 5, and 6.)*

Markets and Prices.—Purchase prices for aluminum scrap, as quoted by American Metal Market (AMM), fluctuated during the year and closed the year at lower levels than at the beginning of the year. The yearend price ranges for selected types of aluminum scrap were as follows: mixed low-copper-content aluminum clips, 39.5 to 40.5 cents per pound; old sheet and cast, 34.5 to 35.5 cents per pound; and clean dry aluminum turnings, 34 to 35 cents per pound.

Prices for UBC's trended downward for most of the year and closed about 6 cents per pound lower than at the beginning of the year. Aluminum producers' buying price range for processed and delivered UBC's, as quoted by AMM, began the year at 40 to 42 cents per pound. The price range at the end of the year widened and decreased to 33 to 37 cents per pound.

In mid-July, AMM discontinued the publication of secondary aluminum ingot prices and substituted an indicator price series. The yearend 1993 indicator prices for selected secondary aluminum ingots were as follows: alloy 380 (1% zinc content), 61.96 cents per pound; alloy 360 (0.6% copper content), 67 cents per pound; alloy 413 (0.6% copper content), 67.09 cents per pound; and alloy 319, 64.52 cents per pound.

The LME began cash trading of a secondary aluminum contract in January. The 1993 annual average price, based on 11 months of trading, was 45.13 cents per pound. Metals Week published an annual average U.S. price of 55.46 cents per pound for A-380 alloy (3% zinc content), the alloy comparable to that traded on the LME.

Foreign Trade.—Exports of aluminum scrap continued to decrease in 1993, reaching their lowest level in 9 years. Japan continued to be the principal destination of exported aluminum scrap, accounting for more than 40% of the total.

Imports for consumption increased compared with those of the previous year. Canada remained the major shipping country to the United States, supplying almost 60% of the total aluminum scrap imports in 1993. *(See tables 7 and 8.)*

World Review.—According to preliminary estimates published by the World Bureau of Metal Statistics in August 1994, world production of secondary aluminum was about 5.6 Mt in 1993. According to its statistics, the United States was the world's largest producer of secondary aluminum, followed by Japan and Germany.

Outlook

As the public and industry become more sensitive to the issue of waste management, the benefits of recycling should become more evident. The aluminum industry, with its long history of recycling experience and its vast network of collection centers, should be well-positioned to take advantage of this increased interest. The domestic and world secondary aluminum industries are expected to continue to expand. In the short term, the growing acceptance of aluminum beverage cans (with their very short life cycle) in overseas markets could lead to a more rapid growth rate in the recovery of aluminum in countries outside the United States, where the aluminum beverage can already dominates the market. In the long term, as more and more aluminum is used in products with longer life cycles, such as automobiles, more scrap will enter the market for recovery, and increase the secondary production levels in both the domestic and world markets of the future.

COPPER AND COPPER ALLOY SCRAP[4]

Background

Definitions, Grades and Specifications.—The Institute of Scrap Recycling Industries, Inc. (ISRI) recognizes about 53 classes of copper alloy scrap. Although there are several grades within each, the major unalloyed scrap categories are No. 1 copper, which contains greater than 99% copper, and No. 2 copper, which contains a minimum of 94% copper. There are special designations for low copper content scrap such as skimmings, ashes, and residues, which contain 12% to 30% copper, and even lower copper content scrap including electronic scrap, refining slags, printed circuit board, and metal-laden waste liquors. In addition, there are numerous copper alloy scrap designations.

Copper and copper alloy scrap may be recovered from post consumer used, wornout or obsolete products (old scrap), or it may be generated during the manufacture of finished products (new scrap). The Bureau of Mines generally measures only that scrap which enters into trade. Manufacturing scrap that is reprocessed internally by the producer or consumer (home or run-around scrap) is generally discounted when measuring scrap demand.

A manufacturer consuming brass mill products such as sheet, strip or rod, may have product yields as low as 40%. New scrap, generated in the form of borings, turnings, stampings, and off-spec products, is readily recycled at brass mills into semifabricates. This mill-return scrap is frequently sold back to the brass mill on long-term buy-back arrangements.

Resources.—Since World War II, the ever-increasing reservoir of copper products has satisfied between 19% and 33% of annual U.S. apparent industrial consumption in the form of old scrap. By 1993, this domestic reservoir of unreclaimed products contained over 70 Mmt of copper. While some of this copper has been disposed in landfills or dissipated to the environment and is not readily recovered, as much as 70% of this copper is still in use or abandoned in place, and hence theoretically available for recycling. Dissipative uses of copper, principally as copper chemicals, constitute only about 0.5% of current copper demand. It is estimated that between 30% and 50% of the unrecovered products have been disposed in landfills.

Estimation of the recycling efficiency for copper is complicated by the varied life cycle of its different end uses and by trade in manufactured products containing copper. Copper in electrical plants and machinery averages 30 years; in nonelectrical machinery, 15 years; in housing, 40 or more years; and in transportation, 10 years. In 1992, the recycling efficiency for copper (old scrap consumed divided by the quantity of old scrap theoretically available using average product sector life-cycles, and adjusted for net scrap trade) was estimated by the U.S. Bureau of Mines to be about 30%. This ignores net trade in copper contained in manufactured and semimanufactured products. By the same calculations, if all the copper that was theoretically available from old scrap were recycled in the United States, old scrap could account for almost three-fourths of domestic apparent consumption. In 1993, old scrap accounted for only 22% of apparent consumption. The rate of old scrap recovery is limited not only by copper's long life and its essential uses, but also by the sensitivity of scrap collection to market prices.

New (manufacturing) scrap, on the other hand, has a short life, about 30 days, and its recovery is limited by domestic manufacturing rates and efficiencies. This wide difference in turnaround and availability has resulted in a gradual increase of new scrap versus old scrap as a component in all scrap collected in the United States.

Technology.—Because of the variety of grades and alternative routes to recycling, an elaborate infrastructure has developed to collect, upgrade, and process copper-bearing scrap prior to shipment to the consumer. For example, copper cables and wires, a prime and valued source of higher grades of unalloyed scrap, must be processed manually or through sophisticated chopping operations, to remove unwanted insulation. While chopped wire is shipped in barrels, stripped cable and other bulky scrap must be sheared and baled to facilitate transport and feed to secondary smelters. Previously, burning of the cable to remove insulation and other combustibles prior to recycling was acceptable; environmental regulation of emissions now generally precludes this.

While No. 1 copper may be consumed directly (remelt) or processed through a refinery, No. 2 copper generally requires refining before it is consumed. Low-grade scrap is generally processed through multi-step smelting and electrolytic refining to produce refined copper, though some, such as electric circuit board scrap, may be treated hydrometallurgically to produce chemical products such as copper sulfate and copper oxide. Electrolytically refined secondary copper is generally interchangeable with primary refined copper and is suitable for wire and cable manufacture. While lower grades of alloy scrap may be processed through smelting, higher grades of sorted scrap are directly consumed (direct melt) in the production of copper alloy products.

Processing complex copper-containing materials, such as drosses, flue dust, catalysts, slimes from electroplating waste water, and metal-rich slags from converter processes requires a versatile production process. Secondary smelters use a three-stage smelting process similar to that employed in primary processing: a first stage primary smelting blast or reverberatory furnace, followed by a converter and anode furnace. Depending on grade, scrap may enter the flowstream at any of the three furnaces.

Alloy copper scrap may be directly consumed at ingot makers, brass mills, or foundries and miscellaneous manufacturers. The scrap is melted in reverberatory or electric induction furnaces, and impurities are skimmed off as dross. Pure metal or master alloy ingots may be added to adjust the composition of the melt before casting into slabs, ingots, billets, etc., or various foundry products.

Economic Factors.—Copper scrap prices are closely correlated to the price of refined copper. However, the price paid for scrap at each level of processing must be sufficiently discounted to allow for all subsequent processing costs. Thus, a scrap collector who must perform such functions as sorting, shipping, chopping, baling, etc. will pay less for scrap than does the consumer. Because of these inherent costs associated with the initial collection and processing of scrap, low refined copper prices will squeeze processing and profit margins and reduce the quantity of scrap that can be economically recovered. The spread between refiner's buying price for No. 2 scrap and refiner's selling price (producer price) for refined copper has varied from 9 cents in 1970 to over 30 cents in the late 1980's. The low spreads in the early 1970's were caused by price controls placed on U.S. copper during this period. The very high spreads of the late 1980's were the result of high refined copper prices and a good supply of scrap.

Structural and Environmental Factors.—Domestic production and consumption of brass and bronze ingot, products from copper-based scrap, declined markedly between the late 1960's and early 1980's owing to substitution of aluminum and plastics for brass and bronze castings, increased import penetration, and the imposition of environmental control regulations on both ingot makers and the consuming foundries. Over that time period, domestic production of alloy ingot fell by

40%, and more than one-half of the approximately 40 ingot makers were closed. The foundry industry underwent a similar contraction. After a period of stabilization and even growth in the late 1980's, contraction in this industry resumed in the early 1990's as a response to numerous environmental regulations including: stricter atmospheric lead emissions standards and worker exposure limits; water discharge regulations; and land-fill disposal restrictions for contaminated foundry sands.

Lead associated with copper scrap continued to pose additional obstacles to the recycling of copper alloy scrap. New drinking water standards required the lowering of the lead content of potable water supplies and may require the complete elimination of lead from brass used in plumbing fixtures for potable water supplies. The addition of up to 8% lead in brass castings and rod greatly improves machineability and casting characteristics. While research to develop new low-lead or lead-free alloys was underway, little effort was being expended to develop the technology to remove lead from existing alloys. Without new technology, these materials could be precluded as feed stock for low-lead or lead free alloy production.

The existence of lead stabilizers in the PVC coverings of copper wire and cable posed a threat to recycling of these materials. The lead-content could result in the waste or "fluff" from wire chopping operations being regulated as a hazardous waste, adding to handling and disposal costs.

Annual Review

The oversupply of copper that led to rising global inventories during 1992 persisted into 1993, for while world refined production and capacity increased slightly, world demand for refined copper remained stagnant. According to data collected by the International Copper Study Group (ICSG) total world consumption of refined copper remained unchanged in 1993 at 11.1 Mmt. Demand in Western Europe was particularly poor, falling by almost 10%. Weak demand in Japan was partially offset by growth in other Asian markets. Refined copper demand in the United States and Canada, however, ran counter to the world trend, rising by 8.5% and 19%, respectively. As a result of these trends, prices for copper and copper scrap moved downward throughout the year, except for a mid-year period when prices were artificially high, reportedly owing to market manipulation. In 1993, the major copper consuming nations or areas of the world were Europe (36%), the United States (21%), and the Middle East and Asia (35%).

In the United States, five secondary smelters and six fire refineries were processing scrap during 1993. Nine electrolytic refineries operated during the year, three of which were dedicated facilities processing secondary anode. Several others purchased or toll-refined secondary anode. About 28 ingot makers consumed copper and copper alloy scrap in the production of brass and bronze ingots and master alloys. Direct-melt scrap was consumed at about 35 brass mills and 160 foundries, chemical plants, and miscellaneous consumers of copper.

In 1993, old scrap consumption, converted to refined metal and alloys, was 555,000 tons of copper, unchanged from that of 1992, and was equivalent to 22% of U.S. apparent consumption. Purchased new scrap, derived from copper fabricating operations, yielded 731,000 tons of copper, up slightly from that of the previous year, and accounted for 57% of copper recovered from all scrap. Of the total copper recovered from copper-, aluminum-, zinc-, and nickel-based scrap, copper smelters and refiners recovered 36%; brass mills, 46%; brass and bronze ingot makers, 10%; and miscellaneous manufacturers, foundries, and chemical plants, 8%. Unalloyed scrap accounted for 51% of copper-based scrap consumed, as shown on table 13.

About 77% of the copper contained in new scrap was consumed at brass mills. Copper in all old and new refined or remelted scrap comprised 39% of total U.S. copper supply and had an equivalent refined value of $2.6 billion. *(See tables 9-16.)*

Market and Prices.—Copper scrap prices trended lower in 1993 following the decline in refined copper prices. With falling prices, however, the scrap discount to refined copper narrowed. In January, the month of peak refined prices, the average brass mill buying price for no. 1 scrap of 94.1 cents per pound, as shown in table 17, was discounted by 11.3 cents from the domestic producer price. The discount averaged about 9 cents during the remainder of the year, except for a period in September and October, when market manipulations reportedly led to artificially high refined prices and an increase in the no. 1 scrap discount to about 14 cents per pound.

The overall U.S. copper market showed a strong recovery from the depressed 1992 level, with demand for refined copper rising by 8.5%. Copper recovered from scrap, on the other hand, was unchanged. A surplus of refined copper led to plentiful supplies, lower prices, and as noted above, narrower processing margins, all of which encouraged the consumption of refined copper at the expense of scrap. Consumption of copper based scrap at brass mills was stagnant, while consumption of refined copper rose by more than 10%. On a tonnage basis, most of the incremental refined demand was from copper wire rod mills, which are almost 100% dependent on refined copper for their feed stock. Domestic foundries experienced a decrease in shipments and a decline in both refined copper and scrap consumption. Foundry consumption of brass ingot, a product of brass scrap, was unchanged. Fire-refined copper *(see table 11)*, the only area of scrap consumption to experience significant growth, increased owing to the strength of tube mill shipments; tube mills are the major consumers of fire-refined copper.

Foreign Trade.—The United States was a net exporter of copper scrap, and one of the largest international sources for copper scrap, followed by France, Germany, and the United Kingdom. U.S. exports of copper scrap have been increasing since the 1960's, when the Asian nations began to industrialize. In 1993 China, Hong Kong, Japan, Korea, Singapore, and Taiwan, combined, accounted for 56% and 63%, respectively, of U.S. unalloyed and alloyed scrap exports. In 1993, exports to China, the largest recipient of domestic scrap, declined significantly. Over-buying of copper during 1993, devaluation of the Chinese currency, imposition of higher tariffs, and a reported shortage of available foreign exchange, combined to significantly reduce Chinese purchases of U.S. scrap. Canada and Mexico were the leading sources for U.S. imports of copper and copper alloy scrap and accounted for 70% of imports in 1993. *(See tables 18 and 19.)*

World Review.—The Western European countries made up the largest single market for scrap in the world. Germany, Italy, France, and the United Kingdom were the leading consumers. The United States was second after the European Community (EC) in total scrap consumption. Asia, mostly Japan, was the third largest scrap consuming area of the world. Copper scrap accounted for an estimated 43% of total annual copper consumption (refined consumption plus estimated copper content of direct-melt scrap) in Western Europe, compared with about 39% of total annual copper consumption in the United States. Consumption of scrap, on a tonnage basis and as a percentage of total copper consumption, has been increasing in Europe over the past several years, principally owing to expansion of secondary refined production in Germany and Italy. In 1993, 20% of refined copper in the United States and 47% of the refined copper produced in Western Europe was derived from copper scrap. In Japan, only about 8% of refined production was from scrap, but, owing to the large quantity of direct melt scrap consumed, about 25% of total copper consumption. In 1993, secondary refined production accounted for about 16% of the world's refined copper production.

Outlook

Over the next decade, copper scrap will continue to be a premium material for the U.S. semifabricating industry. Because scrap is usually a lower-cost alternative to primary metal, it will continue to be of great interest to Far Eastern countries as they expand their industries.

In the United States, however, the recovery of copper from old scrap remained stagnant in 1993, and did not share in the strong growth in copper demand. Old scrap as a percentage of apparent consumption declined from 25% in 1991, to 22% in 1993. The recovery of copper (old scrap) from the large and growing reservoir of copper products in use may be limited by the following factors: (1) copper prices, (2) life of products, (3) available recovery technologies, and (4) changing end-use patterns. In the latter case, electrical applications have been gaining an increasing share of domestic consumption. The long life cycle of building and transmission wire, the growth of consumer electronics, which are difficult to recycle, and the trend toward greater product reliability, could, in the short term, reduce old scrap availability. Increased production efficiencies have significantly affected the availability of new scrap. Industry analysts have observed that the amount of new scrap being generated by manufacturing plants has been cut by as much as 50%. Another factor that will affect copper scrap consumption and processing over the next decade is the limitation on lead in copper plumbing alloys, the result of legislation limiting the content of lead in plumbing fixtures used in potable drinking water supply systems. Leaded brass scrap is the prime feed material to the ingot-making and foundry industries. While extensive research was being conducted on low-lead or lead-free alternative alloys, technology to remove lead from leaded brass scrap was lagging and could prove a future limitation to the recycling of this material.

LEAD[5]

Refined lead is a soft, heavy metal, one of the first metals used by humankind. It has a low melting point, which makes it among the easiest metals to cast, it is the most corrosion-resistant common metal, and it has useful electrical properties. In terms of tonnage of metal consumed, demand for lead is surpassed only by that of aluminum, copper, iron, and zinc. The United States is the world's largest producer and consumer of refined lead. The domestic demand for lead has changed significantly over the past 20 years. In 1972, dissipative uses of lead, particularly in gasoline additives, pigments, ammunition, and chemicals, amounted to more than 400 thousand tons, or about 30% of the reported consumption of 1.35 million tons. In 1993, following the phase-out of lead-based gasoline additives and pigments for interior paint, dissipative use accounted for about 10% of the total demand of 1.36 million tons.

About 67% of the lead used domestically is recovered from scrap. In 1993, approximately 904 thousand metric tons of metal valued at $463 million was recovered from both new and old scrap. The United States exported about 54 thousand tons of lead scrap in 1993, with a value of $14 million. Corresponding imports of lead scrap for the year totaled 90 tons, worth $39 thousand. *(See tables 20, 21, 22, and 23.)*

In 1993, old scrap accounted for 93%, and new scrap for 7%, of the total of 904,000 tons of lead scrap recovered. Of the total old scrap recovered, nearly 95% was supplied from used batteries. The battery industry dominates the lead scrap field just as it dominates the primary lead usage category. In recent years, integrated battery manufacturers/secondary smelters have expanded smelting capacity to fill a vacuum left by the closure of small and medium sized nonintegrated battery breakers, and/or secondary smelters that have closed because of environmental-related pressure. Similarly, the independent scrap dealer is playing a diminished role, as battery manufacturers are entering into buy-back arrangements with retail outlets, both as a marketing tool for new batteries and as a means of ensuring feedstock to their smelters and downstream manufacturing operations.

Domestic Data Coverage

Domestic data for lead scrap are developed by the U.S. Bureau of Mines from voluntary monthly and annual surveys. The larger companies are canvassed monthly and the smaller ones annually. Of the 38 companies producing secondary lead, exclusive of lead in copper-base alloys, to which a survey request was sent, 26 responded, representing 80% of the total refinery production of secondary lead. Production and consumption for the nonrespondents were estimated using prior-year levels adjusted for general industry trends.

Annual Review

Legislation that would affect secondary lead producers was reintroduced in the U.S. House of Representatives in 1993. The legislation, entitled "The Lead-Based Paint Hazard Trust Fund Act of 1993", essentially a revamping of a 1992 bill, proposed a unitary tax of 45 cents per pound on all primary and secondary lead produced domestically and imported. The intent of this legislation was to provide a dedicated revenue of $1 billion per year for use in protecting against lead-based paint hazards in accordance with Title 10 of the Housing and Community Development Act of 1992. By yearend 1993, no significant advancement of the bill had occurred.

Domestic secondary production in 1993 was estimated to have declined by about 1.5% from a near record high in 1992. Secondary lead accounted for 73% of domestic lead production in 1993, reflecting a continued high level of lead-acid battery recycling. Battery Council International statistics indicated that the recycling rate for lead-acid batteries had been 94.4% in 1992.

A significant part of the decline in secondary production in 1993 was in the recovery of lead by nonbattery recyclers. These recyclers, who mainly produced specialty alloys for such uses as solders, brass or bronze ingots, and bearing metals, continued to experience higher costs and lower profit margins in their operations.

Several industry actions occurred in 1993 that will affect lead recycling industry capacity in the United States. RSR Corp., Dallas, TX, announced plans to build a new $60 million auto and industrial lead-acid battery recycling plant in Aiken County, SC. The facility was to be the first greenfield lead-acid battery recycling operation in the southeastern United States and was to be capable of processing 6 million batteries annually. The source of obsolete batteries was expected to come from an eight-State area in the southern United States through existing conversion agreements with battery scrap dealers. RSR expected permitting and construction time for the new facility to take from 3 to 5 years.

GNB Battery Technologies Inc., Atlanta, GA, announced in late 1993 that it was suspending indefinitely plans for a proposed greenfield secondary lead smelter in Waynesboro, GA. The decision coincided with a fine that had been levied by Environmental Protection Agency (EPA) on GNB's facility in Columbus, GA. In a subsequent agreement with EPA, the company planned to begin installation of new pollution control equipment at the Columbus facility.

Refined Metals Corp., Longview, TX, closed indefinitely its secondary smelters in Memphis, TN, and Beech Grove, IN, at the beginning of the year. The combined capacity of the two smelter operations was about 50,000 tons per year.

Outlook

While overall economic growth was somewhat slower than anticipated in 1993, the automotive sector, and its related demand for lead-acid batteries, remained strong through 1994 and was expected to continue as such in the short term. Total vehicle production in the United States rose by more than 10% to about 10.8 million units in 1993, and increased by another 12% in 1994.

The U.S. lead market tightened in 1994 as consumption rose by about 8% and a shorter supply of lead pushed prices higher. Similar market factors are expected to exist in the short term. Secondary production of lead was expected to increase to about 75% of domestic production in this period, as higher prices encouraged more recycling.

TIN[6]

Tin was one of the earliest metals known to humankind. Tin occurs in nature principally as the oxide mineral cassiterite. Tin metal is commonly used as a protective coating or as an alloying metal with other metals. Metal is generally used as the starting point for most uses of tin. The major uses for tin are as follows: cans and containers, 32%; electrical, 22%; construction, 10%; and transportation, 11%; other uses account for the remaining 25%. Tinplating currently uses no scrap tin, but most other fabricated end-use items, especially solder and brass/bronze, use substantial quantities of tin scrap.

About 25% of the domestic supply of tin metal is metal recovered from both new and old tin scrap. In 1993, 11,700 tons of metal valued at an estimated $90 million was recovered from new and old tin scrap.

Old tin scrap is collected at hundreds of domestic scrap yards, at nine tinplate and can detinning plants, and at most municipal collection centers. New tin scrap is generated mainly in the tin mills at six steel plants, numerous brass and bronze plants, and numerous soldermaking plants.

Detinning facilities are unique to the tin scrap industry, in that no other major metal industry has such large-scale facilities to remove plated metal. There are nine domestic detinning plants scattered across the country. Until about 1989, they processed almost solely new tinplate scrap that originated in the tin mills of steel plants and canmaking plants. Since 1989, with new technology that shreds used tin cans, some of the detinning facilities have the capability of also detinning old tin cans. Only in the detinning process does free tin metal see its way to the marketplace; all the alloy forms of tin are merely recycled within their own product-line industries and thus reappear as regenerated alloys. *(See tables 24, 25, 26, and 27.)*

Most tin scrap processing facilities are close to the tin-using industries and to densely populated areas. Most are in the Midwest and Northeast.

Domestic Data Coverage

Domestic scrap data for tin are developed by the USBM from a voluntary survey of the U.S. tin scrap industry. The smaller side of this industry is covered by a canvass sent to five detinning companies monthly; all five responded or are estimated for. The larger side of the tin scrap industry, involving the alloys of tin, is covered largely by a canvass of the copper and lead scrap industries (tin's major coalloys) from which estimates are made for the tin content.

Background

Secondary tin was derived 40% from new scrap and 60% from old scrap. New tin scrap consists mostly of forms of tinplate (side scrap, flitters, cobbles, skeletal punch-outs from can-making etc), drosses from soldering skims, and plating residues and sludges from tinplating lines. Old tin scrap consists mostly of used brass/bronze items (often faucets, fixtures, etc.) and used soldered items (electronic solders from computers, television and radio sets, etc. and plumbing solders from houses and office buildings); since about 1989 some used tin cans have been detinned, and the scrap tin recovered qualifies as old tin scrap.

The solder industry traditionally has consumed large amounts of tin scrap to make solder products. Tin scrap accounts for 42% of the total tin used for solder. The brass/bronze industry, although a smaller user of tin than the solder industry, also traditionally has been a major consumer of tin scrap. Scrap accounts for 52% of the total tin used for brass/bronze.

The average life of tin in its end uses is estimated at 20 years. It is estimated that about 10% of the tin placed in use in any year is dissipated in that same year. Tin in such chemical products as wood preservatives, marine boat hull antifoulant paints, fungicides, tin oxides, and tin tetrachlorides sprayed on glass bottles is quickly dissipated. Some longer lasting tin products also release tin to the environment while in use. For example, tinned electrical copper cables lose tin through weathering or corrosion, whether overhead or underground. The tin in some other end uses is dissipated, even though the products are disposed of in a controlled way; an example would be the used tin cans collected by municipal trash departments and placed in landfills. Currently, about 15% of the domestic requirement for tin is satisfied by old scrap.

Technology.—Tin recycling processes vary according to the nature of the tin scrap. Tin-plated products such as tinned kitchen trays, tinned electrical copper cables, tinplate, or tin cans typically are treated in a batch process at elevated temperatures with a sodium hydroxide solution for a considerable period of time. Typically, an electric current is applied in a reversal of the original plating process. The tinned product is made anodic and electrodes in the batch are made cathodic. Positively charged tin ions leave the tinned product and travel through the electrolytic bath to the negatively charged electrode, where the tin is plated and then can be used as scrap tin for a variety of uses.

For tin alloys, generally there is no attempt to recover the tin as a separate element. Instead, during the alloy refining process the matte is analyzed periodically, and as needed, tin is added to bring the molten batch to the desired specifications.

Secondary tin generally is utilized in the various alloys of tin, especially brass/bronze and solder. These alloys often take the shape of a bar or ingot, but also sometimes appear as rod, wire, plate, pellets, or powder. Traditionally, the brass/bronze industry utilizes the largest percentage of scrap tin to total tin.

Economic Factors.—Scrap prices are generally available only within the industry. But occasionally, publications such as American Metal Market publish some alloy scrap prices and prices for baled old tin can scrap.

There is an active international market in some forms of tin scrap. Generally, the United States has been the world's leading generator of tin scrap, and in some years substantial amounts are exported.

Annual Review

The Steel Can Recycling Institute (SCRI), based in Pittsburgh, PA, announced that henceforth it will be called The Steel Recycling Institute (SRI). The name change reflected a broadening of its mission to encompass not only steel cans (which had been its sole focus since its 1988 founding), but all steel products ranging from appliances to cars. Since SCRI's 1988 inception, the steel can recycling rate had grown from 15% to more than 40%. The overall steel recycling rate has been over 60% for more than 20 years and currently stands at 66%.

The SRI announced that a landmark year was achieved in 1992 for steel can recycling. In 1992, for the first time ever, more than 1 million tons of steel cans were recycled domestically, resulting in a 41% recycling rate. In 1991, the recycling rate was 34%. In the past 5 years, this recycling rate has steadily increased. The SRI delineated the following specific container recycling rates: a) In 1992, more than 12 billion steel food cans were recycled. With a recycling rate of 44%, the steel food can continues to be the Nation's most recycled food container. In 1991, about 36% were recycled; b) the 1992 recycling rate for steel beverage cans (sometimes called bimetal cans) was about 50%. In 1991, about 46% were recycled; and c) in 1992, about 15% of all steel general line cans (paint, aerosol, varnish, etc cans) were recycled. In 1991, about 12% were recycled. The 1 million tons of cans recycled in 1992 equates to about 14 billion steel cans.

In March 1993, in Florida, a 5-month campaign by the SRI to show the State's environmental regulators that steel cans in the State were being recycled at a rate greater than 50%, was successful. Florida had instituted a new advance disposal fee (ADF) on containers that have a recycling rate in the State below 50%. The levy was set at 1 cent per container starting in July 1993, and could increase to 2 cents per container in October 1995. Aluminum cans had earlier been granted exemption due to their high recycling rate, while glass and plastic containers failed to qualify. The stakes were high for steel cans in Florida, where about 106,000 tons of steel containers were distributed in 1991. The SRI was able to demonstrate that steel cans in Florida had a 54% recycling rate.

During the year, the SRI began an initiative calling for increased recycling of all empty paint and aerosol cans. Both items are virtually all tinplate products. SRI targeted these two types of containers as ones that municipalities operating curbside and drop-off recycling programs must include in their efforts if the steel industry is to reach their goal of recycling two out of every three cans by 1995. Paint cans and aerosol cans are categorized as general-line cans (as distinguished from beverage or food cans) in the container industry. Recycling operators have often displayed a reluctance to collect used paint cans and aerosol cans due to the fact that some of them contain residues that could be troublesome to remove. SRI cited two recent studies, one by the Texas Water Commission and the other by S.C. Johnson Wax Co., that reportedly blunted such reluctance.

World Review.—The United States, France, Germany, Japan, and the United Kingdom, generally lead the world in tin recycling activity and innovation. Environmental pressures in those countries for the past 20 years have acted as a powerful incentive.

In contrast to the United States and Europe, where detinning has long been a substantial activity, Japanese industry does little or no detinning because it feels that the tin coating on tinplate has become so thin in the past 20 years that detinning is not economical, and not necessary since the Japanese steel industry uses old tin cans and manufacturers' tin plate scrap as feed for its furnaces. Nippon Steel Corp., the world's largest steelmaker and perhaps the world's largest tinplate producer, was reported to be rapidly increasing the quantity of used steel cans it purchases for recycling at its Kimitsu plant. Nippon began recycling used steel cans at Kimitsu in 1984, and planned to reach a level of 2,000 tons of tinplate scrap recycled by 1995. During 1993, the weight of cans it recycled was reported to have increased to more than 1,000 tons monthly.

Outlook

The near- and long-term outlook for tin recycling is positive, with modest growth expected, about 1% annually. Tin is a high-value industrial metal; as tinplate, one of its main uses, it is easily separated magnetically for recycling. Tin consumption is expected to grow about 1% annually. Scrap is expected to grow from 25% of total metal consumed in 1993 to 27% annually by the year 2000. A major incentive is expected to be environmental legislation, mostly at the local and State level. If tin prices remain relatively high compared with prices of other major metals, the industry will have sufficient incentive to recycle this costly metal.

ZINC[7]

Zinc is the fourth most widely used metal after aluminum, copper, and iron. About three-fourths of consumption is in metal form and one-fourth in compound form. More than 90% of the metal is used for galvanizing steel and for alloys; the remainder is used to produce dust, oxide, and various chemicals. Most metal products find widespread use in the automotive, construction, electrical, and machinery sectors of the economy. Compounds are similarly dispersed in distribution and use, but are mainly used in agricultural, chemical, paint, pharmaceutical, and rubber sectors of the economy.

Annual Review

Nearly one-third of the 1.37 million tons of zinc consumed annually by domestic industries is secondary zinc. In 1993, about 355,000 tons of secondary zinc, valued at about $361 million, was recovered in refined metal, alloys, dusts, and chemicals. Scrap containing about 46,000 tons of zinc and valued at $18 million was exported in 1993, whereas 38,000 tons of zinc in scrap, valued at $14 million, was imported.

Recycled zinc was derived 70% from new scrap and 30% from old scrap. New zinc scrap was generated mainly in galvanizing and diecasting plants, brass mills, and manufacturing facilities when basic zinc materials are consumed. In consisted mostly of drosses, skims, furnace dusts, and residues (from galvanizing and diecasting operations, brass mills, and chemical plants) and clippings from the processing (stamping, trimming, etc.) of galvanized steel sheet and strip, rolled zinc, and brass sheet. Old scrap consisted almost entirely of diecastings, (mainly from scrapped automobiles), brass products, and rolled zinc items, such as gutters, roofing, and engraving plates. Zinc recovery from the burning of tires for energy is small but growing, whereas recovery from both old and new galvanized steel scrap has increased dramatically. Old zinc and brass scrap were collected at hundreds of domestic scrap yards, at more than 200 U.S. automobile and appliance shredding operations, and at numerous municipal collection centers. In 1993, there were 4 primary and 10 secondary smelters that processed scrap, drosses, skims, and/or steelworking electric arc furnace (EAF) dust into slab zinc, zinc alloys, and zinc dust. Seven other plants processed skims, drosses, scrap, and residues into zinc sulfate and/or chloride chemicals. Secondary brass and bronze were recycled at more than 500 secondary smelters, foundries, and ingot makers. A plant in Illinois produced American-process zinc oxide from oxidic secondary materials. Most secondary zinc plants are in the Eastern and Midwestern United States; one plant in Pennsylvania is, by far, the single largest processor secondary zinc. Crude zinc concentrates extracted from EAF dust are produced at six plants. *(See tables 27-29.)*

Background

Technology.—Because of wide differences in the character and content of zinc-bearing scrap, zinc recycling processes vary widely. Zinc-containing metals generally are separated from other materials initially by physical means such as magnetic separation, sink-floating, and hand sorting. In the case of mixed nonferrous metal shredder scrap, zinc can be separated from higher-melting point metals such as aluminum and copper, by selective melting in a sweat furnace. Zinc in galvanized scrap is largely recovered in furnace dust when the scrap is charged into a steelmaking furnace; however one commercial process has been developed to strip zinc from galvanized scrap with a caustic leach prior to recycling the substrate steel to the steelmaking process.

Clean new scrap, mainly brass and rolled zinc clippings and reject diecastings, generally only require remelting before reuse. Drosses, fragmentized diecastings, and mixed high-grade scrap typically are remelted, followed by zinc distillation with recovery as metal, dust, or oxide. Sometimes, high-purity drosses are simply melted and reacted with various fluxes to release the metallic content; often the recovered metal can be used directly as a galvanizing brightener or master alloy. Medium and low-grade skims, oxidic dust, ash, and residues generally undergo an intermediate reduction-distillation-pyrometallurgical step to upgrade the zinc product before further treatment; or they are leached with acid, alkaline, or ammoniacal solutions to extract zinc, which is subsequently recovered as a compound by precipitation-crystallization or as a saleable chemical retained in solution. Almost all of the zinc in EAF dusts is first recovered in an upgraded, impure zinc oxide product; however, several commercial EAF-dust-treatment plants are able to bypass the intermediate step and recover zinc metal directly. The upgraded zinc oxide pyrometallurgical production is almost always shipped to a primary pyrometallurgical zinc smelter for refinement to metal. For the most part, the zinc metals, alloys, dust, and chemical recovered from secondary materials are comparable in quality to those derived from primary materials.

Recovery efficiency is very high from simple remelting, but declines as the number of processing steps increases and, generally, as the zinc content of the scrap declines. Zinc recovery from most secondary processes ranges between 40% and 85%; however, oxide materials, slags, and residues resulting from initial processes may in turn be recycled, resulting in further zinc recovery.

Secondary Refined Products.—Zinc materials made from zinc-base scrap are slab zinc, alloys, dusts, and compounds. Brass scrap, on the other hand, typically is remelted and, with alloy adjustment, recast as brass. Zinc chloride and sulfate compounds are produced largely by acid leaching of zinc skims, drosses, and chemical residues. Impure zinc oxide products and zinc bearing slags are sometimes used as trace element additives in fertilizers and animal feeds. Zinc in brass is the principal form of secondary recovery, although in the past few years, secondary slab zinc has risen substantially because it has been the principal zinc product of EAF dust recycling.

Markets and Prices.—Prices paid for scrap and secondary materials are generally negotiated, often on the basis of a daily or average London Metal Exchange price for zinc metal. Bids are required for U.S. Department of Defense scrap sales. Prices depend on factors such as geographic location, quantity available, quality, grade, the presence of other components or elements, and environmental difficulties in handling, transporting, or treating. In the case of EAF, the dust generator usually pays the dust processor a fee to recycle the material. Typically, there is a basic charge for dust with 20% zinc content; generators of dust with lower zinc content pay more, whereas generators of dust with higher zinc content pay less. Zinc and brass scrap prices are generally not available, although average daily, weekly, or monthly prices for a few specific common types are published in American Metal, Market, Metal Bulletin, and Metal Bulletin Monthly.

Outlook

Driven by public concern for the environment and legislation intended to protect the environment, domestic and world secondary zinc recovery is expected to increase as a percentage of zinc consumption in the next decade. However, the prospect for recovery equivalent to more than 35% to 40% of consumption is relatively poor because of the dissipative nature and diversity of zinc uses. Galvanizing has been the major growth area for zinc, and greater secondary zinc recovery can be expected from this source in the future. Increased processing of low-zinc EAF dust, from other steelmaking processes, and energy-generating tire burning appear to be other sources for near term gains in secondary zinc output. Increased zinc recovery from the recycling of carbon-zinc and alkaline batteries, and municipal incinerator dusts and residues are longer term possibilities. Secondary zinc recycling could dramatically increase after the year 2000 if a substantial number of electric cars, powered by zinc-air batteries, becomes a reality.

[r] Revised.

[1] Recycled metal is metal recovered from purchased scrap.

[2] New scrap is scrap that results from the manufacturing process, including metal and alloy production.

[3] Old scrap is scrap that results from consumer products.

[4] Data may not add to totals shown because of independent rounding.

[5] Quantity is the calculated metallic recovery from aluminum-based scrap, estimated for full industry coverage. Value is estimated based on average annual U.S. market price for primary aluminum metal.

[6] Recoverable copper values in scrap based on annual averages for refined copper.

[7] Transaction value estimated to be London Metal Exchange (LME) average cash value plus 6.5 cents/lb.

[8] Nickel scrap is nickel contained in ferrous and nonferrous scrap receipts. Value is estimated as average annual LME cash price of nickel cathode.

[9] Value estimated based upon Platt's Metals Week (PMW) Tin Composite price. Reevaluation of the tin canvass in 1991 resulted in a substantial lowering of estimated old scrap.

[10] Value based on average annual U.S. zinc metal price published in PMW; for 1989-90, the PMW average prices were based on U.S. or North American Producers' High Grade zinc delivered prices and for 1991-93, the LME spot prices for Special High Grade zinc plus premiums based on market conditions.

[r] Revised.

[1] Apparent supply is production plus net imports plus stock changes. Production is primary production plus recycled metal (see table 1, footnote 1). Net imports are imports minus exports. Apparent supply is calculated on a contained weight basis.

[2] Recycled metal is metal recovered from purchased scrap.

[3] Same as apparent supply defined above but calculated on a monetary value basis.

[4] Monetary values estimated based on the U.S. market price for primary aluminum ingot. Recycle calculated as metal recovered from reported purchased new and old scrap estimated for full industry coverage.

[5] Copper recovered for consumption valued on average annual refined prices.

[6] Lead processors are segregated by primary and secondary producers. This segregation permits inclusion of stock changes in recycle lead supply. Transaction value for U.S. primary production and net imports estimated to be London Metal Exchange (LME) average cash plus 6.5 cents/lb. Stock adjustments value based on actual proportion of stock change to secondary production.

[7] Value of apparent supply and recycle estimated as average annual LME cash price of nickel cathode.

[8] Value estimated based upon Platt's Metals Week (PMW) Composite price.

[9] Value based on average annual U.S. zinc metal price published in PMW; for 1989-90, the PMW average prices were based on U.S. or North American Producers' High Grade zinc delivered prices and for 1991-93, the LME spot prices for Special High Grade zinc plus premiums based on market conditions.

TABLE 3
U.S. APPARENT ALUMINUM SUPPLY AND CONSUMPTION

(Thousand metric tons)

	1989	1990	1991	1992	1993
Primary production	4,030	4,048	4,121	4,042	3,695
Change in stocks:[1]					
Aluminum industry	+61	+2	+45	-100	-171
LME stocks in U.S. warehouses	—	—	-168	-46	+46
National Defense Stockpile	—	—	—	-55	—
Imports	1,470	1,514	1,490	1,725	2,545
Secondary recovery:[2]					
New scrap	1,043	1,034	969	[r]1,144	1,312
Old scrap	1,011	1,359	1,317	1,612	1,632
Total supply	7,615	7,957	7,774	[r]8,322	9,059
Less total exports	1,615	1,659	1,762	1,453	1,207
Apparent aluminum supply available for domestic manufacturing	6,000	6,298	6,012	[r]6,869	7,852
Apparent consumption[3]	4,957	5,264	5,043	5,725	6,540

[r] Revised.

[1] Positive figure indicates a decrease in stocks; negative figure indicates an increase in stocks.

[2] Metallic recovery from purchased, tolled, or imported new and old aluminum scrap expanded for full industry coverage.

[3] Apparent aluminum supply available for domestic manufacturing less recovery from purchased new scrap (a measure of consumption in manufactured end products).

TABLE 4
U.S. CONSUMPTION OF AND RECOVERY FROM PURCHASED NEW AND OLD ALUMINUM SCRAP,[1] BY CLASS

(Metric tons)

Sweated pig	268	11,348	11,281	335
Total integrated aluminum companies, etc.	[r]51,603	2,043,916	2,051,574	43,945
All scrap consumed:				
New scrap:				
Solids	[r]15,961	765,789	764,536	17,214
Borings and turnings	[r]4,706	147,237	147,686	4,257
Dross and skimmings	[r]2,619	142,617	140,018	5,218
Other[3]	[r]8,129	360,527	351,254	17,402
Total new scrap	[r]31,415	1,416,170	1,403,494	44,091
Old scrap:				
Castings, sheet, clippings	[r]21,695	831,324	830,576	22,443
Aluminum-copper radiators	[r]1,304	10,352	10,394	1,262
Aluminum cans	[r]24,863	858,183	870,960	12,086
Other[5]	[r]679	58,411	58,098	992
Total old scrap	[r]48,541	1,758,270	1,770,028	36,783

See footnotes at end of table.

TABLE 5—Continued

U.S. STOCKS, RECEIPTS, AND CONSUMPTION OF PURCHASED NEW AND OLD ALUMINUM SCRAP[1] AND SWEATED PIG IN 1993

(Metric tons)

Class of consumer and type of scrap	Stocks, Jan. 1	Net receipts[2]	Consumption	Stocks, Dec. 31
All scrap consumed—Continued:				
Sweated pig	497	13,028	12,892	633
Total of all scrap consumed	[r]80,453	3,187,468	3,186,414	81,507

[r] Revised.

[1] Includes imported scrap. According to reporting companies, 8.41% of total receipts of aluminum-base scrap, or 265,305 metric tons, was received on toll arrangements.

[2] Includes inventory adjustment.

[3] Includes data on foil, can stock clippings, and other miscellaneous.

[4] Used beverage cans toll treated for primary producers are included in secondary smelter tabulation.

[5] Includes municipal wastes (includes litter) and fragmentized scrap (auto shredder).

TABLE 6

PRODUCTION AND SHIPMENTS OF SECONDARY ALUMINUM ALLOYS BY INDEPENDENT SMELTERS IN THE UNITED STATES

(Metric tons)

	1992		1993	
	Production	Net shipments[1]	Production	Net shipments[1]
Die-cast alloys:				
13% Si, 360, etc. (0.6% Cu, maximum)	41,921	[r]44,703	45,539	44,724
380 and variations	[r]465,503	[r]465,009	517,948	516,863
Sand and permanent mold:				
95/5 Al-Si, 356, etc. (0.6% Cu, maximum)	78,089	67,146	85,064	84,406
No. 12 and variations	W	W	W	W
No. 319 and variations	[r]52,852	[r]52,931	67,373	65,654
F-132 alloy and variations	52,652	51,483	24,025	25,844
Al-Mg alloys	645	644	639	641
Al-Zn alloys	3,086	2,881	3,218	3,468
Al-Si alloys (0.6% to 2.0% Cu)	10,680	10,705	10,840	11,018
Al-Cu alloys (1.5% Si, maximum)	1,664	1,588	1,738	1,726
Al-Si-Cu-Ni alloys	1,352	1,326	1,360	1,395
Other	[r]2,707	[r]2,771	3,792	3,812
Wrought alloys: Extrusion billets	[r]71,486	[r]65,861	80,914	84,880
Miscellaneous:				
Steel deoxidation	3,345	3,413	—	—
Pure (97.0% Al)	59	69	—	—
Aluminum-base hardeners	93	97	93	93
Other[2]	34,262	33,433	34,244	35,233
Total	[r]820,396	[r][3]804,063	876,787	879,757
Less consumption of materials other than scrap:				
Primary aluminum	65,351	—	79,643	—
Primary silicon	35,573	—	39,192	—
Other	3,620	—	4,601	—
Net metallic recovery from aluminum scrap and sweated pig consumed in production of secondary aluminum ingot[4]	[r]715,852	XX	753,351	XX

[r] Revised. W Withheld to avoid disclosing company proprietary data; included with "Sand and permanent mold: Other." XX Not applicable.

[1] Includes inventory adjustment.

[2] Includes other die-cast alloys and other miscellaneous.

[3] Data do not add to total shown because of independent rounding.

[4] No allowance made for melt-loss of primary aluminum and alloying ingredients.

[r] Revised.

[1] Data may not add to totals shown because of independent rounding.

[2] Electrolytically refined and fire-refined scrap based on source of material at smelter level.

TABLE 11

PRODUCTION OF SECONDARY COPPER AND COPPER-ALLOY PRODUCTS IN THE UNITED STATES, BY ITEM PRODUCED FROM SCRAP

(Metric tons)

Item produced from scrap	1992	1993
UNALLOYED COPPER PRODUCTS		
Electrolytically refined copper	331,057	337,221
Fire-refined copper	[r]102,127	122,567
Copper powder	8,826	9,182
Copper castings	[r]493	631
Total[1]	[r]442,503	469,601
ALLOYED COPPER PRODUCTS		
Brass and bronze ingots:		
Tin bronzes	14,006	15,205
Leaded red brass and semired brass	109,565	91,439
High-leaded tin bronze	9,223	10,084
Yellow brass	6,768	7,417
Manganese bronze	5,992	6,763
Aluminum bronze	7,504	7,932
Nickel silver	2,691	2,233
Silicon bronze and brass	6,135	7,075
Copper-base hardeners and master alloys	8,127	7,858
Miscellaneous	3,421	5,444
Total[1]	173,433	161,450
Brass mill and wire rod mill products	738,008	732,713
Brass and bronze castings	[r]44,691	43,864
Brass powder	283	263
Copper in chemical products	292	217
Grand total[1]	[r]1,399,211	1,408,108

[r] Revised.

[1] Data may not add to totals shown because of independent rounding.

TABLE 12
COMPOSITION OF SECONDARY COPPER-ALLOY PRODUCTION IN THE UNITED STATES

(Metric tons)

	Copper	Tin	Lead	Zinc	Nickel	Aluminum	Total
Brass and bronze ingot production:[1]							
1992	[r]140,897	[r]5,331	[r]9,010	[r]17,873	290	31	[2]173,433
1993	130,752	4,815	8,190	17,332	319	42	161,450
Secondary metal content of brass mill products:							
1992	601,355	498	4,920	129,517	(3)	(3)	738,008
1993	590,482	612	6,054	133,827	(3)	(3)	732,713
Secondary metal content of brass and bronze castings:							
1992	[r]39,435	1,004	1,441	[r]2,368	[r]115	[r]328	[r]44,691
1993	38,934	837	1,419	2,458	78	138	43,864

[r] Revised. W Withheld to avoid disclosing company proprietary data.

[1] About 96% from scrap and 4% from other than scrap in 1992 and in 1993.

[2] Data do not add to total shown because of independent rounding.

[3] Withheld to avoid disclosing company proprietary data; included in "Total."

TABLE 13

CONSUMPTION OF COPPER-BASE SCRAP IN 1993

(Metric tons, gross weight)

Scrap type and processor	January	February	March	April	May	June	July	August	September	October	November	December	Total[1]
No. 1 wire and heavy:													
Smelters, refiners and ingot makers	11,074	15,931	12,168	12,345	13,165	15,079	12,019	15,748	15,321	22,264	17,505	14,966	177,585

TABLE 13—Continued
CONSUMPTION OF COPPER-BASE SCRAP IN 1993

(Metric tons, gross weight)

Scrap type and processor	January	February	March	April	May	June	July	August	September	October	November	December	Total[1]
Auto radiators:													
Smelters, refiners and ingot makers	6,444	6,178	5,854	5,261	5,166	5,212	4,526	5,348	5,612	5,659	5,246	5,225	65,731
Foundries and misc. manufacturers	508	508	508	508	508	508	508	508	508	508	508	508	6,097
Bronzes:													
Smelters, refiners and ingot makers	1,162	1,381	1,250	1,044	919	1,201	953	1,219	1,026	1,087	1,048	816	13,106
Brass mills and misc. manufacturers	945	1,045	1,134	1,064	766	930	836	847	846	669	726	710	10,518
Nickel-copper alloys:													
All plants	1,198	1,213	1,401	1,395	1,028	1,196	904	1,141	1,056	1,282	1,498	1,497	14,811
Low grade and residues:													
Smelters, refiners and miscellaneous manufacturers	13,074	15,919	12,525	15,366	13,928	11,780	14,821	15,257	11,529	13,803	11,743	11,562	161,306
Other alloy scrap:[3]													
Smelters, refiners and ingot makers	3,154	2,503	2,991	2,164	2,393	1,844	2,269	2,377	1,804	2,545	1,817	2,063	27,922
Brass mills and misc. manufacturers	541	405	473	554	460	419	495	502	500	604	412	448	5,813
Total alloyed scrap:[1]													
Smelters, refiners and ingot makers	33,242	36,131	32,147	33,198	31,277	29,335	30,066	33,041	29,390	32,132	28,272	27,965	376,197
Brass mills	36,356	36,851	40,891	37,249	35,191	34,483	29,827	33,701	34,623	39,665	34,152	34,876	427,867
Foundries and misc. manufacturers	2,209	2,209	2,209	2,209	2,209	2,209	2,209	2,209	2,209	2,209	2,209	2,209	26,506
Total scrap:[1]													
Smelters, refiners and ingot makers	71,440	76,807	73,903	72,463	74,061	78,503	70,605	79,047	70,119	84,930	70,598	69,278	891,754
Brass and wire-rod mills	65,285	61,286	67,325	65,207	61,342	61,557	54,793	58,692	61,330	68,432	59,715	59,352	744,316
Foundries and misc. manufacturers	5,061	5,061	5,061	5,061	5,061	5,061	5,061	5,061	5,061	5,061	5,061	5,061	60,732

[1] Data may not add to totals shown because of independent rounding.

[2] Includes composition turnings, silicon bronze, railroad car boxes, cocks and faucets, gilding metal, and commercial bronze.

[3] Includes refinery brass, beryllium copper, and aluminum bronze.

TABLE 14

CONSUMPTION OF PURCHASED COPPER-BASE SCRAP[1] IN 1993

(Metric tons, gross weight)

Period	Smelters and refineries		Ingot makers		Brass and wire-rod mills		Foundries, etc.		Total scrap used
	New scrap	Old scrap	New scrap	Old scrap	New scrap	Old scrap	New scrap[e]	Old scrap[e]	
January	15,051	39,875	3,771	12,743	59,387	5,898	2,100	3,000	141,825
February	15,500	43,563	4,060	13,684	58,271	3,015	2,100	3,000	143,193
March	14,998	42,391	3,909	12,605	63,616	3,709	2,100	3,000	146,328
April	14,065	42,822	3,715	11,861	62,069	3,138	2,100	3,000	142,770
May	15,331	43,588	3,506	11,636	59,164	2,178	2,100	3,000	140,503
June	17,097	45,520	3,695	12,191	58,087	3,470	2,100	3,000	145,160
July	12,762	45,453	3,483	8,907	50,204	4,589	2,100	3,000	130,498
August	15,615	48,399	3,961	11,072	55,889	2,803	2,100	3,000	142,839
September	13,707	41,218	3,896	11,298	58,041	3,289	2,100	3,000	136,549
October	18,520	50,986	4,094	11,330	64,764	3,668	2,100	3,000	158,462
November	13,907	42,522	4,461	9,708	57,544	2,171	2,100	3,000	135,413
December	12,832	43,077	3,989	9,380	57,292	2,060	2,100	3,000	133,730
Total	179,385	529,414	46,540	136,415	704,328	39,988	25,200	36,000	1,697,270

[e] Estimated.

[1] Consumption at brass and wire-rod mills assumed equal to receipts.

Tin content of chemical products	—	W	—	—	W
Grand total[2]	900,594	3,749	11,600	W	915,942
1993					
Refined pig lead[3]	436,340	—	—	—	436,340
Refined pig tin[4]	—	75	—	—	75
Lead and tin alloys:					
Antimonial lead	444,954	796	12,083	W	457,833
Lead-base babbitt	330	50	38	—	419
Solder	(5)	(5)	(5)	W	(5)
Type metal	849	43	118	3	1,012
Other alloys, including cable lead	15,858	3,846	74	—	19,778
Total[2]	461,992	4,736	12,312	W	479,040
Tin content of chemical products	—	W	—	—	W
Grand total[2]	898,332	4,811	12,312	W	915,455

W Withheld to avoid disclosing company proprietary data.

[1] Most of the figures herein represent actual reported recovery of metal from scrap.

[2] Data may not add to totals shown because of independent rounding.

[3] Includes remelt lead.

[4] Includes remelt tin.

[5] Included with "Other alloys, including cable lead" to avoid disclosing company proprietary data.

TABLE 22

LEAD RECOVERED FROM SCRAP PROCESSED IN THE UNITED STATES, BY KIND OF SCRAP AND FORM OF RECOVERY

(Metric tons)

	1992	1993
KIND OF SCRAP		
New scrap:		
Lead-base	48,274	52,295
Copper-base	^{r}7,147	^{e}8,000
Tin-base	3	3
Total	^{r}55,424	60,298
Old scrap:		
Battery-lead	^{r}784,255	798,176
All other lead-base	68,051	37,086
Copper-base	^{r}8,611	^{e}8,000
Tin-base	—	—
Total	^{r}860,917	843,262
Grand total	^{r}916,341	903,560
FORM OF RECOVERY		
As soft lead	452,920	425,572
In antimonial lead	424,535	444,954
In other lead alloys	^{r}23,125	17,031
In copper-base alloys	^{r}15,758	^{e}16,000
In tin-base alloys	3	3
Total	^{r}916,341	903,560
Value[1] thousands	^{r}\$709,084	\$632,263

^{e}Estimated. ^{r}Revised.

[1] Value based on average quoted price of common lead.

[r] Revised.

[1] Less than 1/2 unit.

[2] Data may not add to totals shown because of independent rounding.

[3] Also includes other lead-bearing materials containing greater than 10% by weight of copper, lead, or zinc (any one).

Source: Bureau of the Census.

TABLE 24
SECONDARY TIN RECOVERED FROM SCRAP PROCESSED AT DETINNING AND OTHER RECOVERY PLANTS IN THE UNITED STATES

		1992	1993
Tinplate scrap treated	metric tons	W	W
Tin recovered in the form of:			
Metal[1]	do.	137	112
Compounds (tin content)	do.	W	W
Total	do.	137	112
Weight of tin compounds produced	do.	W	W
Average quantity of tin recovered per metric ton of tinplate scrap used	kilograms	2.23	2.01
Average delivered cost of tinplate scrap	per metric ton	$91.85	$118.90

W Withheld to avoid disclosing company proprietary data.

[1] This data is felt to represent 39% and 22%, respectively, of actual industry activity due to non-reporting firms.

TABLE 25
TIN RECOVERED FROM SCRAP PROCESSED IN THE UNITED STATES, BY FORM OF RECOVERY

(Metric tons unless otherwise specified)

Form of recovery	1992	1993
Tin metal[1]	137	112
Bronze and brass[e] [2]	[r]12,781	10,670
Lead and tin alloys:		
Antimonial lead	704	796
Babbitt	78	51
Type metal	47	43
Other alloys[3]	W	W
Total	829	890
Tin content of chemical products	W	W
Grand total	[r]13,747	11,672
Value (thousands)[e] [4]	[r]$121,825	$90,037

[e] Estimated. [r] Revised. W Withheld to avoid disclosing company proprietary data; not included in "Total."

[1] Includes tin metal recovered at detinning and other plants. This data is felt to represent 39% and 22%, respectively, of actual industry activity due to non-reporting firms.

[2] Includes tin recovered from copper-, lead-, and tin-base scrap.

[3] Includes foil, solder, terne metal, and cable lead.

[4] Based on Platt's Metals Week composite price.

TABLE 26

U.S. STOCKS, RECEIPTS, AND CONSUMPTION OF NEW AND OLD SCRAP AND TIN RECOVERED, BY TYPE OF SCRAP

Grand total	XX	XX	XX	XX	XX	XX	4,453	7,219	11,672

[e] Estimated. [r] Revised. W Withheld to avoid disclosing company proprietary data. XX Not applicable.

[1] Tin recovered from new and old copper-base scrap, brass mills, and foundries.

[2] Brass-mill stocks include home scrap, and purchased-scrap consumption is assumed equal to receipts; therefore, line does not balance.

[3] Includes tinplate and other scrap recovered at detinning plants; U.S. Bureau of Mines not at liberty to publish separately.

TABLE 27

STOCKS AND CONSUMPTION OF NEW AND OLD ZINC SCRAP IN THE UNITED STATES IN 1993, BY TYPE OF SCRAP

(Metric tons, zinc content)

Type of scrap	Stocks, Jan. 1	Receipts	Consumption			Stocks, Dec. 31
			New scrap	Old scrap	Total	
Diecastings	333	3,376	—	3,494	3,494	215
Flue dust	W	8,985	4,499	4,477	8,976	W
Fragmentized diecastings	W	W	—	W	W	W
Galvanizer's dross	1,305	64,853	63,631	—	63,631	2,527
Old zinc[1]	81	1,132	—	1,031	1,031	182
Remelt die-cast slab	W	20,298	—	20,227	20,227	W
Remelt zinc[2]	W	W	W	—	W	W
Skimmings and ashes[3]	4,741	38,860	37,583	—	37,583	6,018
Steelmaking dust	W	W	W	W	W	W
Other[4]	5,046	71,423	28,090	43,409	71,499	5,050
Total	11,506	208,927	133,803	72,638	206,441	13,992

W Withheld to avoid disclosing company proprietary data; included in "Other."

[1] Includes engraver's plates and rod and die scrap.

[2] Includes new clippings.

[3] Includes sal skimmings and die-cast skimmings.

[4] Includes chemical residues and solutions and electrogalvanizing anodes.

TABLE 28

PRODUCTION OF ZINC PRODUCTS FROM ZINC-BASE SCRAP IN THE UNITED STATES

(Metric tons)

Product	1989	1990	1991	1992	1993
Electrogalvanizing anodes	W	W	W	W	W
Redistilled slab zinc	97,904	95,708	122,457	127,623	141,472
Remelt die-cast slab	4,167	5,144	W	W	W
Other metal alloys	272	257	W	W	W
Other zinc metal products	15,564	11,804	8,686	15,661	13,713
Secondary zinc in chemical products	57,575	56,135	65,746	73,277	64,979
Zinc dust	24,909	24,105	22,750	20,962	16,506

W Withheld to avoid disclosing company proprietary data, included in "Other zinc metal products."

TABLE 29

ZINC RECOVERED FROM SCRAP PROCESSED IN THE UNITED STATES, BY KIND OF SCRAP AND FORM OF RECOVERY

(Metric tons)

	1992	1993
KIND OF SCRAP		
New scrap:		
Zinc-base	106,751	108,269
Copper-base	[r]126,995	137,327
Magnesium-base	[r]47	33
Total	[r]233,793	245,629
Old scrap:		
Zinc-base	107,755	90,983
Copper-base	[r]23,954	17,303
Aluminum-base	[r]557	873
Magnesium-base	[r]47	44
Total	[r]132,313	109,203
Grand total	[r]366,106	354,832
FORM OF RECOVERY		
Metal:		
Slab zinc	127,623	141,472
Zinc dust	20,962	16,506

SALT

By Dennis S. Kostick

Mr. Kostick, a physical scientist with 15 years of U.S. Bureau of Mines experience, has been the commodity specialist for salt since 1980. Domestic survey data were prepared by Christopher Lindsay, supervisory statistical assistant; and international data tables were prepared by Harold Willis, international data analyst.

Salt is the most important mineral feedstock used by the chemical industry. Sodium chloride, commonly known as salt, is a universal commodity that is known and used by virtually every person in the world. It is an important compound that has a multitude of applications with approximately 14,000 different reported uses. Most individuals usually only associate salt with highway deicing and food processing; however, the largest end-use of salt is as feedstock for chlorine and caustic soda manufacture. These two important inorganic chemicals have a multitude of consumer-related end-use products, such as polyvinyl chloride (PVC) plastic made from chlorine and pulping chemicals manufactured from caustic soda.

Beginning with the 1992 Annual Report, all data are reported in metric units to comply with Public Law 100-418 of August 23, 1988. This Federal law required all Federal agencies to use the metric system of measurement by the end of fiscal year 1992. Although the use of the metric measurement standards was authorized by law since 1866 (Act of July 28, 1866; 14 Statute 339) and the United States was an original signatory party to the 1875 Treaty of the Meter (20 Statute 709), the United States has been the only industrially developed nation that has not universally converted to the metric system from the English system of measurements. Therefore, all data in this report are in metric tons unless otherwise noted. For comparison, 1 metric ton is equal to 2,204.6 pounds whereas 1 short ton is equal to 2,000 pounds. To convert metric tons to short tons, multiply the metric ton figure by 1.10231. To convert short tons into metric tons, divide by 1.10231.

As foreign trade of salt with the United States increases and foreign participation in U.S. salt companies continues, such as with the U.S. subsidiaries of Akzo Salt and Basic Chemicals International of the Netherlands and Sifto Canada of Canada, communicating information with an international standard of measurement becomes more important.

DOMESTIC DATA COVERAGE

Domestic production data for salt are developed by the U.S. Bureau of Mines (USBM) from an annual voluntary survey of U.S. salt-producing sites and of company operations. Of the 27 companies to which a survey request was sent, 25 responded, representing 80% of the total production shown in this report. Data for the two nonresponding companies, North American Salt Co. and Dow Chemical Co., were estimated on the basis of their prior responses to previous annual surveys, the 1993 production estimate survey, or brine production capabilities for chloralkali manufacture based on chlorine production capacities.

BACKGROUND

Salt has been an important commodity throughout history. Its presence has determined the location of cities, migration of populations, and routes of trade caravans. One of the earliest accounts of using salt in political-economic societies was traced to 2200 B.C. in China where Emperor Hsia Yu decreed that Shandong Province would supply the court with salt. The Phoenicians (1200 B.C. to 300 B.C.) were one of the first maritime civilizations to trade salt. Salt became an important universal medium of exchange. The English word "salary" is derived from the Latin term "Salarium argentum," which were the salt rations that Roman soldiers were partially paid for their services. Aside from its use as a medium of monetary exchange, salt also has been used to signify hospitality. The custom of presenting newlyweds wine, bread, and salt shows salt as a lifegiving and sustaining substance. In many areas of the world, it is still the custom for the host to offer bread and salt upon entering the home. The custom is also practiced "out of this world"—it has been a tradition that all former U.S.S.R.-staffed spaceflights carry aloft bread and salt and leave them behind on the orbiting space station as presents for the next visiting crew.

The first production of salt in the United States was in 1614 by the Virginia colonists who evaporated seawater. The practice of extracting salt from subsurface brine was first employed in the United States at Onondaga, NY, in 1788. The first salt "mine" in the United States was dug in 1799 at Saltville, VA. A 1.8-meter-wide by 61-meter-deep (6-foot-wide by 200-foot-deep) shaft was dug to the top of the salt formation before ground water flooded the workings. The saline water in the shaft provided the feedstock to iron kettles, in which the water was evaporated and the salt recovered. In 1862, the first commercial rock salt mine in North America began operating at Avery Island, LA. Solution mining of salt began in about 1882 and consisted of drilling a small diameter well down to a salt bed, pumping freshwater down to dissolve the salt, and pumping the resultant brine to the surface for subsequent evaporation. In 1887, the vacuum pan was adopted for salt production, which incorporated a vacuum during evaporation to allow the water to boil from the brine at a lower temperature. This technological achievement reduced fuel consumption below that of direct-heated units.

Definitions, Grades, and Specifications

Technically, salt is a generic term that describes compounds formed by the partial or complete replacement of the hydronium ion of an acid by a metal or metallic radical. Water and salts are the end products from the chemical reaction between acids and bases. Through time, however, "salt" has become synonymous with sodium chloride (common salt) and will be considered synonymous throughout this chapter.

Naturally occurring sodium chloride is mineralogically known as halite. Pure salt contains 39.3% sodium and 60.7% chlorine by weight. Halite deposits usually contain between 1% and 4% impurities, mainly gypsum, shale, dolomite, and quartz. Rock salt is halite that is mined underground by conventional room-and-pillar techniques.

Evaporated salt is the term applied to fine crystals of salt obtained by evaporating brines, either natural or manufactured from solution mining, in large, vacuum-enclosed or open steam-heated kettles. Solar evaporated salt is the product harvested from shallow ponds after the brine has been exposed to solar and wind evaporation.

The physical characteristics of salt vary with the type of production process. Salt specifications from vacuum pan operations are the same because the process is similar throughout the country. Rock salt, however, can vary in color and composition with locality, and these characteristics influence the specifications of the final product. Some impurities must be removed by chemical treatment or filtration to meet specifications for certain end uses.

There are various standards issued by different organizations that apply to salt. These standards may vary, depending on the intended end use. For example, salt for human consumption requires different specifications than those of salt for deicing highways.

Uses and Products for Trade and Industry

Salt for human consumption is packaged in different sized containers for several specialized purposes. Table salt may contain 0.01% potassium iodide as an additive that provides a source of iodine that is essential to the oxidation processes in the body. Kosher salt, seasalt, condiment salt, and salt tablets are special varieties of salt.

Water conditioning and animal feedstock salt are made into 22.7-kilogram (50-pound) pressed blocks. Sulfur, iodine, trace elements, and vitamins are occasionally added to salt blocks to provide missing nutrients not found naturally in the diet of certain livestock. Salt is also compressed into pellets and used for water conditioning.

There are reportedly about 14,000 different direct and indirect uses of salt. The USBM annually surveys 8 major categories comprising 29 separate end uses.

Chemical.—The greatest quantity of salt used in the chemical industry is by the chloralkali sector. Traditionally, the chloralkali sector included salt consumed for chlorine, coproduct sodium hydroxide (also known as caustic soda and lye), and synthetic soda ash. Since 1986, when the last synthetic soda ash plant closed because of high production costs and competition with less expensive natural soda ash, no synthetic soda ash has been manufactured in the United States. Aside from a few economic deposits of natural soda ash, several countries in the world continue to use salt for synthetic soda ash production.

Salt is used as the primary raw material in chlorine manufacture because it is an inexpensive and widely available source of chlorine ions. For sodium hydroxide production, salt is the main source of the sodium ions. About 98% of the domestic chlorine and sodium hydroxide produced is obtained from the electrolysis of salt brine feedstock using three different cell technologies. The types of cells and percent chlorine manufactured by them are diaphragm, 78%; mercury, 14%; and membrane, 6%.

According to the Chlorine Institute, there were 26 chlorine companies operating 49 plants. Of these, 16 were diaphragm cell plants, 12 mercury cell plants, 6 membrane cell plants, 5 diaphragm and mercury cell plants, 3 diaphragm and mercury cell plants, 3 magnesium cell plants, 1 sodium cell plant, 1 hydrochloric acid electrolysis plant, and 1 diaphragm and magnesium cell plant.

It takes about 1.75 short tons of salt to make 1.0 short ton of chlorine and 1.1 short tons of coproduct caustic soda. The electrolytic process ionizes the sodium chloride compound and selectively allows the ions to migrate through special membranes. Chlorine gas forms at the anode while sodium ions bond with water molecules at the cathode to form sodium hydroxide with hydrogen gas evolving.

Chlorine and caustic soda are considered to be the first generation of products made from salt. These two chemicals are further used to manufacture other materials, which are considered second generation products from salt.

Salt is also used as a feedstock by chemical establishments that make sodium chlorate (by the electrolysis of an acidified salt brine using hydrochloric acid adjusted to a pH of 6.5), metallic sodium (by the electrolysis of a molten salt mixture containing 33.2% sodium chloride and 66.8% calcium chloride, which is added to reduce the melting temperature of salt), and other downstream chemical operations. In powdered soaps and detergents, salt is used as a bulking agent and as a coagulant for colloidal dispersion after saponification. In pharmaceuticals, salt is a chemical reagent and is used as the electrolyte in saline solutions. It is also used as a cofeedstock with sulfuric acid to produce sodium sulfate and hydrochloric acid. This subsector is relatively small, representing only 10% of domestic salt sales for the entire chemical sector and only 5% of total domestic salt consumption.

Food Processing.—Every person uses some quantity of salt in their food. The salt is either added to the food by the food processor or by the consumer through free choice. Salt is added to food as a flavor enhancer, preservative, binder, fermentation control additive, texture aid, and color developer. This major category is subdivided into six applications, in descending order of salt consumption: meat packers, canning, other food processing, baking, dairy, and grain mill products.

In meatpacking, salt is added to processed meats to promote the color development in bacon, ham, and other processed meat products. As a preservative, salt inhibits the growth of bacteria, which would lead to spoilage of the product. Early pioneers used to store their perishables in salt barrels for protection and preservation. Salt acts as a binder in sausages to form a binding gel comprised of meat, fat, and moisture. Salt also acts as a flavor enhancer and a tenderizer. In canning, salt is primarily added as a flavor enhancer and preservative. It also is used as a dehydrating agent, tenderizer, enzyme inhibitor, and as a carrier for other ingredients.

In the "other food processing" category, salt is used mainly as a seasoning agent. Other food processing includes miscellaneous establishments that make food for human consumption (i.e., potato chips, pretzels) and domestic pet consumption (i.e., dog and cat food). In baking, salt is added to control the rate of fermentation in bread dough. It also is used to strengthen the gluten (the elastic protein-water complex in certain doughs) and as a flavor enhancer, such as a topping on baked goods. In the dairy industry, salt is added to cheese as a fermentation control agent and as a color and texture control agent. The dairy subsector includes companies that manufacture creamery butter, natural and processed cheese, condensed and evaporated milk, ice cream, frozen desserts, and specialty dairy products. The final food processing category is grain mill products, which consists of milling flour and rice, and manufacturing cereal breakfast food and blended or prepared flour.

General Industrial.—The industrial uses of salt are diverse. They include, in descending order of salt usage, oil and gas exploration; metal processing; other industrial; pulp and paper; textiles and dyeing; tanning and leather treatment; and rubber manufacture.

In oil and gas exploration, salt is an important component of drilling fluids in well drilling. It is used to flocculate and to increase the density of the drilling fluid to overcome high down-well gas pressures. Whenever drilling activities encounter salt formations, salt is added to the drilling fluid to saturate the solution and minimize the dissolution within the salt strata. Salt is also used to increase the set rate of concrete in cemented casings. In metal processing, salt is used in concentrating uranium ore into uranium oxide (yellow cake). It is also used in processing aluminum, beryllium, copper, steel, and vanadium.

In the pulp and paper industry, salt is used to bleach wood pulp. It also is used to make sodium chlorate, which is added along with sulfuric acid and water to manufacture chlorine dioxide—an excellent oxygen-base bleaching chemical. Although the chlorine dioxide process originated in Germany after World War I, it is becoming more popular because of environmental pressures to reduce or eliminate chlorinated bleaching compounds. In textiles and dyeing, salt is used as a brine rinse to separate organic contaminants, to promote "salting out" of dyestuff precipitates, and to blend with concentrated dyes to standardize them. One of its main roles is to provide the positive ion charge to promote the absorption of negatively charged ions of dyes. In tanning and leather treatment, salt is added to animal hides to inhibit microbial activity on the underside of the hides and to replace some of the moisture in the hides. In rubber manufacture, salt is used to make neoprene rubber, white rubber, and buna rubber. Salt brine and sulfuric acid are used to coagulate an emulsified latex made from chlorinated butadiene.

Agricultural Industry.—Since prehistoric times, humankind has noticed that animals satisfied their salt hunger by locating salt springs, salt licks, or playa lake salt crusts. Barnyard and grazing livestock need supplementary salt rations to maintain proper nutrition. Veterinarians advocate adding loose salt in commercially mixed feeds or in block forms sold to farmers and ranchers. Salt also acts as an excellent carrier for trace elements not found in the vegetation consumed by grazing livestock. Sulfur, selenium, and other essential elements are commonly added to salt licks, or salt blocks, for free-choice feeding.

Water Treatment.—Approximately 1.2 trillion liters (325 billion gallons) of water is used daily in the United States for residential and commercial uses. Many areas of the United States have "hard" water, which contains excessive calcium and magnesium ions that contribute to the buildup of a scale or film of alkaline mineral deposits in household and industrial equipment. Commercial and residential water-softening units use salt to remove the ions causing water hardness. The sodium ions captured on a resin bed are exchanged for the calcium and magnesium ions. Periodically, the water-softening units must be recharged because the sodium ions become depleted. Salt is added and dissolved, and the brine replenishes the lost sodium ions.

Ice Control and Road Stabilization.—The second largest end use of salt is for highway deicing. Gabriel Daniel Fahrenheit, the developer of the Fahrenheit temperature scale (° F), discovered that salt mixed with ice (at a temperature below the freezing point) creates a solution with a lower freezing point than water by itself. The brine forms below the surface of the ice and snow and prevents the water from freezing into ice and bonding with the road surface. Therefore, salt causes snow and ice to melt. Salt is an inexpensive, widely available, and effective ice control agent. It does, however, become less effective as the temperature decreases below about -9.4° C to -6.7° C (15° F to 20° F). At lower temperatures, more salt would have to be applied to maintain higher brine concentrations to provide the same degree of melting. Most winter snowstorms and ice storms occur between -3.9° C to 0° C (25° F and 32° F), a range in which salt is most effective.

In highway deicing, salt has been associated with corrosion to motor vehicles, bridge decks, unprotected steel structures, and reinforcement bar and wire used in road construction. Surface runoff, vehicle spraying, and windblown actions also affect roadside vegetation, soil, and local surface and ground water supplies. Although there is evidence of environmental loading of salt during peak usage, the spring rains and thaws usually dilute the concentrations of sodium in the area.

Salt is also added to stabilize the soil and to provide firmness to the foundation on which highways are built. The salt acts to minimize the effects of shifting caused by changes in humidity and traffic load in the subsurface.

Distributors.—A tremendous amount of salt is marketed through various distributors, some of which specialize in certain markets such as agricultural and water-treatment services. In addition to these two categories, distributor sales include grocery wholesalers and/or retailers, institutional wholesalers, U.S. Government resalers, and other wholesalers and retailers.

Other.—The other uses of salt include categories not discussed above.

Geology-Resources

The definitions of reserves and reserve base are published in the U.S. Geological Survey Circular 831, "Principles of a Resource/Reserve Classification for Minerals."

The oceans are the world's largest resource of salt. Seawater contains 3.5% dissolved solids by weight with sodium chloride representing the major component, approximately 2.5% by weight. The world's oceans contain about 42 x 10^{15} tons (46 x 10^{15} short tons) of sodium chloride, which is equivalent to 530 million cubic kilometers (4.5 million cubic miles) in volume or a cube measuring 795 kilometers (165 miles) on edge.

Domestic salt resources are found mainly in four large depositional basins, covering an area totaling about 0.2 million square hectacres (0.5 million square miles) in 18 States. These basins are (1) the gulf coast, which covers part of Alabama, Arkansas, Florida, Louisiana, Mississippi, and eastern Texas; (2) the Permian, which is in part of Colorado, Kansas, New Mexico, Oklahoma, and western Texas; (3) the Salina, covering part of Michigan, New York, Ohio, Pennsylvania, and West Virginia; and (4) the Williston, encompassing part of Montana, North and South Dakota, and Wyoming. The gulf coast and Permian basins extend into Mexico; the Salina and Williston both extend into Canada. The identified salt resources of the United States are estimated at 55 x 10^{12} tons (61 x 10^{12} short tons) and are being depleted at the rate of about 35 million tons (39 million short tons) annually. At the present level of production, the United States has enough salt to mine for more than 1.6 million years. Solar evaporation of coastal seawater would extend this rate virtually forever.

Salt can be geologically classified by its occurrence as evaporite deposits and in solutions.

Evaporite Deposits.—Bedded, diapiric flow, and playa salts are the major types of dry salt deposits. Bedded salt deposits were formed by the accumulation of precipitated salts on the seafloor of ancient landlocked marine bodies of water. Extensive and widespread evaporation was essential to form these massive rock salt deposits, some of which measure up to 914 meters (3,000 feet) in thickness.

Salt domes form when vertical or lateral pressures are applied to stratified salt deposits in which low-density salt will flow plastically through the surrounding rocks of higher density. The salt domes of Romania, the Federal Republic of Germany, and the gulf coast of the United States are examples of diapiric salt flows. The appearance is usually cylindrical with circular or elliptical diameters. A cap rock of anhydrite is common with overlying layers of gypsum and calcite. Oil, gas, and sulfur are associated with many domes and represent large mineral resources. There are 329 proven salt domes in the gulf coastal province and offshore regions of the United States. Louisiana has 183 domes onshore and offshore; Texas, 83; Mississippi, 61; and Alabama, 2.

Playas are flat, vegetation-free floors of an undrained desert basin that may occasionally be covered by water. Postevaporation minerals such as sodium carbonate, sodium sulfate, sodium chloride, borates, nitrates, phosphates, and potash result from the leaching of the rocks surrounding the basin by water flowing into the playa. Searles Lake in California is a classic example of a salt-bearing playa lake.

Salt in Solution.—Ocean, lake, and ground water are the primary aqueous mediums in which salt is dissolved. Seawater contains many dissolved minerals, the major one being sodium chloride. Other dissolved minerals include various calcium, magnesium, potassium and sulfate compounds.

Water tends to accumulate on land in topographic depressions created by tectonic uplifts or subsidences of the Earth's upper crust. As mineralized solutions from upland sources drain into these basins, solar evaporation concentrates the salts to form saline lakes. The Aral Sea in the former U.S.S.R., Great Salt Lake in Utah, and the Dead Sea between Jordan and Israel are examples of this process.

Ground water is composed of mineralized connate and meteoric water found in permeable sedimentary formations. In some areas, sodium chloride-rich brines migrate to the surface through intersecting fractures and joints in the rock strata to form local salt springs. These springs have attracted animals because they are a source of salt. The springs also indicate where buried salt deposits are located. The salt springs at Saltville, VA, are an example of a locality that was developed based on an occurrence of salt springs.

Technology

Exploration.—Exploring for new salt deposits is based on examination of various geochemical and geophysical information. Analysis of the underlying strata by core drilling, oil and water well logs, or other techniques is the basis for establishing the size of the deposit. Usually the most favorable areas for mine development will be located near the market regions and convenient transportation routes.

The development of mines incorporates strict safety precautions while permitting for the maximum economic recovery of salt. During shaft sinking, water-bearing strata may be encountered, and waterproofing techniques must be employed to prevent mine flooding. At least two access shafts are constructed in room-and-pillar mines to provide adequate safety and ventilation.

Mining.—**Rock Salt.**—Rock salt is mined by the room-and-pillar method, which is similar to that used in coal and trona mining. The salt is drilled, cut, blasted, mucked, crushed, and transported to the surface for processing, which usually involves removing the impurities and screening the material to finer-size fractions.

Underground mining practices of bedded rock salt and domal salt formations are similar except for the height differences within the mines of the two types of operations. For example, bedded formations usually are laterally extensive but are vertically restricted. Salt domes are laterally restrictive but are vertically extensive. Many salt domes have depths in excess of 6,100 meters (20,000 feet), yet many outcrop at the surface. Most gulf coast salt mining operations are generally less than 300 meters (1,000 feet) below the surface. Working at deeper depths is difficult because of higher temperatures and denser rock.

Solar Evaporation.—Solar evaporation is an effective method of producing solar salt in areas of high evaporation and low precipitation. Along coastal margins in many parts of the world, seawater is collected and allowed to evaporate in specially constructed evaporating ponds. Saline lakewater is also processed using this method. The ponds are separated by levees that isolate the brine during different stages of fractional crystallization.

The initial step concentrates the brine to increase the salinity and allow many calcium, magnesium, and iron compounds to precipitate from solution. The brine is circulated among a network of interconnecting ponds, with salinity increasing with each transfer. The brine is then treated with lime to remove excess calcium sulfate and then pumped to evaporation ponds and then transferred to harvesting ponds to permit the salt to crystallize. After about 85% of the salt is precipitated, the remaining supernatant liquid, called "bitterns," can be drained to adjacent ponds for subsequent extraction of magnesium, potassium, bromine, and sodium compounds. The harvesting pond is flooded again with new brine from the lime pond to repeat the cycle. It takes about 5 years once seawater is first introduced into the system for the completion of the crystallization process. The salt is harvested by special tractors equipped with scrapers and ready for processing.

Solution Mining.—The first reported use of solution mining was about 250 B.C. in China when holes were drilled into deep salt deposits. The brine was brought to the surface by pipes made of bamboo. The brine was evaporated over fires fueled with wood, coal, or natural gas. The basis of current technology began in France about A.D. 858. An injection well is sunk, and pressurized freshwater is introduced to hydraulically fracture the bedded salt. Once communication with the production well is established, the brine is pumped to the surface for treatment.

Roof collapse of the overlying strata and surface subsidence are potential problems associated with solution mining; however, producers have taken precautions to minimize these hazards. One method that was once used was injecting air with the water into the salt caverns. The air formed a protective cover between the water and the top of the cavity that reduced the amount of dissolution of the roof.

Processing.—**Rock Salt.**—About 52% of total rock salt produced and imported is for highway deicing. Crushing and screening to the proper physical size is usually the only processing that road salt undergoes. In many operations, these steps are done underground in the mine to minimize haulage and storage costs. In addition, the extremely fine fraction, which often is unusable, remains underground rather than on the surface, which would represent a waste product to be disposed.

Solar Salt.—After harvesting, the salt crystals are washed with dilute brine to remove residual bitterns and impurities. The salt is transferred to processing facilities where it is washed with saline water, dried for about 8 minutes at approximately 300° F, and screened into fine to coarse sizes, depending on the end use of the salt to be sold. Most operations ship solar salt in bags and in bulk, using barges, truck, and rail transportation.

Mechanical Evaporation.—Salt obtained by dehydrating brine using heat alone or in combination with a vacuum is vacuum pan salt. The vacuum pan process conserves energy by utilizing multiple-effect evaporators connected to vacuum pumps. A saturated salt solution will boil at a higher temperature than pure water. When a vacuum is applied, the brine boils at a lower temperature, enabling the superheated vapor that is generated to act as the heating medium for the next evaporator.

The grainer or open pan process uses open, rectangular pans with steam-heated immersion coils to evaporate the water in the brine. Rotating rakes scrape the salt precipitate into a sump or up a ramp, depending on the method, and onto conveyors for debrining and drying treatment. The final product is usually flake shaped rather than the typical cubic form. Flake salt is preferred for production of cheese, butter, and baked goods.

The Alberger process is a modified grainer operation that produces cubic salt with some flake salt. The pans are shallow, circular units with external heating units, rather than heating coils. The open pan process cannot be operated successfully in regions with high humidities because the evaporation rate is too slow and more energy is required to evaporate the brine.

Desalination.—The conversion of saline water into freshwater has important municipal, industrial, and agricultural applications. Aside from obtaining pure water, desalination also produces byproduct salt. There are four processes presently employed in water desalinization and each has different cost and energy factors. The processes are distillation, membrane, freezing, and ion exchange. Some salt from these processes is used by the chemical industry. In some regions, salt is returned to the saline water source. Seawater typically contains 3.5% to 4.5% salt, or 35,000 to 45,000 parts per million. The standard for drinking water in the United States is 500 parts per million.

Byproducts and Coproducts

Salt is a coproduct from various seawater and saline lake operations. Depending on the cost of recovery and processing, certain magnesium, potassium, and bromine compounds can be produced from the bitterns. Subterranean brines also contain borax, calcium chloride, sodium carbonate, and sodium sulfate in addition to those aforementioned. Certain potash operations in the world also produce salt as a coproduct. When discharged to tailing ponds as a byproduct of potash mining, salt is often harvested and sold by second parties.

Economic Factors

Energy and labor costs are important factors that affect production costs, and ultimately the selling price, for all types of salt. After the salt is produced, shipping costs become very important when attempting to sell to a customer that is in proximity to other salt producers. Industry sources indicate that within the United States, a 485-kilometer (300-mile) radius is an effective limit of competition for a producing location before the influence of other competitors is noticed. Some of the major U.S. producers also have foreign subsidiaries that produce salt, which is imported at prices favorable to many consumers because transportation costs are less.

Capital investment and energy costs are important factors that influence the selling price of the type of salt produced. Vacuum pan and open pan processing require more equipment and energy than solution mining, and consequently, the average value of evaporated salt is considerably higher than that of salt in brine.

Prices.—The four types of salt that are produced each have unique production, processing, and packaging factors that determine the selling prices. Generally, salt sold in bulk is less expensive than salt that has been packaged, pelletized, or pressed. Salt in brine is the least expensive salt sold because mining and processing costs are less. Vacuum pan salt is the most expensive because of the higher energy costs involved in processing and the purity of the product. Table 2 lists the historical values of the different types of salt since 1974. The data are compared with 1993 constant dollars to show the effect of inflation and general economic conditions on the values. *(See table 2.)*

Tariffs.—The United States historically imports more salt than it exports. In 1993, U.S. salt imports were more than eight times the level of salt exports. Imports from countries having most-favored-nation (MFN) status enter duty free. However, salt imported from non-MFN countries have a 26% ad valorum tax imposed. The non-MFN countries in 1993 were Afghanistan, Albania, Azerbaijan, Belarus, Cuba, Georgia, Kampuchea, Kazakhstan, Laos, North Korea, Romania, Tajikistan, Turkmenistan, Uzbekistan, and Vietnam.

Operating Factors

Environmental Requirements.—The environmental problems associated with salt mining are few and tend to be localized without major impacts on the environment. A major concern in solution mining is the potential of land subsidence. As the salt is dissolved, some roof collapse may occur, causing sections of the surface to partially or totally fill the cavity. Subsidence is unpredictable, and once the process begins, it must be allowed to finish and reach equilibrium. Another issue pertaining to solution mining is the potential problem of well casing leakage. Any excursion of salt brine could affect ground water supplies, which are protected by various State and Federal water quality regulations. Solar evaporation facilities may substantially disturb coastal marsh areas because of the large extent of the lagoons needed for efficient operation.

Environmental Issues.—The USBM has been actively assessing the environmental issues pertaining to the type and quantity of waste generated in the different steps from mining through postconsumption for many commodities. Some waste that traditionally may have been discarded after mining and processing may be recovered for reuse; other waste in the form of discarded consumer products may be recycled to reclaim various valuable raw materials. Several material flow studies have been completed by the USBM that trace the flow of a commodity from "cradle to grave." A material flow study on salt was conducted by this author.

Salt was selected as a commodity to study because it had a couple of associated environmental issues, such as the environmental effects from deicing salt and salt used in water treatment. In addition, there were issues pertaining to some of the downstream uses, such as in PVC manufacture, that uses salt as feedstock. Cumulative historical data through 1993 on salt consumption for highway deicing indicates that 271 million tons (299 million short tons) has been applied to the Nation's roads since 1940, when salt usage for this purpose first became significant. Although there are several site specific studies that have been done to measure the concentration of salt in the soil and ground water from deicing runoff, there is no indication of any serious and permanent ill effects from the use of more than one-quarter billion tons of salt in the 50 years that salt has been used.

After analyzing all the categories that salt is used in, it is estimated that about three-fourths of the domestic salt consumed is released to the environment and unrecovered while about one-fourth is discharged to landfills, incinerated, or recycled as consumer products derived from salt, such as PVC plastic containers. For further information about the study, please refer to USBM Information Circular IC-9343, "The Material Flow of Salt."

Employment.—According to the Bureau of Labor Statistics, 1,977 people were employed in the domestic rock salt industry in 1993. Of the 13 rock salt facilities surveyed, 880 personnel worked 1.86 million hours underground, 337 people worked 710,026 hours on surface duties, 552 people worked 1,009,156 hours in the mills, and 208 people worked 456,809 hours in the office. Employment data for solar salt, vacuum pan salt, and salt in brine were incomplete or not surveyed by the Bureau of Labor Statistics.

Transportation.—The locations of the salt supplies often are not in proximity of the consumers location, and transportation can become an important cost. Pumping salt brine through pipelines is an economic means of transportation, but cannot be used for dry salt. Large bulk shipments of dry salt in ocean freighters or river barges are low in cost, but are restricted in points of origin and consumption. River and lake movement of salt in winter is often severely curtained because of frozen waterways. As salt is packaged, handled, and shipped in smaller units, the costs are increased and are reflected in higher selling prices.

Oceanborne imports of salt have been increasing in some areas of the United States because they are less expensive with respect to transportation costs than what could be purchased from many domestic suppliers using rail transportation. Salt continued to be one of the most heavily traded chemical industry ores in the world, representing about 66% of world seaborne mineral trade according to a study done in 1989.

ANNUAL REVIEW

Issues

In April 1992, the International Joint Commission on Great Lakes Water Quality recommended that Canada and the United States should begin considering the phasing out of all chlorine and chlorine-base compounds as industrial feedstocks. Representatives of the Commission contend that toxic pollution of the Great Lakes is causing serious long-term biological harm to human, aquatic life, and other wildlife. The debate between environmental groups and the chemical industry continued in 1993. Because most of the salt used for chloralkali manufacture is captive salt brine made by the chemical industry and not dry salt mined, the chlorine issue does not directly affect the majority of the domestic salt industry. However, it does affect some foreign suppliers of dry salt that export to the United States and sell to domestic chlorine and caustic soda producers, such as those in the Pacific Northwest and the Atlantic seaboard.

In response to the discussion, the chlorine industry contracted a formal study of the impact of a chlorine ban on the economies of Canada and the United States.[1] The major findings were that using substitutes for chlorine-based products and processes would cost an additional $91 billion annually to U.S. consumers and $11 billion annually to Canadian consumers. The investments required to construct plants to manufacture chlorine substitutes would cost $67 billion and take 10 to 20 years to accomplish, during which time consumers would pay higher prices for the services and products being eliminated. About 45% of all U.S. industries are direct consumers of chlorine and its coproducts, and all industries are indirect consumers. If chlorine production were terminated, many of the 1.4 million jobs in both nations would be lost, representing $33 billion in lost wages. Finally, a chlorine ban would severely disrupt certain major and economically important markets as the affected industries were forced to substitute less efficient and more costly technologies.

In a related action, the U.S. Environmental Protection Agency in November proposed strict "cluster rule" regulations for the pulp industry that would combine air and water requirements for the first time rather than adressing each one separately. The rule would virtually eliminate all river and other water discharges of dioxin and reduce airborne emissions by 70%. The environmental groups were critical of the proposal because it excluded chlorine dioxide, an oxygen-base bleaching chemical, from being removed.[2]

In August, a proposed amendment to the Clean Water Act was introduced that would ban chlorine as a bleaching agent in pulp and paper manufacture.[3] The proposal, known as the Chlorine Zero Dischage Act of 1993, would require a total phaseout within 5 years of water discharges of any organochloride compounds, byproducts, or metabolites from chlorine or any chlorinated oxidyzing agents used by the pulp producers. The issue would be discussed in the 1994 legislative calandar by the U.S. Congress. An Executive order was signed late in 1993 regarding the purchase and use of recycled paper and products by Federal agencies. Although there was no provision to use chlorine-free paper, paper brightness specifications were revised that currently prevented the use of paper made from processes that minimize emission of harmful byproducts, including chlorinated compounds.[4]

Production

U.S. salt production increased more than 10% in 1993 compared with that of the previous year. The increase, primarily in rock salt production for highway deicing, was mainly attributed to adverse winter conditions that continued into early 1994. According to the USBM survey for 1993, 27 companies operated 67 salt-producing plants in 14 States. Nine of the companies and 12 of the plants produced more than 1 million tons each and accounted for 91% and 59%, respectively, of the U.S. total. Several companies and plants produced more than one type of salt. In 1993, 11 companies (15 operations) produced solar-evaporated salt; 5 companies (17 operations), vacuum pan salt; 10 companies (14 operations), rock salt; and 14 companies (29 operations), salt brine. *(See tables 1, 3, 4, and 5.)*

The five leading States in terms of total salt sold or used were Louisiana, 32%; Texas, 21%; New York, 15%; and Kansas, 6%. Although Louisiana, New York, and Ohio were major rock salt-producing States, a substantial amount of salt was produced in Alabama, Kansas, Louisiana, New York, Ohio, Texas, Utah, and West Virginia as brine for the chemical industry. *(See table 6.)*

U.S. salt production accounted for about 20% of total world production. Production and trade of salt increased compared with that of the previous year. World production of all types of salt decreased slightly. The depressed market for chlorine and environmental problems associated with emissions of chlorinated compounds may affect the short-term status of the world chloralkali industry, which is the largest single consumer of salt.

Cargill Inc. sold about 4,047 hectares (10,000 acres, or nearly 16 square miles) of its property along the northern part of San Francisco Bay in California. The property, appraised at $35 million but sold to the Shell Oil Spill Litigation Settlement Trustee Committee for $10 million, includes about 85% of Cargill's solar salt facility at Napa that ceased production in 1990 because its sole customer, Dow Chemical, terminated chlorine production at its Pittsburgh, CA, site. The land is made up of tidal wetlands, salt ponds, and mud flats and will be used as a wildlife habitat for various fish and birds.

Formosa Plastics Corp. came on-stream in late 1993 with its 570,000-ton-per-year chlorine facility at Point Comfort, TX.[5] The plant will use membrane cell technology and is expected to be fully operational by April 1994. The three chloralkali plants of LCP Chemicals, which was owned by the Hanlin Group that filed chapter 11 proceedings, was sold to HoltraChem Manufacturing. Allied Signal Corp., which sold some of the operations to LCP in 1979, was a minority investor. The purchase involved the plants at Acme, NC; Orrington, ME; and Brunswick, GA, which had a combined capacity of 210,000 tons, as well as the lease and possible future purchase of terminals in Linden, NJ; Syracuse, NY; and Moundsville, WV.[6]

Consumption and Uses

More than 43.6 million tons of domestic and imported salt was consumed in the United States in 1993, based on the annual survey of the U.S. salt producers. The reported percent distribution of salt by major end use was chemicals, 44%; ice control, 25%; distributors, 11%; food and agricultural, 8%; industrial, 6%; primary water treatment, 1%; and other combined with exports, 5%. Distributors represent a substantial share of salt sales by the salt industry; however, all the salt ultimately is resold to many end users. Some customers have specific uses. For a more complete analysis of end-use markets, specific sectors of distribution in table 7 can be combined, such as agricultural and water conditioning with agricultural and water conditioning distribution, respectively.

The chemical industry consumes nearly one-half of the salt produced, primarily salt brine. Although most salt brine is captively produced by chemical producers, many chloralkali manufacturers now purchase brine from independent brine supply companies. In certain cases, brine is captively produced by one chemical company, and any excess brine is sold to neighboring competitors. According to a survey of domestic salt-based chlorine facilities, about 48% of the salt used to manufacture chlorine was captive and 31% was purchased brine. Purchased solar or rock salt comprised 12% and imported rock, solar, and vacuum pan salt comprised 9%. *(See tables 7 and 8.)*

Using Bureau of the Census data, the chlorine and caustic soda industry consumed about 19.1 million tons (21 million short tons) of salt for feedstock, based on the industry average ratio of 1.75 tons of salt required to produce 1 ton of chlorine and 1.1 tons of coproduct sodium hydroxide. Reported consumption of total domestic and imported salt for chlorine manufacture was 17.5 million tons (19.3 million short tons), as noted in table 7. The difference between the calculated and reported quantities was the amount of salt unreported to the USBM from imports or captive brine production of chloralkali producers. Production of chlorine gas and liquid sodium hydroxide, as reported by the Bureau of the Census and The Chlorine Institute, is shown in table 9. *(See table 9.)*

There are approximately 18 domestic companies that operate 37 chlorine-producing plants that used only salt as feedstock. Estimates were made on the chlorine production capacity for individual plants. Based on these estimates and using Bureau of the Census chlorine production data, the U.S. salt-based chlorine industry operated at 92% of capacity. According to The Chlorine Institute, the industry operated at an average of 92% of nominal capacity and 96% of effective capacity in 1993. Because these capacities include chlorine produced from nonsalt sources; i.e., from the electrolysis of magnesium chloride and the oxidation of hydrochloric acid, these data may differ from other reported chlorine capacity utilization information.

Stocks

Total yearend stocks reported by producers were about 2 million tons. Most of these inventories were rock salt and solar salt. Many States, municipalities, distributors, and road-deicing contractors stockpiled additional quantities of salt in anticipation of adverse weather conditions. Rock salt inventories were declining by yearend because of the severe winter in the domestic snow belt.

Markets and Prices

Price quotations are not synonymous with average values reported to the USBM. The quotations do not necessarily represent prices at which transactions actually occurred, nor do they represent bid and asked prices. They are quoted here to serve only as a reference to yearend price levels. Yearend prices were quoted in Chemical Marketing Reporter, as shown in table 10. *(See tables 10 and 11.)*

Foreign Trade

Under the Harmonized Tariff Schedule nomenclature, imports only have one category known as "Salt (including table and denatuted salt) and pure sodium chloride, whether or not in aqueous solution, seawater." The same classificaiton also applies to exports. The trade tables in this report list the previous and current identification codes for salt.

Based on Bureau of Census statistics, the United States in 1993 exported 688,000 tons (758,000 short tons), a decrease of 31% compared with that of the previous year. Salt was shipped to 67 countries through 31 U.S. customs districts, of which the Cleveland, OH, district exported the most. The majority of exports, 73%, was to Canada. The Journal of Commerce's Port Import/Export Reporting Service (PIERS) reported that six domestic salt-producing companies exported 94% of the 378,791 tons (417,545 short tons) exported in 1993. The companies were Akzo Salt Inc., Cargill Salt Co., North American Salt Co. and its subsidiary Sifto Canada, United Salt Co., and Western Salt Co.

The United States imported from 28 countries 5.87 million tons (6.47 million short tons) in 1993, or about 8.5 times more than the quantity of salt that it exported. Although this would indicate that the United States is import reliant on salt to meet its salt requirements, the majority of imported salt was brought into the country by foreign subsidiaries of major U.S. salt producers. Generally, imported salt can be purchased and delivered to many customers at costs lower than the comparable domestic product because production costs are lower abroad and currency exchange rates are more favorable.

The PIERS service reported that 5.26 million tons (5.80 million short tons) was imported; however, PIERS data include only ocean freight and does not include salt shipped by rail or truck over the U.S. land borders with Canada and Mexico. Therefore, Census data and PIERS data often are dissimilar. Using PIERS data, Akzo Salt Co., Cargill Inc., Morton International, and North American Salt Co. imported 62% of the total imports. Five companies that manufacture chlorine, which was the single largest domestic salt market, consumed 16% of total imports, which were primarily solar salt. These companies were ACI Chemicals, Atochem North America, Georgia Pacific Corp., Occidental Chemical Corp., and Weyerhaeuser Co. Three salt distributors, Atlantic Salt Co., Eastern Minerals, and Granite State Minerals, imported 13% of the total salt. The salt producers, salt distributors, and chloralkali producers imported 91% of total PIERS imports; the remainder was to many small direct buyers. Tables 12 through 15 list the import and export statistics reported by the Bureau of Census for 1992 and 1993. *(See tables 12, 13, 14, and 15.)*

World Review

Table 16 lists world salt production statistics for 101 countries based on reported and estimated information. The unification of the two Germany's and the dissolution of the former U.S.S.R. and Yugoslavia in 1992 have modified the list of nations surveyed. World production increased 3% in 1993 compared with that of the previous year. The majority of the increase was in China and the United States. China has been increasing its synthetic soda ash output for domestic glass production, thereby contributing to higher quantities of salt produced. In the United States, all four types of salt showed increases in 1993. *(See table 16.)*

Industry Structure.—The United States remains the world's leading salt-producing nation, representing about one-fifth of total world production. The structure of the U.S. industry has changed throughout the years. In 1970, there were 50 companies operating 95 plants in the United States. Market competition, energy and labor costs, less expensive imports, and an excess of production capacity resulting in the downsizing of the industry through mergers and acquisitions reduced the size of the industry to 27 companies and 67 plants by 1993.

Most countries possess some form of salt production capability with production levels set to meet their own domestic demand requirements with additional quantities available for export. Many developing nations tend to develop their agricultural resources first to feed their population. Development of easily extractable mineral resources follows with salt being one of the first commodities to be mined. Some countries, such as the United States, import a substantial amount of salt to meet total demand requirements because of economic factors.

Capacity.—Each type of salt produced in the world has unique mining, processing, and marketing characteristics that determine the criteria for deriving rated capacities. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable long-term operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgement of the author, can be brought into production within a short period of time with minimum capital expenditure. Capacity data were derived from industry sources, published reports, and estimates based on production trends.

Rock.—Because the majority of rock salt was used for deicing, the operating rate of rock salt facilities fluctuated with the demand for deicing salt, again dependent on the severity of winter weather conditions. During periods of strong demand, production levels often achieve, or exceed in certain situations, the rated capacities. Full mine capacity generally is a function of the hoisting capabilities of the mines. Assuming that the workweek is 5 days (250 workdays per year), two working shifts and one maintenance shift per day, and at least one short-term planned turnaround for the mine and mill per year, the production capacities for domestic rock salt operations in 1993 was 16 million tons (17 million short tons).

Solar.—Solar salt, also known as marine and sea salt, is obtained from the solar evaporation of seawater, of landlocked bodies of saline water, and of discharged brines. Because evaporation rates must exceed the precipitation rates, the climatic conditions and geographic locations of solar evaporation facilities are critical to the successful production and harvesting of solar salt. Therefore, rated capacities generally are based on the historical evaporation patterns within a region and vary depending on the location and the surface areas of the evaporation ponds. Only unpredictable seasonal precipitation and market conditions usually affect the production, and market conditions usually affect the production rates of the facilities. In 1993, total domestic solar salt production capacity was 3.95 million tons (4.35 million short tons).

Vacuum Pan.—The mechanical evaporation of salt by the vacuum pan process is dependent on the number and size of the vacuum crystallizers operating in series. Rated capacities are usually easier to establish because of the proven design performance of the equipment. The total production capacity of the domestic vacuum pan salt producers in 1993 was 4.30 million tons (4.74 million short tons).

Brine.—Brine capacities are difficult to derive because they are based on the variabilities of the injection rate of the solvent and the solubility rates of the underground salt bodies. Both determine the quantity of brine produced. In addition, production levels are dependent on the demand for the products that the brine is being used to manufacture. Therefore, brine production capacity is assumed to be equal to the quantity of brine produced annually. Although data cannot be published for individual companies, the aggregate domestic brine production capacity in 1993 was 18.04 million tons (19.88 million short tons), which was the total quantity of salt brine produced.

OUTLOOK

The outlook for salt for the near future is optimistic. The drawdown of rock salt inventories late in 1993 will cause producers to increase production during early 1994 to meet the demand for deicing salt. Any additional supplies required would have to be imported. Sales of solar salt and rock salt from domestic or import sources for chloralkali manufacture may be in jeopardy, pending the outcome of any proposed legislation to reduce or eliminate the use of chlorine. Despite the adverse publicity regarding chlorine in the environment, chlorine production should be strong since about 18% of total chlorine output is exported as derivatives, such as ethylene dichloride, vinyl chloride monomer, and PVC. In addition, domestic demand for these commodities is estimated to grow at 5% per year for the next few years despite the decline in the use of chlorine in pulp bleaching.

[e]Estimated. [r]Revised.

[1] Data may not add to totals shown because of independent rounding.

[2] Represents that amount sold or used captively within the industry, from the quantity produced and any sold from inventory. Accurate data on beginning and yearend inventories of salt are unavailable and often are underreported because of additional storage underground at mines, warehouses, terminals, etc. However, about 2.5 million tons is estimated to be stored annually nationwide.

[3] The total quantities of salt in inventory are underreported and are excluded in determining the supply-demand balance relationship for salt. However, the difference between production and sold or used is assumed to be because of changes in inventory.

[4] Includes imports for consumption.

[5] Includes salt used in rubber, tanning, other industrial, institutional wholesalers and/or retailers, U.S. Government resale, other wholesalers. Some exports for consumption in overseas territories administered by the United States, and other various minor uses are included.

[6] Represents the difference between the quantity reported to the U.S. Bureau of Mines and total U.S. primary demand. The amount of discrepancy is attributed to variances in inventory and import statistics.

[7] Values are based on the average of all salt producers' valuations reported for bulk, f.o.b. plant, and includes all processing costs, depreciation of equipment, taxes, and profit.

Source: U.S. Bureau of Mines.

rRevised. NA Not available. XX Not applicable.

[1] As reported at salt production locations. The term "sold or used" indicates that some salt, usually salt brine, is not sold but is used for captive purposes by the plant or company. Because data do not include salt imported, purchased, and/or sold from inventory from regional distribution centers, salt sold or used by type may differ from totals shown in tables 7 and 8, which are derived from company reports.

[2] Data may not add to totals shown because of independent rounding.

TABLE 6

SALT SOLD OR USED[1] BY PRODUCERS IN THE UNITED STATES, BY STATE

(Thousand metric tons and thousand dollars)

State	1992		1993	
	Quantity	Value	Quantity	Value
Kansas[2]	1,852	98,620	2,316	103,019

Grand total[2]		4,104	4,127	3,442	4,702	14,567	16,775	[r]17,571	18,006	[r]39,683	43,610

[r] Revised.

[1] The quantity of imports included in the total for each type of salt is the amount reported by the U.S. salt industry, not the quantity reported by the Bureau of the Census that appears in tables 1, 2, 14, and 15.

[2] Data may not add to totals shown because of independent rounding. Because data include salt imported, produced, and/or sold from inventory from regional distribution centers, salt sold or used by type may differ from totals shown in tables 1, 2, 5, and 6, which are derived from plant reports at salt production locations. Data may differ from totals shown in table 8 because of changes in inventory and/or incomplete data reporting.

[3] Less than 1/2 unit.

[4] Includes exports.

Total[2] [5]	4,104	3,442	14,567	22,114	4,127	4,702	16,775	25,604

W Withheld to avoid disclosing company proprietary data; included with "Other."

[1] Each salt type includes domestic and imported quantities. Brine is excluded because brine usually is not shipped out of State.

[2] Data may not add to totals shown because of independent rounding.

[3] Less than 1/2 unit.

[4] Includes shipments to overseas areas administered by the United States, Puerto Rico, exports, some shipments to unspecified destinations, and shipments to States indicated by symbol W.

[5] Because data include salt imported, purchased and/or sold from inventory from regional distribution centers, evaporated and rock salt distributed by State may differ from totals shown in tables 1, 2, and 5, which are derived from plant reports at salt production locations. Data may differ from totals shown in table 7 because of changes in inventory and/or incomplete data reporting.

TABLE 10

SALT YEAREND PRICES

	1992	1993
Salt, evaporated, common:		
80-pound bags, carlots or truckloads:		
North, works, 80 pounds	$4.02	$4.02
Bulk, same basis, per ton	$60.00-61.20	$60.00-61.20
Salt, chemical grade, same basis:		
North, works, 80 pounds	4.30	4.30
Salt, rock, medium, coarse:		
Same basis, 80 pounds	2.70	2.70
Bulk, same basis, per ton	18.00-25.00	18.00-25.00
Sodium chloride, U.S.P.:		
Granular bags, per pound	.29	.29

Sources: Chemical Marketing Reporter. Current Prices of Chemicals and Related Materials, v. 242, No. 26, Dec. 28, 1992, p. 29; and v. 245, No. 1, Jan. 3, 1994, p. 30.

TABLE 11
AVERAGE VALUES[1] [2] OF SALT, BY PRODUCT FORM AND TYPE

(Dollars per metric ton)

Product form	Vacuum pans and open pans	Solar	Rock	Brine
1992				
Bulk	49.88	16.53	17.52	4.35
Compressed pellets	124.83	77.42	XX	XX
Packaged	[r]131.37	54.35	[r]63.15	XX
Average[3]	[r]113.20	32.56	19.63	4.35
Pressed blocks	[r]98.22	[r]82.51	[r]93.40	XX
1993				
Bulk	49.62	15.56	18.40	5.22
Compressed pellets	129.16	49.36	XX	XX
Packaged	124.73	38.71	64.07	XX
Average[3]	111.99	26.13	20.27	5.22
Pressed blocks	100.38	55.12	97.54	XX

[r] Revised. XX Not applicable.

[1] Net selling value, f.o.b. plant, excluding container costs.

[2] Average values calculated using unrounded totals.

[3] Salt value data previously reported were an aggregate value per ton of bulk, compressed pellets, and packaged salt. For time series continuity, an average of these three types of product forms is presented, which is based on the aggregated values and quantities of the product form for each type of salt shown in table 5.

[e] Estimated. [r] Revised.

[1] Table includes data available through June 20, 1994.

[2] Salt is produced in many other countries, but quantities are relatively insignificant and reliable production data are not available. Some salt brine production data for manufacture of chlorine, caustic soda, and soda ash are not reported because of incomplete data reporting by many countries.

[3] Reported figure.

[4] Year ending June 30 of that stated.

[5] Less than 1/2 unit.

[6] From natural soda ash production.

[7] Brine salt production as reported by the Burmese Government in metric tons, was as follows: 1989—60,229; 1990—49,670; 1991—46,835; 1992—46,509 (revised); 1993—58,500 (estimated).

[8] Formerly part of Czechoslovakia; data were not reported separately until 1993.

[9] Dissolved Dec. 31, 1992.

[10] Year begining Mar. 21 of that stated.

[11] Does not include production from Sardinia and Sicily, estimated at 200,000 metric tons annually.

[12] Year ending July 15 of that stated.

[13] Dissolved in Dec. 1991.

[14] Data captioned "Brine salt" for the United Kingdom are the quantities of salt obtained from the evaporation of brines; that captioned "Other salt" are the salt content of brines used for purposes other than production of salt.

[15] Dissolved in Apr. 1992.

CONSTRUCTION SAND AND GRAVEL

By Valentin V. Tepordei

Mr. Tepordei, a geological engineer with more than 20 years of industry experience, has been the construction sand and gravel commodity specialist with the U.S. Bureau of Mines since 1979. Domestic survey data were prepared by the construction sand and gravel survey staff of the Branch of Data Collection and Coordination.

Construction sand and gravel is one of the most accessible natural resources and a major basic raw material used mostly by the construction industry. Despite the relative low value of its basic products, the construction sand and gravel industry is a major contributor to and an indicator of the economic well-being of the Nation.

Beginning with this issue, the statistical information included in the Annual Report for Construction Sand and Gravel is published in metric units in compliance with the provisions of the Metric Conversion Act of 1975 and the Omnibus Trade and Competitiveness Act of 1988 (Public Law 100-418). The information that was published in prior years in short tons was converted to metric tons in this issue of the Annual Report. During 1994, only the totals in each table are published in dual units: metric tons and short tons.

A total of 869 million metric tons [958 million short tons (Mst)] of construction sand and gravel was estimated to have been produced in the United States in 1993, a 4.2% increase compared with the total production of 1992. This tonnage represents the highest production level since the record production of 1978, indicating a significant increase in the demand for construction aggregates in the United States in 1993. *(See table 1.)*

Foreign trade of construction sand and gravel remained relatively small. Exports of construction sand and gravel decreased 20.4% tc 1.1 million metric tons (1.2 Mst), while value decreased 13.2% to $15.6 million. Imports of construction sand and gravel remained unchanged at 1.3 million metric tons (1.5 Mst), while the value decreased slightly to $15.4 million. Domestic apparent consumption of construction sand and gravel was 869 million metric tons (958 Mst).

The major issues of concern to the construction sand and gravel industry continue to be the implementation of the Clean Air Act Amendments of 1990 and their complex legal and technical provisions; the amended Federal Water Pollution Control Act of 1977, the Clean Water Act, section 404, dealing with "wetlands" and the associated "no net loss of wetlands" policy; the Storm Water Pollution Prevention Program; the Occupational Safety and Health Administration's (OSHA) Hazard Communication Standards regulating the use of products containing more than 0.1% crystalline silica; and the provisions of the Federal Endangered Species Act.

DOMESTIC DATA COVERAGE

Domestic production data for construction sand and gravel are developed by the U.S. Bureau of Mines (USBM) from voluntary surveys of U.S. producers. Full surveys of construction sand and gravel producers are conducted for even-numbered years only. For odd-numbered years, only annual estimates for each State are generated based on information provided by the quarterly sample survey of construction sand and gravel and crushed stone producers. This survey provides production estimates by quarters for each State and the nine geographic regions. The sample surveys canvass most of the large companies in each State, accounting for up to 80% of most States' total tonnage. The results of this survey are published each quarter in a separate publication, the Quarterly Mineral Industry Survey.

BACKGROUND

Sand and gravel is a granular, unconsolidated, and usually rounded agglomeration of particles of rocks and minerals, resulting primarily from the natural disintegration and abrasion of rocks through weathering or erosion. Sand and gravel, as one of the most accessible natural resources, has been used since the earliest days of civilization, mostly as a construction material. At the beginning of the 20th century, U.S. production of construction sand and gravel, used mostly for construction purposes, was relatively small and its uses limited. Today, annual sand and gravel production tonnage ranks second in the nonfuel minerals industry after crushed stone and is the only mineral commodity produced in all 50 States. The United States is, in general, self-sufficient in sand and gravel, producing enough to meet all domestic needs and to be a small net exporter, mainly to consumption points along the U.S.-Canadian and U.S.-Mexican borders.

Most sand and gravel is used for construction purposes, mainly as aggregate in concrete; as road base material in the construction and repair of highways, railways, and runways; and as aggregate in asphaltic concrete for paving highways, streets, etc. Construction sand and gravel has one of the lowest average per ton values of all mineral commodities. The constant dollar price has changed relatively little over the past 20 years. Increased operating costs have been partially offset by automation and other means of increasing operating efficiency.

Although construction sand and gravel resources are widespread and in adequate supply nationally, local shortages exist. Land use conflicts and environmental problems associated with rapid urban expansion are major factors contributing to these shortages. In addition, in some geographic areas with sufficient resources, some shortages occur because the proportions of various size fractions of sand or gravel may not meet size specifications of the construction industry. Demand pressures, land use regulations, and the cost of meeting environmental and reclamation requirements are factors that will cause a rising price trend. Larger operations with more efficient equipment, more automation, and better planning and design will be the trend of the industry in the future. This will permit increased use of less accessible and lower quality deposits and will keep prices at competitive levels.

Definitions, Grades, and Specifications

Sand is defined throughout the industry and by the American Society for Testing and Materials (ASTM) as naturally occurring unconsolidated or poorly consolidated rock particles that pass through a No. 4-mesh (4.75-millimeter) U.S. standard sieve and are retained on a No. 200-mesh (75-micrometer) U.S. standard sieve. Gravel consists of naturally occurring unconsolidated or poorly consolidated rock particles that pass through a sieve with 3-inch (76.2-millimeter)-square openings and are retained on a No. 4-mesh U.S. standard sieve.

Sand and gravel is made up of varying amounts of different rock types and is, therefore, of varying chemical composition. Silica is the major constituent of most commercial sands, and lesser amounts of feldspar, mica, iron oxides, and heavy minerals are common. Most applications of sand and gravel have specifications for size, physical characteristics, and chemical composition. A compilation of 42 ASTM Specifications and Test Methods, including the latest revisions and updates pertaining to aggregates, concrete, and admixtures, was reprinted by the National Aggregates Association.[1]

Specifications for sand and gravel used in roadbuilding and concrete construction are often rigid regarding particle size gradation and shape and include physical as well as some chemical properties. However, these specifications can differ in detail from State to State or even from city to city within the State. Soil conditions, climate, and peculiarities in different deposits may necessitate adjustments of requirements of sand and gravel mixtures and chemical composition.

Specifications are written by commercial users; Government agencies, including Federal; State, county, and city construction and highway departments; and the ASTM. Problems arise for the producers of construction aggregates when their product is sold or used in several different cities, counties, or States, many of which may have different specifications. Some progress is being made toward the standardization of aggregate sizes for similar requirements. A need exists for a more active interchange of data and experience among aggregate consumers and producers.

Uses and Products for Trade and Industry

Concrete is made by mixing properly sized aggregate, portland cement, and water into a slurry. Chemical action between the cement and the water results in the crystallization of hydrous calcium aluminum silicates, which causes the mass to bind and harden. Round particles in the aggregate are desirable because they improve the workability of the concrete as it is poured. If broken material is used and angular or flattish fragments exceed about 15% of the total volume, workability can be maintained only by increasing the amount of sand and water, thus reducing strength, or by adding more cement, thus increasing the cost of the concrete.

Sized and broken sand and gravel is used to make asphaltic concrete aggregate and road bases. Broken surfaces adhere to the hot asphaltic mixture better than do rounded surfaces and provide interlocking surfaces that tend to strengthen the asphaltic concrete. Broken particles pack better and tend to move less under load than do rounded particles and, therefore, make better road bases for highway and road construction. This is essential because bases and asphaltic concrete tend to flow when placed under great or long-duration stresses.

Industry Structure

Because of the low unit value, construction sand and gravel is produced near the point of use; therefore, the industry is concentrated in or nearby large, expanding urban areas and, on a transitory basis, in areas where highways, dams, and other large-scale public and private works are under construction. In the United States, sand and gravel is produced in every State. The largest operations tend to be concentrated in the States with the largest populations and largest production of sand and gravel.

Construction sand and gravel is produced in virtually all countries, but relatively few of them publish official statistics on sand and gravel and even fewer regularly survey their industries.

On the basis of tonnage, the construction sand and gravel industry is the second largest nonfuel mineral industry in the United States. In 1992, the last year when a full survey was conducted, there were 4,213 companies producing construction sand and gravel from 5,999 operations with 8,424 pits. The individual operations range in size from those producing millions of tons annually to those reporting less than 25,000 tons per year. Most operations are small, turning out one product or a limited number of products, but most of the tonnage comes from large operations. For example, the 18 operations reporting more than 2 million tons each in 1992 represented only 0.2% of the total number of operations but produced 6.7% of the total tonnage, while 81 operations reporting between 1 and 2 million tons each, representing only 1.4% of the total number of operations, produced 12.2% of the total tonnage. In 1992, most of the construction sand and gravel was produced by operations reporting between 200,000 and 1,000,000 tons each—1,191 operations, or 20% of the total, produced 52.1% of the total tonnage.

The leading companies producing construction sand and gravel, in descending order of tonnage, based on the 1992 survey, were CalMat Co. of Los Angeles, CA; Beazer U.S.A. Inc./Hanson PLC of Walnut Creek, CA; CSR America, Inc., of Atlanta, GA; APAC Inc., of Atlanta, GA, a subsidiary of Ashland Oil of Russell, KY; and Western Mobile, Inc., of Ft. Collins, CO, a subsidiary of Redland PLC of Groby, Leicester, United Kingdom. The top 5 companies operated 203 pits and produced 10.1% of the U.S. total. Three of these five companies are subsidiaries of foreign companies.

Many producers are in the sand and gravel business exclusively, but others are diversified in various degrees in the production of other mineral raw materials, intermediate construction products such as ready-mixed concrete and concrete blocks, final manufactured products, or construction of buildings, roads, and other structures. At the same time, construction companies are entering more into the sand and gravel business to integrate their operations.

Geology-Resources

The processes of formation and deposition impart to sands and gravels the physical characteristics that largely determine the commercial value for a particular use and influence the manner of development. The principal types, based on origin, are stream, glacial, residual, marine, and lake. Windblown deposits are of minor importance. Much of the commercial production is from stream deposits, many of which are deficient in the fines required by present-day grading specifications for concrete aggregates. Stream deposits usually exhibit stratification and often large-size gradation. The beds vary in thickness and sometimes have interspersed lenses of clay or fine sand. The degree of roundness and the particle size varies with the hardness and distance transported. Glacial deposits have the least sorting of all transported deposits, while marine and lake deposits exhibit the best sorting with coarse and fine particles, often well segregated. Residual deposits are found overlying the parent rock and are unstratified mixtures of pebbles, boulders, sand, and clay. They often contain much soft material that prohibits commercial production. Marine or offshore deposits could become more important as inland deposits become depleted or environmentally less desirable to extract. A comprehensive report showing geologic occurrences of potential sources of sand and gravel and crushed stone of the conterminous United States for use as natural aggregates was published by the U.S. Geological Survey.[2]

On the basis of geologic evidence, world reserves are sufficient to meet demands, although not necessarily at precisely the locations where needed. Reserves, which are measurable amounts of sand and gravel that can be produced profitably with current technology under existing economic and political conditions, are controlled mostly by land use and/or environmental constraints. The total sand and gravel resources of the United States are very large. However, the geographic distribution and/or quality of the reserve base often does not match market patterns or requirements.

Technology

Major technological developments that have been instrumental in maintaining adequate production at relatively stable real costs include use of larger operating units, more efficient portable and semiportable plants, unitized plants for versatility of plant capacity, new prospecting methods utilizing aerial and geophysical surveying methods, and greatly increased rehabilitation and resale of mined areas. Use of mined-out pits as lake beds and as sanitary landfill areas has been successful at numerous localities. Automatic controls, along with monitoring by closed-circuit television coordinated with automated counting and recording and radio communications systems, have been installed in many of the larger and newer operations. Along with the use of improved equipment, these have permitted recovery of salable fractions from deposits previously considered too low in quality for profitable exploitation. These practices will increase as pressures build to improve productivity and minimize environmental conflicts.

Exploration.—Sand and gravel deposits, like any mineral deposit, must be explored and evaluated before development. Preliminary examination can establish the extent and nature of the deposits. This is followed by a detailed exploration program aimed at obtaining reasonably accurate information on the quantity of material available, the degree of uniformity throughout the deposit, and, especially, variations in particle size, both vertically and horizontally. Also, the nature and amount of waste materials and the economic feasibility of their removal must be studied.

Geophysical methods are of value in preliminary surveys. Detailed exploration may be achieved by a systematic arrangement of test pits, trenches, boreholes, or other procedures designed to obtain a cross-section of the deposit in conjunction with sampling and testing. Advances in interpretation of aerial photographs and increased application of geophysical techniques have made evaluation of sand and gravel deposits more quantitative. For underwater exploration, mining devices such as dredges and draglines are used. Pilot runs are necessary to determine if required specifications can be met consistently and economically.

Much of the sand and gravel that is being mined in stream, floodplain, alluvial fan, riverbeds and terrain, and glacial deposits is good quality material with nearly equal amounts of gravel and sand and small amounts of unusable material. As these deposits become depleted in future years, less desirable and more expensive sources will have to be developed where mining, reserves, ratio of sand to gravel, quality of material, waste factors, and environmental factors such as waste disposal will present more problems.

Exploration and planning will become more important in assessing deposits, particularly hillslope deposits of older sand and gravel. Grading to meet required slope and setback requirements at hillslope sites may necessitate leaving large tonnages of material unmined. Many millions of tons of material is available, but it may not be of proper quality or ratio of sand to gravel. More deposits of marginal quality will have to be developed to provide for future demand.

Mining.—Sand and gravel generally occur in the same deposit, but the relative proportions of each vary greatly within most deposits. Consequently, the control problem of producing aggregate to rigid specifications involves combinations of many types of equipment like screens, washers, classifiers, crushers, and grinding mills. The two basic sand and gravel mining methods are open pit excavation and dredging. Open pit excavation and processing has four major steps: (1) site clearing—removing trees and vegetation, stripping overburden and topsoil, and transporting, redepositing, or stockpiling it at or off the site; (2) mining—removing the sand and gravel from the deposit; (3) processing—screening, washing, crushing, blending, and stockpiling the mined material to conform to standards and specifications; and (4) reclamation of the extraction area. Processing may or may not take place at the mining site. Mining equipment ranges from small, simple units such as tractor-mounted high-loaders and dump trucks to more sophisticated systems involving large power shovels, draglines, bucket wheel excavators, and belt conveyors. Increasingly, mining systems are being designed to provide for more efficient and economical land reclamation.

Mining with a dredge usually involves mounting the equipment on boats or barges. Suction or bucket-type dredges are used most commonly to harvest sand and gravel from the bottom of a body of water. The sand and gravel is processed either on board or transported to land for processing.

Processing.—Although small amounts of unprocessed bank-run sand and gravel are used for fill, most of the U.S. production is processed in some way. Present methods include washing with water during the screening process, in some cases followed by crushing of the larger particles in cone or gyratory crushers. Secondary crushing may be done by roll crushers. Sizing is done in most plants by horizontal or sloped single or multideck vibratory screens. If necessary, heavy-media separation or jigging is used to remove heavy, unusable materials. Sand for use in construction is freed from clay by log washers or rotary scrubbers. The scrubbing is followed by classification, use of separatory cones or hydroseparators to remove water, and fine screening for grading. Rodmilling is often required for production of small-sized fractions of sand. Transfer of processed sand and gravel from the processing plant to stockpiles or bins is accomplished by flexible combinations of conveyor belts, bucket elevators, and screw conveyors.

Permanent installations are built when large deposits are to be operated for many years. Portable and semiportable units are used in many pits that have an intermediate working life. Several such units can be tied together to obtain large initial production capacity or to add capacity as needed. Mobile screening plants can be quickly moved from one deposit to another without undue interruption or loss of production.

Recycling.—As the Nation moves into an age of increased environmental consciousness, recycling of old concrete and asphalt, used mostly in pavements, is increasing. Local scarcity or high cost of construction aggregates in some areas as well as waste disposal problems are making recycling more attractive economically. In some States, limited recycling, especially in road construction, is either encouraged or required by law. The best utilization for recycled cement concrete is as road base material, because the matrix of concrete cannot be converted back to cement and also because of the lower strength of concrete compared with that of natural aggregates. Sound crushed concrete can make good coarse aggregate, but the fines produced in crushing the concrete have a higher absorption, are more friable, and will require a higher amount of asphalt in asphaltic concrete and a higher amount of mixing water in portland cement.[3] The amount of asphalt roads recycled is significantly larger than that of concrete roads, mainly because asphalt can be rejuvenated with oil additives and used in pavements, significantly reducing the cost of the finished road. Experience has shown that about 35% of crushed asphalt pavement can be recycled into new asphalt mixtures. Proper testing under engineering supervision in all construction projects using recycled materials as aggregates should be performed to ensure that the technical specifications are met.

Byproducts and Coproducts

Small amounts of gold and silver are recovered as a byproduct or coproduct of sand and gravel extraction, particularly in highly sorted deposits.

Economic Factors

Construction sand and gravel is a high-volume, low-value commodity. The industry is highly competitive and is characterized by thousands of operations serving local or regional markets. Production costs vary widely depending on geographic location, the nature of the deposit, and the number and type of products produced. Constant dollar unit values have been quite steady during the past 20 years. As a result of rising costs of labor, energy, and mining and processing equipment, the average unit price of construction sand and gravel increased from $1.1 per ton, f.o.b. plant, in 1970 to $3.63 in 1992. However, the unit price in constant 1982 dollars fluctuated between $2.64 and $2.71 per ton for the same period. Increased productivity achieved through increased use of automation and more efficient equipment was mainly responsible for maintaining the prices at this level. Constant dollar prices are expected to rise in the future because of decreased deposit quality and more stringent environmental and land use regulations.

Accessibility is a problem for the construction sand and gravel industry. The high-volume and low-unit value of sand and gravel requires that operations be close to the market location. Markets for sand and gravel are construction sites that are mostly in areas of high population density. New operations, close to population centers, are difficult to develop because the land is often attractive for other uses such as housing, shopping centers, agriculture, or parks and recreational areas and because of public dislike for mining operations close to populated areas. Existing operations in expanding communities face increasing costs because of increasing land values and increasing restrictions on operations as suburban development comes closer. Deposits are often small, and once exhausted, the operation must be moved to a new site that invariably is farther from the market because closer sites are being used for other purposes.

The industry also faces increasing competition from crushed stone that can substitute for sand and gravel in most of its applications. Stone operations are generally longerlived, can afford greater capital investment for higher efficiency, and often are where competing land use pressures are less severe. The topographically rugged stone-bearing areas are usually less desirable for construction purposes than sand-and-gravel-bearing areas, which are generally flatter.

A 5% depletion allowance based on gross income is allowed for construction sand and gravel. There are no import tariffs.

Operating Factors

Many States, counties, and cities in the United States have zoning laws, and land within each governmental unit is usually zoned to indicate acceptable land uses. If mining is permitted in a zone and a sand and gravel company owns or leases land within that zone, the company may apply for a use permit or its equivalent to begin an operation. If the parcels to be quarried are on lands under both city and county jurisdiction, permits usually must be obtained from each. An acceptable reclamation plan that meets the guidelines or regulations of the appropriate governmental agency must also be approved. Environmental concerns such as noise, dust, beautification, and storage of wastes must be accounted for in a manner satisfactory to the governmental entity involved. Wastewater discharge requirements must be planned for and met. If the deposit to be worked is on a river or land controlled by a river or water or flood control agency, whether municipal, State, or Federal, that agency's requirement must also be satisfied.

In most States, permits for sand and gravel operations require an Environmental Impact Report or Environmental Impact Statement (EIS). A reclamation plan and a use permit application may also be required, with considerable overlap of subject matter with the EIS. A complete EIS may cover all the problem areas at once and facilitate acceptance.

Environmental Issues.—Two main points are involved in environmental land use and reclamation factors. First, the industry must be concerned about any practices that can affect the community environment. An effective effort must be made to reduce noise, air, and water pollution; to reclaim pits after the operation is complete; and to improve the overall appearance of the operating mine, processing plant, and transportation facilities. Second, the industry and community must recognize the time and costs required to protect the environment and the importance of agreeing on fair and realistic environmental standards.

Because sand and gravel is a local commodity, supply deficiencies and cost of material will affect the local community first. Undue delay and unreasonably high cost can strongly affect the movement of sand and gravel into the marketplace. Also, stringent controls by the local government that prevent permits being issued to operators can have adverse economic effects on the communities around them. These conditions can make it difficult to assess the timing and even the possibility of plants going on-stream and can therefore affect the supply of sand and gravel into the marketplace.

Although much progress is being made through premining planning, the sand and gravel industry continues to have problems with environmental controls, land use conflicts, and reclamation practices. Many of these problems are acute because extraction areas and plants must be reasonably near to consumers who are largely in metropolitan areas. Major environmental considerations that must be dealt with in mining and processing sand and gravel are emission of particulate matter into the air, processing water discharge, noise abatement, and employee and public health and safety.

Transportation.—Transportation is a major factor in the delivered price of construction sand and gravel. The cost of moving construction sand and gravel from the plant to the market often exceeds the sales price of the product at the plant. Because of the high cost of transportation, construction sand and gravel continues to be marketed locally. Economies of scale, which might be realized if fewer larger operations served larger marketing areas, would probably not offset the increased transportation costs.

Truck haulage is the main form of transportation used in the construction sand and gravel industry. Many producers have their own truck fleet and deliver their own raw materials and products. A significant and increasing amount of sand and gravel, however, is being hauled by independent truckers because of the cost of maintaining a truck fleet, particularly when the market is highly variable. Rail and water transportation combined account for about 10% to 20% of total construction sand and gravel shipments.

ANNUAL REVIEW

A total of 869 million metric tons (958 million short tons) of construction sand and gravel was estimated to have been produced in the United States in 1993, a 4.2% increase compared with the total production of 1992. This tonnage represents the highest production level since the record production of 1978, indicating a significant increase in the demand for construction aggregates in the United States in 1993. *(See table 3.)*

During the year, production of construction sand and gravel increased every quarter, compared with the same period of 1992, with the largest increases occurring in the third and fourth quarters of 1993.

Legislation

The Department of Transportation and Related Agencies Appropriation Act of 1994 (Public Law 103-122) was signed by the President on October 27, 1993. The act appropriates $20.6 billion for new highway spending, a $2 billion increase from the fiscal year 1993 total. The act also includes a $2.2 billion appropriation in grants for airport construction and provision for a 1-year delay in the imposition of the "crumb rubber" use in highway construction as required by the Intermodal Surface Transportation Efficiency Act (ISTEA) of 1991.

Issues

The implementation of the provisions of the amended Federal Water Pollution Control Act of 1977, the Clean Water Act, section 404, dealing with "wetlands" and the establishment of a "no net loss of wetlands" policy constitutes one of the major areas of concern to the crushed stone industry. There is a significant amount of uncertainty regarding the process of designating some lands as wetlands and whether the current exemptions to the Clean Water Act, section 404, permit program will be maintained in the future. On August 24, 1993, the administration's wetlands policy was announced. The new policy endorses an interim goal of "no overall net loss" of wetlands and a long-term goal of increasing wetlands quantity and quality; provides for administrative appeals of permitting process decisions; establishes deadlines for the Army Corps of Engineers' decisions on permit applications, generally within 90 days; mandates the use of the 1987 Wetlands Delineation Manual by the Army Corps of Engineers, Environmental Protection Agency (EPA), Soil Conservation Service, and Fish and Wildlife Service to identify wetlands; encourages the development of wetland mitigation banks; and promotes the long-term restoration of wetlands through voluntary, nonregulatory programs.

Several bills were reintroduced in the 103d U.S. Congress to replace the current section 404 of the Federal Water Pollution Control Act. These proposed bills plan to provide a concise and structured program for the delineation of wetlands based on their functions and values and will balance the need for effective protection of the Nation's important wetlands with the need for essential community growth and the constitutional rights of landowners.

The complex legal and technical provisions of the comprehensive amendments to the Clean Air Act of 1990 and implementation of regulations for these provisions continues to constitute another major area of concern to the crushed stone industry. One major emphasis of the amendments is the expanded authority given to EPA and the States to enforce the new law and to assess increased penalties. EPA is now authorized to issue administrative orders with penalties of up to $200,000 for noncompliance, and its field inspectors can issue citations for minor violations with penalties of up to $5,000 per day for each violation. The law also includes provisions for new Federal permits to be issued by the State agencies that include source-specific emission limitations and related monitoring, recordkeeping, and reporting requirements. Complying with the new provisions of the Clean Air Act, amendments will constitute a major challenge to all crushed stone producers.

Another issue of concern to the construction aggregates industries is the classification of crystalline silica as a probable human carcinogen by the International Agency for Research on Cancer, an agency of the World Health Organization. OSHA-regulated sites that receive and/or use products containing more than 0.1% crystalline silica must comply with OSHA's Hazard Communication Standards. Both the classification of crystalline silica as a probable human carcinogen and the requirement to quantitatively analyze for crystalline silica at the 0.1% level are controversial.

Production

The production estimates indicate that in 1993 the U.S. production of construction sand and gravel was 869 million metric tons (958 million short tons), a 4.2% increase compared with the total production of 1992. Of the four major geographic regions, the West again led the Nation in the production of construction sand and gravel with 314 million tons, or 36.1% of the U.S. total, followed by the Midwest with 274 million tons, or 31.5% of the total, and the South with 188 million tons, or 21.6%. Compared with 1992, production by major geographic regions increased in the South, 9.4%; in the West, 4.5%; and in the Midwest, 2.4%; while decreasing in the Northeast by 1.9%. *(See table 2 and figure 1.)* Of the nine geographic regions, the East North Central led the Nation with 181 million tons, or 20.9% of the U.S. total. Next was the Pacific with 164 million tons, or 18.9% of the total, and the Mountain with 150 million tons, or 17.2% of the total. Compared with 1992, production increased in all regions except New England, West North Central, and Pacific. The largest increases were recorded in the Mountain region, 13.3%; the East South Central region, 10.7%; and the West South Central region, 9.5%. *(See table 2.)*

The estimated production by quarters for 1993 indicated that most of the construction sand and gravel in the United States was produced in the third quarter, followed by the second quarter and the fourth quarter. Estimated production by each quarter of 1993 was also available for most of the States. *(See table 5.)*

Construction sand and gravel was produced in every State, and the 1993 production estimates indicate that the 10 leading States, in descending order of tonnage, were California, Texas, Ohio, Michigan, Washington, Arizona, New York, Illinois, Minnesota, and Colorado. Their combined production represented 50.5% of the national total. *(See table 4.)*

Compared with 1992, production increased in 34 States, including 8 of the top 10 States. The major increases, in percentage, occurred in Mississippi, 39.8%; New York, 22.3%; and Arizona, 14%. Production decreased in 15 States, with the major decreases, in percentage, occurring in Maine, 27.6%; Minnesota, 10.6%; and California, 6%.

Limited information about the production of construction sand and gravel in foreign countries may be found in the USBM "Minerals Yearbook, Area Reports: International." For nonreporting countries, estimates of sand and gravel and crushed stone outputs can be based on indirect sources of information such as the level of cement consumption.

In the second half of 1993, Beazer USA, Inc./Hanson Industries of Walnut Creek, CA, a subsidiary of Hanson PLC of London, United Kingdom, reorganized its U.S. operations to provide more local operational and financial control and to capitalize on the company's more recognizable names in regional markets. Beazer Northeast became General Materials & Construction Co. of Easton, PA; Beazer Southeast became Benchmark Materials Co. of Research Triangle Park, NC; Beazer Northwest became Kaiser Materials Corp. of Pleasanton, CA; and Beazer Southwest became Southwest Construction Materials and Services Co. of Long Beach, CA. Gifford-Hill & Co. of Dallas, TX, and Spectrum Construction Co. of Virginia Beach, VA, also part of the Beazer Group, will retain their original names.

On November 12, 1993, Martin Marietta Corp. announced that its construction materials division, Martin Marietta Aggregates, will become a separate company, Martin Marietta Materials Inc., in Raleigh, NC. The new company that was incorporated in North Carolina will be a wholly owned subsidiary of Martin Marietta Corp. On December 8, 1993, a registration statement was filed with the Security and Exchange Commission for an underwritten public offering of about 19% of the company's common stocks.

In December 1993, Lafarge Corp. of Reston, VA, announced the restructuring of its North American operations by consolidating 11 cement and construction materials regional operating units into six units. Effective January 1, 1994, Lafarge's new North American organization will include three regional centers for construction materials: Western, based in Calgary, Alberta, Canada; Eastern, based in Toronto, Ontario, Canada; and the United States, based in Canfield, Ohio; and three regional offices for cement's group in Calgary, Alberta, Canada; Montreal, Quebec, Canada; and the United States in Southfield, MI.

Consumption and Uses

Sand and gravel reported by producers to the USBM is actually material that is "sold or used" by the companies and is defined as such. Stockpiled production is not reported until it is sold to a user or consumed by the producer outside its own operation. Because no consumption surveys are conducted by the USBM, the "sold or used" tonnage is assumed to represent the amount produced for domestic consumption and export.

The largest use of construction sand and gravel is as aggregate for the production of concrete, used in nearly all residential, commercial, and industrial buildings, and in most public works projects such as highways and roads, bridges, dams, airport runways, sewer systems, tunnels, etc.

Of the 834 million metric tons (919 Mst) of construction sand and gravel produced in 1992, the last year when a complete survey of producers was conducted by the USBM, 213 Mmt (235 Mst) or 25.6% of the total was for unspecified uses. Of the remaining 588 Mmt (648 Mst) 41% was used as concrete aggregates; 29.9% for road base and coverings and road stabilization; 14.9% as asphaltic concrete aggregates and other bituminous mixtures; 13.7% as construction fill; 1.9% for concrete products such as blocks, bricks, pipes, etc.; 1.5% for plaster and gunite sands; and the remainder for snow and ice control, railroad blast, roofing granules, filtration, and other miscellaneous uses.

To provide a more accurate estimation of the consumption patterns for construction sand and gravel, "Unspecified uses—actual and estimated" are not included in the above percentages. The "Unspecified uses" represent quantities reported by some producers only as their total production without a breakdown by uses and estimated quantities for nonreporting companies. It is recommended that in any marketing or use pattern analysis the quantities included in "Unspecified uses" be distributed among the reported uses by applying the above percentages.

Sand and gravel are usually used mixed, but some uses require only sand or only gravel. Sand is used in mortar, plaster, and gunite and for snow and ice control. Gravel is used to improve or control drainage and as covering and stabilizer on load-bearing surfaces such as unpaved roads, driveways, and parking areas. For 1993, only production estimates were generated for construction sand and gravel, and therefore no information by end uses is available for this year.

Prices

Prices in this chapter are f.o.b. plant, usually at the first point of sale or captive use. This value does not include transportation from the plant or yard to the consumer. It does, however, include all costs of mining, processing, in-plant transportation, overhead costs, and profit. Compared with that of 1992, when the last full annual survey was conducted, the estimated 1993 average unit prices increased only 1.2% to $4.06 per metric ton ($3.63 per short ton).

As a result of rising costs of labor, energy, and mining and processing equipment, the average unit value of construction sand and gravel increased from $1.22 per metric ton, f.o.b. plant, in 1970, to $4.06 in 1993. However, the unit price in constant 1987 dollars declined from $5.48 in 1970 to $2.89 in

1993.

Foreign Trade

The widespread distribution of domestic sand and gravel deposits and the high cost of transportation limits foreign trade mostly to local transactions across international boundaries. U.S. imports and exports are small, representing less than 1% of the domestic consumption.

Exports.—Exports of construction sand decreased 31.4% to 597,000 metric tons, compared with 1992 totals, while value decreased 15.9% to $10.6 million. Canada was the major destination, receiving 61.3% of the total, followed by Mexico with 28.8%. Exports of construction gravel declined 2.9% to 534,000 metric tons, compared with 1992, while value declined 6.9% to $5 million. Canada was the major destination with 88.6% of the total, followed by Mexico with 3.6%. *(See table 6.)*

Imports.—Imports of construction sand and gravel remained at the 1992 level in terms of quantity, 1.3 Mmt, as well as value, $15.4 million. Canada continued to be the major source of imported construction sand and gravel with 73.1% of the total, followed by the Bahamas with 15%. *(See table 7.)*

Current Research

The Center for Aggregates Research (CAR), established by the National Aggregates Association and the National Stone Association and managed through the Aggregates Foundation for Technology, Research, and Education, is the first organization dedicated wholly to aggregates research. A technical advisory committee overviewing the center's activity identified six priority areas of research that include fine aggregates properties and their influence on end products; uses for fines resulting from the processing of aggregates; performance-related tests for aggregates; proper use of aggregates in asphaltic concrete to minimize rutting; prevention of alkali-silica and alkali-carbonate reactivity of aggregates in portland cement concrete; and nature and effects of coatings on aggregates. CAR will concentrate its efforts into these areas.

The University of Texas at Austin and Texas A&M University, the two institutions operated jointly by CAR, already have considerable research in progress related to aggregates. Some of the projects under way are:

- Evaluation of the performance of pavements made with different coarse aggregates including those with different thermal coefficients and the development of design procedures;
- Evaluation of the effectiveness of large stone mixtures in resisting plastic deformation—rutting—in asphalt pavements and recommended design procedures and quality assurance testing and constructability;
- Study of the alkali-silica reaction in concrete containing fly ash. The objectives of the study are to identify the most relevant components of fly ash, portland cement, and aggregates affecting the alkali-silica reaction and to determine the type and amount of a given component to be used in producing high-quality concrete.
- Study of surface friction of seal coat pavements to identify the best methods for determining aggregates properties and characteristics that will accurately predict surface friction performance of seal coats.
- Potential engineering and environmental uses of quarry fines.[4]

The ISTEA of 1991 authorized about $108 million for Strategic Highway Research Program (SHRP) implementation and Long Term Pavement Performance (LTPP) projects. With the completion of SHRP's 5-year research program, the Federal Highway Administration (FHWA) was assigned the responsibility of implementing the research results, products, and techniques through FHWA's Technology Applications program. A series of implementation actions is also being undertaken by the American Association of State Highway and Transportation Officials (AASHTO) and the Transportation Research Board (TRB). AASHTO's Subcommittee on Materials amended its procedures to accept new product standards on a provisional basis for a maximum of 4 years, during which time hands-on testing will be conducted. At the end of 2 years, the product standards can be balloted for acceptance as regular standards, or the provisional status can be extended for an additional 2 years. The Subcommittee on Materials is also developing information about the specific resources needed to implement SHRP products. TRB has created the TRB/SHRP committee, which will provide industry, highway agencies, and research specialists with a continuing forum to coordinate activities related to implementation of SHRP products and continuation of the LTPP program.

Technology

A new mobile conveyor system designed to load or unload bulk commodity railcars was introduced by Granite Rock Co. of Watsonville, CA, at the Rock by Rail Third Conference held in April 1993 in League City, TX. TransloadXpress conveyor system was engineered by Granite Rock Co. to provide a cost-effective, efficient, and fast method of loading and unloading railcars. TransloadXpress can convey bulk materials at rates of up to 800 tons/hour and can unload rail-to-truck systems at rates averaging 300 tons/hour. TransloadXpress can unload materials into waiting trucks for short hauls to the job site or can convey materials directly into portable ready-mix concrete and asphalt plants. TransloadXpress helps the aggregates producer take advantage of the economies of scale offered by rail shipments and also provides significant environmental advantages. According to a study conducted by the Department of Energy, rail delivers more than eight times the energy efficiency of trucking when measured by the required BTU's per ton-mile of transportation.[5]

A comprehensive review of the available microcomputer software for use in the aggregate-producing industry was published by Rock Products magazine. The review includes software for mine planning, geographic information systems, plant design, mining cost analysis, blasting design, scale management, financial modeling, and accounting. Available information on environmental and occupational health and safety standards, State and Federal regulatory requirements, and legal and engineering codes and standards affecting the aggregates industry is also included in the review.[6]

Quarry blasting usually requires considerably greater control than most mining or public works rock blasting. Maximizing the breakage of rock during primary blasting reduces significantly the need for secondary breakage of oversize rock and therefore reduces the energy consumption required to produce the final product. Efficient and cost-effective blasting requires proper selection of blasthole pattern, explosive selection, delay timing, and initiation sequence, as well as a thorough understanding of the impact the blasting will have on nearby structures. A comprehensive review of the technology, including blasting fragmentation, drilling accuracy, explosive performance, ground vibration, blast size and delay timing, and how the technology can be used to reduce blasting costs, was published by Quarry Management magazine and was reprinted by Rock Products magazine.[7]

OUTLOOK

The demand for construction sand and gravel in 1994 is expected to be about 900 million metric tons (992 Mst), a 3.6% increase from that of 1993. Gradual increases in demand for construction aggregates are anticipated, based on increased volume of work on the infrastructure occurring as a result of the funding provided by ISTEA of 1991. The law authorized $151 billion to be spent in the next 6 years on transportation projects, of which $119.5 billion is for highway work and $32.5 billion for mass transit. It is estimated that the demand for construction sand and gravel will reach 930 Mmt (1,025 Mst) in 1995. The projected increases will be influenced by construction activity in the public as well as the private construction sector.

The value of public construction work as part of the gross domestic product has declined constantly from about 3% in the 1950's and 1960's to less than 2% in the 1980's. If this trend begins to reverse in the 1990's, a significant increase in spending for public construction work could be expected that will significantly alter the above forecasts.

Construction sand and gravel f.o.b. prices are not expected to increase significantly, even if the demand for construction aggregates will rise over the above forecasts. However, the delivered prices of construction sand and gravel are expected to increase, especially in and near metropolitan areas, mainly because more aggregates are transported from distant sources.

Total[6] [7]	128,600	234,100	266,400	226,000	[5]868,700	[5]3,530,100	XX

[r]Revised. XX Not applicable.

[1] As revised from data published in the "Crushed Stone and Sand and Gravel in the Fourth Quarter of 1993 Mineral Industry Survey."

[2] Number of companies reporting for the quarterly survey.

[3] Does not include Alaska and Hawaii.

[4] Data may not add to totals shown because of independent rounding and differences between projected totals by States and by regions.

[5] Includes Alaska.

[6] One metric ton is equal to 1,000 kilograms or 2,204.62 pounds. To convert short tons to metric tons, multiply short tons by 0.907185.

[7] Total shown in thousand metric tons and thousand dollars.

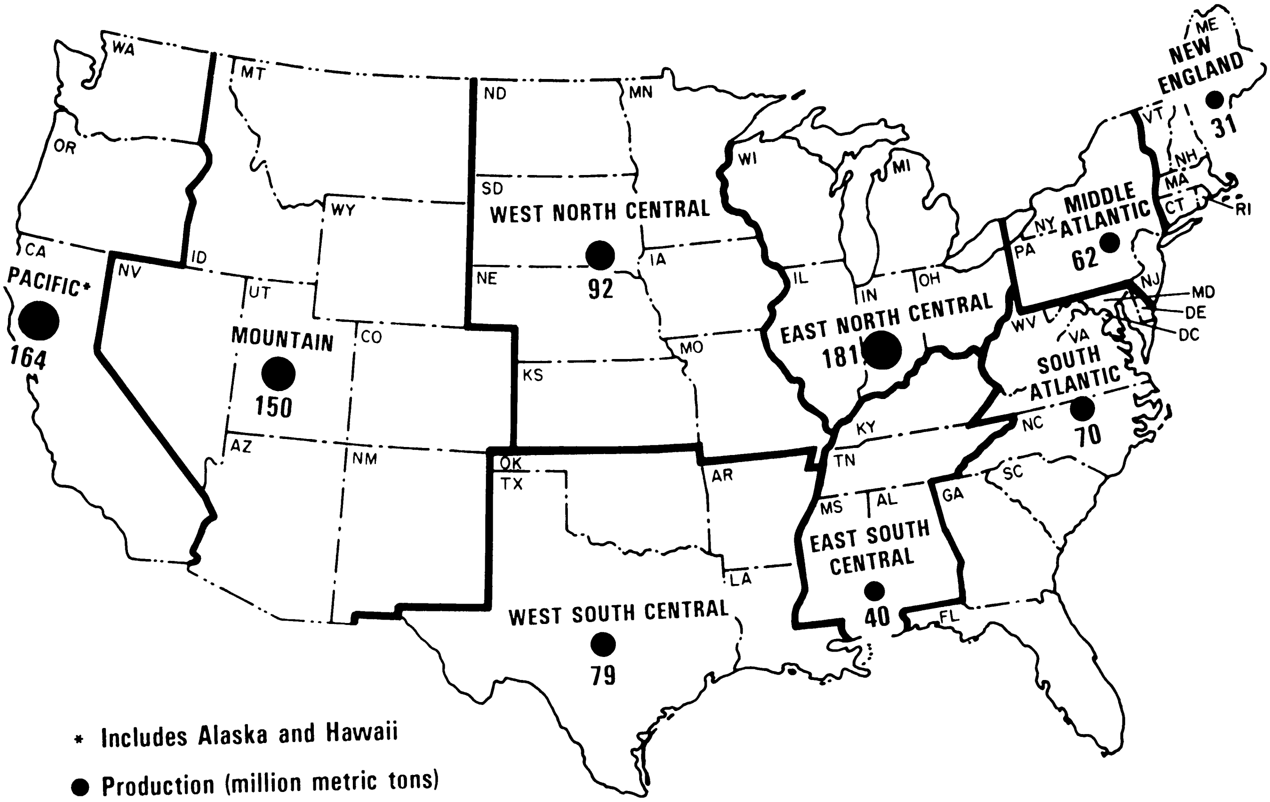
FIGURE 1

PRODUCTION OF CONSTRUCTION SAND AND GRAVEL IN THE UNITED STATES IN 1993, BY GEOGRAPHIC REGION

(Million metric tons)



INDUSTRIAL SAND AND GRAVEL

By Wallace P. Bolen

Mr. Bolen, a physical scientist, has been the commodity specialist for industrial sand and gravel since October 1988. Domestic survey data were prepared by Christopher Lindsay, supervisory statistical assistant; and the international production table was prepared by Jeremy Tidwell, international data coordinator.

Probably no other nonmetallic mineral has more diversified uses than silica (industrial) sand, mainly because of its common occurrence around the world and its distinctive physical characteristics, including hardness, resistance to high temperature and chemical action, and relatively low price. Silica sand is the major component of common glasses, foundry molding and cores, abrasive blast sand, and hydraulic fracturing sand (frac sand). Industrial sand and gravel is also important in ceramics, chemicals, and fillers for rubber and plastics, and also is utilized in golf courses, as a flux in smelting and chemical production, as filter media, and in many other uses.

Complying with the provisions of the Metric Conversion Act of 1975 and the Omnibus Trade and Competitiveness Act of 1988 (Public Law 100-418), this issue of the Annual Report for Industrial Sand and Gravel, the U.S. Bureau of Mines (USBM) will publish most data in metric units, mainly the metric ton. To help ease the transition, this report will contain two total lines, one in metric units and one in English units.

DOMESTIC DATA COVERAGE

The annual survey form was updated in 1992 and used for the collection of data for this 1993 report. After consulting with U.S. producers of industrial sand and gravel, the following new end-use categories were created: whole grain filler/building products; ground fillers; filtration: water (municipal, county, local, etc.); filtration: swimming pool, other; petroleum industry: hydraulic fracturing; petroleum industry: well packing and cementing; recreational: golf course; recreational: baseball, volleyball, play sand, beaches, etc.; and nonmetallurgical flux. The aim of the changes was to produce meaningful end-use categories that more accurately and fully cover the disposition of industrial sand and gravel. Comments or questions on these changes should be directed to the author (see the table of contents page).

Production of industrial sand and gravel in 1993 increased to 26.2 million metric tons, about 4% more than 1992's production. Production increased in response to greater demand for foundry sand, frac sand, specialty glass sand, and for silica used in ceramics production.

Exports of silica sand and gravel increased nearly 31% in quantity but remained virtually unchanged in value compared with that of 1992. Imports of industrial sand and gravel plummeted in quantity (73%) while the associated value remained about $2.5 million. Domestic apparent consumption of industrial sand and gravel in 1993 was 24.5 million tons, an increase of about 2% compared to that of 1992.

Domestic production data for industrial sand and gravel were developed by the USBM from voluntary surveys of U.S. producers. Of the 160 industrial sand and gravel operations surveyed, 133 (83%) reported to the USBM. Their combined production represented about 93% of the U.S. total published in table 1. The production of nonrespondents was estimated mostly using employment data. Of the 160 operations, 153 (96%) were active and 7 idle. *(See table 1.)*

BACKGROUND

One of the first industries to use silica sand was the glass industry. At least 4,000 years ago, long before iron was smelted, glassmaking was already a known craft. Although the place and date of the first manufactured glass are not known, the oldest known specimens of glass are from Babylon (ca. 2600 B.C.) and from Egypt (ca. 2500 B.C.), where the industry was well established by about 1500 B.C. Many varieties of glass were known during Roman times. Little is known of the glassmaking methods used in Europe from the fall of Rome until the 10th century, when stained glass was produced in Venice. After this, Venice remained the leader in fine glassware for the next four or five centuries. In the 17th century, a process for casting glass was invented in France, and later, England began to make flint glass, marking the beginning of modern glass technology.

Glassmaking was apparently the first industry to be transplanted from Europe to North America, first to Mexico and later to the British colonies. The first manufacturing establishment in what is now the United States was a glass factory at Jamestown, VA, built in 1608. The 1885 edition of "Mineral Resources of the United States," the predecessor of today's USBM "Minerals Yearbook," reported a total of 288,000 tons of silica sand produced in 1884 in the United States, under "Glass Materials." In 1993, a total of 24.5 million tons of silica sand was produced in the United States for a variety of uses, of which 10.3 million tons was for glassmaking. Today, glass has become an invaluable product with a multitude of forms and applications.

Metals casting was probably the second industry that used silica sand. Today, the casting industry provides vital components for most modern manufacturing industries. The number of industries using silica sand is growing constantly, as are the products made by using silica sand.

Another early use for silica sand was water filtration. According to an article presented at the Industrial Minerals Forum in London, November 1992, the earliest accounts of water filtration appeared in Greek and Roman writings about 2000 BC. However, early filtration was done at individual households and it was not until 1829 when the first sand filters were employed in a public system.[1]

Definitions, Grades, and Specifications

Sand is defined throughout the industry and by the American Society for Testing and Materials (ASTM) as granular rock particles that pass through a No. 4 mesh (4.75-millimeter) U.S. standard sieve, are retained on a No. 200 mesh (75-micron) sieve, and are the result of natural disintegration or comminution of cemented rock. Industrial sand or silica sand is the term used by the industry for sands that have a very high percentage of silicon dioxide (SiO_2), and are essential materials in glass manufacture, in ferrous and nonferrous foundry operations, in certain chemical and metallurgical processes, for hydraulic fracturing of oil and gas deposits, and in many manufactured products as fillers or extenders.

Most industrial sands have been named for their specific uses; for example, glass sand, foundry sand, abrasive blasting sand, and hydraulic fracturing sand. Almost invariably, these sands, in addition to being high in silica, consist mostly of quartz grains.

Products for Trade and Industry

Silica sand had a wide range of uses in a significant number of industries, the most important being glass and foundry. Other uses were metallurgical and as abrasives, as fillers, for filtration, and for hydraulic fracturing of rock formations to improve recovery in oil wells.

Glass sand was used as a main constituent for manufacturing glass containers, flat glass, safety glass, pressed and blown glass, fiberglass, and a wide variety of specialty glasses such as optical glass and industrial glass.

Glass sand had to meet rigid specifications with respect to purity and silica content, depending on the kind of glass being manufactured. Only a very small amount of iron oxide and chromium compounds could be tolerated, and a high percentage of aluminum, calcium, or magnesium oxides was undesirable. The standards of the American Ceramic Society for glass sand indicated that all grains should pass through a No. 20 mesh screen, between 40% and 60% should be retained on a No. 60 screen, between 10% and 20% on a No. 80 screen, and not more than 5% should pass a No. 100 screen. Sand for first-quality optical glass should contain 99.8% SiO_2 and a maximum of 0.1% aluminum oxide (Al_2O_3) and 0.02% iron oxide (Fe_2O_3). Third-quality flint glass could contain only 95% SiO_2 and as high as 4% Al_2O_3. Only in the low-quality amber glass was the content of Fe_2O_3 permitted to reach 1%.

Most glass manufacturers established their own specifications for the physical size and chemical purity of the raw materials that have to be met by the suppliers of glass sand. Recently, glass manufacturers showed an increased interest in finer glass sands because processing of smaller particles required lower temperatures and, therefore, reduced the consumption of energy.

Foundry sands included molding sand and core sand that were used for casting iron-, aluminum-, and copper-base alloys. Required properties included cohesiveness sufficient to hold together the mold or core when moist, which is achieved by a bonding agent; refractoriness to withstand the high temperature of the molten metal; strength to resist the weight of the metal; permeability to release vapors and gases generated during cooling of the metal; and proper texture and composition to produce a smooth casting that will not react with the metal. Most metals were cast in "green sand," which is a mixture of silica and clay, although to a lesser extent, resins or oils also were used as a bonding agent instead of clays. In the case of naturally bonded foundry sands, the amount of clay minerals present affected their usefulness. Standard tests and specifications for foundry sands were published by the American Foundrymen's Society.[2]

Refractory sands were used in the manufacture of silica brick and tile, quartzite (gannister) being the commonly used raw material. Required properties were "the capability of maintaining the desired degree of chemical and physical identity at high temperatures" and resistance to abrasion, impact, thermal shock, and high level of load. Refractory silica materials were classified based on their general composition and on their distinctive properties. Standard classifications and specifications for silica refractory brick were published by the ASTM.[3]

Quartz sands, on the Knoop scale at 820, are quite hard and are one of the oldest abrasives known. Abrasive sands were quartz sands used in stone sawing, glass grinding, metal polishing, and sand blasting. No rigid specifications existed for these sands, but sound, clean, hard, and closely sized sand grains were required. Purity and grain-shape specifications varied with the type of abrasive action and the requirements of the final product. Traditionally, an angular particle shape with sharp cutting edges was generally required.

Hydraulic fracturing sand was pumped into oil or natural gas wells as a sand-liquid mixture to break up petroleum-bearing formations and act as a propping agent, allowing oil or gas to move more freely toward the producing wells. Some of the major requirements for fracturing sands were spherical, well-rounded grains of clean, dried, and well-screened quartz sand, free of any materials such as feldspar, calcite, and clay. The most common size was 20/40 mesh; other sizes included 6/12, 8/16, 12/20, 40/70, and 70/140, but these sands represented only about 15% of the total sand used as proppant. "Recommended Practices for Testing Sand Used in Hydraulic Fracturing Operations," published by the

American Petroleum Institute, was used as a guide by industry.[4]

Ground sand or silica flour has found wide industrial application as a filler in paint, plastics, rubber, ceramics, and a variety of other products. Mainly because of the diversity of its uses, no standard specifications exist for the silica flour used in most of these applications except grain size and chemical composition. Silica was used in various plastics such as acrylonitrile-butadiene-styrene polymer, polyolefins, polystyrene, polyvinylchloride (PVC), thermoplastic polyester, polyurethane, and epoxy, which is the largest consuming resin. The silica thickens liquid systems, works as a flatting and thixtopic agent, and helps to avoid plateout in PVC.

As a filler and extender in paint formations, ground silica renders paint more resistant to chemical attack because of its acid resistance. The paint's scrubbing and wear resistance, tint retention, durability, and flowability also are enhanced by silica. Additionally, whole grain silica sand was used as a filler in many products that may be categorized as "building products," including, but not limited to, stucco, no-skid floors, and grouts.

Silicon carbide, which was used as an abrasive, for refractory uses, and in specialty ceramics, was produced by the reaction of silica sand (60%) and coke (40%) at elevated temperatures up to 2,400° C. Metallurgical sand was used as a fluxing agent for basic oxides in various smelting operations and as a source of silicon in ferrosilicon manufacture. The ferrosilicon was a steel alloying additive.

Filter sand was used extensively in filtering water for municipalities, industry, swimming pools, and in sewage treatment plants. Traditional sand filters for public water purification use the "slow sand filtration" design, which contains fine sand, 0.3-millimeter grain size, in a bed that ranges from 0.6 to 1.0 meter in thickness. Slow filtration rates require many beds of sand. A representative-size bed would cover about 0.4 hectare, which is about the size of a soccer (European football) field. The sand used was typically subangular, brown, or yellow quartz, with little advantage being given to highly rounded pure quartz. Besides slow sand filtration, "rapid filters" are also employed. Rapid filters use salts to precipitate aluminum or ferric hydroxides, and these filters are backwashed daily to remove materials that are clogging the sand.[5]

Engine sand was used in locomotive haulage to improve traction. Other sands were used in special cements, in manufacturing silica brick and tiles for furnace linings and beds, and in manufacturing pottery. Industrial sand was used also for chemical production, golf courses (both in traps and in green construction), and in a growing variety of building products. Industrial gravel was used as the source material in the production of silicon and ferrosilicon and as a flux for the production of copper, nickel, and elemental phosphorus. Some gravel was used as filtration media, mainly in municipal water-treatment facilities.

Industry Structure

In 1993, 85 U.S. companies with 153 active operations produced silica sand and gravel. The individual industrial sand and gravel operations ranged in size from those producing well over 1 million tons annually to those reporting less than 10,000 tons per year. Most of the production came from large operations that were mostly owned or operated by a small number of companies. In the past 10 to 15 years, there was a gradual trend toward larger operations, mostly because small plants were becoming less economical. The viability of small operations was dependent on demand in local markets, mining conditions, and the degree of processing required to supply the final product.

Beyond the move toward larger operations, the industry also has developed into two groups: one, the larger national or regional companies that produce many grades of silica, and the other, which consists mainly of smaller and local companies that produce industrial sand and gravel for limited uses and often include construction sand and gravel. Because companies that traditionally produced only construction sand and gravel may sometimes produce sand for industrial uses, the number of companies producing industrial sand and gravel could change by upward of 10% annually.

Geology-Resources

U.S. resources of industrial sand and gravel were expected to be sufficient to meet domestic demand in the foreseeable future, although their geographic distribution and quality often did not match market requirements. The availability of these reserves was controlled to a significant degree by land use and/or environmental constraints. Reserves of industrial sand and gravel owned or controlled by domestic producers were estimated to total about 3 to 4 billion tons.

Although silica reserve data for the rest of the world were not available, it could be assumed, on the basis of geologic evidence, that world reserves were sufficient to meet demand, even if not always at the locations where needed.

Industrial sand or silica sand was produced in the United States from a variety of geological formations ranging in age from late Precambrian to mid-Tertiary. About 70 stratigraphic units were known as having an economic potential for this industry. Lithologically, these deposits ranged from quartzites, sandstones with different degrees of cementation, quartz conglomerates, chert deposits, and quartz pegmatites to terrace sands and gravels, and dune sands. Most of the high-quality industrial sand was produced from a few geological formations in the Eastern United States. Oriskany sandstone, or more precisely the Ridgeley formation of Early Devonian age, was one important source of silica sand. It extended from New York State to southern Virginia and eastern Ohio, but was being mined only in central Pennsylvania, northwestern Maryland, and northern West Virginia, where the formation was thick enough to be of commercial value. It was a hard, white orthoquartzite with medium to fine, angular and subangular, and well-sorted grains. The St. Peter sandstone of Middle Ordovician age, extending from Wisconsin and Minnesota through Iowa, Illinois, and east-central Missouri, was another major source of industrial sand. The best known center of production of silica sand from this formation was the Ottawa district of La Salle county, IL, where it was known as "Ottawa sand," and to a lesser degree in southern Wisconsin and east-central Missouri. It was a soft and poorly cemented high-purity orthoquartzite with coarse, rounded grains. The weak cement holding the silica grains together was mostly a light-colored clay.

In addition to the two formations just mentioned, the most important sources of industrial sand in the United States, numerous other deposits were being mined for silica sand in different parts of the country. Included are the Jordan sandstone of Upper Cambrian age in Minnesota and Wisconsin, a primary source of hydraulic fracturing sand; the Raritan formation of Upper Cretaceous age in central New Jersey and the Cohansey sand of probable Miocene age in southern New Jersey; and the Tuscarora quartzite of Lower Silurian age in Pennsylvania and Virginia used for the manufacture of refractory bricks. Other deposits are the Sylvania sandstone of Devonian age in the Detroit area; the Oil Creek and McLish formations of Lower Ordovician age in Oklahoma, a southwestward extension of the St. Peter sandstone; and the Hickory sandstone of Cambrian age in central Texas that produced mostly hydraulic fracturing sand.

In the West, the most important sources of industrial sand were the Ione formation of Eocene age in northern California, the Silverado (Paleocene) and Tejon (Eocene) formations in southern California, and the Eureka quartzite of Middle Ordovician age in central California.

Approximately two-thirds of the U.S. industrial sand and gravel was produced east of the Mississippi River, especially in the industrialized areas of the East North Central, South Atlantic, and Middle Atlantic regions. Of the top six producing States that accounted for about 51% of 1993 production, four—Illinois, Michigan, New Jersey, and Wisconsin—were in the East and the other two—California and Texas—were in the West. The concentration of the industrial sand operations in the eastern part of the United States resulted from the existence of high-quality geologic deposits close to the major consuming industries, glass and foundry. In the south and west, demand from the oil and gas industry in the Louisiana, Oklahoma, and Texas area has been the largest factor for the sustained growth of industrial sand operations in Texas. California production remained large owing to demands from local industry, particularly the glass container industry, with the wine industry consuming a large portion, coupled with the distance of California from the traditional production areas in the Midwest.

Technology

Exploration.—A large number of geologic formations with economic potential as a source of industrial sand have been mapped and described in the literature over many years and were, therefore, well known. Consequently, detailed exploration and development work for new industrial sand operations was expected to occur on some of these formations. The qualities of a silica deposit necessary for a viable operation should include proper particle size, chemical composition, degree of cementation, and deposit uniformity. Also, the nature and amount of waste material and the economic feasibility of its removal and possible use or disposal should be studied. The evaluation of the new deposit should also include an environmental impact study as required by most local or State agencies before authorizing a new mining operation.

If the raw material should prove to meet the requirements and adequate reserves are demonstrated, the development stage of the operation could be started. Economic feasibility and marketing studies should be performed by analyzing all factors important for any such mining operations. Included are the availability of power and water supply, mining and processing costs and requirements, and the condition of nearby roads and highways. Other factors include the proximity of rail haulage; the cost of compliance with local, State, and Federal regulations; and the proximity and density of local population as well as its attitude toward such a project.

Mining.—Most industrial sand was mined from open quarries, but a few underground operations existed, mostly because of an exceptionally thick overburden or environmental limitations. Surface mining methods and equipment varied with the type of the geologic formation, size and configuration of the deposit, production capacity, estimated life of the operation, and location of the deposit with respect to urban centers. The mining methods depended primarily on the degree of cementation of the rock, although most open pit mining operations included site clearing and removal of the overburden; mining of the silica rock or sand; processing of the material, including crushing, screening, and classification; and reclamation of the extraction area. Unconsolidated sands, such as the Cohansey of New Jersey, below the ground water level were dredged. Much of the St. Peter sandstone was first loosened by light blasting and then washed down by hydraulic jets or "monitors" into sumps, from which it was pumped to the processing plants. Harder rock such as the Oriskany sandstone required blasting and primary and secondary crushing before it could be processed.

Processing.—Processing of mined silica sand required specialized operations that varied considerably with the nature of the deposit and the physical and chemical requirements of the desired product. Depending on the degree of cementation, several stages of crushing were necessary to achieve the desired size reduction. Gyratory crushers, jaw crushers, impact mills, or roll crushers were used as primary or secondary crushers, and smooth rolls, media mills, autogenous mills, high-speed hammer mills, or fluid energy jet mills were used for grinding the product down to 50 microns and finer. Some producers employed flotation cells, with a variety of flocculants, to remove unwanted minerals and fines if they were not easily removed through mechanical scrubbing and separation, which most producers installed. Dry or wet screening was used to separate particles of sizes down to about 150 microns, and wet or air classifiers processed particles from 250 microns into the submicron range. Vibratory screens and gyrator screens, in addition to mechanical, hydraulic, or air classifiers, were used, depending on the size distribution required.

Research for the silica mining industry related not only to new methods that increased output and reduced production costs but also to health and safety problems as well as exploration, land management, and reclamation. Significant technological developments instrumental in maintaining adequate production at relatively stable real costs were mostly in the processing plant technology. The use of computerized systems in plant operation and quality control increased; this, along with improved mining and processing equipment, permitted the recovery of salable fractions that were previously considered uneconomical.

Byproducts and Coproducts

Small amounts of gold and silver were recovered occasionally as a byproduct or coproduct from some unconsolidated silica sand deposits. Also, during the processing of some silica resources, other minerals, including clays, feldspars, mica, and quartz crystals, were produced as byproducts and coproducts.

Substitutes

Various materials can be substituted for silica, depending on the application, but most products have a hard time competing on a price basis. As a raw, natural material, nothing can compete with silica as a glass forming oxide; however, on a material level, virgin silica competes with recycled glass, often called cullet. Zircon and carbon grains are two sands that compete with silica but the largest competitor will probably be reclaimed or recycled "spent" foundry sand if cost and quality are acceptable. The silica that is suffering the greatest competition is abrasive blasting sand as garnet, olivine, slags, manufactured abrasives (synthetic abrasives), and many others seek to grab market from silica as consumers fear reported silica health hazards. Substitutes for many other uses also exist.

A recent report of a silica substitute comes from National Mineral Products, a division National Refractories & Minerals Corp. of California. It was introducing a dolomite-based replacement for silica sand in stucco mix applications. The group claims that its product is whiter, brighter, and more consistent than silica.[6]

Economic Factors

Silica sand deposits are nonrenewable resources. New mining methods combined with advances in mineral processing that were introduced during the past decade have increased the number of silica deposits that can be commercially developed.

The industrial sand industry was very competitive, largely because silica sand is a relatively abundant mineral, with supply usually exceeding demand. The delivered price of the product, in addition to quality, was a very important element in any major transaction. The producer with an operation closest to the market had a significant advantage over competitors. Combining sophisticated (and therefore expensive) processing equipment backed by technical knowledge and solid sales expertise was important. For this reason, only a small number of large companies were able to compete successfully and succeed in the silica sand business and supply a wide variety of products. Smaller, less efficient operations became uneconomical as operating costs, as well as costs associated with meeting various Federal, State, and local regulations, continued to increase. The only alternatives they had were to either limit the range of products they supplied to close markets or go out of business.

Prices.—As a result of rapidly rising costs of labor, energy, and mining and processing equipment, 1993 constant dollar prices, per metric ton, all uses, of industrial sand and gravel rose steadily between 1973 to 1983. From 1985 to 1990, 1993 constant dollar prices fluctuated in the 17.88 to 18.86 range, owing to decreased demand and tight competition in some markets. Since 1990, constant dollar prices have fallen from 18.86 to 17.73 as the 1993 constant dollar price dropped to approximately the 1978 adjusted value. Competition, coupled with environmental and recycling policies, could very likely continue to decrease the use of silica in traditional markets. However, specialty markets for silica will probably experience increased consumption, and these higher cost uses will cause the overall constant dollar price to rise through the year 2000.

Costs.—Production costs for silica sand were determined to a large extent by the cost of labor, equipment, energy supply, water availability, and the additional burden of compliance with environmental and safety regulations. Production costs varied widely depending on the nature of the geologic deposit, the geographic location, and the type and number of products produced. Profits were relatively small for most producers, total production costs being close to the f.o.b. selling price per ton.

Tariffs.—There has been no tariff on imported silica sand containing 95% or more SiO_2 and not more than 0.6% iron oxide from most favored nations since January 1, 1987. For all other countries, the tariff for imported silica sand remains $1.94 per long ton.

Depletion Provisions.—The depletion allowance for industrial sand and gravel was 14%.

Operating Factors

Environmental Requirements.—Major environmental considerations that had to be dealt with in mining and processing of industrial sand and gravel were emission of particulate matter into the air, discharge of processing water, and noise abatement. Air pollution constituted a major problem in the processing plants, especially in the drying and packaging stages of finer products such as silica flour, silicosis being the major disease that can be contracted as a result of long-term exposure to silica dust. Because of the high cost of compliance with the environmental regulations designed to reduce this health hazard and possible long-term liabilities associated with it, some companies were no longer producing silica flour or did not plan to produce it in the future. Both wet and dry methods of dust control were used. The most important water pollutant was clay in suspension as a result of washing and screening silica sand. Because of the large quantities of water used to process silica sands and the need of compliance with stringent regulations, the treatment of discharge water by the sand producer was expected to require increasingly sophisticated and expensive processing methods. Significant progress was made in reducing noise pollution, both inside and outside of the operations, including noise and vibration produced by blasting and movement of heavy trucks.

Sand producers had to obtain mining permits from the appropriate governmental agency, which sometimes also required an Environmental Impact Statement (EIS) and a reclamation plan that met its guidelines or regulations. More emphasis was being put by local communities on improving the overall appearance of the operating mines as well as on land reclamation after mining was completed. At the same time, industry and the communities had to recognize the time and costs required to protect the environment and the importance of agreeing on fair and realistic environmental standards. Many States, counties, and towns had zoning laws that regulated land use.

Most of the active silica sand quarries as well as the known deposits were on private land, which was either owned or leased on a long-term basis by the producers. These deposits contained high-quality silica sand and were in the best locations with respect to markets. Unlike the construction sand and gravel industry, the industrial sand industry was usually not significantly affected by increasing land values near populated areas.

Transportation.—Transportation costs for silica sand were often equal or considerably greater than the cost of the product at the processing plant. Because of the large variety and number of consumers of silica sand, long-distance haulage was not uncommon. In 1993, the largest tonnage, 63% of all industrial sand, was shipped by truck because most users require a versatile and rapid delivery system. Substantial quantities, 34% of the total, were shipped by rail, especially when large volumes were sent long distances. The remaining tonnage was shipped by barge or used at the mine.

ANNUAL REVIEW

Legislation and Government Programs

The National Institute for Occupational Safety and Health (NIOSH) released a draft criteria document for review that recommends drastic reductions in the current permissible exposure limits (PEL's) for respirable coal mine dust and crystalline silica. The draft recommends lowering the current PEL for crystalline silica from 0.1 milligram per cubic meter of air (mg/m^3) to 0.05 mg/m^3. NIOSH's responsibility is to make recommendations, but it usually carries a lot of weight with the regulatory agencies. This recommendation applied mainly in relation to coal mining but NIOSH recommendations may eventually be applied to all mining and occupational activities.[7]

Proposed changes in the Safe Water Act and a crackdown on the use of lead in plumbing pipes are aimed at reducing lead levels in areas with high readings. The plan also could benefit silicate chemicalmakers. The best way to lower lead levels is to keep the lead in the pipes by preventing erosion that occurs when water is very acidic or alkaline. The Environmental Protection Agency has recommended several ways to combat the problem, including increasing the pH of the water above 7 to make the water less corrosive by adding alkaline materials such as silicates. Other recommendations also were made that would benefit silicate chemicalmakers.[8]

The Department of Health and Human Services has ordered a review of research that concludes fiberglass insulation used in 90% of U.S. homes is a possible carcinogen. The review was ordered in July after petitions in June 1992 and June 1993 and industry-sponsored research were submitted.[9]

Issues

Issues that concerned and affected silica miners included land use restrictions, respirable silica studies and control, fiberglass health concerns, and foreign trade. The New Jersey Pinelands Commission (PC) proposed heightened restrictions or elimination of mining in a jurisdictional area covering 400,000 hectares (1 million acres) of land in seven counties. The PC was formed in 1980 and implemented tough mining restrictions but included a grandfather clause on land owned by mining operators who were permitted. It was expected that continuing debate and compromise concerning this issue may free more land to mining.[10] New Jersey was the third largest producing State for industrial sand and gravel in 1993.

Silicosis and lung cancer related to respirable silica continued to attract attention in 1993. In the United Kingdom, the Industrial Injuries Advisory Council (IIAC) released a report suggesting a twofold increase risk of lung cancer where there is evidence for silicosis. Two professors suggested that although there were only 50 to 100 cases of silicosis in the United Kingdom each year, there were 35,000 cases of lung cancer, and silicosis risk was masked by smoking.[11] The Wall Street Journal published an article in March titled, "How Sand on a Beach Came To Be Defined as Human Carcinogen." The lengthy article depicted the problems, confusion, and challenges facing those who work with or seek to regulate crystalline silica.[12]

To respond to concerns over respirable silica, producers, consumers, and handlers of industrial sand and gravel were continually seeking to reduce exposure. Allied Colloids developed a specially designed dust suppressant for use on all mineral stockpiles. The suppressant forms a film on the surface of the mineral stockpile, preventing the creation of windborne dust.[13] In a mechanical control method, Australian-based Speedlock Ducting Pty. Ltd. has produced a ducting system designed for use in any enclosed area where crushing, screening, dry processing, or bulk handling of ore takes place. The system was said to provide an easily installed, cost-effective alternative to conventional welded or riveted systems.[14] Additionally, Entecon Ltd. of the United Kingdom, has extended its range of systems for dust-free opening and emptying of bags. The systems are enclosed totally, avoid product contamination, compact and bag empty bags, and handles paper, plastic, woven, or combination bags.[15]

Trade issues that affected the silica industry included actions on glass, ferrosilicon, and silicon carbide. Flat glass trade with Japan was one focus of contention as U.S. flat glass producers sought to increase the amount of glass exports to Japan via trade talks. Tokyo had promised to help open its domestic glass market to foreign competitors such as Guardian Industries Corp., which was trying to get more glass into Japan. However, little progress had been made. Increased exports would benefit U.S. industrial sand producers.[16] The International Trade Commission (ITC) has announced that it is to continue with its investigation into damage inflicted on U.S. industry by imports of silicon carbide from China.[17] In another trade dispute, the U.S. Department of Commerce found dumping of ferrosilicon from Brazil, but the ITC found no injury from imports of ferrosilicon from Egypt.[18]

Production

The Midwest (East and West North Central regions) continued to lead the Nation in production with about 44% of the 26.2 million tons produced in the United States, followed by the South (South Atlantic, East and West South Central regions) with about 34% and the West (Pacific and Mountain regions) with 12%. *(See table 2 and figure 1.)*

The six leading States in the production of industrial sand and gravel, in descending order of volume, were Illinois, Michigan, New Jersey, California, Wisconsin, and Texas. Their combined production represented 51% of the national total. Among these six States, New Jersey experienced a 33% increase in production, Michigan a 31% increase, and Wisconsin and Texas also had sizable increases. Illinois' output remained about the same while California saw a decrease of 6% in production compared to that of 1992. *(See tables 3, 4, and 5.)*

The USBM canvassed 85 producers of industrial sand and gravel with 153 active operations. About 75% of the industrial sand and gravel was produced by 47 operations, each with an annual production of more than 200,000 tons. The 10 leading producers of industrial sand and gravel were, in descending order of tonnage, Unimin Corp., U.S. Silica Co., Fairmount Minerals Ltd., The Morie Co. Inc., Oglebay Norton Co., Badger Mining Corp., Construction Aggregates Corp., WHIBCO Inc., Nugent Sand Co. Inc., and Simplot Industries Inc. Their combined production, from 63 operations, represented 70% of the U.S. total.

There were no major merger and acquisition activities in 1993 but operations did move in and out of the industrial sand and gravel sector as some companies (re)introduced silica for industrial uses while others removed operations from the industrial sand and gravel sector. Tri-Sands Inc., Trafford, AL, reported the closure of its silica operation in Tishomingo County, MS.

FMC Corp.'s phosphorous chemicals division announced that it was lowering the capacity for elemental phosphorus at its plant at Pocatello, ID. Elemental phosphorus production consumes silica as a flux.

Consumption and Uses

Sand and gravel production reported by producers to the USBM was actually material used by the companies or sold to their customers. Stockpiled material was not reported until consumed or sold. Of the 26.2 million tons of industrial sand and gravel sold or used, 39% was consumed as glassmaking sand and 22% as foundry sand. Other important uses were abrasive sand (6%) and frac sand (6%).

The amount of sand sold for container glass declined in 1993 compared to that in 1992, even as the total number of shipments of glass containers rose 2.7% during the year. This decline amidst an increased production of glass containers was reflective of the increased amount of recycled glass going into glass container production. The share of silica sold for glassmaking as a percentage of all silica sold dropped to its lowest level (39%) since 1985, when glass markets consumed only 35% of silica sold.

Container glass was not only being used to produce more containers but also for producing fiberglass. The fiberglass industry reportedly consumed 272,000 tons of cullet in 1992. In 1993, it was expected that just over 320,000 tons would be used. Contamination of cullet was also a concern for the fiberglass industry as the amount of cullet in the batch continues to rise.[19]

Furthering this trend, Denver-based Schuller International Inc., a manufacturer of Manville-brand fiberglass insulation, announced a multiyear contract with Pure

Tech International Inc., Somerset, NJ, to supply glass cullet. Schuler will initially be receiving 20,000 tons per year of recycled glass. Additionally, Owens-Corning announced it will reopen its Jackson, TN, glass fiber plant facility in April 1994, which was closed in 1987. Capacity was not disclosed.

The blasting market also consumed less silica in 1993 as sales fell 8% from those of 1992. The blasting market suffered, not from increased recycling, although there was some blast sand recycled, but from increased concern about health hazards related to respirable silica. Consumers increasingly are using competing materials such as garnet, slags, and glass beads.

On a more positive note, foundry and frac sand sales were up 12% and 9%, respectively, compared to those of 1992. The domestic automotive industry, the leading consumer of foundry sand, had a good sales year while the oil and gas industry worldwide consumed more frac sand, especially for gas wells. The Texas Railroad Commission (TRC) reported that drilling for gas was up sharply in Texas, up 40% in the first 8 months of 1993 compared to that in 1992. Conversely, the TRC expected 1993 oil production in Texas to reach a 50-year low attributed to many factors, especially foreign imports and low crude prices. Nationally, oil production dropped to its lowest volume in 35 years.

Specialty silicas were produced usually by means of chemical processing of natural silica or as a byproduct of other mineral or chemical processing. Although the USBM did not specifically collect information for specialty silicas, their consumption does affect natural silica sales. Specialty silicas included, but were not limited to, fumed silica, fused silica, precipitated silica, sol-gel silica, and ultrahigh-purity silica. These silicas were used in abrasives, catalyst, electronics, food, health care, optics, paper, plastics, refractories, rubber, specialty coatings, and others. In 1991, specialty silicas sales were $1.6 billion and were expected to grow to $2 billion by the year 2000.[20]

Smaller volume markets, traditional and newly developed, continued to consume significant amounts of silica. These markets include chemical, filler, ceramic, and other categories. A division of Rhone-Poulenc crafted a sodium carbonate-silicate cogranulate, the first of its type. The new builder considerably enhances the efficiency of the detergent formula through the combined action of its two components, sodium carbonate and sodium polysilicate. Should this receive wide acceptance as a detergent, it would positively affect consumption of silica via sodium silicate.[21]

In other related developments, Degussa Corp. brought on-line its Waterford, NY, hydrophobic fumed silica plant. The plant will produce *Aerosil,* Degussa's fumed silica, used in silicone rubber sealants, coatings, printing inks, and other applications. Additionally, PQ Corp. has started a 500,000-pound-per-year facility in Kansas City, KS, for the production of silica catalyst. The material formerly was made in Rahway, NJ, and is used in the production of high-density polyethylene. Both of these actions should stimulate greater silica consumption and production in various regions of the United States.

The production of industrial sand and gravel in the United States has developed in response to market location and vice-versa as industry sometimes located near silica resources. Because silica deposits (or resources) are found throughout the United States, locating a consuming industry specifically to be near a silica source was not always a priority, although certainly a consideration. The auto industry, responding to iron, coal, clays, and silica resources, centered in the Midwest, and thus foundry sands were greatly exploited in Illinois, Indiana, Michigan, and Ohio and other regional States. This resulted in more than 75% of the foundry sand being produced in the Midwestern region in 1993.

The glass industry, somewhat conversely, had to locate plants where they could minimize the shipping distance of finished glass products. Hence, glass plants were more evenly distributed as 43% of glass sand was produced in the South region, 33% in the Midwest, 17% in the West, and 7% in the Northeast in 1993. To varying degrees, all silica production was similarly influenced as markets and consuming industries either forced the silica mining location or were forced to locate near the silica source. *(See table 6 and figure 2.)*

Northeast.—Cumberland County, NJ, continued to be the largest source for the glass and foundry sand markets in the region. Unimin, U.S. Silica, Morie, and WHIBCO Inc., all of which operated plants in the county, were among the largest producers of sand for these markets. U.S. Silica's plant in Huntingdon County, PA, also produced significant amounts of sand for the glass market. Morie and Ricci Brothers Sand Co. Inc., both in Cumberland County, NJ, produced a major percentage of the abrasive blast sand in the region.

Midwest.—Unimin's plants in LaSalle and Ogle Counties, IL; LeSueur and Scott Counties, MN; and Columbia County, WI, were among the leaders in producing sand for the blast, foundry, frac, and glass sand markets. Fairmount Minerals, with operations in Berrien and Van Buren Counties, MI, Geauga County, OH, and La Salle County, IL, was a major producer of sand for the blast, foundry, and glass sand markets in the region. U.S. Silica's plant in La Salle County, IL, was a large producer for the glass, foundry, and frac markets and its St. Louis County, MO, operation was a large producer for the glass market. Construction Aggregates Corp., Ottawa County, MI; Nugent Sand Co. Inc., Muskegon County, MI; and Sargent Sand Co., Wexford County, MI; were all large producers for the foundry industry. Badger Mining, Jackson and Green Lake Counties, WI, were major producers for the frac and foundry markets. Manley Brother's of Indiana, LaSalle County, IL, was also a large producer for the blast, foundry, and glass markets. Major producers for the blast sand market included Oglebay Norton Co., Knox and Perry Counties, OH, and Kaw Valley Sand and Gravel Co., Wyandotte County, KS.

South.—Unimin and U.S. Silica Co. were two of the largest producers of sand for the glass and foundry markets. Unimin's major plants were in Izard County, AR; Richmond County, NC; Pontotoc County, OK; Kershaw County, SC; and Frederick County, VA. U.S. Silica's Bullock County, AL; Johnston County, OK; Lexington County, SC; Limestone County, TX; and Morgan County, WV, operations were the major contributors for these markets. Morie's Tuscaloosa County, AL; Marion County, GA; and Carrol County, TN, plants were large producers of foundry and glass sand. Cobb Industrial Corp., Red River Parish, LA; Foster-Dixiana Corp., Lexington County, SC; Huey Stockstill Inc., Pearl River County, MS; Mid-State Sand and Gravel Co., Allen Parish, LA; Pioneer Concrete of Texas Inc., Liberty County, TX; and Specialty Sand Co., Newton County, TX, were large producers of blasting sand. W.R. Bonsal and Co. and B.V. Hedrick Gravel and Sand Co., both in Anson County, NC, produced a large percentage of the industrial gravel used in the production of silicon and ferrosilicon. Oglebay Norton's Texas Mining Co. and Vulcan Materials Co., both in McCulloch County, TX, were the largest producers of frac sand in the region. WHIBCO in Kershaw County, SC, was an important producer of foundry sand. APAC Arkansas Inc., Crawford County, AR; Florida Rock Industries Inc., Putnam County, FL; and Short Mountain Silica Co., Hawkins County, TN, were important producers of glass sand. Oglebay Norton's Texas Mining Co., McCulloch County, TX, was also an important contributor of blast sand in the region.

West.—Corona Industrial Sand Co., Owens-Illinois, Simplot Industries, and Unimin were the four largest producers of glass sand in the region, with major operations in Riverside County, CA; Amador County, CA; Clark County, NV; and Contra Costa County, CA, respectively. Lane Mountain Silica, Stevens County, WA; Lone Star Industries Inc., Monterey County, CA; and P.W. Gillibrand Co., Ventura County, CA, were the major suppliers for the sandblasting industry in the region. Simplot Industries, Clark County, NV, also supplied a large portion of the foundry sand consumed. FMC Corp., Power County, ID; Rhone-Poulenc Basic Chemicals Co., Beaverhead County, ID; and Monsanto Industrial Chemicals Co., Caribou County, ID, each produced industrial gravel for use as a flux in elemental phosphorus production.

Recycling.—Recycling of silica sands was limited to some foundry sands, particularly those used for making cores and molds with no-bake resin-bonded sands, some abrasive and airblasting sands, and, increasingly, postconsumer glass and scrap glass (cullet) that substitutes for batch mix (including industrial sand). Most glass recycling was restricted to container glass, with green and amber being consumed at a higher rate than flint because it was more difficult to use in the batch mix. Glass recycling was put at 33% in the United States for 1992, the fifth straight year of growth. This included glass containers used in glasphalt and those that were refilled and represents an increase from the 1991 rate of 31%.[22]

As the level of glass used increases, so does the level of quality required. Contamination of cullet by ceramics and nonmagnetic materials was an increasing concern. Because of the increased use of cullet, restrictions on the iron and chromium levels in glass sands have become stricter and the proportion of refractory particles allowed has been reduced to almost zero. The Fe_2O_3 content of a typical glass silica sand is now as low as 0.015% to 0.02% for flint glass manufacture and 0.1% to 0.15% for colored glass. Additionally, recycling of amber and green glass was substantially greater than flint glass, and therefore lower grade deposits are in less demand.[23]

A new sand recycling technology promises to provide tremendous environmental and economic benefits to the U.S. foundry industry. Developed at Navistar International Transportation Corp., Indianapolis, IN, it is the world's first electric infrared sand reclaimer. The sand reclaimer combines high-intensity infrared heating with "fluidized bed" technology to reclaim all types of foundry sand. The projected benefits of the system at full production scale are substantial and include both environmental and economic factors.[24]

International trends toward increased recycling of glass and foundries sands and innovative ideas on recycling other materials should influence greater recycling of silica products.

Transportation

Of the total industrial sand and gravel produced, 63% was transported by truck from the plant to the site of first sale or use, up from 56% in 1992; 34% was transported by rail, down from 38% in 1992; 3% was transported by waterway; and 1% was not transported. Because most of the producers did not report shipping distances or cost per ton per mile, no transportation cost data were available.

Prices

Compared with that of 1992, the average value, f.o.b. plant, of U.S. industrial sand and gravel increased slightly to $17.33 per metric ton. Average unit values for industrial sand and industrial gravel were $17.78 and $10.90 per ton, respectively. Nationally, ground industrial sand used as fillers for rubber, paint, and putty, etc., had the highest value per ton ($104.27), followed by silica for well packing and cementing ($72.09), ground silica for molding and core facings, ($57.73), ground silica sand used in ceramics ($51.53), silica for swimming pool filters ($44.40), ground silica used for fiberglass ($41.11), ground silica for scouring cleansers ($36.60), and frac sand ($30.83).

Industrial sand and gravel price changes were greatly mixed because some markets were level, others had small increases or decreases, and still others experienced large increases or decreases. This situation was possible because although the silica was essentially the same, most markets were very independent from each other and price competition was influenced by availability, regulations and health concerns, and competition from other materials. Those end uses that sustained greater prices in 1993, compared to those of 1992, included: blasting, ceramics, fiberglass, fillers, filtration, and frac sand. Silica for container and flat glass, foundry, roofing granules and fillers, and traction experienced a decrease in unit value.

The average value per ton of industrial sand and gravel was highest in the West

($20.31), followed by the South ($17.90), the Northeast ($17.46), and the Midwest ($16.03). Prices can vary greatly for similar grades of silica at different locations in the United States. For example, glass sand average value per ton varied markedly, from $19.87 in the West to $11.53 in the Midwest. Tighter supplies and higher production costs in the West and much greater competition in the Midwest caused the difference in the cost of sand and gravel in these two regions.

Foreign Trade

Exports.—Exports of industrial sand, compared with those of 1992, increased 31% to 1,751,000 tons, while the value remained about the same. Export distribution is as follows: 80% went to Canada, 5% went to Japan, 4% went to Brazil, and the remainder went to numerous other countries throughout the world. This situation, where there was greater tonnages exported but an insignificant change in the associated value, occurred mainly because of two reasons. The distribution of grades that make up the total exports changes from year to year and different grades have different values. Also, the prices may change for the same product in response to increased competition or changes in supply contracts.

Imports.—Compared with those of 1992, imports for consumption of industrial sand dropped 73% to 44,000 tons valued at $2.4 million. Silica imports vary greatly from year to year but are always rather insignificant. Australia supplied 95% of the silica imports for 1993, averaging near $42 per ton. The Australian imports were the relatively low priced silica while higher priced silica came from Belgium, Canada, France, Italy, Japan, Sweden, the United Kingdom, and Venezuela. *(See tables 7 and 8.)*

World Review

World production of industrial sand and gravel, based on information usually provided by foreign Governments, was estimated to be 108 million tons, virtually unchanged from that of 1992. The United States was the leading producer, followed by, in descending order, the Netherlands, Germany, France, and Austria. Most countries in the world had some production and consumption of industrial sand and gravel because of its basic uses in glass and foundries. However, because of variation in descriptions and usage for silica sand and gravel, it was difficult to get reliable information. Beyond those countries listed, many other countries were believed to have had some type of silica production and consumption. *(See table 9.)*

Current Research and Technology

Reports on advances in glasses, ceramics, fillers, and chemicals that would consume or affect the industrial sand and gravel industry were scattered throughout various journals, magazines, and periodicals. Some have been mentioned earlier in this report and others are briefly highlighted on the following pages.

J.M. Huber Corp. has made what it calls a breakthrough in synthetic precipitated silica technology. The company says that materials using this technology offer advantages in lower rolling resistance and enhanced fuel mileage. The silica would be used in place of carbon black in tires. Huber is calling tires made using such silicas "green" tires to denote their environmentally friendly nature.[25]

Panhandle Eastern Corp. has become the first U.S. natural gas pipeline company to install a fiberglass reinforcement on an in-service gas pipeline. The 12-inch-wide reinforcement wraps consist of glass fibers impregnated with a polymer-based resin that, when treated with a special adhesive and wrapped around the weakened area of a steel pipe, restore the pipe's integrity.[26]

In 1988 and 1990, this report discussed the use of glass to encapsulate radioactive or hazardous waste. The process was still being investigated in 1993 but the outlook was dampened, to some degree, by results from research at Argonne National Laboratory. Its research showed that slow dripping water can change the largely nonreactive borosilicate glass into a form that facilitates the flaking of microscopic mineralized shards. More important, the Department of Energy-funded study shows some of the waterborne flecks bear unexpectedly enriched concentrations of certain interred radionuclides.[27]

Hoechst AG, Frankfurt, Germany, was planning a new plant to produce the novel detergent builder SKS-6 (layered silicic acid). This plant replaces a detergent phosphate plant that was closed on the site in 1992. SKS-6 works as an ion exchanger and reportedly better than zeolites that are currently used. The new product is produced in a two-stage drying process where sodium silicate raw material is transformed first to an amorphous and then to a crystalline product.[28]

Silica is not normally considered a lightweight aggregate but according to a recent article a rather simple process may yield a light weight. Silica and sodium carbonate are dissolved in a digester to produce water glass. The liquid is then converted to dense sandy particles that are then processed in a carousel furnace where they expand 25 times. The product, *Cylafoam*, has been tested by Oak Ridge National Laboratories and yields good thermal properties.[29]

Blasch Precision Ceramics Inc., Schnectady, NY, has developed a new commercial process for producing high-precision fused silica parts. The process can be used to manufacture large or small fused silica parts of complex shape, with fine edges and typical tolerances of ±0.001 inch per linear inch without machining.[30]

OUTLOOK

Demand

The forecast range of total U.S. demand in the year 2000 was expected to be 25 to 30 million tons for industrial sand and gravel. Probable demand was expected to be about 28 million tons. All forecasts were based on previous performances for this commodity within various end uses and contingency factors considered relevant to the future of the commodity.

Glass Sand

Since 1987, annual demand for glass sand has fluctuated between 10 and 11.1

million tons. The amount of sand consumed for container glass has generally decreased since 1987 mainly because some glass containers were being replaced by aluminum cans and plastic containers and also because the amount of glass being recycled was increasing. Additionally, many manufacturers of container glass were using thinner walls in glass containers, and this process had cut down on the amount of sand used. However, glass fibers and novel uses for glass may offer new avenues for silica sales for glass.

Forecasts for specialty glasses, particularly fiber optics, were proffered by various groups in 1993. A study by Business Communications Co., Inc., concluded that silica is the most important advanced glass, with a wide spectrum of applications, such as optical fibers, optical devices and lenses, dielectric layers, and antireflective and radiation-resistant coatings. It was projected that overall precursor-derived advanced glasses will account for sales of almost $1.9 billion by the year 2000 as a result of 20% growth annually.[31]

KMI Corp., Newport, RI, forecasted very positive growth for fiber-optic components, including cable, for countries, regions, and worldwide. It predicted world growth at 20% per year through the year 2000. For Mexico and South America, growth was predicted at a whopping 30% per year for the next 6 years, the highest growth rate in the world.[32]

In a different glass market, Certain-Teed Corp., Valley Forge, PA, predicted strong recovery for the fiberglass-reinforced plastics industry because shipments in 1993 were expected to exceed 375,000 tons of fiberglass reinforcements for the first time.[33]

Overall, although demand for specialty glasses is expected to increase, the large tonnage consumers—the container and flat glass segments—will probably experience little total growth. Therefore, demand for glass sand was expected to grow very slowly in quantity until the year 2000. Probable demand for glass sand for the year 2000 was forecast to be 11.5 million tons with a range of 9 to 12.5 million tons.

Foundry Sand

The use of foundry sand was seen to be dependent mainly on automobile production. Another important factor for the future consumption of virgin foundry sand was the recycling of used foundry sand. The level of recycling, though not clear, was thought to be increasing. Other materials or minerals compete with silica as foundry sand but these other "sands" usually suffer a price disadvantage.

Based on foundry activity, competing materials, and recycling, the probable forecast for silica foundry sand consumption in the year 2000 was expected to be 6 million tons and the demand range was expected to be 5 to 7 million tons.

Hydraulic Fracturing Sand

Frac sand was sold in greater volumes in 1993 compared to those of 1992. The Baker-Hughes' cumulative rig count comparing year to year data revealed 1993 consistently ahead of 1992 as the year ended 13.5% ahead of yearend 1992. U.S. production of oil will likely suffer as imports have continued to control a higher percentage of supply but natural gas production has seen steady increases. Based on these factors, demand was expected to grow for this end use during the decade, partially due to strong exports and a growing demand for natural gas. Probable demand for hydraulic fracturing sand for the year 2000 was expected to be 1.9 million tons, with a range of 1.6 to 2.2 million tons.

Other Silica Markets

Because of the many uses of silica it is difficult to forecast silica demand with great precision. Some factors affecting future demand have been discussed but a few additional factors are worth mentioning. Texas and New Mexico are becoming the focal points of a miniboom in the construction of microchip processing plants. Texas Instruments Inc., Motorola Inc., and Advanced Micro Devices, Inc., all have new plants planned for the region. Strong growth in the semiconductor market, approaching 20% worldwide, has spurred the construction of these facilities.[34]

Consumption of sodium silicates for use in detergents and water treatment will grow at a rate of 2.5% annually through 1997, according to Freedonia Group Inc., Cleveland, OH. Developments affecting these uses were discussed earlier in this report. Industrial sand will be the major silica source for the silica, boding well for U.S. producers.[35]

As mentioned in the consumption and uses section, specialty silicas should see good growth this decade. More particularly, TCP Business Research Group, Basel, Switzerland, predicted the U.S. silicon compounds industry will grow at a rate of 5.3% annually through 1997. High average annual growth is expected for silicone elastomers, with liquid, two-component heat-cured silicones that can be injection-molded. Other silicones to see good growth include silicon alloys used in superalloy production and silicones used in household and personal products. Silicates for paper bleaching and water treatment were predicted to grow less quickly.[36]

Adequacy of Supply

Domestic production was expected to continue to meet more than 99% of demand through the year 2000. Imports, mostly from Australia, Canada, and Europe, were expected to remain minor.

The United States was the largest producer and consumer of silica sand among the market economy countries and was self-sufficient in this commodity. Most of it was produced in the eastern part of the United States, where the largest deposits and major markets are. A significant amount of silica sand also was produced in the West and Southwest, mostly in California and Texas.

Because the unit price of silica sand was relatively low, except for a few end uses that required a high degree of processing, the location of silica sand deposits in relation to the market was an important factor that may work for or against a sand producer. Consequently, a significant number of relatively small operations supplied local markets with a limited number of products.

The constant dollar price of domestic

silica sand had fluctuated since 1983 and was expected to continue fluctuating because of strong competition among producers for retention of dwindling markets for traditional uses.

Possible Supply-Demand Changes

Several factors could affect supply-demand relationships for silica sand. Further increases in the development of substitute materials for glass and cast metals could reduce demand for glass sand and foundry sand. These substitutes, mainly polymers and ceramics, would likely increase demand for ground silica, which is used as a filler in plastics; for glass fibers, which are used in reinforced plastics; and for silica, either chemically, whole grain, or ground, which is used to manufacture ceramics. Also, increased efforts to reduce waste and increase recycling could hinder glass sand demand. However, with advances in high-tech materials, silica sand may see increased consumption for fiber optics and other silicon and glass compounds. Although developments could cause demand for silica sand to decrease, the total value of production could increase because of the increased unit value of the more specialized sands.

An increase in the price of oil on the international market would stimulate domestic drilling and extraction from new and old oil deposits. This would increase demand for domestic hydraulic fracturing sand.

Concern over the use of silica as an abrasive due to health concerns and the imposition of stricter legislative and regulatory measures concerning silica exposure could decrease demands in many silica markets. Silica sand for use in the abrasive blast industry was being attacked as a health hazard as marketers of competing materials, including garnet, slags, and olivine, pushed the use of their "safer" abrasive medium.

Development of more efficient mining and processing methods are expected to continue. This will enhance development of lower grade silica sand deposits closer to markets but not presently mined. Such developments are expected to increase silica sand reserves.

[e] Estimated. [r] Revised.

[1] Table includes data available through July 19, 1994.

[2] In addition to the countries listed, Angola, Antigua and Barbuda, The Bahamas, and China, among others, produce industrial sand, but current available information is not adequate to formulate estimates of production levels.

[3] Reported figure.

[4] Fiscal years beginning July 1 of that stated.

[5] Formerly part of the U.S.S.R., which was dissolved in Dec. 1991. Information was inadequate to formulate reliable estimates of production prior to 1992.

[6] Fiscal years beginning Mar. 21 of that stated.

[7] Less than 1/2 unit.

[8] Washed product.

[9] Dissolved in Apr. 1992.

[10] Includes rough and ground quartz as well as silica sand.

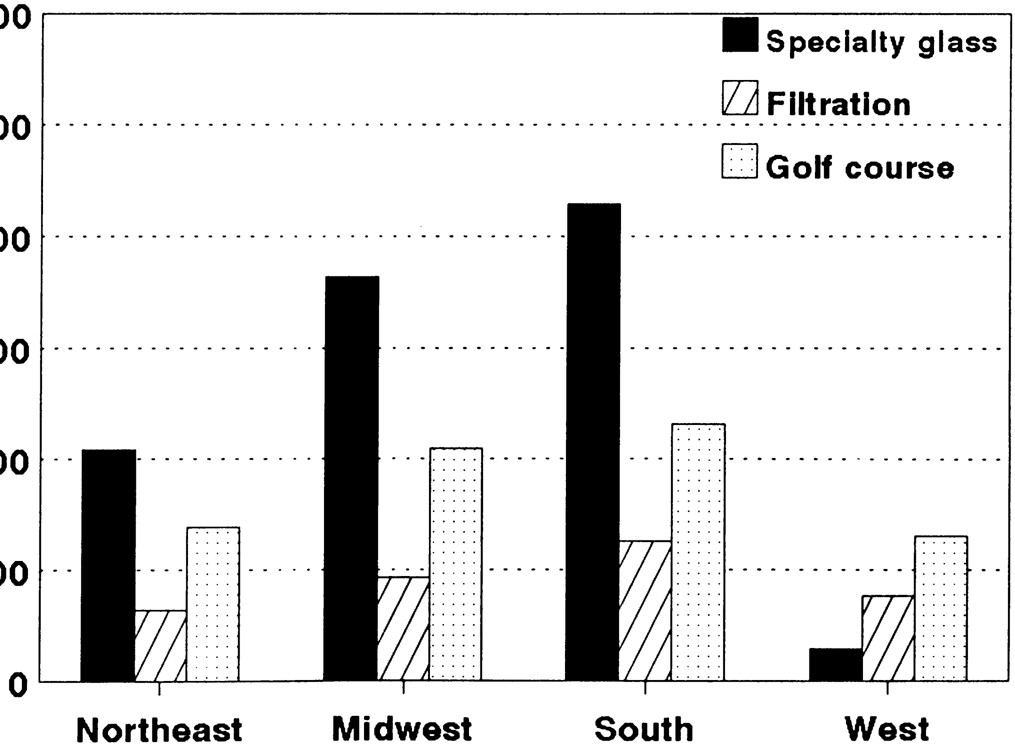
(Thousand metric tons)



SILICON

By Larry D. Cunningham

Mr. Cunningham, a physical scientist with 14 years of U.S. Bureau of Mines experience, has served as the commodity specialist for silicon since 1992. Domestic survey data and trade data were prepared by Mr. Kevin Bacon, statistical assistant.

Silicon (Si) is a light chemical element with metallic and nonmetallic characteristics. In nature, silicon combines with oxygen and other elements to form silicates. Silicon in the form of silicates constitutes more than 25% of the Earth's crust. Silica is a silicate consisting entirely of silicon and oxygen. Silica (SiO_2) as quartz or quartzite is used to produce silicon-base products for the aluminum, chemical, iron, and steel industries.

The average annual dealer import price for silicon metal and ferrosilicon declined from that of the previous year. Based on contained silicon, overall domestic production remained at about 370,000 metric tons and consumption of silicon increased to about 560,000 tons.

Overall U.S. trade volume of silicon exports was down by 20%, while overall trade volume of silicon imports decreased by 3%. The U.S. International Trade Commission (ITC) and the U.S. Department of Commerce (DOC) concluded their antidumping and countervailing duty investigations on ferrosilicon imports from a number of importing countries.

DOMESTIC DATA COVERAGE

Domestic production data for the silicon commodity are developed by the U.S. Bureau of Mines by means of monthly and annual voluntary surveys. The "Silicon Alloys" survey canvasses the operations listed in table 2. The figures in table 1 represent 100% of the production and shipments from these operations. *(See tables 1 and 2.)*

BACKGROUND

Definitions, Grades, and Specifications

Silicon metal and ferrosilicon are referred to by the approximate percentage of silicon contained in the material and by the maximum amount of trace impurities present. There are two standard grades of ferrosilicon, with one grade approximately 50% silicon and the other 75% silicon by weight. In addition to the standard grades of ferrosilicon, there are miscellaneous silicon alloys that contain silicon and other elements. The most common of these alloys are magnesium ferrosilicon and calcium silicon. However, other elemental additions include barium, boron, manganese, strontium, and titanium.

Metallurgical-grade and polycrystalline silicon metal are referred to by their minimum silicon content and maximum impurity level. Typical impurities cited for metallurgical silicon metal are aluminum, calcium, and iron. Typical polysilicon impurities include boron, carbon, and phosphorus and are commonly measured at the parts per million and parts per billion levels.

The American Society for Testing and Materials (ASTM) publishes standards for ferrosilicon and silicon metal. ASTM Specification A100 covers seven regular grades of ferrosilicon for steelmaking and foundry uses designated A, B, C, D, E, F, and G and subgrades designated as low-aluminum, boron-bearing, and calcium-bearing. ASTM recommends that the producer furnish with each shipment an analysis showing the silicon content and, on request, also include aluminum, boron, calcium, carbon, manganese, phosphorus, and sulfur contents. ASTM Specifications A518 and A861 cover high-silicon cast iron castings and high-silicon iron pipe and pipe fittings for corrosion-resistant uses.

Products for Trade and Industry

Several grades of ferrosilicon are produced and sold in the United States. Most of the ferrosilicon consumed domestically in 1993 was either 50%- or 75%-grade material, the majority 50%-grade material. The domestic silicon industry in 1993 continued to supply about 60% of all ferrosilicon products. Of the miscellaneous silicon alloys consumed in the United States, magnesium ferrosilicon is the most significant. Almost all ferrosilicon products are consumed by the iron and steel industry.

Metallurgical-grade silicon metal is used by the primary aluminum, secondary aluminum, and chemical industries. The products sold to these industries vary considerably in their specifications. The chemical and primary aluminum industries generally require more stringent specifications than those of the secondary aluminum industry. In addition, the chemical industry requires that the metal be ground into a fine powder rather than the lump form used by the aluminum industry.

The first crystalline silicon was made in 1854. Comprehensive investigations of the effects of silicon in steel stimulated a great demand for silicon in the steel industry in the 1880's, and with the development of the electric furnace in the late 1800's came expanded production of ferrosilicon. By 1949, the first silicon pure enough for use in transistors and other semiconductor devices was produced. Beginning in 1951, commercial production of high-purity silicon gave impetus to the rapidly expanding electronics industry.

Polycrystalline silicon (ultrapure, 99.9%) was a product largely confined to research until 1956, when its use in manufacturing components for commercial applications was estimated to have exceeded that used for research. By 1958, an estimated 20,412 kilograms of high-purity silicon valued at $16 million was consumed by the electronics industry for the manufacture of diodes, rectifiers, and transistors.

Geology-Resources

The United States has an abundance of silica deposits for the production of ferrosilicon and silicon metal. For the production of these materials, 98% to 99% purity is preferred. However, trace amounts of aluminum and iron also are acceptable. Physically, the material should not contain fines and should not crumble easily.

Technology

Silicon metal and ferrosilicon are produced by the reduction of silica (SiO_2) to silicon (Si) in a submerged arc electric furnace. A typical charge consists of silica as beneficiated quartz or quartzite; coal, coke, or charcoal as a reductant; wood chips for porosity; and, when producing ferrosilicon, iron in the form of steel scrap or iron ore. During the furnace operation, raw materials are periodically charged into the top of the furnace, and the molten metal or alloy is periodically tapped at the bottom of the furnace and cast into chills or ingots. The material is then crushed to specific size requirements starting at about 20 centimeters down to 200 mesh.

Metallurgical-grade silicon metal is the starting material for high-purity silicon consumed by the electronics industry. First, silicon metal is used to produce an intermediate product such as silicon trichlorosilane (TCS). A vapor deposition process is then used to form a rod or boule of high-purity polycrystalline silicon (polysilicon) from the TCS. A single crystal boule is made from polysilicon by two methods. The Czochralski (CZ) method uses a seed crystal to grow a rod of single crystal silicon from a molten crucible of polysilicon. The Float Zone (FZ) method uses an induction coil to produce a molten zone within a rod of polysilicon. The coil starts at one end of the boule where a seed crystal starts the crystal growth. The coil moves slowly down the boule, allowing a single crystal to be formed. After being sliced into wafers, the silicon is used by the electronics industry to produce integrated circuits.

Recovery of silicon from secondary sources is not normally practiced. The only secondary possibility is recovery from scrap metal. However, any value of contained silicon would be incidental to the value of the primary metal. In 1993, the average price for ferrosilicon was about $0.41 per pound and the average price for silicon metal was about $0.66 per pound. For the future, recycling of silicon in the form of ferrosilicon and silicon metal is expected to be insignificant.

Byproducts and Coproducts

Silicon metal and ferrosilicon furnaces produce a material that is referred to as silica fume, silica dust, or microsilica. Originally, this material was considered of little or no value. However, microsilica is now used as an additive in a number of different products, including high-strength concrete.

Economic Factors

Production of silicon metal and silicon alloys is extremely power intensive, requiring a power input, for some operations, of up to 14,000 kilowatt-hours per ton of silicon content.

The location of ferrosilicon and silicon metal smelters is normally determined by balancing marketing costs against processing costs. Consequently, on a worldwide basis, smelting plants are near iron and steel industries or trade routes serving them, where cheap fossil fuel or electric energy is available or where a combination of these factors exists. The availability of hydroelectric power in large quantities at competitive prices, the lack of a sizable steel industry, and the presence of deep natural and ice-free harbors contributed to Norway becoming the largest exporter of ferrosilicon in the world. The high cost of electric power, proximity to world trade routes, and the demands of an established iron and steel industry have made Germany, Japan, and the United Kingdom three of the world's largest importers of silicon metal and ferrosilicon. During the 1980's, Brazil established itself as a major producer of silicon ferroalloys and silicon metal, joining countries such as Canada, Iceland, and Norway that have low power costs. In contrast, high power costs have forced Japanese ferroalloy producers to cease production of silicon metal and drastically curtail silicon ferroalloy production.

By 1960, consumption of high-purity silicon by the electronics industry was more than 31,751 kilograms. However, the market was becoming saturated with material resulting from increased output by new plants and the expanded production from older ones. Prices were in the range of $150 to $330 per pound compared with an average price of $330 per pound for metal consumed in 1958. By the mid-1960's, improvements in silicon devices and the increased use of integrated circuits in the computer and aerospace industries had contributed to an accelerated consumption of high-purity silicon.

Demand for metallurgical-grade silicon alloys and metal is determined by the level of activity in the steel, ferrous foundry, aluminum, and chemical industries and is little affected in the short term by prices for these materials. As a result, prices tend to vary widely with changes in demand and supply.

From the period 1955-69, the price of silicon alloys and metallurgical-grade metal remained stable. During this 15-year period, the domestic producer price fluctuated between \$0.12 and \$0.145 per pound for the 50%-grade ferrosilicon and between \$0.181 and \$0.219 per pound for metal.

Prices began to rise in the early 1970's owing to higher costs of scrap iron, metallurgical-grade coal, electric power, and the cost of newly installed pollution control devices to comply with local and Federal Government standards, which became effective in 1975. Responding to increased demand, rising inflation, and higher energy costs, prices rose steadily from 1977 to 1981.

By the end of 1988, domestic producers reportedly were operating at close to capacity. However, the record-high prices of 1988 had declined significantly by yearend 1992. The steady decline in prices was mainly caused by the oversupply of material resulting from the reactivation of idle capacity; the development of new capacity in South America; and the escalation of low-cost imports from China, South America, and countries of the former U.S.S.R. Consequently, production cutbacks were scheduled by several domestic producers as global production outpaced demand, resulting in a continued soft world market. Prices rebounded in 1993 with the price for ferrosilicon at the highest level since 1990 and the price for silicon metal at the highest level since 1988.

Principal elements in the cost of silicon and ferrosilicon production are (1) delivered costs of the ore; (2) energy cost; (3) cost of reductant coke or low ash coal; (4) cost of iron in the form of steel scrap, if required; and (5) labor. The cost of all these elements, and particularly the cost of energy, has increased rapidly since 1970. In addition, new capital costs for pollution control equipment were added.

ANNUAL REVIEW

Legislation and Government Programs

In April, the U.S. Department of Energy's (DOE's) Sandia National Laboratories, NM, reportedly signed a 5-year \$100 million agreement with Sematech, a consortium of semiconductor manufacturers. Each party will provide about one-half of the funding under the agreement. The goal of Sematech is to increase the U.S. competitiveness in the production of computer chips. Sandia will assist Sematech in programs such as equipment modeling and design, materials and process analysis, and contamination-free manufacturing research. Over the previous 5 years, the U.S. Department of Defense reportedly provided about \$100 million per year to Sematech's research.[1]

During the year, the DOC and the ITC concluded their antidumping and countervailing duty investigations on ferrosilicon imports from Argentina, China, Egypt, Kazakhstan, Russia, Ukraine, and Venezuela. The agencies determined that ferrosilicon imports from these countries, with the exception of Argentina and Egypt, were sold at less-than-fair value and caused material harm to the domestic industry. The DOC assessed the dumping duty for China at 137.73%; Kazakhstan, Russia, and Ukraine at 104.18%; and Venezuela at 9.55%. Also, Venezuela was assessed a countervailing duty of 22.08%. Antidumping investigations in the case of ferrosilicon imports from Brazil were continuing.

The DOC and ITC investigations were instituted in response to petitions filed by AIMCOR, Alabama Silicon Inc., American Alloys, Globe Metallurgical Inc., Silicon Metaltech Inc. (American Silicon Technologies), and union locals of the United Autoworkers of America, the United Steelworkers of America, and the Oil, Chemical & Atomic Workers.

In February, the DOC announced Final Scope Rulings—Antidumping Duty Orders on Silicon Metal from Argentina, Brazil, and China. In 1991, the DOC and the ITC had determined that imports of silicon metal, containing between 96% and 99.99% silicon by weight, from these countries were sold at less-than-fair value in the United States and caused material harm to the domestic industry. The DOC assessed the dumping duty for China at 139.49% and Argentina at 8.65%. The duty for Brazil was assessed against individual producers over a range of 87.79% to 93.2%. In March 1992, petitioners in the original investigation requested that DOC determine that material containing a lower silicon content, between 89% and 96% silicon by weight, because of a higher aluminum content, is covered by the antidumping duty order in effect for silicon metal imports from China. After its formal inquiry, the DOC concluded that silicon metal with a high aluminum content containing between 89% to 96% silicon by weight is within the scope of the class or kind of material subject to the antidumping duty orders on silicon metal from Argentina, Brazil, and China.

In August, the DOC also announced the results of its preliminary administrative review of the antidumping duty order on silicon metal from Brazil. DOC's review of Brazil covered four manufacturers/exporters during the period March 29, 1991, through June 30, 1992, and indicated the existence of dumping margins. DOC preliminarily determined that a margin of 88.24% exists for Eletrosilex Belo Horizonte.

In mid-December, the DOC announced final results of its administrative review of the antidumping duty order on silicon metal from Argentina. DOC's review of Argentina covered two manufacturers/exporters during the period March 29, 1991, through July 31, 1992. DOC determined that a margin of 2.06% exists for Electrometalurgica S.A.I.C. (Andina) and a margin of 54.67% exists for Silarsa S.A. A margin of 8.65% exists for "all others," the rate established in the final notice of the initial duty order.

DOC's administrative review of the antidumping duty order on silicon metal from China was terminated in late December, with no changes being made to the initial duty order.

In August, the U.S. Trade Representative announced that the Generalized System of Preferences (GSP), which had expired on July 4, 1993, was extended to September 30, 1994. The GSP extension was part of the Budget Reconciliation Act signed by the President. The legislation extending the GSP was retroactive to July 4. Additionally, the legislation removed the statutory prohibition against providing GSP benefits to the countries that made up the former U.S.S.R. Under GSP, the United States grants duty-free access to goods from more than 140 developing countries and territories. U.S. import duties for silicon products range from duty free to 9% ad valorem for most-favored-nation (MFN) status and from $0.044 per kilogram of contained silicon to 45% ad valorem for non-MFN status.

In Proclamation 6599 of September 30, 1993, the U.S. President designated Russia as a beneficiary developing country for purposes of the GSP. GSP status for Russia is part of the administration's overall efforts to help that country pursue badly needed market reforms. Kazakhstan, Romania, and Ukraine also were being considered for GSP status.

Production

Overall gross production of silicon products in the United States decreased 2% compared with that of 1992. Production of silicon metal was relatively unchanged, while production of ferrosilicon and miscellaneous alloys was down by about 4%. Overall shipments of silicon-containing products decreased by 3%. Producer stocks of silicon-containing materials were down by 13% overall. Ferrous scrap used in the production of these products was estimated to be about 150,000 tons.

Alabama Silicon Inc. reportedly reopened its ferrosilicon plant in Bessemer, AL, in October. The plant, closed since early January 1992, had an annual capacity of about 18,000 tons. Alabama Silicon is receiving financial backing from AIOC Corp., New York, NY, a metals trading company. AIOC will have exclusive marketing rights to Alabama Silicon's ferrosilicon production.[2]

Simetco Inc., Canton, OH, reportedly filed a voluntary petition in September for chapter 11 bankruptcy protection for reorganization purposes. Simetco's silicon metal facility in Montgomery, AL, has a reported annual capacity of about 40,000 tons.[3]

Globe Metallurgical Inc., headquartered in Cleveland, OH, announced the purchase of a 12,000-ton-per-year silicon metal plant in Springfield, OR, from Dow Corning of Midland, MI. Globe, a major U.S. producer of silicon metal, completed the purchase of the plant in mid-1993 for an undisclosed amount. The plant will be staffed by former Dow employees who have accepted permanent positions with Globe. The plant's silicon metal production is intended to service the west coast aluminum market. The new acquisition, along with Globe's silicon metal production facilities in Beverly, OH, and Selma, AL, reportedly increases the company's annual silicon metal capacity to about 65,000 tons.[4]

Applied Industrial Materials Corp. (AIMCOR), Denver, CO, announced in late September its intention to sell the company's Metals and Minerals Group. AIMCOR is a major international supplier of industrial carbon products and a producer of ferroalloys. The Metals and Minerals Group, headquartered in Pittsburgh, PA, includes 11 plants, inclusive of AIMCOR's ferrosilicon facility in Bridgeport, AL; a laboratory facility; and 2 sales offices. The Group employs about 270 people in Canada, Mexico, and the United States. AIMCOR's decision to sell the Group is based on the company's long-term objectives of focusing on its carbon products business. The Group will be sold as one unit or as separate metals and minerals units.[5]

Union Carbide Corp., Danbury, CT, announced in July that the company had completed the sale of its OrganoSilicon Products, Systems and Services (OSi) business to DLJ Merchant Banking Partners L.P. and affiliates of the New York investment banking firm of Donaldson, Lufkin & Jenrette Inc. The $300 million selling price consists of $220 million in cash plus $80 million of preferred stock, convertible into 30% of the voting common stock in the new company. Union Carbide indicated that the transaction essentially concludes the company's asset sales program announced in December 1991, which was intended to reduce debt, improve debt to capitalization, and improve interest coverage.[6] Union Carbide's OSi worldwide sales in 1992 were reported to be about $350 million.[7] The OSi business manufactures fluids and chemicals used in fiberglass, reinforced plastics, textiles, coatings, automotive, adhesives, pharmaceutical, agricultural, electrical, personal care, thermoplastics, sealants, and other specialty markets. The new silicones company will be known as OSi Specialties Inc. and reportedly will retain the current work force of more than 1,100 employees worldwide.[8]

It was reported in late December that OSi Specialties had completed a $15 million project to upgrade and expand its organofunctional silanes production at the company's plant in Sisterville, WV. The 15% increase in capacity was said to be part of OSi's ongoing expansion program to meet growing market needs. Further expansions were planned at Sisterville and at a plant in Termoli, Italy.[9]

Consumption and Uses

The aluminum industry used silicon metal in the production of wrought and cast products, while ferrosilicon was used primarily as a deoxidizing and alloying agent in the production of iron and steel products. Metallurgical-grade silicon metal also was used as the basic raw material in the manufacturing of many chemical products and intermediates such as silicones and silanes. Overall reported consumption of silicon alloys and metal for most major end uses was up in 1993. *(See table 3.)*

U.S. apparent consumption of silicon metal and silicon-containing ferroalloys was estimated to be about 560,000 tons of contained silicon. Consumption of silicon metal was estimated at 225,000 tons, while consumption of ferrosilicon and miscellaneous silicon alloys was estimated to be about 335,000 tons. Compared with that of 1992, consumption of silicon metal increased by 15%, while consumption of ferrosilicon and other alloys was down slightly. Ferrosilicon and miscellaneous silicon alloys continued to account for about 60% of all the silicon materials consumed, based on silicon content.

Markets and Prices

Table 4 shows the average annual import price for 50%- and 75%-grade ferrosilicon as well as silicon metal. Prices are posted in cents per pound of contained silicon. Overall ferrosilicon prices were on the increase compared with those of the previous year, with the 50%- and 75%-grade material following similar price change patterns. The import price for 50%-grade ferrosilicon increased progressively from a range of $0.37 to $0.375 per pound to a range of $0.44 to $0.45 by yearend. The import price for 75%-grade ferrosilicon rose from a range of $0.355 to $0.363 per pound to $0.435 to $0.45 in mid-September, where it remained through December.

The import price for silicon metal started the year at $0.663 to $0.668 per pound, rose to $0.67 to $0.685 by midyear, then fell in the fourth quarter to finish the year at $0.59 to $0.62. *(See table 4.)*

Foreign Trade

U.S. exports of ferrosilicon decreased about 30% compared with those of 1992, based on gross weight, while total value of the exports was down by about 20%. About 70% of the exported material continued to be shipped to Canada and Mexico. Silicon metal exports increased by 25% based on gross weight, with total value of the exports up by more than 40%. Canada, Japan, and Mexico were major recipients of the materials.

U.S. imports of silicon-containing alloys were down by 19% compared with those in 1992. Imports of ferrosilicon categorized as "55% to 80% silicon, other" decreased by 6% based on gross weight, with the total value for this category down by 18%. Brazil and Norway were the leading suppliers for this category. Overall volume and value of ferrosilicon categorized as "Other," which included all ferrosilicon of less than 55% silicon content, decreased substantially. There were no imports from countries of the former U.S.S.R. in this category compared with more than 80% of the total in 1992. Brazil and Norway accounted for 28% and 33%, respectively, of total imports. The schedule of tariffs that applied during 1993 to U.S. imports of selected silicon materials is given in table 5.

Overall imports of silicon metal products increased substantially. Imports of silicon metal categorized as "99.00 to 99.99% silicon" rose significantly. Canada continued as the leading supplier, providing about 50% of both total volume and value. Imports of "Other" silicon metal increased substantially, with Russia supplying about 70% of both volume and value for this category.

The U.S. net import reliances for ferrosilicon and silicon metal products were estimated to be 38% and 28%, respectively, compared with 38% and 17% the previous year. The overall import reliance for silicon products was estimated to be 34%. *(See tables 5, 6, and 7.)*

World Review

Brazil.—In September, Italmagnesio S. A. of Brazil entered into a receivership period of 2 years, similar to U.S. chapter 11 bankruptcy protection, for the purpose of restructuring the company's debt. Annual production capacity at Italmagnesio's silicon alloys and metal facilities in the Minas Gerais and Sao Paulo states was reported to be about 60,000 tons. Production and sales were said to be continuing as normal at Italmagnesia's subsidiaries.[10]

Brazil's Commerce Secretariat reportedly proposed that a 5% import tax be imposed on aluminum, cast iron, cobalt, ferroalloys, lead, tin, and zinc. Domestic producers had claimed that they needed tariff protection owing to low world prices, high imports from the former U.S.S.R., and exchange rate difficulties. Consumers were in opposition to the tax, citing a potential increase in processor/consumer production costs.[11]

Anuário da Indústria Brasileira de Ferroligas (ABRAFE), the Brazilian ferroalloy producers' association, reported 1992 production as follows: 45%-grade ferrosilicon, 4,620 tons; 75%-grade ferrosilicon, 239,218 tons; calcium-silicon, 22,756 tons; and silicon metal, 93,734 tons. ABRAFE reported 1992 domestic sales as follows: 45% (50%)-grade ferrosilicon, 3,711 tons; 75%-grade ferrosilicon, 53,771 tons; calcium-silicon, 3,118 tons; and silicon metal, 9,896 tons. Exports in 1992 were reported as follows: 45% (50%)-grade ferrosilicon, 13,324 tons; 75%-grade ferrosilicon, 178,116 tons; calcium-silicon, 20,660 tons; and silicon metal, 67,916 tons.

China.—According to The TEX Report, Chinese exports of ferrosilicon were at an alltime high: 340,000 tons valued at $156.6 million, compared with 280,000 tons valued at $130.72 million in 1992.

European Union (EU).—In September, the European Commission announced that it had imposed provisional antidumping duties on ferrosilicon imports from China and the Republic of South Africa. The Commission assessed the dumping duty for China at 49.7% and South Africa at 47.4%. However, South African producer Rand Carbide was assessed a duty of 34.7%. The provisional duties became effective September 23, 1993, for a 4-month period. The Commission determined that imports from both countries injured producers in the EU. EU producers reportedly had claimed that substantial dumping of material was eroding EU market prices.[12]

The EU became effective November 1, 1993, and is the "umbrella" term encompassing the European Community, the Common Foreign and Security Policy, and the Justice and Home Affairs.[13]

In December, the European Commission also imposed antidumping duties on ferrosilicon imports from a number of other importing countries and companies. The duties resulted from investigations that reportedly began in

May 1992. The Commission assessed the dumping duty for Kazakhstan, Russia, and Ukraine at 74% each; Iceland and Norway at 6.8% each; Sweden at 7.4%; and Venezuela at 20.4%. The general duty for Brazil was assessed at 20.5% (with the exception of a 9.2% duty for Companhia Brasileira Carbureto de Calcio, a 22.8% duty for Companhia de Ferro Ligas da Bahia, and a 20.5% duty for Rima Eletrometalurgia S.A., Companhia Paulista de Ferro Ligas, and Minasligas-Companhia Ferroligas Minas Gerais, respectively). The duties became effective December 10, 1993.[14]

France.—Rhone-Poulenc of France reportedly signed an agreement with Germany's Possehl to acquire Possehl's silicon subsidiary for an undisclosed amount. Possehl specializes in room-temperature vulcanizing silicone elastomers.[15] Rhone-Poulenc's purchase of Possehl will strengthen the company's presence in Germany, which is the third largest silicones market worldwide.[16] Additionally, Rhone-Poulenc planned to invest $47 million at its Roussillon site to construct a hydrochloric acid recycling plant. The company uses the acid to produce methyl chloride, a raw material used for its silicones production business. The use of recycled hydrochloric acid reportedly will reduce the company's salt wastes and also result in a 30% reduction in water consumption. The recycling plant was expected to begin operation by the end of 1995.[17]

India.—Indsil Electrosmelt Ltd. made plans for the construction of a new ferrosilicon plant in the Palghat district of Kerala State. Annual production capacity was planned to be about 7,800 tons. Startup of the $3.87 million plant was scheduled for November.[18] Indsil also planned to build two new powerplants in Kerala to provide electricity for its ferrosilicon facility. Additionally, Silcal Metallurgie reportedly was investing in a new plant, also in the Palghat district, to produce ferrosilicon and silicon metal. The plant was scheduled for completion in March 1995 and was to have an annual capacity of about 16,500 tons of product. Travancore Electro-Chemical Industries Ltd. reportedly was seeking loans from the Industrial Bank of India and the World Bank to build two new powerplants in Kerala to support its ferrosilicon operation. Travancore's annual production of ferrosilicon was reported to be about 7,000 tons. Monnet Ferroalloys, a ferrochrome producer, made plans to install furnaces at its facility in Raipur for the production of ferrosilicon and high-carbon ferromanganse.[19] Also, Indian ferroalloy producers reportedly were asking the Government to impose antidumpimg duties on ferrosilicon imports from Bhutan, China, and South Africa. The duties would be similar to those imposed in September by the European Commission on ferrosilicon imports from China and South Africa. The Government was said to be resisting the imposition of such duties.[20]

Japan.—According to The TEX Report, Japan's production of ferrosilicon was about 32,800 tons, compared with about 41,600 tons in 1992. Imports of ferrosilicon into Japan totaled about 516,700 tons, compared with about 416,000 tons the previous year. China continued as the leading supplier, accounting for about 254,000 tons of the imports. Imports of silicon metal into Japan increased to about 151,800 tons. Silicon metal imports from China and Brazil totaled about 76,600 tons and 44,900 tons, respectively. Consumption of silicon metal by the Japanese aluminum alloy sector decreased to about 51,000 tons, owing in part to reduced automobile production.

South Africa, Republic of.—The TEX Report reported that Silicon Technology Pty. Ltd. (Silitech), a subsidiary of Chromecorp Technology Pty. Ltd., inaugurated its ferrosilicon plant at Ballengeich, Natal, South Africa in July. A 40-megavolt-ampere (M•VA) electric furnace reportedly was started in May, and a 56-M•VA furnace started in July. Annual combined ferrosilicon production capacity at the plant was planned to be about 55,000 tons.

Venezuela.—CVG Fesilven CA reportedly commissioned a new ferrosilicon furnace in May. The company now operates three ferrosilicon furnaces with a combined annual production capacity of about 80,000 tons.[21] Additionally, state-owned Fesilven announced plans to seek financial investment, domestic and foreign, in the company. Fesilven reportedly is 88% owned by the Venezuelan Government and 12% by private domestic and foreign banks.[22]

OUTLOOK

Demand for silicon metal is driven by consumption in the aluminum and chemical industries. For 1994, industry sources indicate that Western World silicon metal demand will increase by 4%. In the aluminum industry, silicon metal demand is expected to increase by about 3%, with the automotive sector contributing to this growth. Within the chemical industry, silicon metal is used to produce a wide variety of silicone-base products and intermediates. For 1994, industry sources indicate that Western World silicon metal demand in the chemical industry will increase by about 6%. Additionally, Chemical Week reported that the domestic silicon compounds industry will grow by more than 5% per year through 1997. Silicon growth in this sector is attributed to silicone elastomers (particularly injection-moldable silicone rubbers), silicon alloys used in superalloy production, and silicones used in household and personal care products, all of which are expected to increase about 7% per year during this period.[23]

Ferrosilicon is consumed primarily by the iron and steel industry. The industry uses ferrosilicon for deoxidation of molten metal and as an alloying agent. The outlook for steel is discussed in the Iron and Steel Annual Report. For 1994, no significant increase in Western World steel production is expected. Domestic steel production in 1994 is expected to experience little change over that of 1993. Domestic consumption of ferrosilicon is not expected to exceed the 390,000 tons consumed in 1990. Additionally, the past pattern of domestic ferrosilicon supply is expected to be altered in the future. In 1993, the DOC imposed antidumping and countervailing duties on a number of major importing nations alleging injury to the domestic ferrosilicon industry.

SILVER

By Robert G. Reese

Mr. Reese, a physical scientist with the Branch of Metals, has been the commodity specialist for silver for 12 years. Domestic survey data were prepared by Lisa Conley and Kevin Bacon, statistical assistants; and international data tables were prepared by Virginia Woodson, international data coordinator.

Domestic silver mine production declined for the third consecutive year, owing primarily to a decline in byproduct silver production attributed to lower nonferrous metals prices. Silver was produced by 115 mines in 20 States. Nevada, Arizona, and Idaho were the largest silver-producing states, accounting for about two-thirds of the production. The largest 15 mines each produced more than 30 tons of silver and accounted for nearly 87% of the total domestic production. The value of domestic production was $227 million.

Commercial-grade silver is material that is at least 99.9% pure silver. In the United States, about 20 companies produced commercial-grade silver from either primary or recycled material. Although most of these companies were headquartered in the northeast, many had collection sites or plants in locations throughout the country. Aiding the recycling of silver were many other companies throughout the country that collected the material and produced a semirefined product that could be converted to commercial-grade silver.

Many companies and probably thousands of artisans scattered throughout the country consumed silver in 1993; 30 of the largest companies accounted for more than 90% of the silver consumed in arts and industry. About 50% of the commercial-grade silver consumed in the United States was used in the manufacture of photographic products; 20% in electrical and electronic products; 10% in electroplated ware, sterlingware, and jewelry; and 20% in other uses.

DOMESTIC DATA COVERAGE

Domestic mine production data for silver were developed by the U.S. Bureau of Mines from four separate, voluntary surveys of U.S. operations. Typical of these surveys was the lode mine production survey of copper, gold, lead, silver, and zinc. Of the 115 silver-producing lode mines to which a survey form was sent, 112 responded, accounting for an estimated 92% of the total U.S. mine production shown in tables 1, 2, 4, and 5.

ANNUAL REVIEW

Legislation and Government Programs

Near the end of May, coins commemorating the 50th anniversary of U.S. involvement in World War II were available for sale through the U.S. Mint. Enacted on October 14, 1992, Public Law 102-414, the World War II 50th Anniversary Commemorative Coins Act, authorized the production of not more than 1 million $1 silver coins, 300,000 $5 gold coins, and 2 million half-dollar copper-nickel clad coins. The three coins were legal tender and included inscriptions of the coin's face value, the years "1991-1995," and the words "Liberty," "In God We Trust," and "E Pluribus Unum." The silver coin consisted of a 90% silver-10% copper alloy, weighed 26.73 grams, and had a diameter of 3.8 centimeters. As specified by Public Law 102-414, the silver coin was emblematic of the Battle of Normandy. The obverse depicts an American soldier advancing on the beach at Normandy, while the reverse depicts the sleeve insignia of Supreme Headquarters Allied Expeditionary Force and a quote from General Eisenhower's D-Day message to his troops. Included in the sales price of each coin was its face value and the cost of labor, materials, dies, machinery, and various expenses, including overhead, marketing, and shipping required to design and issue the coins. Also added to the price of each coin was a surcharge of $35 per gold coin, $8 per silver coin, and $2 per clad coin. The law authorized distribution of surcharges collected from coinage sales to the Battle Of Normandy Foundation and the American Battle Monuments Commission. As authorized, the Battle Of Normandy Foundation would receive the first $3,000,000 collected to create, endow, dedicate, and promote visits to a "United States D-Day and Battle of Normandy Memorial" in Normandy, France. The American Battle Monuments Commission would receive the next $7,000,000 collected for the expenses incurred in establishing a memorial on Federal land in the District of Columbia or its environs to honor members of the U.S. Armed Forces who served in World War II and to commemorate U.S. participation in that war. If coinage sales produced more than $10,000,000 in surcharges, the Battle Of Normandy Commission would receive 30% of the excess money, while the American Battle Monuments Commission would receive the remaining 70%. Any funds not spent by the two groups would be returned to the U.S. Treasury for disbursement to a fund established by "An Act to provide standards for placement of commemorative works on certain Federal lands in the District of Columbia and its environs, and for other purposes," approved November 14, 1986.

On December 14, the President signed Public Law 103-186, the Jefferson Commemorative Coin Act of 1993, which authorized the U.S. Mint to produce not more than 600,000 legal tender silver coins to commemorate the 250th anniversary of the birth of Thomas Jefferson. The coin was to be 90% silver and 10% copper, weigh 26.73 grams, and have a diameter of 3.8 centimeters. Included on each coin was a profile of Thomas Jefferson; a frontal view of his home, Monticello; the year, 1993; and the words "Liberty," "In God We Trust," "United States of America," and "E Pluribus Unum," along with the coin's face value of $1.00.

Public Law 103-186 required the Mint to use silver from the National Defense Stockpile to manufacture the coins. Besides the cost of designing and issuing the coins, (including labor, materials, dies, use of machinery, overhead expenses, marketing, and shipping), the price of each coin was to include a $10 surcharge. Surcharges collected from the sales of the first 500,000 coins were to be paid to the Jefferson Endowment Fund to be used as a source of support for Monticello and its historic furnishings and for the Fund's educational programs. Surcharges received from the sale of the remaining 100,000 coins were to be paid to the Corporation for Jefferson's Poplar Forest, to be used for the restoration and maintenance of Poplar Forest.

Production

Silver was produced from precious-metal ores at 76 lode mines and from base metal ores at 36 lode mines. In 1993, 15 mines each produced more than 30 tons of silver; their aggregated production equaled 87% of total domestic production. Silver also was produced at nine placer operations.

In mid-November, Cyprus Minerals Co. and AMAX Inc. merged, forming one of the world's largest mining companies, Cyprus Amax Minerals Co. Before the merger, Cyprus Minerals produced silver primarily as a byproduct of its copper operations. AMAX's principal precious metals asset was its 40% holding in Amax Gold Inc. Most of the silver-producing operations of the new company were located in the United States.

At yearend, Hecla Mining Co. and Equinox Resources Ltd., a Canadian company, executed an agreement, subject to various conditions, providing for Hecla to acquire Equinox. Equinox's principal assets included the American Girl Mine and the Rosebud project. The American Girl Mine, in Imperial County, CA, produced gold and byproduct silver. The Rosebud project in northern Nevada was estimated to contain 1.8 million tons of proven and probable ore grading 69 grams of silver and 9 grams of gold per ton.

Alaska.—Commercial production at the Greens Creek Mine ceased in April, reportedly in response to depressed metals prices. Although only in operation for part of the year, the Greens Creek Mine processed about 103,000 tons of ore and recovered nearly 58 tons of silver.[1] In 1992, the mine had processed 441,200 tons of ore and recovered nearly 218 tons of silver. During 1993, Kennecott Greens Creek Mining Co., manager of the mine, continued exploration of the deposit, and recalculated proven and probable reserves using different criteria and estimating techniques than used previously. The exploration activities reportedly resulted in the discovery of a significant new mineralized zone. At yearend 1993, Greens Creek's estimated proven and probable reserves were about 5.8 million tons grading 549 grams of silver per ton, 5 grams of gold per ton, 14.4% zinc, and 4.7% lead.

During the year, throughput improved at the Red Dog Mine following modification of the mine's concentrator. The changes were made in response to previous problems encountered in processing some difficult ore types. In the third quarter, Cominco Ltd., the mine's operator, undertook several other projects, including expansion of the grinding facilities, to increase Red Dog's production rate. The operation processed more than 1,700,600 tons of ore in 1993, compared with 1,435,200 tons of ore in 1992.[2] Average silver content of the processed ore declined from 99 grams to 96 grams per ton. Several of the projects undertaken during 1993 were intended to improve the operation's dust control. Dust control reportedly is a problem in the Arctic because the low temperatures make conventional treatments ineffective. Enclosing outside conveyors and stockpiles and constructing a specialized truck loading station were among the projects completed to improve air quality.

California.—Milling of stockpiled ore at Lac Mineral Ltd.'s mined-out Colosseum Mine continued in 1993. The open pit operation recovered a small quantity of gold and byproduct silver using a carbon-in-pulp processing plant. The company began closure of the minesite in June, and expected the work to be completed in 1994.

At the Shumake Mine, leaching resulted in the production of 303 kilograms of gold and 1 ton of silver. During 1992, the mine produced 846 kilograms of gold and 4 tons of silver.[3] Mining ceased at Shumake in February 1992 following exhaustion of ore reserves. Leaching was expected to end in 1994.

Idaho.—Production at the Black Pine Mine was adversely affected during the first half of the year. A harsh winter followed by a wet spring, combined with lower than expected ore grades, resulted in lower precious metals production. To offset these initial production shortfalls, Pegasus Gold Inc. operated the mine's processing plant at a higher rate during the remainder of 1993. Near midyear, additional carbon columns were installed to increase the processing plant's capacity. Ore occurs at Black Pine in a series of small deposits. During the year, Pegasus obtained permission to expand two existing pits at the minesite. In 1993, the mine produced 2 tons of gold and 890 kilograms of silver.[4]

Kinross Gold Corp. purchased the DeLamar Mine in August from Kennecott Corp. The purchase represented the second change in ownership of the mine during 1993. Kennecott initially acquired the mine as part of its purchase of NERCO Inc., the resource subsidiary of

Pacific Corp. To dispose of the noncoal assets of Nerco, Kennecott subsequently sold the mine to Kinross. In 1993, the DeLamar Mine produced 1.3 tons of gold and nearly 53 tons of silver, essentially unchanged from the previous year when the mine produced 1.2 tons of gold and 57 tons of silver.[5]

At the Lucky Friday Mine, continued success in reducing operating costs enabled the mine to operate throughout the year despite depressed prices for most of the year. For the year, the mine produced 66 tons of silver, 30 kilograms of gold, nearly 18,000 tons of lead, 4,000 tons of zinc, and 300 tons of copper from 163,000 tons of ore.[6] In 1992, Lucky Friday produced 63 tons of silver, 30 kilograms of gold, 19,000 tons of lead, 3,800 tons of zinc, and 308 tons of copper.

The Sunshine Mine continued to operate at about one-half capacity throughout 1993. The mine's operating rate had been cut in early June 1991, owing in part to low silver prices. For the year, silver production declined slightly, owing in part to a rock burst during the fourth quarter. Reported silver production was about 71 tons, compared with 79 tons in 1992.[7] The mine was expected to continue operating at this reduced level until either the silver price increased sufficiently to justify reopening the closed portions of the mine or the exploration program found enough high-grade ore to justify increasing the operating rate.

Montana.—Gold and silver production increased at the Beal Mountain Mine for the second consecutive year. Company officials attributed the increased production primarily to the efforts of the mine's employees. In 1993, Beal Mountain recovered nearly 2 tons of gold and 267 kilograms of silver. In 1992 and 1991, the mine produced 249 kilograms and 243 kilograms of silver, respectively.[8]

Montana Resources Inc., 49.9% owned by ASARCO Incorporated, milled more than 15 million tons of copper ore from its Continental Pit. The resulting concentrate contained approximately 24 tons of byproduct silver.[9]

At its Kendall Mine, Canyon Resources Corp. mined approximately 1.6 million tons of ore and extracted about 2 tons of gold and 1 ton of silver.[10] Although all known ore at the open pit mine was expected to be depleted during 1994, leaching was expected to continue into 1996.

Production at the Montana Tunnels Mine remained essentially unchanged from the previous year despite adoption of a revised mining plan to exploit deeper reserves discovered in late 1992. To access the new deep reserves, the revised plan required the near-term mining of additional waste rock and lower grade ore. To minimize the impact of the new plan, company officials increased mill throughput. During 1993, Montana Tunnels mined 4.5 million tons of ore and recovered 2 tons of gold, nearly 44 tons of silver, 6,400 tons of lead, and 16,300 tons of zinc.[11] Precious metal production in 1992 was 2 tons of gold and 41 tons of silver.

Asarco temporarily closed the Troy Mine in April in response to continued low silver prices. During its 4 months of operation, concentrates produced at the Troy Mine contained approximately 25 tons of silver.[12]

Production at the Zortman/Landusky Mine declined for the second consecutive year, and operating costs reportedly increased. Company officials attributed the higher costs in part to increased investment in reclamation and other factors. For 1993, the Zortman/Landusky Mine recovered more than 3 tons of gold and nearly 17 tons of silver.[13]

Nevada.—With two separate purchases, Placer Dome increased its land holdings near its Bald Mountain gold mine. In January, Placer acquired the rights to 41 unpatented claims for $5 million. In August, Placer purchased all the assets of USMX Inc. in the Alligator Ridge mining district, which included two gold-silver-producing areas and associated plant and equipment. With the acquisitions, Placer has the right to explore and produce gold on nearly 39,000 hectares. The Bald Mountain Mine, a heap-leach operation, produced nearly 3 tons of gold and a small quantity of silver during the year.[14]

Although Battle Mountain Gold Co. depleted the ore reserves of the Fortitude deposit, additional deposits near its Battle Mountain Complex were either under development or evaluation by yearend. In 1993, Battle Mountain recovered approximately 2 tons of gold and 4 tons of silver compared with 6 tons and 13 tons of gold and silver, respectively, in 1992.[15] For 1993, the company processed nearly 140,000 tons of ore through its on-site carbon-in-pulp mill and leached an additional 1.6 million tons. Future gold and silver production at the Battle Mountain Complex is expected to be from the Reona and Phoenix (formerly known as the Fortitude Extension) deposits.

Leaching continued at the mined-out Buckhorn Mine through yearend, producing a small quantity of gold and byproduct silver. In 1994, company officials expected to continue leaching at Buckhorn as part of its heap decommissioning program. Workers completed reclamation of the mine's pits, waste dumps, and access roads.

Production at the Bullfrog Mine increased during the year owing, in part, to the continuation of high-grade ore shoots first encountered in 1992. Other factors contributing to the higher production were reaching full production at Bullfrog's underground operations and changes made to the mine's operating plan and mill. In 1993, the mine produced 11 tons of gold and nearly 15 tons of silver.[16]

Among the assets acquired by Kinross through its purchase of the noncoal holdings of Nerco in August was the Candelaria Mine. Although mining activity had been suspended since November 1990, gold and silver production continued through the leaching of previously mined ore. Studies undertaken by Kinross revealed the potential for profitably operating the mine. Subsequently, following rehabilitation of some plant facilities, the mine returned to production in

November.

In late 1993, Kennecott, operator of the Denton-Rawhide Mine, increased crusher capacity at the mine from 3.4 million tons to 4.4 million tons. Kennecott accomplished the expansion through the addition of a surge pile and associated materials handling equipment. For the year, Denton-Rawhide produced 3 tons of gold and 31 tons of silver.[17]

Although ongoing reclamation at the Florida Canyon Mine resulted in a reduction in the number of acres disturbed by the operation, the mine set new production records for the second consecutive year. Company officials attributed the higher production in part to improved ore grades, higher ore throughput, expanded plant capacity, and improved recoveries. For 1993, Florida Canyon produced more than 3 tons of gold and a small quantity of byproduct silver.[18]

Silver production at the McCoy/Cove Mine increased significantly for the third consecutive year. In 1993, the mine produced 387 tons of silver, compared with 246 tons in 1992 and 175 tons in 1991.[19] Company officials attributed the increased production, in part, to the replacement of small, higher cost equipment and increased mill throughput combined with higher recoveries and higher grade feed material. The McCoy/Cove Mine consisted of two deposits, about 2 kilometers apart. Production at the Cove deposit initially utilized both surface and underground methods. However, the company suspended underground operations in early 1993 when the pit bottom reached the depth of the underground workings. At the McCoy deposit, the pit remained closed, and only the underground operation produced ore. It was expected that the underground operations at the McCoy deposit would be completed in 1994. The discovery of additional reserves at McCoy may permit reopening the pit at some future date. Gold production also increased from 9 tons in 1992 to 12 tons in 1993.

Mining ceased at the Paradise Peak Mine following exhaustion of the mine's known reserves in August. Although the mill closed in May following exhaustion of millable reserves, heap leaching continued through yearend. FMC Gold Co., owner and operator of the mine, reported that the mill processed 533,000 tons of ore and added an additional 3.6 million tons to the leach pads. The company began reclamation of the mine site during the year and was expected to continue reclamation in 1994, during which time some additional gold and silver was expected to be recovered from the leaching operation. In 1993, the mine produced approximately 5 tons of gold and 25 tons of silver.[20] In 1992, the mine produced about 8 tons of gold and 60 tons of silver.

Despite a slight drop in the quantity of ore mined, 1993 silver production at the Rochester Mine was the highest in the mine's 7 years of operation. Gold production also increased. For the year, employees mined 6.6 million tons of ore and recovered 185 tons of silver and 2 tons of gold.[21] Company officials attributed the increased production in part to slightly higher ore grades. In 1992, the mine produced about 6,674,000 tons of ore and recovered about 169 tons of silver and 2 tons of gold. Prior to 1993, the largest quantity of silver produced at the Rochester Mine was 178 tons in 1991.

Other States.—Cyprus Amax Minerals Co. halted mill operations at the Copperstone Mine in Arizona. Mining at the open pit mine ended in 1992 following the exhaustion of economically recoverable ore reserves. Reclamation of the site, which produced gold and a small quantity of byproduct silver, continued throughout 1993.

At its Leadville Mine, Asarco processed nearly 200,000 tons of ore, producing concentrates containing approximately 11 tons of silver, essentially unchanged from the previous year.[22]

In 1993, the San Luis Mine in Costilla County, CO, produced 2 tons of gold and 840 kilograms of silver.[23] In 1992, the mine produced 2 tons of gold and 871 kilograms of silver.

In Missouri, at its Sweetwater Mine, Asarco produced lead concentrate containing 5 tons of silver. In 1992, the Sweetwater Mine produced approximately 3 tons of silver in concentrate. Similarly, for 1993 and 1992, Asarco's West Fork Mine produced 8 tons and 10 tons of silver, respectively, in concentrate.[24]

Production at the Magmont Mine in Missouri continued to decline. Company officials continued to forecast the 1994 shutdown of the mine owing to ore exhaustion. In 1993, Magmont milled slightly more than 631,000 tons of ore compared with nearly 873,000 tons of ore in 1992.

In December, Lac Minerals prematurely halted leaching operations at the Richmond Hill Mine in South Dakota owing, in part, to continued problems with acid rock drainage at the site. The problem, first discovered in the summer of 1992, was the subject of several in-depth studies. By yearend, Lac used the study results to develop a remediation and reclamation plan for closing the site. In 1993, the open pit heap-leach operation recovered 333 kilograms of gold and 490 kilograms of silver.[25]

In Utah, Kennecott received the permits necessary for construction of a new copper smelter at the Bingham Canyon Mine. Construction began in July and was expected to be completed by mid-1995. For 1993, byproduct gold and silver production at Bingham Canyon, at 16 tons and 137 tons, respectively, was essentially unchanged from the previous year's output.[26]

Production at Hecla Mining Co.'s Republic Unit continued to drop as ore grades declined. In 1993, the mine treated 101,000 tons of ore and produced approximately 2 tons of gold and 9 tons of silver.[27]

World Review

Estimated world silver production decreased slightly in 1993 as the output of most countries remained essentially unchanged from that of the previous year. Lower production in Australia, Canada, Chile, and the United States more than negated slightly higher outputs in many other countries. Analysts attributed the lower overall world production to a drop in silver recovered as a byproduct at many nonferrous metal mines. The lower output of these operations reflected the lower prices for their primary product.

CPM Group estimated that world fabrication demand for silver, excluding coinage, increased in 1993 by more than 14%, to 21,000 tons, owing primarily to continuing significant growth in demand for silver in India.[28] Demand for silver in industrialized countries such as the United States, however, remained essentially unchanged.

OUTLOOK

The dominant component of domestic silver supply remains byproduct silver, recovered in the processing of other nonferrous metals, such as copper, gold, lead, and zinc. Most nonferrous ores contain some silver. Processing these ores concentrates the silver either in a waste stream or with the principal product. Once concentrated, the additional cost to recover the silver is minimal. As a result, in many instances the quantity of silver produced is probably more dependent on the price of the primary metal than on the price of silver. Another important consideration when forecasting domestic silver supply is the ongoing effort to reduce operating costs. It is believed that recent declines in domestic supply reflect primarily price movements for both silver and other nonferrous metals. However, recent improvements in some prices, including that of silver, will likely result in domestic silver production ranging between 1,400 and 2,000 tons during the years 1994-96. Worldwide, mine production of silver should remain at about 15,000 tons.

During the next few years, the industrial demand for silver likely will follow the general economy, either upward or downward, but remain at approximately 3,700 tons. Worldwide, silver demand will grow slightly as new markets in less-developed countries gradually begin to open.

W Withheld to avoid disclosing company proprietary data; included in "Other States."

[1] Less than 1/2 unit.

[2] Includes Alaska, Illinois, Kentucky, Michigan, New York, South Carolina, Tennessee, Wisconsin, and States indicated by symbol "W."

[3] Data may not add to totals shown because of independent rounding.

TABLE 3
TWENTY-FIVE LEADING SILVER-PRODUCING MINES IN THE UNITED STATES IN 1993, IN ORDER OF OUTPUT

Rank	Mine	County and State	Operator	Source of silver
1	McCoy and Cove	Lander, NV	Echo Bay Mining Co.	Gold ore.
2	Rochester	Pershing, NV	Coeur Rochester Inc.	Do.
3	Bingham Canyon	Salt Lake, UT	Kennecott-Utah Copper Co.	Copper ore.
4	Red Dog	NW Arctic, AK	Cominco Alaska Inc.	Zinc ore.
5	Sunshine	Shoshone, ID	Sunshine Mining Co.	Silver ore.
6	Lucky Friday	do	Hecla Mining Co.	Lead-zinc ore.
7	Mission Complex[1]	Pima, AZ	ASARCO Incorporated	Copper ore.
8	Greens Creek	Southeastern Alaska, AK	Kennecott Greens Creek Mining Co.	Zinc ore.
9	Kinkross-Delamar	Owyhee, ID	Kinkross Delamar Co.	Gold ore.
10	Montana Tunnels	Jefferson, MT	Pegasus Gold Corp.	Zinc ore.
11	Sierrita	Pima, AZ	Cyprus Minerals Co.	Copper ore.
12	White Pine	Ontonagon, MI	Copper Range Co.	Do.
13	Troy	Lincoln, MT	ASARCO Incorporated	Do.
14	Denton-Rawhide	Mineral, NV	Kennecott Rawhide Mining Co.	Gold ore.
15	Candelaria	do	NERCO Metals Inc.	Silver ore.
16	Ray Unit	Pinal, AZ	ASARCO Incorporated	Copper ore.
17	Continental	Silver Bow, MT	Montana Resources Inc.	Do.
18	Morenci	Greenlee, AZ	Phelps Dodge Corp.	Do.
19	Paradise Peak	Nye, NV	FMC Gold Co.	Gold ore.
20	Zortman-Landusky	Phillips, MT	Pegasus Gold Corp.	Do.
21	Bagdad	Yavapai, AZ	Cyprus Minerals Co.	Copper ore.
22	San Manuel	Pinal, AZ	Magma Copper Co.	Do.
23	Chino	Grant, NM	Phelps Dodge Corp.	Do.
24	Pinto Valley	Gila, AZ	Magma Copper Co.	Do.
25	West Fork	Reynolds, MO	ASARCO Incorporated	Lead-zinc ore.

[1] Includes Eisenhower, Mission, Pima, and San Xavier Mines.

[r] Revised. W Withheld to avoid disclosing company proprietary data; included in "Total." XX Not applicable.

[1] Less than 1/2 unit.

[2] Withheld to avoid disclosing company proprietary data, included in gold ore.

[3] Includes gold-silver, lead, zinc, copper-lead, lead-zinc, copper-zinc, copper-lead-zinc ores, and old tailings, etc.

[4] Includes silver recovered from fluorspar ores.

[5] Withheld to avoid disclosing company proprietary data, included in copper ore.

[r] Revised. W Withheld to avoid disclosing company proprietary data; included in "Total."

[1] Includes metal recovered at lode mines by gravity methods.

[2] Includes old tailings and some nonsilver-bearing ores not separable, in amounts ranging from 0.04% to 0.12% of the totals for the years listed. Excludes fluorspar, molybdenum, and tungsten ores from which silver was recovered as a byproduct and excludes ores leached for recovery of copper.

[3] Data may not add to totals shown because of independent rounding.

[4] Less than 1/2 unit.

TABLE 6

SILVER PRODUCED IN THE UNITED STATES BY CYANIDATION[1]

(Metric tons)

Year	Extraction in vats, tanks, and closed containers		Leaching in open heaps or dumps[2]	
	Ore treated	Silver recovered[3]	Ore treated	Silver recovered[4]
1989	38,855,007	300	119,199,347	490
1990	45,120,367	290	138,988,157	494
1991	[r]36,127,100	[r]253	[r]126,766,107	[r]467
1992	[r]45,294,189	[r]325	[r]116,337,024	[r]419
1993	41,356,497	312	167,218,080	509

[r] Revised.

[1] May include small quantities recovered by leaching with noncyanide solutions and by proprietary processes.

[2] May include tailings and waste ore dumps.

[3] May include small quantities recovered by gravity methods.

[4] May include metal recovered by leaching of previously mined ore at some inactive mines.

[e] Estimated. [r] Revised.

[1] Recoverable content of ores and concentrates produced unless otherwise specified. Table includes data available through July 1, 1994.

[2] In addition to the countries listed, Botswana produces silver (probably 1 kilogram or less per year) and Thailand may produce silver, but information is inadequate to make reliable estimates of output levels.

[3] Of total production, the following quantities, in kilograms, are identified as placer silver (the balance being silver content of other ores and concentrates): 1989—58,000; 1990—52,000; 1991—40,000; 1992—42,000 (revised); and 1993—40,000 (estimated).

[4] Smelter and/or refinery production.

[5] Less than 1/2 unit.

[6] Reported figure.

[7] Formerly part of Czechoslovakia; data were not reported separately until 1993.

[8] Dissolved Dec. 31, 1992. All production from 1989-92 came from the Czech Republic.

[9] Includes production from imported ores.

[10] Dissolved in Dec. 1991.

[11] Dissolved in Apr. 1992.

[12] Year beginning Apr. 1 of that stated.

[13] Data may not add to totals shown because of independent rounding.

SLAG—IRON AND STEEL

By Cheryl Cvetic Solomon

Ms. Solomon, a physical scientist with 8 years of U.S. Bureau of Mines experience, has been the commodity specialist for iron and steel slag since 1990. Domestic survey data were prepared by Robin Kaiser, statistical assistant.

Iron and steel slags are byproducts of the iron and steel industry. They are used not only in construction and roadbuilding, but also in other ways such as in waste stabilization. Slags are used in road bases, various types of concrete aggregates, fill, glass manufacture, mineral wool, railroad ballast, and soil conditioning.

Research during the year not only continued to study blended slag in cement, but also investigated other uses for slag such as uses in bricks and tiles as well as uses in adsorbing toxic chemical constituents.

Total slag consumption decreased by 11%, partly due to a decrease in production. Domestic consumption of reported iron slag showed a 15% decrease when compared with that of 1992, while the consumption of reported steel slag decreased by almost 4%.

DOMESTIC DATA COVERAGE

Data for sales, use, and transportation of iron and steel slag are developed by the U.S. Bureau of Mines from a voluntary survey of U.S. processors. Of the 99 operations canvassed, 97 responded, representing 99% of the total sales or use quantity data shown in table 1. Quantity data were estimated for the remaining operations. Value data had to be estimated for several operations using reports from prior years adjusted by industry trends.

BACKGROUND

Definitions, Grades, and Specifications

Slags are produced in many metallurgical operations, but this publication deals exclusively with iron slag and steel slag produced during the ironmaking and steelmaking processes.

In the production of iron, the blast furnace is charged with iron ore, flux stone (limestone and/or dolomite), and coke for fuel. Two products are obtained from the furnace: molten iron and slag. The slag consists primarily of the silica and alumina from the original iron ore combined with calcium and magnesium oxides from the flux stone. It comes from the furnace as a liquid at temperatures of about 2,700° F, resembling molten lava.

The blast furnace operation is a continuous process. The raw materials are fed into the top, and the products, molten iron and liquid slag, are drawn off at regular intervals throughout the entire day. Slag is produced at an average worldwide rate of 220 to 370 kilograms of slag per ton of hot metal or pig iron. The slag is usually run into iron ladles for conveyance to the cooling pit, or it may run straight into a cooling pit close to the furnace. When the material cools and solidifies, the gases create voids within the structure. These voids impart special engineering properties when the slag is used as an aggregate.

The density and porosity of the slag are affected by the conditions of cooling as well as by its chemical composition. Depending upon the manner in which the molten slag is cooled and solidified, three distinct types of blast furnace slag can be produced: air-cooled, expanded, and granulated.

Air-cooled slag is allowed to run into a pit adjacent to the furnace or is transported in large ladles and poured into a pit some distance away. Solidification takes place under the prevailing atmospheric conditions, after which cooling may be accelerated by water sprays on the solidified mass. After a pit has been filled and cooled sufficiently to be handled, the slag is dug, crushed, and screened to desired aggregate sizes.

Expanded slag is formed by controlled processing of molten blast furnace slag with water, or with water and other agents such as steam or compressed air, or both. The formation of gases and steam increases the cellular or vesicular nature of the slag, producing a lightweight product. Several methods of expanding the slag are employed involving the pouring of molten slag in open pits or the use of mechanical devices, one of which produces particles in pellet form. Expanded slag is a strong, lightweight aggregate suitable for making lightweight concrete, either as building blocks or as structural elements for buildings or for bridge decks.

Granulated slag is produced when molten slag is cooled rapidly by means of high-pressure water jets and solidifies into a glassy, granular product. This is the most rapid cooling process, producing little or no crystallization. The granulated slag may be crushed and screened or pulverized for various applications.

The steel industry also produces steel slag during the steelmaking process. The manufacture of steel involves the removal from the iron of excess quantities of carbon and silicon by oxidation. Steel slag is composed of roughly 50% lime. The other two main constituents are silica and iron oxide. The steel slag contains significant iron quantities and few voids, making it a tough, hard, heavier material. Different types of steel slag are generated from the open-hearth, basic oxygen, and electric arc furnaces.

Air-cooled and expanded slag are defined by ASTM Standard C 125-88.[1] Granulated slag is specified by ASTM C 989-88, "Standard Specification for Ground Iron Blast Furnace Slag for Use in Concrete and Mortars," which was first published in 1982.[2]

The specifications for steel slag aggregate used in asphaltic concrete are covered by ASTM D 5106-91, "Standard Specification for Steel Aggregates for Bituminous Paving Mixtures."[3]

Industry Structure

In general, most slag processors operate under contracts of 3 to 10 years with steel companies. The services the slag processors typically offer to the steel mill industry are hauling and transporting the slag away from the mill site, processing the slag, and recovering and distributing metallics and nonmetallics. Because slag hauling and processing facilities are capital intensive, the slag processors usually try to negotiate a long-term initial contract with the steel company to recover the capital investment. Subsequent contracts may be shorter.

Depending upon the specific situation at the mill site, the slag processor may assume ownership of the slag at the point of discharge or process it for a fee and/or market the finished product and pay royalties to the steel company on sales. Some steel companies may allow the processor to share in royalties on these sales. Although there are many variations in the way a particular slag processor and steel mill will set up their agreement, two possible options are considered here. The slag company may be paid to haul and transport the slag, process it, and market the finished product. The steel company, in turn, receives a royalty on the completed sale and a purchase discount on material recycled to the mill. Second, in a minority of the contracts, the slag processor takes ownership of the material and pays little or no royalties to the mill. In this situation, the slag processor would be assuming 100% of the site development and capital costs, including facilities for screening, metallic separation, and crushing and heavy equipment, such as slag pot haulers, to move the material.

Technology

Slag processing systems include the following, in A. W. Cooper's "Slag Handling in the Ironmaking Industry."[4]

Pit Granulation.—Molten slag is poured, either from a slag ladle or directly from the furnace, into a pit filled with water, or is hit with sprays of water to rapidly quench it. The blast furnace slag forms granules that have a glassy or vitrified structure. The slag granules are then separated from the granulation water and transported to the drying and grinding plant.

Gravel Layer Filter Bed System.—Pit granulation is developed further with the gravel layer filter bed system. The slag is granulated at the furnace in a granulation head by high-pressure water sprays. The slag slurry flows down a runner to an agitating tank where water is injected to keep the slag in suspension. The slag is dewatered and then excavated by a computer-controlled bucket crane. The gravel layer filter bed keeps the water in the system in a closed circuit, thus preventing water pollution. Blue Circle Cement Inc. of Sparrows Point, MD, has operated a gravel layer system since 1981.

Filter Hopper System.—Filter hopper systems use large dewatering silos lined with screens to dry the slag. This system extends the filtering system upward to conserve plant space. However, because the filtering is less efficient in the filter hopper system, pumping the slurry is necessary in the filter hopper.

Slag Pelletizer.—The slag pelletizer was developed by National Slag Ltd. in Hamilton, Ontario, as a means of bringing very high hydrogen sulfide gas emission levels typical of the "pit foaming" process under control.[5] Pelletized slag is produced by expanding molten blast furnace slag under water sprays and then passing the flow of this pyroplastic material over a spinning drum on which fins are mounted. The fins break up the slag, which then forms into pellets owing to surface tension. Although previous expanding processes have been of the batch type, this is a continuous process so that gaseous emissions are effectively diluted by generation over a long period of time. Because of this rapid cooling, the pelletizer can be thought of as an "air granulator."

The pelletizer has been installed in at least eight countries. Currently in Canada, about 400,000 tons of slag is pelletized annually and separately ground for use as a cementing material by the St. Lawrence Cement Co., Lafarge Canada Inc., and St. Mary's Cement. The pelletizers are installed near Hamilton, Ontario, where the major steel producers are located.

Operating Factors

Environmental Requirements.—Slag processors have had to be aware of environmental considerations, in much the same manner as have other mineral processing or manufacturing industries. During the past decade, concerns about the environment as embodied in the Clean Air Act of 1990 or Solid Waste and Clean Water legislation have grown. Concurrently, recycling and reuse of materials have become firmly established.

In keeping with public and private emphasis on improving the environment and preventing environmental harm, the slag industry has taken an active stance toward environmental responsibility in slag plant operations. Installation of new equipment, incorporation of improved operating procedures, and increased emphasis on such slag processing as slag granulation and other types of processing have all favorably impacted the slag industry.

At the same time, the emphasis on reuse of materials has meant that slag, which has been used as far back as Roman times, has been given renewed interest as a useful byproduct that serves as a substitute for mined aggregates. In addition, the use of slag as a commercial product is vastly more useful to the environment than it would be if it were landfilled.

Because of the different ways in which iron and steel slags can be utilized and the variety of steel slags available in the market, the slag processor can advise the user of iron and steel slags as to the best possible use for any given slag.

ANNUAL REVIEW

Legislation and Government Programs

The Interstate Commerce Commission proposed exempting from regulation about 30 commodities that railroads transport.[6] Commodities that would no longer come under commission scrutiny included crushed or broken stone or riprap, aggregate or ballast sand or gravel, rock salt, etc. Blast furnace slag products such as pig iron and slag also were to be deregulated.

Production

Slag was produced in 30 States and by 18 companies. *(See tables 2 and 3.)*

The Edward C. Levy Co. was one of Detroit's largest private businesses.[7] The company was involved in processing and marketing slag as its first line of business and in natural aggregates, such as sand and gravel. The Edward C. Levy Co. owned Lyon Sand and Gravel Co., Detroit Lime Co., Asphalt Products Co., Clawson Concrete Co., Cadillac Asphalt Paving Co., Burroughs Materials Co., Oakland Sand and Gravel Co., and North Mickelson Sand and Gravel.

Heckett Co. processed iron and steel slag at 22 plants. Harsco, of which Heckett Co. is the subsidiary, entered into a purchase agreement with MultiServ International N.V., a major international provider of metal reclamation and related steel mill purchases. The combined operation of Heckett and MultiServ provided steel mill services to more than 130 locations in 28 countries, making it the largest worldwide provider of such steel mill services.

Harsco also won a contract to supply steel mill services to the recently started Mexicali, a Mexican minimill owned by Compania Siderurgica de California. Harsco negotiated a 10-year, $8 million slag handling and metallic recovery contract for work at the mill located just south of the border between Los Angeles, CA, and Phoenix, AZ. Harsco had five other such contracts with Mexican steelmakers and was expected to sign more in the near future.[8]

The Levy Co. of Portage, IN, fully reconstructed approximately 26 kilometers (km) of the I-94 highway between LaPorte and Gary, IN, with blast furnace slag. The slag was used as subbase, open-graded drainage layer, asphalt, and concrete. Total amount of slag used on the highway was 425,000 tons. The Levy Co. also used steel furnace slag chips in a 48,000-ton asphalt project. The slag comprised 65% of the project by weight.

Standard Lafarge closed its West Aliquippa plant during the year. Standard Lafarge provided the subbase for portions of the I-79 highway in western Pennsylvania.

Consumption and Uses

Sales of slag products generally reflected demand from the construction industry. The Department of Commerce reported that value of new construction in 1993, $470.4 billion, increased by 8% compared with that of 1992.[9] The value of highway and street construction, $37.3 billion, was estimated to have increased by approximately 7% from that of 1992.

Many of the projects involving slag in 1993 were related to highway repaving projects. Blast furnace slag was used as a ground product to replace portland cement in concrete, as a special lightweight aggregate in blocks and highrise buildings, as a concrete aggregate replacing common concrete aggregates and sands, as a highly skid-resistant asphalt aggregate, and as a road base where the rough, interlocking surface and shape and cementitious properties enhance its load-bearing values.

Air-cooled blast furnace slag was the predominant form of iron slag processed in the United States, accounting for 85% of blast furnace slag sales in 1993. In 1993, 10,477,000 tons of air-cooled slag was used with a value of $61,685,000. The most significant end use in 1993 for air-cooled slag was as a road base. Air-cooled blast furnace slag also was used as an asphaltic concrete aggregate, other concrete aggregate fill, mineral wool, glass manufacture, railroad ballast, and sewage treatment. *(See table 4 for related data.)*

Consumption of combined expanded and granulated slag was 1,864,000 tons valued at $41,943,000. Granulated slag was predominantly used in the manufacture of cement and expanded slag in the manufacture of lightweight concrete blocks.

Steel slag is principally used for highly skid-resistant asphalt road surfaces, road bases, and asphaltic aggregates.

Reported steel slag consumption decreased by almost 4% compared with that of 1992. *(See table 5.)* Steel slag used in asphaltic concrete increased by 21% while that of fill decreased by the same amount. Steel slag used on road bases increased by approximately 11%.

Transportation

Most slag is used within about a 50-km radius of its source. Trucking costs make slag uncompetitive with mined aggregates when transportation distances exceed about 50 km. Some slag may be delivered over greater distances to areas that do not have other aggregates for use in construction and roadbuilding.

Of all the iron and steel slag products sold in 1992, 84% traveled by truck, with an average marketing range of 45 km; 4% traveled by waterway, with an average range of 404 km; and 4% traveled by rail, with an average range of 400 km. The remaining 8% was used at the plant where it was processed. *(See table 6.)*

Markets and Prices

The average price, f.o.b. plant, for all blast furnace slag was approximately $8.40 per ton, almost 9% more than that of 1992. *(See table 7.)* Air-cooled blast furnace slag averaged 5.89 per ton, virtually the same as that in 1992. However, with the exception of the 1991 data, prices for air-cooled slag increased year after year since the early 1970's. Granulated and expanded slag price information was withheld to avoid disclosing company proprietary data. The unit value for steel slag increased from $3.19 per ton in 1992 to $3.43 per ton in 1993.

Foreign Trade

Statistics developed by the U.S. Department of Commerce, Bureau of the Census, indicated that approximately 162,000 tons of granulated blast furnace slag was imported during 1993. Ninety-seven percent of these imports was from Canada. Sixty-one percent reportedly entered through Cleveland, OH, almost 39% through Buffalo, NY, and less than 1% through Savannah, GA. The Canadian imports may be expanded or pelletized slag.

Exports of granulated slag were 3,498 tons. Sixty-three percent of the slag exports went to Canada, with the remaining going to eight other countries.

World Review

A summary was made of blast furnace slag production in Europe, including Austria, Belgium, Finland, France, Germany, Italy, Luxembourg, the Netherlands, Portugal, Spain, Sweden, and the United Kingdom. Approximately 25 million tons of blast furnace slag was produced. It was estimated that 55% of this was granulated slag.

Australia.—Approximately 3 million tons of iron and steel slag was produced, about the same as that in 1992. There were no significant changes in slag production from 1992 at the iron and steel production centers in Australia. About 375,000 tons of blast furnace slags was used in Australian cements, with another 500,000 tons used in road construction and as an aggregate in concrete. Slag production and consumption centered around the iron and steel slag produced by BHP Steel in two areas in Australia—Port Kembla and Newcastle.

In the Port Kembla area of New South Wales was the slag processor Australian Steel Mill Services (ASMS), a consortium of Edward C. Levy Co. of Detroit, MI, and Queensland Cement Co., a wholly owned subsidiary of Holderbank Co. Approximately 1.3 million tons of blast furnace slag was processed into 700,000 tons of air-cooled slag and 600,000 tons of granulated slag. Approximately 50% to 60% of both types was used for road pavements, concrete aggregate, and cement manufacture. The rest was stockpiled. Approximately 500,000 tons of basic oxygen furnace (bof) slag was produced, with 100,000 tons used for road pavements and the rest stockpiled.

Significant progress was made in the recognition of blast furnace slag as a heavy-duty pavement material with its use as a subbase layer for the third runway at Sydney's major airport. About 300,000 tons of a blast furnace slag mix was supplied to the project. Competition from other aggregates, including mined aggregate, was intense for this and all other civil projects in the Port Kembla area.

BHP announced that it intended to construct a new blast furnace at Port Kembla, confirming that the complex would remain as an integrated unit for the foreseeable future. The new furnace was to replace two smaller older furnaces.

The Australasian Slag Association released a 24-page booklet entitled "A Guide to the Use of Slag in Roads." The booklet was published in conjunction with the State Roads and Traffic Authority as part of its drive to make greater use of recycled materials. The booklet also was endorsed by Vicroads, the Victorian State roads authority.

In Newcastle, there were three slag contractors, Boral Quarries, of Boral Ltd.; Steel Cement, Ltd. (owned mainly by a consortium of Australian and Japanese companies); and Steelstone Services of Australia. The first two contractors produced approximately 500,000 tons of blast furnace slag; 50% was air-cooled slag used in road pavements and construction and 50% was granulated slag used in cement manufacture and road construction. The latter contractor produced about 200,000 tons of steel slag, of which 50,000 tons was used for road construction and the balance was stockpiled.

All blast furnace slag produced in Newcastle was used productively in the marketplace and more could have been sold if it had been available. Sales were assisted by the shortage of natural rock close to the main market area. Small shipments of granulated blast furnace slag (gbfs) were exported to Hawaii where its silicate content was used as a soil conditioner. Some export sales of gbfs also were made to Southeast Asia.

The State Roads and Traffic Authority of New South Wales began to make extensive use of road pavement material in the Newcastle region comprising 70% basic oxygen furnace slag, 25% blast furnace granulated slag, and 5% fly ash. The use of the blast furnace slag mix in this manner was expected to be expanded. All of the components in the mix were byproducts from the BHP steel mill.

Approximately 350,000 tons of blast furnace slag and 125,000 tons of steel slag also were produced in Whyalla, South Australia, but the plant was not near a significant market, and this slag was therefore not sold. Electric arc furnace slag also was produced in Melbourne, Victoria, and in Newcastle, New South Wales.

Blast furnace slag cement marketed in Australia conformed to Australian Standard AS 1317. AS 1317 permitted slag to represent 20% to 65% of the total cementitious content.[10]

Belgium.—As in the past, all the production of blast furnace slag, about

2.3 million tons in 1992, was granulated. This 18% reduction in the amount of blast furnace slag available, compared to that in 1991, was due to decreased hot-metal production as well as to a reduced rate of slag produced per ton of hot metal. The cement industry was by far the main customer. An increase in the price of the slag over the $9 per ton of 1991 accompanied the reduction in production.

Steel slag production was also slightly reduced from the 1 million tons produced in 1991. The applications for steel slag remained principally for forest, farm and industrial roads, parking lots, stabilization of deposits, and hydraulic engineering. The cement industry consumed small quantities of steel slag for use in making clinker and for agriculture as soil liming agent. The production of electric arc furnace (EAF) slag rose. The EAF slag could enter the heavy-duty road market more easily than the BOF slag because it was not classified under the common designation of "steel slag." The EAF slag was also more stable than BOF slag because of its lower free lime content.

Canada.—Lafarge Canada purchased the Spragg slag cement plant in Blind River, Ontario, from Koch Minerals at yearend. The Spragg plant processes slag from Algoma steel. Lafarge Canada also operated the Stony Creek slag plant in Hamilton, Ontario. Stony Creek processes the slag from Dofasco and Stelco in Hamilton, Ontario.

Ninety thousand cubic meters of steel slag was used to provide stability to the soil under Highway 416 leading into Ottawa. The slag project took 1 year and cost $2.5 million.[11]

France.—In 1993, 12.57 million tons of pig iron and 4.27 million tons of blast furnace slag were produced, or 360 kilograms (kg) of slag was produced for every ton of pig iron. This compared with 13 million tons of pig iron and 4.7 million tons of blast furnace slag produced in 1992. Of this slag, approximately 2.12 million tons was granulated, 2 million was air-cooled, and 0.15 million was pelletized or processed in other ways. Sales of slag, 5 million tons compared with 6.9 million tons in 1992, included the slag produced, slag from stocks, and older slag banks. The amount of granulated and pelletized cement sold was 2.5 million tons, less than the 3.5 million tons in 1992. Of the granulated and pelletized slag, 1.9 million tons was used in cement, 0.3 million tons was used for coarse slag and slag sand on roadways, 0.2 million tons of lightly crushed slag was used on roadways, 0.02 million tons was a mixture of granulated slag and crushed air-cooled slag used to make road bases, and 0.08 million tons was used by the company or for other uses. Seventy-one percent of the granulated slag was utilized in France, up by 8% compared to that in 1992, and the remainder was utilized abroad.

Sales of crushed air-cooled slag were 2.4 million tons, less than the 2.7 million in 1992, and included slag from stocks and from older slag banks. Of the air-cooled slag, 55% was used on roadways, 30% as coarse slag, 9% for concrete and slag bricks, 2% for ballast, and 4% in other uses. Two thousand tons of expanded slag was sold. Ninety-eight percent of the air-cooled and expanded slag was used in France, the same as in 1992.

There were approximately nine blast furnaces in operation. Sollac at Dunquerque had three blast furnaces, Sollac at Fos-Sur-Mer had two, Lorfonte at Rombas had two, and Lorfonte at Hayange had two. Production at the SMN Unimetal blast furnace at Caen, which had granulated 100% of production, stopped in 1993.

Steel slag (not including EAF slag) was processed mainly at Dunkerque and Fos. Compared with 12.43 million tons in 1992, 11.77 million tons of liquid steel was produced in 1993. Seventy-four thousand seven hundred tons of slag was used in the blast furnace and 91,200 tons was used in the steel furnace. In 1993, 217,400 tons of steel slag was sold, compared with 242,700 tons in 1992. Of the amount in 1993, 29% was used on roads, 25% used at the cement plant, 20% in agriculture as fertilizer, and 26% used in various other ways. Steel slag banks amounted to 247,300 tons in 1993 compared with 612,000 tons in 1992.

Germany.—There was 6.81 million tons of blast furnace slag produced in Germany and 7.41 million tons was sold, compared with 7.08 and 8.25 million tons, respectively, in 1992. Almost 88% of the slag produced came from nonphosphorus pig iron production, 1.9% from basic Bessemer pig iron production, and 2.1% from special pig iron production. Some of the blast furnace slag sales were taken from stores of slag produced in prior years. About 57% of the slag was air-cooled slag used for road construction, 39% was granulated slag for cement, 3% was granulated slag for road construction, 1% was foamed slag for road construction, and less than 1% was air-cooled slag for fertilizer. There was 4.24 million tons of steel slag produced in Germany, compared with 4.7 million in 1992, with 88% being sold. Sixty percent was used as aggregate for roads, 18% was recycled back to the blast furnace, 12% was for landfill, 7% was for fertilizer, and 3% was for other uses.

Slag used in Germany must conform to special requirements for leachability (in addition to conforming to certain technological requirements). The leaching was done according to German Standard DIN 38 414. There were no common limits within Germany for the application of byproducts. Therefore, the state of Northrhine-Westfalia (Nordrhein-Westfalen) created special limits for each of 11 byproducts. According to the leachability of the slags, they could be used as aggregates in various fields of application, such as aggregates in road construction in asphalt or unbound layers; in ground water protection areas as an aggregate under layers impermeable to water (such as asphalt or concrete layers), and in other ways.

India.—India produced approximately 35 million tons of steel and blast furnace slag, 30 million tons of fly ash from thermal powerplants, and 3 million tons of lime sludge.[12]

The Steel Authority of India (SAIL) was expected to convert enormous quantities of byproducts generated from its ironmaking and steelmaking processes into materials suitable for use in construction and as substitutes for mined aggregate.[13] The byproducts were blast furnace slag, steel slag, and fly ash from the powerplants, among others. SAIL produced approximately 1,000 kg of these solid byproducts for each ton of steel.

The Tata Steel cement plant at Sonadih in Madhya Pradesh began cement production in 1993.[14] Sonadih was part of a 1.73-million-ton-per-year cement project with plants in two locations, Sonadih and Jojobera. The Jojobera plant was expected to begin producing portland slag cement in January 1994. The blast furnace slag was to be made available by the Tata Steel Works. The company was planning to market its products with Associated Cement Cos., Ltd. Sagar Cements also had two plants with 1,000 tons per day of capacity, consisting of 400 tons per day of ordinary portland cement at Mathampally and 600 tons per day of portland blast furnace slag at Salur.[15] Sagar Cements established a slag cement grinding unit at Kharasavalasa district, Andhra Pradesh, with a capacity of 600 tons per day of portland blast furnace slag cement. The unit was to have a slag dryer, cement mill, and packaging plant. Sagar Cements was to receive 70,000 tons annually of high-quality slag from the Vishakapatnam Steel Plant for 10 years.

Japan.—In 1993, 35.2 million tons of slag was produced, compared with 35 million in 1992. Sixty-five percent was blast furnace slag and the remaining was steel slag, virtually the same as that in 1992. In 1993, 21.82 million tons of blast furnace slag was consumed compared with 24.08 million tons in 1992. Also in 1993, 14.27 million tons of slag was used in cement, 88% being granulated and the rest air-cooled slag. During the year, 4.37 million tons of slag was used for roads or railroads, 1.17 million was used for public works, 754,000 tons went for coarse concrete and fine aggregate, 360,000 was used as fertilizer, 292,000 was used to improve the soil, and 602,000 tons was consumed in other uses.

Although the amount of total blast furnace slag has remained about the same since 1976, the amount of granulated slag that has been processed has grown from 3 million tons in 1976 to 14.46 million in 1993. The amount of air-cooled slag conversely decreased from 23 million tons in 1976 to 7.5 million tons in 1993.

There were two types of steelmaking slag, one was BOF slag and the other was EAF slag. The amount of the former production was 9.8 million tons and that of the latter was 2.47 million tons in 1993. EAF slag was expected to increase following the increased steel production by the electric arc process. In 1993, 9.3 million tons of BOF and 2.4 million tons of EAF slags were used (although only 70% of the EAF slags is accounted for here). More than 4 million tons of steel slags was used in public works, 1.85 million tons was recycled, 1.55 million tons was used on roads, 1.33 million tons was used in landfills, 628,000 tons was used in cement, 382,000 tons was used for soil improvement, and 109,000 tons was used as fertilizer; 1.92 million tons went for other uses.

Owing to its promotion of technology for the advanced reuse of energy and resources, the Japanese steel industry has been viewed as a representative recycling industry. All of the blast furnace slag is usefully recycled, much of it as an ingredient of cement, while more than 75% of BOF and EAF slag is recycled.[16]

The following standards exist for slag in Japan: JIS A 5011 covers Air-Cooled Iron Blast-Furnace Slag Aggregate for Concrete, JIS A 5012 covers Granulated Blast Furnace Slag Fine Aggregate for Concrete, and JIS A 5015 covers Slag for Road Construction—blast furnace and steel slag.

Other standards were published by The Japan Society of Civil Engineers on the design and construction of concrete containing ground granulated blast furnace slag used as an admixture, by the Nippon Slag Association on the design and construction of road base and subbase with crushed blast furnace slag, and by the Japan Road Association on the design and construction of asphalt pavement.[17]

Netherlands.—Blast furnace slag production amounted to about 1.2 million tons. Ninety-seven percent of the iron slag was granulated and almost entirely sold to the cement industry. A small quantity was used in mixtures for road building. The remaining part was air cooled and used as a component for road building.

Steel slag production from BOF steelmaking amounted to about 500,000 tons. About 16% of this steel slag was returned to the BOF as process slag, 20% was used in marine engineering, and 24% was used in road construction as the main component in mixtures with granules. The remaining 40% was put in stock and could be used in large projects as a replacement for sand. Much attention was given to upgrade steel slag by means of separation and aging so that it would be an acceptable replacement for natural aggregates used in road construction and concrete production.

New Zealand.—The main producer of slag in New Zealand was BHP New Zealand Steel Co. Iron-bearing sand was the source of metallics, iron was obtained through the smelter process, and steel by the KOBM process. The slag was processed and marketed by a joint-venture company comprising BHP and the Slag Reduction Co. of Scunthorpe, England, trading as the Slag Reduction Co. (New Zealand) Ltd. The company created markets for slag products in conventional uses such as asphalt and road pavements as well as in other uses such as filter media for wetlands and oxidation ponds.

KOBM slag also was used as a soil conditioner, particularly for growing lettuce and carrots. Sales of slag products were close to production levels. In addition, approximately 16,000 tons of electric arc furnace slag was produced by Pacific Steel.

Russia.—A joint venture was set up at a plant in Chelyabinsk to make concrete and steel out of raw ore and steel accumulated at the Satkinskij Metallurgical Enterprise defense production.[18] The joint venture was established by Commonwealth Connection, a U.S. company, for joint venture with Russia. The Multilateral Investment Guarantee Agency (MIGA), a World Bank affiliate, provided $9.9 million in insurance for Multiserv Russia, S.A., for its investment in machinery and equipment for a steel slag processing operation in Magnitogorsk, Russia. This was MIGA's first coverage in Russia.

United Kingdom.—The amount of blast furnace slag produced in 1993 was approximately 3.3 million tons, just slightly more than that in 1992. The percentage of granulated slag and pelletized slag, about 28%, was expected to increase as the new granulator at Llanwern came into full production. In Britain, all air-cooled blast furnace slag, about 22% of the total blast furnace slag, was sold as aggregate in coated materials and asphalts, principally for roads. The remaining 50% of blast furnace slag went to unbound road use and general construction. The latter figure included a small amount sold as a filter medium for water treatment.

Slag was produced in the United Kingdom at the British Steel plants—Scunthorpe and Teesside in England and Llanwern and Port Talbot in Wales. In England, East Coast Slag, owned by British Steel and Tarmac PLC, marketed the slag produced at Scunthorpe and Teesside. In Teesside, the iron slag was produced at Redcar and the steel slag was produced at Lackenby. In Wales, Cambrian Stone, owned by British Steel and Wimpey Hobbs of George Wimpey PLC, marketed the slag produced at Llanwern and Port Talbot.

There were two granulators, one at Scunthorpe and one at Llanwern, which were commissioned in 1993. Two of the plants in the United Kingdom also used pelletized slag.

British Steel produced 1.5 million tons of BOF slag in 1993. Approximately 200,000 tons of BOF slag was sold for use in roads, in unbound and in bituminous mixes.

British Steel negotiated selling equipment from the Scottish Ravenscraig plant, which closed in 1992, to an Indonesian company, Gunawan Dianjaya, which planned to reassemble it in northeast Malaysia. The plant would be the largest steel plant in Southeast Asia.[19] Castle Cement of Glasgow, Scotland, which had received slag from this plant prior to its closure, imported slags from France and received raw materials from Redcar and Port Talbot in South Wales. The material was ground, processed, and marketed in Scotland. About 100,000 tons of this processed slag was sold in 1993.

There was interest in the United Kingdom in limiting freshly quarried aggregates to build highways, roads, offices, and houses in England and Wales. Because the supply of aggregates was expected to be limited, a price rise was expected. Recycled materials, such as blast furnace slag, were expected to benefit.[20]

The principal means of regulating slag was the British Standard (BS). In addition, other Digests issued by the Building Research Establishment, although not carrying the force of a BS, were conformed to by slag processors. BS 6699 was used for blast furnace slag used in cement, ground granulated blast furnace slag (ggbfs). This ggbfs was for supply directly to the concrete manufacturer, ready-mixed, site-mixed, or precast. The BRE Digest No. 363 covered sulfate resistance of concrete and specified a 14% maximum Al_2O_3 content. BS 1047 covered air-cooled blast furnace slag for aggregates.

Current Research

A new mud-to-cement conversion technology eliminated mud displacement problems, improved zonal isolation, and eliminated mud to cement incompatibility, which was common with conventional cementing practices.[21] Ggbfs and common inexpensive alkaline activators could be added to any water-based mud to form a cementitious slurry. The slurry was simple to use, cost effective, and was shown to significantly reduce mud disposal costs in environmentally sensitive areas because most of the mud was used as the base for the cement instead of being disposed or discarded.

At the Institute of Materials in Austria, slags as a replacement for natural sand in cements were shown to be equivalent to the sand.[22] Production and processing of slag could be tailored to out perform the aggregates currently used. Applications of slag were presented for the concrete, plastering, and environmental technology industries.

The effect of the addition of 15% and 30% fly ash or 50% ggbfs to ordinary portland cement on the corrosion resistance of the reinforcement in concrete was studied in a program of long-term exposure in seawater. The use of these admixtures resulted in a decrease in the corrosion rate, especially after long exposure times. The most effective protection was given by the 30% fly ash mix. This result was related to the chloride content and the chloride binding capacity of the admixtures.[23]

The cement and concrete research group of the King Fahd University of Petroleum and Minerals continued to conduct fundamental and applied research toward the production of durable concrete compatible with the environmental conditions of the countries along the Arabian Gulf.[24] The drastic shortening of the useful service life of reinforced concrete structures in the eastern coastal areas of Saudi Arabia owing to reinforcement corrosion, sulfate attack, and salt weathering was of major concern to the construction industry in this region. Evaluating the performance of high-performance materials, such as fly ash, blast furnace slag, and silica fume in resisting reinforcement corrosion has been the active research area of the group.

Ggbfs used to partially replace portland cement and silica fume in cement pastes were investigated under different curing regimes at the People's Republic of China Tongji University, Department of Material Science and Engineering.[25] The influence of long-term hydration at 25° C, hydrothermal curing at 80° C, and strong drying at

200° and 400° C on the composition and microstructures of slag-portland cement was investigated by using various methods. The slag was found to be an additive that improved the intrinsic properties of the cement paste.

Research conducted in Czechoslovakia studied the influence of an alkali-silicate admixture on mortar properties.[26] The admixture significantly increased the strength of the mortars made from portland cement and silica fume or blast furnace slag. The admixture allowed the value of compression strength to be accelerated when it was added to mortar incorporating slag and with slag mortar. Further results showed that mortars with the admixture had an increased content of hydration products and substantially more dense pore structure than mortars of the same composition, but without the admixture.

In Australia, it was determined that the manufacture of cements based on calcium sulfoaluminate required lower firing temperatures and lower grinding energy as compared to ordinary portland cements.[27] Some of these low-energy cements could be formulated to develop high early strength and other performances similar to ordinary portland cement. It was found that a number of byproducts such as blast furnace slag, fly ash, bauxite fines, and phosphogypsum could be employed without affecting the hydraulic behavior of the cement. Blast furnace slag and fly ash also could be used as blending components of the fired products.

An investigation was conducted at the University of Delft in the Netherlands into the cement equivalence factors for fly ash in concrete.[28] The work was part of research aimed at taking the contribution of fly ash to strength development and other properties of concrete into account on the minimum cement content and maximum water-cement ratio required to achieve these properties by the Dutch Concrete Standards. Ordinary Portland Cement, rapid hardening portland cement, and portland blast furnace slag cement were studied. Concrete compositions with a range of water-cement ratios, two fly ash-cement ratios, and three curing regimes were studied as functions of concrete compressive development. The equivalence factor increased when the water-cement ratio decreased. This dependence was lowest for the portland blast furnace slag cement and decreased with increasing age.

A study was made at the Cemkut GMBH in Budapest, Hungary, of the grinding and quality characteristics of composite cements produced from clinker and two additional interground additives such as granulated blast furnace slag, fly ash, trass, and limestone.[29] The grindabilities of cements made up of three components proved to be better than that of the clinker. Water demand and workability depended upon the particle-size distribution, which was influenced by the grindability and nature of the interground additives. The more easily ground components had wider particle-size distributions and generally had lower water demands. To achieve standard strengths, the composite cements had to be more finely ground than cements without interground additives. In addition to having favorable grinding characteristics, composite cements made of clinker, ggbfs, and limestone also gave the best consistencies at high compressive strengths.

The permeability and mechanical properties of blast furnace slag concretes made of neutral (CaO/SiO_2 almost equal to 1) and low alumina content (Al_2O_3 almost equal to 8.5%) slags were investigated at the Technical Research Center of Finland.[30] Portland cement, blended cement, and alkali-activated slag concretes were compared with one another. The influence of the type of cementing materials on the mechanical properties was investigated. The effect of microcracks in the alkali-activated slag concrete on the mechanical properties of concrete was studied.

Studies were done at the University of Aberdeen in Aberdeen, Scotland, and at CSIRO in New South Wales, Australia, to study the reducing characteristics of blast furnace slag and their influence on the redox potential of slag-cement pore solutions.[31] The continued and increasing use of slag cements in the construction industry was expected to require consideration of the effect of the electrochemically reducing pore solution on the passivation of steel reinforcement in the cement system. Studies on steel embedded in portland cement and slag cement matrices were presented. The model proposed that the reducing components of blast furnace slag would impede the early formation of oxidized passive layers on steel in high blast furnace loaded blast furnace slag and ordinary portland cement concretes and could gradually degrade previously formed oxide layers. Thus, the corrosion behavior of steel in blast furnace slag and ordinary portland cement matrices was considered to be different from that in other cementitious systems.

Blast furnace slag containing CaO, SoO_2, Al_2O_3, and MgO as main constituents was investigated as a possible raw material for tile manufacturing.[32] Samples were made from 50% to 80% by weight slag and modified by varying amounts of SiO_2, Al_2O_3, Li_2O, and TiO_2. The properties of the tile thus prepared were investigated using differential thermal analysis, X-ray diffraction, and scanning electron microscopy.

Stroikeramika, a Leningrad tilemaking plant, also conducted experiments with ceramic wall tiles to assess the possibility of using blast furnace slag to manufacture these tiles.[33]

Samples of blast furnace slag from the East-Slovak Metallurgical Works in Kosice were studied at the Institute of Civil Engineering, in Bratislavia, Slovakia. Various ages and granulometry were investigated with respect to their chemical and mineralogical composition.[34] The blast furnace slags' tendency to ferrous and gamma-dicalcium disintegration was assessed as well as their hydraulic activity under normal and hydrothermal conditions. The experiments showed the slags to be uniform in their properties and suitable for their application as aggregate for concrete.

Trinecke Zelezarny, an iron company in Trinec in the Czech Republic, began manufacturing slag-pumice and slag-concrete bricks at its Hutni Metallurgy Waste division.[35] No mortar materials were needed for vertical joints. The bricks could be used for all kinds of masonry, including ceilings.

Ggbfs was used to make sand-lime bricks in India.[36] Laboratory results revealed that good quality bricks could be produced at sufficiently low pressure of 5 megapascals and the manufacturing process of these bricks did not require firing or autoclaving for strength development.

The phosphorus removal efficiency of three gravel-based constructed wetland systems was investigated in a study conducted at the University of Western Sydney Hawkesbury, Sydney, Australia, in which secondary sewage effluent was treated.[37] Laboratory phosphorus adsorption experiments were conducted with regional gravels and alternative adsorptive media, including industrial slag and ash byproducts. The results of a range of adsorption capacities indicated that further investigations into the use of industrial byproducts to treat industrial waste substrata were warranted.

At the National Center for Metallurgical Research in Madrid, Spain, granulated blast furnace slag was used to reduce the toxicity of electric arc steelmaking flue dust by means of a stabilization process.[38] The process made it possible to immobilize the metal contents that make the flue dust a hazardous product. Stabilization first involved pelletizing the steelmaking flue dust and then coating these pellets with a mix composed of slag-based hydraulic binders. Experiments indicated that various slag binding mixes containing portland cement, gypsum, and lime reduced the mobility of flue dust metals. The mobility of the metals has lead to flue dust being classified as a hazardous product.

SsangYong Cement of South Korea provided a grant to the National University of Singapore to fund joint research into the study of how to produce more durable cement.[39] The joint project was to explore the potential of portland blast furnace slag cement.

The granulated slag of a steel plant was analyzed for major and minor components.[40] It was found to contain iron and manganese (along with some other metals in traces) in a state suitable for causing electrochemical reduction of a number of extraneously added metal ions. By controlling parameters such as weight of slag used, pH, concentration, and flow rate, a scheme for the selective removal of toxic metal ions such as Hg(II), Pb(II), Cu(II), and Zn(II) was carried out. The method showed promise in the removal of toxic metal ions from solutions and effluents.

OUTLOOK

The total amount of blast furnace slag produced was not expected to increase during the next year because the amount of pig iron was expected to stay at about the 48-million-ton level. (See Iron and Steel Annual Report 1993.) In addition, gradual improvements have been made in the ironmaking process. One of these is that the amount of fluxstone, such as limestone or dolomite, that is added to the blast furnace has decreased somewhat over the past few years. This directly affects the amount of slag produced, or the total amount available to be sold.

Of the types of blast furnace slag, granulated slag used in cement was likely to increase somewhat relative to air-cooled slag due to a number of factors. Portland cement was forecast to be in short supply at least through 1994, and granulated slag could replace this portland cement at a lower cost. In addition, granulation of slag impacted favorably on energy usage because less portland cement would be manufactured, a process that utilizes large amounts of energy. With respect to other environmental considerations, granulation of slag was favorable compared to other types of iron blast furnace processing in that there are fewer emissions to the air with granulation. Research was expected to continue to emphasize the advantages of the chemical properties of slag when blended with cement. Prices of granulated slag were expected to rise as the price of portland cement rose, with the upper limit being the price of cement.

Production of steel slag was expected to rise owing to a slight increase in steel production. EAF slag production was expected to continue to increase relative to BOF slag production. Consumption of steel slag as a whole was not expected to increase significantly.

SODA ASH

By Dennis S. Kostick

Mr. Kostick, a physical scientist with 15 years U.S. Bureau of Mines experience, has been the commodity specialist for soda ash since 1979. Domestic survey data were prepared by Maria Arguelles, statistical assistant; and international data tables were prepared by Ted Spittal, international data coordinator.

Virtually every home has materials containing glass, soap and detergents, paper, textile, and food. All of these consumer products contain soda ash—a compound made from the mineral trona that most people have never heard of. Chemically, soda ash is known as sodium carbonate. It is the 11th largest inorganic chemical in terms of production of all domestic inorganic and organic chemicals, excluding petrochemical feedstocks. Internationally, there are two types of soda ash—natural and synthetic. The United States is the world's largest soda ash-producing nation with the world's largest natural deposit of trona, the ore from which soda ash is refined. Because the majority of world output is made synthetically, which usually is more expensive to manufacture, U.S. natural soda ash is extremely competitive in world markets. *(See table 1.)*

DOMESTIC DATA COVERAGE

Soda ash production data are collected by the U.S. Bureau of Mines from monthly, quarterly, and annual voluntary surveys of U.S. soda ash operations. Of the six soda ash operations to which a survey request was sent, all responded, representing 100% of the total production data shown in this report.

Reported consumption data by end use are collected quarterly from the marketing and sales departments of each company within the industry. Import and export statistics are obtained from the U.S. Department of Commerce, Bureau of the Census, and analyzed using trade data provided by the Journal of Commerce's Port Import Export Reporting Service (PIERS). The export data collected by the Census Bureau may not correspond to the export data provided by the soda ash producers in the quarterly survey of soda ash sales or the PIERS data. The discrepancy between the export data sets is because Census data report the transaction on the date the cargo physically departed from the U.S. port whereas soda ash producers consider a shipment as exported when it leaves the plant. The overland transit time between the plant and port and any carryover export inventory, both in domestic and foreign warehouses or teamtracks, are the major reasons for the difference between the export data.

BACKGROUND

Although soda ash represented about 2.3% of the total $32 billion nonfuel mineral industry that was surveyed by the U.S. Bureau of Mines in 1993, its use in many familiar household products consequently contributes substantially to the gross national product of the United States. Soda ash is one of the basic inorganic chemicals produced in the world. Most countries do not have economic deposits of sodium carbonate-bearing minerals and must produce soda ash by various manufacturing techniques, which are labor-, capital-, and energy-intensive. In addition, the processes generate byproduct sodium chloride and calcium chloride, which are usually discharged as waste effluent that contribute to environmental problems.

Natural soda ash was probably first obtained as evaporite incrustations along the edges of alkaline lakes in Lower Egypt. It was used about 3,500 B.C. to make ornamental glassware, as evidenced by many of the early Egyptian glass artifacts. The Egyptians also mixed lime and soda ash to make caustic soda. The caustic soda was combined with silicate minerals obtained from the Sinai Desert. This made a soluble silica, which was added to aluminum-rich Nile River silt, producing a silica-aluminate cement mortar with superior bonding properties. In the Old Testament, it was referred to as neter but has also been known as natrium, kali, trona, and natron. Until the 18th century, soda ash was obtained mainly by burning seaweeds and marine plants, leaching the soluble material from the ashes, and evaporating the solutions to dryness. About 13 tons of ash yielded 1 ton of sodium carbonate and 14 kilograms (30 pounds) of iodine as a byproduct. The final material was very impure but could be used in the manufacture of glass and soap and detergents. Pliny, a Roman historian in the first century A.D., listed soda ash in the manufacture of glass, as a medicine for colic pains and skin eruptions, and for making bread.

In 1791, Nicolas Leblanc, a French chemist, developed a process for making soda ash from "salt cake" (from salt and sulfuric acid), coal, and limestone. The French Revolution interfered with its development, and his patent and factory were confiscated with him receiving only token compensation. Napoleon returned his factory to him but Leblanc was not able to raise enough capital to reopen it, and he committed suicide in 1806. More than 30 years passed before the process first became successful in Liverpool, England. The process was not used successfully in the United States except during a short period from July 1884 to January 1885 at Laramie, WY.

Ernest and Alfred Solvay developed an improved method for making soda ash from salt, coke, and limestone, with ammonia as a catalyst, in the early 1860's. That process was first used in the United States in 1884 at Syracuse, NY, in a plant that continued to produce soda ash until 1986. It was the first of about 10 synthetic Solvay plants that were in operation by 1939 in the United States, and ironically, the last one to close. The Solvay process gained in popularity over the years and is now the basic method used throughout the world for making synthetic soda ash. In addition to the Solvay plants, there were three electrolytic process plants in Tyrone, PA, Covington, VA, and Luke, MD, that were operated by West Virginia Pulp and Paper Co. in 1939.

The site of the first commercial production of natural soda ash in the United States was from two deposits known as the Soda Lakes near the present town of Fallon, NV. Asa L. Kenyon acquired title to Little Soda Lake in 1855 and sold it to Higgins and Duffy in 1868, when the first 300 tons of natural soda ash was produced. Production of adjacent Big Soda Lake began in 1875 and reached its peak in 1887. The brines became diluted as the lake levels rose in 1907 because regional dam construction affected the local water table. Searles Lake in California was originally mined for borax as early as 1874. Soda ash production began in 1926 by the West End Chemical Co. American Potash Corp., formerly the American Trona Corp., was the second company to produce soda ash at Searles Lake in 1931.

Definitions, Grades, and Specifications

The following terms are used in the soda ash industry:

Ammonia-Soda Process.—Also known as the Solvay process and lime-soda process.

Dense Soda Ash.—Has a bulk density of 0.96 to 1.06 grams per cubic centimeter (60 to 66 pounds per cubic foot). It is produced by hydrating light soda ash followed by dehydration through calcination to produce denser crystals. In Eastern Europe, dense ash is made by compressing light ash between rollers to increase the density, followed by screening.

Light Soda Ash.—Has a bulk density of 0.51 to 0.62 gram per cubic centimeter (32 to 39 pounds per cubic foot). It is produced by calcining the sodium sesquicarbonate precipitate recovered from the carbonation towers or vacuum crystallizers.

Natural Soda Ash.—Soda ash produced from trona ore, sodium carbonate-bearing brines, or surface mineralization.

Soda Ash.—Synonymous with sodium carbonate. It is a general term that can apply to soda ash produced from natural sources or from various chemical processes.

Sodium Sesquicarbonate.—Can refer to the name for the chemical composition of trona or the chemical process that produces a light- to intermediate-grade of soda ash having an average bulk density of 0.8 gram per cubic centimeter (50 pounds per cubic foot).

Synthetic Soda Ash.—Term for soda ash produced from one of several chemical processes, such as the Solvay process.

Trona.—The principal ore from which soda ash is made. It is composed of sodium carbonate, sodium bicarbonate, and water. The monoclinic crystals are prismatic to tabular, with colors ranging from translucent (spar variety) to shades of brown, which vary depending on the amounts of contained organic matter. Trona has a specific gravity of 2.17 with a hardness of 2.5 to 3 on the Mohs scale. About 1.8 tons of trona is required to produce 1 ton of soda ash.

The terms "soda ash" and "sodium carbonate" are used interchangeably. The material manufactured from Wyoming trona normally contains more than 99.8% sodium carbonate, and the sodium chloride content ranges between 0.01% to 0.02%. The amount of iron is less than 10 parts per million. Searles Lake brines are processed to yield a product of similar high quality, with salt and sodium sulfate as the principal trace impurities. The average material produced by a Solvay soda ash plant is about equal to the natural product in sodium carbonate content, but often contains a larger quantity of salt. Dense soda ash, because of its greater bulk density, may command a higher price than the light variety and is preferred for glass manufacture because the light soda ash leads to frothing in the glass melt. Light soda ash is preferred by many chemical and detergent industries because it dissolves more readily. Sodium sesquicarbonate has an intermediate bulk density and is used in some detergent and bath salts.

The average Wyoming dense soda ash produced by the five Wyoming producers is nearly identical. All the companies provide chemical and physical analyses of their material and list the typical specifications of their products. The typical range of specifications for the various constituents are sodium carbonate, 99.6% to 99.8%; sodium sulfate, 0.02% to 0.15%; sodium chloride, 0.01% to 0.08%; and small trace amounts of arsenic, boron, calcium, copper, magnesium, and silica dioxide. The dense soda ash produced at Searles Lake contains 99.8% sodium carbonate, 0.10% sodium sulfate, and 0.10% sodium chloride. Although some product literature available from some of the European synthetic soda ash companies indicate that the composition data are averages of routine work control analyses and should not be considered as specifications, a typical chemical analysis lists the sodium carbonate content as 99.4%; sodium sulfate, 0.03%; sodium chloride, 0.2% to 0.4%; and small concentrations of iron oxide, calcium, and magnesium.

Typical official specifications for soda ash include American National Standard K60, 11-1956 (R1969) "Standard Specifications for Soda Ash," which appears as the American Society for Testing and Materials (ASTM) Designation D458-74 (Reapproved 1979); and British Standard (BS) 3674: 1963 "Specifications for Sodium Carbonate (Technical Grades)." The British Standard specifies, among other requirements, not less than 57.25% Na_2O and not more than 0.005% Fe_2O_3; the ASTM, a minimum of 99.16% Na_2CO_3. Both standards specify methods of testing. Technical-grade soda ash meets Federal specification O-S-571 F, Type II (LITE®) and III (Dense). It also meets American Well Water Assocation Standard B201-87. Photographic-grade sodium carbonate complies with the standards specified by the American Standard Institute PH 4.227-1974. Food-grade sodium carbonate is covered by the Food Chemicals Codex.

Industry Structure

The U.S. soda ash industry is composed of six companies; five in Wyoming and one in California. All produce natural soda ash only either from sodium carbonate-rich brines or from underground mining of trona ore. Foreign investment in U.S. soda ash operations has risen from 10% of capacity in 1981, when Societe Nationale Elf Aquitaine of France bought Texasgulf Chemical Co., to 46% in 1993. Five of the six U.S. companies have either Australian, Belgian, French, or Japanese partners. FMC Wyoming Corp. remains the only U.S. producer without any foreign ownership. The refinancing of the Harris Chemical Group in late 1993 resulted in terminating the share held by Oriental Chemical Industries of the Republic of South Korea. *(See tables 2 and 3.)*

Geology-Resources

The definitions of resources, reserves, and reserve base are published in U.S. Geological Survey Circular 831, Principles of a Resource/Reserve Classification for Minerals. Briefly, "resources" describe the quantity of ore present, regardless of grade or ease of extraction. The "reserves" are the portion of the resource that are economic to mine using the current technology and value of the commodity.

There are numerous sodium carbonate-bearing mineral occurrences throughout the world; however, only 95 deposits in 26 countries have been geologically evaluated.[1] Although several of these deposits have been quantified, most are economically insignificant or too remote to be commercially developed. The largest and the most economically significant deposit is the trona deposit in southwest Wyoming. All soda ash deposits can be classified in one of five modes of occurrences. In decreasing order of economic importance, they are as follows: buried, surface or subsurface brines, crystalline shoreline or bottom crusts, shallow lake bottom crystals, and surface efflorescences.

There are 14 sodium carbonate-bearing minerals that contain varying percentages of sodium carbonate. They are, in descending order of sodium carbonate content (with bicarbonate converted to carbonate), thermonatrite, 85.5%; Wegscheiderite, 74.0%; trona, 70.4%; nahcolite, 63.1%; bradleyite, 47.1%; pirssonite, 43.8%; tychite, 42.6%; northupite, 40.6%; natron, 37.1%; dawsonite, 35.8%; gaylussite, 35.8%; shortite, 34.6%; burkeite, 27.2%; and hanksite, 13.6%.

The trona found in the Green River Formation in southwest Wyoming is an excellent example of a buried trona deposit. The Wilkins Peak Member contains 42 beds of trona, 25 of which have a thickness of 0.91 meter (3 feet) or more. Eleven of these exceed 1.83 meters (6 feet) in thickness covering an area more than 3,100 square kilometers (1,200 square miles). The trona beds were deposited about 50 million years ago in the early to middle Eocene epoch in an ancient freshwater lake, named "Lake Gosiute" by Clarence King in 1878. The sodium and carbonate constituents of trona owe their respective origins to the leaching of the extensive pyroxene-andesite volcanic ash layers and the seasonal influxes of carbonate-rich sediments into the local depositional basin. In addition, subterranean thermal springs contributed a significant quantity of dissolved alkaline carbonates as well as sodium, calcium, silica, and bicarbonate ions. Trona can precipitate only in the presence of abundant carbon dioxide, which probably was supplied from the atmosphere and/or the biogenic decay of Eocene plant and aquatic remains. For 4 million years, Lake Gosiute went through many stages of filling and evaporation, thereby depositing more than 42 beds of trona on the lake bottom along with repetitive beds of marlstone, limestone, oil shale, and sandstone-mudstone. The decrease of the inflow to the lake was probably in response to climatic changes that resulted in the final evaporation of the waters. The former Lake Gosiute is the present Green River Basin.

Assuming 1.8 tons of trona yields approximately 1 ton of soda ash, about 47 billion tons (52 billion short tons) of identified soda ash resources could be obtained from the 56 billion tons (62 billion short tons) of bedded trona and the 47 billion tons (52 billion short tons) of interbedded or intermixed trona and halite that are in beds greater than 1.22 meters (4 feet) thick. Approximately 34 billion tons (37 billion short tons) of reserve base soda ash could be obtained from the 36 billion tons (40 billion short tons) of halite-free trona and the 25 billion tons (27 billion short tons) of interbedded or intermixed trona and halite in beds more than 1.83 meters (6 feet) thick. Although about 15 million tons (16 million short tons) of trona is presently being mined annually, with these minable reserves Wyoming could supply all domestic requirements for more than 3,100 years at the 1991 demand level. As technology improves in the future, mining of the subeconomic grades of ore would further extend the life of the trona deposit to more than 5,100 years. With Wyoming reserves estimated at 20 billion tons (22 billion short tons), the United States, through this one deposit, could supply the world all the soda ash to meet the current demand levels for about 630 years.

The U.S. Government established a Known Sodium Leasing Area (KSLA) in Wyoming within the perimeter of the trona depositional basin. The trona within the KSLA is subject to Federal and State leasing regulations and private lease agreements. Although most of the leasable trona averages 93% sodium sesquicarbonate, several areas contain lower grade trona because of local depositional contamination along the lake margins, thereby reducing the reserve estimates of that particular area.

A series of Pleistocene playa lakes rich in evaporate minerals found in California comprise the second largest reserves of sodium carbonate in the United States. Subsurface sodium carbonate-bearing brines and crystalline material comprise the resource at Searles Lake, which is a nearly dry playa 15 kilometers (9 miles) long by 11 kilometers (7 miles) wide with an area of about 104 square kilometers (40 square miles). Surface sodium-bearing crystalline minerals predominate at Owens Lake, which was first mined in 1885 by the Inyo Development Co. Both deposits have combined reserves of about 817 million tons (900 million short tons).

Two potential sources of soda ash—nahcolite (natural sodium bicarbonate) and dawsonite (sodium-aluminum-carbonate)—are associated with oil shale in the Piceance Creek basin in northwest Colorado. Identified resources of 29 billion tons (32 billion short tons) of nahcolite and 17 billion tons (19 billion short tons) of dawsonite, equivalent to 18 billion tons and 6 billion tons (20 billion short tons and 7 billion short tons), respectively, of sodium carbonate resources, would be available as a byproduct of oil shale processing or as single mineral extraction. These deposits were formed in middle Eocene time with the nahcolite occurring as aggregates (62%), disseminated crystals (24%), and impure beds (14%).

The only other commercial natural soda ash deposit in the Western Hemisphere, excluding those in the United States, occur at Lake Texcoco, near Mexico City, Mexico. Two caliche layers at a depth of 46 meters (150 feet) act as a filter and reservoir for the sodium carbonate-rich brine resource. With an average concentration of about 7% sodium carbonate, the resource contains about 180 million tons (200 million short tons) of available soda ash.

The Rift Valley of eastern Africa has several alkaline lakes resembling those of California. Only Lake Magadi in Kenya is presently in production. The soda ash reserves of these lakes are renewed annually from natural active volcanic sources. Other African countries that may become future suppliers of soda ash are Chad, Ethiopia, Niger, the Republic of South Africa, Tanzania, and Uganda. Botswana developed its Sua Pan salt and soda ash deposit in 1991. Elsewhere, deposits of natural soda ash occur in Bolivia, Brazil, Canada, India, Pakistan, the former U.S.S.R., and Venezuela. Plans are under way to develop deposits in China at Xilin Gol and in the Wulan Buh desert area. A trona deposit in Turkey near Beypazari also has been under consideration for development with several companies conducting exploration, drilling, and market feasibility studies.

Technology

Soda ash from Wyoming trona is mined, crushed, dried, dissolved, filtered, recrystallized, and redried. In California, soda ash from sodium carbonate-bearing brines is solution mined, carbonated, filtered, dried, decomposed, bleached, and recrystallized to dense soda ash.

Exploration.—Because of the scarcity of economic soda ash deposits in the world, many nations continue to search for new prospects. Smaller and less well-known deposits often are reevaluated by different groups at different times and with usually the same results. As new techniques of exploring are developed and used, such as Landsat satellite remote sensing imagery and side-scanning radar, new deposits may be discovered.

In the United States, exploring for soda ash continues. An area near the junction of the Black's Fork and Green River in southwest Wyoming has potential. Some of the ground water near Farson, WY, contains dissolved trona and organic matter creating a "black trona water." In Oregon, a few companies have expressed interest in evaluating the sodium carbonate deposits at Summer Lake and Abert Lake, which are near several pulp and paper manufacturers. These manufacturers have traditionally obtained their soda ash and caustic soda pulp-bleaching chemicals from Wyoming and Washington producers, respectively. As soda ash and caustic soda prices increase and overland transportation costs rise, these Oregon deposits may have commercial significance because their locations are nearer to the pulp markets.

Mining.—Commercial mining of Wyoming trona began in 1948, with the first mining on Federal land commencing in 1950. Between 1950 and 1993, more than 253 million tons (279 million short tons) of trona (equal to about 141 million tons or 155 million short tons of soda ash) has been mined. Only about 0.8% of the 36 billion tons (40 billion short tons) of halite-free trona reserve base has been used since mining began.

Underground mining of Wyoming trona is similar to coal mining, except that trona is a harder mineral than coal. The five present Wyoming soda ash producers use room-and-pillar, longwall, shortwall, and solution mining techniques individually or in combination. The room-and-pillar method has an ore extraction efficiency rate of about 45% (55% of ore remains as pillars for structural integrity), the longwall and shortwall methods each have efficiency rates of about 75%, and solution mining has an efficiency rate of about 30%. These rates are important when calculating the amount of reserves that are minable. Based on the types of mining techniques, the author used a 60% average extraction efficiency rate to calculate reserves (remaining 40% stays in-place as pillars for structural integrity and unavailable for present extraction). The ore is undercut, drilled, blasted, mucked, crushed, and transported to the surface by well-established methods and various state-of-the-art mining equipment. The conventional blasting method using prilled ammonium nitrate and fuel oil (ANFO) is a standard and reliable method. Continuous mining uses vehicles equipped with a rotating cylindrical cutter. Continuous miners are used by Tg Soda Ash, Inc., in its shortwall technique. The longwall technique was used by General Chemical (Soda Ash) Partners and is now used by FMC Wyoming Corp. Adopted from coal mining use, the longwall method uses a special track-mounted shearer that moves in front of a hydraulic-operated roof support system.

FMC has pioneered the use of solution mining to dissolve and recover deeply buried trona. Using an array of injection and recovery wells, a solvent (dilute sodium hydroxide) is introduced under pressure to dissolve the underlying trona. This technique has had moderate success since its first commercial debut in 1985. Beginning in 1990, FMC used the majority of the output from its solution mining for the manufacture of caustic soda, from which some sodium cyanide was produced.

To reduce mining costs and maintain their competitiveness in the world, many Wyoming soda ash companies implemented continuous belt and mobile track conveyor systems to transport trona underground more efficiently. This new haulage system has replaced ore-carrying shuttle cars, reduced the mine work force, and increased the quantity of ore mined per shift. Companies also have been considering eliminating conventional mining but retaining other mining methods sometime in the foreseeable future to further reduce labor, safety, and other operating costs.

Subterranean brines between 15 and 107 meters (50 and 350 feet) below the surface at Searles Lake in California are extracted using an array of injection and recovery wells drilled down to specific depths where mineral concentrations favor maximum extraction. The Argus plant of North American Chemical Co. uses sodium carbonate-rich brines found in the Mixed Layer zone 67 meters to 95 meters (220 feet to 310 feet) below the surface. Solar concentration ponds are used to aerate and concentrate the brine to improve processing efficiency.

Processing.—Crushed trona is calcined in a rotary kiln at 163° to 204° C (325° to 400° F) to dissociate the ore by the monohydrate process, which produces only dense soda ash with carbon dioxide and water as byproducts. The calcined material is combined with water to dissolve the soda ash and to allow separating and discarding of the insoluble material such as shale and shortite by settling and/or filtration. The waste material is piped in a slurry to containment basins, also known as tailing ponds. The resulting clear liquid is concentrated as necessary by triple-effect evaporators or mechanical vapor recompression crystallizers, and the dissolved soda ash precipitates as crystals of sodium carbonate monohydrate, $Na_2CO_3 \cdot H_2O$. The crystallization temperature is about 100° C (212° F), which is below the transition temperature of monohydrate to anhydrous soda ash. Other dissolved impurities, such as sodium chloride or sodium sulfate, remain in solution. The crystals and liquor are separated by centrifugation. The sodium carbonate monohydrate crystals are calcined a second time at 300° F to remove water of crystallization. The resultant finished product is cooled, screened, and shipped by rail or truck in bags or bulk.

An alternate method of soda ash production from trona is the sesquicarbonate process. Crushed trona is first dissolved and filtered to remove insoluble impurities. The liquor is evaporated in vacuum crystallizers, and the sodium sesquicarbonate precipitate is cooled to 38° C (100° F) and centrifuged to produce a pure product, which has uses as such. The sesquicarbonate can be further calcined at 204° C (400° F) to produce anhydrous soda ash of light to intermediate density.

The complex brines of the lower level of Searles Lake are first treated with carbon dioxide gas obtained from the gases emitted from the calciners and from the monoethanolamine (MEA) towers that process the powerplant flue gases into purified CO_2. The carbon dioxide gas reacts with the brine in carbonation towers to convert the sodium carbonate in solution to sodium bicarbonate, which will precipitate under these conditions. The sodium bicarbonate is separated from the remainder of the brine by settling and filtration and is then calcined to convert the product to light soda ash. The decarbonated brine is cooled to recover borax and Glauber's salt. The light soda ash is fed to rotary bleaching units that operate at 427° C to eliminate any residual organics. The product is concentrated and conveyed to sodium monohydrate crystallizers operating at 88° C to produce larger sized crystals. The material is screened, dewatered, washed, and dried and dehydrated in steam tube dryers at 260° C. The final product is 99.7% sodium carbonate.

At Owens Lake in California, crude soda ash has been mined and processed by Lake Minerals Corp. by simply digging perimeter channels that allow the interstitial fluids to drain. The surface was tilled to promote evaporation to reduce moisture content, followed by harvesting with front-end loaders.

At Lake Magadi, Kenya, crude trona is dredged from surface crusts, crushed, washed, and calcined to convert the sodium sesquicarbonate to soda ash. At Lake Texcoco in Mexico, underground brines were recovered and sent to a surface spiral concentrator to promote the solar concentration of the sodium carbonate in solution. On the Kola Peninsula in Russia, soda ash is recovered from processing nepheline-bearing rocks. Nepheline, a sodium-potassium-aluminum silicate, is calcined in rotary kilns to yield alumina, potash, and soda ash. The alumina content of the rocks is about one-half that of bauxite but the mining and processing produces byproduct soda ash. The Petukhi and Tanatar (Mikhaylovskiy) natural soda ash lakes in Altay Kray of West Siberia provide some source of natural product.

Synthetic soda ash using the Solvay process uses salt and limestone as raw materials. A purified sodium chloride brine is saturated with ammonia and carbon dioxide gas to produce ammonium bicarbonate, which reacts with the salt to form sodium bicarbonate and ammonium chloride. The sodium bicarbonate is calcined at 177° to 218° C (350° to 425° F) to light soda ash, and the gases produced are recycled back to the liquid phase. The liquid containing ammonium chloride is reacted with milk of lime to recover the ammonia and to produce byproduct calcium chloride. Limestone and coke are required to make the milk of lime. Dense soda ash is produced by hydrating light ash to produce larger sodium carbonate monohydrate crystals. The crystals are dehydrated in dryers to change the bulk density. To produce 1.0 ton of synthetic soda ash requires about 2.8 tons of steam, 1.7 tons of salt, 1.4 tons of limestone, 0.6 ton of coal for the boilers, and about 0.2 ton of coal for the dryers. Disposition of effluent streams containing high concentrations of calcium chloride and sodium chloride is a major problem for all Solvay soda ash plants. The Solvay process discharges about 1.7 tons of waste products that include sodium chloride and calcium chloride.

Other chemical processes can produce synthetic soda ash. In Japan, an ammonium chloride coproduction process, a variation of the Solvay process, is used to convert all the sodium content of the salt into soda ash, whereas the Solvay process converts only about 70% of the sodium. The Japanese process also produces byproduct ammonium chloride that can be used as a fertilizer for growing rice in wetlands. The New Asahi process also was developed in Japan and uses less energy than the traditional Solvay process. An electrolysis-free process to produce vinyl chloride monomer with coproduct soda ash was developed in the Netherlands but has not been in commercial operation. The method yields soda ash instead of caustic soda and uses steam and carbon dioxide instead of electricity. The energy consumption is reported to be one-half that of the Solvay process.

Recycling.—There is no recycling of soda ash by producers; however, many glass container manufacturers are using cullet glass, thereby reducing soda ash consumption.

Byproducts and Coproducts

Borax, potassium chloride, sodium chloride, and sodium sulfate are produced as coproducts with soda ash by North American Chemical in California. In Wyoming, only value-added products, such as sodium bicarbonate, sodium hydroxide (caustic soda), sodium sesquicarbonate, sodium sulfite, and sodium tripolyphosphate, are produced from trona ore. Soda ash-bearing purge liquors and waste streams, normally considered waste byproducts, have been sold to powerplants for flue gas desulfurization because of their sodium carbonate content.

Substitutes

Sodium hydroxide can be substituted for soda ash in some applications, but usually only at a higher cost and when available. About 1.3 tons of soda ash must be used to have the same chemical effect as 1.0 ton of caustic soda. Soda ash is usually shipped in dry, bulk form whereas caustic soda is transported as a liquid in various-sized closed containers.

An alternate source of soda ash is nahcolite, natural-occurring sodium bicarbonate found in a vast deposit in Colorado. The nahcolite could be converted to soda ash by calcination.

Economic Factors

Prices.—The list prices of natural and synthetic soda ash historically were identical until the mid-1970's when higher energy costs and costs to implement the controls imposed by antipollution legislation caused the synthetic soda ash price to increase compared to that of the natural material. New natural soda ash producers came on-stream in 1976 and 1982 and contributed to slight changes in price-value trends. Changes in the domestic demand pattern also affected average annual values, especially after 1980, when domestic demand declined.

The list prices quoted in trade journals or by producers differ from the annual average values reported to and by the U.S. Bureau of Mines. The values are the combined total revenue of California and Wyoming natural bulk, dense soda ash sold on an f.o.b. plant basis at list-prices, spot prices, discount, long-term contracts, and for export, divided by the quantity of soda ash sold. This value may or may not correspond to the posted list prices.

Tariffs.—The United States imposes a 1.2% ad valorem tariff on imports of soda ash from countries having most-favored-nation (MFN) status. There is a 8.5% ad valorem tariff on imports from non-MFN sources.

Many nations levy import tariffs or antidumping duties of varying percentages on U.S. soda ash. In Western Europe, an antidumping duty of 67.5 European Currency Units (about $67.13 per ton) had been imposed on U.S. soda ash sold on the continent; however, the duty was rescinded in late 1990. Import tariffs in some other countries in 1993 were as follows: India, 112.75%; Philippines, 25%; Australia, 12.50%; Argentina, 10.50%; Brazil, 10%; Mexico, 10%; Taiwan, 10%; Thailand, 10%; Colombia, 10%; Republic of South Korea, 8%; Indonesia, 5%; Japan, 3.9%; and Malaysia, 2%. Some of these duties will decline over time.

Although the United States sought to obtain as its highest priority in the Uruguay Round of the General Agreement on Tariffs and Trade (GATT) negotiations a zero-for-zero tariff elimination, the tariff proposal was not accepted. A compromise was to be introduced in early 1994 that would harmonize several chemical tariffs to 5.5% over various periods of time depending on the present rate of duty in a particular GATT country. This was known as the Chemical Tariff Harmonization Agreement (CTHA). Under this agreement, the 10% duty on imports into the European Union [EU—formerly the European Community (EC) as of November 1, 1993] would be reduced to 5.5% by July 1999. The planned rate of reduction is: July 1995 to 9.34%; July 1996 to 8.38%; July 1997 to 7.42%; July 1998 to 6.46%; and July

1999 to 5.5%.

Taxes.—The total effective tax rate on the Wyoming trona industry is about 12.64% and comes from two major taxes. The trona severance tax of 5.5% is a State excise tax on minerals as they are removed from the ground and are applied as a percentage of assessed valuation. The collected taxes are disbursed to the Permanent Wyoming Mineral Trust Fund (2.0%), the General Fund (2.0%), and the Capital Facilities Revenue Account (1.5%). The property, or ad valorem, tax is about 7.14% of the assessed value of trona produced from the mines. The ad valorem taxes on trona are higher than any other Wyoming minerals, including oil, gas, and coal. Other ad valorem taxes are placed on the assessed value of real property (buildings and equipment) and State sales and use taxes on equipment and facilities.

Royalties.—Soda ash mined on Federal lands is subject to the Mineral Leasing Act of 1920, which provides royalty payments to the U.S. Government. The Federal royalty is 5% of the quantity or gross value of the output of the product at the point of shipment to market. Each Federal lease also has other costs, such as bonds, acreage rental fees, sodium prospecting permit application fees, and permit bonds.

In Wyoming, the soda ash deposit within the KSLA is under the jurisdiction of the U.S. Government [administered by the Bureau of Land Management (BLM)], the State, and the Union Pacific Railroad, which was given alternate 0.4-hectare (1-square-mile) sections north and south of the railway it constructed in the 1860's. Of the almost 370,301 hectares (915,000 total acres) of sodium mineral estate, the Federal ownership is 55.7%, Union Pacific, 38.1%; and the State, 6.2%. Sixteen lessees hold 53 active and inactive Federal leases having a total of 306,669 hectares (75,783 acres). To prevent a possible land monopoly, no lessee may hold more than 6,216 hectares (15,360 acres) of Federal land, but may lease more private or State land. The State royalty rate is tied to the Federal rate of 5%; however, the private royalty rate varies. One-half of all Federal royalties collected by the Minerals Management Service is disbursed back to Wyoming for various State and local programs.

An effort was made in December 1992 to raise the Federal royalty rate from 5% to 8% on all new Wyoming sodium leases and any to be renewed. The proposed action was opposed by all five Wyoming soda ash producers and the issue continued into early 1993 when the BLM evaluated the comments raised by the industry before implementing the recommendation. After further study, the BLM, in August, recommended that the royalty rate should be increased to 8% and the proposal was forwarded higher within the U.S. Department of the Interior for final endorsement; however, no decision was made by yearend.[2]

In California, the Federal Government maintains 33 sodium mineral leases having 10,846 hectares (26,799 acres). The major lessee is North American Chemical Co., which produces soda ash, sodium sulfate, and borax on its sodium leases on Searles Lake. Salt also is produced on-site by Pacific Salt Co.

Depletion Provisions.—The mineral depletion allowance granted to the mining industry through legislation passed by the U.S. Government has been an important inducement for companies willing to accept the risk and high cost of mining development. The concept of depletion allowances for minerals is similar to the depreciation of other assets. Although cost depletion and percentage depletion are two methods used to compute depletion deductions, most companies prefer to use the latter. About 100 mineral categories are entitled to percentage depletion. The rates range between 5% and 22% of the gross income from the mineral property, depending on the mineral and location (foreign or domestic), and are subject to a limitation of 50% of the net income from the property. The significance of percentage depletion is that the deduction is based on the quantity of the first marketable product (soda ash and not trona) and not necessarily on the amount invested. The mineral depletion allowance for soda ash is 14% for U.S. companies mining from domestic or foreign sources.

Operating Factors

Operating factors are different for mining companies than for manufacturing facilities engaged in producing natural soda ash and synthetic soda ash, respectively. The shift in U.S. soda ash production from synthetic to natural has been caused by higher costs attributed to the greater energy and labor requirements of the Solvay process and to environmental regulations. Within the natural soda ash industry, the operating factors vary for producing the commodity from brines and from trona ore.

Environmental Requirements.—U.S. natural soda ash facilities do not have difficult problems disposing of effluents. Residual insoluble material is piped to surface tailing ponds and allowed to settle. Some soda ash in solution that is not economically recoverable from processing is discharged and is converted to sodium decahydrate in the ponds and precipitates on the bottom of ponds to become an additional source of soda ash if needed. For example, FMC has been dredging some of its sodium decahydrate that has been accumulating since 1950. Some pond water is recirculated into the mines and used as drilling and cutting coolant. Because of changes in environmental legislation in Wyoming, Solvay Minerals Inc. has begun discharging its waste material into abandoned sections of its underground mine, thereby using less surface area on the surface for tailing ponds. The expense of underground discharge is partially offset with the reduction in costs of constructing and maintaining surface tailing ponds.

The alkaline surface ponds, with a pH up to 10.5, have posed some problems for migratory fowl that land on the ponds. The alkaline solutions strip the insulative natural oils from the feathers, thereby increasing the vulnerability of the birds to death from hypothermia. Also, birds have drowned because of the weight of sodium decahydrate that crystallizes on them when the temperature falls below 4° C (40° F). All trona producers have established a rehabilitation program to recover and release contaminated birds and to minimize the mortality and morbidity rate.

Land surrounding trona operations in Wyoming is relatively undeveloped, and the influx of large numbers of workers has caused great strain on the local facilities for housing, schools, shopping, and entertainment. Soda ash companies have provided financial assistance to aid local government in handling any overloads caused by the migration of their employees and families into the community. The companies have given financial aid to employees purchasing homes in the surrounding communities and other fringe benefits such as low-cost transportation to and from work.

Toxicity.—Although soda ash is not considered a highly toxic substance, contact with the eyes may be injurious and prolonged contact with the skin may cause irritation, especially to those who have allergic reactions to alkaline materials. It also has been found to be corrosive to the stomach lining if ingested. It has an acute oral lethal dose (LD50) of 2.8 grams per kilogram (when tested on a rat) and a primary skin irritation index (PSII) of 2.54 (when tested on a rabbit). Simultaneous exposure to soda ash and lime dusts should be minimized because in the presence of moisture, as from perspiration, the two materials combine to form caustic soda, which is very harmful. Soda ash is not flammable, and the dust is not explosive.

Employment.—According to a survey conducted by the U.S. Bureau of Mines, the Wyoming soda ash industry employed 1,191 people in the 5 trona mines and 1,540 people in the soda ash refineries in 1993. The total quantity of trona mined by these workers was 14,491,288 tons in 1993. Of the five Wyoming companies, only FMC and General Chemical are unionized. The workers are represented by United Steelworkers Union Local 15320.

Energy Requirements.—Natural soda ash plants consume considerably less energy per unit of product produced than do synthetic soda ash facilities. As the cost of energy has increased since the 1973 energy crisis, the differential in production costs between natural and synthetic soda ash has become greater. Excluding energy costs to transport the material to market, this is one of the major reasons why U.S. natural soda ash has maintained its competitiveness in the world market and why several synthetic soda ash producers have expressed interest in obtaining a partnership or ownership in the U.S. soda ash industry.

An early U.S. Bureau of Mines energy study using 1973 data indicated that 15.8 million British thermal units (Btu's) was required to produce 1 ton of synthetic soda ash, whereas the energy requirement to produce the same quantity from trona was 7.2 million Btu. The domestic soda ash industry has reduced its energy requirements significantly since 1973 by replacing gas-fired dryers with steam-tube units and installing mechanical vapor recompression units to replace triple-effect evaporators. The industry has also converted to coal exclusively or combined with other fuel sources. Plants operated by Tg and Solvay Minerals and the Argus plant operated by North American Chemical Co. use coal only. As a result of these energy-saving measures, the Wyoming soda ash industry lowered its energy requirement to a range of 4.5 to 6 million Btu, depending on the individual producer. An estimated one-half of the energy consumed in natural soda ash refining using triple-effect evaporators is for evaporating, one-third is for calcining, and the remainder, for drying.

These energy requirements exclude the amount of energy needed to ship soda ash to foreign markets. Although it has been estimated that it would take about 2.9 million Btu of additional energy to transport soda ash by rail and by ship to Western Europe, nevertheless natural soda ash production requires less energy than the Solvay process or any other synthetic technique.

Transportation.—The western geographic locations of the domestic natural soda ash industry often pose problems because of the great shipping distance to most foreign customers. Even within the United States, the majority of domestic consumption is in the Midwest and east of the Mississippi River. Overland and ocean transportation rates become important factors in the delivered price of soda ash and must be considered seriously in negotiations with foreign consumers who often have alternate supply sources. Bulk freight rates usually can be reduced by shipping in larger volumes, such as in 7,500-ton unit trains.

The railroad is the dominant mode of transportation for the shipment of soda ash. In Wyoming, the Union Pacific Railroad provides the main service to the industry. All bulk soda ash that is railed is carried in covered hopper cars, each handling about 98 tons. Although the railroad companies make their cars available, most soda ash companies have their own sizable fleet.

Beginning in 1985, soda ash was shipped in large quantities by truck. Bonneville Transloaders, Inc. trucked soda ash from Green River to the Burlington Northern Railroad's line at Shoshoni, WY. Of the almost 8.4 million tons (9.2 million short tons) of soda ash produced in Wyoming, Bonneville trucks about 770,000 tons (850,000 short tons) out of Green River. Other trucking companies have started similar operations with the Southern Pacific (shipping more than 227,000 tons or 250,000 short tons per year) and Denver Rio Grande Railroads to compete with Union Pacific.

The railroad companies have been involved in establishing soda ash bulk loading terminals at ports to handle large volumes of material for export. Kansas City Southern Railroad's terminal at Port Arthur, TX, has a railcar unloading capacity of about 1,000 tons per hour. Material is conveyed to a ship loader spout for transfer to bulk cargo ocean vessels. Port Arthur was the third largest port of the 24 ports that shipped soda ash in 1993, most of which was shipped to South America. The Columbia-Snake customs district in the Pacific Northwest has a bulk loading terminal that transported the most soda ash in 1993, 70% of the U.S. total exports. Asia, Europe, and South America were the three largest regions that received soda ash through this customs district.

ANNUAL REVIEW

Issues

There has always been competition between natural soda ash and synthetic soda ash production beginning in the 18th century with soda ash extracted from the burnt remains of seaweed and the manufactured product obtained from the Leblanc process. For the next 200 years, natural soda ash mined from mineral deposits has competed with that derived by newer chemical processes, such as the Solvay process. This competition became very evident in the early 1980's when the European industry sought to limit imports from the United States by successfully appealing to the then EC Commission [name changed to European Union (EU) effective November 1, 1993] for an antidumping investigation. This ultimately resulted in the imposition of an antidumping duty that remained in place until late 1990 when the Commission rescinded the duty after it conducted its own investigation of the European producers that showed they effectively restricted trade opportunities with U.S. producers.

Many foreign synthetic soda ash producers now have become advocates of having a presence in the Green River natural soda ash community. With the European producers' acquisitions or partnerships of some of the U.S. facilities (Societe Nationale Elf Aquitaine of France owning Tg Soda Ash, Rhône Poulenc of France owning 51% of Rhône-Poulenc Basic Chemical Co., and Solvay S.A. of Belgium owning 80% of Solvay Minerals Inc.), the international competitive situation has begun to change. Approximately 38% of the Wyoming soda ash production capacity was European-owned in 1993 (Tg Soda Ash with 1.3 million short tons, Rhône-Poulenc with 1.17 million short tons, and Solvay with 1.6 million short tons). Highlighting this membership is Solvay S.A., the world's foremost leader in soda ash production and experience. With Solvay's announcement to close facilities in Belgium and Germany, other European producers followed with similar statements. Chemische Fabrik Kalk and Matthes und Weber closed their plants in Germany. Ironically, the Matthes and Weber plant was sold to the U.S. company North American Chemical Co. Indications of further closings in Europe continued at yearend. In addition, Solvay and Rhône-Poulenc have been negotiating for taking majority ownership of the two plants in Poland. Lastly, the French Government included Rhône-Poulenc and Elf Aquitaine in its list of 21 state-owned companies that it intends to sell in a privatization effort. The global restructuring of the world soda ash industry of the 21st century has begun.

In the first half of 1993, the major domestic issue was the proposed increase in the Federal royalty rate on Wyoming soda ash. The BLM announced that it intended to raise the rate from 5% to 8% on all new leases and those up for renewal. The increase was proposed because there has not been any change in the Federal royalty rate in more than 30 years; the increase would bring the Federal rate up to that of the Union Pacific Railroad, which is the other major land owner in the area; and the increase would generate additional Federal and State revenue. All five Wyoming soda ash producers opposed the proposal and submitted their comments to the BLM for review. The producers cited declining demand in the United States and in certain export markets, especially in Western Europe, as the major reason for opposing any increase at this time and felt a 3% increase in the rate was unjustified. The BLM conducted a thorough study of the issue and by August had recommended to follow through with the royalty rate increase.[3] The final decision was to be made by higher authority within the U.S. Department of the Interior; however, no decision had been made by yearend.

The important issue of the last half of 1993 pertained to the formal antidumping investigation by the European Commission. The complaint was submitted in June through the European Chemical Industry Council by five of the six European synthetic soda ash producers. The European producers claimed that they lost market share by price undercutting by U.S. exporters. Allegedly, the U.S. share of the EU market has risen from 1% in 1990 to 11.3% in 1992. Rumors of an impending investigation began earlier in the year caused a decrease in soda ash shipments from the United States. By yearend, the U.S. export market to Europe had declined by about 400,000 tons compared with 1992. A final decision by the Commission was expected by April 1994.[4]

Production

U.S. production of natural soda ash from California and Wyoming decreased 4% to 8,959,059 tons. The U.S. soda ash industry operated at 81% of total nameplate capacity in 1993. Most of the decrease in production was because of reduced export sales to Europe. A total of 96,336 tons of soda ash equivalent from soda liquors and mine waters was included in the total and used primarily for neutralizing powerplant process water. The liquors represent a growing market for soda ash producers and provide additional revenue. In addition, 134,863 tons of soda ash equivalent was used to manufacture chemical caustic soda by FMC, Solvay Minerals, and Tg Soda Ash. There was 14,491,288 tons of trona mined in Wyoming in 1993.

FMC Wyoming Corp.'s expansion of 545,000 tons (600,000 short tons) that it announced in 1992 was put on hold for 1 year pending final evaluation of other projects.[5] Owens Lake Soda Ash Co., the joint venture between Vulcan Materials Co. and Lake Minerals Corp., a subsidiary of Cominco American Inc., continued with its efforts to design and construct a 545,000-ton (600,000-short-ton) soda ash refinery at Owens Lake, CA. The company completed a draft environmental impact report on its project and applied for its permit applications with State and Federal agencies.[6] The Wold Trona Co. was formed in June 1993 with plans to construct a beneficiated trona facility with an annual capacity of 1.13 million tons (1.25 million short tons). An underground mine would provide the surface refinery with raw material that would be beneficiated using a dry process, resulting in a final product containing 96% to 98% sodium carbonate suitable for certain customers that do not require high-purity soda ash. The material also could be converted to chemical caustic soda to compete with chemical caustic soda produced by three of the Wyoming soda ash firms and electrolytic caustic soda manufactured as a coproduct from chlorine production. Construction of the project was planned to begin as early as mid-1995 with production scheduled for late 1997.[7]

About 480 mine workers of the United Steelworkers Union Local 15320 of General Chemical Corp.'s Green River mine went on strike on August 2 because of health care benefits. There also were disagreements with the company's retirement plan. The plant continued to operate using 160 salaried employees from some of General's other chemical plants and headquarters. The strike ended on November 22 with the ratification of a new 3-year contract. The effect of the strike had virtually no impact on the production of soda ash during this time period.[8]

Consumption and Uses

U.S. apparent consumption and reported consumption in 1993 remained virtually the same as that in 1992. The discrepancy between the two forms of consumption was attributed to disagreement between the sources of export data used to derive consumption statistics. The two sources were the Bureau of the Census, which reports exports upon departure from the U.S. port, and the soda ash producers, who consider a shipment as exported when their export association, the American Natural Soda Ash Corp. (ANSAC), takes charge at California or Wyoming plant sites. Transit times between the plant and port, which can take about 2 to 3 weeks before the cargo is actually exported, and carryover export inventories contribute to the discrepancy between reported and apparent consumption as well.

The recovery of the domestic economy in late 1993 was indicated by increased soda ash sales to the flat glass sector for the domestic construction and automobile manufacturing industries. The industrial building construction industry consumed about 57% of all flat glass made, whereas the automotive glass sector used 25%. Based on reported industry sales, the manufacture of flat glass products increased 3.8% in 1993 compared with 1992 and rose 10.8% from 1991, according to the Bureau of the Census. Glass container shipments increased 2.7% in 1993 from that of the previous year and rose 4.2% from 1991. Glass container production, however, rose only 1.8% in 1993 from that of 1992. Figure 1 shows the domestic production of glass containers and flat glass from 1989 through 1993. The economic recovery of the domestic construction and automotive industries is shown with the rise in the flat glass sector beginning in the third quarter of 1993. *(See figure 1.)*

Glass manufacture represented about 49% of domestic soda ash consumption, with the container sector comprising 28%; flat, 14%; fiber, 4%; and specialty, 3%. The other end uses include chemicals (primarily sodium bicarbonate, sodium chromates, sodium phosphates, and sodium silicates), 23%; soap and detergents, 13%; distributors, 5%; flue gas desulfurization and miscellaneous, 3%; and pulp and paper and water treatment, 2% each. *(See table 4.)*

Detergents are the third largest use of soda ash. Soda ash is used as a builder to emulsify oil stains, reduce the redeposition of dirt during washing and rinsing, provide alkalinity for cleaning, and soften laundry water. In addition, soda ash is a component of sodium tripolyphosphate (STPP), another major builder in detergent formulations, but soda ash consumption has been decreasing because phosphatic detergents can contribute to the environmental problems of eutrophication. Many regions of the Nation have adopted phosphate limitations or bans. These areas represent about 40% of the U.S. population. In response to the environmental issue, detergent manufacturers began reformulating their detergents to make compact and superconcentrated products. The reformulations require sodium silicates and synthetic zeolites, which are made from soda ash. Liquid detergents, which do not contain any soda ash, compete with powdered detergents and command 40% of the household laundry detergent market, up from only 15% in 1978.

Stocks

Yearend stocks of dense soda ash in domestic plant silos, warehouses, terminals, and on teamtracks amounted to 274,302 tons. Producers indicate that a potential supply problem could exist when inventories fall below 180,000 tons. Most consumers of soda ash do not have storage facilities to accommodate large quantities of soda ash and must rely on suppliers to provide the material on a timely basis. The majority of the U.S. soda ash producers that have been exporting to Europe have several foreign warehouses for product storage. These warehouses serve the needs of most foreign soda ash consumers that purchase U.S. soda ash.

Markets and Prices

About two-thirds of U.S. soda ash production is consumed domestically, with the remainder dedicated for export sales. In the domestic market, the large volume buyers of soda ash are primarily the major glass container manufacturers, whose purchases are seasonal (more beverage containers made in second and third quarters for summertime beverage consumption). Soda ash sales to the flat glass sector are usually dependent on the state of the economy because the largest use of flat glass is in automobile manufacture and residential housing and commercial building construction. These two major industrial sectors are especially sensitive to changing economic conditions. If construction starts and automobile sales are up, soda ash sales will proportionally follow.

The average annual value for dense natural soda ash, f.o.b. Green River, WY, and Searles Valley, CA, was $81.95 per ton ($74.34 per short ton), which was an 8% decrease from that of the previous year. The value is not a "price"; it is the value of the combined revenue of California and Wyoming bulk dense soda ash sold on an f.o.b. plant basis at list prices, spot prices, discount, long-term contracts, and for export, divided by the quantity of soda ash sold. The list price for Wyoming bulk, dense soda ash remained at $98 per short ton while the California price for the comparable product held at $123 per short ton. *(See table 5.)*

Foreign Trade

U.S. soda ash exports declined 5% in 1993 to 2.79 million tons. U.S. exports to 50 countries, on a regional basis, were as follows: Asia, 46%; South America, 18%; Europe, 16%; North America, 11%; Oceania, 3%; Africa and the Middle East, 2% each; and Central America and the Caribbean, 1% each. The biggest change was with Europe, which represented 23% of export shipments in 1992. The reason for the decline was primarily because of the antidumping investigation initiated by the European soda ash industry.

The six domestic members of ANSAC renewed their commitment to promoting U.S. export sales by signing a new 10-year agreement. ANSAC has been very successful in expanding the export market and will continue to increase sales to Africa, Asia, and the Middle East.[9] ANSAC negotiated with Saleh & Abdulaziz Abahsain Co., Ltd., to be the exclusive distributor for ANSAC in Saudi Arabia. A warehouse with a storage capacity of 10,000 tons will be located in Dammam, Saudi Arabia, for shipment within the Kingdom or to surrounding nations.

The U.S. soda ash industry was found guilty of dumping in the early 1980's by the EC Commission that resulted in the imposition of an antidumping duty of 67.5 European Currency Units (about $67.13 per ton). An investigation by the Commission in 1991 of the European soda ash producers found that the European industry conspired to restrict trade initiatives with the United States in the early 1980's. The producers were fined $64 million, and the antidumping tariffs on U.S. soda ash were removed in late 1990. Although soda ash export sales to all of Europe in 1992 rose to 689,348 tons; a 1,586% increase from that of 1980, exports in 1993 were 445,196 tons—a 35% decrease from that of the previous year. *(See tables 6, 7, and 8.)*

World Review

Industry Structure.—The largest consumers of soda ash tend to be the developed nations; however, these countries also usually have lower growth rates compared to developing countries that have greater demands for consumer products. Although the production and consumption quantities vary among the countries, the end-use patterns are basically the same (e.g., glass, chemicals, and detergents are the major sectors). Although the United States is the largest soda ash-producing country in the world, foreign ownership in the U.S. soda ash industry is presently 46% of nameplate capacity.

Ten countries have the capacity to produce more than 1 million tons annually. They are, in descending order, the United States, China, Russia, Germany, India, Japan, France, Romania, Bulgaria, and Ukraine. Most of these countries have large populations that require consumer products made with soda ash. The lesser developed nations tend to have greater soda ash demand and higher rates of growth as soda ash-consuming industries are developed. *(See table 9.)*

Capacity.—World soda ash production capacity is about 35 million tons divided among 36 countries. Approximately 70% of world capacity is synthetic soda ash and 30% is natural. The United States represents 30% of world capacity and 95% of the total natural capacity.

The largest soda ash company in the world, excluding state-owned facilities, is Solvay S.A. of Belgium. With its acquisition of Tenneco Minerals' natural facility in Wyoming in 1992, it operates 10 plants in 8 countries and has a combined annual capacity of about 6.07 million tons. With the announced closure of two of its plants by yearend 1993, Solvay's total will decrease by 600,000 tons. FMC Wyoming Corp. of the United States is the second largest company, with 2.59 million tons (2.85 million short tons) of capacity.

Albania.—Although there was no written confirmation of the action, the synthetic soda ash plant at Vlora reportedly closed during 1993. The plant had an annual production capacity of about 30,000 tons.

Australia.—Penrice Soda Products announced that it plans to expand capacity by 25% to 500,000 tons by 1996. The goal was to export 40% of total production to various Asian markets that are forecast to grow in the next decade. The project was expected to cost $20 to $30 million.[10]

Belgium.—On May 24, 1993, at 12:00 a.m., Solvay of Belgium issued a press release that formally stated that it would close its synthetic soda ash plant at Couillet during 1993. This announcement is of historical significance because this facility was the first Solvay plant built in the world. It was constructed in 1864 by Ernest Solvay, the founder of the company that bears his name. Competition from Bulgaria, Romania, and the United States was cited as the reason for the closure of this facility and Solvay's other plant in Heilbronn, Germany. The Belgian operation had a production capacity of about 350,000 tons per year. Workers went on strike at the Couillet plant after negotiations regarding the forthcoming layoffs of 185 workers broke off. About 270 employees were affected by the closure. Both facilities accounted for about 10% of Solvay's total capacity.[11]

China.—In a move to become more efficient, 18 soda ash manufacturers merged to form Suda Alkali Industrial Corp. The organization has a combined capacity of 4.46 million tons per year.[12]

Colombia.—Industry sources indicate that its last synthetic soda ash plant closed sometime during 1993. Colombia imported more than 74,000 tons from the United States in 1993, almost double from the 38,000 tons imported in 1992.

France.—Rhône-Poulenc stated that it planned to invest $7.1 million to convert almost all of the light soda ash to dense soda ash at its plant in Nancy. The improvement would provide the company the opportunity to serve the glass and detergent sectors that are growing in France and Germany.[13]

Germany.—Solvay announced the closure of its plant in Heilbronn by yearend that had an annual capacity of 250,000 tons. Problems with raw material sourcing and its relative small size contributed to the closure. The operation employed 270 workers.[14] In addition, Chemische Fabrik Kalk, which was owned by BASF subsidiary Kali und Salz, announced it would close its soda ash plant at Cologne by yearend. The facility had a capacity of 300,000 tons per year. The operation encountered similar problems like those at Heilbronn—small size and dependent on more expensive transported rock salt as feedstock. Increased use of cullet, glass imports, and rising environmental costs also were cited as reasons for the closure.[15] The company arranged to continue to supply its customers soda ash obtained from a long-term contract with Rhône-Poulenc, which would provide the material from either of its plants in Nancy, France, or Green River, WY. Rhône-Poulenc's natural soda ash from the United States would be available from the terminal at Zeebrugge in Belgium.[16]

In December, the soda ash plant operated by Matthes und Weber at Duisburg was sold to the Harris Chemical Group that owns North American Chemical Co. at Searles Lake in California. The facility has an annual soda ash capacity of 270,000 tons. The operation was to be closed by Matthes und Weber until the acquisition occurred. The Harris Chemical Group plans to modernize and consider expanding the product line. Most of the output is consumed by Matthes' parent company, Henkel, for detergent manufacture. About two-thirds of synthetic soda ash production is light ash with the remainder being dense soda ash. Chemische Fabrik Kalk's plant that closed is about 55 kilometers from Duisburg; therefore, there may be opportunities to sell into that surrounding market.[17]

India.—Nirma Chemical Works Pvt. Ltd., an Indian detergent manufacturer, was considering constructing a synthetic soda ash plant at Una in Gujarat. The project would have a capacity of 300,000 tons annually and would supply feedstock for the detergent plant. Humphreys and Glasgow Consultants in Bombay were selected as contractors in the proposed $210 million project that was planned to be on-stream by 1997.[18]

Iran.—Plans were announced to expand the dense soda ash facility at Shiraz. Alexanderwerk of Germany will be the primary contractor. The plant has a present production capacity of 60,000 tons per year.[19]

Mexico.—Production of natural soda ash from Lake Texcoco outside Mexico City ceased in August, according to reliable industry sources; however, the event was unrecorded by the trade publications. Production from this deposit, which was the only other commercial natural soda ash operation outside of the United States that operated in the Western Hemisphere, was estimated at about 160,000 tons annually.

United Kingdom.—Brunner Mond, which operates two synthetic soda ash plants at Lostock and Winnington, announced it would invest $7.5 million to construct a new dense soda ash plant at its Lostock facility. The expansion was to come on-stream by January 1995. More than $4.5 million was spent to install new process control equipment at Mond's Winnington plant.[20]

OUTLOOK

The antidumping investigation that began in mid-1993 resulted in reduced exports to Europe, causing an oversupply situation in the U.S. soda ash industry. In terms of operating efficiency, the domestic soda ash industry operated at 81% of nameplate capacity. A flat domestic market and reduced export sales contributed to the decline in the 1993 average value of soda ash. If the European Commission rules in favor of the U.S. producers (of which 38% of the Wyoming producers are European-based companies or European soda ash producers), it is anticipated that U.S. exports will rebound in the near future and exceed that of the alltime record of 2.96 million tons that was set in 1992. The U.S. industry is optimistic that both the domestic and foreign economies are recovering, signaling an improvement in general soda ash sales.

Exports

Despite the setback in exports to the European market, the outlook for U.S. soda ash exports remains optimistic. The two largest exporting organizations in the world are Solvay and ANSAC, which includes Solvay as a member. From its strategic location in Wyoming, Solvay is poised to penetrate markets in Asia, Central America, and South America that would be economically inaccessible from its European bases. Although ANSAC is prohibited from exporting to the European Union nations, the six individual U.S. soda ash producers will continue to strive to increase exports to that region pending a successful outcome to the antidumping investigation. Market conditions in Europe remained stagnant at yearend; however, economic recovery should begin in early 1994. The strength of the U.S. dollar relative to European currency and the decrease in the European soda ash sales price will probably lessen U.S. soda ash export sales for the short term. Because of the higher cost structure of manufacturing synthetic soda ash, it is doubtful that the European sales price can remain low for very long before it has an adverse economic affect on the producers. The gradual reduction in the import duties in the EU promulgated by the GATT negotiations will assist U.S. soda ash exporters by the end of the century.

Figure 2 shows a comparison of the top 18 countries the United States exported to during 1993. These nations represented 76% of the total export market. It is interesting to note that the bulk of the exports went to nations with some of the lowest import duties, ranging between 2% and 10%. Exports of less than 100,000 tons were to countries with import duties more than 10%. Using economic data from various Federal agencies, figure 3 lists the top 13 countries that imported U.S. soda ash and the respective nations' gross domestic product (GDP). The majority of the countries were emerging economies in Asia and South America. Of a total estimated world GDP of $19.746 trillion (foreign GDP converted to U.S. dollars), these nations represented 26% of the total world GDP. Most of these countries are targeted to expand their industries that produce consumer products such as glass, chemicals, and detergents. These developing nations have a greater demand for soda ash than many of the developed countries, such as the United States and several countries in Europe. Only Japan, with a GDP approaching $2.5 trillion, was the standout nation with a large GDP and a major soda ash importer. With no natural salt resources to supply feedstock to its soda ash refineries, Japan has started to change its position from being an exclusive soda ash producer to being a consumer supplying itself with product shipped from its U.S. partnerships in the Wyoming soda ash industry. It is foreseeable that Japan may choose to close at least one of its five facilities operating in Japan because of rising raw material costs and environmental considerations.

Because soda ash is considered to be a mature chemical commodity that tends to grow parallel population trends, future growth opportunities are favorable in areas with modest population growth rates, such as some of the countries shown in figure 4, which are the same ones previously discussed in terms of exports and GDP. Of these 13 nations, future growth in soda ash consumption appears favorable in Indonesia, Mexico, the Philippines, Thailand, and Venezuela. Many of the Southeast Asian markets are growing as a result of economic and technical outreach initiatives initiated by changes in the social and political institutions in those countries. These areas represent a tremendous export potential in the future for the U.S. soda ash industry. Some of the current import duties in these Asian countires that are in excess of 10% will decline as a result of the GATT treaty.

Export opportunities to the Middle East and South America also are very favorable. In addition, it is likely that some South American production capacity could be reduced as certain countries examine the operating economics of some facilities. Argentina, Brazil, Colombia, and Venezuela are probable areas for future growth in soda ash consumption. *(See figures 2, 3, and 4.)*

Glass

U.S. consumption of soda ash in the glass container sector declined for the sixth consecutive year because of (1) the increasing use of cullet; (2) the national interest in recycling; and (3) the continuing competition with polyethylene terephthalate (PET) plastic containers.

The United States is becoming more concerned about the environment than in previous years. The volume of waste accumulating in municipal landfills is a growing national problem. Glass reportedly accounts for 8.4% of disposable household waste. Glass recycling has been increasing with the average recycling rate approaching 38% nationally. Although the recycling of glass has had an adverse effect on soda ash consumption, industry sources indicate that the impact has leveled and that soda ash consumption should begin to stabilize in the glass container sector. In flat glass usage, the construction and automotive sectors are beginning to recover from the economic downturn that began earlier in the decade. Figure 5 shows the estimated quantity of glass used in U.S.-built automobiles since 1976. More glass was used per vehicle in 1993 than in the past 17 years—approximately 40.14 kilograms of glass per automobile. The quantity of glass as a function of total vehicle weight also has risen since 1976. In 1993, 2.8% of the automobile was glass, based on an average vehicle weight of 1,429 kg (3,149.5 pounds). In 1976, only 2.3% of the vehicle weight was glass, using an average vehicle weight of 1,706 kg (3,760.5 pounds). The increase in flat glass usage is reflected in the rise in soda ash sales, as shown in table 4. It is expected that this sector will remain strong throughout the next 2 years.

Although the outlook for the U.S. soda ash industry is very good, the structure of the industry continues to change as foreign participation increases. The United States will remain an important supply source of inexpensive natural soda ash for international consumption. However, a growing percentage will be shipped by the foreign partners of the U.S. resource—primarily Australia, Belgium, France, and Japan. More shares of the U.S. soda ash industry are available for joint venture at the present time. *(See figure 5.)*

^{e}Estimated. ^{r}Revised. NA Not available.

[1] Natural and synthetic except where noted.

[2] Natural soda ash only for 1987 and thereafter; natural and synthetic from yearend 1983-86.

[3] Also known as apparent consumption (production plus imports minus exports plus or minus stock changes) and is equal to "Total U.S. primary demand."

[4] Estimated consumption for 1983-86 was based on industry sources; reported consumption 1987 and thereafter were from quantitative and qualitative quarterly surveys of producers' sales. Other end-use categories were incorporated in the survey.

[5] Includes soda ash used in petroleum and metal refining, leather tanning, enamels, etc. Also includes data in categories indicated by "NA."

[6] Because end-use data prior to 1987 were estimated, industrial demand and U.S. primary demand calculations (both based on production, trade, and inventory data) were assumed to be equal to total U.S. consumption. Beginning with 1987, reported consumption data by end-use often disagreed with derived apparent consumption calculations that necessitated, including an "Undistributed" category account for the discrepancies. These discrepancies are because of the fluctuating balance of inventory in transit from plants to domestic or export destinations, and unsold foreign inventories of U.S. producers.

[7] Values are the combined total revenue of California and Wyoming natural, bulk, dense soda ash sold on an f.o.b. plant basis, at list prices, spot prices, discount, long-term contracts, and for export, divided by the quantity of soda ash sold. This value may or not be synonymous with the posted list prices of the commodity. Implicit price deflator for gross domestic product used to derive constant 1993 dollars, 1987=100.

	Total production	8,994,717	9,156,036	9,004,790	9,378,883	8,959,059

[r] Revised.

[1] Includes soda ash equivalent from soda liquors, purge liquors, and mine water sold to powerplants for water treatment: 95,027 tons in 1989, 111,894 tons in 1990, 117,289 tons in 1991, 137,433 tons in 1992, and 85,084 tons in 1993.

[2] Data are from the Bureau of the Census and may vary from the quantity reported by the producer and/or importer. Actual imports are proprietary data but have been distributed into appropriate end-use categories and included in "Total domestic reported consumption."

[3] Reported consumption data do not agree with apparent consumption data shown in tables 1 and 3 because of dissimilar sources of export data. The data vary because of different reporting periods, overland transit time between plant and port, and carryover export inventory.

[4] As reported by producers. Includes Canada. Data may not necessarily agree with that reported by the Bureau of Census for the same periods.

[5] Revised from monthly Mineral Industry Surveys data because of 181 metric tons (200 short tons) of misreported exports data in first quarter 1989.

[6] Represents soda ash from domestic origin (production and inventory changes) and imports, and for exports.

[7] An extra 23,548 metric tons (25,957 short tons) of coproducer sales is included in total, but specific end-use breakout is unknown.

TABLE 5

SODA ASH YEAREND PRICES

		1992	1993
Sodium carbonate (soda ash):			
Dense, 58%, Na_2O 100-pounds, paper bags, carlot, works, f.o.b.	per short ton	$146.00	$146.00
Bulk, carlot, same basis tons	do.	98.00	98.00
Light 58%, 100-pounds, paper bags, carlot same basis	do.	151.00	151.00
Bulk, carlot, same basis tons	do.	103.00	103.00

[1] Less than 1/2 unit.

[2] Data representing imports from the United States as reported by Statistics Canada, International Trade Division.

[3] Formerly part of Yugoslavia.

[4] The majority was bagged and transshipped to China.

[5] Dissolved in Apr. 1992.

[6] Data may not add to totals shown because of independent rounding.

Source: Bureau of the Census and Statistics Canada, as adjusted by the U.S. Bureau of Mines.

TABLE 8

U.S. IMPORTS FOR CONSUMPTION OF SODA ASH

Year	Disodium carbonate[1]	
	Quantity (metric tons)	Value[2] (thousands)
1989[3]	128,790	17,396
1990	145,534	20,495
1991	134,312	21,299
1992	71,663	12,772
1993	88,930	17,084

[1] Beginning in 1989, import data were reclassified under the Harmonized Commodity Description and Coding System (HS Code No. 2836200000). Prior years were classified under the Tariff Schedule of the United States, Annotated, TSUSA No. 4208400 (calcined) and No. 4208600 (hydrated and sesquicarbonate).

[2] C.i.f. value at U.S. ports.

[3] Also contains sodium carbonate, hydrated and sesquicarbonate.

Source: Bureau of the Census.

SODIUM SULFATE

By Dennis S. Kostick

Mr. Kostick, a physical scientist with 15 years of U.S. Bureau of Mines experience, has been the commodity specialist for sodium sulfate since 1979. Domestic survey data were prepared by Maria Arguelles, statistical assistant; and international data tables were prepared by Doug Rhoten, international data coordinator.

Sodium sulfate ranked 47th of the 50 major nonfuel inorganic chemicals produced in the United States in 1993 according to a national survey.[1] Although it is an unfamiliar compound to most people, sodium sulfate is used to make several consumer products used by virtually everyone, such as detergents, brown paper bags, textiles, and glass. Sodium sulfate is produced from naturally occurring brines or crystalline mineral sources and as a byproduct from different chemical processes. Natural sodium sulfate is produced from mineral deposits found in California and Texas. It is also found as a constituent of saline lakes, such as the Great Salt Lake in Utah. Synthetic sodium sulfate is recovered as a byproduct from various manufacturing processes. Both types of sodium sulfate have several important and useful applications in various consumer products.

DOMESTIC DATA COVERAGE

Domestic production and inventory data for natural sodium sulfate are developed by the U.S. Bureau of Mines from monthly and annual surveys of U.S. operations. Of the three natural sodium sulfate operations to which a survey request was sent, all responded, representing 100% of the natural sodium sulfate data used in this report.

Synthetic sodium sulfate data were collected by the U.S. Department of Commerce, Bureau of the Census, from quarterly and annual surveys (aggregate data published in Current Industrial Reports, Inorganic Chemicals, MQ28A and MA28A) of companies engaged in recovering and selling byproduct sodium sulfate. Any revised Census Bureau data have been included using most recent Census Bureau statistics. These data are aggregated with U.S. Bureau of Mines natural sodium sulfate data and included in several tables. *(See table 1.)*

BACKGROUND

Natural sodium sulfate was known to have been used as a medicine as early as the 16th century. It was first accurately described in 1658 by Johann Rudolf Glauber, a German chemist whose name is still associated with the hydrated crystal, Glauber's salt ($Na_2SO_4 \cdot 10H_2O$), and the anhydrous mixed sulfate, Glauberite ($Na_2SO_4 \cdot CaSO_4$).

Glauber and other researchers prepared sodium sulfate by reacting common salt with sulfuric acid. The invention of the Kraft process for making pulp and paper in 1880 provided the first major industrial market for sodium sulfate.

Definitions, Grades, and Specifications

The following terms are used in the sodium sulfate industry:

Anhydrous Sodium Sulfate.—Refined sodium sulfate or the mineral thenardite (Na_2SO_4). Named for the French chemist, Louis Jacques Thenard, thenardite is a colorless to white mineral with a specific gravity of 2.67 and a hardness of 2.5 to 3. Because of its whiteness and purity, it is used in detergents, pharmaceuticals, dyestuffs, glass, and ceramic glazes. Commercial-grade material has a bulk density of about 1.23 grams per cubic centimeter (77 pounds per cubic foot).

Byproduct Sodium Sulfate.—Synonymous with synthetic sodium sulfate. It is recovered as a byproduct from various chemical and textile manufacturing processes.

Glauber's Salt.—Same as the mineral mirabilite (Latin "sal mirabile" or "wonderful salt"), sodium sulfate decahydrate ($Na_2SO_4 \cdot 10H_2O$). The mineral contains 55.9% water of crystallization and forms opaque to colorless needlelike crystals.

High Purity.—Refers to anhydrous sodium sulfate with a purity of 99% or greater. Usually sold to detergent, glass, and textile industries.

Low Purity.—Some processes occasionally produce sodium sulfate that does not meet certain physical or color specifications required by certain consumers despite being a chemically pure product. This grade of sodium sulfate is generally sold to sectors that are not as concerned about whiteness or particle size, such as the pulp and paper industry, at reduced prices.

Natural Sodium Sulfate.—Sodium sulfate obtained from mining crystalline sodium sulfate-bearing minerals or from sodium sulfate-bearing brines.

Salt Cake.—Normally refers to impure sodium sulfate containing 90% to 99% Na_2SO_4. Because of its impurity or possible discoloration, it usually is sold only to the pulp and paper industry.

Synthetic Sodium Sulfate.—Same as byproduct sodium sulfate.

Sodium sulfate made from natural brine usually contains less than 0.5% total impurities, but that produced as a byproduct of other manufacturing may contain much larger quantities. The material meeting U.S. Pharmacopeia (U.S.P.) specifications and that intended for glassmaking must contain at least 99% sodium sulfate. In addition, glassmakers' grade must be low in iron and heavy metals. Technical grades of sodium sulfate may have from 2% to 6% impurities. Purchases of detergent- or rayon-grade sodium sulfate are based primarily on whiteness. Its sodium chloride content may be between 1.5% and 2.0%, and its iron content between 60 and 100 parts per million.

Industry Structure

Three companies produced natural sodium sulfate from a total of three plants in California, Texas, and Utah. The domestic natural sodium sulfate industry supplied about one-half of the total output of U.S. sodium sulfate. Because of the location of these plants, most natural sodium sulfate is marketed in the West and southern Gulf coast areas of the Nation. Byproduct material was supplied by 14 companies operating 15 plants primarily in the Midwest and Mid-Atlantic regions. Total rated production capacity in 1993 was 780,000 tons, and the industry operated at 85% of this capacity. *(See table 2.)*

Geology-Resources

Sodium is the sixth most abundant element in the Earth's crust. Sodium sulfate-bearing mineral deposits are geologically young, mainly of postglacial age. Sodium sulfate is widespread in occurrence and is a common component of seawater and many saline or alkaline lakes. Economic reserves of natural sodium sulfate are estimated at 3.3 billion metric tons worldwide. With world production of natural sodium sulfate averaging about 1.8 million tons per year, supplies are sufficient to meet anticipated demand for several centuries. The quantity of synthetic sodium sulfate is dependent on the longevity of the manufacturing firms recovering byproduct sulfate.

Surface depressions or lakes that have no outlets and are fed by spring waters flowing over volcanic rocks containing sulfide minerals commonly yield soluble sulfide salts that are oxidized by contact with the air to produce sulfates. Some minerals over which the spring water may flow contain the sulfates directly, such as bentonite or gypsum. When an inland lake of this type evaporates and becomes highly concentrated in salts, one of the first salts to precipitate would be mirabilite, also known as Glauber's salt, which has very poor solubility at low temperatures. During seasonal temperature variations, the sulfate will precipitate preferentially to the lake bottom.

Thenardite and mirabilite are the only sodium sulfate minerals that are commercially important. Many economic deposits of sodium sulfate are in the form of crystalline beds of mirabilite such as those found in Canada and the former U.S.S.R., which has the world's largest sodium sulfate resource in the Kara-Bogaz-Gol Gulf. Because mirabilite converts to thenardite when exposed to air, its outer surface may develop a thenardite crust. Some buried sedimentary formations contain very large deposits of thenardite and glauberite, such as the deposit in Villarrubia de Santiago in Spain.

Sodium sulfate is also found dissolved in underground brines in California, Texas, and other parts of the world. The sulfate is usually converted to mirabilite when extracted from the brine by mechanical refrigeration techniques. *(See table 3.)*

Technology

The technology to mine and process natural sodium sulfate involves mechanical refrigeration or natural chilling to induce crystallization followed by dissolution, filtration, evaporation, and drying. Recovery of byproduct sodium sulfate from chemical processes involves various techniques.

Mining.—Sodium sulfate is extracted from the upper level of the Searles Lake brine in California and is treated separately from the carbonate-rich lower level and mixed layer brines. The subterranean sodium sulfate-bearing brines in western Texas are the simplest of the domestic brine deposits. Mechanical refrigeration is used to extract Glauber's salt crystals from the brine. The Great Salt Lake in Utah also contains valuable quantities of sodium sulfate. Brine from the most concentrated northwest segment of the lake is pumped into solar evaporation ponds on the eastern shore of the lake where sodium chloride first precipitates as the water evaporates. Sodium sulfate crystals precipitate in a fairly pure state when winter weather cools the brine to -1° to 4° C (30° to 40° F). The crystals are picked up by large earth-moving machinery and stored outdoors until further processing to anhydrous sodium sulfate can take place.

Processing.—At Searles Lake, the brine is first cooled at about 16° C (60° F) to precipitate borax crystals, which are removed from the system for subsequent further processing and sale. A second cooling to about 4° C (40° F) precipitates the sodium sulfate in the form of Glauber's salt. These crystals are separated from the brine on a rotating drum filter. They are then redissolved in fresh water in a vacuum crystallizer. After the second separation and drying, the crystals are about 98.2% sodium sulfate. Additional treatment can obtain a 99.3% purity. Major impurities remaining are sodium chloride, sodium carbonate, and boron.

In Texas, after the crystals are processed in rotary drum vacuum filters and washed, they are melted and dehydrated using mechanical vapor recompression evaporators, which are more energy efficient than triple-effect evaporators or submerged gas burners. Final classifying, centrifuging, drying in rotary kilns, and screening converts the Glauber's salt to marketable anhydrous sodium sulfate of 99.7% purity.

Purification and dehydration procedures at the facility on the Great Salt Lake are similar to those of other sodium sulfate plants. The purity of the final product is between 99.5% to 99.7%.

Sodium sulfate also is produced as a byproduct of the production of ascorbic acid, boric acid, cellulose, chromium chemicals, lithium carbonate, rayon, resorcinol, and silica pigments. It also is recovered from certain flue gas desulfurization operations. The Mannheim and Hargreaves furnace processes also produce byproduct sodium sulfate. In the Mannheim furnace, salt and sulfuric acid are reacted to form hydrogen chloride (HCl) and sodium sulfate. The Hargreaves furnace produces HCl and sodium sulfate by the reaction of sulfur dioxide, sodium chloride, air, and water. The Mannheim process is the major method used in Europe, but its use in the United States has decreased considerably since less expensive methods to produce HCl became available.

Recycling.—Because of environmental concerns regarding sulfur emissions from pulp and paper mills, many Kraft pulpers were installing pollution abatement equipment to reduce sulfur losses in the pulping process. This will result in more sodium sulfate being recycled and less used in batch makeup solutions.

Byproducts and Coproducts

The brines of Searles Lake in California contain sodium sulfate as well as coproduct borax, potassium chloride, sodium chloride, and soda ash. The Great Salt Lake in Utah is a source of magnesium compounds, potassium sulfate, sodium chloride, as well as sodium sulfate. There are no secondary products produced from the brines in Texas.

Some manufacturers of ascorbic acid, boric acid, cellulose, chromium chemicals, lithium carbonate, rayon, resorcinol, and silica pigments produce sodium sulfate as a byproduct of the process. The sodium sulfate is considered a waste product but has marketability.

Economic Factors

Prices.—Producers of natural sodium sulfate tend to market and sell most of their own product, but most synthetic producers use major chemical distributors or chemical supply companies as sales agents. The principal product made and sold by the synthetic sodium sulfate producer is the primary economic factor. Because sodium sulfate is considered a waste product, it will be sold at a price that ensures prompt sales. This practice tends to set the rates at which the natural product can be sold.

The list prices quoted in trade journals or by producers of all grades of sodium sulfate differ from the annual average values reported by the U.S. Bureau of Mines. The value represents the combined amount of total revenue of domestic natural sodium sulfate sold at list prices, spot prices, long-term contracts, discounts, and export divided by the aggregated quantity of sodium sulfate sold. The published value does not necessarily correspond to the posted list price. *(See table 4.)*

Tariffs.—Import tariffs serve to protect the interests of domestic producers for particular products. For sodium sulfate, a 32.5-cents-per-ton tariff is imposed on imported anhydrous sodium sulfate from countries having most-favored-nation (MFN) status and $2.95 per ton from those with non-MFN status. There are no import tariffs on imported salt cake, regardless of the country of origin. The non-MFN countries in 1993 were Afghanistan, Albania, Azerbaijan, Belarus, Cuba, Georgia, Kampuchea, Kazakhstan, Laos, North Korea, Romania, Tajikistan, Turkmenistan, Uzebekistan, and Vietnam.

Royalties.—Sodium sulfate mined on Federal lands is subject to the Mineral Leasing Act of 1920, which provides for royalty payments to the U.S. Government. The royalty is 5% of the quantity or gross value of the output of the product at the point of shipment to market. Each Federal lease also has other costs, such as bonds, acreage rental fees, sodium prospecting permit application fees, and permit bonds. The Searles Lake sodium sulfate deposit is the only resource with active operations that has any Federal leases. Because of the variety of the brine constituents, the operator has a commingling agreement with the U.S. Government to compute royalties.

Depletion Provisions.—Legislation passed by the U.S. Government provides an allowance for the depletion of natural resources, notably timber and minerals. The depletion allowance is an important inducement for companies willing to accept the risk and high cost of mining development. The concept of depletion allowances for minerals is similar to the depreciation of other assets. Although cost depletion and percentage depletion are two methods used to compute depletion deductions, most companies prefer to use the latter. About 100 mineral categories are entitled to percentage depletion. The rates range between 5% and 22% of the gross income from the mineral property, depending on the mineral and location (foreign or domestic), and are subject to a limitation of 50% of the net income of the property. The mineral depletion allowance for natural sodium sulfate is 14% for U.S. companies mining from domestic or foreign sources.

Operating Factors

Operating factors are different for mining companies producing natural sodium sulfate compared with manufacturing facilities recovering byproduct sodium sulfate. The quantity of synthetic sodium sulfate recovered is directly associated with the production capabilities of the primary industry (e.g., rayon, lithium carbonate, etc.) and the sulfate recovery rates.

Environmental Requirements.—Land usage may become a problem when sodium sulfate is obtained by solar evaporation, as in the case of the Great Salt Lake brines. Large areas of relatively flat land are required to allow for adequate concentration and evaporation. When land values are high, the capital required for land acquisition may increase operating costs. Disposal of the waste liquors from which sodium sulfate was extracted may develop into a major ground water discharge problem in some areas. Reinjection of spent solutions into underground source strata is expensive but often is the only acceptable method of disposal.

Because sodium sulfate is water-soluble, most releases of sodium sulfate to the environment affect water quality rather than air or land quality. These releases are mainly from Kraft pulp mills, which typically discharge between 5,000 to 15,000 tons (5,500 to 16,500 short tons) of sodium sulfate per year per site. The resulting drinking water concentrations have been estimated as high as 38.8 milligrams per liter, which is significantly below the maximum concentration level of 250 milligram per liter set by the National Secondary Drinking Water Standard. Problems associated with chemical effluents discharged from manufacturing plants that recover sodium sulfate also have caused environmental concerns not attributed to sodium sulfate. The second largest byproduct sodium sulfate facility in the United States at Front Royal, VA, owned by Avtex Fibers Inc., was closed in late 1989 by Federal and State regulatory agencies because of contaminated water discharges containing carbon disulfide and polychlorinated biphenyls (PCB's). These toxic chemicals were produced from rayon manufacture, not sodium sulfate recovery.

Toxicity.—Sodium sulfate was deleted in early 1989 from the list of toxic chemicals under section 313 of Title III of the Superfund Amendments and Reauthorization Act of 1986. The U.S. Environmental Protection Agency determined that there was no evidence that sodium sulfate caused, or could reasonably be anticipated to cause, adverse human health or environmental effects as specified in the act.

Employment.—According to the Bureau of Labor Statistics and industry sources, approximately 300 persons are employed in mining and processing natural sodium sulfate in the United States. No data are available on the number of personnel employed in recovering byproduct sodium sulfate.

Energy Requirements.—The energy requirements to mine natural sodium sulfate are minimal compared with the amount of energy required to process it. An early U.S. Bureau of Mines energy survey reported that 4.5 million British thermal units (Btu's) was required to produce 1 ton of natural sodium sulfate. With the interest in conserving energy, some technical improvements, such as the installation of mechanical vapor recompression crystallizers, have reduced the overall energy requirement to slightly less than 2 million Btu's per ton of sulfate produced.

Transportation.—All natural sodium sulfate is shipped in bulk or in bags by either rail or truck. The mode of transportation depends on the location of the customer, quantity purchased, and difference in freight rates. Because of the location of the natural producers in the West and Southwest, very little natural sodium sulfate is shipped to the East because transportation rates reduce its competitiveness with synthetic sodium sulfate. Consumers in the Midwest and East tend to rely on synthetic sodium sulfate produced in various Midwest and Southern locations.

ANNUAL REVIEW

U.S. sodium sulfate production increased 6% in 1993 to 651,000 tons according to preliminary statistics from the Bureau of the Census. Production of natural sodium sulfate from three domestic locations declined 5% to 327,000 tons, which was the lowest level since 1958 when production was 315,000 tons. Output from byproduct sources increased 21% compared with that of the previous year. The increase in production was attributed to the improved national economic conditions that affected some of the industries that recover byproduct sodium sulfate. Although the United States is one of the largest producers in the world of natural and synthetic sodium sulfate, its share has decreased from 23% of world production total in 1980 to 15% in 1993.

Issues

Although there was excess supply of sodium sulfate during the first half of 1993, the situation changed in the last half of the year as inventories were reduced because of greater demand in the domestic textile industry and increased consumption by the domestic detergent manufacturers.

The U.S. Environmental Protection Agency issued a proposal that would reduce and prevent future discharges of dioxin and other toxic compounds from pulp and paper mills into rivers and other surface waters. About 350 pulp and paper mills would be affected, costing the industry $4 billion in capital expenses and $600 million to implement.[2] The proposal is to restrict chlorine-based bleaching chemicals and use oxygen-base bleaching chemicals for pulp delignification. Sodium chlorate and oxygen are the two preferred chemicals to use. The Rapson R8 process, which is the most widely used system in the pulp industry, uses sodium chlorate, sulfuric acid, and methanol to produce chlorine dioxide and byproduct sodium sulfate. The sodium chlorate can be produced on-site at various pulp mills. By producing their own sodium sulfate, certain pulp mills would not have to purchase any sodium sulfate, thereby reducing the demand for saltcake sold by the natural or byproduct sodium sulfate industry. In addition, sodium sulfite mills often sell their waste effluent that contains sodium sulfate to Kraft pulp mills for makeup saltcake.

Production

U.S. total sodium sulfate production increased 6% in 1993 primarily because of increased demand for detergent-grade sodium sulfate for powdered home laundry detergents and carpet freshener products, and increased demand by the textile industry.

Lenzing A.G. of Austria, which operates a rayon plant in Lowland, TN, and recovers byproduct sodium sulfate, announced plans at midyear to increase rayon production capacity by 25% in 1994. This would increase sodium sulfate recovery by about 8,000 tons annually.[3] *(See tables 5 and 6.)*

Consumption and Uses

Domestic sodium sulfate apparent consumption increased 22% from that of the previous year. Despite early concerns about potential supply shortages, the majority of the consuming sectors had sufficient quantities available. Most of the same economic conditions that affected demand in 1992 still remained in 1993. Imports for consumption of sodium sulfate, primarily from Canada, rose slightly to meet domestic demand requirements.

Sodium sulfate consumption by the soap and detergent industry, which has been the largest consumer of sodium sulfate, grew slightly in 1993. Sodium sulfate is used as an inert filler to provide bulk in powdered laundry detergents. Typical laundry detergent formulations historically had consisted of about 35% sodium sulfate but the quantity recently has shrunk to about 15%. The emergence of superconcentrated liquid detergents may erode some of the market held by powdered products. Dishwasher detergents, which contain about 28% sodium sulfate, are being challenged by concentrated dishwasher products. Another use of sodium sulfate in the detergent sector is the carpet deodorizer market. Approximately 10% of the North American detergent industry is represented by this market. About 40% of U.S. sodium sulfate demand is for detergents.

Sodium sulfate consumption remained stagnant in the Kraft pulping industry because of the economic recession affecting the paper industry, and recycling of paper products. Public awareness about the environmental issue of nondegradable plastic packaging made many people prefer brown paper grocery bags (produced by the Kraft process), which degrade in landfills much more readily than plastic bags. Kraft pulping represents about 25% of the total demand for sodium sulfate. As more pulp mills convert to sodium chlorate bleaching technology that produces byproduct sodium sulfate, less make up sodium sulfate will be sold by natural or other byproduct producers.

The use of sodium sulfate in textiles is increasing, especially in the Southeast. Salt traditionally has been used in the dyeing process to separate organic contaminants, promote "salting out" of dyestuff precipitates, and blending with dyes to standardize concentrated dyes. The equipment used in this process used stainless steel, which was susceptible to corrosion because of the salt. The textile industry began substituting the salt with sodium sulfate, which is not corrosive to the manufacturing equipment. Approximately 140,000 tons of sodium sulfate was consumed by the textile industry in 1993, accounting for about 19% of domestic sodium sulfate consumption. This sector is estimated to grow about 2% annually.

Stocks

Inventories of natural sodium sulfate stored at yearend 1993 by the three producers were 41,863 tons, which was a 11% decrease over that of the previous year. The material stockpiled was anhydrous sodium sulfate. Synthetic sodium sulfate was marketed mainly through major chemical distributors, which have separate storage facilities from the producers.

Markets and Prices

The average value declined to $76.53 per metric ton ($69.39 per short ton) in 1993 from $77.97 per metric ton ($70.73 per short ton) in 1992 for bulk sodium sulfate, f.o.b. mine or plant.

Giles Chemical Industries Inc., which acquired Ashland Chemical Inc.'s sodium sulfate business, announced a $5 per ton increase in its off-list price for bagged product, effective November 1, 1993. Its prices were $182 per short ton for 50-pound bags and $172 per ton for 100-pound bags, f.o.b. Atlanta, GA; $185 per ton for 50-pound bags, $180 for 100-pound bags, and $190 per ton for 2,000-pound supersacks, f.o.b. Baltimore, MD; and $171 per ton for 50-pound bags and $161 per ton for 100-pound bags, f.o.b. Lowland, TN.[4] *(See table 7.)*

Foreign Trade

U.S. exports of 89,000 tons were 43% lower in 1993 when compared with those of the previous year. Of the eight countries that crude sodium sulfate was exported to, Colombia received 31%, followed by Australia, 24%; Republic of Korea, 19%; and New Zealand, 9%. Eighteen nations imported anhydrous sodium sulfate from the United States. The major ones were Guatemala, 27%; Venezuela, 27%; Mexico, 18%; and Australia, 17%.

Total imports amounted to more than 163,000 tons in 1993; an increase of 3% compared with those of the previous year. Canada supplied virtually all of the U.S. imports of crude sodium sulfate. Canada also was the primary source of anhydrous sodium sulfate entering the United States through the Great Falls, MT, Pembina, ND, and Duluth, MN, customs districts. Some imports were received from Germany and the United Kingdom. *(See tables 8 and 9.)*

World Review

Industry Structure.—About 55% of the world sodium sulfate production in 1993 was from natural sources; the balance was represented by synthetic sodium sulfate recovered from various chemical and manufacturing processes. Although the U.S. Bureau of Mines collects or estimates data from 31 sodium sulfate-producing countries, other countries are known or assumed to have produced synthetic sodium sulfate, but production statistics are not reported, and available information is inadequate to make reliable estimates of output. *(See table 10.)*

Spain and the United States were the largest producers of total sodium sulfate, representing 18% and 15%, respectively, of the world total. Mexico produced 11%, followed by Canada, 7%; Japan, 6%; the former U.S.S.R., 5%; and Germany, 3%. These seven countries accounted for approximately 62% of the world's output of total sodium sulfate, based on obtainable production data.

Capacity.—The data in table 2 are rated capacities for domestic natural operations and byproduct recovering facilities in 1993. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable long-term operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure.

Mine capacity for natural sodium sulfate is derived from available company data on ore throughput to the refinery. The ore refers to mined crystalline sodium sulfate, harvested precipitate, or sodium sulfate-bearing brines. Refinery capacity for natural sodium sulfate pertains to the total amount of anhydrous sodium sulfate that the plant is capable of processing from the ore. Synthetic sodium sulfate-refining capacity is dependent on the production capabilities of the primary industry and the sodium sulfate recovery rates.

Canada.—Ormiston Mining and Smelting began small-scale production of soda ash at its Ormiston, Saskatchewan, natural sodium sulfate facility. The plant will use a new process to convert its surplus sodium sulfate into commercial-grade soda ash for use in Canada or in the United States.[5]

OUTLOOK

Sodium sulfate is a mature commodity that tends to follow the domestic economic trends. Supply of product in the short term will probably not be a problem for consumers as new capacity is scheduled to be online in 1994. For example, GNB Inc.'s new battery recycling center in Waynesboro, GA, will generate about 27,000 tons of byproduct sodium sulfate annually beginning in 1994. In addition, Lenzing A.G. will add another 8,000 tons of byproduct capacity when an expansion at its Lowland, TN, plant is completed, also in 1994.

U.S. consumption of sodium sulfate is expected to decline in the pulp and paper sector with the emergence of replacement technology to replace chlorine-based bleaching agents in pulp and paper production. Although sales to the textile industry have been favorable, this sector alone cannot compensate for overall declining sodium sulfate consumption.

[e]Estimated. [r]Revised.

[1] Includes natural and synthetic. Total production data for synthetic sodium sulfate, obtained from the Bureau of the Census, were revised in Feb. 1994 MQ28A Inorganic Chemicals, Current Industrial Report.

[2] The value for synthetic sodium sulfate is based upon the average value for natural sodium sulfate.

TABLE 2

U.S. PRODUCERS OF NATURAL AND SYNTHETIC SODIUM SULFATE IN 1993

Product and company	Plant nameplate capacity (thousand metric tons)	Plant location	Source
Sodium sulfate, natural:			
Great Salt Lake Minerals & Chemicals Corp.	45	Ogden, UT	Salt lake brine.
North American Chemical Co., Westend plant	218	Trona, CA	Dry lake brine.
Ozark-Mahoning Co.[1]	141	Seagraves, TX	Do.
Total	404		
Sodium sulfate, synthetic:			
Lenzing A.G.[2]	34	Lowland, TN	Rayon manufacture.
Courtaulds North American Inc.	45	La Moyne, AL	Do.
Flour Corp., Doe Run Co.	9	Boss, MO	Battery recycling.
4M Paper Corp.	6	Ft. Madison, IA	Pulping process.
FMC Corp.	41	Bessemer City, NC	Lithium carbonate.
Hoffman-La Roche Inc.	14	Belvidere, NJ	Ascorbic acid.
W. R. Grace & Co. Organic Chemicals Div.	8	Nashua, NH	Chelating agents.
J. M. Huber	32	Etowah, TN	Silica pigment.
Do.	14	Havre de Grace, MD	Do.
Indspec Chemical Corp.	35	Petrolia, PA	Resorcinol manufacture.
North American Rayon Corp.	14	Elizabethton, TN	Rayon manufacture.
Occidental Chemical Corp.	109	Castle Hayne, NC	Sodium dichromate manufacture.
Public Service of New Mexico	6	Waterflow, NM	Flue gas desulfurization.
Teepak, Inc.	6	Danville, IL	Cellulose manufacture.
Star Enterprise[3]	3	Delaware City, DE	Flue gas desulfurization.
Total	376		
Grand total	780		

[1] Ozark's Brownfield plant, owned by Atochem North America (formerly Pennwalt), was placed on standby in Sept. 1987; 64,000 tons of capacity is not included in total industry capacity.

[2] Acquired from BASF July 1992.

[3] Owned by Saudi Refining Inc. (50%) and Texaco Inc. (50%).

NOTE.—Climax Chemicals Co.'s Hobbs, NM, plant closed in 1992, and Cyprus Mineral Co.'s facility at Kings Mountain, NC, reportedly has been closed.

TABLE 3

WORLD NATURAL SODIUM SULFATE RESERVES AND RESERVE BASE

(Million metric tons)

	Reserves	Reserve base[1]
North America:		
Canada	84	272
Mexico	165	227
United States	857	1,361
Total	1,106	1,860
Europe:		
Russia	1,814	2,268
Spain	180	272
Total	1,994	2,540
Africa:		
Botswana	188	227
World total[2]	3,300	4,600

[1] The reserve base includes demonstrated resources that are currently economic (reserves), marginally economic (marginal reserves), and some of those that are currently subeconomic (subeconomic resources). These definitions of reserves and reserve base are published in U.S. Geological Survey Circular 831, "Principles of a Resource/Reserve Classification for Minerals."

[2] Rounded.

NOTE.—Resources of sodium sulfate are known to also exist in Antarctica, Argentina, Chile, India, Iran, Italy, Mongolia, Romania, the Republic of South Africa, and Turkey. Production of synthetic sodium sulfate is dependent on the supply and demand of the primary product.

TABLE 4

TIME-VALUE RELATIONSHIPS FOR SODIUM SULFATE

Year	Average annual value,[1] dollars per ton			
	Natural sodium sulfate			
	Actual value		Based on constant 1993 dollars[2]	
	Short ton	Metric ton	Short ton	Metric ton
1971	16.00	17.64	52.28	57.64
1972	16.26	17.92	50.67	55.84
1973	17.26	19.03	50.53	55.71
1974	23.99	26.44	64.60	71.19
1975	41.48	45.72	101.93	112.35
1976	49.25	54.29	113.85	125.50
1977	46.09	50.81	99.68	109.89
1978	46.06	50.77	92.35	101.79
1979	55.69	61.39	102.79	113.31
1980	62.42	68.81	105.25	116.03
1981	71.03	78.30	108.84	119.98
1982	83.00	91.49	119.75	131.99
1983	93.30	102.85	132.89	146.49
1984	92.16	101.59	125.78	138.65
1985	92.19	101.62	121.29	133.70
1986	86.11	94.92	110.37	121.53
1987	86.72	95.59	107.71	118.72
1988	78.81	86.87	94.21	103.84
1989	83.05	91.55	95.07	104.80
1990	87.66	96.63	96.09	105.93
1991	79.23	87.34	83.61	92.16
1992	70.73	77.97	72.54	79.92
1993	69.39	76.53	69.39	76.53

[1] Based on the average valuation by producers of their annual total production and reported sales. The values incorporate the price differences change by producers for the finished product sold in bulk at the plant.

[2] Final implicit price deflators for 1993 are based on gross domestic product and not gross national product, which was used previously. Based on 1987=100.

[e]Estimated. [r]Revised.

[1] Natural and synthetic except where noted. Synthetic sodium sulfate data obtained from the Bureau of the Census are revised periodically and may differ from previous published reports by the U.S. Bureau of Mines. World production data also are periodically revised on receipt of updated information.

[2] Natural sodium sulfate only.

[3] Estimated using data from "Chemical Profile" issues on sodium sulfate by Chemical Marketing Reporter for 1983, 1986, and 1989.

[4] Included with "Other" prior to 1992.

[5] Includes ceramics, chemicals (potassium sulfate, sodium hyposulfite, sodium sulfide, sodium silicate, and sodium aluminum sulfate), feed supplements, printing inks, sulfonated oils, textile dyeing, veterinary medicines, and viscose sponges.

[6] Dollars per ton for natural sodium sulfate, f.o.b. mine or plant.

[7] Although data from 1990 and thereafter will be published in metric units, historical values based on short tons will continue to be published for reference.

[8] Final implicit price deflators for 1993 are based on gross domestic product and not gross national product, which was used previously. Based on 1987=100.

TABLE 10—Continued

SODIUM SULFATE: WORLD PRODUCTION, BY COUNTRY[1]

(Metric tons)

Country[2]	1989	1990	1991	1992	1993[e]
Synthetic—Continued:					
United States[10]	345,555	315,604	342,576	272,484	[e]323,751
Yugoslavia[11]	50,333	37,953	[e]35,000	—	—
Total	[r]2,455,704	[r]2,357,317	[r]2,141,336	[r]1,942,715	1,964,551
Grand total	[r]4,868,319	[r]5,057,006	[r]4,741,606	[r]4,404,663	4,356,000

[e] Estimated. [r] Revised.

[1] Table includes data available through May 31, 1994.

[2] In addition to the countries listed, Norway, Poland, Romania, and Switzerland are known or are assumed to have produced synthetic sodium sulfate, and other unlisted countries may have produced this commodity, but production figures are not reported, and general information is inadequate for the formulation of reliable estimates of output levels.

[3] Natural mine output, excluding byproduct output from the nitrate industry, which is reported separately under "Synthetic" in this table.

[4] Byproduct sodium sulfate is known to be recovered but reliable data are not available; not included under "Synthetic."

[5] Series reflects output reported by Industrias Penoles plus an additional 22,000 tons estimated production by Sulfato de Viesca.

[6] Na_2SO_4 content of glauberite and thenardite.

[7] Dissolved in Dec. 1991; however, information is inadequate to formulate reliable estimates for individual countries, other than listed in this table.

[8] Reported figure.

[9] Byproduct of nitrate industry.

[10] Derived approximate figures; data presented are the difference between reported total sodium sulfate production (natural and synthetic not differentiated) and reported natural sodium sulfate sold by producers (reported under "Natural" in this table).

[11] Dissolved in Apr. 1992.

CRUSHED STONE

By Valentin V. Tepordei

Mr. Tepordei, a geological engineer with more than 20 years of industry experience, has been the crushed stone commodity specialist with the U.S. Bureau of Mines since 1981. Domestic survey data were prepared by the crushed and broken stone survey staff of the Branch of Data Collection and Coordination.

Crushed stone is one of the most accessible natural resources and a major basic raw material used by a wide range of industries from construction to agriculture, chemicals, and complex industrial processes. Despite the relative low-value of its basic products, the crushed stone industry is a major contributor to and an indicator of the economic well-being of the Nation.

Beginning with this issue, the statistical information included in the Annual Report for Crushed Stone is published in metric units in compliance with the provisions of the Metric Conversion Act of 1975 and the Omnibus Trade and Competitiveness Act of 1988 (Public Law 100-418). The information that was published in prior years in short tons was converted to metric tons in this issue of the Annual Report. During 1994, only the totals in each table are published in dual units: metric tons and short tons.

A total of 1.1 billion metric tons (1.23 billion short tons) of crushed stone was produced for consumption in the United States in 1993, a 5.9% increase compared with the total production of 1992. This tonnage represents the second highest production level ever recorded, indicating a continued increase in the demand for construction aggregates in the United States in 1993. *(See table 1.)*

About three-quarters of the crushed stone production continued to be limestone and dolomite, followed by granite, traprock, sandstone and quartzite, miscellaneous stone, calcareous marl, marble, volcanic cinder and scoria, shell, and slate, in order of volume. *(See table 2.)*

Foreign trade of crushed stone continued to remain relatively minor in 1993. Exports increased 31.9% to 4.8 million metric tons (5.3 million short tons), while value decreased 9.5% to $39.3 million compared with that of 1992. Imports of crushed stone, including calcium carbonate, increased 20% to 8.4 million metric tons (9.3 million short tons), while the value increased 22.4% to $74.3 million. Domestic apparent consumption of crushed stone was 1.1 billion metric tons. *(See tables 1, 22, and 23.)*

The major issues of concern to the crushed stone industry continue to be: the implementation of the Clean Air Act Amendments of 1990 and its complex legal and technical provisions; the amended Federal Water Pollution Control Act of 1977, the Clean Water Act, Section 404, dealing with "wetlands" and the associated "no net loss of wetlands" policy; the Storm Water Pollution Prevention Program; the Occupational Safety and Health Administration's (OSHA) Hazard Communication Standards regulating the use of products containing more than 0.1% crystalline silica; and the provisions of the Federal Endangered Species Act.

DOMESTIC DATA COVERAGE

Domestic production data for crushed stone are developed by the U.S. Bureau of Mines (USBM) from voluntary surveys of U.S. producers. Full surveys of crushed stone producers are conducted for odd-numbered years only. For even-numbered years, only annual estimates for each State are generated based on information provided by the quarterly sample survey of crushed stone and sand and gravel producers. This survey, implemented by the USBM in 1989, provides production estimates by quarters for each State and the nine geographic regions. The sample surveys canvass most of the large companies in each State, accounting for most of each State's production. The results of this survey are published each quarter in the Quarterly Mineral Industry Survey of Crushed Stone and Sand and Gravel Producers.

Of the 5,371 crushed stone operations surveyed, 3,213 operations with 3,915 quarries were active. Of these, 2,748 operations with 3,335 quarries representing 85.5% of the total number of operations reported to the USBM survey, and their total production represented 91.8% of the total U.S. crushed stone output. The nonrespondent's production was estimated using employment data and/or adjusted prior years' production reports. Of the 2,748 reporting operations, 519 operations with 602 quarries did not report a breakdown by end use. Their production represented 21.6% of the U.S. total and is included in table 13 under "Unspecified uses, actual." The estimated production of 465 nonresponding operations represented 8.2% of the U.S. total and is included in table 13 under "Unspecified uses, estimated." A total of 1,210 quarries were either idle or presumed to have been idle in 1993 because no information was available to estimate their production. A total of 677 operations were closed down since 1991, the last year when a full survey of crushed stone producers was conducted.

BACKGROUND

Crushed stone is a term applied to rock that has been broken and/or crushed after quarrying. It is a low-value product characterized by its "place value," a term that describes the importance of the location of the geologic deposit in reference to the market. Stone in its multitude of forms represents a very significant part of the Earth's crust. As one of the most accessible natural resources, it has been used since the earliest days of our civilization. First used as a tool or weapon, it was then used as a construction material, and later, in its crushed form, as one of the basic raw materials for a wide variety of uses, ranging from agriculture and chemicals to complex industrial processes.

The beginnings of the crushed stone industry are difficult to trace, but it is known that the Greeks, and later the Romans, the first great road builders, used limestone and lime extensively.[1] In the 19th century, the mining of crushed stone was labor intensive. Men with sledge hammers and shovels used their muscles to work the quarries and produce crushed stone that was used mostly for road and railroad construction.[2] The modern crushed stone industry began in England in about 1815 and expanded rapidly after the invention of the mechanical rock crusher in 1858.[3] Today's crushed stone industry is vastly different. It evolved from a labor-intensive to a capital-intensive industry where the work force mostly directs and controls sophisticated and powerful equipment operating in the quarries.

In the United States, railroad ballast was the principal market for the crushed stone industry during the last half of the 19th century. Passage of the Federal Aid Highway Act in 1916 acknowledged the national importance of highways, and subsequent highway construction created a new and significantly larger market. The crushed stone industry grew tremendously, especially in the second half of this century. Production increased from 130 million tons in 1928 to a high of 1.25 billion tons in 1988, mainly owing to rapidly increasing demand for highway, railroad, and other construction work. Today the volume of crushed and broken stone produced is greater than that of any other mineral mined in the United States. The United States is, in general, self-sufficient in crushed stone, producing enough to meet most of the domestic needs. Small quantities of crushed stone, used mostly as construction aggregates, are being imported by water from the Bahamas, Canada, and Mexico.

Most of crushed stone is used for construction purposes, mainly as aggregate with or without a binder. Road base or road surfacing material, macadam, riprap, and railroad ballast are the major uses without a binder. Aggregate for cement and bituminous concrete in highway and road construction and repair and in residential and nonresidential construction are the major uses for aggregates with a binder. Other uses include cement and lime manufacture, agriculture, metallurgical flux, and fillers and extenders.

Although crushed stone resources are widespread and in adequate supply in most parts of the United States, local shortages exist. Land use conflicts and environmental problems associated with rapid urban expansion are major factors contributing to these shortages. Demand pressures, land use regulations, and the cost of meeting environmental and reclamation requirements are factors that will cause a rising price trend. Larger operations with more efficient equipment, more automation, and better planning and design will be the trend of the industry in the future.

Definitions, Grades, and Specifications

Crushed and broken stone is a term applied to rock that has been broken and/or crushed into smaller, irregular fragments or ground to specified particle sizes. Crushed stone is also classified by kind of stone, including limestone, dolomite, marble, shell, granite, traprock, sandstone, quartzite, slate, volcanic cinder and scoria, and miscellaneous stone. The terminology used by the crushed stone industry is not always consistent with mineralogical definitions. Limestone and dolomite are rocks composed, respectively, of the minerals calcite, $CaCO_3$, and dolomite, $CaMg(CO_3)_2$; however, they are usually called limestone by the industry, and intermediate varieties are seldom distinguished. Some deposits of limestone consist chiefly of the mineral aragonite, which has the same composition as calcite, but has a different crystal structure. Marble may include any calcareous rock that will accept a polish. Marl is calcitic and contains varying amounts of shale or clay. Granite includes the coarser grained igneous rocks such as true granite and syenite. Gneisses, although metamorphic rocks, are usually included with granite. Quartzite is a well cemented sandstone that is indurated to the extent that, when fractured, it breaks across the grain. Traprock includes all dense, dark, and fine-grained igneous rocks such as basalt, diabase, and gabbro.

Crushed stone in its different rock types and particle sizes is used in a wide variety of applications in many industries, including construction, chemical, metallurgical, and agriculture. For the purpose of collecting and disseminating production information, the USBM generally accepts the rock type classification and the principal end uses and their definitions as reported by the crushed stone producers.

Specifications for crushed stone are numerous because of the large number and the variety of uses, the diversity of stone types, and the variations in physical and chemical requirements for different uses. Various national specifications and tests exist for crushed stone products, but the most active organizations in preparing and reviewing them are the American Society for Testing and Materials (ASTM)[4] and American Association of State Highway and Transportation Officials (AASTO). For construction aggregates, these are regarded by industry as guide or reference specifications. State specifications are often much more stringent and vary from State to State. The most common specifications and tests relate primarily to gradation, but soundness, shape, abrasion resistance, porosity, chemical compatibility, and content of soft particles are also important.[5] Specifications for construction aggregates are written by commercial users; government agencies, including Federal, State, county, and city construction and highway departments, and the ASTM. Problems arise for the producers of construction aggregates when their product is sold or used in several different cities, counties, or States, many of which may have different specifications. Some progress is being made toward the standardization of aggregate sizes for similar requirements. A need exists for a more active interchange of data and experience among aggregate consumers and producers.

Specifications for limestone used in portland cement manufacture require a content of more than 75% calcium carbonate ($CaCO_3$) and less than 3% magnesium carbonate ($MgCO_3$). For white portland cement, the iron content of the raw materials should be very low, less than 0.01%. Because raw materials are finely ground for processing, chert nodules or coarse quartz grains are undesirable. Limestone for lime manufacture should contain more than 90% calcium carbonate, often more than 97% or 98%, less than 5% magnesium carbonate, and less than 3% of other impurities. For lime produced in vertical kilns, 12.7 to 20.3 centimeters stone is recommended, while in rotary kilns 0.95 to 6.35 centimeters stone may be used. Limestone and dolomite should be sufficiently hard so as not to decrepitate when heated. High-magnesium lime made from dolomite should contain more than 40% magnesium carbonate.

Specifications for the use of limestone or dolomite as fluxstone vary with the pyrometallurgical process, the kind of ore processed, and the final use of the slag; silica content should not exceed 2% to 5%, magnesia content should be less than 4% to 15%, and sulfur less than 0.1%. Size specifications also vary and include ranges from 2.5 to 10 centimeters, 5 to 10 centimeters, and 7.6 to 15 centimeters. The limestone or dolomite used for glassmaking should contain at least 98% $CaCO_3$ or $MgCO_3$, respectively, and less than 0.05% to 0.02% iron oxide. Size specifications vary with the manufacturer and the kind of glass being produced, but uniformity is a major requirement; usually 100% of the material should pass a No. 10 sieve (2 millimeter) and 96% to 100% should be retained on a No. 100 sieve (0.15 millimeter).

Requirements for agricultural limestone are not very rigid and depend on the specific use: as direct application to soil, as filler and conditioner for fertilizers, in animal mineral feeds, or as poultry grit. In all of these applications, $CaCO_3$ or $MgCO_3$ equivalent or content is of major significance. Many individualized specifications exist for a wide variety of industrial applications, mostly pulverized limestone for rock dusting, or as asphalt, plastic, rubber, paper, or paint fillers or extenders.[6]

Uses and Products for Trade and Industry

The ultimate use of crushed stone determines the specification for particle size and gradation, shape, rock type, and chemical composition. Crushed stone can be used without any binder, for a variety of construction or industrial applications, or it may be mixed with a matrix binding material such as bituminous or portland cement. The most common use of crushed stone for construction purposes is as aggregate without a binder, including road base or road surfacing material, macadam, riprap, railroad ballast, filter stone, etc. The second largest use of crushed stone is as aggregate for cement and bituminous concrete in a variety of forms and applications in residential and nonresidential construction, highway and road construction and repair, airports, dams, sewers, and foundations. Sized crushed stone is used to make asphaltic concrete aggregate and road bases. Broken surfaces adhere to the hot asphaltic mixture better than rounded surfaces do and provide interlocking surfaces that tend to strengthen the asphaltic concrete. Broken particles pack better and tend to move less under load than rounded particles do and, therefore, make better road bases for highway and road construction. This is essential because bases and asphaltic concrete tend to flow when placed under great or long duration stresses. Other uses include limestone for cement and lime manufacturing and as agricultural limestone used as direct application to soil, as filler and conditioner for fertilizers, in animal mineral feeds, or as poultry grit. Smaller amounts of crushed stone are used for a wide variety of applications ranging from metallurgical fluxing of antimony, copper, iron, lead, and zinc to the manufacture of glass, ceramic pottery, paper, and as fillers and extenders in asphalt, paint, rubber, and plastics.

A growing amount of limestone is being used in the removal of sulfur oxides from stack gases, primarily from coal burning electric generating stations, and for mine dusting to enhance mine safety by reducing the explosion risk of highly combustible coal dust.

Industry Structure

Because of the low unit value, crushed stone is usually produced near the point of use; therefore, the industry is concentrated mostly in or nearby large, rapidly expanding urban areas. Crushed stone is produced in every State except Delaware, with more than 75% of the national total coming from two major geographic regions, the South and Midwest. The largest quarries tend to be concentrated in the States with the largest population and largest productions of crushed stone.[7]

Although limestone is produced in all States except Alaska, Delaware, Louisiana, New Hampshire, and North Dakota, the major producing States are east of the Rockies. Crushed marble is produced mostly in the eastern part of the United States in Alabama, Georgia, and Pennsylvania. Crushed granite is produced primarily in Appalachia, with Georgia, North Carolina, South Carolina, and Virginia being the largest producing States. Crushed traprock is produced mainly in the northeast and the Pacific

Coast States, with California, Connecticut, Massachusetts, New Jersey, Oregon, and Washington the largest producing States. Crushed sandstone and quartzite are produced in 27 States led by Arkansas, California, and Pennsylvania. Most crushed slate is produced in the eastern part of the United States, mainly in Arkansas, Georgia, and Virginia. Shell, primarily oyster residue, is produced by dredging along the gulf coast. Volcanic cinder is produced in the West, mainly in Arizona, California, and New Mexico.

On the basis of tonnage, the crushed stone industry is the largest nonfuel mineral industry in the United States. The industry is widespread and has a large variation in operation size, kind of stone, and size of material produced. The individual companies range in size from small, independent producers with one quarry to large, diversified corporations with 50 or more crushed stone operations.

In 1993, 1,566 companies produced crushed stone from 3,213 operations with 3,915 active quarries. Individual crushed stone quarries range in size from those producing between 1 and 11 million tons annually to those reporting less than 50,000 tons per year. However, most of the tonnage comes from large operations. In 1993, for example, 71 operations each reporting production of more than 2 million tons per year represented only 2.2% of the total number of operations, but accounted for 19.6% of total crushed stone production. *(See table 7.)* The large operations are owned or operated by a small number of companies. In 1993, the combined production of the top 10 producers operating 509 quarries accounted for 31% of the total output of crushed stone in the United States.

The 10 leading producers were Vulcan Materials Co., Beazer USA Inc./Hanson PLC, Martin-Marietta Aggregates, CSR America, Inc., Rogers Group Inc., Lafarge Construction Materials, Florida Rock Industries Inc., Tarmac America, Inc., Dravo Basic Materials Co., and Lone Star Industries Inc.

In the past several years, significant changes in the structure of the crushed stone industry have occurred, caused primarily by mergers and acquisitions. An established and well-managed company with significant reserves in the ground becomes a potential target of larger companies trying to lock up sufficient reserves or expand into the aggregate business. Some of the recent acquisitions were made by foreign companies or were associated with the influx of foreign capital. Four of the top 10 crushed stone-producing companies in 1993 are subsidiaries of foreign companies.

The United States is the largest producer of crushed and broken stone among the market economy countries. Other major producing countries are Australia, Canada, France, Germany, Japan, and the United Kingdom. Some information about the production of crushed stone in foreign countries may be found in the USBM Minerals Yearbook Volume III, Area Reports: International. For nonreporting countries, estimates of crushed stone outputs can be based on indirect sources such as the level of cement consumption.

Geology-Resources

Bedrock deposits are classified on the basis of their origin into sedimentary, igneous, and metamorphic rocks. Sedimentary rocks were produced from the consolidation of loose sediments through chemical or mechanical sedimentation. Limestone, which is primarily calcium carbonate ($CaCO_3$), and dolomite, which is calcium-magnesium carbonate ($CaMg(CO_3)_2$), are the most common sedimentary rocks produced through chemical or biochemical sedimentation. Limestone and dolomite formations are widespread in the United States, with most of the deposits being of Paleozoic age, with a few of Mesozoic and Tertiary age. Most States have adequate reserves for use in construction and other applications that do not require chemically pure stone.[8] High-calcium limestone and high-purity dolomite make up only a small fraction of all limestone and dolomite formations, and they occur in restricted areas, mostly in the eastern part of the United States, with some formations in the Western States as well.[9] High-purity dolomite deposits are more limited in occurrence than the high-calcium limestone. Of the clastic sedimentary rocks that are produced through mechanical sedimentation, only sandstones, rocks consisting predominantly of cemented sand-size particles, are, to a limited extent, used as crushed stone.

Igneous rocks, rocks that solidify from molten volcanic magma, are classified as intrusive and extrusive rocks. Intrusive or plutonic rocks are those that were formed deep beneath the ground surface, are coarse grained, and include granite, diorite, and gabbro as rock types. Extrusive or volcanic rocks are igneous rocks that were formed from molten volcanic magma at the Earth's surface, are fine-grained, and include andesite, rhyolite, and basalt. Plutonic and volcanic rocks are further subdivided on the basis of mineralogy in light-colored igneous rocks with high-silica content that includes granite, diorite, rhyolite, and andesite, and dark-colored igneous rocks low in silica content that include gabbro, diabase, and basalt, commonly called traprock. Granite and traprock are the most common igneous rock types used as crushed stone. Granite occurs primarily in the eastern part of the United States from Maine to Georgia, along the Appalachian Range where major producing States are located. It also occurs in Arkansas, Minnesota, Missouri, Oklahoma, Texas, and Wisconsin and in all Western States except Utah. Most of the traprock occurs in California, Hawaii, Idaho, Oregon, and Washington in the West; in Connecticut, Maryland, Massachusetts, New Jersey, New York, North Carolina, Pennsylvania, and Virginia in the East; and to a smaller extent in Minnesota and Texas.

Metamorphic rocks are formed from preexisting rocks through mineralogical, chemical, and structural changes produced by high heat and pressure. The metamorphic rocks include gneisses, marbles, quartzite, slates, and schists. Marble, quartzite, and slate are the major types of metamorphic rocks used to some extent as crushed stone. Marble occurs primarily in Alabama, Georgia, New York, Vermont, and Virginia in the East and in California and Texas in the West.

A comprehensive report showing geologic occurrences of potential sources of crushed stone and sand and gravel of the conterminous United States for use as natural aggregates was published by the U.S. Geological Survey.[10]

On the basis of geologic evidence, stone resources of the United States and the world are sufficient to meet demands, although not always precisely at the locations where needed. Reserves, which are measurable amounts of crushed stone that can be produced profitably with current technology under existing economic and political conditions, are controlled mostly by land use and/or environmental constraints. The actual volume of stone available is so vast as to preclude the necessity of measurement on a large scale. The local shortages that occasionally exist are caused less by a lack of stone than by urban encroachment or zoning regulations that force closure of operating quarries or prevent the development of new ones.

Technology

Major technological developments have been instrumental in maintaining adequate production at relatively stable real costs in the crushed stone industry. Equipment manufacturers usually conduct most of the research related to improvements in the mining and processing of crushed stone operations. Larger, more efficient equipment is being developed and improved constantly. The use of computerized control systems in plant operation and quality control has increased significantly in recent years. Automatic controls, along with monitoring by closed-circuit television coordinated with automated counting and recording and radio communications systems, have been installed in many of the larger and newer operations. Automated plants have significantly improved operating efficiency and produce the optimal product mixture to fit market requirements at lower cost.

As part of the national drive to reduce air pollution, significant progress is being made toward the desulfurization of stack gases resulting from coal burning electric generating stations and some industrial installations.[11] Limestone and lime are used as chemically reactive agents in most of the dry or wet scrubbing processes as well as in the treatment of acidified waters, specifically lakes and streams.

Exploration.—A large number of geologic formations that have economic potential as a source of crushed stone have been mapped and described in the literature over the years. Consequently, detailed exploration and development work for any new crushed stone operation will most probably be done on one of these formations. However, in the event that a new stone deposit is discovered, more exploration and evaluation work would be required before development. Preliminary examination can establish the extent and nature of the deposit. This is followed by a detailed exploration program aimed at obtaining reasonably accurate information about the quality of the available material, including the kind of stone, its chemical composition and degree of cementation, and the degree of uniformity throughout the deposit. Also, the nature and the amount of waste material and the economic feasibility of its removal, processing, and marketing must be studied. In most cases, an environmental impact study is required by local or State agencies.

If the raw material cost and quality are proven to be adequate and sufficient reserves are demonstrated, the development stage of the operation can be started. Economic feasibility and marketing studies include: analysis of the availability of power and water supply; mining and processing costs and requirements; the condition of nearby roads and highways and the proximity of rail haulage; the cost of compliance with local, State, and Federal regulations; and the proximity and density of local population, as well as its attitude toward such a project.

Mining.—Most crushed and broken stone is mined from open quarries; however, in many areas, factors favoring large-scale production by underground mining are becoming more frequent and more prominent.

Surface mining equipment varies with the kind of stone mined, the production capacity needed, the size and shape of the deposit, estimated life of the operation, location of the deposit with respect to urban centers, and other important factors. Ordinarily, drilling is done with tricone rotary drills, long-hole percussion drills, and churn drills. Blasting in smaller operations may still be done with dynamite, but in most medium- to large-size operations ammonium nitrate-fuel oil mixtures (AN-FO), which are much lower in cost, are used.

Underground operations are becoming more common, especially for limestone mining in the central and eastern parts of the United States, as the advantages of such operations are increasingly recognized by the producers. By operating underground, a variety of problems usually connected with surface mining such as environmental impacts and community acceptance are significantly reduced. Underground room-and-pillar mines can be operated on a year-round basis, do not require extensive removal of overburden, and produce a minimum of environmental disturbance. The need for less surface space is also an important factor in areas of high land costs. Subsidence has not been a problem in areas mined, and the conventional practice has been to leave 12% to 15% of pillar areas and 2 to 2.5 meters of stone in the mined roof. A specific advantage of underground quarries is the creation of valuable storage facilities. In many cases, the value of the sale or rental of the storage space may exceed the value of the stone mine. Thus, the incentives for producing stone from underground mines can be enhanced by the economic advantages of subsequent use of the excavated areas.

Loading and hauling equipment has grown larger as increased demand for stone has made higher production capacities necessary. Track-mounted equipment is still used extensively, but hydraulic, tire-mounted hauling equipment is predominant.

Processing.—Processing plants have become larger and more efficient, in part because of an increase in the use of computerized control systems. Programmable controllers and/or computers are viewed today as valuable tools that improve operating efficiency and product quality. Primary crushing is often done at or near the pit, usually by jaw or gyratory crushers, but impact and other special types of crushers are also used for nonabrasive stone or stone that tends to clog conventional crushers. The cost effectiveness of permanent crushing installations can be limited because the raw material moves away from the primary stage. It becomes increasingly expensive to haul material from the production face to the crushing plant. Improved crusher technology and increased capacity toward greater equipment mobility are accelerating the use of in-pit movable primary crushers. There is an increased interest in the use of portable crushers ranging in size from 500 tons per hour up to 5,000 tons per hour. For secondary crushing, a variety of comminution equipment is used, depending on plant size, rock type, and kind of material being produced. Cone crushers and gyratory crushers are the most common types used, but impact crushers, including hammer mills, and roll crushers are often used. Belt conveyors are being used extensively to haul material within the quarry because they provide continuous operation, low maintenance costs, low work force requirements, and reduced noise levels. Conveying systems are often associated with in-pit crushers and consist of several portable units and a stationary field conveyor. The portable conveyors, usually in 30- to 60-meter lengths, make the connection between the portable crusher and the field conveyor and provide a good range of motion. The increased use of conveyors reduces significantly the use of haul trucks in quarries.

Screening is the single most important part of the processing cycle of crushed stone particles. A wide variety of screen types exists, and their selection is a function of the material processed as well as the final product required. Inclined vibratory screens are most commonly used in stationary installations, while horizontal screens are used extensively in portable plants. For screening large sizes of crushed stone, grizzly bars, rod decks, and heavy punched steel or plastic plates are used; for smaller sizes, woven wire, welded wire cloth, rubber, or plastic screens are used.

Processed crushed stone is usually stored in open areas except for relatively small quantities that go to the loadout bins. In the more efficient plants, the crushed stone is transported from the storage piles on belt conveyors through tunnels installed under the piles, thus facilitating the blending of any desired mixture of sizes from different piles.

Recycling.—As the Nation moves into an age of increased environmental consciousness, recycling of old concrete and asphalt, used mostly in pavements, is increasing. Waste disposal problems as well as local scarcity or high cost of construction aggregates in some areas are making recycling more attractive economically. In some States, limited recycling, especially in road construction, is either encouraged or required by law. The best utilization for recycled cement concrete is as road base material, because the matrix of concrete cannot be converted back to cement, and also because of the lower strength of concrete compared with that of natural aggregates. Sound crushed concrete can make good coarse aggregate, but the fines produced in crushing the concrete have a higher absorption, are more friable, and will require a higher amount of asphalt in asphaltic concrete and a higher amount of mixing water in portland cement.[12]

The amount of asphalt roads recycled is significantly larger than that of concrete roads, mainly because asphalt can be rejuvenated with oil additives and used in pavements, significantly reducing the cost of the finished road. Experience has shown that about 35% of crushed asphalt pavement can be recycled into new asphalt mixtures. Proper testing under engineering supervision in all construction projects using recycled materials as aggregates should be performed to ensure that the technical specifications are met.

Byproducts and Coproducts

Clay of good quality is sometimes encountered in limestone overburden and is mined as a coproduct. Gypsum is often encountered beneath beds of limestone and is mined as a coproduct. Amphibolite rock often occurs as formations paralleling spodumene-bearing pegmatitic dikes and is mined concurrently with these, notably in North Carolina. This coproduct of lithium mining is marketed primarily as roadstone. Stone is also mined in conjunction with many metallic ores and nonmetallic minerals, but seldom does a market exist for it.

Economic Factors

Crushed stone is a high-volume, low-value commodity. The industry is highly competitive and is characterized by thousands of operations serving local or regional markets, largely because stone is an abundant mineral. Production costs are determined mainly by the cost of labor, equipment, energy, and water, in addition to the costs of compliance with environmental and safety regulations. These costs vary depending on geographic location, the nature of the deposit, and the number and type of products produced. Despite having one of the lowest average per ton values of all mineral commodities, the constant dollar price of crushed stone has changed relatively little over the past 20 years. Increased productivity achieved through increased use of automation and more efficient equipment was mainly responsible for maintaining the prices at an almost constant level.

The delivered price of the product, in addition to quality, is a particularly important element in any major transaction because of the low unit value of crushed stone, and therefore, producers that are closest to markets have a significant advantage. Sophisticated equipment backed by technical knowledge combined with solid sales expertise are becoming very important. For this reason, large companies are better able to compete in the crushed stone business, especially when there is a need for a wide variety of products. Smaller, less efficient operations become less economical as operating costs, as well as costs associated with meeting various Federal, State, and local regulations, continue to increase. The only alternatives these producers have are to supply local markets with a limited number of products. The gradual trend toward larger operations has continued, mostly because the stone industry is capital intensive, and it is becoming less economical to operate small quarries. The viability of small operations is dependent on the demand in the local markets, mining costs, and the degree of processing required to supply the final product.

A 5% depletion allowance based on gross income is allowed for crushed stone used in construction, including aggregates. The depletion allowance for chemical and metallurgical crushed stone is 14%.

Operating Factors

Many States, counties, and cities in the United States have zoning laws, and land within each governmental unit is usually zoned to indicate acceptable land uses. If mining is permitted in a zone and a crushed stone company owns or leases land within that zone, the company may apply for a use permit or its equivalent to begin an operation. If the parcels to be quarried are on lands under both city and county jurisdiction, permits usually must be obtained from each. An acceptable reclamation plan that meets the guidelines or regulations of the appropriate governmental agency also must be approved. Environmental concerns such as noise, dust, beautification, and storage of wastes must be accounted for in a manner satisfactory to the governmental entity involved. Wastewater discharge requirements must be planned for and met. If the deposit to be worked is on land controlled by a State or Federal agency, that agency's requirements also must be satisfied.

In most States, permits for crushed stone operations require an Environmental Impact Report (EIR) or Environment Impact Statement (EIS). A reclamation plan and a use permit application also may be required, with considerable overlap of subject matter with the EIS. A complete EIS may cover all the problem areas at once and facilitate acceptance.

Environmental Requirements.—Many of the environmental problems facing crushed stone producers arise because a great number of stone quarries and processing plants are in suburban areas near the major crushed stone markets. Major environmental considerations that must be dealt with in mining and processing of crushed stone are emission of particulate matter into the air, discharge of processing water, noise abatement, and employee and public health and safety. Air pollution constitutes a major problem in processing plants, especially in the drying and packaging stages of fine particle products such as limestone used as fillers or extenders. Both wet and dry methods of dust control are used. The most important water pollutant is clay in suspension that results from washing and screening crushed stone. Because of the large quantities of water used to process stone and the need for compliance with often stringent regulations, the treatment of discharge water by crushed stone producers is becoming a necessity that may require sophisticated and expensive processing methods. Significant progress has been made in reducing noise pollution both inside and outside of the quarries, including noise and vibration produced by blasting and movement of heavy trucks. Therefore, the industry must be concerned first about any practices that can affect the community environment. An effective effort must be made to reduce noise, air, and water pollution and to improve the overall appearance of the operating mine, processing plant, and transportation facilities. Second, the industry and community must recognize the time and costs required to protect the environment and the importance of agreeing on fair and realistic environmental standards. Because crushed stone is a local industry, the effect of supply deficiencies and cost of material will affect the local community first. Undue delay and unreasonably high cost can strongly affect the movement of crushed stone into the marketplace. Also, stringent controls by the local governments that prevent permits being issued to operators can have adverse economic effects on the communities around them. These conditions can make it difficult to assess the timing and even the possibility of plants going on-stream and can therefore affect the supply of crushed stone into the marketplace.

Although much progress is being made through premining planning, the crushed stone industry continues to have problems with environmental controls, land use conflicts, and reclamation practices. Many of these problems are acute because extraction areas and plants must be reasonably near to consumers who are largely in metropolitan areas.

Transportation.—Transportation is a major factor in the delivered price of crushed stone. The cost of moving crushed stone from the plant to the market often equals or exceeds the sale price of the product at the plant. Because of the high cost of transportation and the large quantities of bulk material that have to be shipped, crushed stone is usually marketed locally. The high cost of transportation is responsible for the wide dispersion of quarries around the country, usually near highly populated areas.

However, increasing land values combined with local environmental concerns are moving crushed stone quarries farther from the end-use locations, increasing the price of delivered material. Economies of scale, which might be realized if fewer, larger operations served larger marketing areas, would probably not offset the increased transportation costs.

Truck haulage is the main form of transportation used in the crushed stone industry, despite the fact that it is the most expensive mode of transportation on a cost-per-ton/per-kilometer basis. Many producers have their own truck fleet and deliver their own raw materials and products. A significant and increasing amount of crushed stone, however, is being hauled by independent truckers because of the cost of maintaining a truck fleet, particularly when the market is highly variable. Rail and water transportation combined account for about 8% of total crushed stone shipments. In recent years, an increased amount of crushed stone is being shipped into the United States by water from Bermuda, Canada, and Mexico using large ocean going vessels. Some of these are self-unloading vessels.

ANNUAL REVIEW

In 1993, a total of 1.1 billion metric tons (1.23 billion short tons) of crushed stone was produced for consumption in the United States, a 5.9% increase compared with that of 1992. This tonnage represents the second highest production level ever recorded in the United States.

Legislation

Department of Transportation and Related Agencies Appropriation Act of 1994 (Public Law 103-122) was signed by the President on October 27, 1994. The act appropriates $20.6 billion for new highway spending, a $2 billion increase from the fiscal year 1993 total. The act also includes a $2.2 billion appropriation in grants for airport construction and provision for a 1-year delay in the imposition of the "crumb rubber" use in highway construction as required by the Intermodal Surface Transportation Efficiency Act of 1991.

Issues

The implementation of the provisions of the amended Federal Water Pollution Control Act of 1977, the Clean Water Act, Section 404, dealing with "wetlands" and the establishment of a "no net loss of wetlands" policy constitutes one of the major areas of concern to the crushed stone industry. There is a significant amount of uncertainty regarding the process of designating some lands as wetlands and whether the current exemptions to the Clean Water Act, Section 404, permit program will be maintained in the future. On August 24, 1993, the administration's wetland policy was announced. The new policy endorses an interim goal of "no overall net loss" of wetlands and a long-term goal of increasing wetlands quantity and quality; provides for administrative appeals of permitting process decisions; establishes deadlines for the Army Corps of Engineers decisions on permit applications, generally within 90 days; mandates the use of the 1987 Wetlands Delineation Manual by the Army Corps of Engineers, Environmental Protection Agency (EPA), Soil Conservation Service, and Fish and Wildlife Service to identify wetland; encourages the development of wetland mitigation banks; and promotes the long-term restoration of wetlands through voluntary, nonregulatory programs.

Several bills were reintroduced in the 103d U.S. Congress to replace the current Section 404 of the Federal Water Pollution Control Act. The new proposed bills plan to provide a concise and structured program for the delineation of wetlands based on their functions and values and will balance the need for effective protection of the Nation's important wetlands with the need for essential community growth and the constitutional rights of landowners.

The complex legal and technical provisions of the comprehensive amendments of 1990 to the Clean Air Act and the implementing regulations for these provisions continues to constitute a major area of concern to the crushed stone industry. One major emphasis of the amendments is expanded authority given to EPA and the States to enforce the new law and assess increased penalties. EPA is now authorized to issue administrative orders with penalties of up to $200,000 for noncompliance, and its field inspectors can issue citations for minor violations with penalties of up to $5,000 per day for each violation. The law also includes provisions for new Federal permits to be issued by the State agencies that include source-specific emission limitations and related monitoring, recordkeeping, and reporting requirements. Complying with the new provisions of the Clean Air Act Amendments will constitute a major challenge to all crushed stone producers.

Another issue of concern to the construction aggregates industries is the classification of crystalline silica as a probable human carcinogen by the International Agency for Research on Cancer, an agency of the World Health Organization. OSHA-regulated sites that receive and/or use products containing more than 0.1% crystalline silica must comply with OSHA's Hazard Communication Standard. Both the classification of crystalline silica as a probable human carcinogen and the requirement to quantitatively analyze for crystalline silica at the 0.1% level are controversial.

Production

A total of 1.1 billion metric tons (1.23 billion short tons) of crushed stone was produced for consumption in the United States in 1993, a 5.9% increase compared with that of 1992. *(See table 1.)* Of this total, 793 million metric tons or 71% was limestone and dolomite, 169 million tons or 15.1% was granite, and 84 million tons or 7.6% was traprock. The remaining 6.3% was shared, in descending order of quantity, by sandstone and quartzite, miscellaneous stone, calcareous marl, marble, volcanic cinder and scoria, shell, and slate. *(See table 2.)*

A comparison of the four major geographic regions indicates that in 1993 the South continued to lead the Nation in the production of crushed stone with 516.5 million metric tons or 46.3% of the total, followed by the Midwest with 332.5 million metric tons or 29.8%, and the Northeast with 148.1 million metric tons or 13.3%. Approximately 76% of the total U.S. crushed stone output was produced in two major geographic regions, the South and the Midwest. *(See table 3.)*

Of the nine geographic regions, the South Atlantic led the Nation in the production of crushed stone with 271 million metric tons or 24.3% of the U.S. total. Next was the East North Central region with 208 million metric tons or 18.6% of the total, followed by the Middle Atlantic with 126 million metric tons or 11.3%.

A comparison of the estimated 1992 and reported 1993 production data by regions indicates that the output of crushed stone increased in all regions except the East South Central. The largest increases were recorded in the Pacific, +26.5%; the South Atlantic, +18.6%; and the Middle Atlantic, +10.9%.

Crushed stone was produced in every State except Delaware. The 10 leading States in the production of crushed stone, in order of volume, were Texas, Pennsylvania, Florida, Illinois, Missouri, Ohio, Virginia, Georgia, Kentucky, and North Carolina. Their combined production represented 51% of the national total.

In the second half of 1993, Beazer USA, Inc./Hanson Industries of Walnut Creek, CA, a subsidiary of Hanson PLC of London, United Kingdom, reorganized its U.S. operations to provide more local operational and financial control and to capitalize on the company's more recognizable names in regional markets. Beazer Northeast became General Materials & Construction Co. of Easton, PA; Beazer Southeast became Benchmark Materials Co. of Research Triangle Park, NC; Beazer Northwest became Kaiser Materials Corp. of Pleasanton, CA; and Beazer Southwest became Southwest Construction Materials and Services, Co. of Long Beach, CA; Gifford-Hill & Co. of Dallas, TX, and Spectrum Construction Co. of Virginia Beach, VA, that were also part of the Beazer Group will retain their original names.

On November 12, 1993, Martin Marietta Corp. announced that its construction materials division, Martin Marietta Aggregates, will become a separate company, Martin Marietta Materials Inc., located in Raleigh, NC. The new company that was incorporated in North Carolina will be a wholly owned subsidiary of Martin Marietta Corp. On December 8, 1993, a registration statement was filed with the Security and Exchange Commission for an underwritten public offering of about 19% of the company common stocks.

In December 1993, Lafarge Corp. of Reston, VA, announced the restructuring of its North American operations by consolidating 11 cement and construction materials regional operating units into 6 units. Effective January 1, 1994, Lafarge's new North American organization will include three regional centers for construction materials: Western, based in Calgary, Alberta, Canada; Eastern, based in Toronto, Ontario, Canada; and the United States, based in Canfield, OH; and three regional offices for cement's group located in Calgary, Alberta, Canada; Montreal, Quebec, Canada; and the United States in Southfield. MI.

Limestone.—The 1993 output of crushed limestone, including some dolomite, increased 13.1% to 724 million metric tons valued at $3.5 billion, compared with the 1991 totals. *(See table 2.)* In addition to the quarries reporting only limestone, 35 operations with 40 quarries reported producing limestone and dolomite, without making a distinction between the two kinds of stone. Their production, 15.6 million metric tons, was included with the limestone, and therefore, the limestone totals shown in this chapter include an undetermined amount of dolomite, in addition to the dolomite reported separately.

Limestone was produced by 940 companies at 1,959 operations with 2,109 quarries in 47 States. Leading States, in order of tonnage, were Texas, Florida, Missouri, Kentucky, and Pennsylvania; these five States accounted for 37% of the total U.S. output. *(See table 8.)* Leading U.S. producers were, in order of volume, Vulcan Materials Co., Beazer USA/Hanson, CSR America, Inc., Martin Marietta Aggregates, and Rogers Group, Inc. These five companies accounted for 21.7% of total U.S. output of limestone.

Dolomite.—Production of dolomite increased 7.9% to 69 million metric tons valued at $382 million, compared with the 1991 reported totals. *(See table 2.)* Crushed dolomite was reportedly produced by 92 companies at 142 operations with 148 quarries in 28 States. An additional undetermined amount of dolomite is included in the total crushed limestone. Leading States in the production of dolomite, in order of tonnage, were Pennsylvania, New York, Ohio, Virginia, and Indiana; these five States accounted for 42.9% of the total U.S. output. *(See table 8.)* Leading U.S. producers were Vulcan Materials Co., Asarco-American Limestone Inc., Lone Star Industries, Evered Bardon PLC, and Stabler Co.-Eastern Industries Inc. Their combined production represented 43.5% of the total U.S. dolomite production.

Marble.—Production of crushed marble increased only 2.5% to 3.5 million metric tons valued at $74 million. *(See table 2.)* Crushed marble was produced by 11 companies with 21 operations and 38 quarries in 8 States. Leading producers of crushed marble, in order of tonnage, were Georgia Marble Co., ECC Construction Materials Ltd., and Onoda Cement Co.; their combined production represented 86% of the total U.S. output.

Calcareous Marl.—Output of marl decreased slightly to 5.2 million metric tons valued at $26 million. *(See table 2.)* Marl was produced by 12 companies at 12 quarries in 7 States. South Carolina accounted for 55.6% of total U.S. output. *(See table 9.)* Leading producers, in order of tonnage, were Holnam Inc., Capital Aggregates Inc., and Giant Group Ltd.; their combined production represented 60.1% of the total U.S. output.

Shell.—Shell is mainly derived from fossil reefs or oyster shell. The output of crushed shell decreased 60.8% to 1.9 million metric tons valued at $12.3 million. *(See table 2.)* The decrease is mostly due to the restrictions imposed on the industry in Louisiana as a result of concerns that shell dredging produces irreversible damage to the environment. Crushed shell was produced by 14 companies from 14 operations in 5 States.

The major producing States were Florida and Louisiana, and the leading producers, in order of tonnage, were Dravo Basic Materials Co., Quality Aggregates Inc., and Highlands Co.; their combined production represented 67.9% of the U.S. output.

Granite.—Compared with that of 1991, the 1993 output of crushed granite increased 14.3% to 169 million metric tons valued at $1 billion. *(See table 2.)* Crushed granite was produced by 162 companies at 344 operations with 468 quarries in 34 States. Leading States, in order of tonnage, were Georgia, North Carolina, Virginia, South Carolina, and New Jersey; these five States accounted for 73.8% of the U.S. output. *(See table 10.)*

Leading U.S. producers, in order of tonnage, were Vulcan Materials Co., Martin Marietta Aggregates, Beazer USA/Hanson, Florida Rock Industries, Inc., and Tarmac America, Inc.; their combined production represented 56.3% of the U.S. total.

Traprock.—Production of crushed traprock increased 7.6% to 84.3 million metric tons valued at $525 million. *(See table 2.)* Traprock was produced by 256 companies at 373 operations with 593 quarries in 26 States. Leading States, in order of tonnage, were Oregon, Virginia, Washington, New Jersey, and California; these five States accounted for 62.1% of U.S. output. *(See table 10.)* Leading U.S. producers, in order of tonnage, were Evered Bardon PLC, Luck Stone Corp., Vulcan Materials Co., Beazer USA/Hanson, and Seubert Excavators, Inc.; their combined production accounted for 23% of the total U.S. output.

Sandstone and Quartzite.—The combined output of crushed sandstone and quartzite increased 7.2% to 30 million metric tons valued at $182.1 million. *(See table 2.)* Crushed sandstone was produced by 106 companies at 130 operations with 187 quarries in 33 States, while crushed quartzite was produced by 26 companies at 27 operations with 34 quarries in 16 States. Leading States in the production of sandstone and quartzite, in order of tonnage, were Pennsylvania, Arkansas, and South Dakota; their combined production represented 47.1% of the U.S. output. *(See table 10.)* Leading producers of sandstone and quartzite, in order of tonnage, were Western Mobile Inc., Arkola Sand and Gravel Co., Eucon Co., Martin-Marietta Aggregates, and Latrobe Construction Co. The combined production of the top five producers represented 26.8% of the total U.S. output.

Slate.—Compared with that of 1991, the 1993 output of crushed slate increased 29% to 1.9 million metric tons valued at $12.6 million. *(See table 2.)* Crushed slate was produced by 9 companies at 10 quarries in 6 States. Most of the crushed slate is produced in North Carolina. Leading producers, in order of tonnage, were Martin Marietta, Mariposa Aggregates Co., and Lesuer-Richmond Slate Corp.

Volcanic Cinder and Scoria.—Production of volcanic cinder and scoria remained practically unchanged at 2 million metric tons valued at $13.4 million. *(See table 2.)* Volcanic cinder and scoria were produced by 30 companies from 45 operations with 124 quarries in 14 States. Leading States, in order of volume, were California, New Mexico, and Hawaii; their combined production accounted for 39.3% of the total U.S. output. *(See table 11.)* Leading producers, in order of tonnage, were Martin Marietta, the Bishop Red Rock Inc., and Stoney Point Rock Quarry Inc; their combined production accounted for 43.9% of U.S. output.

Miscellaneous Stone.—Output of other kinds of crushed stone increased 16.6% to 24.9 million metric tons valued at $134.8 million. *(See table 2.)* Miscella-neous stone was produced by 108 companies from 133 operations with 175 quarries in 29 States. Leading States, in order of volume, were Pennsylvania, California, and Texas; their combined production accounted for 39.1% of the total U.S. output. *(See table 11.)* Leading producers, in order of tonnage, were Evered Bardon PLC, Anchorage Sand & Gravel Co., and Herzog Stone Products, Inc.

Consumption and Uses

Crushed stone production reported to the USBM is actually material that was either sold or used by producers. Stockpiled production is not reported. Therefore, the "sold or used" tonnage represents the amount of production released for domestic consumption or export in a given year. Because some of the crushed stone producers did not report a breakdown by end use, their total production is reported under "Other unspecified uses, actual." The estimated production of nonrespondents is reported under "Other unspecified uses, estimated."

In 1993, U.S. consumption of crushed stone was 1.1 billion metric tons valued at $5.9 billion, a 5.9% increase from the estimated consumption of 1992 and a 12% increase from the reported consumption of 1991. Of the 1.1 billion metric tons of crushed stone consumed in 1993, 332 million metric tons or 29.7% of the total was unspecified uses—actual and estimated. Of the remaining 784 million metric tons, about 82.7% was used as construction aggregates, mostly for highway and road construction and maintenance; 13.6% for chemical and metallurgical uses, including cement and lime manufacture; 2% for agricultural purposes; 1.4% for special uses and products; and 31% for other unspecified uses. *(See table 13.)* To provide a more accurate estimation of the consumption patterns for crushed stone, the "Unspecified uses" are not included in the aforementioned percentages. It is recommended that in any use pattern or marketing analysis the quantities included in "Unspecified uses" be distributed among the reported uses by applying the aforementioned percentages.

Limestone.—Of the 724 million metric tons of crushed limestone consumed, 213 million metric tons or 29.5% was reported as "Other unspecified uses." Of the remaining 510 million metric tons of crushed limestone reported by uses by the producers; 75.9% was used as construction aggregates; 19.7% for chemical and metallurgical uses, including cement and lime manufacturing; 2.7% for agricultural purposes; and 1.4% for special uses and products. *(See table 14.)*

Dolomite.—Of the 69 million metric tons of crushed dolomite consumed, 9.1 million metric tons or 13.2% was reported as "Other unspecified uses." Of the remaining 59.9 million metric tons of crushed dolomite reported by uses by the producers, 91.8% was used as construction aggregates, 3.7% for chemical and metallurgical uses, and 2.7% for agricultural purposes. An additional undefined amount of dolomite consumed in a variety of uses, mostly construction aggregates, is reported with the limestone. *(See table 14.)*

Marble.—Of the 3.5 million metric tons of crushed marble consumed, 1.8 million metric tons or 51.4% was reported as "Other unspecified uses." Of the remaining 1.7 million metric tons of crushed marble reported by uses by the producers, 65.3% was used as miscellaneous uses, including fillers and extenders, 26.5% for cement manufacture, and 7.7% as construction aggregates. *(See table 16.)*

Calcareous Marl.—Of the 5.2 million metric tons of crushed calcareous marl consumed, 2.2 million metric tons or 42.5% was reported as "Other unspecified uses." Of the remaining 3 million metric tons of crushed marl reported by uses by the producers, 80.8% was used for cement manufacturing, and the remaining 19.2% as construction aggregates and for agricultural purposes.

Shell.—Of the 1.9 million metric tons of crushed shell consumed, 774,000 metric tons or 39.7% was reported as "Other unspecified uses." Of the remaining 1.2 million metric tons of crushed shell reported by uses by the producers, 97.8% was used as construction aggregates.

Granite.—Of the 169 million metric tons of crushed granite consumed, 53.3 million metric tons or 31.5% was reported as "Other unspecified uses." Most of the remaining 116 million metric tons of crushed granite reported by uses by the producers was used as construction aggregates. *(See table 17.)*

Traprock.—Of the 84 million metric tons of crushed traprock consumed, 22.5 million metric tons or 26.7% was reported as "Other unspecified uses." Most of the remaining 62 million metric tons of crushed traprock reported by uses by the producers was used as construction aggregates. *(See table 17.)*

Sandstone and Quartzite.—Of the 24 million metric tons of crushed sandstone consumed, 10.3 million metric tons or 42.3% was reported as "Other unspecified uses." Most of the remaining 14 million metric tons of crushed sandstone reported by uses by the producers were used as construction aggregates. *(See table 18.)*

Of the 6 million metric tons of crushed quartzite consumed, 2.6 million metric tons or 44% was reported as "Other unspecified uses." Most of the remaining 3.4 million metric tons of crushed quartzite reported by uses by the producers was used as construction aggregates. *(See table 18.)*

Volcanic Cinder and Scoria.—Of the 2.1 million metric tons of volcanic cinder and scoria consumed, 821,000 metric tons or 39.1% was reported as "Other unspecified uses." Most of the remaining 1.3 million metric tons of crushed volcanic cinder and scoria reported by uses by the producers was used as construction aggregates. *(See table 19.)*

Miscellaneous Stone.—Of the 34 million metric tons of miscellaneous crushed stone consumed, 18.2 million metric tons or 53.7% was reported as "Other unspecified uses." Of the remaining 15.8 million metric tons reported by uses by the producers, 83.3% was used as construction aggregates and 15.5% was used for cement manufacturing. *(See table 19.)*

Prices

Prices in this chapter are f.o.b. plant, usually at the first point of sale or captive use. This value does not include transportation from the plant or yard to the consumer. It does, however, include all costs of mining, processing, in-plant transportation, overhead costs, and profit.

The 1993 average unit price per metric ton of crushed stone increased 2.9% to $5.30, compared with that of 1991, the last time when an annual survey of the crushed stone producers was conducted. By kind of stone, the average unit prices showed increases of 62.4% for calcareous marl, 10.9% for sandstone and quartzite, 4.7% for limestone, 3.8% for granite, 3.6% for slate, and 2.2% for volcanic cinder and scoria. At the same time, the average unit prices for shell decreased 29.3%, for marble 13.3%, and for traprock 3.6%, while the prices for dolomite and miscellaneous stone remained unchanged.

Transportation

For 369 million metric tons or 33.1% of the total 1.1 billion metric tons of crushed stone produced in 1993, no means of transportation was reported by the producers. Of the remaining 747 million metric tons of crushed stone, 73.1% was reported as transported by truck from the processing plant or quarry to the first point of sale or use, 6.5% was transported by rail, and 6.2% by waterway. About 11.8% of the total production was reported as not transported and therefore used on-site. Information regarding means of transportation used by the producers to ship crushed stone in each geographic regions is also provided. *(See table 20.)*

Foreign Trade

The widespread distribution of domestic crushed stone deposits and the high cost of transportation limits foreign trade mostly to local transactions across international boundaries. U.S. imports and exports are small, representing less than 0.5% of the domestic consumption. However, shipments of crushed stone by water from Canada and especially Mexico are increasing.

Exports.—Exports of crushed stone increased 31.9% to 4.8 million metric tons compared with that of 1992, while value decreased 9.5% to $39.3 million. About 83% of the exported crushed stone was limestone, Canada being the major destination with 86.8% of the total crushed stone. *(See table 22.)*

Imports.—Imports of crushed stone increased 20% to 8.4 million metric tons compared with that of 1992, while the value increased 15.1% to $69 million. About 95.8% of the imported crushed stone was limestone.

Imports of natural calcium carbonate fines increased from 2,000 to 44,000 metric tons. *(See table 23.)*

Shipments of crushed stone from the Bahamas, Canada, and Mexico into the United States continued in 1993. The imported crushed stone was used mostly as construction aggregates or for cement manufacturing. This trend is expected to continue and the volume of imports, especially from Mexico, to increase.

Current Research

The Center for Aggregates Research (CAR) established by the National Aggregates Association and the National Stone Association and managed through the Aggregates Foundation for Technology, Research, and Education (AFTRE), is the first organization dedicated wholly to aggregates research. A technical advisory committee overviewing the center's activity identified six priority areas of research that include: fine aggregates properties and their influence on end products; uses for fines resulting from the processing of aggregates; performance-related tests for aggregates; proper use of aggregates in asphaltic concrete to minimize rutting; prevention of alkali-silica and alkali-carbonate reactivity of aggregates in portland cement concrete; and nature and effects of coatings on aggregates. CAR will concentrate its efforts into these areas.

The University of Texas at Austin and Texas A&M University, the two institutions jointly operating CAR, have already considerable research in progress related to aggregates. Some of the projects underway are as follows:

- Evaluation of the performance of pavements made with different coarse aggregates, including those with different thermal coefficients and the development of design procedures;

- Evaluation of the effectiveness of large stone mixtures in resisting plastic deformation—rutting—in asphalt pavements, and recommended design procedures and quality assurance testing and constructability;

- Study of the alkali-silica reaction in concrete containing fly ash. The objectives of the study are to identify the most relevant components of fly ash, portland cement, and aggregates affecting the alkali-silica reaction and to determine the type and amount of a given component to be used in producing high-quality concrete;

- Study of surface friction of seal coat pavements to identify the best methods for determining aggregates properties and characteristics that will accurately predict surface friction performance of seal coats; and

- Potential engineering and environmental uses of quarry fines.[13]

The Intermodal Surface Transportation Efficiency Act of 1991 authorized about $108 million for Strategic Highway Research Program (SHRP) implementation and Long Term Pavement Performance (LTPP) projects. With the completion of SHRP's 5-year research program, the Federal Highway Administration (FHWA) was assigned the responsibility of implementing the research results, products, and techniques through an FHWA Technology Applications program. A series of implementation actions also are being undertaken by AASHTO and the Transportation Research Board (TRB). AASHTO's Subcommittee on Materials amended its procedures to accept new product standards on a provisional basis for a maximum of 4 years, during which time hands-on testing will be conducted. At the end of 2 years, the product standards can be balloted for acceptance as regular standards, or the provisional status can be extended for an additional 2 years. The Subcommittee on Materials is also developing information about the specific resources needed to implement SHRP products. TRB has created the TRB/SHRP committee, which will provide industry, highway agencies, and research specialists with a continuing forum to coordinate activities related to implementation of SHRP products and continuation of the LTPP program.

Technology

A new mobile conveyor system designed to load or unload bulk commodity rail cars was introduced by Granite Rock Co. of Watsonville, CA, at the Rock by Rail Third Conference that was held in April 1993 in League City, TX. TransloadXpress conveyor system was engineered by Granite Rock Co. to provide a cost-effective, efficient, and fast method of loading and unloading rail cars. TransloadXpress can convey bulk materials at rates of up to 800 tons/hour, and can unload rail-to-truck systems at rates averaging 300 tons/hour. TransloadXpress can unload materials into waiting trucks for short hauls to the job site or can convey materials directly into portable ready-mix concrete and asphalt plants. TransloadXpress helps the aggregates producer take advantage of the economies of scale offered by rail shipments and also provides significant environmental advantages. According to a study conducted by the Department of Energy, rail delivers more than eight times the energy efficiency of trucking when measured by the required BTU's per ton-mile of transportation.[14]

Quarry blasting usually requires considerably greater control than most mining or public works rock blasting. Maximizing the breakage of rock during primary blasting reduces significantly the need for secondary breakage of oversize rock and therefore of energy consumption required to produce the final product. Efficient and cost-effective blasting requires proper selection of blasthole pattern, explosive selection, delay timing, and initiation sequence, as well as a thorough understanding of the impact the blasting will have on nearby structures. A comprehensive review of the technology, including blasting fragmentation, drilling accuracy, explosive performance, ground vibration, blast size, and delay timing, and how the technology can be used to reduce blasting costs was published by Quarry Management magazine and was reprinted by Rock Products magazine.[15]

A comprehensive review of the available microcomputer software for use in aggregate-producing industry was published by Rock Products magazine. The review includes software for mine planning, geographic information systems, plant design, mining cost analysis, blasting design, scale management, financial modeling, and accounting. Available information on environmental and occupational health and safety standards, State and Federal regulatory requirements, and legal and engineering codes and standards affecting the aggregates industry is also included in the review.[16]

OUTLOOK

The demand for crushed stone in 1994 is expected to be about 1.17 billion metric tons (1.29 billion short tons), a 5% increase compared with that of 1993. Gradual increases in demand for construction aggregates are anticipated after 1994 as well, based on increased volume of work on the infrastructure that is being financed by the Intermodal Surface Transportation Efficiency Act of 1991 and the recovery of the U.S. economy. The law authorized $151 billion to be spent in the next 6 years on transportation projects, of which $119.5 billion on highway work and $32.5 billion on mass transit.

It is estimated that the demand for crushed stone will reach 1.3 billion tons in 1995. The projected increases will be influenced by construction activity primarily in the public as well as the private construction sector.

Crushed stone f.o.b. prices are not expected to increase significantly, even if the demand for construction aggregates will rise over the forecasts. However, the delivered prices of crushed stone are expected to increase, especially in and near metropolitan areas, mainly because more aggregates are transported from distant sources.

Total[6] [7]	XX	XX	XX	XX	XX	XX	XX	XX	1,137,800	6,021,300

XX Not applicable.

[1] As published in the "Crushed Stone and Sand and Gravel in the Fourth Quarter of 1993 Mineral Industry Survey."

[2] All percentage changes are calculated using unrounded totals.

[3] Data may not add to totals shown because of independent rounding, and differences between projected totals by States and regions.

[4] To avoid disclosing proprietary data, certain state totals do not include all kinds of stone produced within the State; the portion not shown has been included with "Other."

[5] Due to a low number of reporting companies, no production estimates by quarters were generated.

[6] One metric ton is equal to 1,000 kilograms or 2,204.62 pounds. To convert short tons to metric tons, multiply short tons by 0.907185.

[7] Total shown in thousand metric tons and thousand dollars.

TABLE 7

CRUSHED STONE SOLD OR USED IN THE UNITED STATES IN 1993, BY REGION AND SIZE OF OPERATION

TABLE 13

CRUSHED STONE SOLD OR USED BY PRODUCERS IN THE UNITED STATES IN 1993, BY USE

Use	Quantity (thousand metric tons)	Value (thousands)	Unit value
Coarse aggregate (+1 1/2 inch):			
Macadam	4,878	$22,929	$4.70
Riprap and jetty stone	20,365	109,597	5.38
Filter stone	8,344	46,424	5.56
Other coarse aggregate	6,154	42,400	6.89
Coarse aggregate, graded:			
Concrete aggregate, coarse	100,766	564,289	5.60
Bituminous aggregate, coarse	78,656	442,089	5.62
Bituminous surface-treatment aggregate	20,531	125,735	6.12
Railroad ballast	14,581	80,997	5.55
Other graded coarse aggregate	20,941	121,382	5.80
Fine aggregate (-3/8 inch):			
Stone sand, concrete	19,679	123,448	6.27
Stone sand, bituminous mix or seal	22,237	109,845	4.94
Screening, undesignated	30,624	148,269	4.84
Other fine aggregate	2,904	16,790	5.78
Coarse and fine aggregates:			
Graded road base or subbase	185,925	794,557	4.27
Unpaved road surfacing	31,661	144,358	4.56
Terrazzo and exposed aggregate	1,947	15,623	8.02
Crusher run or fill or waste	41,482	189,425	4.57
Other coarse and fine aggregates	19,566	102,405	5.23
Other construction materials[1]	15,788	91,353	5.79
Roofing granules	1,334	12,748	9.56
Agricultural:			
Agricultural limestone	12,521	72,962	5.83
Poultry grit and mineral food	2,054	25,442	12.39
Other agricultural uses	821	4,939	6.02
Chemical and metallurgical:			
Cement manufacture	84,318	318,070	3.77
Lime manufacture	15,126	99,157	6.56
Dead-burned dolomite manufacture	286	1,192	4.17
Flux stone	3,192	15,744	4.93
Chemical stone	508	2,749	5.41
Glass manufacture	500	6,120	12.24
Sulfur oxide removal	2,361	12,857	5.45
Special:			
Mine dusting or acid water treatment	1,263	11,142	8.82
Asphalt fillers or extenders	3,714	27,823	7.49
Whiting or whiting substitute	2,259	75,210	33.29
Other fillers or extenders	3,795	88,694	23.37
Other miscellaneous uses:			
Abrasives	13	78	6.00
Flour (slate)	W	W	W
Paper manufacture	W	W	W
Other specified uses not listed	3,060	23,278	7.61

See footnotes at end of table.

TABLE 13—Continued

CRUSHED STONE SOLD OR USED BY PRODUCERS IN THE UNITED STATES IN 1993, BY USE

Use	Quantity (thousand metric tons)	Value (thousands)	Unit value
Unspecified:[2]			
Actual	240,597	$1,346,073	$5.59
Estimated	91,268	479,452	5.25
Total[3]	1,116,000	5,915,500	5.30
Total[4] [5]	1,230,200	5,915,500	4.81

W Withheld to avoid disclosing company proprietary data; included with "Other specified uses not listed."

[1] Includes stone used in drain fields, building products, and waste material.

[2] Includes production reported without a breakdown by use and estimates for nonrespondents.

[3] Data may not add to totals shown because of independent rounding.

[4] One short ton is equal to 907 kilograms or 2,000 pounds. To convert metric tons to short tons, divide metric tons by 0.907185.

[5] Total shown in thousand short tons and thousand dollars.

TABLE 14

CRUSHED LIMESTONE[1] AND DOLOMITE SOLD OR USED BY PRODUCERS IN THE UNITED STATES IN 1993, BY USE

(Thousand metric tons and thousand dollars)

Use	Limestone		Dolomite	
	Quantity	Value	Quantity	Value
Coarse aggregate (+1 1/2 inch):				
Macadam	1,931	8,778	1,764	8,295

Whiting or whiting substitute	2,241	74,671	(5)	(5)
Other fillers or extenders	2,019	27,993	383	8,856
Other miscellaneous uses:				
Abrasives	13	78	—	—
Other uses not listed	[6]1,727	[6]13,358	598	7,067
Unspecified:[7]				
Actual	152,381	789,536	8,061	41,182
Estimated	60,778	298,328	1,072	6,103
Total[8]	723,500	3,540,300	69,400	382,000
Total[9] [10]	797,600	3,540,300	76,500	382,000

W Withheld to avoid disclosing company proprietary data; included with "Other construction materials" or "Other agricultural uses."

[1] Includes a minor amount of limestone-dolomite reported without a distinction between the two.

[2] Includes waste material.

[3] Includes building products, waste material, and "Roofing granules."

[4] Includes "Poultry grit and mineral food."

[5] Included with "Other uses not listed."

[6] Includes paper manufacture.

[7] Includes production reported without a breakdown by end use and estimates for nonrespondents.

[8] Data may not add to totals shown because of independent rounding.

[9] One short ton is equal to 907 kilograms or 2,000 pounds. To convert metric tons to short tons, divide metric tons by 0.907185.

[10] Total shown in thousand metric tons and thousand dollars.

W Withheld to avoid disclosing company proprietary data; included with "Total withheld" and "Other uses." XX Not applicable.

[1] Includes a minor amount of limestone-dolomite reported without a distinction between the two.

[2] Data may not add to totals shown because of independent rounding.

[3] One short ton is equal to 907 kilograms or 2,000 pounds. To convert metric tons to short tons, divide metric tons by 0.907185.

[4] Total shown in thousand short tons and thousand dollars.

TABLE 16

CRUSHED MARBLE SOLD OR USED BY PRODUCERS IN THE UNITED STATES IN 1993, BY USE

(Thousand metric tons and thousand dollars)

Use	Quantity	Value
Coarse aggregate, graded:		
Concrete aggregate, coarse	14	299
Coarse and fine aggregates:		
Crusher run or fill or waste	15	65
Other construction materials[1]	102	3,163
Agricultural:		
Poultry grit and mineral food[2]	15	214
Chemical and metallurgical:		
Cement manufacture	451	2,485
Special:		
Mine dusting or acid water treatment	3	77
Whiting or whiting substitute	3	99
Other fillers or extenders	975	49,585
Other specified uses not listed	131	86
Unspecified:[3]		
Actual	1,676	14,120
Estimated	122	3,062
Total[4]	3,500	74,000
Total[5] [6]	3,900	74,000

[1] Includes filter stone, graded roadbase or subbase, riprap and jetty stone, roofing granules, stone sand, concrete, terrazzo, and exposed aggregates and unpaved road surfacing.

[2] Includes other agricultural uses.

[3] Includes production reported without a breakdown by end use and estimates for nonrespondents.

[4] Data may not add to totals shown because of independent rounding.

[5] One short ton is equal to 907 kilograms or 2,000 pounds. To convert metric tons to short tons, divide metric tons by 0.907185.

[6] Total shown in thousand short tons and thousand dollars.

TABLE 17
CRUSHED GRANITE AND TRAPROCK SOLD OR USED BY PRODUCERS IN THE UNITED STATES IN 1993, BY USE

(Thousand metric tons and thousand dollars)

Use	Granite		Traprock	
	Quantity	Value	Quantity	Value
Coarse aggregate (+1 1/2 inch):				
Macadam	946	4,184	225	1,541
Riprap and jetty stone	2,810	20,555	1,248	10,434
Filter stone	1,631	11,578	787	4,564
Other coarse aggregate	777	4,267	1,018	8,889
Coarse aggregate, graded:				
Concrete aggregate, coarse	20,646	137,128	6,442	49,454
Bituminous aggregate, coarse	13,644	92,246	5,557	36,104
Bituminous surface-treatment aggregate	2,734	21,702	2,013	15,867
Railroad ballast	7,899	46,484	2,604	14,732
Other graded coarse aggregate	2,440	16,522	3,050	22,171
Fine aggregate (-3/8 inch):				
Stone sand, concrete	4,122	25,395	1,554	15,905
Stone sand, bituminous mix or seal	4,811	23,853	1,470	9,863
Screening, undesignated	9,100	46,374	1,538	9,041
Other fine aggregate	666	4,192	583	4,602
Coarse and fine aggregates:				
Graded road base or subbase	28,565	142,608	18,390	92,193
Unpaved road surfacing	2,005	8,756	4,062	18,817
Terrazzo and exposed aggregates	357	2,701	139	530
Crusher run or fill or waste	4,692	25,398	3,580	16,349
Other coarse and fine aggregates	1,184	7,014	4,393	30,353
Other construction materials	3,998	24,973	[1]1,909	[1]11,813
Roofing granules	—	—	893	9,167
Special:				
Asphalt fillers or extenders	1,824	8,664	22	170
Other fillers or extenders	([2])	([2])	171	429
Other uses not listed	[3]795	[3]5,374	139	727
Unspecified:[4]				
Actual	43,434	275,713	14,412	93,024
Estimated	9,843	56,760	8,094	48,754
Total[5]	168,900	1,012,400	84,300	525,500
Total[6] [7]	186,200	1,012,400	92,900	525,500

[1] Includes drain fields.

[2] Included with "Other uses not listed."

[3] Includes other agricultural uses and poultry grit and mineral food.

[4] Includes production reported without a breakdown by end use and estimates for nonrespondents.

[5] Data may not add to totals shown because of independent rounding.

[6] One short ton is equal to 907 kilograms or 2,000 pounds. To convert metric tons to short tons, divide metric tons by 0.907185.

[7] Total shown in thousand short tons and thousand dollars.

TABLE 18
CRUSHED SANDSTONE AND QUARTZITE SOLD OR USED BY PRODUCERS IN THE UNITED STATES IN 1993, BY USE

(Thousand metric tons and thousand dollars)

Use	Sandstone		Quartzite	
	Quantity	Value	Quantity	Value
Coarse aggregate (+1 1/2 inch):

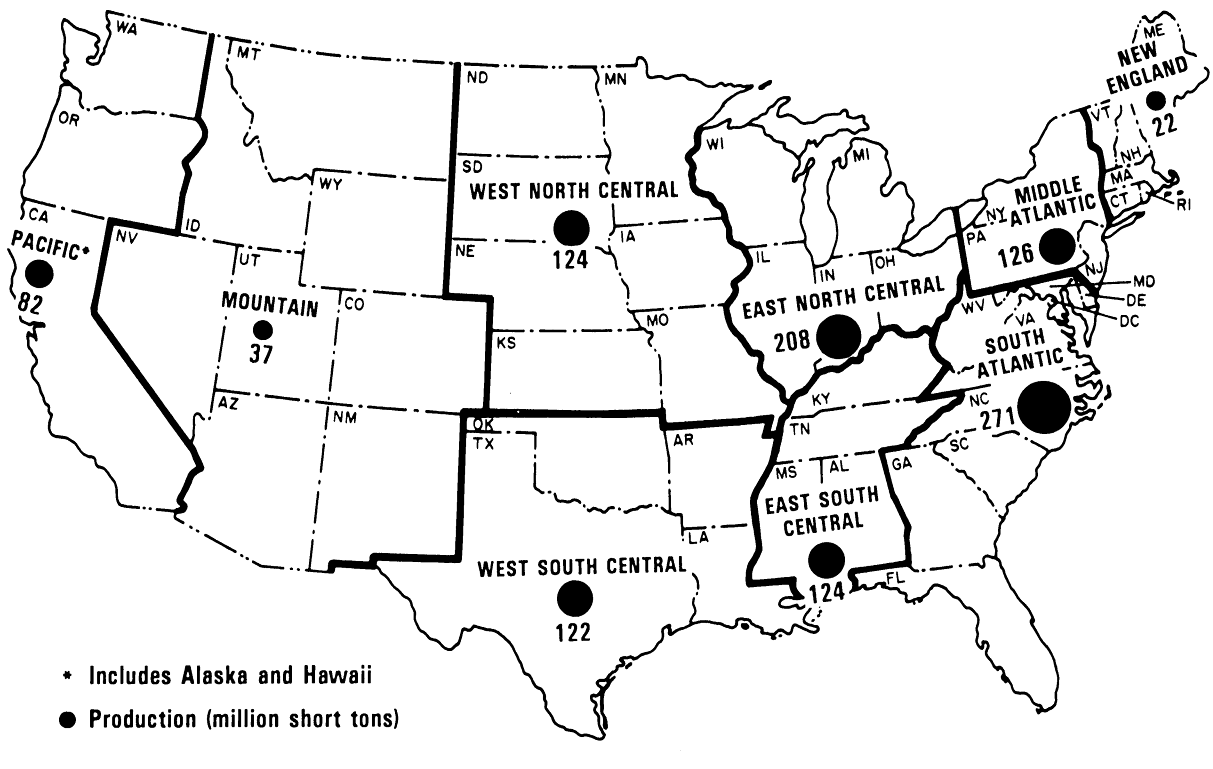
FIGURE 1

PRODUCTION OF CRUSHED STONE IN THE UNITED STATES IN 1993, BY GEOGRAPHIC REGION



DIMENSION STONE

By Harold A. Taylor, Jr.

Mr. Taylor, a physical scientist with 28 years of industry and Federal Government experience, including U.S. Bureau of Mines experience, has been the commodity specialist for dimension stone since 1981. Domestic survey data were prepared by Robin Richardson, statistical assistant.

Production of dimension stone increased slightly to 1.24 million metric tons (1.36 million short tons) valued at $217 million. Slightly more than one-half of the dimension stone produced was granite. Limestone, marble, sandstone, slate, and quartzite also were produced.

Exports of dimension stone increased 5% in value to $58 million. The value of dimension stone imports for consumption decreased slightly to $398 million, equivalent to 183% of the value of domestic production.

DOMESTIC DATA COVERAGE

Domestic production data for dimension stone are developed by the U.S. Bureau of Mines (USBM) from voluntary surveys of U.S. producers of rough and finished dimension stone. Of the 318 dimension stone operations surveyed for 1993, including those that were idle, 264, or 83%, responded, representing 92% of the value shown in table 1. Production data for nonrespondents were estimated using preliminary production reports, adjusted prior years' production levels, and employment data. *(See table 1.)*

BACKGROUND

Definitions, Grades, and Specifications

Dimension stone is a natural rock material that has been selected, trimmed, or cut to specified or indicated shapes or sizes, with or without one or more mechanically dressed surfaces. This includes rough stone, rubble, ashlar, blocks, panels, tile, and curvilinear shapes. Finished surface requirements may vary from a controlled fractured surface to ground and polished. The most prominent required qualities of dimension stone are strength, toughness, hardness, and resistance to environmental damage. Color and grain structure contribute largely to price and marketability. The principal types of dimension stone used in construction are granite, marble, limestone, sandstone, and slate.

Stone classification by type in the dimension stone industry is somewhat ambiguous and does not correspond in some respects with the same terms used in mineralogical rock descriptions. The USBM generally accepts the classification reported by producers. Granite includes all feldspathic crystalline rocks of predominantly interlocking texture with mineral grains visible to the naked eye; these include igneous and metamorphic rocks, including quartz diorites, syenites, quartz porphyries, gabbros, anorthosites, and gneisses. White, gray, black, pink, and red are the common colors for granite, but greens, browns, and other shades are produced in some localities.

Limestone includes dolomitic types as well as calcitic. The latter contain less than 5% magnesium carbonate ($MgCO_3$). Dolomitic limestone contains 5% to 40% $MgCO_3$. Marble is a recrystallized (metamorphosed) limestone containing grains of calcite or dolomite or both. In commercial usage, it is any calcareous crystalline rock or serpentine, a hydrous magnesium silicate, capable of taking a polish. Travertine is a type of marble similar to onyx except that it is precipitated from warm or hot water; it has a banded cellular structure and contains cavities up to 1 centimeter in width that are lined with microstalactites. Dark green serpentines are classified as marble in the industry because they are often crisscrossed with marblelike veinlets of lighter materials, chiefly calcite or dolomite, and because of their ability to take a high polish.

Commercial sandstone is a sedimentary rock consisting mostly of quartz, sometimes with feldspar, or rock fragments of clastic texture bonded by silica, clay, calcite, or iron oxide. Bluestone is a dense, hard, fine-grained feldspathic sandstone that splits easily along a plane into thin, smooth slabs. It is commonly dark or slate gray in color, and its name no longer has color significance. Brownstone is a feldspathic sandstone of brown reddish-brown color caused by abundant interstitial iron oxide. Flagstone may be either a sandstone or a slate that splits into large, thin slabs.

Quartzite is a metamorphic equivalent of sandstone that has been firmly cemented by secondary silica or by recrystallization so that it is essentially homogeneous and fractures through rather than around the original sand grains.

Slate is a fine-grained metamorphic rock derived from shale, siltstone, or claystone. It has prominent cleavage that is oriented independently from the original sedimentary bedding. Mineral constituents are quartz, mica, sericite, or chlorite with assorted minor accessories. Shale is composed mostly of original clay minerals, and cleavage is parallel to the bedding.

Traprock is a commercial term for all dark, igneous rocks too fine in grain size to be called black granite. In addition to extrusive flow rocks such as basalt, andesite, or dacite, traprock includes intrusive igneous rocks such as diabase, diorites, gabbros, pyroxenites, amphibolites, and peridotites.

Miscellaneous stones used for dimension purposes include schist, soapstone, argillite, and many others.

Geology-Resources

Domestic resources of most types of dimension stone used in construction are practically unlimited. There is considerable interstate transportation of certain types of stone such as Indiana limestone, Georgia marble and granite, and Vermont granite, marble, and slate. A lack of deposits of certain specific varieties of dimension stone especially noted for their aesthetic qualities in architecture and artifact manufacture is an important cause of importation of these varieties; for example, brightly colored marbles from Italy.

Technology

Mining.—Present mining methods range from antiquated and very inefficient to modern and technically superior. Quarrying methods include use of various combinations of diamond saws, wire saws, diamond wire saws, chain saws, channeling machines, drilling machines, wedges, and broaching tools. The choice of equipment depends on the type of dimension stone, size and shape of deposit, production capacity, labor costs, economics, and management investment attitudes.

Little blasting is done in the mining of dimension stone. Blocks cut from the face are sawed or split into smaller or thinner blocks for ease in transportation and handling and taken to processing plants, often at the quarry site, for final cutting and finishing operations.

Processing.—Stone-sawing equipment includes large circular saws 3 meters or more in diameter, some with diamond inserts and some using other abrasives; diamond circular saws of smaller size; and reciprocating diamond-bladed or loose-abrasive gang saws for multiple cuts. Various types of diamond and other equipment are used for smoothing, polishing, edging, and decorating the finished stone products. *(See table 2.)*

Economic Factors

The depletion allowance for dimension stone is 14%. Dimension stone quarries are generally in hilly areas remote from areas of dense population. Because land use for other purposes is limited, the cost of land is reasonable.

Transportation costs for dimension stone are high because of its weight and because special handling methods are required to prevent damage to the finished stone. A single stone panel broken in transit not only results in the loss of the many employee-hours of skilled labor required to produce it, but also can cause construction delays that are even more costly. Nevertheless, dimension stone is routinely shipped long distances by motor and rail freight, and special domestic varieties are shipped by ocean freight to foreign countries.

Operating Factors

Environmental requirements vary from State to State and are often a cause of conflict between State or local governments and the quarry operators.

Stone primary and waste products are not toxic, nor are the supplies utilized in their production. However, sufficient exposure to silica-rich stone dust can cause silicosis.

The approximate number of employees in the dimension stone industry by stone kind are granite, 9,600; limestone, 1,100; marble, 1,500; slate, 950; and sandstone and other dimension stone, 850. Of the total 14,000 employees, about 3,100 are employed in quarrying and approximately 10,900 in finishing operations. Major States for employment were Georgia with 2,100 employees, Vermont with 1,700, Minnesota with 1,250, North Carolina with 850, Texas with 700, and Indiana with 650.

Fuel is used to power quarrying equipment, and electricity is used for sawing and finishing. Water is used in some quarries to cool equipment such as chain saws and in sawing and finishing plants to cool the equipment; water consumption is relatively minimal in all instances.

ANNUAL REVIEW

Production

Dimension stone was produced by 162 companies at 256 quarries in 35 States, including Puerto Rico. Leading States, in order of tonnage, were Georgia, Indiana, and Massachusetts, together producing 39% of the Nation's total. Of the total production, 51% was granite, 30% was limestone, 9% was sandstone, 3% was slate★3% was marble, and the remaining 4% was miscellaneous stone. Miscellaneous stone included quartzite, argillite, schist, soapstone, and traprock (basalt). Leading producing companies in terms of tonnage were Fletcher Granite Co. Inc., in Massachusetts and New Hampshire; Cold Spring Granite Co., principally in California, Minnesota, South Dakota, and Texas; and Rock of Ages Corp. in New Hampshire and Vermont.

Granite.—Dimension granite includes all coarse-grained igneous rocks. Production increased 5% to 624,200 tons and decreased 5% in value to $110.5 million. Granite was produced by 58 companies at 100 quarries in 19 States. Georgia continued to be the leading State, producing 28% of the U.S. total, followed by Massachusetts and Vermont. These three States together produced 64% of the U.S. total. Fletcher Granite Co., Cold Spring Granite, and Rock of Ages were the leading producers and accounted for 47% of U.S. production by tonnage.

Limestone.—Dimension limestone includes bituminous, dolomitic, and siliceous limestones. It was produced by 36 companies at 44 quarries in 14 States. Indiana, the leading State, was followed by Wisconsin and Kansas. Leading producers were Indiana Limestone Co. Inc., Halquist Stone Co. Inc., and Eden Stone Co., Inc. The top three companies accounted for 31% of U.S. output.

Halquist Stone Co. of Sussex, WI, has been planning a large expansion of its limestone tile business. The company bought a tile line that was installed near the end of the year. Domestic demand for limestone tile has been increasing rapidly, mostly as a substitute for marble and granite.

Marble.—Dimension marble includes certain hard limestones, travertines, and any other calcareous stone that can be polished. Dimension marble was produced by 9 companies at 16 quarries in 9 States, including Puerto Rico. Vermont, Georgia, and Tennessee, in order of tonnage, were the three leading States, accounting for approximately 62% of U.S. output. Leading producers were Vermont Quarries Corp., Dixie Marble Inc., and Georgia Marble Co. The top three companies accounted for 78% of the U.S. output.

Vermont Marble Co. disposed of its dimension marble operations. The company leased its Danby marble quarry to R.E.D. Graniti, which plans to increase production and sell the product as rough block, mostly overseas. The operating subsidiary is Vermont Quarries Corp.

Vermont Marble also sold its verde antique quarry to Marble Modes of New York, NY, which will be operated as Vermont Verde Antique International Inc. Marble Modes added a diamond chain saw and plans to reequip the rest of the quarry. Some of the finishing equipment was sold to U.S. Quarried Slate Products Co., and the balance of the equipment and plant was sold to Gawet Marble & Granite Inc.

Gawet also bought the Luck Stone Co. operation in Tennessee as part of a major expansion. The purchase included a quarry for Tennessee pink marble and a plant built in 1989, including gang saws, a polisher, a tile line, and other cutting and finishing equipment. Gawet will operate its newly acquired operation under the name Tennessee Marble Co.

Sandstone.—Dimension sandstone includes calcareous- and siliceous-cemented sandstones or conglomerates. Quartzite, which is also included, may be described as any siliceous-cemented sandstone. Sandstone was produced by 26 companies at 45 quarries in 14 States. The leading three States were, in order of volume, Ohio, Utah, and Oklahoma. Briar Hill Stone Co., American Building and Stone, Inc. and Rock Island Stone Co. were the leading producers and accounted for 35% of U.S. production. In addition to the quantities shown in table 6, dimension quartzite totaled 27,822 tons worth $2,716,000. The tonnage was 33% flagging.

Slate.—Dimension slate was produced by 19 companies at 26 quarries in 6 States. The two leading States, Vermont and Pennsylvania, in order of volume, accounted for 69% of U.S. output. The top three producers, U.S. Quarried Slate Products Inc., A. Dally and Sons Inc., and Alfred McAlpine Inc., accounted for an estimated 44% of U.S. output by volume.

Miscellaneous Stone.—Miscellaneous dimension stone was produced by nine companies from nine quarries in five States and totaled 34,846 tons valued at $4,034,000. *(See tables 3, 4, 5, and 6.)*

Consumption and Uses

Dimension stone was marketed over wide areas. Industry stockpiles were not monitored, and production during 1993 was assumed to equal consumption.

Consumption of domestic dimension stone increased slightly to 1.24 million tons valued at $217 million. Ashlars and partially squared, dressed pieces were 17% of the total value of consumption, followed by curbing with 15%; rough monumental stone with 13%; rough blocks for building and construction with 12%; dressed monumental stone with 12%; and other uses, 31%.

Of the total consumption of domestic granite, 29% by value was curbing, 25% was rough monumental stone, and 15% was dressed monumental stone.

Consumption of domestic limestone totaled 366,018 tons valued at $50.2 million, of which 40% was ashlars and partially squared pieces, 19% by value was dressed slabs and blocks for building and construction, and 18% was rough blocks for building and construction.

Limestone tile is an important new product that is rapidly gaining popularity. For several years now, tiles made out of hard limestone have sometimes been used as substitutes for other stones, particularly granite tile. These tiles (or slabs) have sometimes been domestic, but more commonly were French or Spanish limestones. They were used in applications where granite or marble are customarily used. Now tile of softer limestones are being made and sold. Specific applications known include some flooring areas not subject to heavy traffic or grit-bearing footwear. *(See tables 7, 8, 9, 10, 11, and 12.)*

In a long-enduring trend before 1980, building dimension stone was replaced to a large extent by concrete, glass, brick, stainless steel, aluminum, porcelain-enameled steel, and plastics. These materials are used in the manufacture of modern mass-produced building modules and precast building panels. The installed cost of many of these alternate materials has been lower than that of stone. Since 1980, stone has been increasingly preferred for more dignified buildings where its architectural adaptability, permanence, and prestige are of prime importance. A movement back to stone has occurred because of the greater impact of rising energy costs on these substitutes. Resin-bonded stone panels made from stone chips are becoming an important substitute for dimension stone.

Slate has to meet competition from many sources. As roofing material, alternates such as sheet metal, wood shingles, asbestos-cement shingles, and tile are available. For blackboards, it competes with colored glass, porcelain-enameled steel, and special painted surfaces.

Two helpful articles on stone in

Washington, DC, appeared in Stone World. One described the stone used in the building now being leased to the USBM as its headquarters.[1] The other identified the stones used in the major monuments, the U.S. Capitol, a number of major nearby buildings, and thumbnailed the present local quarries.[2]

Prices

The average price for dimension stone decreased to $176 per ton, down slightly from $182 in 1992.

Foreign Trade

Exports.—Exports of dimension stone, more than 50% of which was granite, increased 5% in value.

Imports.—Imports for consumption of dimension stone decreased slightly in value to $398 million, mostly because of minor decreases in imports of major categories of dimension stone. On a value basis, marble accounted for 48% of imports, followed by granite, 27%. *(See tables 13, 14, 15, and 16.)*

World Review

Although some production of dimension stone occurred in most countries of the world, the major producer again was Italy, accounting for about one-half of world production. Other major producers were Brazil, China, Finland, India, Norway, Portugal, Spain, Sweden, Turkey, and the United States.

Internazionale Marmi e Macchine Carrara S.p.A. has issued the following updated production statistics for certain nations: For granite in 1992, China produced 1,867,000 tons; India (1991-92), 989,500 tons; Italy, 1,100,000 tons; Korea (Republic of), 1,380,000 tons; South Africa (Republic of), 574,800 tons; and Spain, 980,000 tons. For granite in 1991, China produced 652,000 tons; Italy, 1,374,000 tons; Korea (Republic of), 1,541,000 tons; South Africa (Republic of), 672,600 tons; and Spain, 1,150,000 tons. For marble in 1992, China produced 678,000 tons; France, 634,000 tons; India (1991-92), 1,966,400 tons; Italy, 4,800,000 tons; Mexico, 712,000 tons; Portugal, 962,000 tons; Spain, 2,000,000 tons; and Turkey, 650,000 tons. For marble in 1991, China produced 625,000 tons; France, 686,100 tons; Italy, 4,115,000 tons; Mexico, 750,000 tons; Portugal, 950,000 tons; Spain, 2,210,000 tons; and Turkey, 650,000 tons.

Australia.—Fraser Range Granite NL announced that it will shortly begin to quarry four kinds of granite in the Fraser Range area of Western Australia. Its commercial production began in mid-1992 to fill some building contracts in Sydney. It hopes to export significant amounts of rough block.

Canada.—Jarvis Resources Ltd. announced the availability of marble tile, slabs, and sills in polished, honed, and sand finishes from its new finishing plant. There are six colors and veinings in gray and gray-brown colors presently available, with additional types to come later. These quarries are 35 kilometers north of Sudbury, Ontario.

India.—The International Labour Office in Geneva, a United Nations agency, documented the bonded labor practices in the Indian dimension stone industry in its "World Labour Report 1993." Bonded labor is a defacto form of slavery, because it involves giving an advance that the laborer has to pay from future earnings. But at very low wages and with the employer usually charging for tools and/or accommodations, the debt is never repaid. On the death of the original laborer, the employer may insist that the debt be honored by the child, thus creating another bonded laborer. Bonded laborers in all industries in India may number in the millions, although the Government of India acknowledges only 353,000! Many of these laborers are children. Although the Government is attempting to stop the practice, its prosecution of guilty employers is minimal and its laborer rehabilitation program is not very effective yet. Bonded laborers are concentrated in a few industries, one of which is stone quarrying.

According to information in Dimensional Stone, bonded laborers, particularly children, are used in many quarries in India. The dimension stone product is often exported to U.S. and world markets. Dimensional Stone urged the industry not to do business with firms unwilling to certify that they are nonusers of bonded laborers and now refuses to take advertisements from such firms. The All India Granites & Stone Association wrote the magazine to protest the policy and the political smears behind it, stating that bonded labor was totally nonexistent in the industry, that the industry always paid its laborers at least the minimum wage with liberal leave and bonuses for festivals, and that the industry's employees totaled fewer than 200,000.

A number of sizable quarries, particularly granite, have been recently opened in Rajasthan State. Total capacity for finished marble slabs in Rajasthan is 37 million square meters and for marble tile is 14 million square meters; these numbers represent the majority of all-India marble capacity. A joint venture called Immaculate Stones Ltd. announced it would build a granite quarrying and finishing operation in 1994 in Orissa State with the collaboration of Italian dimension stone equipment manufacturer Terzago S.p.A. Nagarjuna Granites Ltd. is expanding its plant to an annual capacity of 75,000 square meters of tile and panel. Charminar Granites Exports Ltd. announced it would build an operation in Andhra Pradesh with capacities of 50,000 square meters of tile per year and 40,000 square meters of slab and panel per year.

Canadian granite monument producers filed a dumping and subsidy case against Indian black granite memorials and slabs more than 8 centimeters thick with Revenue Canada Taxation. Revenue Canada Taxation will collect information from the complainants and the defendants; a nonresponse will result in a determination for the other side. If a preliminary determination of injury results, a duty of 89% could be imposed; it would be permanent upon a final determination of injury.

Italy.—Ifint, the investment arm of Fiat's (automotive) Agnelli family, has purchased a stake in Georgia Marble Co. for $100 million from First Chicago Corp., along with 17 other firms for a grand total of $300 million.

The Carrara area has the potential for a sizable crushed marble industry based on the waste from dimension marble production. The amount of waste available is immense and incalculable; it blankets the mountains, giving the appearance of snow. The large amount of waste is the result of innumerable years of quarrying; Carrara marble yields minimal waste per ton quarried. According to a survey of 55 dumps, almost one-half of the material is unusable, low-calcium carbonate Pietra di Cardozo, a material with a sizable crystalline silica content. Several crushed marble plants using waste as a raw material already exist, one of them at Pianello.

Korea, Republic of.—Il Shin Stone Co., one of the countries largest producers, has expanded to the point that it has 22 gangsaw plants around the country and finishes 240,000 square meters of granite per month, two-thirds of which is domestically consumed.

Portugal.—Portugal produces major amounts of such stones as granite (250,000 tons produced in 1991) and limestone, but the largest amount produced is the 950,000 tons of marble. Granite is mostly produced in the north near such cities as Porto and Braga. Limestone is quarried at scattered locations, several of which are in the far south near Tavira. Marble is mostly produced east of Lisbon in the Estremoz-Evora area; this area alone has 240 quarries and is a major center for finishing operations. However, new environmental laws, including the establishment of national parks, are expected to impede the opening of new quarries.[3]

South Africa, Republic of.—South African granite producers are shifting their exports from rough block to polished slab to save on transportation costs. For example, 30% of the original rough block is lost as waste after conversion to polished slab. Their transportation and handling costs total 70% of the value of the stone by the time it arrives in Italy.

Keeley Granite, the major granite producer, has acquired extensive mineral rights to the Rustenburg Gray and African Red granites. Several Italian firms have bought into local granite producers. South African black granite producers have been troubled with competing material from Zimbabwe.

Current Research

An article on the latest methods for removing stone dust from the water and air circulating in a stone finishing plant was published. A variety of air and water filtration systems was described. Air filtration systems have the advantage of cleaning the air in a more controlled way rather than opening a window or door and having employees wear face masks.[4]

In response to stone consumers' need for lightweight materials, Pedrini S.p.A. began offering a sectioning machine that can make 6.5-millimeters- (0.25-inch)-thick granite tile. In addition, the company is offering a scanning machine that inspects marble and granite tile for uniformity of color, broken corners, cracks, and other defects.

The reinforced thin-cut stone panel can be used in places where weight is a consideration, such as elevators and yachts. The stone is only 5 millimeters (3/16 inches) thick and is often anchored to a metal honeycomb.

OUTLOOK ★ ★

Projected demand for dimension granite totaled 1.3 million tons for 1995 and 2 million tons for the year 2000. Demand for dimension marble totaled 300,000 tons for 1995 and 500,000 tons for the year 2000. Demand for dimension limestone totaled 360,000 tons for 1995 and 400,000 tons for the year 2000, while demand for slate ought to be 35,000 tons in 1995 and 37,000 tons in the year 2000. This slow rate reflects a major drop in the market for building stone in 1989-93 and a welcomed recovery later in the 1990's. Certain segments will continue to grow rapidly, such as for uses in kitchens and bathrooms. The supply will be adequate and is likely to shift in favor of domestic producers.

Rough blocks or slabs of marble, travertine, and other calcareous monumental or building stone	2515.00.0000		
Marble and travertine:			
Crude or roughly trimmed	2515.11.0000	$3.46 per cubic meter	$22.95 per cubic meter.
Marble, merely cut	2515.12.0010	2.1% ad valorem	13% ad valorem.
Travertine, merely cut	2515.12.0020	6% ad valorem	50% ad valorem.
Other calcareous stone alabaster	2515.20.0000	6% ad valorem	50% ad valorem.
Rough blocks or slabs of granite, porphyry, basalt, sandstone, and other monumental or building stone	2516.00.0000		
Granite:			
Crude or roughly trimmed	2516.11.0000	Free	$8.83 per cubic meter.
Merely cut	2516.12.0000	4.2% ad valorem	60% ad valorem.
Sandstone:			
Crude or roughly trimmed	2516.21.0000	Free	$5.30 per cubic meter.
Merely cut	2516.22.0000	6% ad valorem	50% ad valorem.
Other monumental or building stone	2516.90.0000	6% ad valorem	50% ad valorem.
Setts, curbstones, and flagstones	6801.00.0000	4.2% ad valorem	60% ad valorem.
Worked monumental or building stone	6802.00.0000		
Tiles and cubes under 7cm square, granules	6802.10.0000	6.9% ad valorem	40% ad valorem.
Other stone and articles with a flat or even surface:			
Marble, travertine and alabaster:	6802.21.0000		
Travertine	6802.21.1000	6% ad valorem	50% ad valorem.
Other	6802.21.5000	2.1% ad valorem	13% ad valorem.
Other calcareous stone	6802.22.0000	6% ad valorem	50% ad valorem.
Granite	6802.23.0000	4.2% ad valorem	60% ad valorem.
Other stone	6802.29.0000	7.5% ad valorem	30% ad valorem.
Other:			
Marble, travertine, and alabaster:	6802.91.0000		
Marble:			
Slabs	6802.91.0500	2.8% ad valorem	15% ad valorem.
Other	6802.91.1500	6% ad valorem	50% ad valorem.

TABLE 2—Continued

U.S. IMPORT DUTIES ON DIMENSION STONE

Tariff item	HTS No.	Most favored nation (MFN)	Non-MFN
		Jan. 1, 1994	Jan. 1, 1994
Other—Continued:			
Marble, travertine, and alabaster—Continued:			
★ Travertine:			
Articles of subheading 6802.21.1000 that have been dressed or polished, but not further worked	6802.91.2000	6% ad valorem	50% ad valorem. ☆
Other	6802.91.2500	5.3% ad valorem	40% ad valorem.
Alabaster	6802.91.3000	5.3% ad valorem	50% ad valorem.
Other calcareous stone	6802.92.0000	6% ad valorem	50% ad valorem.
Granite	6802.93.0000	4.2% ad valorem	60% ad valorem.
Other stone	6802.99.0000	6.5% ad valorem	40% ad valorem.
Worked slate and articles:	6803.00.0000		
Roofing slate	6803.00.0010	6.6% ad valorem	25% ad valorem.
Other	6803.00.0050	3.7% ad valorem	25% ad valorem.

Total	366,018	5,203	50,230
Total[2]	403,466	5,203	50,230

[1]Includes Alabama, Arkansas, California, Iowa, Minnesota, New Mexico, New York, Ohio, Oklahoma, Texas, and Utah.

[2]One short ton is equal to 907 kilograms or 2,000 pounds. To convert metric tons to short tons, divide metric tons by 0.907185.

TABLE 6
DIMENSION SANDSTONE SOLD OR USED BY PRODUCERS IN THE UNITED STATES IN 1993, BY STATE

State	Quantity (metric tons)	Cubic feet (thousands)	Value (thousands)
New York	8,202	116	$870
Ohio	25,738	391	1,207
Pennsylvania	13,196	186	1,655
Other[1]	66,223	934	4,000
Total[2]	113,358	1,629	7,731
Total[3]	124,956	1,629	7,731

[1]Includes Alabama, Arizona, Arkansas, California, Colorado, Indiana, Kansas, Michigan, North Carolina, Oklahoma, and Utah.

[2]Data may not add to totals shown because of independent rounding.

[3]One metric ton is equal to 907 kilograms or 2,000 pounds. To convert metric tons to short tons, divide metric tons by 0.907185.

TABLE 7

DIMENSION STONE SOLD OR USED BY PRODUCERS IN THE UNITED STATES IN 1993,[1] BY USE

Use	Quantity (metric tons)	Cubic feet (thousands)	Value (thousands)
Rough stone:			
Rough blocks for building and construction	243,803	3,413	$26,004
Irregular-shaped stone[2]	102,171	1,240	9,467
Monumental	209,279	2,539	28,371
Other[3]	24,769	317	2,623
Dressed stone:			
Ashlars and partially squared pieces	194,612	2,662	37,899
Slabs and blocks for building and construction	53,921	750	24,144
Monumental	41,757	486	25,083
Curbing	222,400	2,921	32,922
Flagging	61,313	854	5,230
Flagging (slate)	5,988	—	866
Roofing slate	14,091	—	10,891
Structural and sanitary	4,560	—	3,906
Flooring slate	4,230	—	2,918
Other[4]	52,328	658	6,606
Total	1,235,222	15,840	216,930
Total[5]	1,361,599	15,840	216,930

[1] Includes Puerto Rico.

[2] Includes rubble.

[3] Includes rough stone used for flagging and unspecified uses.

[4] Includes minor amount of paving blocks, slate used for billiard tabletops, blackboard, bulletin boards and school slates, and unspecified uses.

[5] One short ton is equal to 907 kilograms or 2,000 pounds. To convert metric tons to short tons, divide metric tons by 0.907185.

TABLE 8

DIMENSION GRANITE SOLD OR USED BY PRODUCERS IN THE UNITED STATES IN 1993, BY USE

Use	Quantity (metric tons)	Cubic feet (thousands)	Value (thousands)
Rough stone:			
Rough blocks for building and construction	81,264	1,039	$13,169
Irregular-shaped stone[1]	16,640	197	1,698
Monumental	205,717	2,492	27,497
Dressed stone:			
Ashlars and partially squared pieces	50,593	661	12,795
Slabs and blocks for building and construction	15,008	200	6,268
Monumental	36,954	424	16,059
Curbing	214,116	2,806	32,369
Other[2]	3,948	52	628
Total[3]	624,240	7,872	110,484
Total[4]	688,107	7,872	110,484

[1] Includes rubble and a minor amount of uses not specified.

[2] Includes stone used for flagging, paving block, and unspecified uses for dressed stone.

[3] Data may not add to totals shown because of independent rounding.

[4] One short ton is equal to 907 kilograms or 2,000 pounds. To convert metric tons to short tons, divide metric tons by 0.907185.

TABLE 9

DIMENSION LIMESTONE SOLD OR USED BY PRODUCERS IN THE UNITED STATES IN 1993, BY USE

Use	Quantity (metric tons)	Cubic feet (thousands)	Value (thousands)
Rough stone:			
Rough blocks for building and construction	128,800	1,918	$8,862
Irregular-shaped stone[1]	56,449	756	5,333
Dressed stone:			
Ashlars and partially squared pieces	84,688	1,191	20,009
Slabs and blocks for building and construction	25,652	371	9,420
Flagging	27,461	375	2,517
Other[2]	42,969	592	4,089
Total	[3]366,018	5,203	50,230
Total[4]	403,467	5,203	50,230

[1] Includes uses not specified.

[2] Includes dressed monumental, curbing, and unspecified uses for dressed stone.

[3] Data do not add to total shown because of independent rounding.

[4] One short ton is equal to 907 kilograms or 2,000 pounds. To convert metric tons to short tons, divide metric tons by 0.907185.

TABLE 10

DIMENSION MARBLE SOLD OR USED BY PRODUCERS IN THE UNITED STATES IN 1993,[1] BY USE

Use	Quantity (metric tons)	Cubic feet (thousands)	Value (thousands)
Rough stone:			
Rough blocks for building and construction	16,875	219	$3,329
Other[2]	5,263	68	1,000
Dressed stone:			
Ashlars and partially squared pieces	1,355	18	W
Slabs and blocks for building and construction	7,522	98	7,702
Other[3]	4,626	60	9,224
Total	35,641	463	[4]21,254
Total[5]	39,288	463	21,254

W Withheld to avoid disclosing company proprietary data; included with "Other."

[1] Includes Puerto Rico.

[2] Includes rubble, irregular-shaped stone, moumental stone, and unspecified uses.

[3] Includes stone used for monumental purposes, a small amount of flagging, and unspecified.

[4] Data do not add to total shown because of independent rounding.

[5] One short ton is equal to 907 kilograms or 2,000 pounds. To convert metric tons to short tons, divide metric tons by 0.907185.

TABLE 11

DIMENSION SANDSTONE SOLD OR USED BY PRODUCERS IN THE UNITED STATES IN 1993, BY USE

Use	Quantity (metric tons)	Cubic feet (thousands)	Value (thousands)
Rough stone:			
Rough blocks for building and construction	14,309	202	$465
Irregular-shaped stone[1]	21,621	302	1,842
Other[2]	110	2	27
Dressed stone:			
Ashlars and partially squared pieces	43,734	645	3,235
Slabs and blocks for building and construction	2,446	36	305
Flagging	21,537	310	1,240
Other[3]	9,603	133	617
Total[4]	113,358	1,629	7,731
Total[5]	124,956	1,629	7,731

[1] Includes rubble.

[2] Includes uses not specified.

[3] Includes dressed monumental, curbing, and unspecified uses for dressed stone.

[4] Data may not add to totals shown because of independent rounding.

[5] One short ton is equal to 907 kilograms or 2,000 pounds. To convert metric tons to short tons, divide metric tons by 0.907185.

TABLE 12

DIMENSION SLATE SOLD OR USED BY PRODUCERS IN THE UNITED STATES IN 1993, BY USE

Use	Quantity (metric tons)	Value (thousands)
Flagging	5,988	$866
Roofing	14,091	10,891
Structural and sanitary purposes	4,560	3,906
Flooring	4,230	2,918
Other[1]	3,758	1,858
Total	32,628	[2]20,440
Total[3]	35,966	20,440

[1] Includes a minor amount of slate used for billiard tabletops, blackboard, school slates, and unspecified uses.

[2] Data do not add to total shown because of independent rounding.

[3] One short ton is equal to 907 kilograms or 2,000 pounds. To convert metric tons to short tons, divide metric tons by 0.907185.

TABLE 13
U.S. EXPORTS OF DIMENSION STONE, BY TYPE

Type	1992 Quantity (thousand metric tons)	1992 Value (thousand dollars)	1993 Quantity (thousand metric tons)	1993 Value (thousand dollars)	Major destination in 1993, (percent)[1]
Marble, travertine, alabaster worked	19	2,839	34	2,561	Canada, 40.
Marble, travertine—crude or roughly trimmed	4	1,154	3	936	Canada, 46.
Marble, travertine—merely cut, by sawing or otherwise	4	2,070	5	1,103	Mexico, 29.
Granite, crude or roughly trimmed	60	12,253	61	13,787	Italy, 40.
Granite, merely cut by sawing or otherwise	47	18,444	73	17,840	Japan, 35.
Granite, dressed, worked	12	6,010	9	5,178	Canada, 70.
Sandstone, crude or roughly trimmed	1	138	1	286	Canada, 90.
Sandstone, merely cut, by sawing or otherwise	6	1,221	6	1,227	Canada, 94.
Slate, worked and articles of slate	NA	7,695	NA	11,065	The Bahamas, 29.
Slate, whether or not roughly trimmed or merely cut	NA	380	NA	740	Canada, 58.
Other calcareous monumental or building stone; alabaster	5	918	4	942	Canada, 40.
Other monumental or building stone	11	1,782	15	2,223	Canada, 50.
Total	NA	54,904	NA	57,888

SULFUR

By Joyce A. Ober

Mrs. Ober, a physical scientist with 16 years of industry and U.S. Bureau of Mines experience, has been a commodity specialist since 1986. Domestic survey data were prepared by Pamela G. Shorter, statistical assistant; and the international production table was prepared by Ron Hatch, international data coordinator.

Domestic production of sulfur increased for the first time since 1989, but consumption declined for the fourth consecutive year. However, the United States maintained its position as the leading producer and consumer of sulfur and sulfuric acid in the world. The quantity of sulfur recovered during the refining of petroleum and the processing of natural gas continued its upward trend established in 1938, the year the U.S. Bureau of Mines (USBM) started publishing data on the production of this type of sulfur. The production of sulfur through the Frasch process was slightly higher than it had been in 1992 although listed production data only represents 10 months of Frasch data to conform with proprietary data requirements. Frasch production increased as a result of significant improvements in production rates at the newest Frasch mine. Total production of sulfur from all sources increased but shipments decreased and stocks grew.

Byproduct sulfuric acid from the Nation's nonferrous smelters and roasters, essentially mandated by laws concerning sulfur dioxide emissions, supplied a significant quantity of sulfuric acid to the domestic merchant acid market. Marketing continued to be difficult for some producers because smelters were near western copper mines and far from major sulfuric acid markets.

Worldwide, sulfur production was virtually unchanged from that of 1992, with a 13% decrease in Frasch production and a 6% increase in the amount recovered from petroleum and natural gas processing. Frasch production was lower because the final Mexican mine closed during the year, Polish mines operated at low rates, Iraq had not resumed full production following the war in the Persian Gulf, and political and economic problems continued in Eastern Europe and the former U.S.S.R. Recovered elemental production increased in Asia, the Middle East, North America, and Western Europe; decreased in Eastern Europe and the former U.S.S.R.; and remained about the same in the rest of the world. Nearly three-quarters of the world's elemental sulfur production came from recovered sources; the quantity of sulfur supplied from these sources was dependent on the world demand for fuels and petroleum products, not on the demand for sulfur.

World sulfur consumption decreased an estimated 8%. Consumption in fertilizer production decreased, and consumption for a myriad of industrial uses continued to be pressured by environmental constraints placed on the products produced or effluents from the chemical processes utilizing sulfur or its major derivative, sulfuric acid.

World trade of elemental sulfur decreased by an estimated 1.7 million metric tons, about 11% below levels recorded in 1992. U.S. sulfur inventories increased 64% during 1993, and worldwide producers' stocks of elemental sulfur increased a more modest 11%. *(See table 1 and figure 1.)*

DOMESTIC DATA COVERAGE

Domestic production data for sulfur are developed by the USBM from four separate, voluntary surveys of U.S. operations. Typical of these surveys is the "Elemental Sulfur" survey. Of the 175 operations to which a survey request was sent, all but 1 responded, representing virtually 100% of the total production shown in table 1. Production data for the nonrespondent was obtained from another public source.

BACKGROUND

Sulfur, through its major derivative sulfuric acid, ranks as one of the more important elements utilized by humanity as an industrial raw material. It is of prime importance to every sector of the world's industrial and fertilizer complexes. Sulfuric acid consumption has been regarded as one of the best indexes of a nation's industrial development.

Also known as brimstone, "the stone that burns," sulfur was used in small quantities for thousands of years. Ancient people were probably first drawn to native sulfur by its bright yellow color and pungent odor. Early humanity used sulfur as a colorant for cave drawings, as a fumigant, for medicinal purposes, and as incense. As early as 2000 B.C., the Egyptians used sulfur in the bleaching of linen textiles. In the Odyssey, Homer refers to its use as a fumigant. During the Peloponnesian War, fifth century B.C., the Greeks burned a sulfur-pitch mixture to generate suffocating gases. The Romans combined brimstone with tar, pitch, and other combustible materials to produce the first incendiary weapons. Muslims during the "Golden Age of Arabic Science," from about A.D. 700, developed alchemy and were probably the first producers of sulfuric acid. Sulfur is a necessary ingredient in gunpowder, which was developed as a pyrotechnic in China by the 10th century. Gunpowder's introduction into Europe led to its use in warfare in the 14th century and made sulfur an important mineral commodity for the first time.

However, it was not until the birth of the science of chemistry in the 1700's and the growth of chemical industries in the 1800's that sulfur became of major importance to the world outside of its use in warfare. Early chemists soon recognized the importance of sulfuric acid as the cheapest and most versatile of the mineral acids, and it rapidly became and remains the most commonly used acid in the chemical industry. More sulfuric acid is produced in the United States every year than any other chemical; about 96 million tons was produced in 1993.[1]

Sulfur is one of the few elements that occurs in the native, or elemental, state. It also occurs combined with iron and base metals as sulfide minerals, and with the alkali metals and alkali earths as sulfate minerals. In petroleum, sulfur is found in a variety of complex organic compounds, and in natural gas as hydrogen sulfide (H_2S) gas. In coal, sulfur occurs in complex organic compounds and as "coal brasses" (pyrites-marcasite). Commercial production of sulfur in the United States is accomplished by a variety of methods dictated by the source of sulfur.

Definitions, Grades, and Specifications

Bright Sulfur.—Crude sulfur free of discoloring impurities and bright yellow in color.

Brimstone.—Synonymous with crude sulfur.

Broken Sulfur.—Solid crude sulfur crushed to minus 20-centimeter size.

Crude Sulfur.—Commercial nomenclature for elemental sulfur.

Dark Sulfur.—Crude sulfur discolored by minor quantities of hydrocarbons ranging up to 0.3% carbon content.

Elemental Sulfur.—Processed sulfur in the elemental form produced from native sulfur or combined sulfur sources, generally with a minimum sulfur content of 99.5%.

Frasch Sulfur.—Elemental sulfur produced from native sulfur sources by the Frasch mining process.

Native Sulfur.—Sulfur occurring in nature in the elemental form.

Prilled Sulfur.—Solid crude sulfur in the form of pellets produced by cooling molten sulfur with air or water.

Pyrites.—Iron sulfide minerals that include pyrite, marcasite, and pyrrhotite.

Recovered Sulfur.—Elemental sulfur produced from combined sulfur sources by any method.

Slated Sulfur.—Solid crude sulfur in the form of slatelike lumps produced by allowing molten sulfur to solidify on a water-cooled, moving belt.

Sulfur Ore.—Unprocessed ore containing native sulfur.

Sulfuric Acid.—Sulfuric acid of commerce produced from all sources of sulfur, generally reported in terms of 100% H_2SO_4 with a 32.69% sulfur content.

Products for Trade and Industry

Elemental sulfur of commerce, sometimes called crude sulfur or brimstone, may be marketed in either the liquid or the solid phase, generally with a minimum sulfur content of 99.5%. Most elemental sulfur marketed in North America is sold as liquid sulfur. In worldwide commerce, sulfur is shipped either as broken sulfur or formed sulfur. Formed sulfur—prills, slates, and pastilles—is generally preferred to broken sulfur because it is less prone to dusting and the release of fugitive dust at terminals where sulfur is stored and transferred from one transportation mode to another. Sulfuric acid may be sold at various strengths, usually depending on the requirements of the consumer. The acid is generally marketed on a 100% basis, but is normally shipped at 66° Baume (93% H_2SO_4), as 98% acid, or as 20% to 22% fuming oleum, which is sulfur trioxide dissolved in sulfuric acid.

Industry Structure

Over the centuries, many fundamental changes have occurred in the sources of sulfur supply. Early civilizations obtained their meager requirements from native sulfur deposits in or around volcanoes. The increase in demand for sulfur in the late 1700's and early 1800's was largely satisfied from extensive native sulfur deposits in Sicily. Monopolistic practices by the owners of sulfur mining facilities in Sicily led to exorbitant sulfur prices, causing consumers to adopt iron pyrites as the second major sulfur source during the mid- to late 19th century. The development in 1895 of the Frasch process for mining the large native deposits associated with salt domes in Louisiana and Texas brought a new and important source of sulfur to the United States and world markets. Frasch sulfur and pyrites maintained their joint predominance as world sulfur sources through the mid-1970's.

With small beginnings in the 1930's and increasing significantly from the 1950's onward, environmentally mandated or involuntary sulfur recovered during natural gas processing and petroleum refining grew to surpass Frasch sulfur and pyrites as the world's major source of sulfur. In addition, increasing quantities of byproduct sulfuric acid from smelting operations have been produced to comply with pollution control laws and environmental regulations worldwide.

Sulfur in its various forms is produced worldwide, with no single nation predominating as a producer or supplier to world markets. In 1993, world sulfur production and consumption amounted to 52.3 million and 53.1 million metric tons, respectively. The United States was the world's largest producer and consumer; the United States also was a net importer of sulfur. Following the breakup of the U.S.S.R., Canada became the second largest sulfur producer and maintained its position as the world's leading exporter of elemental sulfur. China, the world's third largest producer and largest pyrites producer, was also the third largest sulfur consumer, satisfying most of its sulfur requirements from internal sources. Ranking other leading producers in terms of sulfur production has become difficult, with Japan, Mexico, Poland, Russia, and Saudi Arabia all producing between 2 million and 3 million tons in 1993. Poland and Saudi Arabia followed Canada as leading exporters with nearly identical amounts.

Geology-Resources

Sulfur is widely distributed in nature, constituting 0.060% of the Earth's crust. Sulfur combines with most other elements, except the inert gases and nitrogen. Practically all plant and animal life on Earth contains some sulfur. Only a very small portion of the world's sulfur resources occurs in sufficiently concentrated quantities to justify commercial extraction by mining or other recovery methods. Sulfur is one of the few substances found in nature in the elemental form; it also occurs combined with other elements as sulfides, sulfates, or organic compounds in sedimentary, metamorphic, and igneous rocks, as well as in all fossil fuels. By type, sulfur deposits are classified as follows:

Native (Elemental) Sulfur Deposits.—These include deposits (1) in anhydrite-limestone cap rock on the top and flanks of salt domes, (2) in bedded anhydrite-gypsum evaporite basin formations, and (3) in unconsolidated volcanic deposits. In salt dome cap rock and evaporite beds, the sulfur is believed to have been formed by hydrocarbon reduction of anhydrite, assisted by bacterial action. Volcanic sulfur was produced by the reaction between escaping hydrogen sulfide and sulfur dioxide.

Large deposits over salt domes are mined in the gulf coast regions of the United States and Mexico. Extensive deposits in evaporites are mined in west Texas, Iraq, Poland, and the former U.S.S.R. Together, these deposits are by far the principal source of mined elemental sulfur, generally extracted by the Frasch hot-water process. Most volcanic sulfur occurrences are in the circum-Pacific belt. Volcanic sulfur deposits are locally important, but furnish only a minor portion of the world's sulfur supply.

Sulfide Deposits.—These include deposits of (1) ferrous sulfides (pyrite, marcasite, and pyrrhotite) that, while they may contain minor quantities of nonferrous metals, are generally mined and processed for their sulfur content and (2) nonferrous metal sulfides, which are mined for their metal content and in the processing produce sulfur in the form of sulfuric acid. In order of importance from the quantity of acid produced, sulfide minerals of copper, lead, zinc, molybdenum, nickel, mercury, arsenic, antimony, and silver are the most noted in the nonferrous sulfide group.

Sulfate Deposits.—These include bedded deposits of anhydrite and gypsum. Although they are mined on a large scale worldwide for their mineral content, they represent one of the world's largest, yet virtually untapped sulfur resources. Existing technology can recover elemental sulfur from these sources, but the economics are presently unfavorable.

Natural Gas.—Hydrogen sulfide occurs as a component of natural gas in many parts of the world. To market this "sour" natural gas, the hydrogen sulfide must be removed and, consequently, as additional sour natural gas fields have been brought into production, elemental sulfur recovered from these fields has become a major source of the world sulfur supply. Major deposits of sour natural gas occur in western Canada, the Near East, and the former U.S.S.R.; substantial deposits occur in the mountain and gulf coast regions of the United States and in Germany, France, Mexico, and Venezuela.

Petroleum and Tar Sands.—Complex organic sulfur compounds occur as a component of petroleum and tar sands in a wide range of concentrations. In the refining of petroleum or bitumen from tar sands, a portion of the sulfur is removed and recovered in the elemental form. Changing environmental regulations have required larger proportions of contained sulfur to be removed annually. The vast petroleum reserves of the Near East contain high percentages of sulfur, as do many of the recent discoveries in Mexico and off the U.S. west coast. Additionally, Canadian tar sands constitute a major sulfur resource.

Coal and Oil Shale.—Sulfur occurs as pyrites or complex organosulfur compounds in varying concentrations in both coal and oil shales. Although little sulfur is produced from these vast resources at present, the potential for large-scale output exists in the United States and in the rest of the world.

Economic Factors

During the past 20 years, world sulfur price leadership has shifted from dominance by the U.S. Frasch producers to the Canadian exporters. The transfer was aided in the 1980's by Canada's ability to export most of its production from the Port of Vancouver and by its willingness to ship large volumes of sulfur from vatted stocks. The maturation of Sultran Ltd., dealing almost exclusively with sulfur destined for the offshore market, into a well-organized and skilled transportation arm of the Canadian sulfur industry aided immeasurably in Canada's ascension to world price leadership. However, the steep price reductions in the past 3 years have confused the issue of price leadership. Canada's role is still very important, but the oversupply of sulfur in Europe, Poland, and Saudi Arabia also has had an effect on prices.

In the United States, the quoted liquid Frasch sulfur price, f.o.b. terminal Tampa, FL, has traditionally been the benchmark price. Toward the end of 1992, the industry abandoned this practice. Although a Tampa Frasch price was published weekly in trade publications, reports in those publications indicated that contract prices were not greatly influenced by these posted prices, and only one Frasch producer continued to post weekly prices. Recovered sulfur producers, in many cases, consider the economic desirability of producing sulfur subordinate to the necessity of producing it. As a result, domestic recovered elemental sulfur producers normally offer sulfur at a price significantly below the Tampa quote to ensure prompt sale and reduce storage costs. This marketing strategy has resulted in restricting Frasch sulfur sales from many market areas that they formerly served.

During the 1980's, the sulfur price

showed a significant degree of volatility compared with its prior history, and the early years of the 1990's continued that trend. *(See figure 2.)*

Operating Factors

Increasing environmental concerns have had an impact on the sulfur industry, as they have had on most other industries. The effects on the sulfur industry can be interpreted as both positive and negative as far as sulfur is concerned, but certainly positive in terms of decreasing pollution.

Even before the Clean Air Act became law in 1977, oil refineries and natural gas processors realized the necessity of removing sulfur from their products and offgases. The USBM began collecting data on recovered sulfur in 1938, and references were made to this type of sulfur prior to that, but with no official data to quantify the recovery. At first, recovered sulfur was considered a waste material, not a commercial byproduct. As time went on, the importance of recovered sulfur increased as sulfur demand increased faster than the supply of Frasch and other native sulfur. Recovered sulfur became the primary domestic source of elemental sulfur in 1982.

The Clean Air Act set limits on the quantity of pollutants that could be released into the atmosphere. Sulfur dioxide was identified as one of the most common pollutants and one of the major contributors of acid rain, known to damage both natural and artificial environments. New gas-cleaning apparatus removed as much sulfur dioxide as was technologically possible from offgases. Petroleum refiners and gas processors have recovered increasingly greater percentages of sulfur from the gas stream as elemental sulfur, metal smelters (especially nonferrous metals) recovered byproduct sulfuric acid, and coal and oil burning electric powerplants recovered byproduct gypsum (calcium sulfate), cutting emissions dramatically. The type of byproduct recovered was determined by the sulfur content of the gas stream; elemental sulfur was recovered when the sulfur dioxide content was relatively high.

Amendments to the Clean Air Act of 1990 required a 50% reduction of sulfur dioxide emissions by the year 2000, and electric power stations are believed to be the source of 70% of all sulfur dioxide emissions. For this reason the 1990 amendments will concentrate on the further reduction of emissions from electric utilities. Existing technology to recover elemental sulfur from powerplant offgases has a cost estimated to be 50% higher than the cost of recovering byproduct gypsum. Although some byproduct gypsum is consumed in the same end uses as natural gypsum, much of it is disposed as waste.[2] Although no utilities currently are recovering commercial quantities of elemental sulfur in the United States, two projects have been announced. Tampa Electric Co. will recover 75,000 to 90,000 tons of sulfuric acid (25,000 to 30,000 tons sulfur equivalent) annually at its powerplant in Polk County, FL.[3] A full-scale sulfur recovery system will be installed at PSI Energy's Wabash River generating station in Terre Haute, IN. Expected to be completed in 1995, this plant should recover about 14,000 tons of elemental sulfur per year.[4] As landfill costs become higher, elemental sulfur recovery will become a more attractive alternative to byproduct gypsum production.

Over the years, larger quantities of sulfur have been recovered for a number of reasons, including increased petroleum refining and natural gas processing, more stringent limitations on sulfur dioxide emissions, and higher sulfur contents of the crude oil refined. Other contributing factors are lower sulfur content limits set on petroleum-based fuels.

As sulfur supplies, either as elemental sulfur or byproduct sulfuric acid, have grown due to increased environmental awareness, the demand for sulfur has decreased in some consuming industries for the same reason. Some industries (i.e., uranium processing) have contracted or completely disappeared owing to concerns regarding environmental damage caused by their processes. Other industries, such as titanium dioxide production, have converted to more environmentally "friendly" processes that do not use sulfuric acid. In addition, many consumers who continue to use sulfuric acid are putting new emphasis on regenerating or recycling spent acid.

Another area where improved air quality has had an impact on sulfur use is in agriculture. As reduced sulfur dioxide emissions decreased acid rain, sulfur content of soils also has decreased. Sulfur is now recognized as an important plant nutrient, necessary for the most efficient use of other nutrients and optimum plant growth. Because many soils are now deficient in sulfur, a demand for sulfur-containing fertilizers has been created, and farmers must now apply a nutrient that previously had not been required.

Increased environmental awareness has created a dilemma for sulfur producers. While pollution reduction requirements have created increased supplies of sulfur and sulfur products, similar requirements have caused a decrease in demand. This situation will persist and the imbalance between supply and demand could increase, causing inventories to continue to increase. Disposing of excess sulfur, recovered while cleaning the air to protect the environment, may create another environmental problem.

ANNUAL REVIEW

Legislation and Government Programs

The 1990 amendments to the Clean Air Act required a 50% reduction from 1980 levels of sulfur dioxide emission nationwide by the year 2000. The 1990 Act contained an innovative measure to control emissions through market-based incentives rather than more traditional, strict, inflexible rules. The Emission Allowance Market (EAM) makes it possible for companies that have been able to reduce emissions at their operations to sell unneeded allowances to companies that have not been able to meet pollution reduction requirements.

Other types of pollutants will eventually be controlled by this process, but sulfur dioxide will be managed first. Because electric powerplants are believed to be the source of about 70% of all sulfur dioxide emissions in the United States, the EAM currently concentrates on that industry. In 1993, the

Environmental Protection Agency proposed the expansion of the EAM program to include all facilities that emit pollutants linked to acid rain.[5] The Chicago Board of Trade (CBoT) administers allowance sales.

Utilities are assigned emission allowances based on historic fuel consumption and sulfur dioxide emission data. These assigned allowances will decrease over time to meet the goal of 50% reduction. Additional allowances are available for purchase on the open market. Each utility must buy its assigned allowances directly from the Government at a predetermined price. If a specific power station finds it cannot meet its pollution requirements, it must buy additional allowances on the open market or from another utility that has reduced its emissions and thus possesses emission allowances that are in excess of its needs. Additional allowances may be purchased directly from companies offering them for sale or through auctions at the CBoT. All of the Government's unassigned allowances will be sold through CBoT.

Phase 1 of the EAM program will affect the 10 largest power stations in 21 Eastern and Midwestern States. Compliance will be required by January 1, 1995; sales of future emission allowances began at the CBoT in March. Phase 2 will encompass approximately 700 remaining smaller utilities with compliance required by January 1, 2000. As time passes, all emission allowances will be purchased through auction or on the open market, with none through direct sale from the Government.[6]

Production

Elemental Sulfur.—Elemental sulfur production was slightly higher in 1993 than it was the previous year, but shipments were 7% lower in quantity and 38% lower in value.

Production statistics are collected on a monthly basis and published in the USBM Sulfur Monthly Mineral Industry Survey. Beginning in November 1993, significant improvement of the production level at one of the Frasch mines resulted in one Frasch company becoming the dominant producer with more than 75% of the total Frasch production and shipments. When this situation occurs, the data must be withheld from publication or aggregated with other data to avoid revealing company proprietary data. For this reason all Frasch data listed represent only 10 months of collected data, with the additional 2 months of data aggregated with the corresponding information for sulfur recovered during natural gas processing.

As a result, meaningful comparison of Frasch and recovered sulfur data between 1993 and 1992 is not possible and has not been attempted.

Frasch.—Native sulfur associated with the cap rock of salt domes and in sedimentary deposits is mined by the Frasch hot-water method, in which the native sulfur is melted underground and brought to the surface by compressed air. In 1993, four Frasch mines operated in Louisiana and Texas. Mines in Texas were Pennzoil Sulphur Co., at Culberson, and Texasgulf Inc. (TG), at Boling Dome in Wharton County. Freeport Sulphur Co. owned and operated two mines in Louisiana, the Caminada Pass Mine 14 kilometers offshore in the Gulf of Mexico and Main Pass, 27 kilometers offshore.

Texasgulf Inc.'s Newgulf Frasch Mine on Boling Dome closed in December after more than 60 years of production from this deposit. With the closure of the mine, the town of Newgulf, TX, believed to be the only remaining company town in the United States, closed also. Built by the company in 1928 to provide housing and services for the workers at the mine, including shopping, churches, schools, and recreational facilities, the houses were being sold to individuals for relocation off company property.[7]

Main Pass is the newest Frasch mine in the world, with production beginning in April 1992. The mine reached full capacity of about 5,400 tons per day at the end of December 1993, earlier than anticipated after a slower than expected startup. At capacity, Main Pass is believed to be the lowest cost Frasch operation in the world due to its high water and thermal efficiencies. Freeport pumps about 33% less water for each ton of sulfur produced than other Frasch producers.[8] The National Society of Professional Engineers named Main Pass one of the top eight U.S. engineering achievements of 1992.[9]

Improved production rates at Main Pass prompted Freeport to announce the closure of its Caminada Pass Mine, with total shutdown expected by early 1994. The cost of producing sulfur from Caminada was significantly higher than at Main Pass, and Main Pass alone will supply the company's internal consumption and sales requirements.[10]

Recovered.—Recovered elemental sulfur, a nondiscretionary byproduct from petroleum refining, natural gas processing, and coking plants, was produced primarily to comply with environmental regulations that were applicable directly to emissions from the processing facility or indirectly by restricting the sulfur content of the fuels sold or used by the facility. Recovered elemental sulfur was produced by 59 companies at 150 plants in 26 States, 1 plant in Puerto Rico, and 1 plant in the U.S. Virgin Islands. Most of these plants were of relatively small size, with only 22 reporting an annual production exceeding 100,000 tons. By source, 52% was produced at 3 coking plants and 86 refineries or satellite plants treating refinery gases. The remainder was produced by 27 companies at 61 natural gas treatment plants. The five largest recovered-sulfur producers in 1993 were Exxon Co. U.S.A., Standard Oil Co. (California), Standard Oil Co. (Indiana), Mobil Oil Corp., and Shell Oil Co. The 50 plants owned by these companies accounted for 53% of recovered elemental sulfur output during the year. *(See tables 2, 3, and 4.)*

Byproduct Sulfuric Acid.—Byproduct sulfuric acid at copper, lead, molybdenum, and zinc roasters and smelters amounted to 13% of the total domestic production of sulfur in all forms. Eight acid plants operated in conjunction with copper smelters, and eight were accessories to lead, molybdenum, and zinc smelting and roasting operations. The six largest acid plants (all at copper mines) accounted for 81% of the output. The five largest producers of byproduct sulfuric acid were all copper producers. They were Phelps Dodge Corp., Magma Copper Co., ASARCO Incorporated, Kennecott Corp., and Cyprus Miami Mining Corp. Their eight plants produced 86% of the 1993 total. *(See table 5.)*

Pyrites, Hydrogen Sulfide, and Sulfur Dioxide.—The total sulfur contained in these products did not constitute a significant portion of total domestic sulfur production. *(See figure 3.)*

Consumption and Uses

Domestic consumption of sulfur in all forms was about 8% lower in 1993 than it was in 1992. In 1993, 83% of the sulfur consumed was obtained from domestic sources compared with 79% in 1991 and 77% in 1990. The sources of supply were domestic elemental sulfur, 71%, and combined domestic byproduct sulfuric acid, pyrites, hydrogen sulfide, and sulfur dioxide, 12%. The remaining 17% was supplied by imports of Frasch and recovered elemental sulfur.

The USBM collected end-use data on sulfur and sulfuric acid according to the Standard Industrial Classification of industrial activities. Shipments by end use of elemental sulfur were reported by 59 companies, and shipments of sulfuric acid were reported by 50 companies. Shipments of both elemental sulfur and sulfuric acid were reported by seven companies.

Sulfur differs from most other major mineral commodities in that its primary use is as a chemical reagent rather than a component of a finished product. Its predominant use as a chemical reagent generally required that it first be converted to an intermediate chemical product prior to its initial use by industry. The largest sulfur end use, sulfuric acid, represented 87% of reported consumption with an identified end use. Some identified sulfur end uses were tabulated in the "Unidentified" category because these data were proprietary. Data collected from companies that did not identify shipment by end use also were tabulated as "Unidentified." Although there are no supporting data, it could be reasonably assumed that a significant portion of the sulfur in the "unidentified" category was shipped to sulfuric acid producers or was exported.

Sulfuric acid, because of its desirable properties, retained its position, both domestically and worldwide, as the most universally used mineral acid and the largest volume inorganic chemical in terms of the quantity produced and consumed. U.S. consumption of sulfur in sulfuric acid (100% basis) was slightly lower in 1993 owing to decreases in demand for sulfuric acid in industrial uses. Demand for sulfuric acid for the production of phosphoric acid, the largest single end use, was 5% lower than that of 1992. Sulfuric acid demand for copper ore leaching, the second largest end use, increased 7% according to reports from sulfuric acid producers. Reported shipments of sulfuric acid for petroleum refining and other petroleum and coal products were not significantly different from those of 1992, but reported consumption of elemental sulfur in those end uses was 85% higher.

According to the 1993 canvass reports, company receipt of spent or contaminated sulfuric acid for reclaiming totaled 2.3 million tons. The largest source of this spent acid continued to be the petroleum refining industry, which accounted for 49% of the total returned. About 900,000 tons of spent acid was reclaimed from chemical producers. The remaining reclaimed acid was from manufacturers of ferrous and nonferrous metals, paper, storage batteries, and some unidentified sources.

The largest use of sulfur in all forms, for agricultural purposes, decreased from 9.3 million tons in 1992 to about 9.0 million tons due to decreases in consumption for the production of nitrogenous and phosphatic fertilizers. Consumption in phosphatic fertilizers was nearly 5% less than that in 1992, reflecting the condition of the phosphate industry. The estimated quantity of sulfur needed to manufacture exported phosphatic fertilizers decreased by 500,000 tons to 4.4 million tons, indicating that consumption for fertilizers intended for domestic consumption was nearly the same as it had been in 1992. *(See tables 6, 7, and 8 and figure 4.)*

Stocks

Yearend inventories held by Frasch and recovered elemental sulfur producers increased 71% from those of 1992, indicating an oversupply situation. Combined yearend stocks amounted to approximately a 43-day supply compared with a 23-day supply in 1992, a 34-day supply in 1991, a 40-day supply in 1990, and a 37-day supply in 1989 based on apparent consumption of all forms of sulfur. *(See table 9.)*

Markets and Prices

The posted price for Frasch sulfur exterminal Tampa, FL. began the year at $88 per ton and dropped to $83 in March and $68 in November. On the basis of total shipments and value reported to the USBM, the average value of shipments of Frasch sulfur, f.o.b. mine, for domestic consumption and exports combined decreased from $58.15 to $51.60 per ton. The average value, f.o.b. plant, for shipments of recovered elemental sulfur varied widely by geographic region; the national average value for the year was $25.06 per ton, almost $20 per ton less than the average for 1992. The average value for all elemental sulfur was $31.86 per ton in 1993, 34% lower than that in 1992. *(See table 10.)*

Foreign Trade

Exports of elemental sulfur from the United States, including the U.S. Virgin Islands, decreased 32% in quantity and 43% in value. According to the Bureau of the Census, exports from the west coast were 536,000 tons or 82% of total U.S. exports.

The United States continued to be a net importer of sulfur; imports exceeded exports by about 1.4 million tons in 1993. Frasch and recovered sulfur from Mexico and recovered elemental sulfur from Canada, both delivered to U.S. terminals and consumers in the liquid phase, furnished nearly 100% of all U.S. sulfur import requirements. Total elemental sulfur imports decreased 25% in quantity; imports by rail from Canada decreased 18%, while waterborne shipments from Mexico were 41% lower than those in 1992. Imports from other sources were negligible.

The United States also had significant trade in sulfuric acid. Sulfuric acid exports increased slightly from those of 1992. Imports, which were significantly greater than exports, 40% of which were by rail from Canada and 31% waterborne from Europe. The tonnage increased 23% from the quantity reported in 1992; the value of imported sulfuric acid increased 3%. Approximately 776,000 tons of acid was imported into the Tampa, FL, area, about 70% higher than the Tampa acid imports of the previous year. Two sulfuric acid terminals were established there in 1989. *(See tables 11, 12, 13, and 14.)*

World Review

Although world production was virtually unchanged from that of 1992, consumption was down for the fifth consecutive year, and prices were lower in terms of constant dollars than they had been for at least 20 years and probably longer. Frasch producers experienced production cutbacks, and as consumption decreased, international competition for available markets became more intense.

Industry Structure.—In 1993, the global sulfur industry remained divided into two sectors, discretionary and nondiscretionary. In one, the mining of sulfur or pyrites was the sole objective; this voluntary production of native sulfur or pyrites was based on the orderly mining of discrete deposits, with the objective of obtaining as nearly a complete recovery of the resource as economic conditions permit. In the other, sulfur or sulfuric acid was recovered as an involuntary byproduct, the quantity of output subject to demand for the primary product irrespective of sulfur demand. In 1993, involuntary sources represented almost 66% of the elemental sulfur produced worldwide.

Poland, Ukraine, and the United States were the only countries that produced 1 million tons or more of native sulfur using either the Frasch method or conventional mining methods. Small quantities of native sulfur were produced in Asia, Europe, and North and South America. Pyrites were the prime sulfur source in southern Africa, China, much of Eastern Europe, Finland, Italy, North Korea, and Spain and were an important source in Scandinavia and Philippines.

Recovered elemental sulfur was the predominant sulfur source in Canada, France, Germany, Russia, Saudi Arabia, and the United States. Additionally, recovered elemental sulfur was an important source in Iran, Japan, and Mexico.

International sulfur trade was dominated by a limited number of exporting countries; exports from Canada, Saudi Arabia, Poland, Germany, the United States, and Mexico, in descending order of the quantity shipped, accounted for 81% of sulfur trade in 1993. Major sulfur importers in 1993 were Morocco, the United States, India, Tunisia, and Brazil, in descending order of importance, all with imports of more than 1 million tons.

Capacity.—The data in table 15 are rated capacity for Frasch mines, elemental sulfur mining facilities and attendant beneficiation plants, pyrites mines and plants, sulfur and/or sulfuric acid recovery units associated with petroleum refineries, natural gas processing plants, metal smelting operations, electric powerplants, and coke ovens as of December 31, 1993. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable long-term operating rate, based on the physical equipment of the facility, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with a minimum of capital expenditure. Rated capacity is not equivalent to engineering (design) capacity of installed equipment.

Frasch mines operate continuously, and capacity is related to the quantity of superheated water that can be injected into the associated sulfur deposit. The nature of Frasch mining makes capacity quite variable over time and depends on the number of "steaming wells," water injection rates, water losses from the formation, location of wells within the deposit, and length of time that the deposit has been worked. The rated capacity or realizable capacity of a Frasch mine generally decreases as the deposit becomes depleted.

Petroleum refineries—large, very costly, and complex processing facilities designed to produce a spectrum of fuels and petrochemical products—operate continuously. Sulfur recovery units make up only a small segment of these facilities; because sulfur recovery is mandated by environmental considerations, the installed sulfur recovery capacity at petroleum refineries generally exceeds the expected sulfur production. To ensure that the loss of a sulfur recovery unit does not require the shutdown of the entire refinery, multiple sulfur recovery units, each capable of servicing the petroleum refinery, are installed. The quantity of sulfur recovered by domestic petroleum refineries in the United States during 1993 was equal to slightly more than 50% of the installed engineering capacity. Rated capacity for petroleum refineries is assumed to be 50% of installed engineering capacity.

Natural gas processing plants may be installed to service gasfields and/or oilfields that contain significant quantities of associated gas. Gas plants are designed to accommodate the natural gas from a specific field that may contain, in addition to methane, which is sold as pipeline gas, varying amounts of nitrogen, carbon dioxide, helium, condensable hydrocarbon liquids, and poisonous hydrogen sulfide. The poisonous nature of hydrogen sulfide makes its removal from pipeline gas imperative. Sulfur removal and recovery plants in natural gas facilities vary in size from small units rated at 5 to 10 tons per day to multiple-train plants capable of recovering thousands of tons per day. In general, sulfur recovery rates from gasfields approximate installed engineering capacity, based on a 340- to 345-day-per-year operation of all units, in the first 7 years of operation. In succeeding years, sulfur recovery declines steadily because the gas apparently becomes "sweeter" over time and because gas flow rates drop as the field is depleted. Rated capacity for gas processing plants is based on the age of the plant and its recent production history.

Rated capacity for plants operating in conjunction with metal smelters, powerplants, and coking operations is assumed to approximate engineering capacity. Where information on design capacity is unknown, rated capacity was estimated to be equal to the greatest output recorded by a plant or country in the past 5 years. World rated sulfur annual production capacity is significantly lower than the installed world engineering capacity of approximately 91 million tons. *(See table 15.)*

Abu Dhabi.—Sulfur recovery has increased significantly during the past 2 years; sulfur production tripled in 1993 and was expected to expand further. Although still a relatively minor sulfur producer, the events in Abu Dhabi indicate what can be expected as more countries become increasingly environmentally conscious. Existing, but never operated, sulfur recovery apparatus was refurbished and enlarged at the Das Island gas processing plant and put into operation. Prior to this, the sulfur gas stream had been flared, releasing sulfur dioxide into the atmosphere.[11]

Canada.—Production of elemental sulfur was 7.3 million tons, 12% higher than that of the previous year, byproduct sulfuric acid contributed an additional 900,000 tons of sulfur equivalent. Still the world's leading sulfur exporter, Canadian exports were down sharply in 1993 because the Canadian sulfur export organization, Prism Sulphur Corp., chose to stockpile rather than sell at prevailing low prices. With production up and exports down, stocks increased 2.3 million tons to about 5.6 million tons by the end of the year. Sulfur recovered from natural gas processing represented 78.8% of total Canadian production, with 7.3% from oil sands and 2.8% from oil refining. The remaining 11.1% was recovered as byproduct sulfuric acid from nonferrous smelters.

The majority of Canadian sulfur is produced in Alberta and British Columbia. With the completion of Shell Canada's Caroline natural gas recovery project in Alberta, an additional 1.5 million annual tons of sulfur capacity became operational in March. Sulfur from Caroline is destined for the offshore market with no facilities in place for shipping liquid sulfur to the United States. Production will be formed at a nearby forming facility or poured to block, the industry term for stockpiling that describes the process of pouring molten sulfur into huge forms with the sulfur forming solid blocks when cooled.[12]

Iraq.—The Mishraq Mine has the capacity to produce 1.6 million tons of Frasch sulfur and may have been upgraded to 2 million tons; the mine was not damaged during the Gulf War. Although reports from Iraq stated that the mine was approaching capacity in 1992,[13] there has been no evidence that has occurred. With Jordan as the only possible outlet due to the continued United Nations trade embargo, it is doubtful that production was more than 200,000 tons. If and when sanctions are lifted, production from Iraq will add to the worldwide surplus.

Kazakhstan.—Sulfur production began at the Tengiz oil and gas condensate field in the Republic of Kazakhstan in 1991. In April 1993, Chevron reached a 40-year agreement with the Government of Kazakhstan for a 50% interest in the further development of the Tengiz and Korolov oilfields and gasfields. Tengiz was believed to have huge oil reserves and associated sour gas. Korolov was much smaller, but with a higher sulfur content.

Originally, four production phases were planned for Tengiz, but for the time being, only Tengiz I and Tengiz II are expected to be completed. Tengiz II was expected to come on-stream in 1992, but experienced delays. If all phases of the project are completed, sulfur recovery capacity could be more than 3 million tons per year when oil production reaches its peak in the year 2010.

British Gas Corp. and Azienda Generali Italiana Petroli S.p.A. (AGIP) were negotiating with the Government of Kazakhstan concerning a joint venture to develop the Karachaganak oil and sour gas condensate field. Société Nationale Elf Aquitaine also was doing some seismic testing in the Temir area, but was far from producing any oil or gas, and thus farther from producing sulfur there.[14]

Kuwait.—Oil production resumed at the end of 1991 after oil well fires were extinguished and some refineries repaired following the Gulf War. Refinery repairs were slower than expected, and sulfur recovery was possible at only one refinery before the end of 1992. Sulfur recovery resumed at the other refineries in Kuwait early in 1993.[15]

Mexico.—Once a large Frasch producer, Mexico's last Frasch mine closed in May 1993 owing to the poor economics of Frasch sulfur. Three other Mexican mines closed in 1992. All remaining assets from the Government-owned sulfur operations were ceded to Petóleos Mexicanos (PEMEX), the Government-owned petroleum company. Pemex became responsible for the storage, transportation, and sales of its recovered sulfur. All sales had formerly been handled by the Frasch producers.[16]

Morocco.—Morocco was a major world importer of elemental sulfur because of consumption at its phosphate fertilizer facilities at Safi and Jorf Lasfar. Imports were about 2.6 million tons in 1993, a 4% increase from that of 1992.

Poland.—Native sulfur production has fallen more than 50% from nearly 4 million tons in 1991 to about 1.9 million tons in 1993. The new Osiek Mine officially opened near Grzybow in September after several months of test production. Production at the new mine, at the Jeziorko Mine at Tarnobrzeg, and the old Grzybow Mine is expected to maintain production at about 1993 levels in 1994.

The cost of production was reported to have been cut by about 50% by using a system to recycle hot water from nearby power stations, cutting labor costs, and closing nonproductive facilities (i.e., kindergartens and holiday homes).

Production ceased at the Machow Mine in 1992, but final transfer of the operation to local authorities was delayed. Environmental problems continue at Machow, and the cost of remediation, including the elimination of hydrogen sulfide emissions from the pit, was estimated at more than $200 million.[17] *(See table 16.)*

OUTLOOK

The outlook for the global sulfur industry is simple to describe: increased output and decreased consumption resulting in lower prices and growing inventories. Specific details are much more difficult. Which producers will suffer most from the oversupply situation is a question that can only be answered over time.

World sulfur demand is forecast to increase at an annual rate of about 1% per year for the next 10 years. World demand is projected to attain 55.6 million tons in 1998 and increase to about 60 million tons in the year 2003. In the short term, an optimistic forecast for U.S. sulfur demand is an increase from 11.8 million tons consumed in 1993 to 13.7 million tons in 1998 and 14.4 million tons in the year 2003; a more likely estimate is an increase to 13.5 million to 14.0 million tons by the end of the period.

Almost two-thirds of sulfur consumption in the United States is for agricultural uses. More than 80% of U.S. agricultural sulfur demand and almost 60% of world agricultural sulfur consumption was for the manufacture of phosphoric acid in 1993. World demand for phosphate fertilizers is forecast to increase at an annual rate of about 2.3% for the next 10 years. This indicates improved growth over predictions of the past few years, but is based on the fact that 1993 was an unusually bad year for fertilizer producers. It is assumed that 90% of the growth will be for the production of phosphoric acid to produce high-analysis fertilizers, which will directly affect world sulfur demand. Consumption of sulfur for phosphate fertilizer manufacture in the United States is divided into two main components: (1) demand for phosphate fertilizers consumed by domestic farmers and (2) demand for exported phosphate fertilizers.

In 1993, an estimated 4.4 million tons of sulfur was required to manufacture the phosphatic fertilizers exported from the United States compared with 3.5 million tons of sulfur for domestic phosphoric fertilizer use. Sulfur demand for domestically consumed phosphates is forecast to increase slightly for the next 2 years to make up for low production in 1993 and remain relatively stable thereafter.

The broad spectrum industrial or nonagricultural sulfur use category accounted for almost 39% of U.S. sulfur consumption and about 43% of world sulfur demand. Although significant variations in demand for the diverse elements within this broad category are expected in the United States and other geographic areas, world industrial demand is expected to average less than a 1% increase annually over the next 10 years, reaching almost 24 million tons in the year 2003.

The necessity for the removal of sulfur from solid, liquid, and gaseous effluents for environmental protection has caused the production of sulfur and sulfur compounds from these sources to exceed production from primary sources of supply. The long-term prospect is that 85% or more of the world sulfur supply will come from environmentally regulated sources and that output from these sources will be produced regardless of world sulfur demand. As a result, it is probable that after the turn of the century, no new operation that produces sulfur as its primary product will be developed, except where it may be deemed necessary for political or social reasons and more voluntary operations will be curtailed. In 1980, voluntary sources of production—Frasch, native sulfur, and pyrites—accounted for 50% of world output, about 55 million tons. In 1993, these same sources supplied only 34% of world production, 52.6 million tons.

It is anticipated that in the short term, owing to decreased production at Frasch operations, world sulfur supply and demand will be closely balanced, and by the end of 1993 there were indications of tightening of supplies available for sale. However, a number of new recovered facilities were completed during the year and more will be completed soon, are under development, or are in the planning stage, further increasing supply sources.

In 1993, developments and changes at Frasch and other voluntary producers seem to be maintaining a relatively stable level of production with a slight downward trend. However, recovered sulfur production will continue to expand at a faster pace than demand, and as more countries enact environmental legislation on a par with North American and European laws, tremendous new quantities of sulfur will be recovered. More stringent regulation and compliance will be long-term developments and cannot be quantified at the current time, but changes are inevitable.

Statistics show that an oversupply situation existed in 1993; however, the decision by some producers to build stocks rather than sell at unfavorable prices resulted in what appeared as tightened supplies by yearend and indications that prices were beginning to rise. Material could continue to be withheld from sale through 1994, but if prices rise, sales at former levels could resume, and prices will once again fall. World sulfur production is predicted to reach nearly 61 million tons in 1998 and 64 million tons in 2003.

Total	$992,598	$931,339	$812,633	$542,758	$335,318
Exports, elemental[4] [5]	$107,126	$109,327	$119,713	$69,662	$39,726
Imports, elemental[5]	$209,465	$206,450	$241,749	$129,894	$49,627
Price, elemental, dollars per metric ton, f.o.b. mine or plant	$86.62	$80.14	$71.45	$48.14	$31.86
World: Production, all forms (including pyrites)	[r]58,924	[r]58,026	[r]55,723	[r]52,740	[e]52,270

[e] Estimated. [r] Revised.

[1] Includes 10 months of Frasch sulfur data. Two remaining months of Frasch data included with recovered sulfur data to conform with proprietary data requirements.

[2] Includes Puerto Rico and the U.S. Virgin Islands.

[3] Includes corresponding Frasch sulfur data for November and December.

[4] Includes exports from the U.S. Virgin Islands to foreign countries.

[5] Includes value of exports from the U.S. Virgin Islands to foreign countries.

TABLE 2

PRODUCTION OF SULFUR AND SULFUR-CONTAINING RAW MATERIALS IN THE UNITED STATES

(Thousand metric tons)

	1992		1993	
	Gross weight	Sulfur content	Gross weight	Sulfur content
Frasch sulfur	2,320	2,320	[1]1,904	[1]1,904
Recovered sulfur[2]	7,048	7,048	[3]7,665	[3]7,665
Byproduct sulfuric acid (100% basis) produced at copper, lead, molybdenum, and zinc plants	3,948	1,292	4,244	1,387
Other forms[4]	8	3	8	3
Total	XX	10,663	XX	10,959

XX Not applicable.

[1] Includes 10 months of Frasch sulfur data. Two remaining months of Frasch data included with recovered sulfur data to conform with proprietary data requirements.

[2] Includes Puerto Rico and the U.S. Virgin Islands.

[3] Includes corresponding Frasch sulfur data for November and December.

[4] Includes hydrogen sulfide, liquid sulfur dioxide, and pyrites.

TABLE 3

RECOVERED SULFUR PRODUCED AND SHIPPED IN THE UNITED STATES, BY STATE

(Thousand metric tons and thousand dollars)

State	1992			1993		
	Production	Shipments		Production	Shipments	
		Quantity	Value		Quantity	Value
Alabama	421	419	24,263	397	397	14,410
California	699	702	18,389	750	742	4,342
Florida	47	47	W	47	47	W
Illinois	267	269	12,285	297	295	8,340
Louisiana	732	731	42,936	[1]1,251	[1]1,124	[1]44,991
Michigan and Minnesota	184	185	7,708	158	157	733
Mississippi	659	679	32,001	589	580	12,752
New Mexico	54	55	1,424	50	50	321
North Dakota	82	82	1,723	81	81	1,825
Ohio	43	44	2,813	54	54	2,415
Pennsylvania	56	57	2,688	71	71	2,131
Texas	2,008	2,010	99,323	[1]2,312	[1]2,306	[1]67,376
Wyoming	1,056	1,067	31,712	907	909	6,981
Other[2]	740	746	38,173	695	706	21,810
Total[3]	7,048	7,094	315,438	7,665	7,521	76,060

W Withheld to avoid disclosing company proprietary data; included with "Other."

[1] Includes corresponding Frasch sulfur data for November and December.

[2] Includes Arkansas, Colorado, Delaware, Indiana, Kansas, Kentucky, Montana, New Jersey, Utah, Virginia, Washington, Wisconsin, Puerto Rico, the U.S. Virgin Islands, and data indicated by symbol W.

[3] Data may not add to totals shown because of independent rounding.

TABLE 4

RECOVERED SULFUR PRODUCED AND SHIPPED IN THE UNITED STATES, BY PETROLEUM ADMINISTRATION FOR DEFENSE (PAD) DISTRICT

(Thousand metric tons)

District and source	1992		1993	
	Production	Shipments	Production	Shipments
PAD 1:				
Petroleum and coke	317	318	281	280
Natural gas	47	47	47	47
Total[1]	364	365	328	327
PAD 2:				
Petroleum and coke	698	699	721	716

Total	783	784	804	799
PAD 3:[2]				
Petroleum	2,620	2,639	2,856	2,869
Natural gas	1,352	1,354	[3]1,832	[3]1,690
Total	3,972	3,993	4,688	4,559
PAD 4 and 5:				
Petroleum	889	901	958	950
Natural gas	1,041	1,052	885	886
Total[1]	1,930	1,952	1,843	1,836
Grand total[1]	7,048	7,094	7,665	7,521

[1] Data may not add to totals shown because of independent rounding.

[2] Includes Puerto Rico and the U.S. Virgin Islands.

[3] Includes corresponding Frasch sulfur data for November and December.

TABLE 5

BYPRODUCT SULFURIC ACID[1] PRODUCED IN THE UNITED STATES

(Thousand metric tons, sulfur content, and thousand dollars)

Year	Copper plants[2]	Zinc plants[3]	Lead and molybdenum plants[3]	Total	Value
1989	1,005	134	51	1,190	103,526
1990	1,105	135	54	1,294	116,356
1991	1,101	137	64	1,302	106,891
1992	1,093	139	59	1,291	86,743
1993	1,191	130	66	1,387	61,062

[1] Includes acid from foreign materials.

[2] Excludes acid made from pyrites concentrates.

[3] Excludes acid made from native sulfur.

TABLE 6

CONSUMPTION OF SULFUR[1] IN THE UNITED STATES

(Thousand metric tons)

	1989	1990	1991	1992	1993
Frasch:					
Shipments	3,780	3,676	3,120	2,600	[2]1,477
Exports	330	348	448	362	246
Imports	1,086	1,129	1,259	845	100
Total	4,536	4,457	3,931	3,083	1,331
Recovered:					
Shipments[3]	6,475	6,483	6,682	7,094	[4]7,521

Unspecified sources	[r]2,084	[r]1,998	[r]1,798	[r]1,721	1,786
Gypsum	20	10	10	10	10

[e] Estimated. [r] Revised. W Withheld to avoid disclosing company proprietary data; included with "Byproduct: Unspecified sources."

[1] Table includes data available through July 26, 1994.

[2] In addition to the countries listed, a number of nations may produce limited quantities of either elemental sulfur or compounds (chiefly H_2S or SO_2) as a byproduct of petroleum, natural gas, and/or metallurgical operations, but output, if any, is not quantitatively reported, and no basis is available for the formulation of reliable estimates of output. Countries not listed in this table that may recover byproduct sulfur from oil refining include Albania, Bangladesh, Brunei, Burma, Costa Rica, Guatemala, Honduras, Jamaica, Malaysia, Nicaragua, Paraguay, and the Republic of Yemen. Albania and Burma may also produce byproduct sulfur from crude oil and natural gas extraction. No complete listing of other nations that may produce byproduct sulfur from metallurgical operations (including processing of coal for metallurgical use) can be compiled, but the total of such output is considered as small. Nations listed in the table that may have production from sources other than those listed are identified by individual footnotes.

[3] The term "source" reflects both the means of collecting sulfur and the type of raw material. Sources listed include the following: (1) Frasch recovery; (2) native, comprising all production of elemental sulfur by traditional mining methods (thereby excluding Frasch); (3) pyrites (whether or not the sulfur is recovered in the elemental form or as acid); (4) byproduct recovery, either as elemental sulfur or as sulfur compounds from coal gasification, metallurgical operations including associated coal processing, crude oil and natural gas extraction, petroleum refining, tar sand cleaning, and processing of spent oxide from stack-gas scrubbers; and (5) recovery from the processing of mined gypsum. Recovery of sulfur in the form of sulfuric acid from artificial gypsum produced as a byproduct of phosphatic fertilizer production is excluded because to include it would result in double counting. It should be noted that production of Frasch sulfur, other native sulfur, pyrites-derived sulfur, mined gypsum-derived sulfur, byproduct sulfur from extraction of crude oil and natural gas, and recovery from tar sands are all credited to the country of origin of the extracted raw material; in contrast, byproduct recovery from metallurgical operations, petroleum refineries, and spent oxides are credited to the nation where the recovery takes place, which in some instances is not the original source country of the crude product from which the sulfur is extracted.

[4] Less than 1/2 unit.

[5] Reported figure.

[6] May also produce limited quantities of byproduct sulfur from oil refining.

[7] Formerly part of Czechoslovakia.

[8] All production in Czechoslovakia from 1989-92 is believed to have come from the Czech Republic.

[9] Dissolved Dec. 31, 1992.

[10] Data represent byproduct production from eastern states.

[11] Official Polish sources report total Frasch and native mined elemental sulfur output annually, undifferentiated; this figure has been divided between Frasch and other native sulfur on the basis of information obtained from supplementary sources.

[12] Sulfur is believed to be produced from Frasch and pyrite, and as a petroleum byproduct, however information is inadequate to formulate reliable estimates.

[13] Includes estimated byproduct production from synthetic fuels.

[14] Data may not add to totals shown because of independent rounding.

[15] Dissolved in Dec. 1991.

[16] Includes 10 months of Frasch sulfur production data. Two remaining months of "Frasch" data included with "Byproduct: Natural gas" data to conform with proprietary data requirements.

[17] Includes Frasch sulfur production data for November and December.

[18] Dissolved in Apr. 1992.

FIGURE 1
TRENDS IN THE SULFUR INDUSTRY IN THE UNITED STATES

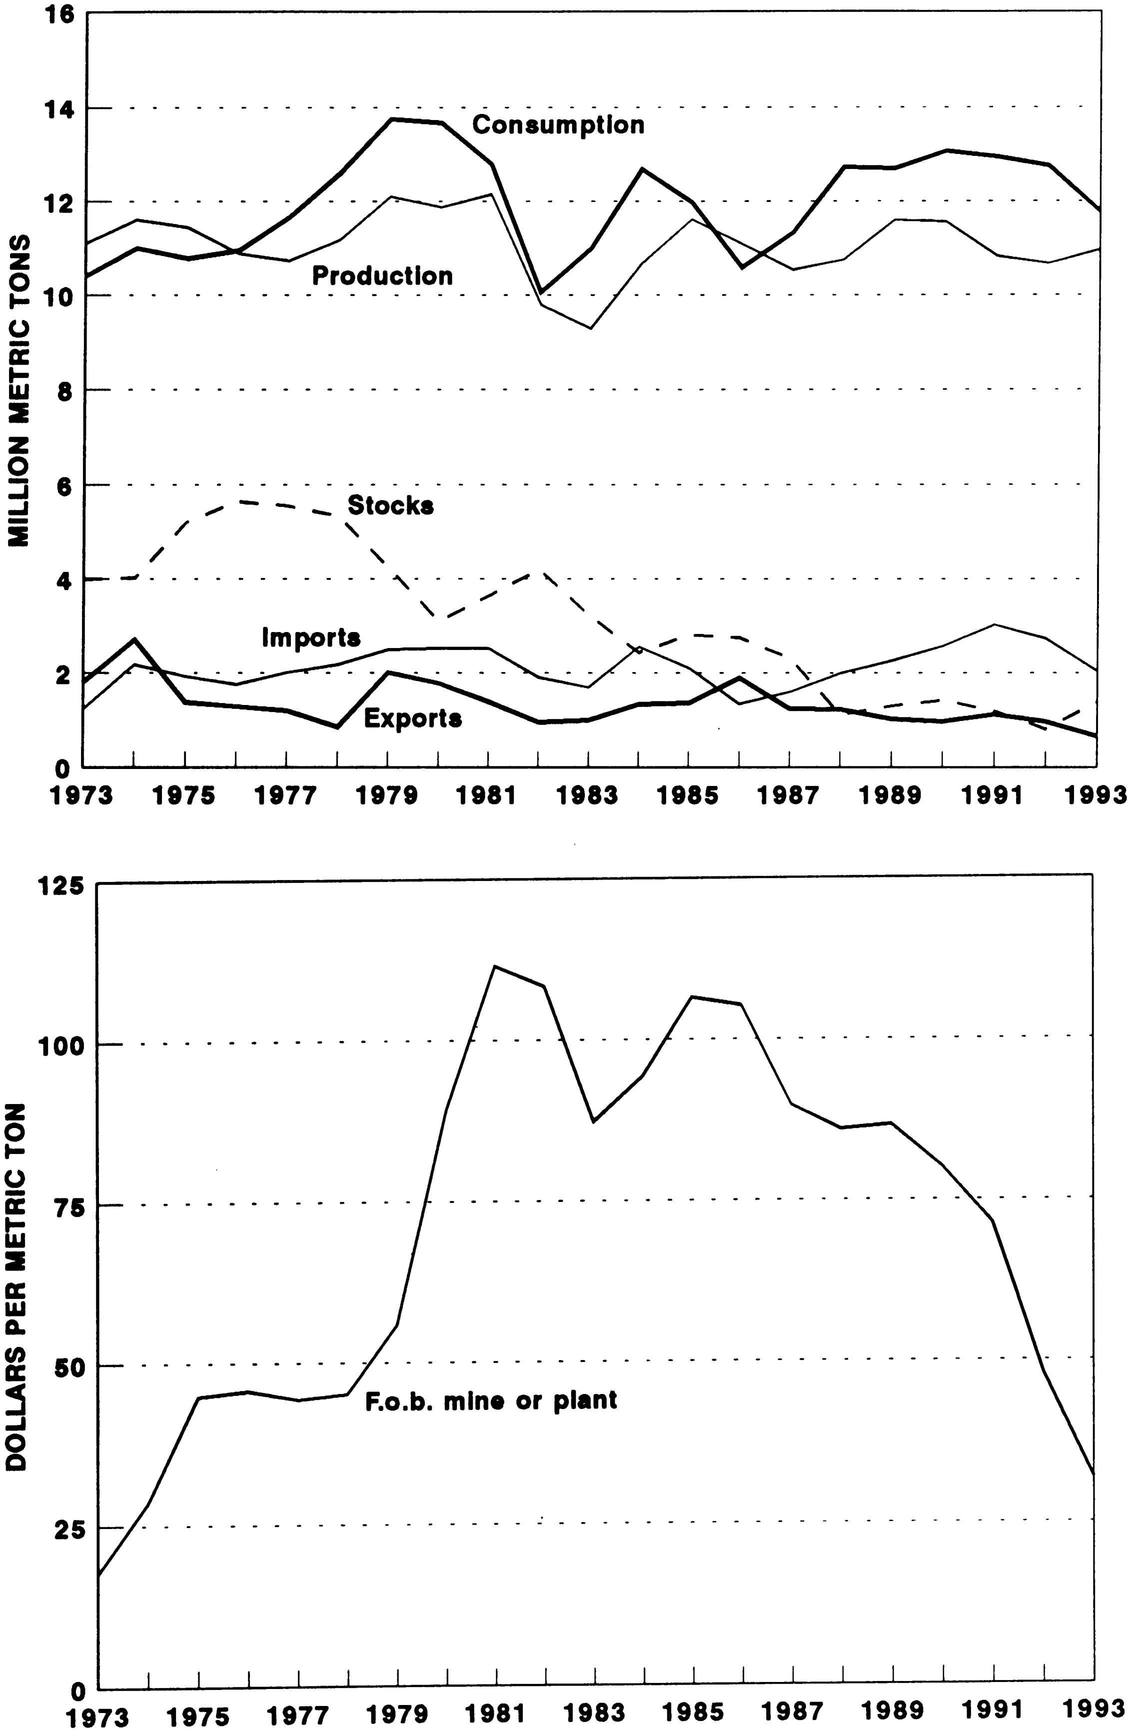

FIGURE 2

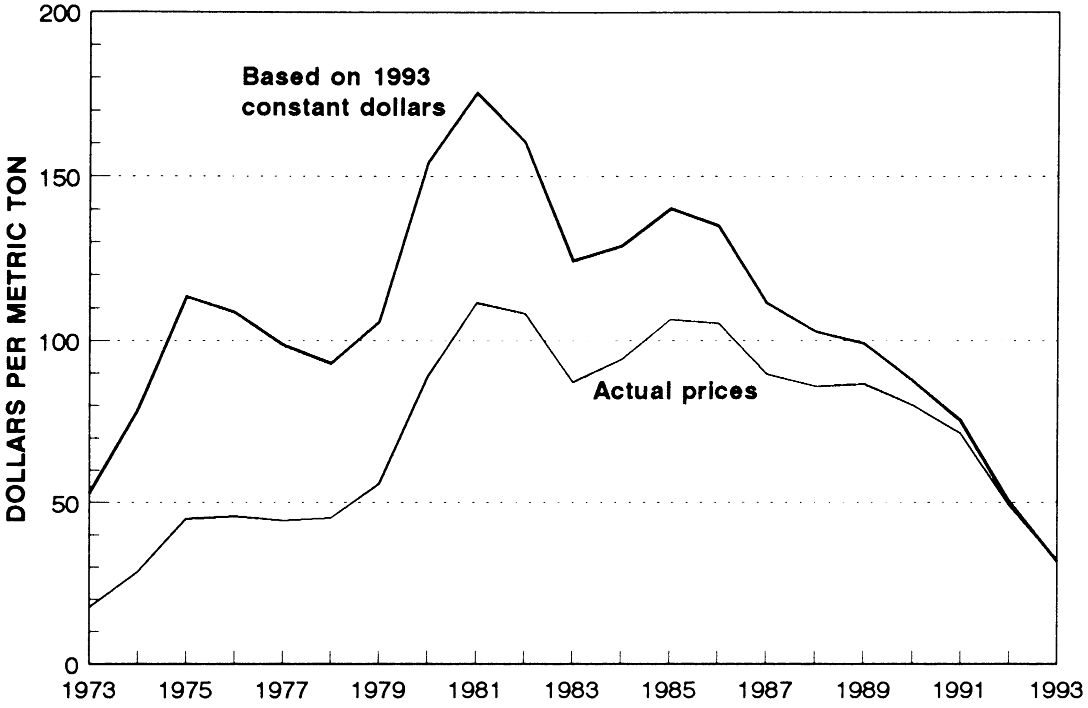
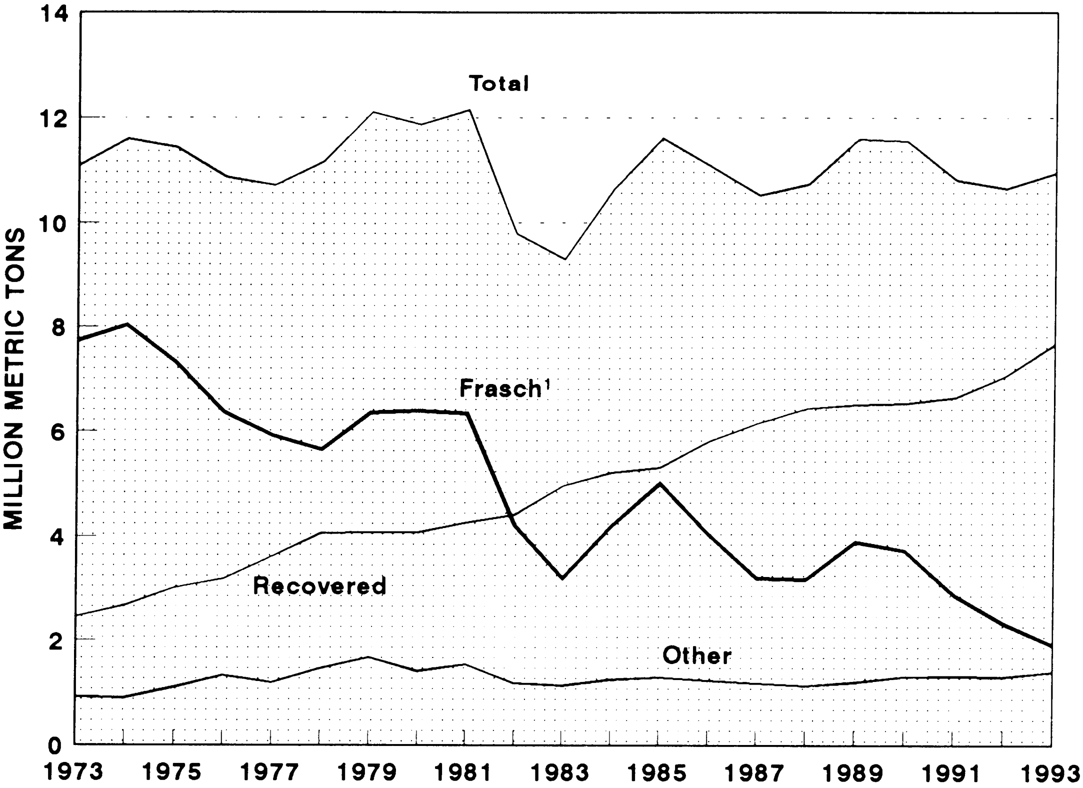
TIME-PRICE RELATIONSHIPS FOR SULFUR

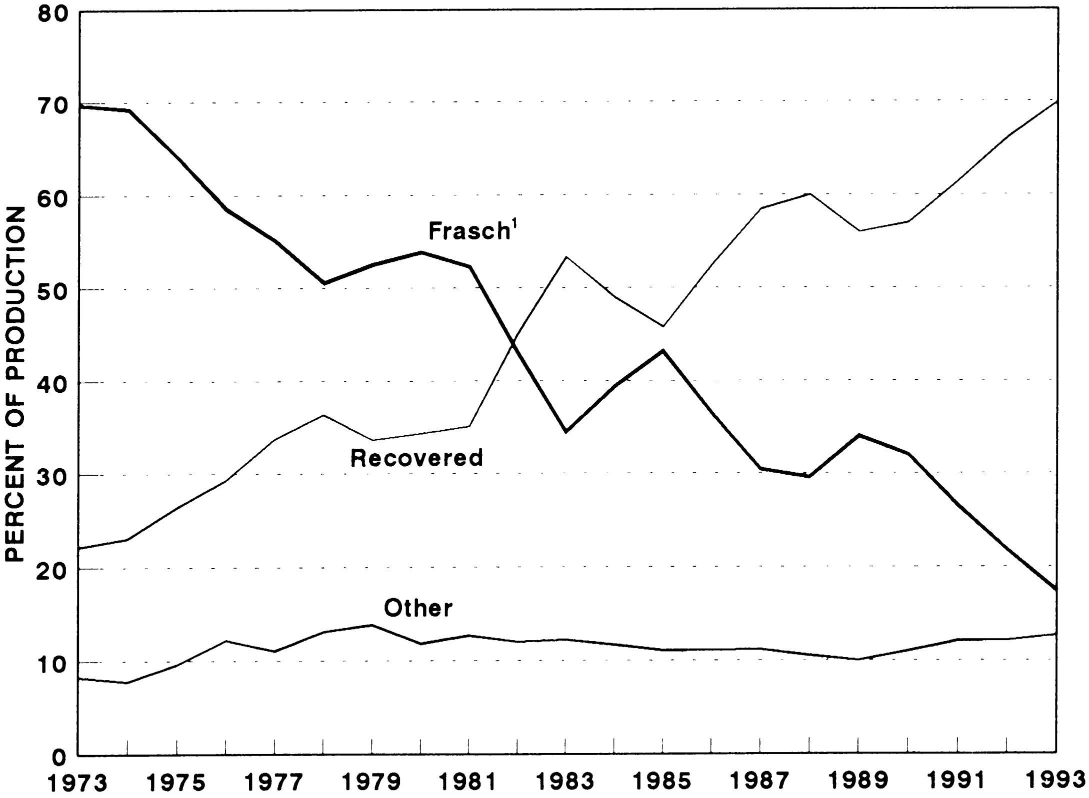


Based on the average reported prices for elemental sulfur (Frasch and recovered), f.o.b. mine and/or plant, these prices reflect approximately 90% of the shipments of sulfur in all forms during 1973-93.

FIGURE 3

TRENDS IN THE PRODUCTION OF SULFUR IN THE UNITED STATES



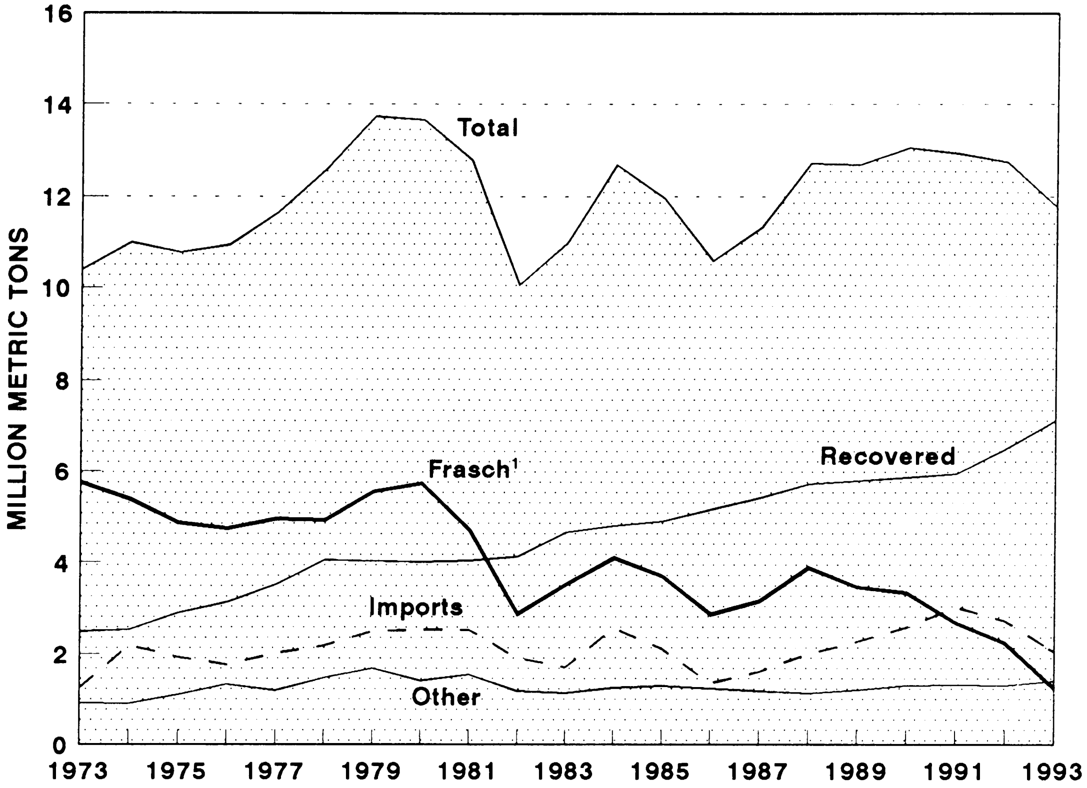


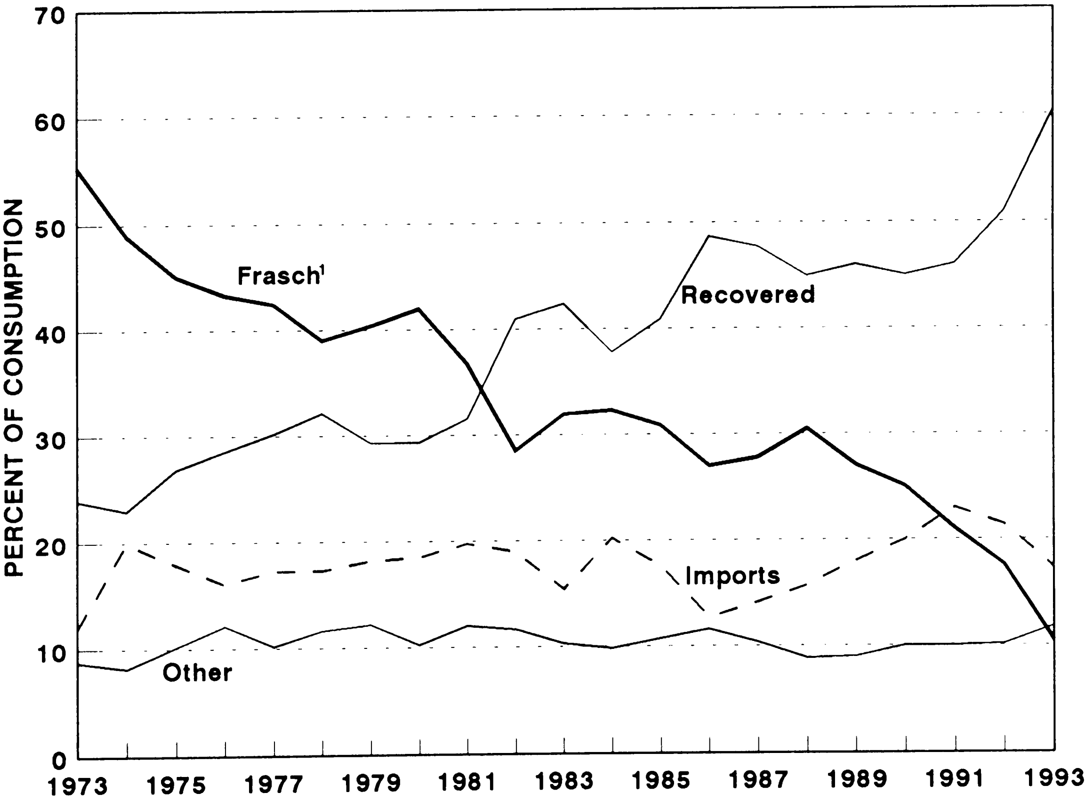
---

[1] Includes 10 months of Frasch sulfur data for 1993. Two remaining months of Frasch data are included with recovered sulfur data to conform with proprietary data requirements.

FIGURE 4

TRENDS IN THE CONSUMPTION OF SULFUR IN THE UNITED STATES





---

[1] Includes 10 months of Frasch sulfur data for 1993. Two remaining months of Frasch data are included with recovered sulfur data to conform with proprietary data requirements.

TIN

By James F. Carlin, Jr.

Mr. Carlin, a physical scientist with the Branch of Metals, has been the commodity specialist for tin for 14 years. Domestic survey data were prepared by Elsie Isaac, statistical assistant; and international data tables were prepared by Jeremy Tidwell and Amy Durham, international data coordinators.

Domestic mine production of tin in 1993, a byproduct from one gold placer deposit in Alaska, was negligible. Twenty-five firms consumed about 86% of the primary tin used domestically. The major uses were as follows: cans and containers, 32%; electrical, 22%; construction, 10%; transportation, 11%; and other, 25%. The estimated value of primary metal consumption in 1993 was about $270 million.

About 11,700 metric tons of purchased old and new tin scrap, including tin alloys, was recycled in 1993. Of this, about 7,200 tons was old scrap. More than one-sixth of the tin consumed in the United States was produced from old scrap at detinning plants and 119 secondary nonferrous metal processing plants. There was continued interest in the recycling of used tin cans, largely due to the rising costs and limited space of landfills. The recycling rate for steel cans was above 40% in 1993, having risen from 15% in 1988.

Six thousand and twenty-two tons of pig tin was sold from the National Defense Stockpile in 1993, leaving 145,395 tons in inventory, all of which is authorized for ultimate disposal.

World tin mine output in 1993 remained essentially the same as that in 1992, the result of producer efforts to restrict production. Nevertheless, there was an excess of tin on the world market for the 12th consecutive year. Excess stocks were believed to be about 40,000 tons of tin at yearend.

The price of tin remained in a fairly narrow band throughout the year, declining somewhat and finishing the year at a level that was low by historical standards. Concern over the continuation of low tin prices was widespread among tin producers. In July, the tin price reached a 25-year low on the London Metal Exchange. Most world producers had a break-even point substantially above the prevailing tin price. Many producers announced production cutbacks or shutdowns.

Tin was mined in 29 countries in 1993, of which the top 5 accounted for about 75% of the world total of 178,000 tons. China was the largest producer with 26% of the world total, followed by Indonesia (16%), Brazil (15%), Bolivia (10%), and Peru (8%). World tin reserves were estimated at 7 million tons and were considered adequate to meet the world's tin requirements in the near future. The bulk of these tin reserves was in Asia and South America.

DOMESTIC DATA COVERAGE

Domestic consumption data for tin are developed by the U.S. Bureau of Mines from a voluntary survey of U.S. tin users. All of the 290 consumers to which a survey request was sent responded. *(See table 1.)*

BACKGROUND

Definitions, Grades, and Specifications

Primary or virgin tin metal is cast and sold as bars, ingots, pigs, and slabs in weights of 50 kilograms or less. Most of the tin metal imported into the United States is in the form of 45-kilogram pigs.

The American Society for Testing and Materials, Philadelphia, PA, announced a modification to the existing Standard Specification for Pig Tin (B339). Now, tin users may specify a new level of tin purity called "Grade A Tin for the Manufacture of Tinplate"; this specification calls for a new, lower lead impurity level of 0.020% maximum under the normal Grade A specification. This change was in response to industry concerns in recent years about possible deleterious effects caused by lead in tinplate.

The Steel Can Recycling Institute (SCRI), based in Pittsburgh, PA, announced that henceforth it will be called the Steel Recycling Institute. The name change reflected a broadening of its mission to encompass not only steel cans (which had been its sole focus since its 1988 founding), but all steel products, ranging from appliances to cars.

ANNUAL REVIEW

Production

The Cache Creek Mine, in the Tofty District near Manley Hot Springs, AK, was the only mine in the United States to produce significant amounts of tin concentrates. The tin was recovered as a byproduct of gold mining. The mine, owned by Shoreham Resources, Inc., Houston, TX, was in its fourth year of production. The tin output from the mine amounted to only a small fraction of domestic tin requirements.

The United States was believed to be the world's largest producer of secondary tin. Tin metal recovered from new tinplate scrap and from used tin cans was the only type of secondary tin available in the marketplace as free tin; other secondary tin was available in scrap materials as an alloying ingredient.

Secondary tin from recycled fabricated parts was used in many kinds of products and was a major source of material for the solder and the brass and bronze industries. The SCRI was funded by five domestic tinplate producers to advance the collection, preparation, and transportation of can scrap. SCRI maintained a program of having representatives in various regions of the United States work with municipalities, scrap dealers, and detinners to promote the recycling of tin cans. During 1993, SCRI announced that henceforth it would be called the Steel Recycling Institute (SRI). The name change reflected a broadening of its mission to encompass not only steel cans (which had been its sole focus since its 1988 inception), but all steel products ranging from appliances to cars. Since SRI's 1988 beginning, the steel can recycling rate grew from 15% to over 40% in 1993. SRI announced some landmark achievements for the previous year, 1992, including:

(1) For the first time ever, more than 1 million tons of steel cans (about 14 billion) was recycled domestically, resulting in a 41% recycling rate (up from 34% in 1991).

(2) In the 5 years through 1992, the recycling rate steadily increased, moving toward the steel industry's overall recycling rate of 66%.

(3) In 1992, more than 12 billion steel food cans were recycled. With a recycling rate of 44%, the steel food can continues to be the Nation's most recycled food container (in 1991, about 36% was recycled).

(4) The 1992 recycling rate for steel beverage cans (sometimes called bimetal cans) was about 50% (in 1991, about 46% was recycled).

(5) In 1992, about 15% of all steel "general line" cans (paint, aerosol, varnish, etc. cans) was recycled (in 1991, about 12% was recycled).

The SRI began an initiative calling for increased recycling of all empty paint and aerosol cans. SRI targeted these two types of containers as ones that municipalities operating curbside and dropoff recycling programs must include in their efforts if the steel industry is to reach its goal of recycling two out of every three steel cans by 1995. Paint cans and aerosol cans are categorized as "general-line" cans in the container industry, and steel cans hold a dominant market position in those styles. Recycling operators have displayed a reluctance heretofore to collecting used paint cans and aerosol cans due to the fact that some of them contain some residues that could be troublesome to remove. SRI cited two current studies, one by the Texas Water Commission and the other by S.C. Johnson Wax Co., that reportedly blunted such reluctance.

Consumption and Uses

Primary tin consumption remained about the same as that in 1992. All major consumption categories experienced similar demand as in 1992.

Tinplated steel and tin-free steel accounted for 26% of the 132 billion cans shipped domestically; aluminum accounted for 74%. This compared to 1992 figures showing steel accounting for 27% of the 131 billion cans shipped domestically and aluminum accounting for 73%. Aluminum held an overwhelming advantage in the beverage can market, while steel dominated in the food can and the "general-line" markets.

Bev-Pak Inc., headquartered in Des Plaines, IL, with production facilities in Monticello, IN, announced that effective in early 1994 it would be switching all of its three beverage can production lines to aluminum, thereby eliminating its status as a steel purchaser and a major producer of steel cans. The company started in the late 1980's and immediately forged for itself a special niche as a producer of steel cans. Bev-Pak had claimed about 50% of the domestic steel beverage can market and a 2% share of the total U.S. beverage can market. The beverage can market has been increasingly dominated by aluminum during the past 30 years. The company attributed the switch in materials to recently lowered prices for aluminum can sheet and to the end of its contracts with Coca-Cola, Pepsi Cola, and 7-Up, which had desired steel cans for certain steel-producing Midwestern States. Industry sources felt the switch by Bev-Pak represented about a 1% slice of the 4-million-ton-per-year tin mill products market. Another major firm in the beverage can market, the Ball Corp., based in Muncie, IN, had been for many years a major producer of steel cans but ceased its steel can manufacturing 2 years ago; Ball had steel can production lines in Ohio and Texas. Crown Cork & Seal Co., headquartered in Philadelphia, PA, still operated two steel can production lines that can be switched between aluminum and steel feedstocks.

U.S. Can Corp., headquartered in Oak Brook, IL, announced it has agreed to purchase Baltimore, Md-based, Steeltin Can Corp. and two affiliated firms. Steeltin is a regional producer of containers for the specialty food and paint markets. *(See tables 2, 3, and 4.)*

Markets and Prices

Marketing of tin metal in the United States was performed mostly through trading firms, which imported the tin from a variety of countries and warehoused the tin in this country until they sold it to customers. Foreign-owned trading firms tended to dominate the field. Most tin dealers were based in or near New York, NY. Some tin also was marketed directly in the United States by large foreign producers who maintained sales offices here and sold their tin metal, usually on a 1-year contract basis, only to the largest users. Foremost among these direct-sale operations was Indo-Metal Corp., which served as the exclusive North American sales outlet for tin metal produced by Indonesia's Government-owned tin production organization.

The price of tin metal, as published in Metals Week, generally declined rather steadily throughout the year, ending the year at 15% below the beginning price. The LME remained the primary trading focus for tin. The Kuala Lumpur Commodities Exchange in Malaysia continued as an active tin trading forum.

The London Metal Exchange (LME) announced that Pittsburgh, PA, would be its next U.S. warehouse location for approved delivery of all LME-traded metals (except copper), including tin. Although Pittsburgh was chosen as the locale, specific warehouse facilities there still needed to be chosen, inspected, and approved. Pittsburgh was the 10th U.S. location for LME-approved deliveries. In addition to tin, the warehouse was able to handle aluminum, lead, nickel, and zinc.

Foreign Trade

For the second consecutive year, Brazil was the major source of U.S. tin metal imports. Bolivia ranked second, followed by Indonesia, China, and Hong Kong (apparently a transhipper).

Imports increased substantially, perhaps in response to lower Government stockpile disposals.

Imports of tin in all forms (ore and concentrate, metal, and waste and scrap) remained free of U.S. duty. *(See tables 5, 6, and 7.)*

World Review

Australia.—The first stage of the Emmaville tin project in New South Wales was completed with the commissioning of the first of two tin concentration plants. Associated Gold Fields Ltd. and Q International Resources Ltd. each own 25% of the property, with the privately held New South Wales firm, Transit Mining Ltd., holding the remaining 50%. The project is now ready to enter its next phase with the construction of a second, larger concentrator at the mine. The projected facility, with a total capacity of 100 cubic meters (m^3) per hour, was expected to be operational by mid-1994. Once completed, the plant could produce about 130 tons of concentrates monthly compared with current output of about 20 tons monthly. Indicated reserves are 500,000 m^3, with 4 kilograms of tin per m^3. At full capacity, the project was expected to have a life of 3 years. The joint-venture partners partly lease and partly own the smaller concentrator but will fully own the second one. Concentrates were being sold to Malaysian smelters on a trail basis, with average grades of 70% tin.

Renison Consolidated Goldfields Ltd. announced that it was considering developing additional tin prospects at its underground mine in Tasmania. A new deposit, Rendeep, was identified below existing workings, and a feasibility study was commissioned with a yearend completion date. A 600-meter shaft would be needed to access the new prospect.

Belgium.—One of the few remaining European tin smelters, Metallo-Chimique, in Beerse, announced plans to increase production in 1993 to about 6,600 tons of refined tin from 5,000 tons in 1992. The firm also produces lead and copper from scrap sources around the world. Its total scrap consumption is estimated to be about 17,000 tons monthly.

Bolivia.—The executive director of the Government-owned mining organization, COMIBOL, announced that all but one of COMIBOL's mines may cease production soon. He attributed low metal prices for the organization's continued heavy losses. Some of the targeted mines were tin mines. The Colquiri Mine, a tin-zinc mine, may be one of them. COMIBOL intended to send invitations to tender for the construction of a new treatment plant at Colquiri to produce tin oxide. One tin mine that COMIBOL foreshadowed to remain open was the Huanuni Mine, which produces high-grade tin ore for the Vinto tin smelter.

The Government-owned smelting organization, Empresa Nacional de Fundiciones (ENAF), announced that it expected to produce about 19,000 tons of tin metal in 1993, including 4,000 tons for Peru's Minsur tin mine under a toll contract. The tin smelter at Vinto had raised production steadily since 1987, when output was only 2,600 tons out of a capacity of 25,000 tons. The smelter produces two grades of tin metal: A-1, which grades 99.5% tin and comprised 40% of output; and A-2, which graded 99.99% tin and comprised 60% of output. ENAF announced that the smelter's entire output had low lead content. About 70% of ENAF's output was exported to the United States, while another 20% remained in South America.

The Bolivian Supreme Court authorized the Bolivian Government to evict tin miners who had been occupying the Catavi tin mine. This paved the way for the Brazilian tin mining organization, Paranapanema, to begin working tin tailings at Catavi, which it had been leasing from COMIBOL since June 1992. The unlawful occupation of the mine had caused Paranapanema to suspend its operations for about 18 months. Paranapanema agreed to pay COMIBOL a 5% production royalty pegged to international tin prices. It reportedly planned to invest $8 million in the project and expected to construct a concentrator by mid-1995.

It was announced that Japan's Metal Mining Agency would continue drilling operations in 1993-94 in the Alto Colquiri area of Bolivia. Large reserves of lead, silver, tin, and zinc reportedly were confirmed there. The Japanese agency began undertaking geological and physical studies of the Colquiri area in 1991 as part of Japan's assistance program to Bolivia. Recent exploration excavation confirmed the existence of about 500,000 tons of ore containing 0.7% tin, 3.38% zinc, and 0.7% lead. In addition, an estimated 190,000 tons of reserves containing 0.5% tin, 1.12% zinc, and 0.14% lead was discovered as pits were dug deeper, and large veins believed to have a high content of tin and zinc were found. The drilling site was adjacent to the Colquiri Mine, owned by Bolivia's state-operated Corporacíon Minera de Bolivia (COMIBOL), whose reserves could be exhausted in less than 10 years.

Brazil.—The recently privatized Cia. Siderurgica Nacional (CSN), the country's largest steel producer, announced plans to invest $20 million to begin making thinner gauge tinplate. The aim was to better compete with a local aluminum smelter that supplied a Reynolds Aluminum plant here; the latter reportedly controlled 100% of the domestic beverage can market. CSN, which makes 0.15- to 0.26-millimeter-gauge tinplate mostly for motor oil cans, would begin making 0.11-millimeter-gauge tinplate in 1995 for two-piece cans for breweries and soft drink firms. To facilitate these developments, CSN signed a technical assistance agreement with Hoogovens Group (Holland) and was negotiating a similar agreement with Thyssen Steel AG (Germany).

The Metalurgica Matarazzo Group announced it would invest $35 million to build a plant to make 900 million steel cans annually. Matarazzo expected a future partnership with CSN involving tinplate and tin cans. CSN indicated that its studies in Brazil have shown no clear preference for one type (aluminum or steel) of metal can over the other, in contrast to the United States, where aluminum beverage cans predominated, and Europe where steel cans predominated.

Mineracão Canopus, the country's fourth largest tin mining company, announced plans to reduce output at its mines in Para State by 40%, in view of continued low tin prices. Canopus, a subsidiary of Brazil's Silex Trading, was expected to produce only 750 tons of tin metal this year. This is the second cut Canopus enacted in recent years; 2 years ago it cut output 20%, to 1,200 tons annually. Canopus indicated that because of the geological makeup of its mines, which were based on alluvial and rock cassiterite deposits, it was not economically worthwhile to mine at prices below $6,000 per ton. Reserves at its three mine sites were limited, so the firm wanted to defer exploiting them until the price went up. Canopus' ore was transported from Para State, in Amazonia, to São Paulo State for toll-smelting at SNA Minerios e Metais. The company indicated that it exported its entire output, mostly to Europe and the United States, with about 15% going to Argentina.

Cia. Estanifera do Brasil (Cesbra) announced it would continue to toll smelt tin concentrate in 1993 from Peru's Minsur tin mine, under a renewal of an agreement in operation for 2 years. The new 2-year renewal calls for the tin metal to be exported to the United States. Minsur also had some tin-in-concentrate toll smelted at Bolivia's ENAF smelter, with the balance of its mine output shipped to tin smelters in Malaysia.

Clear evidence emerged of continued smuggling of tin values from the Bom Futuro tin mine in Rondônia State. In one raid, Federal police seized 20 tons of cassiterite being smuggled from the mine site. The cassiterite was in almost 600 sacks, later held in a Federal police warehouse. Although cassiterite smuggling from Bom Futuro was generally thought to be much lower that 3 years ago, the 20-ton haul was described by Federal police as being "the tip of the iceberg."

Canada.—Rio Algon Ltd. announced that it was finalizing contract terms with a Toronto-based environmental services company for the destruction and reclamation of the facilities and land around the defunct East Kemptville tin mine in Nova Scotia. Dismantling was expected to start by yearend. The Provincial government of Nova Scotia had unsuccessfully sought an operator for the mine during the past year in an attempt to save the approximately 200 jobs the facility represented. Rio Algon officials estimated costs of about $10 million to tear down the buildings and restore the site. However, some reclaimable assets from the mill would reduce the net costs. Prior to its closure a few years ago, the mine was the largest tin mine in North America.

China.—Moves were underway to open the country's mining sector to more foreign investment. The Beijing Ministry of Geology and Mineral Resources and the United Nations sponsored a conference in May to consider suggestions on draft rules for foreign exploration and exploitation of mineral resources. The Government intended to grant 20-year permits, renewable for 10 years, to foreign firms to explore a maximum area of 100 km^2 for minerals. There would be no limit for regional geological, geophysical, and geochemical surveys and airborne remote sensing geological surveys. Under the draft law, foreign companies could explore either on their own or in partnership with Chinese organizations. The conference felt that China should speed up the exploration of its mineral resources to keep pace with the country's rapid economic growth, which was 12% last year and could exceed 10% this year.

The Kawasaki Steel Corp. (Japan) announced that it was nearing completion of a feasibility study for the construction of a new tinplating line in China. Kawasaki had been approached in late 1992 by officials from the Wuxi semi-integrated steelworks near Shanghai about building a tinplating line there. The Wuxi works currently produced only bar steel and reportedly desired to broaden its base to supply tinplate for food cans. The feasibility study reportedly included options to build a 60,000-, 100,000-, or 150,000-ton-per-year line.

The Nippon Steel Corp. (Japan) announced it had begun a feasibility study in China for the construction of tinplate manufacturing facilities in Guangzhou, Guangdong Province. The initiative was taken by the Guangdong Provincial government, which would like to have a plant able to make thin tinplate for food and beverage cans. The tin mills operating in China could only make heavy gauge tinplate.

Reports indicated that the new Shanghai Metals Exchange (SHME) became the world's third largest such exchange only 1 year after its opening. In its first year SHME traded 8 million tons of nonferrous metals. Volume totaled $27 billion. The SHME planned to increase domestic brokers from the present 55 to 68. It served more than 1,000 customers in China and planned to include foreign members by yearend. Tin was one of six metals traded on the SHME along with aluminum, copper, nickel, pig iron, and zinc.

France.—The Government announced plans to privatize several long-time Government-owned organizations, including Europe's largest steelmaker, Usinor Sacilor SA. Usinor ranked as one of the world's largest tin users for its sizable tinplate operations.

Germany.—The two largest German steelmakers, Thyssen and Krupp Hoesch, announced the merger of their tinplate, electrical steels, and stainless steels flat products operations. Officials were clear that this was not a precursor to merging the two steel giants. Under the new system, Thyssen would run the merged tinplate and electrical steels operations, while Krupp Hoesch would run the stainless flat products operations. The division of authority paralleled the partners' relative strengths. Thyssen's Rasselstein subsidiary has long been the leader in German tinplate production (its 1993 output of 670,000 tons per year represented about 70% of Germany's tinplate manufacture), while Krupp Hoesch was Germany's largest factor in stainless flat products.

Th. Goldschmidt AG acquired the tin chemicals operations of Rhône-Poulenc at Clamecy, France, and conditionally acquired Pitt Metals & Chemicals, Inc. in Pittsburgh, PA. The Pitt transaction was pending U.S. Government approval. Goldschmidt viewed its new acquisitions as complementing its existing production facilities in Germany and broadening its technology base. The firm's offerings soon would include the major inorganic compounds used mostly in metal finishing, as catalysts in chemical processes, stabilizers, and intermediate chemicals. Goldschmidt reportedly favored inorganic tin compounds in its product mix because of their environmental record and ease of recycling.

Hong Kong.—The financially ailing Mainland Metals and Minerals Co. was absorbed by a group of creditors. The creditors group comprised five firms: Cheerglory Traders, Pacific Capital, ING Bank, BRI Finance, and Zhu Kuan Co. A Mainland representative indicated that these five creditors have suspended their own claims to their debts, settled a number of outstanding debts to other customers, and planned to inject further capital as and when necessary. Mainland's production had ceased before the takeover; the smelter began again operating around the clock and producing at the rate of 5,000 tons yearly.

Indonesia.—Government-owned tin producer P.T. Tambang Timah announced it was continuing with a program of restructuring designed to maintain profitability despite eroding tin prices. The first phase of the restructuring began a few years ago and eliminated noncore business and social commitments such as schools for employees' children. Then the company relocated its administrative departments from Jakarta to the island of Bangka, where most mining and smelting operations were located. Timah credited these moves with speeding up decision making and reducing overhead. Also, technical improvements were made to production equipment and supporting facilities. The second phase of Timah's restructuring involves staff development, education, training, and more effective use of human resources. Timah anticipated 1994 tin production to be similar to that of 1993. All of Timah's domestic tin mine production was smelted at the firm's Bangka and Mentok tin smelters, which have a total capacity of about 32,000 tons annually. Most of the output (95%) is exported, with 50% going to Asian consumers and the balance to the United States and Europe.

Renison Consolidated Goldfields Ltd. (Australia) announced plans to expand its tin mining operations in Indonesia. It planned to raise output at its 75%-owned Indonesian subsidiary, P.T. Koba Tin, from 7,500 tons yearly to 10,000 by commissioning another dredging unit. The new dredger was to be similar to the Merapin unit already operating and was to start operations in late 1995. The dredger was operating in Malaysia, and Renison calculated it could take 28 months to decommission it and transport it to Indonesia. The dredger represented an investment of $14 million and followed the discovery of 10 years worth of additional tin reserves in the Bemban area of Indonesia. Average tin grades were said to be high, and Renison expected to effect a reduction in its already low operating costs as a result of the investment.

Japan.—Nippon Steel Corp., the world's largest steelmaker and perhaps the world's largest tinplate producer, reportedly was rapidly increasing the quantity of used steel cans it purchases for recycling at its Kimitsu plant. Since the start of 1993, the weight of cans recycled was reported to have increased to more than 1,000 tons monthly. Nippon, which started recycling used steel cans at Kimitsu in 1984, planned to reach a level of 2,000 tons recycled within 1 or 2 years.

Malaysia.—Malaysia Mining Corp. (MMC), once the world's largest tin mining organization, announced the imminent cessation of all domestic tin mining operations because of low tin prices. MMC announced that it would concentrate on its more lucrative diamond and gold properties, often in other countries. It was reported that MMC had been losing money on its tin operations for several years. In the early 1950's, Malaysia had about 1,000 tin mines, compared with fewer than 100 in 1993. At the start of 1993 MMC operated 10 dredges. Some observers faulted the absence of a vigorous tin exploration program to seek new higher grade deposits as the older deposits became excessively worked down to lower grade status. Other observers noted that Malaysia's fast growing economy created a situation where much potential mining land was economically unviable for mining because the surface value (for other economic pursuits) was much higher. MMC retained 42% ownership in Malaysia Smelting Corp., which was one of the country's two large tin smelters.

The Zemex Corp. (United States) announced that it had sold its 70% ownership of Perangsang Pasifik Senderian Berhad, its tin dredging operation in Malaysia, to Americo Co., an Oklahoma-based oil and gas producer.

Zemex had been known for many years as Pacific Tin Corp., then based in New York, NY. In recent years Zemex relocated its headquarters, changed its name, and restricted its operations to focus on industrial mineral, metal, and metal powder markets.

A consortium of 10 Malaysian tin mining organizations announced it would travel to Vietnam to discuss with local parties a possible joint venture to mine tin in Vietnam. The consortium included Osborne & Chappel International, GB Mining, Foo Nyit Tse & Brothers, Gopeng Mining, & Selangor Dredging. This new interest in Vietnam may have originated from discouraging prospects in Malaysia. Malaysia had long been the world's leading tin producer but now ranked sixth in world tin mine production behind China, Bolivia, Indonesia, Brazil, and Peru in 1993.

Netherlands.—Hollandsche Metallurgische Industrie Billiton (HMIB) announced the cessation of making tin chemicals, anodes, and granules. Billiton closed its tin smelter at Arnhem in 1992 and hoped the restricted operation would be able to concentrate on the downstream market effectively. However, recessionary conditions throughout Europe impeded sales of such products, especially tin tetrachloride, which was used in the making of polyvinyl chloride (PVC). In 1993, 30 people worked at HMIB. Production was expected to cease in early 1994.

Russia.—The Government announced that tin could be exported without special documentation or quotas as part of the Government's liberalization of foreign trade. Officials at the Novosibirsk Tin Works declared they would keep their traditional ties with state trader Raznoimport, but would also forge their own direct trading links. Much of Novosibirsk's activities involved toll smelting deals for Portuguese and British tin mines. Novosibirsk reportedly was a 35,000-ton-per-year-capacity tin smelter currently operating at 60% of capacity. Like many metallurgical operations in Russia, it has been struggling with large price increases in energy and transport. Reports indicated that the Novosibirsk tin smelter was exporting to Europe freshly toll-smelted tin ingots as well as some material believed to be from old smelter inventory. This tin was reportedly mostly of three nines quality and was being offered at discounts of $30 to $70 per ton to the LME cash price. Toward yearend, plans were underway to privatize the smelter. Overseas investment in the smelter remained a future possibility.

South Africa, Republic of.—The Rooiberg Tin Co. announced that it would be monitoring the financial viability of its tin mining operations. Rooiberg had implemented a survival plan in 1992 to stave off possible closure while instituting a rehabilitation program. Under the plan, mining operations were refocused on high-grade ore reserves, and mine throughput was cut from 15,000 tons to 6,000 tons monthly. The company continued to operate at that level, which led to lower refined metal production at the Rooiberg smelter. Refined metal production was running at only 450 tons yearly, with a smelter capacity of 2,000 tons yearly. The smelter's output was consumed entirely in the domestic market. Earlier concerns that Rooiberg's higher-grade reserves would be exhausted soon were eased by the finding of new ore reserves. These new reserves gave the mine an operating expectancy of up to 5 years.

Thailand.—Once ranked in the top echelon of world tin producers, reports reflected the compression of mining activity in the country, a result of low tin prices. The Government's Department of Mineral Resources announced that 86 tin-mining operations were forced to stop production in 1991 and 1992, with a loss of 1,400 jobs. Thailand's largest tin smelter, Billiton's Thailand Smelting and Refining Co. (Thaisarco), reported that its use of domestic ore declined by 42%, to 2,840 tons, in the first half of 1993, while imports of tin concentrates rose by 155%; overall, ore consumption was down by 20% in the same period. Thaisarco's output was expected to reach 8,000 tons in 1993; 4,595 tons was produced in the first half. About 60% of this output was used domestically, while most tin exports went to Japan.

United Kingdom.—British Steel Corp. announced the commissioning of a wide tinplate coil line at its Trostre, Wales, Tin Mill. The $75 million line would allow the plant to produce tinplate coils in widths up to 122 centimeters, up from the current 99 centimeters. The Trostre plant would have the capability of producing up to 212,000 tons of the new, wider coil annually. The wider coils increasingly were preferred by beverage can makers. British Steel was Europe's second largest and the world's fourth largest steelmaker.

The Cookson Group, headquartered in London and the world's largest solder producer, announced it would reorganize its solder operations by merging two of its major U.S.-based firms: Federated-Fry Metals Inc., mostly an industrial solder producer, and Alpha Metals Co., primarily an electronic soldermaker. The new company would be called the Alpha-Fry Group and would continue to market all brand names currently available from each firm.

British Steel Corp. launched a new steel top for beverage cans, which stems from joint research work with Hoogovens (the Netherlands) and Rasselstein (Germany), two other large tinplate producers. The new top is designed to counter aluminum's position in the container market. The top, with a twin push-button operating system, was being introduced with a standard can body. But the three partners expected to have a 30% lighter body available next year. The brand name, "ECOTOP," was selected by British Steel to illustrate the environmental advantage it felt steel cans have over aluminum.

Current Research

In the United States, Dentsply International Corp., Milford, DE, a major supplier of dental alloys (amalgams), announced a collaboration between itself and the National Institute of Standards and Technology (NIST) to produce a mercury-free direct-filling alternative for conventional dental amalgams. Their joint work involved a process based on earlier NIST electrochemical powder technology. The alternate material involved the use of biocompatible metallic powders (e.g., silver-coated tin). The pairs of metals underwent fast diffusion to form an in situ intermetallic compound at body temperature. Although silver and tin were the principal ingredients, other formulations containing copper and gold also were being examined.

In the United States, Airco Gases Co., Murray Hill, NJ (a subsidiary of BOC Ltd., United Kingdom), announced it had three patents pending for the development of a controlled nitrogen atmosphere system for wave soldering applications. The system was said to virtually eliminate dross formation and to require less flux. Solder represented one of the major uses of tin.

In the United States, researchers at Rockefeller University, New York, NY, announced development of a new drug containing tin that appeared to cure babies suffering from jaundice, a common and potentially dangerous ailment in newborn infants. Tin-mesoporphyrin (SnMP) reportedly blocked the production of bilirubin, the yellow pigment from unprocessed bile that in instances of jaundice builds up in the blood faster than the baby's liver can process it. Severe cases of bilirubinemia can lead to brain damage or harm the central nervous system. The new drug was a synthetic chemical relative of heme, the iron-containing pigment in red blood cells. The SnMP molecule contained tin instead of iron.

In Japan, Sumitomo Light Metal Industries Ltd. announced development of a copper water supply tube with pure tin. The newly developed tube, marketed as Super Tin Coat (STC), was tested for 2 years in Hokkaido, Ibaragi Prefecture, with impressive results.

In the United Kingdom, the International Tin Research Institute (ITRI), funded by the Association of Tin Producing Countries (ATPC), announced it was progressing on several fronts in identifying potential new end uses for tin and developing existing technologies, as follows:

(1) For tinplate, ITRI was attempting to improve deposition techniques used in the passivation process that enhances corrosion resistance and lacquer adhesion.

(2) For solder, ITRI is investigating lead-free solders and higher grade pastes for miniature and surface-mounted electronic applications. Several low-lead or lead-free solders developed by ITRI with financial assistance from the British Government were being evaluated. ITRI hypothesized that if these solders, which contained about 90% tin, were to replace conventional 60% tin solders, world tin consumption in the solder category could increase by 20,000 tons yearly.

(3) In the categories of tin utilized for tinning and specialized alloys, which ITRI feels may account for 19% of world tin consumption, ITRI research focused on reducing the environmental impact of tin-nickel and tin-zinc coating and plating processes.

(4) In the field of tin chemicals, ITRI investigated the use of tin compounds in fire retardants, pigments, and paints; in all three fields, tin made inroads commercially. Tin-zinc compounds reportedly were less combustible and also emit less toxic fumes and tars than other retarding agents. ITRI projected the potential tin market could be quite large, perhaps tens of thousands of tons annually.

(5) In a new market, cooperation between ITRI and companies in Germany, Portugal, and Spain led to the development of a tin-only bottle capsule (primarily for wine) to capitalize on concerns about lead contamination in traditional capsules.

OUTLOOK

Domestic demand for primary tin is expected to grow slowly in the next few years, at a rate of perhaps 1% per year. However, new applications, especially those in which tin is substituted for toxic materials, could double that rate as early as 1996.

As long as the price of tin remains historically low, there appears to be little incentive to explore or develop domestic tin reserves. Thus, it is highly likely that domestic requirements for primary tin will continue to be met by imports and Government stockpile sales.

[e]Estimated. [r]Revised. W Withheld to avoid disclosing company proprietary data; not included in "Total."

[1]Data for 1989 and 1990 are derived in part from UNCTAD. Wherever possible, total smelter output has been separated into primary (from ores and concentrates) and secondary (tin metal recovered from old scrap). This table reflects metal production at the first measurable stage of metal output. Table includes data available through July 19, 1994.

[2]May include some secondary metal.

[3]Formerly part of Czechoslovakia; data were not reported separately until 1993.

[4]Dissolved Dec. 31, 1992. All production in Czechoslovakia from 1989-92 came from the Czech Republic.

[5]Reported figure.

[6]All production in the U.S.S.R. from 1989-91 came from Russia.

[7]Dissolved in Dec. 1991.

TITANIUM

By Joseph M. Gambogi

Mr. Gambogi, a physical scientist with 11 years of Government and industry experience, has been a commodity specialist since 1988. Domestic survey data were prepared by Robin Kaiser, statistical assistant; and international data tables were prepared by David Mann, Section of International Data.

Titanium (Ti) is a lightweight metal well known for corrosion resistance and its high strength-to-weight ratio. Titanium comprises about 0.62% of the Earth's crust and occurs primarily in the minerals, anatase, brookite, ilmenite, leucoxene, perovskite, rutile, and sphene. Although titanium is best known for its use as a metal alloy, titanium is primarily used in the form of titanium dioxide (TiO_2), widely used as a white pigment in paints, paper, and plastics. Other minor uses of titanium minerals include ceramics, chemicals, welding rod coatings, heavy aggregate, and steel furnace flux.

Although the supply and demand of titanium products moved toward a balance in 1993, the past year was a year of consolidation in the global titanium industries. The TiO_2 pigment industry operated at capacity utilization rates estimated at less than 90%, and several pigment producers delayed capacity expansions or acquired existing operations rather than proceeding with planned expansions. Meanwhile, heavy-mineral producers scaled back production levels at various locations to better align themselves with demand by the pigment industry. In the titanium metal industry, depressed aerospace markets kept demand for titanium metal products to less than one-half of what it was just a few years ago. Several titanium metal producers closed reduction, melting, and fabrication facilities.

In 1993, the United States was a net importer of titanium concentrates and a net exporter of titanium pigment and metal products. Domestic consumption of titanium concentrates increased by 1.2% on a gross weight basis or 0.3% based on TiO_2 content. Production of TiO_2 pigment exceeded the 1992 level by 2.2%, while apparent consumption of TiO_2 pigment increased by 2.9%. Titanium ingot production decreased by 0.7%, while ingot consumption increased by 7.2%. Production of titanium sponge was withheld to avoid disclosing company proprietary data. *(See table 2.)*

DOMESTIC DATA COVERAGE

Consumption data for titanium raw materials are developed by the U.S. Bureau of Mines (USBM) from one voluntary survey of domestic operations. Of the 31 operations canvassed, 26 responded, representing more than 99% of the data in table 7. Data for nonrespondents were estimated based on prior-year consumption levels.

BACKGROUND

Definitions, Grades, and Specifications

Ilmenite is the most abundant titanium mineral, with the chemical formula $FeTiO_3$, and theoretical composition of 52.7% TiO_2 and 47.3% FeO. However, the term "ilmenite" also is used to include material that has been oxidized and leached during weathering, containing up to 70% TiO_2, about 25% to 30% iron oxides, and about 5% of oxides of other elements. When the alteration is extreme, the residual material is essentially amorphous to finely crystalline TiO_2 and is called leucoxene.

Rutile is essentially crystalline TiO_2, and commercial concentrates usually contain about 95% TiO_2. Synthetic rutile or rutile substitutes are derived from ilmenite by processes involving oxidation and reduction treatments followed by leaching of iron. Synthetic rutile concentrates approach rutile in chemical composition but, being residual leached grains, are porous and composed of very fine crystallites, while natural rutile grains are usually single crystals. Anatase also is crystalline TiO_2, but has a different crystal structure than rutile. Although research is ongoing, anatase is not a suitable feedstock for pigment production.

Commercially available titaniferous slags made by electric furnace smelting of ilmenite with carbon contain 70% to 85% TiO_2. Slags being produced at the end of 1993 were 80% TiO_2 slag from Sorel, Quebec; 85% TiO_2 slag from Richards Bay, Republic of South Africa; and 75% TiO_2 slag from Tyssedahl, Norway.

Titanium tetrachloride ($TiCl_4$), the intermediate compound from which titanium metal and chloride-process TiO_2 are manufactured, is a colorless to pale yellow liquid at room temperature, with a boiling point of 136° C.

Titanium sponge metal is the primary metal form obtained by vapor-phase reduction of $TiCl_4$ with magnesium or sodium metal. It is called sponge because of its appearance and high porosity. Most titanium ingot for forging into billet and mill products is obtained by melting sponge in a vacuum-arc furnace, with or without scrap titanium or alloying additions.

Titanium dioxide pigment is characterized by its purity, refractive index, particle size, and surface properties. The particle size is critical and must be closely controlled within the range of about 0.2 to 0.4 micron to develop optimum pigment properties. The superiority of TiO_2 as a white pigment is mainly due to its high refractive index and resulting light-scattering ability, which impart excellent hiding power and brightness. Titanium dioxide pigments are produced as two major types: rutile and anatase. Rutile-type pigment is less reactive with paint vehicles in sunlight than anatase pigment and is preferred for use in outdoor paints. Anatase pigment has a bluer tone than the rutile type, is somewhat softer, and is used mainly in indoor paints and in paper manufacturing.

There are no rigid specifications for raw materials to be used as feed for making $TiCl_4$ for metal or pigment manufacture, or for ilmenite or slag to be used in the sulfate pigment process. However, certain impurities such as chromium, columbium, manganese, phosphorus, and vanadium can seriously impair pigment properties, so these impurities are an important consideration in the selection of concentrates for pigment production. Concentrates to be used for making $TiCl_4$ should be low in calcium and magnesium, which form high-boiling-point chlorides that cause trouble in fluid-bed chlorinators.

Industry Structure

On a gross weight basis, about 40% of the world's TiO_2 feedstocks are supplied by three titanium slag producers: Richards Bay Minerals (RBM), the Republic of South Africa; QIT Fer et Titane Inc., Canada; and Titania A/S, Norway. The remaining 60% of demand is supplied by producers of ilmenite and rutile concentrates (both natural and synthetic). Most of the production facilities for these concentrates are found in Australia, India, Malaysia, Norway, Sierra Leone, and the Republic of South Africa. Some of the largest producers of these feedstocks are Cable Sands Ltd., Consolidated Rutile Ltd. (CRL), Indian Rare Earths Ltd. (IREL), Renison Goldfields Consolidated Ltd. (RGC), Sierra Rutile Ltd., the TiWest joint venture, and Westralian Sands Ltd.

World TiO_2 pigment output in 1993 came from about 60 separate facilities ranging in annual capacity from a few thousand metric tons to nearly 300,000 tons. The world's four largest TiO_2 pigment producers are E. I. du Pont de Nemours & Co. Inc. (Du Pont), SCM Chemicals Inc., Tioxide Group PLC, and Kronos Inc. These four companies own or control about 60% of world capacity. Another 20% of world capacity is divided between Bayer AG, Ishihara Sangyo Kaisha, Kemira Oy, Kerr-McGee Chemical Corp., Sachtleben Chemie GmbH, and Thann et Mullhouse. The remaining 20% of world capacity was divided between about 20 other producers. An estimated 40% of the world's capacity is in North America while about 39% is in Europe (Eastern and Western).

There are 10 major producers of titanium sponge in the world. In Japan there are three producers: Sumitomo SiTix Corp. Ltd., Showa Titanium Co. Ltd., and Toho Titanium Co. Ltd. In the United States, there are two producers, Oregon Metallurgical Corp. (Oremet) and Titanium Metals Corp. of America (TIMET). The United Kingdom's one sponge producer is Deeside Titanium Co. China has one known producer in Shanghi. Within the former U.S.S.R., there are producers at Berezniki, Russia; Ust Kamenogorsk, Republic of Kazakhstan; and Zaporozhe, Ukraine.

The titanium mining and pigment industries are moderately integrated from raw materials to semifinished products. Most of the sponge metal producers do not own their own titanium mine. In the United States, one metal producer purchases mineral concentrates for the production of titanium sponge, while the other domestic producer purchases $TiCl_4$.

Technology

Exploration.—Hard-rock ilmenite deposits, because of their inherent magnetic properties, are readily amenable to the application of aero- and ground-magnetic geophysical surveys. These deposits generally respond to such surveys by reflecting abnormally positive magnetic intensities, although in some cases negative magnetic anomalies may result. Once such anomalies are mapped, further exploration may take place in the form of detailed geological observations and ultimately drilling to test the anomalies and delineate the associated ilmenite deposit.

If initial diamond drilling indicates an economic deposit, development drilling proceeds on a set grid pattern of about 100 meters. Intermediate holes are drilled to fill in major gaps in information on geologic structure or ore continuations. Drill cores are visually logged and split for chemical assay to determine TiO_2 and iron content.

Sand deposits of titanium minerals are mostly near continental margins where erosion of regional granitic and metamorphic rocks containing ilmenite and rutile has led to accumulation of these minerals in coastal plain sediments. Working and reworking of these sediments by ocean waves on beaches and in streams resulted in various degrees of sand sorting and concentration by particle size, density, and resistance to abrasion. Well-sorted sands are much more likely hosts for ilmenite, rutile, and other heavy minerals than are unsorted sands.

Titanium minerals are dark in color, and their concentration in predominantly quartz sands is often readily visible. Initial discovery has often been made through surface observation. In exploration, hand panning of samples has been a very useful exploration tool. Some titanium mineral ore bodies are detectable by ground or airborne magnetometer surveys or, if monazite or zircon is present, by low-level radiometric surveys.

Drilling to determine the extent of sand deposits in the first phase of development should be done to a depth of at least 15 meters and preferably 30 meters. The type of drill needed will depend on the nature of the ground, including the presence of clay, hardpan, roots, stumps, and other organic material, as well as the depth of the water table.

Approximate minimum requirements

for an economic sand deposit of titanium minerals include reserves of 300,000 to 1 million tons of TiO_2 content in rutile or ilmenite; and heavy-minerals content in the ore of 1% to 5%, depending on the mix of ilmenite, rutile, and other valuable minerals.

Mining and Concentration.—For mining sand deposits of titanium minerals, a dredge is usually used. This may be bucket-ladder type but is more likely to be suction type. The dredge floats in its own pond, digging forward and stacking tailings aft. Rough concentration, the separation of heavy minerals from the lighter quartz-feldspar-mica fraction, is usually accomplished by wet-gravity methods. The Humphreys spiral has been standard for this separation since its introduction about 1940, but pinched-sluice separators of various designs also have been used. The Reichert cone concentrator, which operates on the pinched-sluice principle, has been successful for large-tonnage operations. Flotation also has been used to some degree. For separating the minerals from stream-type deposits, jigs usually are chosen because they are the concentrating device least sensitive to extreme grain-size variation.

The final wet-mill concentrate is dried, usually in a rotary kiln, prior to further treatment. The subsequent flowsheet depends on the mineral assemblage to be treated. Ilmenite and rutile are usually removed together by electrostatic separation. The ilmenite-rutile conductor fraction of dried wet-mill concentrate is then subjected to high-intensity magnetic separation, yielding a final ilmenite product. The rutile fraction is further cleaned by screening and additional electrostatic separation. Zircon and monazite products are recovered from the nonconductor fraction of the wet-mill concentrate by a combination of gravity, electrostatic, and high-intensity magnetic separation.

Ilmenite is also mined from two hard-rock deposits, one in Canada, and one in Norway. The ore bodies are massive, and open pit mining is practiced. At Tellnes, Norway, the ore is crushed, ground, and subjected to wet-magnetic separation to recover magnetite. An ilmenite concentrate containing about 44.5% TiO_2 is recovered by flotation of the nonmagnetic portion, as was formerly done at the MacIntyre Development, Tahawus, NY, where ilmenite mining ceased in 1982. At Allard Lake, Quebec, ore at 32% to 36% TiO_2 is shipped from the mine to the beneficiation plant at Sorel, Quebec; some of the ore is shipped to steel companies as a substitute for fluorspar flux. For upgrading to slag, the ore is crushed and ground, concentrated by gravity methods, roasted to remove sulfur, mixed with a reducing agent, and smelted in an electric arc furnace. A high-purity pig iron is produced. The titanium is concentrated in the slag, known as Sorelslag, which contains 80% TiO_2. Because the iron content of the slag is low, its use reduces the quantity of iron sulfate in the liquid effluent of sulfate process pigment plants. Because of its relatively high content of magnesium and calcium, which cause operating problems during chlorination, Sorelslag is not used to make $TiCl_4$.

At Richards Bay, Republic of South Africa, both rutile and ilmenite are produced from heavy-mineral sand deposits. The ilmenite, containing about 50% TiO_2, is relatively low in magnesium and calcium and is smelted with carbon in an electric furnace to produce an 85% TiO_2 slag. Because of its low content of the aforementioned impurities, the Richards Bay slag is acceptable for manufacturing $TiCl_4$ and is also a feed material for the sulfate pigment process.

Materials made from ilmenite that have a TiO_2 content approaching that of natural rutile are known as synthetic rutile or beneficiated ilmenite. Processes to produce rutile substitutes from ilmenite fall into three general classes: those in which the iron is completely reduced to metal and separated from the reaction mass either physically or chemically, those in which iron is reduced to the ferrous state and chemically leached away from the titanium, and those in which the ilmenite is selectively chlorinated to remove iron and other impurities. Richards Bay slag also may be regarded as a rutile substitute because of its high grade (85% TiO_2) and suitability for the manufacture of $TiCl_4$.

Pigment Production.—Titanium dioxide pigment is produced commercially by two methods that require different raw materials. In the sulfate process, ilmenite or titanium slag is reacted with sulfuric acid, a portion of the iron sulfate formed may be crystallized and removed, and titanium hydroxide is precipitated by hydrolysis, filtered, and calcined. In the chloride process, rutile is converted to $TiCl_4$ by chlorination at 850° to 950° C in the presence of petroleum coke. All U.S. commercial chloride-process plants use fluid-bed chlorinators, although static-bed systems can be used for this purpose.

Titanium tetrachloride so prepared may be used either in making pigment, or with additional purification, for reduction to metal. In making pigment, the $TiCl_4$ is oxidized with air or oxygen at about 1,000° C, and the resulting fine-size TiO_2 is calcined at 500° to 600° C to remove residual chlorine and any hydrochloric acid that may have formed in the reaction. Aluminum chloride is added to the $TiCl_4$ to ensure that virtually all of the titanium is oxidized in the rutile crystalline form. Recoveries of TiO_2 in pigment are approximately 90% and 80% to 85% for chloride process and sulfate process plants, respectively.

Metal Production.—Feed materials needed for metal production are similar to those for chloride-process pigment because the formation of $TiCl_4$ is required in both cases. Titanium sponge is produced by reducing $TiCl_4$ with sodium or magnesium under an inert atmosphere at temperatures up to 1,040° C. Residual chlorides are removed by vacuum distillation, inert gas sweep, or after cooling and crushing, by leaching in very dilute acid. The sponge is compacted, usually with some scrap and alloying additions, and made into ingot by two or more successive melting operations.

Recycling.—Scrap titanium generally accounts for 40% to 50% of ingot production. Scrap is generated by producers of ingot and mill products and by consumers of mill products in fabricating finished products or components. It is estimated that up to 75% of titanium ingot metal becomes scrap during processing to finished parts.

Clean and well-segregated scrap, processed to remove impurities, is blended with sponge metal and alloying constituents and remelted to ingot. Remelting is mainly by vacuum-arc consumable-electrode processing. Cold-hearth melting (electron-beam and plasma-arc) also is used, especially for chips and turnings. Cold-hearth melting is very effective in ensuring removal of high-density inclusions, such as tungsten carbide tool particles, which settle out in the hearth area during melting. A substantial quantity of titanium scrap, particularly unprocessed turnings, is consumed directly or in making ferrotitanium for use in steel and other alloys.

Economic Factors

Tariffs.—The duties shown in table 1 reflect results of the Tokyo Round of Multilateral Trade Negotiations completed in 1979 under which tariffs on many items were reduced in several stages over the period January 1, 1980, to January 1, 1987. *(See table 1.)*

Depletion Provisions.—The depletion allowance for ilmenite and rutile is 22% when mined from domestic deposits and 14% from foreign deposits.

Operating Factors

Environmental Requirements.—Heavy-mineral sand mining presents few serious environmental hazards. The land is restored by returning the bulk of the sand after removal of the ore minerals. Dune areas can be left in nearly their original form, and the sand can be stabilized by seeding and replanting.

The major environmental problem in the titanium industry is the disposal of wastes from pigment-producing processes that use ilmenite, generating up to 3.5 tons of waste per ton of product. Solutions to this problem required the development of methods to neutralize and control the effluent now produced by the sulfate pigment process, mainly a solution of waste sulfuric acid and ferrous sulfate heptahydrate. Deep well disposal has been used for waste ferric chloride produced when ilmenite is used to make $TiCl_4$. In processes for making synthetic rutile, the effluent solutions are treated to regenerate the original leaching agent, such as hydrochloric acid, which is recycled, and to form useful byproducts such as sodium sulfate, ammonium sulfate, and iron oxide. In sulfate-process technology, there is a strong trend away from disposal of waste materials in streams or in the ocean. Both U.S. sulfate-process producers now are using waste treatment plants that neutralize acid effluent with limestone and lime, and produce gypsum and iron oxide byproducts.

Toxicity.—Titanium is a nontoxic material, as demonstrated by the use of TiO_2 in cosmetics and the use of titanium for making pacemakers and other implant devices for humans. However, some titanium compounds can be hazardous; for example, $TiCl_4$, which reacts violently with water or moisture in the air, forms TiO_2 and hydrochloric acid.

Energy Requirements.—According to a 1975 study for the USBM, energy requirements for alluvial mine production are about 5.1 million British thermal units (Btu) per ton of TiO_2 in concentrate. Production of pigment requires about 75 to 112 million Btu per ton of TiO_2, depending on the process and feed material used. Titanium sponge production uses from 408 to 466 million Btu per ton of metal, of which about 248 to 270 million Btu is required to regenerate the reductant and chlorine. The conversion of sponge metal to titanium ingot requires an additional 46 million to 57 million Btu per ton of titanium ingot.

ANNUAL REVIEW

Strategic Considerations

Security of Supply.—Dependence on foreign rutile sources for the production of titanium metal could be eased or eliminated in an emergency in two ways, using current commercial processing methods: (1) Synthetic rutile could be made from domestic ilmenite now being mined in Florida, or ilmenite that could be mined from other deposits; (2) Titanium tetrachloride for metal production could be made directly from ilmenite, as is done by Du Pont for TiO_2 pigment manufacture. Another possible solution to this problem is the development of new processes that utilize domestic ilmenite and perovskite that contain too much calcium and magnesium to be used directly for making $TiCl_4$. Availability of such processes would encourage production of domestic ilmenite. Titanium concentrates currently used to make $TiCl_4$ for metal production are mostly imported rutile and synthetic rutile, but domestic concentrates could be used for this purpose in an emergency, possibly at higher cost.

Stockpile.—The Defense Logistics Agency (DLA) began a modernization program in 1992. The National Defense Stockpile's (NDS) inventory in December contained 23,555 tons of specification metal and 9,857 tons of nonspecification material. In 1993, the Defense National Stockpile Center considered bids for the sale of 10,000 short dry tons (sdt) of rutile held in the NDS. However, only 1,218 sdt of material was sold in 1993. In June, DLA released its 1994 Annual Materials Plan, which included authorization to dispose of 20,000 sdt of rutile held in the stockpile. At the end of 1993, DLA held about 38,000 sdt in the stockpile.

Issues

Processing of some mineral sands by

certain methods results in the concentration of radioactive elements in the waste or byproduct streams. Monazite and xenotime, both rare-earth, thorium phosphates, are the usual minerals of consequence because 100% separation of a heavy-minerals deposit is impossible to obtain within economic considerations. Monazite inclusions within the mineral grains and/or ionic substitution of uranium, thorium, and radium within the mineral lattice result in some radioactive contamination. During the processing of titanium minerals, some concentration occurs in waste product streams. Generally, if the combined weight of uranium and thorium exceeds 0.05%, the materials are considered to be sources for these radioactive elements. Domestic requirements for licensing source material, definitions, exemptions, and other pertinent information are found in the Code of Federal Regulations, Energy, 10, Part 40 (10 CFR 40). The Environmental Protection Agency (EPA) is currently examining the generation and disposal practices for wastes that contain relatively low levels of naturally occurring radioactive materials. Consequently, mineral feedstock producers are closely examining the level of radioactive elements present in mineral deposits under development and are actively researching for remediation methods.

Although the United States has large reserves of titanium in the form of ilmenite, nearly all U.S. titanium sponge production has been derived from imported rutile and synthetic rutile. This heavy reliance on foreign concentrates has developed because most producers of $TiCl_4$ prefer rutile or synthetic rutile over ilmenite as plant feed material.

Production

Concentrates.—U.S. producers of ilmenite in 1993 were RGC (USA) Mineral Sands, Inc. at Green Cove Springs, FL; Du Pont at Starke and Highland, FL, both from mineral sands deposits; and P. W. Gillibrand Co., Simi Valley, CA, as a coproduct of its rock, sand, and gravel operations. RGC was the only U.S. producer of natural rutile. Kerr-McGee was the sole domestic producer of synthetic rutile at Mobile, AL.

Du Pont began dredging and mineral separation operations at its Maxville site in Florida. The new dredge was reported to have extended the mine life to the year 2010. The startup of dredging operations at Maxville coincided with a partial shutdown of the company's nearby Highland operations.[1]

Ferrotitanium.—Ferrotitanium was produced by Galt Alloys Inc., Canton, OH, and Shieldalloy Metallurgical Corp., Newfield, NJ. The two standard grades produced were 40% and 70% titanium.

Metal.—Titanium sponge metal was produced by two firms in Nevada and Oregon. Titanium ingot was produced by the two sponge producers and by nine other firms in seven States. About 30 companies are known to produce titanium mill products and castings. Production of ingot and mill products decreased by 0.7% and 1.0%, respectively. Production of titanium sponge was withheld to avoid disclosing company proprietary data. *(See tables 3 and 4.)*

Early in 1993, TIMET successfully commissioned a 10,000-ton-per-year expansion of titanium sponge capacity at its Henderson, NV, facility. The expansion was based on a Vacuum Distillation Process (VDP) developed by Toho Titanium Co. During the fourth quarter, TIMET and the United Steelworkers of America union failed to reach a contract agreement, and union employees began a strike at TIMET's Henderson facility. During the strike, which was unresolved at the end of 1993, TIMET continued to operate the facility with salaried employees and supplemental outside workers.[2]

Oremet began a restructuring and downsizing of its work force and was reported to be planning to reduce its salaried work force by 20%. However, Oremet did not expect production at its Albany, OR, facility to be affected. Depressed demand was cited as a driving force to reduce fixed costs and overhead.[3]

Titanium Dioxide Pigments.—Titanium dioxide pigments were produced by 5 companies at 11 plants in 9 States. Production of TiO_2 pigment exceeded the 1992 level by 2.2%. Capacity utilization for the domestic pigment industry was about 86%. *(See tables 5 and 6.)*

The Tioxide Group reached an agreement with NL Industries to acquire a 50% interest in NL's subsidiary Kronos' TiO_2 pigment facility at Lake Charles, LA. The agreement was reported to include an exchange of technologies between the two companies. The Lake Charles facility was recently commissioned with 80,000 tons per year of chloride-based capacity.[4]

Consumption and Uses

Concentrates.—On a gross weight basis, U.S. reported consumption of TiO_2 in concentrates increased 1.2% from the 1992 level. Titanium pigments accounted for 98% of total consumption. Based on TiO_2 content, consumption of concentrates was evenly divided between ilmenite, ruile, and titanium slag. *(See table 7.)*

Ferrotitanium.—Reported consumption of titanium in the form of ferrotitanium and scrap in steel and other alloys was 5,944 tons, a 20% increase from the 1992 level. Stainless, heat-resisting, and other alloy steel were the largest end-use categories of ferrotitanium and scrap. *(See table 9.)*

Metal.—Sponge and ingot consumption increased by 6.9% and 7.2%, respectively. Consumption of scrap for remelting increased by about 3% and supplied a calculated 50% of ingot feedstock. Net shipments of mill products increased by 2.9%, and casting shipments decreased by about 8%. Estimated U.S. mill product usage by application was as follows: commercial aerospace, 50%; military aerospace, 20%; and nonaerospace uses, 30%. Nonaerospace uses include those in the specialty chemical, pulp and paper, oil and gas, marine, and medical industries. *(See table 4.)*

Pigment.—Apparent domestic consumption of TiO_2 pigments was about 1.03 million tons, 2.8% more than in 1992. The paint, paper, and plastics industries were the largest consumers of pigment. Other consuming industries included ceramics, fabrics and textiles, floor coverings, printing ink, and rubber. *(See table 8.)*

Stocks

Consumer inventories of titanium concentrates decreased 6.2% on a gross weight basis, but increased 0.9% based on TiO_2 content. Producer stocks of TiO_2 pigments increased to about 116,000 tons, a 13.8% increase from that of 1992. Industry stocks of titanium sponge increased 51%, while stocks of titanium scrap decreased by about 9%. *(See table 10.)*

Markets and Prices

Overcapacity and depressed demand continued to affect prices in the titanium ore, pigment, and metal markets. Published prices for titanium concentrates, pigments, and metal products are presented in table 11. However, based on the customs value of imports for consumption, the average price for finished pigment was estimated to have decreased by about 2% compared with that of 1992. Similarly, prices for ilmenite, synthetic rutile, and natural rutile were estimated to have decreased by 12%, 4%, and 17%, respectively. Owing largely to increased imports from Russia and Ukraine, the average price for imported sponge was estimated to have decreased by 38%. In contrast to the rest of the titanium industry, the average price for titanium slag was estimated to have increased by about 9%. *(See table 11.)*

Foreign Trade

In March, the Department of Commerce (DOC) published the final results of its administrative review of an antidumping duty order on titanium sponge from Japan. The DOC concluded that the dumping margins for Showa Denko K.K. and Toho Titanium were 0% for the period November 1, 1990, to October 31, 1991. Although the antidumping orders were not removed, a 0% cash deposit rate was made effective on April 8, 1993. In November, the DOC published the preliminary results of another administrative review for Showa during the period November 1, 1991, to October 31, 1992. The DOC's preliminary determination was to revoke the antidumping duty order.[5]

The Office of the U.S. Trade Representative (USTR) reviewed the qualifications of Ukraine and Russia for designation under the Generalized System of Preferences (GSP) program. The GSP program grants qualified countries duty-free status for a limited level of imports. On September 30, 1993, GSP status was approved for Russia and was scheduled to become effective October 16, 1993. Under the GSP program, titanium mill products may enter the country duty free. However, imports of titanium sponge, ingot, and billet are not eligible for duty-free status under the GSP program.

Domestic producers of titanium requested the DOC begin an antidumping review of titanium sponge from the Republic of the Commonwealth of Independent States (C.I.S.). In their request, the producers stated the existing 83.96% antidumping margin was inadequate and named the major production sources and their agents in Kazakhstan, Russia, and Ukraine. The DOC planned to conduct an antidumping review covering the period from August 1, 1992, to July 31, 1993. *(See tables 12, 13, 14, and 15.)*

World Review

Capacity.—The capacity data in this report are for mines and benefication plants, sponge metal facilities, and TiO_2 pigment plants as of December 31, 1993. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time at a normally sustainable long-term operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes operating plants and temporarily closed facilities that, in the opinion of the author, can be brought into production within a short period of time with minimum capital expenditure. Mine and mill capacity for the production of titanium concentrates, metal production plant capacity, and TiO_2 pigment plant capacity are generally based on close to 365 days per year operation, three shifts per day. Capacity figures are based on information obtained from the producing companies, from news items, and from USBM estimates. *(See tables 3, 5, and 17.)*

Reserves.—U.S. reserves of ilmenite and rutile occur mainly in ancient beach sand deposits in Florida. Ilmenite concentrates from the U.S. sand deposits contain about 60% to 65% TiO_2, while those from rock deposits contain 45% to 50% TiO_2. Other U.S. resources include rock deposits of ilmenite in California, Minnesota, New York, and Wyoming, and sand deposits of ilmenite and/or rutile in Georgia, Idaho, New Jersey, North Carolina, Oregon, and South Carolina, as well as large quantities of accessory rutile in porphyry copper ores and mill tailings. The U.S. reserve base of 34.7 million tons of TiO_2 occurs as 23.5 million tons in ilmenite, 9.8 million tons in perovskite ($CaTiO_3$), and 1.4 million tons in rutile. Outside of the United States, major reserves are in Australia, Brazil, Canada, China, India, Norway, and the Republic of South Africa. *(See tables 16 and 18.)*

The USBM has compiled a computerized file of worldwide mineral deposit data called the Minerals Availability System (MAS). The MAS Advanced Deposit Information Tracking System contains location and descriptive information on mineral occurrences, mines, and mineral processing operations worldwide. Most of the reserve and resource data found in this report were derived from MAS reports. A public access version containing nonproprietary information contained in the MAS data base is available on request.

Australia.—ISK Mineral Sands was reported to have exhausted its Waroona mineral sands deposit near Perth, Australia. Owing to poor market conditions, ISK delayed the development of its Darndanup heavy-mineral deposit near Bunbury, Western Australia. The delay in developing Darndanup resulted in the closure of ISK's Picton mineral separation plant.[6]

Westralian Sands Ltd. (WSL) was planning to double its synthetic rutile capacity at its Capel facility in Western Australia. However, the company was waiting for an improvement in market conditions before proceeding with the project.[7]

At yearend, Tiwest, the Kerr McGee and Minproc Holdings Ltd. joint venture, suspended its synthetic rutile production at its Chandala, Australia, facility. Tiwest planned to suspend operations at Chandala for at least 6 months. During the shutdown, Kerr McGee planned to continue operating its synthetic rutile plant at Mobile, AL.[8]

RGC completed an upgrade of its Narngulu synthetic rutile facility and major modifications to its Eneabba West dredge. The company also conducted pilot-scale testing of a process to remove radionuclides from synthetic rutile.[9]

Brazil.—Du Pont America do Sul withdrew from a project to develop the Tapira anatase deposit. Following Du Pont's withdraw from the project, Companhia Vale do Rio Doce (CVRD) announced plans to develop the Tapira deposit with Andrade Guitierrez Quimica. CVRD estimated the reserves at Tapira to be more than 500 million tons.[10]

Canada.—Tiomin Resources Inc. announced the completion of pilot plant gravity separation testing on heavy-mineral concentrate produced at Natashquan, Quebec. Tiomin has contracted Mineral Deposits Ltd. to establish a design for a production-scale plant and produce a capital cost estimate.[11]

Tioxide planned to close its pigment production at Tracy, Quebec, and suspend its expansion at Becancour, Quebec. However, Tioxide planned to continue operating the finishing operations at Tracy. Tioxide recently appealed an order by the Canadian Government to stop the discharge of effluent from the Tracy facility into the St. Lawrence River.[12]

China.—A 15,000-ton-per-year pigment plant was reported to have been brought on-stream at Yumen, Ganzu Province. Another 15,000-ton-per-year facility was planned for completion in 1996 at Jinan, Shandong Province.[13]

France.—Cezus SA and TIMET formed an agreement where, over a 2-year period, TIMET would acquire Cezus' titanium business. During the 2-year takeover, TIMET would act as the exclusive agent for Cezus, and Cezus would manufacture titanium products solely on behalf of TIMET.[14]

India.—According to industry sources, Cochin Minerals & Rutile Ltd. began operation of a 10,000-ton-per-year synthetic rutile facility at Kerala. Ilmenite was supplied to the plant from a domestic source.

Japan.—According to the Japan Titanium Society, Japan's titanium sponge production and shipments during 1993 were 14,428 tons and 15,094 tons, respectively. Ingot production was 11,968 tons, and mill product shipments were 7,646 tons.

Toho Titanium completed a project to improve its sponge facility at Chigasaki, Japan. During the project, the batch size was increased from 1.6 tons to 7.4 tons. However, the plant's total capacity of 10,800 tons per year was reported not to have changed.[15]

Kazakhstan.—Two Japanese companies were reported to have agreed to help in the development of the Kara-Otel titanium ore deposit in Kazakhstan. The Kazakh Ministry of Industry also was reported to be interested in developing the Shokash and Obykhovskoe deposits.[16]

Mexico.—Du Pont opened a technical center north of Mexico City. The center was built to provide technical support for the Du Pont SA de CV pigment production facility in Altamira near Tampico in Tamaulipas State.[18]

Mozambique.—According to industry reports, Kenmare Resources PLC was moving forward in the development of the Congolone Mineral Sands Project. The ore body was reported to contain 3.25% heavy minerals and could yield 418,000 tons of ilmenite annually.

Netherlands.—TiO_2 pigment producer, TDF Tiofine BV, was purchased by Kemira Oy. Although the original Tiofine facility was a sulfate-route plant, the sulfate plant was closed in 1989 and replaced by a chloride facility in 1990. Tiofine's 45,000-ton-per-year chloride route facility at Botlek will be operated by Kemira Pigments.[19]

Norway.—RMI Titanium Co. and Permascand AB announced a joint venture to manufacture heavy walled titanium tubular products. A new production facility was planned for construction in Norway. The joint venture was intended to produce titanium tubular products sold primarily in the oil and gas, petrochemical, and pulp and paper industries. Pending the completion of the new facility, titanium tubular products were manufactured by Permascand in Sweden.[17]

Russia.—Lakokraska, a paint industry association, was seeking investors to expand pigment capacity in Russia. The first project planned for construction was a 50,000-ton-per-year sulfate route TiO_2 pigment plant in Yekaterinberg. The development of a heavy-mineral deposit in the Chelyabinsk region near Yekaterinberg was expected to provide an ilmenite feedstock for the plant. Meanwhile, a Russian oil investment corporation, Nipek, was planning the development of a titanium ore deposit in the Komi Republic of Russia.[20]

Sierra Leone.—CRL acquired a 50% interest in SRL from Nord Resources Corp. Under the acquisition agreement, CRL and Nord each held 50% in a new holding company called Sierra Rutile Holdings Ltd. that held 100% of the issued capital of SRL. SRL operation in Sierra Leone is a major source of rutile concentrate.[21]

South Africa, Republic of.—As part of a major corporate restructuring, the South African conglomerate, Gencor increased its interest in RBM from 25% to 50%. The remaining 50% interest was held by RTZ Corp. RBM operates Tisand Ltd., a heavy-mineral producer of ilmenite, rutile, and zircon, and Richards Bay Iron and Titanium Co., the world's largest producer of titanium slag. At yearend, RBM awaited a decision by the South African Government for the approval of the development of the Lake St. Lucia heavy-mineral deposit. Reserves at St. Lucia were estimated to be 276 million tons containing 9.74 million tons of ilmenite, 0.94 million tons of rutile, and 1.66 million tons of zircon.[22]

According to industry reports, Anglo American Corp. planned to commission its Namakwa Sands project in 1994. At full production, the project will produce 195,000 tons of slag, 38,000 tons of rutile, and 140,000 tons of zircon annually.

Taiwan.—Du Pont delayed plans to open a 60,000-ton-per-year pigment facility at Kuan Yin until the first quarter of 1994. The facility was originally scheduled to start up in October 1993. Oversupply of global production capacity was cited as the reason for the delay.[23]

United Kingdom.—At the end of 1993, the United Kingdom's sole titanium sponge producer, Deeside Titanium, closed its sponge facility. The company had an estimated production capacity of 5,000 tons per year, but recent production levels were reported to be well below capacity.[24]

Owing to poor market conditions, Tioxide reduced its sulfate-route TiO_2 pigment capacity at its Grimsby, United Kingdom, facility. Capacity at the sulfate-route plant was lowered from 100,000 tons per year to 70,000 tons per year. However, the company was reported to have plans to add chloride-route capacity at the Grimsby facility.[25]

Vietnam.—WSL was reported to be investing in the modernization and possible expansion of a heavy-minerals operation in Ha Tinh, Vietnam. The investment represented a 60% interest in the Hah Tinh operation. The remaining interest was held by the Provincial government and the Vietnamese Ministry of Heavy Industry. WSL planned to increase capacity at Ha Tinh from about 35,000 tons per year to 150,000 tons per year.[26] *(See table 19.)*

Current Research

The USBM is currently engaged in research to produce titanium at competitive cost. This research is being conducted under cooperative agreements with titanium producers, parts fabricators, members of the automotive industry, and the U.S. Army Tank Command. Much of the research is focused on developing technologies using three different approaches to produce titanium powder or granules suitable for powder metallurgy applications. The first approach is based on a liquid-liquid interaction of two streams of molten salt, one stream containing $TiCl_4$, the other stream containing magnesium or sodium. When the streams are combined, titanium powder is formed and is then separated using decantation and vacuum evaporation of the residual salt. The second approach involves a vapor-vapor phase reaction of $TiCl_4$ and gaseous magnesium. Titanium powder or granules that form during the reduction of $TiCl_4$ are separated using an electrostatic precipitator. The third approach involves a liquid-vapor reduction of gaseous $TiCl_4$ with molten magnesium or sodium.

OUTLOOK

Although global TiO_2 pigment capacity utilization was estimated to be below 90% in 1993, demand for titanium pigment is expected to grow annually between 3% and 4% for the period 1994-97. During the same period, some facilities are expected to close because they are not cost competitive or cannot meet environmental regulations. Subsequently, additional capacity may be needed within the next few years. Asia has been targeted as one area of high growth in demand and as a location for future pigment expansions. For several technological and environmental reasons, increased demand is expected to be met though expansions using chloride-route technology.

As it has in the past, total demand for titanium feedstocks is expected to follow that for titanium pigments. However, as a consequence of increased chloride route capacity and more stringent environmental restrictions, demand should increase at a higher rate for high-TiO_2 feedstocks, including high-grade ilmenite (60% TiO_2), natural and synthetic rutile, and titanium slag.

For the next few years, total demand for titanium metal is not likely to return to levels reached in the late 1980's. However, demand is expected to grow moderately and should be driven by increased consumption by commercial markets. Exports from Russia and Kazakhstan are expected to continue to affect the global market. Consequently, further consolidations in the titanium metal industry are likely.

Total consumption[2]	6,023	6,032	4,979	4,943	5,944

W Withheld to avoid disclosing company proprietary data; included with "Miscellaneous and unspecified."

[1] Includes ferrotitanium, titanium scrap, and other titanium additives.

[2] Data may not add to totals shown because of independent rounding.

TABLE 10

U.S. STOCKS OF TITANIUM CONCENTRATES AND PIGMENT, DECEMBER 31

(Metric tons)

	Gross weight	TiO_2 content
Ilmenite:[1]		
1991	250,762	146,129
1992	245,766	141,313
1993	173,351	105,262
Titanium slag:[1]		
1991	88,079	72,280
1992	138,509	112,487
1993	137,275	112,865
Rutile:[1]		
1991	208,030	196,526
1992	148,983	140,224
1993	189,784	179,411
Titanium pigment:[2]		
1991	72,108	[e]68,503
1992	108,173	[e]101,478
1993	123,079	[e]115,521

[e] Estimated.

[1] Consumer stocks.

[2] Bureau of the Census. Producer stocks only.

TABLE 11
PUBLISHED PRICES OF TITANIUM CONCENTRATES AND PRODUCTS[1]

		1992	1993
Concentrates:			
Ilmenite, f.o.b. Australian ports	per metric ton	$58.00-$62.00	$61.00-$64.00
Rutile, bagged, f.o.b. Australian ports	do.	380.00-414.00	370.00-400.00
Rutile, bulk, f.o.b. Australian ports	do.	345.00-387.00	365.00-390.00
Rutile, large lots, bulk, f.o.b. U.S. east coast	do.	510.00-520.00	NA
Titanium slag, 80% TiO_2, Canada[e]	do.	264.00	276.00
Titanium slag, 85% TiO_2, Republic of South Africa[e]	do.	310.00	330.00
Metal:			
Sponge	per pound	3.50- 4.00	3.50- 4.00
Mill products:			
Bar	do.	7.50- 9.00	7.50- 9.00
Billet	do.	6.00- 7.50	6.00- 7.50
Plate	do.	8.50- 9.50	8.50- 9.50
Sheet	do.	7.50- 8.00	7.50- 8.00
Ferrotitanium:	do.	1.40- 1.50	1.15- 1.20
Scrap:			
Turnings, unprocessed	do.	.65- .80	.40- .45
Pigment:			
Titanium dioxide pigment, f.o.b. U.S. plants anatase	do.	.99	.99
Titanium dioxide pigment, f.o.b. U.S. plants, rutile	do.	.92- .95	.92- .95

[e] Estimated based on U.S. imports for consumption. NA Not available.

TABLE 15—Continued

U.S. IMPORTS FOR CONSUMPTION OF TITANIUM METAL, BY CLASS AND COUNTRY

Class and country	1991 Quantity (metric tons)	1991 Value (thousand)	1992 Quantity (metric tons)	1992 Value (thousand)	1993 Quantity (metric tons)	1993 Value (thousand)
Wrought products and castings—Continued						
France	41	515	8	655	45	733
Germany	60	1,115	18	841	6	683
Japan	317	8,350	201	4,757	231	6,705
Russia[1]	—	—	—	—	33	299
Sweden	7	$431	19	$399	28	$680
United Kingdom	68	2,799	44	1,631	195	5,370
Other	30	1,466	18	905	9	608
Total[3]	914	24,014	456	12,830	600	17,237

[1] Formerly part of the U.S.S.R.; data were not reported separately until 1992.

[2] Dissolved in Dec. 1991; however, information is inadequate to formulate reliable estimates for individual countries.

[3] Data may not add to totals shown because of independent rounding.

[4] Less than 1/2 unit.

[5] Includes blooms, sheet, bars, slabs, and other unwrought.

[6] Includes bars, castings, foil, pipes, plates, profiles, rods, sheet, strip, tubes, wire, and other.

Source: Bureau of the Census.

TABLE 16

U.S. TITANIUM RESERVES AND RESERVE BASE IN 1993

(Thousand metric tons of TiO_2 content)

	Reserves			Reserve base[1]		
	Ilmenite	Rutile	Total	Ilmenite and perovskite[2]	Rutile and anatase[3]	Total
Arkansas	—	—	—	—	200	200
California	—	—	—	600	—	600
Colorado	—	—	—	9,800	—	9,800
Florida	7,800	300	8,100	7,800	300	8,100
New York	—	—	—	7,900	—	7,900
Tennessee	—	—	—	5,600	900	6,500
Virginia	—	—	—	1,600	—	1,600
Total	7,800	300	8,100	33,300	1,400	34,700

[1] The reserve base includes demonstrated resources that are currently economic (reserves), marginally economic (marginal reserves) and some of those that are currently subeconomic (subeconomic resources).

[2] Ilmenite except for the 9.8 million tons in Colorado perovskite.

[3] Rutile except for the 200,000 tons in Arkansas anatase.

[e] Estimated. [r] Revised. W Withheld to avoid disclosing company proprietary data; not included in "Total."

[1] Table includes data available through Aug. 10, 1994.

[2] Ilmenite is also produced in Canada and in the Republic of South Africa, but this output is not included here because an estimated 90% of it is duplicative of output reported under "Titaniferous slag," and the rest is used for purposes other than production of titanium commodities, principally as steel furnace flux and heavy aggregate.

[3] Excludes production of unbeneficiated anatase ore.

[4] Reported figure.

[5] Formerly part of the U.S.S.R.; data were not reported separately until 1992.

[6] Dissolved in Dec. 1991. All production in the U.S.S.R. from 1989-91 came from Russia and Ukraine.

[7] Slag is also produced in Norway but is not included under Titaniferous slag to avoid duplicative reporting. Beginning in 1988, about 25% of Norway's ilmenite production was used to produce slag containing 75% TiO_2.

[8] Contains 80% TiO_2.

[9] Contains 85% TiO_2.

TUNGSTEN

By Gerald R. Smith

Mr. Smith, a physical scientist with 30 years of research and commodity experience with the U.S. Bureau of Mines, has been the commodity specialist for tungsten since 1986. Domestic survey data were prepared by Dwayne Penn, statistical assistant; and the world production table was prepared by Jeremy Tidwell, international data coordinator.

The unique high-temperature properties of tungsten and its alloys can be utilized advantageously in the production of numerous end-use items. The high melting point, high density, good corrosion resistance, and good thermal and electrical conductivity properties of tungsten and its alloys and the excellent cutting and wear-resistant properties of its carbide continue to provide important items for consumption in the domestic and military sectors.

Total reported domestic consumption of tungsten in primary end-use categories increased by about 10% in 1993 compared with that of 1992. Demand generally increased in the cemented carbide end-use sectors that included the combined cutting tool, mining tool, oil drilling equipment, and wear-resistant component industries. Demand for mill products made from metal powder as well as demand for tungsten chemicals and directly reusable tungsten scrap also increased in 1993. Counter to these increases was a decrease in the use of ferrotungsten in steels, which included the tool, alloy, and stainless steel sectors. A gradual strengthening of the U.S. economy influenced the overall increase in demand for tungsten products during 1993.

The average Metal Bulletin (London) combined price for wolframite and scheelite concentrates, instituted in April 1992, declined about 38% in 1993 compared with that of 1992. The concentrate price trend for 1993 continued the downward trend that existed in 1992, increasing only slightly in the final 2 months of the year.

Prices for ammonium paratungstate (APT) on the world market decreased during 1993, consistent with the declining prices for concentrates. According to quotations in Metals Week, the average price for APT on the U.S. market, duty-paid and delivered to processing plants, decreased by 21% from an average of $58.42 per metric ton unit (mtu) in January to an average of $46.30 per mtu by yearend. Similarly, quotations for Chinese No. 1 Grade APT in Hong Kong declined by 25% during the year from an average price of $39.50 per mtu to an average of $29.50 per mtu. The average price of APT on the European free market decreased by 26%, from $47 per mtu to $35 per mtu, according to quotations published in Metal Bulletin (London).

As a result of the weak tungsten market, at least eight additional tungsten mine operators in the West, including two in the United States, were forced either to reduce concentrate production, to suspend production and place their mine on care-and-maintenance status, or to close their mines permanently.

The pattern of imports of tungsten materials by U.S. processors during 1993 showed a further shift away from tungsten concentrate and toward the intermediates ammonium paratungstate, tungsten oxide, and sodium tungstate. The shift continued a trend that began in 1991, subsequent to the imposition of the 151% antidumping tariff on imports of concentrate from China that effectively halted such imports. China, however, continued to be the dominant supplier of tungsten materials to the United States in 1993, providing about 44% of all imported tungsten materials.

A summary of the important U.S. and international statistics for 1993 and the previous 4 years are shown in table 1. *(See table 1.)*

DOMESTIC DATA COVERAGE

Domestic production data for tungsten are developed by the U.S. Bureau of Mines by means of two separate, voluntary surveys. These surveys are "Tungsten Ore and Concentrate" and "Tungsten Concentrate and Tungsten Products." Of the 14 mining and 15 processing operations to which survey requests were sent, response was received from 64% and 100%, respectively, of those operations surveyed. Production and stock totals for the survey respondents are shown in table 1.

BACKGROUND

Definitions

Tungsten, a silvery gray metal, has an atomic number of 74 and an atomic weight of 183.92. Its most outstanding physical property is its high melting point of 3,410° C, the highest of all metals. Tungsten is one of the heaviest elements, with a density of 19.3 grams per cubic centimeter at 20° C. It has good corrosion resistance, good thermal and electrical conductivity, and a low coefficient of expansion. At temperatures above 1,650° C, tungsten has the highest tensile strength of all metals.

Tungsten concentrate is sold in units of tungsten trioxide (WO_3). In the United States, sales are based on the short ton unit of WO_3. This is equivalent to 1% of a short ton, or 20 pounds of WO_3 and contains 7.19 kilograms (15.86 pounds) of tungsten. In most other countries, tungsten is sold in the mtu and contains 7.93 kilograms (17.48 pounds) of tungsten.

Natural or synthetic scheelite concentrate, in nodular form, is ideal for direct addition to steel melts because the calcium is removed as slag. Fine material in either synthetic or natural scheelite is not desirable because of high dust losses. Wolframite concentrate is not satisfactory for steelmaking because of the manganese and tin content.

Tungsten ores and concentrates are converted into the following intermediate products: APT, tungstic acid, sodium tungstate, tungsten metal powder, and tungsten carbide powder. Most of the APT is reduced to tungsten metal powder, which then is processed into tungsten carbide powder.

Tungsten alloys and tungsten mill products such as rod, wire, and sheet are produced from hydrogen-reduced tungsten metal powder. The tungsten carbide produced from powder is cemented, usually with cobalt, to form various cutting and wear-resistant tools and parts.

Tungsten chemicals (APT, tungstic acid, and sodium tungstate) are produced as coproducts at some tungsten processing plants and as primary products at others. When not processed further into metal powder, they generally are used in the chemical industry.

Products for Trade and Industry

Tungsten materials can be divided into four major classes, depending on use: (1) a carbide in cutting and wear-resistant materials, and welding and hard-facing rods; (2) mill products made from essentially pure metal; (3) an alloy constituent in high-speed and tool and die steels, superalloys, and nonferrous alloys; and (4) various chemicals and compounds for nonmetallurgical applications.

The extreme hardness of tungsten carbide at temperatures exceeding 1,000° C makes it a preferred metalworking material for cutting edges of machine tools subject to intense wear or abrasion and for metal surfaces in forming and shaping dies. The mining and petroleum industries use tungsten carbide in drill bits, in the cutting edges of earth-moving equipment, and in crushing machinery. Tungsten carbide is used widely in wear parts of transportation and electrical equipment.

In most applications, tungsten carbide generally is cemented with a powdered cobalt metal binder by compaction and sintering. The cobalt content can range from about 3 to 25 weight percent, with the higher content providing greater shock resistance at a sacrifice in hardness. Tantalum and/or titanium carbides are used in conjunction with tungsten carbide in certain cutting and chipping tools. Also, coatings such as titanium carbide, titanium nitride, and aluminum oxide on tungsten carbide are used extensively to increase the life of inserts for machining applications.

Mill products made from pure or substantially pure tungsten metal powder are used in significant quantities by the electrical and electronic industries. Tungsten wire is used as the filament in electric lamps and as cathodes for electronic tubes. Disks produced from tungsten rods or sheet are used in automotive distributor points, although this end use is declining as the number of automobiles with electronic ignition systems increases. They also are used as contact points in numerous manufactured products. Tungsten metal is employed as heat and radiation shielding, as electrodes for inert-gas welding, as components of X-ray and cathode-ray tubes, and as heating elements in high-temperature resistance furnaces. Tungsten metal is used by the aerospace industry because it retains its strength at elevated temperature in reducing or inert atmospheres. The use of tungsten as a heavy metal for counterweights and balances, especially by the aircraft industry, has been replaced, to a significant extent, by depleted uranium, which approaches the density of tungsten.

Cast tungsten carbide is used principally as a hard-facing material. In this application, carbide particles are applied by a welding process to provide an abrasion-resisting surface layer on the surface to be coated. The carbide may be initially in the form of rod or loose grains in a tube.

As an alloy constituent, tungsten is used primarily in the production of high-speed steels and tool and die steels. Hardness and oxidation resistance at elevated temperatures are the most important properties possessed by these steels, which are used for machinery and equipment in the metalworking, construction, and mining industries. Certain grades of stainless and other alloy steels contain tungsten to improve wear and abrasion resistance, shock resistance, corrosion resistance, and/or strength at high temperatures.

Tungsten is an important constituent in a wide variety of superalloys and nonferrous alloys. Tungsten-containing superalloys are being utilized increasingly in high-temperature applications for their high-temperature strength and oxidation resistance. Tungsten alloyed with copper or silver is used for electrical contacts to provide wear resistance with adequate electrical conductivity.

Nonmetallurgical applications of tungsten include chemicals used in textile dyes, paints, enamels, toners, and coloring glass. Certain tungsten compounds are luminescent and used as phosphors in pigments, X-ray screens, television picture tubes, and fluorescent lighting. Sodium tungstate is employed as a corrosion inhibitor and a fireproofing agent in textiles. APT is used in making catalysts for the refining of petroleum. Among other chemical applications, tungsten compounds are used in chemical-vapor deposition, as catalysts in other chemical processing, and as laboratory reagents.

The chief nonindustrial use of tungsten is in armor-piercing ordnance, but this has been replaced, in part, by depleted uranium.

ANNUAL REVIEW

Legislation and Government Programs

The fiscal year 1994 Defense Authorization Bill, passed by the U.S. Congress in November 1993 and signed by the President in early December 1993, contained no authority for the sale of tungsten from the National Defense Stockpile (NDS) for the period October 1, 1993, through September 30, 1994. Tungsten was last authorized for sale from the NDS in fiscal year 1989 when tungsten ore concentrate was used as payment material in support of the NDS ferroalloy upgrading program. At the beginning of fiscal year 1994, the NDS contained 37,336 metric tons of contained tungsten, of which approximately 93% was in the form of tungsten ore concentrates.

The antidumping tariff on imports of tungsten ore concentrates from China, initially imposed on October 28, 1991, was continued during 1993. Interested parties were afforded the opportunity to request administrative review of this antidumping order in an announcement published by the Department of Commerce, International Trade Administration (ITA) in the Federal Register, November 3, 1993. The ITA did not receive any requests for review of this order by the November 30, 1993, deadline. Accordingly, the imposition of the tariff will continue indefinitely. As is the procedure in such antidumping orders, the ITA will again afford the opportunity to request an administrative review during the next anniversary month of the antidumping order.

The Federal Trade Commission (FTC), in an announcement published in the Federal Register, November 15, 1993, requested comments on a proposal to add certain lamps to the list of products subject to the provisions of an existing Appliance Labelling Rule (16 CFR Part 305). Lamp products proposed to be subject to this rule, entitled "Rules Concerning Disclosures of Information About Energy Consumption and Water Use for Certain Home Appliances and Other Products Required Under the Energy Policy and Conservation Act," included general service fluorescent lamps; medium-base, compact fluorescent lamps; and incandescent reflector lamps. The action was taken pursuant to the Energy Policy Act of 1992, which directed the FTC to prescribe, by April 24, 1994, rules requiring such lamp products to be labeled with disclosures that will enable purchasers to select the most energy-efficient lamps that will meet their requirements. The proposed rule will serve to supplement rule 16 CFR 409, issued in 1970 to cover labeling requirements for general service incandescent electric lamps.

Strategic Considerations

Tungsten is an important strategic material necessary for defense purposes, including the industrial base. Currently, the heavy-metal alloys of tungsten, containing 3% to 10% nickel and small quantities of iron or copper, are used in several of the smaller diameter projectiles for penetrating armorplate. Cemented tungsten carbide parts, which exhibit excellent cutting and wear-resistant properties, are vital to the U.S. metalworking, machining, construction, transportation, mining, and oil and gas drilling industries. Tungsten mill products and powders are essential to the lamp and lighting industry as filaments and electrodes; to the electrical and electronic industries as wear-resistant, electrically conductive contact surfaces; and to the superalloy and steel industries as alloying components. The Department of Defense (DOD) relies heavily on the maintenance of a broad domestic production base to cover mobilization contingencies. The entire tungsten industry, from mined ore to manufactured products, thus represents an important component of the U.S. defense policy. The DOD continually assesses the U.S. ability to produce tungsten to ensure that this and other sources of supply are sufficient to meet current and projected levels of demand necessary to preserve the national defense.

Issues

During 1993, prices for concentrates and intermediate materials continued to decline, causing at least eight additional tungsten mine operators in the West, including two in the United States, either to reduce concentrate production, to suspend production and place their mine on care-and-maintenance status, or to close their mines permanently. Although China remained the principal supplier of tungsten products to the world market during 1993, it, also, was not immune to the adverse market conditions. As a result of China's decision in late 1992 to eliminate Government subsidies to tungsten miners, numerous smaller mines reportedly were forced to close because they could not be operated economically. According to industry observers, this further increased the use of existing, but unknown, quantities of Chinese stocks of concentrate to meet domestic and world demand. By yearend 1993, many observers believed that stocks of Chinese concentrate nearly had been depleted. The quantity of tungsten materials available from Russia and certain other members of the Commonwealth of Independent States (C.I.S.) remained relatively small during 1993. Furthermore, uncertainties remained regarding the extent to which the C.I.S. might become a source of tungsten supply to the world market as it makes the transition to a market economy. Given all of these tungsten market factors, by yearend 1993 industry analysts believed a more balanced supply-demand condition was being approached.

Production

The already low tungsten mining activity in the United States further declined in 1993 as the continuing low prices for concentrate and the growing use of intermediate tungsten materials made mining uneconomical and impractical. The sole producer of tungsten concentrate in 1993 was U.S. Tungsten Corp., a division of Strategic Minerals Corp., at its Pine Creek Mine, Bishop, CA. Major processors of tungsten materials in 1993 were Buffalo Tungsten Inc., Depew, NY; General Electric Co., Euclid, OH; Osram Sylvania, Inc. (formerly GTE Products Corp.), Towanda, PA; Kennametal Inc., Latrobe, PA, and Fallon, NV; Teledyne Firth Sterling, LaVergne, TN; and Teledyne Advanced Materials (formerly Teledyne Wah Chang Huntsville), Huntsville, AL. Net production statistics for tungsten metal powders, carbides, and chemicals are shown in table 2. *(See table 2.)*

Curtis Tungsten Inc., operator of the Andrew Tungsten Mine near Los Angeles, CA, declared a force majeure in 1993, citing low tungsten concentrate prices, and did not produce any concentrate during the year.

U.S. Tungsten Corp., Bishop, CA, continued to produce a limited quantity of concentrate during 1993. As with its mine production, operations at its APT conversion facility were limited because of the low prices existing in the tungsten market.

GTE Corp., Stamford, CT, completed the sale of its North American lamp and lighting business to Osram, a Siemans AG company based in Munich, Germany, in early 1993. Included in this sale was GTE Products Corp., Towanda, PA, a tungsten processor and producer of a variety of tungsten materials and end-use items. Additionally, GTE Corp. completed the sale of its GTE Valenite cemented carbide division, Troy, MI, to Cincinnati Milacron Inc., Cincinnati, OH, effective February 1, 1993. The new company, named Valenite Inc., became a wholly owned subsidiary of Cincinnati Milacron.

Kennametal Inc., Latrobe, PA, a producer of tungsten carbide for use in cemented carbides, completed purchase of the cemented carbide tool and tooling system manufacturing business of Hertel AG, Furth, Germany, in the fourth quarter of 1993. According to a Kennametal executive, it was anticipated that the shared resources of the two companies would provide substantial opportunities for improved operating efficiency in Europe.

General Electric Co. (GE) announced on October 4, 1993, that it was discontinuing production of tungsten carbide powder at its Euclid, OH, facility. As a result, the company would no longer be a market supplier of the carbide, which is used to produce cutting and wear-resistant components for a variety of applications. GE planned to focus on the production of tungsten metal powder, both for internal consumption in the manufacture of wire for its lamp and lighting business, and for supply to end-use consumers in various specialty applications.

Consumption and Uses

Total reported domestic consumption of tungsten in primary end-use categories (table 3) increased by about 10% in 1993 compared with that of 1992. Demand generally increased in the cemented carbide end-use sectors that included the combined cutting tool, mining tool, oil drilling equipment, and wear-resistant component industries. Demand for mill products made from metal powder, as well as demand for tungsten chemicals and directly reusable tungsten scrap, also increased in 1993. Counter to these increases was a decrease in the use of ferrotungsten in steels that included the tool, alloy, and stainless steel sectors. *(See table 3.)*

Reported consumption of obsolete tungsten scrap, reprocessed either chemically or physically for reuse, decreased to 2,158 tons of contained tungsten in 1993 from 2,638 tons in 1992. Increased competition associated with the continued low prices for primary and intermediate tungsten materials likely contributed to the decline in demand for this form of scrap.

Gradual strengthening of the U.S. economy influenced the overall increase in demand for tungsten products during 1993. A slow economic recovery in the major industrial sectors of auto, aerospace, and construction, where a significant quantity of tungsten is consumed as cemented carbide components, was begun in 1993. Demand for cemented carbide components in the oil drilling industry fluctuated during 1993. The number of operating oil drilling rigs in the United States rapidly declined from a yearly high of 928 in early January to a yearly low of 600 rigs in mid-March, then gradually increased to 883 rigs by yearend 1993, according to figures reported by the International Association of Drilling Contractors and Baker Hughes Inc.

Markets and Prices

The average Metal Bulletin (London) combined price for wolframite and scheelite concentrates, instituted in April 1992 (table 4), declined to $34.56 per mtu tungsten oxide from an average $55.36 per mtu in 1992. The concentrate price trend for 1993 continued the downward trend that existed in 1992, increasing only slightly in the final 2 months of the year. *(See table 4.)*

Prices for APT on the world market decreased during 1993, consistent with the declining prices for concentrates. According to quotations in Metals Week, the average price for APT on the U.S. market, duty-paid and delivered to processing plants, decreased by 21% from an average of $58.42 per mtu in January to an average of $46.30 per mtu by yearend. Similarly, quotations for Chinese No. 1 Grade APT in Hong Kong declined by 25% during the year from an average price of $39.50 per mtu to an average of $29.50 per mtu. The average price of APT on the European free market, decreased by 26%, from $47 per mtu to $35 per mtu, according to quotations published in Metal Bulletin (London).

Foreign Trade

Comprehensive lists of U.S. export and import trade statistics by material quantity and value and by country of destination and origin are shown in tables 5 through 13. Import tariff rates for the various materials are shown in table 14. *(See tables 5 through 14.)*

The pattern of imports of tungsten materials by U.S. processors during 1993 showed a further shift away from tungsten concentrate and toward the intermediates ammonium paratungstate, tungsten oxide, and sodium tungstate. The shift continued a trend that began in 1991, subsequent to the imposition of the 151% antidumping tariff on imports of concentrate from China that effectively halted such imports. In addition, as concentrate prices declined during this period, other concentrate producers were forced to close their mines or reduce production, further decreasing the supply of concentrate to the market. In 1993, concentrate represented a 36% share of the combined imports of concentrate and intermediates from all sources, compared with a 63% share in 1992 and an 87% share in 1990, prior to the antidumping tariff. The share of these combined imports of concentrate and intermediate materials provided by China as intermediate materials was 51% in 1993.

Total U.S. imports of all tungsten materials increased by 13% in 1993 compared with those of 1992. China continued to be the dominant supplier, providing about 44% of all imported tungsten materials. China's share of the total quantity of tungsten materials imported by the United States was up about 18 percentage points compared with that of 1992. The total quantity of tungsten materials imported from China increased from 1,820 tons of contained tungsten in 1992 to 3,280 tons in 1993. Of the total tungsten imports from China in 1993, the percentage imported as intermediate products was 74%, unchanged from that of 1992. Major suppliers of concentrates to the United States in 1993 included Bolivia (44%), Peru (17%), Portugal (14%), and Rwanda (8%).

World Review

Capacity.—Rated capacity for mines and mills as of December 31, 1993, was approximately 42,000 tons of contained tungsten. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable long-term operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure.

Mine capacity for tungsten is based on published reports, maximum production statistics, and estimates. The latter is utilized particularly for certain countries where capacity information is either incomplete or unavailable. Estimated annual mine production capacity declined by about 12% in 1993 compared with that of 1992. Some of this decline was attributed to an estimated lower capacity in the C.I.S., associated with the transition to a market economic system within the individual republics of the former U.S.S.R. Decline in mine capacity was attributed further to the apparent closure of additional smaller, inefficient mines in China, as well as to production declines at some larger mines, following the discontinuation of Government subsidies to tungsten mines during the last quarter of 1992.

Australia.—Poseidon Ltd., owner of the Mount Carbine wolframite mine in Queensland, sold most of the equipment at the mine during 1993, effectively closing the mine permanently. Efforts to find a buyer for the mine were unsuccessful, considering the depressed state of the tungsten concentrate market in 1993. Earlier poor market conditions had forced the closure of the Mount Carbine facility and subsequent placement on care-and-maintenance status in late 1986, about 1 year after Poseidon had purchased a controlling interest in the mine from Queensland Wolfram Pty. Ltd. Concentrate was produced from the open pit portion of the mine during the early 1980's, but plans to recover concentrate from the underground portion of the mine had to be cancelled when the closure occurred in 1986.

Annual concentrate production and consumption statistics for the world are shown in tables 15 and 16, respectively. *(See tables 15 and 16.)*

Austria.—The Mittersill Tungsten Mine, Mittersill, was forced to close because of the depressed tungsten market. Wolfram Berbau and Huttengesellschaft, operator of the mine, disclosed that the mine was placed on care-and-maintenance status at the end of February 1993. Until market conditions improved, concentrates were expected to be obtained from the spot market, as necessary, to supplement the company's existing concentrate stocks in support of its tungsten metal powder production operation. According to the operators, the concentrate production portion of the company's integrated facility for making the tungsten powder had become uneconomical in light of the existence of low-priced tungsten intermediate materials on the world market.

China.—According to published reports, China began a more centralized procedure to control the issuance of export licenses for tungsten concentrates and intermediate products, effective April 1, 1993. Under the revised procedure, licenses were to be obtained from the main office of the Ministry of Foreign Economic Relations and Trade (MOFERT) in Beijing through the head offices of China National Nonferrous Metals Import and Export Corp. (CNIEC) and China National Minerals and Metals Import and Export Corp. (Minmetals). Prior to this new ruling, licenses were issued directly to Provincial branches of CNIEC and Minmetals by local branch offices of MOFERT. The previous, less restricted licensing procedures likely contributed, in part, to overproduction, resulting in lower market prices, particularly when coupled with declining worldwide demand for tungsten. In related action, the Chinese limited the number of tungsten materials for which the Provincial branches of CNIEC and Minmetals could receive export licenses to that of blue oxide and sodium tungstate. Export licenses for tungsten concentrates and the remaining intermediate products, excluding tungsten metal powder and tungsten carbide powder, were then planned to be issued to the head offices of CNIEC and Minmetals.

The cemented carbide industry in China continued to expand, according to a report presented to the delegates at the sixth International Tungsten Symposium held in Guangzhou, China, in November 1993. A member of the Zhouzhou Cemented Carbide Co., Hunan Province, China, stated that carbide production had passed the 5,000-ton-per-year mark in

1993. China nearly doubled its cemented carbide production in the 1980's, increasing from 2,400 tons in 1980 to 4,740 tons in 1990.

Commonwealth of Independent States.—During 1993, there were increased efforts by the republics of the former U.S.S.R to market a variety of tungsten-containing materials and products. Metallurgical operations that were formerly staffed and funded to meet the defense and aerospace requirements, as well as the domestic needs for mining and metalworking, were continuing their plans to provide quality tungsten merchandise to the market. The merchandise expected to be marketed included tungsten oxide, and metal and carbide powders, as well as a number of wrought shapes, such as rod, wire, tube, strip, and foil, and certain end-use products, consisting of cemented carbide cutting tools, drill bits, and wear parts.

International Tungsten Industry Association (ITIA).—The International Tungsten Industry Association (ITIA) held its sixth International Tungsten Symposium in Guangzhou, China, November 2-4, 1993. Speakers from eight countries presented a wide range of papers covering subjects, including tungsten supply, demand, pricing, trade patterns, recycling, and mining, as well as technological developments in process control, extractive metallurgy, and end-use applications. Information provided by the China Tungsten Industry Association on tungsten production and consumption in China generated particular interest at the symposium. According to a published report, the information presented by the Chinese at the meeting still left a number of questions unanswered regarding the actual production and consumption statistics. There seemed to be general agreement among the attendees, however, that production of both concentrate and intermediate products was down appreciably and that the inventories of these materials also had declined recently. The actual inventory levels still remained uncertain. In an attempt to provide an explanation for its international pricing structure, Chinese officials cited a number of factors, in addition to production costs, that affected this structure. These included the maintenance of unspecified production levels to avoid unemployment, the sale of stockpiled material worldwide, the decline in sales to Eastern Europe and the C.I.S., the existence of domestic competition for the tungsten market, and the desire by consumers to acquire less expensive tungsten materials.

Japan.—Japan reportedly closed its last tungsten mine in September 1993. The mine, in Yamaguchi prefecture and owned by Tanaka Kogyo, supplied a portion of Japan's demand for tungsten, but for most of 1993 it operated well below capacity. Falling market prices for the intermediate tungstates made it more economical and practical to import additional quantities of the intermediates, mainly from China, than to domestically produce and process the concentrate.

Peru.—Minera Regina ceased production of concentrate from tailings at its Palca XI tungsten mine southeast of Lima at the end of July 1993. The company began producing concentrate from tailings in the first quarter of 1993, after persistent low prices for concentrate resulted in the termination of all new mining at the facility. As a result of this closure of the tailings processing unit, Minera Regina subsequently invoked force majeure and temporarily suspended shipments of concentrate to its customers.

Portugal.—The Panasquiera tungsten mine near Fundao was closed at the end of 1993. According to a spokesperson from the parent company, Minorco SA of Portugal, the relentless decline in the tungsten market was the reason for the closure. Efforts to continue operation of the mine through a management buy-out initiative were unsuccessful. Purchase of the mine by another company remained a possibility. Production at the Panasqueira Mine had been reduced to about 30% of capacity by late 1993. The Panasquiera Mine was the last operating tungsten mine in Europe following the placement of Austria's Mittersill Mine on care-and-maintenance status at the end of February 1993. There reportedly were no plans to place the Panasquiera Mine on care-and-maintenance status.

Russia.—Russia was approved for Generalized System of Preferences (GSP) trade status, effective October 16, 1993, following the signing of a proclamation by the President on September 30, 1993, to carry out this action. Under GSP, imports of numerous Russian materials were permitted to enter the United States duty free rather than be assessed the duty that presently exists under most-favored-nation trade status. Tungsten materials affected by the new GSP status included concentrates, ferrotungsten, carbide powder blends, and certain forms of waste and scrap.

United Nations Conference on Trade and Development (UNCTAD).—The Second Meeting of the Intergovernmental Group of Experts on Tungsten (IGE) was held in Geneva, Switzerland, November 8-10, 1993. A representative from the UNCTAD Secretariat's office provided an overview of the status of the world tungsten industry. A pessimistic picture of the current situation and short-term outlook for the tungsten market was presented in this overview. Significant production decreases that had occurred recently were tempered by declining demand, leaving the tungsten market in a continued weak position. Poor performance of the world economy and changing structural conditions in both the economy and industry were significant factors affecting demand. In addition, there were major geographical shifts in the international source of supply. The latter contributed to an abundant availability of tungsten materials in recent years that provoked an associated market instability. Prospects for recovery in the tungsten market were contingent on a significant strengthening of the world economy. The need to improve transparency in the statistics provided by the member IGE countries to UNCTAD again was expressed during this meeting. With regard to the examination of statistics, it was stated that the task before the IGE was to update, revise, and strengthen these statistics. Despite efforts to make the UNCTAD statistics as complete as possible, significant gaps that could only be remedied by member countries remained.

The IGE again discussed the matter of submission of project proposals for funding under UNCTAD's Common Fund for Commodities. The fund supports developmental activities within the individual commodities embraced by UNCTAD. At the first meeting of the IGE, a decision had been made to request the Secretary General of UNCTAD to submit for funding, on its behalf, two separate proposals, one from the Chinese delegation entitled "Development of the Rare Earth Doped Cemented Carbide and its Mechanism Research," and one from the ITIA entitled "Health and Environmental Effects Testing of Tungsten Materials." The IGE's recommendation for financing of these proposals was approved on a technical and market basis, provided that no written statement to the contrary, with explanation, was received from any member of the IGE by the Secretary General of UNCTAD by February 11, 1993. Subsequently, the Secretary General of UNCTAD received two letters, one from the delegation from the United Kingdom expressing objections to China's proposal and one from the Chinese delegation expressing objections to the ITIA's proposal. Both delegations contended that the proposals did not fulfill the criteria for financing under UNCTAD's Common Fund. Prior to the second meeting of the IGE, the Director General of the Common Fund for Commodities rejected both of the IGE's project proposals submitted for funding. The chairman of the second meeting suggested that the Chinese delegation resubmit its proposal at the third meeting and stressed that other delegations also consider submitting proposals at this meeting.

A provisional agenda for the third meeting of the IGE was adopted. Essentially, the IGE agreed that its future activities should again include the following: a review of the current market situation, short-term outlook, and medium- to long-term perspectives; a consideration of project proposals submitted by Governments and industry for possible financing under UNCTAD's Common Fund for Commodities; and a consideration of other ways, means, and measures to improve the functioning and stability of the tungsten market through strengthened international cooperation between Governments and industries of producing and consuming countries.

Current Research

Russian scientists developed a method for depositing tungsten films in a glow discharge system using tungsten chlorides. Glow discharge is a luminous electrical discharge process without sparks through a gas. The process was said to enable the deposition of films with controlled grain size, texture, and composition at temperatures that avoided significant interaction between substrate and coating. Excellent results were obtained with tungsten films deposited on a variety of articles that were subsequently exposed to ion radiation, thermocycling, and high temperatures.[1]

The service life of crucibles used for melting rare-earth metals was increased significantly through the development of a new tungsten alloy containing 20% yttria. Excellent corrosion resistance was exhibited by the new alloy prepared by pressure sintering. This corrosion resistance, combined with improved flexural strength of the tungsten, permitted crucibles to be made with greater durability than conventional types made of tantalum. Using the new alloy, infiltration of crucible material into the molten rare-earth metals was reduced to 10% of that occurring with a tantalum crucible, thereby increasing by tenfold the service life of the crucible.[2]

A technique was developed to impart wear-resistant properties equivalent to that of cemented tungsten carbides to the surface of ordinary steels and stainless steels. In this surface reforming technique, the base metal steel is diffused to form an adherent bond with a cemented tungsten carbide layer while sintering the tungsten carbide target material in a vacuum. Preparation of coated steel, wear-resistant parts with greater variations in size, shape, and machining method and at lower cost than solid, wear-resistant cemented carbide parts were said to be possible.[3]

Dense, complex electronic components consisting of tungsten and copper were prepared without the need of an infiltration step using a new W-Cu powder called Tungstar developed by Sylvania Chemicals and Metals, Towanda, PA. The components can be produced with copper uniformly dispersed throughout solely by utilizing pressing and sintering steps. Elimination of the infiltration step simplifies the manufacture of components such as heat sinks and also permits the creation of smaller parts. Content of the copper in the components can range from 1% to 50% depending upon the thermal and electrical characteristics required in the practical use of the component.[4]

A new thermochemical processing method for preparing high surface area powders, starting from homogeneous precursor compounds, was developed. The method was applied successfully to the synthesis of novel nanostructured tungsten- and tungsten carbide (WC)-base materials. Nanostructured WC-cobalt powders were consolidated by low-pressure plasma spraying and by cold compaction and liquid-phase sintering. The use of vanadium carbide (VC) as a grain growth inhibitor was essential to mitigate the WC grain growth during liquid-phase sintering. Theoretically dense, VC-doped WC-cobalt materials prepared by this method displayed superior hardness, and wear and cracking resistance.[5]

A method was discovered to extend the life of an Earth satellite using a fine, doped tungsten heating element in association with the thruster burns that are used to periodically correct the satellite's orbit. Under normal conditions, solar winds, lunar gravity, the Earth's magnetic field, and other forces regularly move a satellite out of its prescribed orbit. During a satellite's average life of 15 years, most of the onboard thruster fuel is burned during these orbit corrections. In the new method described, the tungsten heating element effectively adds energy to the exhausting propellant during each thrust motor burn, thereby extending the useful period of the onboard fuel and, therefore, the life of the satellite.[6]

OUTLOOK

Based on reported consumption of all tungsten products during the first 5 months of 1994, the total annual demand for tungsten materials in the United States in 1994 was estimated to be about 8,000 tons of contained tungsten. This would represent an increase in consumption of approximately 6% compared with the 7,581 tons reported for 1993. The economic recovery rate in 1994 is expected to exceed slightly the modest gains the economy experienced in 1993. As a result, overall demand for cutting and wear-resistant components integrally associated with the metalworking, machining, construction, transportation, mining, and oil and gas drilling industries is expected to increase moderately in 1994. In particular, the consumption of cemented carbide tool bit inserts is expected to increase as the automobile market grows and the requirement for machined automobile parts correspondingly rises. In the short term, demand for tungsten in the lighting, electrical, and electronic sectors is expected to continue to increase slowly, although there could be a significant erosion of this demand, should the recent breakthroughs in the development of tungsten-free light bulbs begin to capture a portion of the lighting market. The general rate of growth in tungsten demand will continue to be dampened by the effects of substitution in the cutting and wear-resistant component industries as well as by technological improvements within the industry that result in a more efficient use of tungsten.

The sources of future supplies of tungsten concentrate and intermediate materials for U.S. consumption became less certain by the end of 1993 as producers were forced either to decrease production or to close their operations as a result of a continuing poor market. China, the traditional major supplier of tungsten to the market, experienced a significant production decline, with a further decline possible in the short term. Additionally, China was believed to have nearly exhausted its supply of concentrate stocks. Consequently, a more balanced tungsten supply-demand condition began to emerge at the end of 1993. In the short term, the tungsten market is expected to correct for the transition from an oversupply of tungsten to one that more closely balances its supply and demand, effectively allowing for the entrance of more producers into the market.

[e] Estimated. [r] Revised.

[1] Source, unless otherwise specified, is Tungsten Statistics, UNCTAD Committee on Tungsten.

[2] Revised to zero.

[3] Estimated by the U.S. Bureau of Mines.

[4] Combined internal consumption plus that which was processed to intermediate products and subsequently exported.

[5] Apparent consumption, production plus imports minus exports.

[6] Formerly part of the U.S.S.R.; data were not reported separately until 1992.

[7] Dissolved in Dec. 1991.

[8] Reported figure; excludes 2 months of "withheld" data.

[9] Reported figure; excludes 3 months of "withheld" data.

VANADIUM

By Henry E. Hilliard

Mr. Hilliard, a physical scientist with more than 20 years of U.S. Bureau of Mines experience, has been the commodity specialist for vanadium since 1986. Domestic survey data were prepared by Sherwood Jordan, statistical assistant; and international data tables were prepared by Jeremy Tidwell, international data coordinator.

Vanadium is a member of a group of elements, including columbium and molybdenum, which, when present in small amounts in alloys, can have a significant effect on their properties. Manufacturers of automobiles and machinery recognized this as far back as the early 1900's, incorporating steels containing vanadium for toughness and fatigue resistance of axles, crankshafts, gears, and other critical components. Vanadium improves the properties of alloys because it reacts with carbon and nitrogen to form refractory carbides and carbonitrides, which act as precipitation strengtheners and grain refiners. For some time, about 95% of vanadium used has been consumed by the ferrous and nonferrous alloy industries.

In addition to its metallurgical uses, vanadium has a wide range of chemical applications. The catalytic activity of vanadium oxide enables the controlled catalytic oxidation of naphthalene and o-xylene to phthalic anhydride and of butane and benzene to maleic anhydride to take place. Both compounds are essential monomers in the production of polyesters and plastics. The first use of a vanadium catalyst in the production of sulfuric acid was employed in the United States in 1926. Since that time, vanadium oxide catalysts have replaced platinum as the catalyst of choice for producing sulfuric acid. Vanadium catalysts have the advantages of superior resistance to poisoning and being relatively abundant and inexpensive compared to platinum. Sulfuric acid has been an important item of commerce for more than 200 years and has been known since the Middle Ages.

The lingering economic downturn that had been dampening U.S. vanadium demand in recent years was still very much in evidence in 1993. The pickup experienced in the rest of the economy had not yet reached the vanadium industry. The heavily steel-dependent vanadium industry found that the recovery that occurred in the domestic economy was not enough to return the industry to the good health it enjoyed during the second half of the 1980's. There were signs, however, that the worst was probably over. Most major markets for downstream vanadium products perked up in 1993, and production of vanadium pentoxide (V_2O_5) started growing again after stagnating in 1992. *(See figure 1.)* As the tables and graphs of this report illustrate, the vanadium industry's performance for the past 4 years, in terms of demand and production, though certainly disappointing when measured against conditions of the late 1980's, held up relatively well for a period of recession. Production never declined significantly, though it essentially stopped growing in 1992, and shipments dipped only slightly, falling off less than 10% in 1992, a loss that was recovered in 1993. Just as the industry never fell sharply into recession, the overall message of 1993 seems to be that it would not rebound quickly to prosperity.

DOMESTIC DATA COVERAGE

Domestic consumption data for vanadium are developed by the U.S. Bureau of Mines from a voluntary survey of all known domestic consumers. In 1993, there were 83 responses to the consumption survey, representing 81% of the total canvassed. These 83 respondents are estimated to have accounted for 95% of total domestic consumption, or about 3,121 metric tons. The estimated consumption of nonrespondents, derived using their past consumption relationships, trends, and data from nonsurvey sources, was about 164 tons. The consumption quantity of 3,973 tons shown in table 1 is the U.S. Bureau of Mines estimate of total U.S. (reported) vanadium consumption.

BACKGROUND

Definitions, Grades, and Specifications

The term ferrovanadium as used by the U.S. Bureau of Mines includes vanadium-carbon-iron-nitrogen proprietary alloys as well as the conventional forms of ferrovanadium. Some of the more common commercial products are listed in table 2. A standard specification for ferrovanadium has been developed by the American Society for Testing Materials (ASTM).[1]

Aluminum-vanadium master alloys contain fixed ratios of vanadium to aluminum and are used in the manufacture of titanium alloys. Amounts of vanadium up to 1 weight percent (wt %) improve the strength of titanium-base alloys and promote their thermal stability in the presence of moderate amounts of aluminum. When amounts greater than 4 wt % are added, the titanium-base alloy can be significantly strengthened by heat treatment. The three most important commercial titanium alloys containing vanadium are Ti-6Al-4V, Ti-6Al-4V-2Sn, and Ti-8Al-1Mo-1V. The Ti-6Al-4V alloy presently accounts for more than 50% of the titanium-base alloy market.

Products for Trade and Industry

Vanadium is usually traded on the international market in the form of technical-grade V_2O_5 and 50% to 80% FeV. Most world exports of vanadium raw material are in the form of vanadium-bearing iron slag from China and the Republic of South Africa. The U.S. and Western European converters are the major importers of these raw materials. U.S. and Western European converters are the major exporters of downstream vanadium products such as vanadium oxides and FeV to the many small consuming countries. These converters also compete for the major markets for pentoxide and FeV in Japan and the Republic of Korea. Trade in ferrovanadium is dominated by the major European and U.S. converters. A large part of this trade is within Europe, but exports also are made to many other consuming countries. *(See table 8.)*

Industry Structure

The vanadium industry has a five-tiered structure with facilities on six continents. As expected, mines and oilfields form the base of the structure (figure 1). Since 1979, an estimated 83% of world production has come from vanadiferous magnetite (Fe_3O_4). The principal sources of the magnetite ore were China, the Republic of South Africa, and Russia. World vanadium production for 1987-91 is shown in table 14. The other 17% of the vanadium was recovered from other pertroliferous materials and spent catalysts.

The second tier is a set of economically unrelated facilities that include (1) pig iron plants with slag recovery units, (2) elemental phosphorus smelters, and (3) generators of petroleum residues, fly ash, and spent catalysts that contain vanadium either as the active material or as a contaminant.

The third tier consists of (1) acid leaching plants with solvent extraction circuits and (2) salt roasting operations. Technical-grade V_2O_5 and NH_4VO_3 are the principal products at this level.

To have an easily marketable product, it is customary at this point to either convert the oxides into an alloy or upgrade their purity to greater than 98.5 wt %. The two traditional alloy products have been the 80 wt % ferrovanadium and 35 wt % aluminum-vanadium master alloy. Variations of five different reduction processes are currently in use throughout the world, with aluminum, carbon, or silicon serving as the reductant. These conversion and upgrading plants, which form the fourth tier of the structure, may be a considerable distance from the mills and slag plants and frequently blend feed materials to improve recovery.

Of the more than 30 privately owned vanadium companies, only 1, the Republic of South Africa's Highveld Steel & Vanadium Corp., operates facilities at all 4 lower levels and can be considered totally integrated. Highveld has plants that process vanadiferous magnetite ores from the Bushveld Igneous Complex. Two other producers, Shieldalloy Metallurgical Corp. and Strategic Minerals Corp. (Stratcor), have extensive operations on the second, third, and fourth tiers. Shieldalloy traditionally used Highveld slag as its starting material for low vanadium grades of ferrovanadium.

The fifth tier is composed of producers of vanadium specialty alloys, high-purity vanadium metal, primary vanadium chemicals, and vanadium catalysts. Reading Alloys Inc., Akzo Chemical Co., and Teledyne Wah Chang Albany illustrate the diversity of operations at this level.

The Republic of South Africa is the world's largest producer of ore and vanadium-bearing slag. Its annual production of more than 17,000 tons is approached only by production in Russia. The bulk of Russian production has been traditionally consumed internally or by other Eastern European countries. In 1993, vanadium products of Russian origin began appearing in the United States, Europe, and Japan. Other major producers include China and the United States. Canada, Japan, and Western Europe are heavily dependent on imports of vanadium slag and pentoxide from the Republic of South Africa.

Geology-Resources

Vanadium is found in many parts of the world, usually in association with other minerals. There are few ores from which vanadium can be economically extracted as a single product. It is, therefore, often extracted as a byproduct or coproduct in the production of other elements, such as iron, phosphorus, or uranium. Increasing amounts are being recovered from petroleum residues and spent catalysts. The world also has extensive subeconomic resources of vanadium contained in oil sands, carbonaceous shale, and bauxite.

The crustal abundance of vanadium is estimated to be 100 to 150 parts per million (ppm), about twice that of copper, 10 times that of lead, and almost 100 times that of molybdenum.[2] As a result, trace vanadium mineralization occurs in a wide range of geologic provinces and environments. At the same time, ore deposits of vanadium are rare because much of the vanadium in igneous rocks occurs dispersed in the relatively insoluble trivalent state and substitutes for ferric iron in chromite, ferromagnesian silicates, ilmenite, and magnetite. Because of the substitutional phenomenon at the atomic level, vanadium is more abundant in mafic (those high in magnesium and iron) than silicic rocks. Gabbros and norites typically contain 200 to 300 ppm vanadium compared with 5 to 80 ppm for granites. When mafic rocks weather in a humid climate, the vanadium remains in the trivalent state or is weakly oxidized to the relatively insoluble tetravalent state. In either case, the vanadium is captured along with aluminum in the residual clays. Subsequent leaching of the clays can produce bauxite and lateritic iron ores that contain 400 to 500 ppm vanadium. When mafic rocks are intensely oxidized in an arid climate, some of the vanadium is converted to the pentavalent state. The pentavalent cation is considerably more soluble than the trivalent cation, is readily dissolved by ground water, and can be transported over long distances. This transport phenomenon can be observed in arid parts of Western Australia where carnotite precipitates from ground water in calcreted drainage systems.[3] At Yeelirrie, for example, thin films of carnotite were formed in the voids and cavities of river fill when ground water percolated through a tertiary river channel.

Organic materials frequently play a key role in the depositional process by helping to create a reducing environment. At many locations on the Colorado Plateau, carnotite, tyuyamunite, and other secondary uranium-vanadium minerals replace fossil logs and other carbonized plant debris. Some of the best examples of this phenomenon can be seen in the Monument Valley and White Canyon districts where uranium-vanadium ores have been deposited in paleochannels of the Shinarump Member of the Upper Triassic Chinle Formation. Fossils in the Shinarump indicate that the stream channels were cut into the underlying Moenkopi mudstones and then filled with sands, pebbles, and plant debris before the end of the Triasssic Period 195 million years ago. Although the uranium-vanadium ores are associated with plant remains, the two elements were precipitated from aqueous solutions percolating through the stream channels long after the host sandstones and conglomerates had formed. The genesis and age of the mineralization remain controversial.

The role of vanadium during the formation of fossil fuels is obscure. There appears to be a relationship between the relatively high concentration of vanadium in coal and petroleum and the burial and subsequent degradation processes that apparently formed the fuels from organisms. The structures of the vanadyl porphyrins found in crude oil are approximately identical to the structures of chlorophyll (magnesium-centered porphyrins present in green plants) and hemoglobin (iron-centered porphyrins present in the red corpuscles of blood). The ratio of vanadium to nickel in crude oil is a function of the oxidation-reduction potential (Eh), the hydrogen ion activity (pH), and sulfide activity of the environment in which the oil source rocks were deposited. The two metals both form stable metallo-organic complexes in the high molecular weight fractions of crude oil.[4] Cleavage of these vanadium and nickel bonds will not occur unless the crude oil is subjected to a temperature greater than 300° C. As a result, the vanadium-to-nickel ratio remains constant for a specific reservoir even when the lower molecular weight components migrate away. The ratio is therefore useful in identifying unmetamorphosed crude oil from different depositional facies of the same source rock.

Technology

Mining.—In the United States, vanadium is recovered as a principal mine product from Arkansas clay, as a coproduct from carnotite ores, and from ferrophosphorus slag as a byproduct in the production of elemental phosphorus. Increasingly, vanadium also is being recovered from petroleum refinery residues, fly ash, and spent catalysts. In China and the Republic of South Africa, vanadium is recovered as a byproduct of pig iron production from titaniferous magnetite.

Processing.—The steel industry accounts for more than 80% of the world's consumption of vanadium as an additive to steel. It is added to the steelmaking process as a ferrovanadium alloy, which is produced commercially by the reduction of vanadium pentoxide or vanadium-bearing slag with aluminum, carbon, or ferrosilicon.

The first stage in the processing of vanadium-bearing ore is the production of an oxide concentrate. The ore is crushed, ground, screened, and mixed with a sodium salt. This mixture is roasted at about 850° C to convert the oxides to water-soluble sodium metavanadate. The vanadium is extracted by leaching with water and precipitated at pH 3 as sodium hexavanadate (red cake) by the addition of sulfuric acid. The red cake is fused at 700° C to yield a dense, black product that is sold as technical-grade vanadium pentoxide. Technical-grade vanadium pentoxide contains a minimum of 86 wt % pentoxide and a maximum 8 wt % sodium oxide. The red cake may be purified further by dissolving it in an aqueous solution of sodium carbonate. Aluminum, iron, and silicate impurities precipitate from solution upon pH adjustment. Ammonium metavanadate is then precipitated by the addition of ammonium chloride. The precipitate is calcined to give a vanadium pentoxide product of greater than 99.8% purity.

Vanadium is extracted as a coproduct with uranium from carnotite by direct leaching of the ore with sulfuric acid. An alternative method is roasting the ore followed by countercurrent leaching with dilute sulfuric acid. In some cases, the first leach may be with a sodium carbonate solution. The uranium and vanadium are then separated from the pregnant liquor by liquid-liquid extraction techniques.

More recently spent catalysts have become a major source of vanadium. The catalyst may be either oxidation catalyst used in the production of sulfuric acid and maleic anhydride or hydroprocessing catalyst used in petroleum refining. Vanadium is recovered by first roasting the material in a controlled atmosphere to solubilize the vanadium and other trace metals; e.g., molybdenum and nickel. It is then milled, leached, and filtered to enable the separation of solids from the solution containing vanadium. The solutions go through various precipitation steps prior to the precipitation of vanadium as ammonium metavanadate, which is then decomposed and fused to form V_2O_5 or used directly to make other vanadium chemicals. AMAX Metals Recovery Inc., Braithwaite, LA, uses a somewhat different process to recover cobalt, molybdenum, nickel, and vanadium from alumina-based spent catalysts. The process developed by AMAX in the early 1980's uses a two-stage caustic leach process, one to solubilize vanadium and molybdenum, and the other to solubilize alumina. This process separates the spent catalysts into four products: molybdenum trisulfide, vanadium pentoxide, alumina trihydrate, and a nickel-cobalt concentrate.

In China and the Republic of South

Africa, vanadium is concentrated in slag resulting from the production of pig iron from magnetite ore. The ore, containing 1.5% to 2.5% vanadium pentoxide, is partially reduced with coal in rotary kilns. The ore is then melted in an enclosed furnace that produces a slag containing most of the titanium and pig iron containing most of the vanadium. After the titanium-bearing slag is removed, the molten pig iron is blown with oxygen to form a slag containing 12 to 24 wt % vanadium pentoxide. The slag is separated from the molten metal and then may be used as a high-grade vanadium raw material in the usual roast-leach process.

In the aluminothermic process for preparing ferrovanadium, a mixture of technical-grade pentoxide, aluminum, iron scrap, and a flux are charged into an electric furnace, and the reaction between aluminum and pentoxide is initiated. The reaction is highly exothermic, producing very high temperatures. The temperature can be controlled by adjusting the particle size of the reactants and the feed rate of the charge and by using partially reduced pentoxide or by replacing some of the aluminum by a milder reductant. Ferrovanadium containing up to 80 wt % vanadium can be produced by this method.

Ferrovanadium also can be prepared by the thermit reaction, in which vanadium and iron oxides are coreduced by aluminum granules in a magnesia-lined steel vessel or in a water-cooled crucible. The reaction is initiated by a barium peroxide-aluminum ignition charge. This method also is used to prepare vanadium-aluminum master alloys for the titanium industry.

The production of ferrovanadium by the reduction of vanadium concentrates with silicon involves a two-stage process in which technical-grade vanadium pentoxide, ferrosilicon, lime, and flurospar are heated in an electric furnace. An iron alloy containing about 30% vanadium but undesirable amounts of silicon is produced. The silicon content of the alloy can be reduced by adding more pentoxide and lime to effect the extraction of most of the silicon into the slag phase. An alternative process involves the formation of a vanadium-silicon alloy by the reaction of vanadium pentoxide, silica, and coke in the presence of a flux in an arc furnace. The molten metal reacts with vanadium pentoxide yielding ferrovanadium. The silicon reduction method has not been used extensively.

A process developed by Foot Mineral Co., Cambridge, OH (now Shieldalloy Metallurgical Corp.), has been used to produce tonnage quantities of ferrovanadium. This process involves the reaction of vanadium-bearing iron slag with silica, flux, and a carbon reductant followed by refinement by vanadium pentoxide. The reaction takes place in a submerged electric arc furnace yielding a ferrovanadium alloy containing about 40 wt % vanadium, 3.5 wt % silicon, 3.8 wt % manganese, 0.1 wt % carbon, and the remainder iron.

Substitutes

Various metals, such as columbium, manganese, molybdenum, titanium, and tungsten, are, to some degree, interchangeable with vanadium. So far there are no substitutes for vanadium in the all-important aerospace titanium alloys, which were used in jet engine mountings and wing structures. High-purity vanadium compounds were used as catalysts in the production of sulfuric acid, maleic anhydride, and in pollution control technology where it was required to remove hydrogen sulfide gas from flu gases (Stretford Process). In only a few chemical applications could platinum or nickel replace vanadium catalyst.

Economic Factors

Prices.—The U.S. producer price of ferrovanadium (FeV) declined by more than 25% over the past 12 months from an average of $5.28 per pound vanadium content to an average of $3.95 per pound. Similarly, vanadium pentoxide prices fell from $1.68 per pound in January to $1.28 per pound at the end of the year. The decline of vanadium prices was attributed to lower grade material of Russian origin forcing down the price of higher grades. The free market price for Russian V_2O_5 was about $1.50 per pound in January 1993. That was $0.05 to $0.15 below the free market price for Chinese and South African (Highveld) material.

Tariffs.—U.S. import duties on selected vanadium items as of January 1, 1993, are listed in table 3. The tariff listing includes rates for both most-favored-nation (MFN) and non-MFN status.

Operating Factors

Environmental Requirements.—Because some segments of the geochemical cycle of thorium and uranium coincide with the vanadium cycle, the environmental considerations of vanadium mining are frequently linked to the management of radioactive mine wastes. In addition to careful placement and containment of tailings ponds, special attention must be given to preventing or limiting radioactive contamination of ground water aquifers and to the impoundment and long-term storage of mill tailings and mine waste to control radon daughter exhalation.

In 1982, the U.S. Environmental Protection Agency (EPA) published a regulation dealing specifically with the mining of vanadium ores and uranium-radium-vanadium ores.[5] Under these rules, the concentration of uranium in mine drainage must be less than 4 milligrams per liter per day for 30 consecutive days. In addition, the U.S. Nuclear Regulatory Commission has issued two regulatory guides dealing with personnel monitoring at uranium mills and processing facilities. The two guides delineate techniques for performing a bioassay on workers routinely exposed to airborne yellowcake (U_3O_8) or airborne uranium ore dust.[6]

In October 1983, EPA published rules dealing with the stabilization and long-term control of mill tailings at inactive uranium-vanadium processing sites.[7] These rules, which took effect on December 6, 1983, required uranium-vanadium mill operators to install plastic liners or other protective barriers under their tailings piles to prevent uranium, its radioactive daughter products, and nonradioactive toxic substances such as selenium from contaminating ground waters. Each tailings pond was required to have an earthen cover to minimize emissions and prevent erosion of the sandy surface by wind and rain. The rules also limited radon release from the surface of the pile to 20 picocuries per square meter per second.

Toxicity.—Vanadium compounds are irritants chiefly to the conjunctiva and respiratory tract. Prolonged exposure may lead to respiratory irritations with mucus discharge and lower respiratory tract irritation with bronchitis and chest pains.[8] Other noted effects of vanadium and its compounds have included contact dermatitis, conjunctivitis, and discoloration of the tongue. Vanadium in high concentrations may alter metabolic processes in animals and humans. The reported toxic effects of exposure to vanadium compounds have been acute, never chronic. Toxic effects vary with the compound involved; e.g., vanadium oxytrichloride ($VOCl_3$) liberates hydrogen chloride gas, and the oral lethal dose (LD_{50}) for V_2O_5 dust in rats is 23 milligrams per kilograms of body weight.[9] The lethal dose value is used to express the toxicity of many compounds and is determined by experiment. As used here, it is milligrams of V_2O_5 per kilogram of body weight (taken by mouth) that is lethal to 50% of the experimental animals.

Vanadium metal and its alloys pose no particular health or safety hazard, but they do react violently with certain materials, including bromine trifluoride (BrF_3), chlorine, and some strong acids. The toxicity of vanadium alloys depends on other components in the alloy.

The adopted threshold limit values for time weighted averages for airborne vanadium, including oxide and metal dusts of vanadium, is 0.5 milligram per cubic meter; the value for fumes of vanadium compounds is 0.05 milligram per cubic meter. These limits are for normal 8-hour workday and 40-hour workweek exposures. The short-term exposure limit is 1.5 milligrams per cubic meter for dust.[10] The ammonium salts of vanadic acid and vanadium pentoxide have been listed as toxic constituents in solid wastes under the Resource Conservation and Recovery Act.[11]

ANNUAL REVIEW

Legislation and Government Programs

There was a glut of uranium fuel in the domestic commercial market in 1993, much of it attributed to the Russians, who have been exporting commercial-grade uranium for several years. At least in part because of Russian inroads, U.S. uranium oxide (U_3O_8) production declined from about 17,000 tons in 1980 to less than 4,000 tons in 1990. At the same time, coproduction of vanadium pentoxide from uranium-vanadium ores declined from 5,000 tons to 1,200 tons. Meanwhile, imports from Russia and other republics of the former U.S.S.R. rose from near zero to more than 2,700 tons per year. The U.S. Department of Commerce made a preliminary finding in 1992 that Russia was "dumping" uranium in the United States at unfairly low prices. Consequently, Russia and five other former Soviet republics accepted strict quotas imposed by the U.S. Department of Commerce that essentially exclude them from the U.S. market until the price of uranium rises $3 or more above its yearend price of about $10 per pound. At the end of 1991, when U.S. producers decided to take action, uranium imports from the former U.S.S.R. were about 3 million pounds per month. Under the new agreement, Kazakhstan, Russia, Ukraine, and Uzbekistan were excluded from the U.S. market until the price of uranium rose to $13. At $13, they could ship 2.9 million pounds per year. The quota was to rise with price. At $21, the quotas would be lifted. The $13 threshold, however, was never reached in 1993, so Russia and the other former Soviet republics were unable to export uranium to the United States. By late 1993 the Russians began pressing for a more liberal uranium policy, and by the end of 1993 the Commerce Department accepted terms that would allow Russia to export up to 42 million pounds of uranium to the United States over the next 10 years. The new terms required that every pound of Russian vanadium imported must be matched with a newly mined pound of U.S. uranium, and the blend must be sold to utilities for at least the prevailing market price. Final action on the deal was expected in early 1994.

Strategic Considerations

Vanadium is classified as a strategic and critical material because of the significant import dependence of the United States for its vanadium supply and because of the essential use of vanadium in equipment for defense, energy, and transportation.

Steel producers in the market economy countries (MEC) of Japan, the United States, and Western Europe shared a common concern about lack of economically viable domestic vanadium raw materials. Also, MEC vanadium supply was from only a few sources, chiefly China and the Republic of South Africa and from just three or four suppliers in these countries. China was expected to soon become a net importer of vanadium, leaving only South Africa and perhaps the Commonwealth of Independent States as the only major sources. Japan and Western Europe are more heavily dependent on imports than the United States.

Stockpile

The purpose of the National Defense Stockpile (NDS) is to ensure the supply of critical materials for military and civilian needs in the event of a national defense emergency. The vanadium inventory consists entirely of V_2O_5, which represents 651 tons of contained vanadium. At the current annual rate of U.S. consumption, that is about a 3-month supply. Although the goal for vanadium in the National Defense Stockpile at the end of 1992 was about 7,000 tons of contained vanadium, it was reduced to zero in 1993. There is no FeV in the stockpile. No date has been set for the disposal of vanadium in the stockpile. By law, the NDS cannot be used for economic or budgetary purposes.

Issues

Prior to about 1984-85, more than one-half of the vanadium mined in the United States was recovered as a coproduct with uranium from sandstone mined on the Colorado Plateau. Companies recovering vanadium from uranium ores were hurt by the downturn in nuclear powerplant construction in the aftermath of the Three Mile Island nuclear reactor accident and the subsequent reduced demand for enriched uranium. Worldwide recession, high interest rates, and the cancellation of powerplant construction in the United States caused the Nuclear Exchange Corp. (Nuexco) exchange value of uranium oxide (U_3O_8) to decline from $40.75 per pound in early 1980 to less than $10 per pound in 1991. The exchange value is Nuexco's judgment of the price at which transactions for significant quantities of uranium concentrates could be concluded on a specified date. Value is based on bids to buy and offers to sell, as well as recently completed and pending transactions.

A direct result of the price decrease was mill closing and decommissioning, personnel cutbacks, and canceled development and expansion plans. This unstable situation had the potential for creating a much higher degree of dependence by the United States on imports of vanadium raw materials. However, some of the slack was taken up by increased recovery of vanadium from petroleum residues, including spent petroleum catalysts. Recovery of vanadium from this source began during the 1973 and 1978 Arab oil embargoes. After being cut off from light crude from the Middle East, refiners were forced to process crude oils with high-sulfur and high-metal content. The trend toward heavier, sour crude led to the production of large volumes of petroleum coke that contained high concentrations of metals. This material has become an important source of vanadium, and in some instances, molybdenum and nickel. At the same time, the combustion of increasingly metalliferous fuel oils at powerplants created a second source of feed materials in the form of fly ash and boiler scale. More V_2O_5 produced in the United States is now being recovered from refinery residues, fly ash, boiler scale, and spent catalysts than ever before. In 1993, the United States recovered 2,700 tons of vanadium oxides from petroliferous materials.

Production

Vanadium is often considered to be an uncommon element, but actually its abundance in the Earth's crust is comparable to or greater than that of copper, nickel, and zinc. Although there is a plentiful supply of vanadium, it is one of the most expensive elements to recover. In most cases, whether vanadium occurs as a primary ore, a coproduct, or in petroleum, the vanadium content of the material usually runs 1.5% V_2O_5 or less. V_2O_5 is the principal starting material for the production of all vanadium compounds. Therefore, when one speaks of vanadium production or the supply side of the industry, only those involved in the production of V_2O_5 should be included.

At yearend, there were five companies producing V_2O_5 in the United States. Of these, one was a totally integrated company that produced V_2O_5, vanadium chemicals, FeV, and other vanadium alloys. The others produced mainly V_2O_5 from a variety of raw materials.

Consumption, Uses, and Stocks

Vanadium has been used as an alloying element in steel since 1902, when it was first added to tool steels used for high-speed machining operations. It was found that vanadium prevented grain growth in tungsten-bearing steels and enabled the steels to maintain their hardness at the high temperatures generated in tool steels during high-speed machining. Vanadium is also widely used in high-temperature steels used in steam powerplants. Chromium-vanadium steels are used for steel pipes and headers, and molybdenum-vanadium steels are used for rotors in turbines because of the high creep resistance produced by vanadium carbides.

Metallurgical applications accounted for more than 95% of vanadium consumption, with about 83% for steelmaking. Relatively small quantities of vanadium were used for alloying with nonferrous metals, mostly aluminum. Nonmetallurgical applications included catalysts, ceramics, and vanadium chemicals. The dominant nonmetallurgical use was in catalyst. Much less was consumed in ceramic and electronics (batteries).

Reported yearend consumers' and producers' stocks of vanadium oxides, metal, alloys, and chemicals totaled 1,019 tons of contained vanadium; there was 1,084 tons in stocks at yearend 1992.

Foreign Trade

Overall exports of vanadium products were essentially unchanged in 1993. Canada and Mexico were the leading importers of U.S. materials. Most countries imported almost exclusively V_2O_5. Canada, the Republic of Korea, and Venezuela also imported substantial quantities of FeV.

Imports for consumption of downstream vanadium compounds increased by more than 36% in 1993; imports of raw material slag, ash, residues, and spent catalysts were up by more than 40%.

World Review

Industry Structure.—Vanadium was traded on the world market in vanadium-bearing slag, petroleum residues, technical-grade V_2O_5, and FeV. The Republic of South Africa was the largest producer with more than 60% of the MEC market. Most of the Republic of South Africa's exports of vanadium were in the form of vanadium-bearing iron slag. Japan and Western Europe were the chief importers of this material. The United States imported slag from the Republic of South Africa and fly ash, petroleum residues, and spent catalyst from many other sources. The large importers of vanadium raw materials; e.g., slag, were the chief exporters of V_2O_5, FeV, and other downstream vanadium products. This trade was dominated by a few large West European converters who competed not only within Europe, but also exported to many large and small consumers outside of Europe. Reliable statistics from Russia were not available, but it is believed to be second only to the Republic of South Africa in vanadium production. Most Russian trade was thought to be with other East European countries. However, significant quantities of Russian and Czech material began to find its way into the world market.

Capacity.—The data in table 12 are rated capacity for mills producing vanadium oxides as of December 31, 1993. Included in this data is capacity to produce vanadium-bearing slag and petroleum coke. Rated capacity is defined as the maximum quantity of product that can be produced on a normally sustainable, long-term operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgement of the author, can be brought back into production within a short period with minimum capital expenditure.

Canada.—A mineral deposit that may have sufficiently high concentration of vanadium and titanium for commercial development has been discovered in Manitoba. The deposit was discovered on land owned by the Cross Lake First Nation Indian band. The site is about 80 kilometers southeast of Cross Lake Village. An agreement was worked out between Gossan Resources and Cross Lake First Nation wherein Gossan owns 51% of the claim and Cross Lake Mineral Exploration owns 49%. Gossan officials said that intense exploration would begin in January 1994. Mining could start as early as mid-1995. According to Gossan officials, total deposits of iron, titanium, and vanadium could reach 40 million tons. Manitoba Government officials stated that the ore concentrations were likely to be sufficient for commercial development, because a major international mining company had expressed interest in developing the deposit. Estimated startup cost reportedly was C$250 million.

Czech Republic.—Czech-based Mníšek Ferozliatinárske Zavody, Š. P., announced plans to expand FeV production in 1994. The action follows an earlier agreement with a group of Japanese companies to form a joint venture to produce FeV. The group included Nissho Iwai. According to company officials, the joint venture, called Nikom, will produce 1,300 tons of FeV in 1993 and 1,500 tons in 1994. Nikom plans to sell most of its production in the Far East with the remainder going to Europe. Mníšek owns a V_2O_5 plant that supplied feed for its FeV operations. Vanadium-bearing iron slag for the V_2O_5 plant was imported from Russia. Vanadium pentoxide capacity was estimated at 3.5 to 4 million pounds per year. Ferrovanadium capacity was estimated at 1,500 tons per year and could easily be expanded to 2,000 to 3,000 tons per year.

United States.—Stratcor, Danbury, CT, announced an agreement under which it will exclusively market FeV from Russia's largest FeV producer, Tulachermet Corp., in North America. Tulachermet produces 52% FeV low in aluminum, which, according to Stratcor, will be advantageous to continuous casting operations and producers of low aluminum products. The agreement resulted in the curtailment of FeV production at the company's Niagara Falls, NY, plant. About one-half of the 80 workers at the New York plant were laid off. The plant has an annual capacity of about 4,000 tons per year FeV. Stratcor also formed an alliance with Bear Metallurgical Corp., Butler, PA, to toll convert V_2O_5 produced by U.S. Vanadium Corp. U.S. Vanadium, located in Hot Springs, AR, is a subsidiary of Stratcor. The Hot Springs plant will be expanded to supplement specialty vanadium chemicals and vanadium-aluminum operations at Niagara Falls.

An expansion at Stratcor subsidiary Vametco in Brits, Republic of South Africa, produced FeV to be marketed in Japan and Europe. The Vametco expansion totally integrated the facility, bringing total vanadium capacity to about 10 million pounds per year, including FeV, Nitrovan, and V_2O_5.

OUTLOOK

U.S. vanadium prices continued to decline in 1993 despite an apparent increase in demand. The failure of prices to improve may have been caused by market oversupply through all of 1993. There were indications that market conditions would improve in 1994-95. The tool steel industry is a relatively large consumer of vanadium. The Association of Manufacturing Technology, based in McLean, VA, reported that orders for U.S.-made machine tools hit a 5-year high in 1993. The Association said December 1993 tool orders were up more than 37% at $319 million, compared with November's $232 million, and up 55% from December 1992's $206 million. The gain in machine tool orders is considered an indicator of economic activity. The increase in machine tool orders this year should show up in stronger demand for vanadium beginning in fourth quarter 1994 and continuing in 1995. Another boost in demand for vanadium could come in 1994 as the automotive industry increases its demand for automotive alloys that contain vanadium. U.S. auto production increased by more than 5% in 1993 and is expected to increase by more than 9% in 1994.

More than 95% of the demand for vanadium is driven by steel and nonferrous metallurgical applications. This dependence of the vanadium industry on the demand for steel products is not likely to change in the near future. The remaining demand is driven by chemicals applications. The reader is referred to the outlook section of the Iron and Steel Annual Report for more information on the short-term outlook for the steel industry. An excellent analysis of the chemical industry was published in the June 1993 issue of Chemical & Engineering News.

World: Production from ore, concentrate, slag[4]		[r]32,967	[r]30,906	[r]28,162	[r]25,933	[e]25,200

[e] Estimated. [r] Revised. W Withheld to avoid disclosing company proprietary data.

[1] Recoverable vanadium contained in uranium and vanadium ores and concentrates received at mills, plus vanadium recovered from ferrophosphorus derived from domestic phosphate rock.

[2] Produced directly from all domestic ores and ferrophosphorus slag; includes metavanadates.

[3] Includes vanadium recovered from fly ash, residues, and spent catalysts.

[4] Excludes U.S. production.

TABLE 2
CHEMICAL SPECIFICATIONS FOR COMMERCIAL FORMS OF FERROVANADIUM

Alloy	Composition, weight-percent (maximum unless otherwise specified)							
	Vanadium	Carbon	Nitrogen	Aluminum	Silicon	Phosphorus	Sulfur	Manganese
50% to 60% ferrovanadium	50.0-60.0	0.2	—	2.0	1.0	0.05	0.05	—
70% to 80% ferrovanadium	70.0-80.0	—	—	1.0	2.5	.05	.10	—
80% ferrovanadium	77.0-83.0	.5	—	.5	1.25	.05	.05	0.50

TABLE 4
U.S. VANADIUM PENTOXIDE PRODUCERS

Producer	Plant location	Capacity (metric tons pentoxide per year)
AMAX Metals Recovery Inc.	Braithwaite, LA	1,800
Gulf Chemical & Metallurgical Corp.	Freeport, TX	1,400
Kerr-McGee Chemical Corp.	Soda Springs, ID	2,000
UMETCO Minerals Corp.	Blanding, UT	6,800
U.S. Vanadium Corp.	Hot Springs, AR	6,800

TABLE 5
U.S. CONSUMPTION AND CONSUMER STOCKS OF VANADIUM MATERIALS, BY TYPE

(Kilograms of contained vanadium)

Type	1992		1993	
	Consumption	Ending stocks	Consumption	Ending stocks
Ferrovanadium[1]	[r]3,580,121	[r]326,642	3,607,756	297,501
Oxide	14,716	7,584	W	9,203
Ammonium metavanadate	W	W	2,170	1,896
Other[2]	[r]484,429	[r]57,714	362,651	20,666
Total	[r]4,079,266	[r]391,940	3,972,577	[3]329,267

[r] Revised. W Withheld to avoid disclosing company proprietary data; included with "Other."

[1] Includes other vanadium-iron-carbon alloys as well as vanadium oxides added directly to steel.

[2] Consists principally of vanadium-aluminum alloy and small quantities of other vanadium alloys and vanadium metal.

[3] Data do not add to total shown because of independent rounding.

TABLE 6
U.S. CONSUMPTION OF VANADIUM IN 1993, BY END USE

(Kilograms of contained vanadium)

End use	Quantity
Steel:	
Carbon	1,413,087
Stainless and heat resisting	32,517
Full alloy	788,696
High-strength low-alloy	981,104
Tool	373,349
Unspecified	10,427
Total	[1]3,599,179
Cast irons	21,021
Superalloys	13,166
Alloys (excluding steels and superalloys):	
Cutting and wear-resistant materials	339
Welding and alloy hard-facing rods and materials	W
Magnetic alloys	W
Other alloys	308,921
Chemical and ceramic uses:	
Catalysts	W
Pigments	W
Miscellaneous and unspecified	29,951
Grand total	3,972,577

W Withheld to avoid disclosing company proprietary data; included with "Miscellaneous and unspecified."

[1] Data do not add to total shown because of independent rounding.

TABLE 7

PRODUCERS OF VANADIUM ALLOYS OR METAL IN THE UNITED STATES IN 1993

Producer	Plant location	Products[1]
Bear Metallurgical, Corp.	Butler, PA	FeV.
KB Alloys Inc.	Henderson, KY	VAl, ZrVAl.
Do.	Wenatchee, WA	Do.
Reading Alloys Inc.	Robesonia, PA	NiV, VAl, V.
Shieldalloy Metallurgical Corp.	Cambridge, OH	FeV, Ferovan.[2]
Do.	Newfield, NJ	FeV.
U.S. Vanadium Corp.	Niagara Falls, NY	FeV, VAl, Nitrovan.[2]
Teledyne Wah Chang Albany	Albany, OR	V, VAl.

[1] FeV, ferrovanadium; V, vanadium metal; VAl, vanadium-aluminum alloy; ZrVAl, zirconium-vanadium-aluminum alloy; NiV, nickel-vanadium alloy.

[2] Registered trademark for proprietary products.

[e] Estimated. [r] Revised. W Withheld to avoid disclosing company proprietary data; not included in "Total."

[1] In addition to the countries listed, vanadium is also recovered from petroleum residues in Germany, and several other European countries, but available information is insufficient to make reliable estimates. Table includes data available through July 28, 1994.

[2] Production in this section is credited to the country that was the origin of the vanadiferous raw material.

[3] All production in the U.S.S.R. from 1989-91 came from Russia.

[4] Includes production for Bophuthatswana.

[5] Data on vanadium content of vanadium slag are estimated on the basis of a reported tonnage of vanadium-bearing slag (gross weight) multiplied by an assumed grade of 14.1% vanadium.

[6] Data may not add to reported totals shown because of independent rounding of estimated detail.

[7] Dissolved in Dec. 1991.

[8] Production in this section credited to the country where the vanadiferous product is extracted; available information is inadequate to permit crediting this output back to the country of origin of the vanadiferous raw material.

[9] Reported figure.

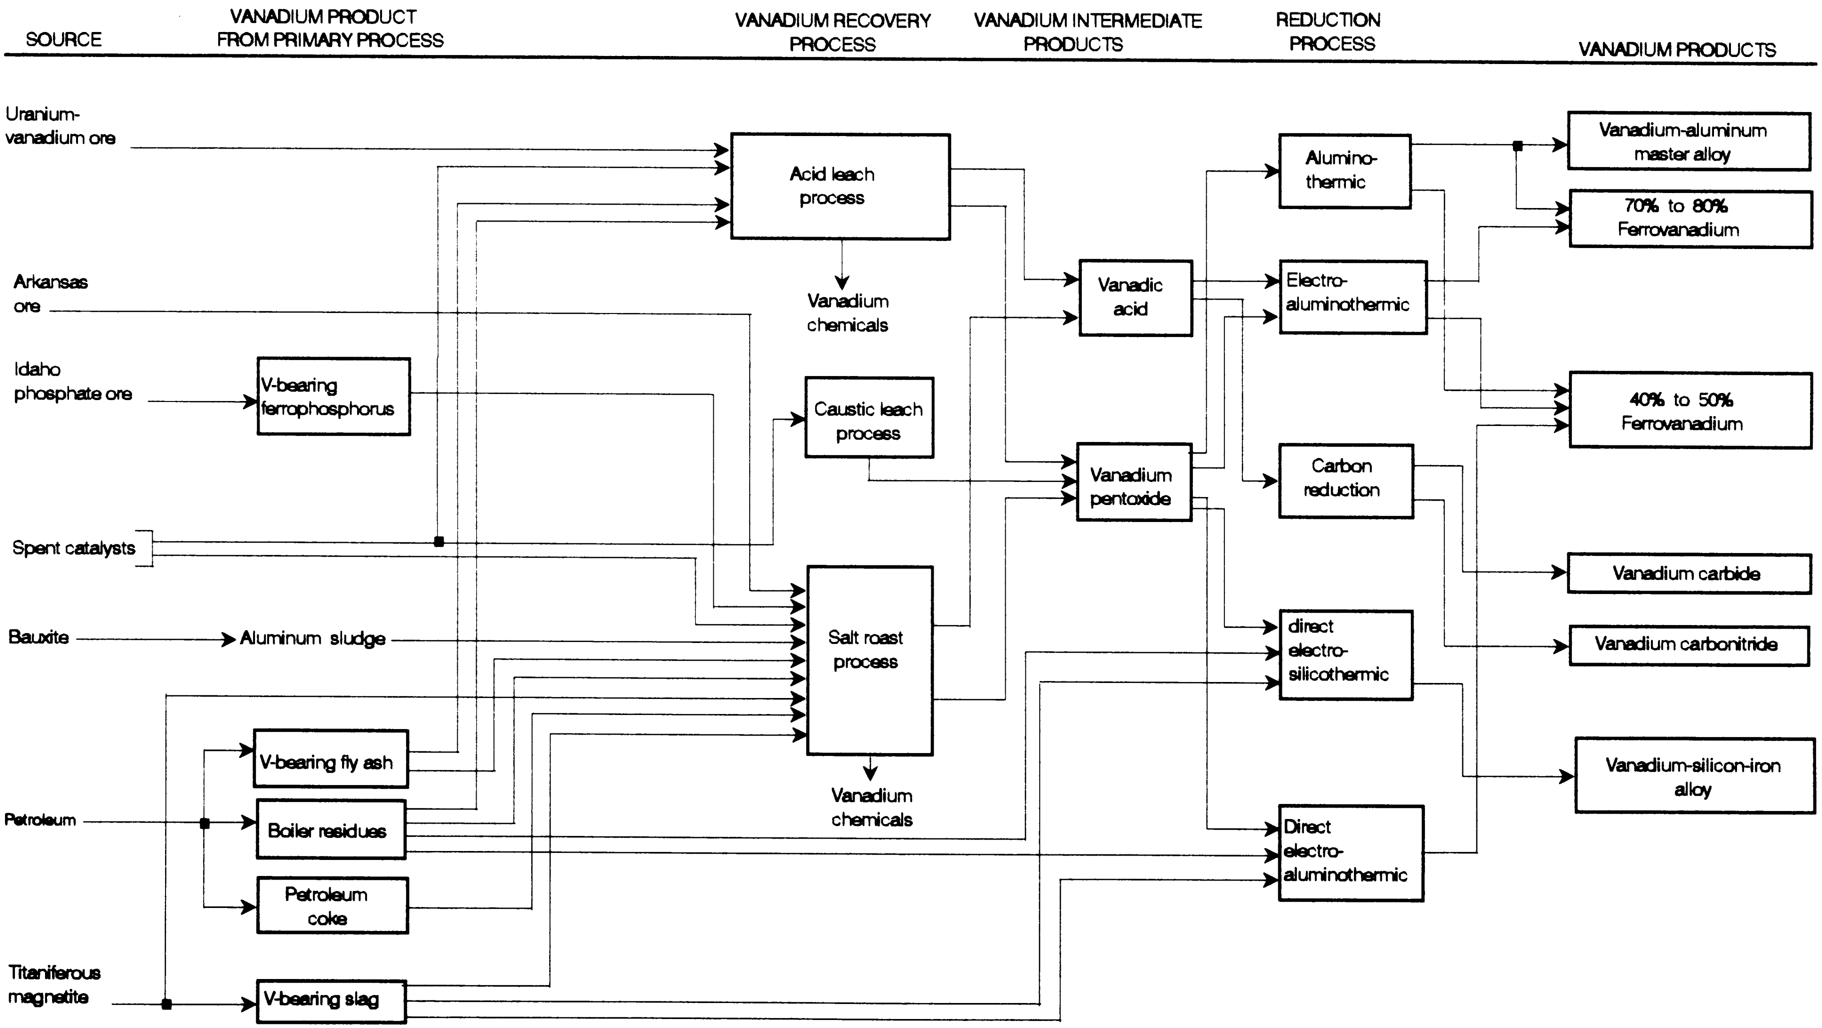
GENERALIZED FLOWSHEET FOR THE PROCESSING OF VANADIFEROUS RAW MATERIALS



ZINC

By Stephen M. Jasinski

Mr. Jasinski, a physical scientist with 7 years of U.S. Bureau of Mines experience, has been a commodity specialist in the Branch of Metals since 1988. Domestic survey data were prepared by Gloria A. Peebles, statistical assistant. International production tables were prepared in collaboration with country specialists in the Division of International Minerals.

Zinc was produced at 24 mines in the United States in 1993. For the third consecutive year, Alaska was the leading zinc-producing State, followed by Tennessee, New York, Missouri, Colorado, and Montana. U.S. mine production greatly exceeded smelter capacity, which resulted in a net export of 250,000 metric tons of zinc in concentrates. The value of zinc mine production was $520 million.

Four primary smelters produced slab zinc in 1993 from domestic and primary ore and scrap materials. Ten secondary smelters produced slab zinc using about 70% new scrap and 30% old scrap. A detailed discussion of the secondary zinc industry is contained in the Recycling—Nonferrous Metals Annual Report. Total slab zinc production was about 380,000 tons, a slight decrease from 1992, caused by the closure of one primary zinc smelter in September.

The domestic zinc industry continued to improve despite a reduction in mine and smelter production. Apparent consumption of zinc in all forms increased 11% and imports of slab zinc grew by 12% to meet the demand. Domestic apparent consumption of slab zinc grew 9% from that of 1992. The increase was greatest in the galvanizing and diecasting industries owing to strong growth by the U.S. automobile industry. Zinc use in brass and bronze products and other uses showed modest increases. The chemical, rubber, and paint industries used zinc in compound form and as zinc dust at about the same level as in 1992.

In 1993, 355,000 tons of zinc in waste and scrap, including 109,000 tons in old scrap, was recovered in the form of slab zinc, brass, zinc-base alloys, dust, oxide, and other chemicals.

U.S. producer prices, which are based on the London Metal Exchange (LME) price for zinc, declined to record-low levels. The price drop was attributed to an oversupply caused by LME stocks nearly doubling in 1993.

World mine production of zinc decreased 5%. Australia, Canada, China, Peru, and the United States were the top producers, accounting for nearly 60% of the world total.

Identified world resources of zinc total about 1.8 billion tons. The world reserve base was estimated at 330 million tons and reserves at 140 million tons. Canada has the largest reserves, 15% of the world total, and Australia has the largest reserve base, 20%. The U.S. share of reserves and reserve base was 11% and 15% percent, respectively.

DOMESTIC DATA COVERAGE

Domestic data for zinc were developed by the United States Bureau of Mines (USBM) from five separate, voluntary surveys of U.S. operations. Typical of these was the "Slab Zinc" consumption survey sent out monthly or annually, depending on consumption quantities; small consumers are canvassed annually. Consumption for nonrespondents was estimated using their prior-year consumption adjusted for industry trends.

Reported consumption for slab zinc, however, accounted for only 67% of apparent metal consumption, a reflection of the low current response rate for the voluntary industry surveys.

ANNUAL REVIEW

Strategic Considerations

Supply.—U.S. mine and smelter production capacity can supply only about one-half of domestic zinc requirements. The domestic ore reserve base is large, but could not be tapped adequately until after the first year of an emergency situation. Domestic smelter capacity is inadequate and would limit refined zinc output. It also would severely limit the country's ability to produce strategic and critical zinc byproduct elements such as cadmium and germanium.

Zinc mine production in Alaska accounted for nearly one-half of U.S. output; however all output from the State is exported. Even if Alaskan zinc concentrates were redirected to U.S. smelters, there is not enough domestic production capacity to process the material. U.S. mine output greatly exceeds smelter capacity and in 1993 resulted in the net export of 250,000 metric tons of zinc in concentrate. An additional strategic factor related to production in Alaska is that more than 80% of the State's output is inaccessible for 9 months of the year because of sea ice.

Although imports constitute a large part of the U.S. zinc supply, about 60% of the zinc metal, concentrates, and compounds comes from Canada and Mexico; therefore the risk of supply disruption is low.

Stockpile.—A stockpile for zinc for national defense purposes has been maintained for more than 50 years. In 1992, the President signed Public Law

102-484, which authorized the disposal of the entire inventory of zinc from the National Defense Stockpile (NDS). The Defense Logistics Agency (DLA), which maintains the NDS, was authorized to sell 68,000 tons in FY 1993 and 43,545 tons in FY 1994; it sold 19,000 tons during calendar year 1993.

Production

Mine Production.—U.S. zinc mine output decreased 8% in 1993, despite higher production at the Red Dog Mine in Alaska. This was a result of several mine closures. The 20 leading mines accounted for more than 98% of production, with 5 leading mines accounting for 75%. For the third consecutive year, Alaska was the leading zinc-producing State, followed by Tennessee, New York, Missouri, Colorado, and Montana. The leading domestic producers were ASARCO Incorporated, Cominco Alaska Inc., Union Zinc Co., and Zinc Corporation of America (ZCA).

The Red Dog Mine in northwestern Alaska and the Greens Creek Mine on Admiralty Island accounted for nearly all zinc production in Alaska in 1993. The Red Dog Mine, which began operations in late 1989, is owned by NANA Regional Corp. Inc. and leased to Cominco Alaska Inc., a subsidiary of Cominco, Ltd., which owns and operates the mining and processing facilities. NANA is paid a royalty that is scheduled to increase after the capital investment plus interest is recovered by Cominco.

In 1993, the grinding circuit was improved, resulting in increased production. By the end of the year, zinc concentrate production was at design capacity. An expansion of the grinding circuit was initiated late in the year and completed early in 1994, and improvements were made to the concentrator circuit. Zinc concentrate production was expected to be above design capacity in 1994. According to the Cominco annual report, zinc recovery was 81%, up 5% from 1992, and total ore milled was 1,700,600 tons, or 265,400 tons more than in 1993. The ore grade was 18.4% zinc, down 1.5% from last year. A total of 235,200 tons of zinc in zinc concentrate and bulk lead-zinc concentrate was produced in 1993, an increase of 17,000 tons from 1992. Ore reserves at yearend were 56.8 million tons averaging 18.4% zinc, 5.7% lead, and 93 grams per ton silver. An additional 14.1 million tons of lower-grade ore was classified as inferred reserves.

The Greens Creek Joint Venture is a consortium 53% owned by RTZ Ltd, through its Kennecott subsidiary, Greens Creek Mining Co.; and 47% owned by minority partners Hecla Mining Co., Exalas Resources Corp., and CSX Alaska Mining Inc. The mine was closed in April because of low metal prices. It produced 5,200 tons of zinc in concentrates, according to the RTZ annual report. Development and engineering activity continued at the mine.

In Tennessee, zinc was produced at seven underground mines, four owned by Asarco in the eastern part of the State and three owned by Jersey Miniere Zinc Co. (JMZ) in the western part. Asarco's production was 56,000 tons of zinc in concentrates, down 11,900 tons from 1992. Asarco's ore reserves at yearend were 4.8 million tons averaging 3.28% zinc. The drop in production was caused by the failure of a ball mill at Asarco's Young Mine in late July, which was not repaired until November. This also forced the temporary closure of three of the company's mines for the same period. JMZ reduced output from its Jefferson City Mine by 25% in July because of low metal prices and declining reserves.

In Missouri, zinc was produced as a coproduct of lead at nine underground lead mines along the Viburnum Trend by three companies, Asarco, The Doe Run Co., and Cominco American Inc., a subsidiary of Cominco Ltd. According to the Asarco annual report, production of zinc in concentrate at the West Fork and Sweetwater Mines was 15,900 tons, an increase of 2,000 tons. Ore reserves at yearend were 23.7 million tons, averaging 0.86% zinc. Zinc output at the Magmont Mine, a joint venture of Cominco American and Dresser Industries, continued to drop as the ore body was nearly depleted; the mine was scheduled to be closed in 1994. According to the Cominco annual report, the Magmont mill processed 630,000 tons of ore grading 1.2% zinc, yielding 6,200 tons of zinc in 10,200 tons of concentrate. At yearend, the ore reserves were 2.5 million tons, averaging 8.3% lead, 1.2% zinc, and 0.3% copper.

In Colorado, zinc was produced only as a coproduct of gold-silver operations at the Leadville Unit, managed by Asarco, but owned jointly with the Resurrection Mining Co. Production of zinc in concentrate was 13,900 tons. At yearend, ore reserves were 635,000 tons, averaging 8.1% zinc.

In Montana, the Montana Tunnels Mining Co., a subsidiary of Pegasus Gold Inc., milled 4.6 million tons of ore in 1993, containing 16,300 tons of zinc, 6,350 tons of lead, 2,137 kilograms of gold, and 43,545 kilograms of silver. Zinc recovery was 88%, with the mill feed averaging 0.52% zinc. At yearend, proven and probable reserves were 32.4 million tons, grading 0.60% zinc, 0.22% lead, 0.6 gram of gold per ton, and 10 grams of silver per ton. The reserves are lower than in 1992 because material containing less than 0.5 gram gold per ton is being stockpiled for processing when economic conditions are more favorable.

In January, Equinox Resources Ltd., placed its Van Stone Mine in Washington on a care and maintenance basis because of low metal prices. The mine had reopened in August 1992 after being closed for 9 months. The mine had an annual production capacity of 14,000 tons of zinc in concentrates.

In September, Exxon Coal & Minerals Co. formed a 50-50 joint venture with Rio Algom Ltd., of Canada, to develop the Crandon zinc-copper deposit in Northeastern Wisconsin. The companies began permitting procedures early in 1994 and anticipated beginning shipments of concentrates by the end of 1999. Development of this project was to require a capital expenditure of $300 million. The deposit has reserves of 27 million tons, grading 9.4% zinc and 0.4% copper, with lead, gold, and silver in byproduct quantities. In 1986, Exxon had proposed a mining program for the site and applied for permits, but shelved the project due to unfavorable economic conditions. The new mining program was to be similar to that of 1986, except that production will be reduced 25%, and the program will be modified to meet current environmental standards and improvements in technology.

Smelter and Refinery Production.—Refined metal production was down about 4% because of the closure of one plant at the end of September. ZCA, Jersey Miniere Zinc (JMZ), and Big River Zinc Co. operated four primary zinc refineries in 1993. ZCA closed its Bartlesville, OK, electrolytic refinery at the end of September because of low metal prices and for renovations that were expected to take one year to complete. The plant has a production capacity of 54,000 tons per year. Secondary slab zinc was produced at 10 plants from waste and scrap materials. The largest secondary producer was ZCA at its electrothermic primary smelter in Monaca, PA. A substantial part of the plant's feed material was crude zinc calcine recovered from steel mill electric arc furnace (EAF) dust by ZCA's sister company, Horsehead Resource Development Co. The largest producers of zinc metal at secondary plants were Huron Valley Steel Corp., Interamerican Zinc Co., and Gulf Metals Corp.

Zinc Oxide.—In 1993, seven companies produced French-process zinc oxide only and one company, Eagle Zinc Co., produced American-process zinc oxide. Some impure zinc oxide produced at secondary plants was sold directly for agricultural purposes. The principal producers in 1993 were Asarco, Eagle Zinc, North American Oxide Inc., and ZCA.

Consumption and Uses

Zinc is found in many manufactured products, but its role is not obvious to the public because it tends to lose its identity in the products. Zinc-containing products were used extensively in 1993 for construction, transportation, electrical, machinery, and chemical purposes. Zinc-coated steel sheet, structural shapes, fencing, storage tanks, fasteners, nails, and wire rope were widely used in all types of construction, including transmission and radar towers, industrial plants, culverts, roads, bridges, and airfields. Zinc sacrificial anodes were used to protect ship hulls, offshore oil drilling rigs, submerged and buried steelwork, tanks, and pipes. Brass was used as shell casings in ammunition, and for tubes, valves, motors, pipes, refrigeration equipment, heat exchangers, communication units, and electronic devices. Zinc die-cast parts, such as handles, grilles, bezels, brackets, locks, hinges, gauges, pumps, mounts, and housings were used extensively in vehicles, machinery, business machinery, appliances, household hardware, and scientific and electronic equipment. Zinc dust was used in primers and paints; in alkaline dry cell batteries; in the sherardizing process to protectively coat nuts, bolts, and small parts; for the precipitation of noble metals from solution; and in the zinc industry for the removal of impurities, such as copper, cadmium, and lead, before electrolysis. The metal casings of dry cell zinc-carbon batteries were zinc. In 1993, 29,000 tons of Special High Grade (SHG) zinc was used by the U.S. mint to produce 12.1 billion pennies.

Zinc compounds were used in corrosion-inhibiting paint primers, chemical catalysts, welding and soldering fluxes, fungicides and pharmaceuticals, paints, rubber, phosphors for cathode ray tubes, ceramics, and additives for lubricating oils and greases. Zinc ferrites were used in electrical devices, such as transformers, coils, amplifiers, and motors.

Domestic consumption of slab zinc rose about 110,000 tons to 1.1 million tons in 1993. Galvanized zinc protective coatings, mainly on steel sheet and strip, continued to be the principal use of zinc metal, consuming an estimated 54%; followed by zinc-base die-cast alloys, 21%; brass alloys, 14%; and other uses 11%. SHG accounted for about 55% of the reported consumption, followed by Prime Western (PW), 25%; High-Grade (HG), 12%; and other grades, 8%. Overall, zinc metal accounted for more than 75% of the total zinc in final products in 1993, and zinc chemicals accounted for the balance.

Consumption of zinc in the production of copper-based alloy for brass mills, ingotmakers, and foundries increased nearly 40,000 tons in 1993, to 345,200 tons, according to the Copper Development Association Inc. (CDA). Consumption was evenly split between refined metal and zinc contained in brass and bronze scrap. According to the CDA, brass mills accounted for 87% of the total zinc consumed as metal and scrap in producing copper-based alloys.

Apparent domestic consumption of zinc oxide was about 160,000 tons. Domestic production was 102,000 tons, whereas net imports were 30,400 tons. USBM information on zinc oxide consumption reflects only shipments as reported by the domestic producers; because reporting is incomplete, the consumption data listed in table 11 account for only about 80% of the market. Of the reported amounts, the rubber and chemical industries continued to be the principal consumers.

Stocks

Metal stocks held by domestic producers, merchants, and consumers continued to decline in 1993 and were at the lowest levels since the early 1940's. This reflected the general trend toward lower inventories and just-in-time deliveries. Inventories of slab zinc at domestic primary smelters totaled 10,300 tons at yearend, compared with 12,300 tons at the end of 1992, according to the American Bureau of Metal Statistics (ABMS). Metal stocks in other countries (exclusive of Eastern Europe and China) continued to rise sharply in 1993. According to the International Lead and Zinc Study Group (ILZSG), stocks in Western countries were 1,580,000 tons at the end of 1993, up 450,000 tons from the end of 1992. Virtually all the additional stocks were placed into LME warehouses, as industrial stocks tended to remain at 1992 levels. ILZSG data indicated that 85% of the metal stock rise was attributable to increased exports from Eastern Europe and China.

Markets and Prices

Since 1991, U.S. zinc producers have used the LME as their price basis. For domestic metal, sellers generally charged either a premium of 2-to-5 cents per pound over the LME spot price or some average of LME prices to account for delivery and/or importing costs. The price reported in table 1 was published by Platt's Metals Week, which based its price on the daily LME spot price for SHG plus a premium that reflected market conditions.

The domestic zinc price began the year on an upward trend at 50.52 cents per pound and reached a high for the year in February, averaging 50.90 cents per pound for the month. LME stocks increased throughout the year, causing prices to drop. An all-time low price of 39.66 cents per pound was set on the LME in September. Speculation about smelter closures in Europe and a drop in the availability of concentrates led to a gradual increase in price from October until yearend, when it finished at 46.4 cents per pound. That was still 7% lower than in January. The average for the year was 46.16 cents per pound.

Foreign Trade

The value of U.S. exports of basic zinc materials, including waste and scrap, was about $197 million, down from $283 million in 1992, owing to lower zinc prices in 1993. Exports of zinc concentrates increased slightly; however, their value was almost $100 million lower than in 1992.

General imports of zinc concentrates relative to imports for consumption continued to be high because of shipments of Canadian concentrates through Skagway, AK, to world markets. Imports of slab zinc were up nearly 80,000 tons to meet increased domestic demand in 1993. Slab zinc accounted for about 71% of the total value of imports.

World Review

Western world mine production dropped 5% in 1993; however, smelter production increased slightly. Consumption in Western countries grew about 75,000 tons in 1993, according to ILZSG. In Eastern countries, mine and smelter output increased, whereas consumption deceased slightly. Net exports from Eastern Europe to Western countries continued to grow, further swelling world stocks to more than 1.5 million tons at yearend, up 450,000 tons from 1992. Virtually all excess metal went into LME stocks.

According to ILZSG, world annual zinc mine capacity was 7 million tons, but this figure was believed to be low because data were not available for every mine in the former republics of the U.S.S.R. World annual smelter capacity was 8 million tons.

OUTLOOK

U.S. demand for zinc is forecast to rise slowly, increasing from about 1.15 million tons in 1993 to 1.25 million tons by the year 2000. No major shifts in zinc use are foreseen, although some present uses may decline owing to substitution. Over the next 5 years, zinc-air and other zinc battery systems may become important for electric vehicle propulsion or for load-leveling and power backup systems.

Although the United States has an adequate resource base, imports are expected to account for more than one-half of the domestic supply during the next decade, especially if the Bartlesville, OK, smelter remains closed. No new primary smelters are likely to be built because of permitting delays and potential long-term liability threats posed by Superfund legislation. The improvements at the Red Dog Mine are expected to boost production and will likely keep the United States as a major exporter of zinc concentrates. Projected growth in demand also will maintain the United States as the world's largest importer of refined zinc metal.

Secondary zinc metal recovery from waste and scrap is anticipated to be a strong growth sector for the zinc industry. Domestic secondary zinc production could constitute at least 40% of total zinc metal and compounds used annually by the year 2000. The increasing trend in public policy to encourage recycling likely will impact more zinc-containing products, such as batteries. Large-scale use of zinc in electric vehicle batteries could boost secondary zinc consumption to more than 50% of the U.S. total by early in the next century.

23	Lucky Friday	Shoshone, ID	Hecla Mining Co.	Lead-zinc ore.
24	Van Stone	Stevens, WA	Equinox Resources	Zinc ore.

[1] Includes Brushy Creek Mill.

TABLE 4

PRIMARY AND SECONDARY SLAB ZINC PRODUCED IN THE UNITED STATES

(Metric tons)

	1989	1990	1991	1992	1993
Primary:					
From domestic ores	229,870	230,470	217,691	r227,116	214,246
From foreign ores	30,435	32,234	35,585	r44,751	26,036
Total	260,305	262,704	253,276	r271,867	240,282
Secondary:					
At primary smelters	W	W	W	W	W
At secondary smelters	W	W	W	W	W
Total	97,904	95,708	122,457	127,623	141,472
Grand total (excludes zinc recovered by remelting)	358,209	358,412	375,733	r399,490	381,754

rRevised. W Withheld to avoid disclosing company proprietary data.

TABLE 5

DISTILLED AND ELECTROLYTIC ZINC, PRIMARY AND SECONDARY, PRODUCED IN THE UNITED STATES, BY GRADE

(Metric tons)

Grade	1989	1990	1991	1992	1993
Special High	113,819	116,647	W	W	W
High	79,145	86,006	96,469	100,250	89,934
Continuous Galvanizing	48,252	50,577	41,358	50,503	65,385
Controlled Lead	W	W	W	W	W
Prime Western	116,993	105,182	237,906	r248,737	226,435
Total	358,209	358,412	375,733	r399,490	381,754

rRevised. W Withheld to avoid disclosing company proprietary data, included in "Prime Western."

TABLE 6

SLAB ZINC ANNUAL PRODUCTION CAPACITY OF PRIMARY ZINC PLANTS IN THE UNITED STATES, DECEMBER 31, BY TYPE OF PLANT AND COMPANY

(Metric tons)

Type of plant and company	Slab zinc capacity	
	1992	1993
Electrolytic:		
Big River Zinc Corp., Sauget, IL	82,000	82,000
Jersey Miniere Zinc Co., Clarksville, TN	98,000	98,000
Zinc Corp. of America, Bartlesville, OK[1]	54,000	54,000
Electrothermic:		
Zinc Corp. of America, Monaca, PA[2]	146,000	146,000
Total available capacity	380,000	380,000
Total operating capacity	380,000	326,000

[1] Temporarily closed in Sept. 1993.

[2] Includes secondary capacity.

TABLE 7

U.S. CONSUMPTION OF ZINC

(Metric tons)

	1989	1990	1991	1992	1993
Slab zinc, apparent (rounded)	1,060,000	992,000	933,000	1,035,000	1,148,000
Ores and concentrates (zinc content)	2,107	2,178	W	W	W
Secondary (zinc content)[1]	249,122	245,692	W	W	W
Total (rounded)	1,311,000	1,240,000	1,165,000	1,276,000	1,367,000

W Withheld to avoid disclosing company proprietary data; included in "Total."

[1] Excludes secondary slab and remelt zinc.

TABLE 8

U.S. REPORTED CONSUMPTION OF SLAB ZINC IN 1993, BY INDUSTRY USE AND GRADE

(Metric tons)

Industry use	Special High Grade	High Grade	Prime Western	Remelt and other grades	Total[1]
Galvanizing	73,868	79,006	148,268	71,138	372,279
Zinc-base alloys	156,862	W	W	W	157,676
Brass and bronze	45,371	W	W	W	107,137
Zinc oxide	W	W	—	—	63,448
Other	W	W	W	—	73,169
Total	403,696	116,500	182,309	71,202	773,709

W Withheld to avoid disclosing company proprietary data; included in "Total."

[1] Data may not add to totals shown because of independent rounding.

TABLE 9

ROLLED ZINC PRODUCED AND QUANTITY AVAILABLE FOR CONSUMPTION IN THE UNITED STATES

(Metric tons)

	1992	1993
Production[1]	48,160	W
Exports	5,423	6,600
Imports for consumption	171	135
Available for consumption	44,391	W

W Withheld to avoid disclosing company proprietary data.

[1] Includes other plate more than 0.375 inch thick and rod and wire.

TABLE 10

ZINC CONTENT OF PRODUCTION AND SHIPMENTS OF ZINC PIGMENTS AND COMPOUNDS[1] IN THE UNITED STATES

(Metric tons)

	1992		1993	
	Production	Shipments	Production	Shipments
Zinc chloride[2]	6,332	6,309	4,235	4,238
Zinc oxide	[r]103,939	103,037	102,157	101,912
Zinc sulfate	28,236	27,763	20,506	19,855

[r] Revised.

[1] Excludes leaded zinc oxide and lithopone.

[2] Includes zinc content of zinc ammonium chloride.

TABLE 11

REPORTED DISTRIBUTION OF ZINC CONTAINED IN ZINC OXIDE SHIPMENTS, BY INDUSTRY[1]

(Metric tons)

	1989	1990	1991	1992	1993
Agriculture	1,520	1,764	1,822	W	1,584
Ceramics	2,780	2,618	2,973	W	W
Chemicals	22,462	20,723	20,177	W	W
Paints	4,695	4,579	3,848	3,669	3,419
Photocopying	W	W	W	W	W
Rubber	57,781	56,622	55,254	W	65,280
Other	13,277	12,681	11,990	99,368	31,629
Total	102,515	98,987	96,064	103,037	101,912

W Withheld to avoid disclosing company proprietary data; included in "Other."

[1] In addition, zinc oxide was imported as follows, in metric tons: 1989-59,557; 1990-49, 454; 1991-38,215; 1992-38,997; and 1993-35,874; distribution cannot be distinguished by industry.

TABLE 12

U.S. EXPORTS OF ZINC ORES AND CONCENTRATES, BY COUNTRY

(Zinc content)

	1992		1993	
	Quantity (metric tons)	Value (thousands)	Quantity (metric tons)	Value (thousands)
Australia	114	[r]$1,020	—	—
Belgium	[r]51,848	[r]29,630	48,641	$22,011
Canada	[r]136,576	[r]90,910	110,209	35,916
Finland	—	—	14,807	3,993
Germany	[r]28,854	[r]20,197	33,293	13,852
Haiti	4	51	—	—
India	—	—	154	40

[e]Estimated. [r]Revised.

[1] Wherever possible, detailed information on raw material source of output (primary—directly from ores, and secondary—from scrap) has been provided. In cases where raw material source is unreported and insufficient data are available to estimate the distribution of the total, that total has been left undifferentiated (primary and secondary). To the extent possible, this table reflects metal production at the first measurable stage of metal output. Table includes data available through July 28, 1994.

[2] Excludes zinc dust.

[3] Data may not add to totals shown because of independent rounding.

[4] All production in Czechoslovakia from 1989-92 came from Slovakia.

[5] Dissolved Dec. 31, 1992.

[6] Reported figure.

[7] Sales.

[8] Formerly part of Czechoslovakia; data were not reported separately until 1993.

[9] Dissolved in Dec. 1991.

[10] Dissolved in Apr. 1992.

ZIRCONIUM AND HAFNIUM

By Joseph M. Gambogi

Mr. Gambogi is a physical scientist with the Branch of Industrial Minerals. Domestic survey data were prepared by Debra Nolan, Section of Nonferrous Metals Data. World production data are provided by country specialists in the Division of International Minerals.

Zirconium and hafnium are relatively abundant in the Earth's crust; however, zircon (zirconium silicate) is the only naturally occurring mineral of commercial significance. Zircon is a byproduct of the mining and processing of heavy-mineral sands for the titanium minerals rutile and ilmenite. The major end uses of zircon are refractories, foundry sands (including investment casting), and ceramic opacification. Zirconium and hafnium metal are both contained in zircon at a ratio of about 50:1. Zirconium-clad fuel rods and hafnium control rods make up the core of nuclear reactors. Commercial-grade zirconium, unlike nuclear grade, contains hafnium and is used in the chemical process industries because of its excellent corrosion resistance.

World zircon production was estimated to have increased by 10% in 1993. A 5% growth in demand for zircon was attributed primarily to increased consumption by China in the ceramic tile industry. Consumption was estimated to have increased by 5%, and stocks of zircon were reported to be near record low levels.

DOMESTIC DATA COVERAGE

Data for zirconium and hafnium materials are developed by the U.S. Bureau of Mines from one voluntary survey of domestic operations. Of the 32 operations surveyed, all responded, representing 100% of the domestic data in table 1. *(See table 1.)*

BACKGROUND

Definitions, Grades, and Specifications

Zirconium and hafnium are chemically similar elements with atomic numbers 40 and 72, respectively. Both elements are classified in the periodic table as members of Group 4b, have only one oxidation state, +4, and have similar ionic radii. Owing to these similar properties, zirconium and hafnium are usually found together in nature.

Zircon purity is commonly measured by the combined zirconium dioxide (zirconia)-hafnium dioxide (hafnia) content. Hafnium occurs in zircon in a typical ratio of 1 part hafnium to 50 parts zirconium. Commercially available zircon typically grades 64.5% to 66% combined zirconia-hafnia. Zircon grades are similar on a worldwide basis, but no standard requirement exists.

Standard-grade zircon has a typical analysis of 65% minimum zirconium dioxide-hafnium dioxide, 0.25% maximum titanium dioxide, and 0.12% maximum iron oxide. Intermediate-grade zircon has a typical analysis of 65.5% zirconium dioxide-hafnium dioxide, 0.03% maximum titanium dioxide, and 0.1% maximum iron oxide. Premium-grade zircon has a typical analysis of 66% minimum zirconium dioxide-hafnium dioxide, 0.1% maximum titanium dioxide, and 0.05% maximum iron oxide. Zirconium metal for the chemical process industry is available in three American Society for Testing and Materials (ASTM)-approved grades: R60702 for unalloyed zirconium, R60704 for the tin-iron alloy, and R60705 for the niobium alloy. Zirconium alloys for the nuclear industry, the compositions of which are specified, are designated as Zircaloy-2, Zircaloy-4, or Zr-2.5 Cb.

Hafnium metal as produced by the Kroll process is called hafnium sponge or "Kroll-process" sponge or metal. After refining by the iodide process, the metal is called crystal bar.

Industry Structure

Zirconium ore minerals are sold by mine producers directly to processors, consumers, and commodity brokers. Primary ore concentrate of zircon and baddeleyite may be used in certain industrial uses with little or no processing, but most applications require additional processing. Processors grind the concentrates to specification for certain applications or convert zircon and baddeleyite to refined products such as zirconium metal, hafnium metal, alloys, high-purity zirconia, and other compounds. Extensive processing is required to produce ultra-purity powders and nuclear-grade metals. Processors producing oxide and metal are often partially integrated. Fabricated and semifabricated products are often sold directly to manufacturers.

Geology-Resources

Zircon is a common accessory mineral in igneous rocks. It is frequently found associated with silicic rocks, including granite, granodiorite, syenite, monzonite, and nepheline syenite. Zircon is also found in pegmatites, crystalline limestone, and the metamorphic rocks gneiss and schist. From an economic viewpoint, sedimentary placer deposits are the most significant.

Placer deposits originate when chemical and mechanical weathering liberates minerals from the source rock. This is followed by transport of the minerals to the sea by water, wind, and gravity. Upon reaching the sea, deposits of economic value form primarily by hydraulic sorting. Heavy minerals, including zircon, are concentrated by marine currents and wave action. Mechanical sorting by the sea and wind further sorts the grains to produce well-sorted beach deposits.

Technology

Economic concentrations of zircon are found in association with other heavy minerals such as ilmenite, monazite, and rutile. Heavy-mineral sand deposits usually are mined by floating cutterhead- or bucket wheel-dredges that handle up to 2,800 of sand per hour. Sand recovered by these techniques is sent to a wet mill and treated by wet-gravity methods, using spirals, cones, sluices, or jigs to produce a mixed heavy-mineral concentrate containing zircon. The mixed concentrate typically contains other economic minerals such as the titanium minerals, ilmenite, leucoxene, and rutile, and often smaller amounts of the rare-earth mineral monazite.

The mixed heavy-mineral concentrate is scrubbed, dried, and screened, and the individual heavy minerals are separated by electrostatic, electromagnetic, magnetic, and gravity processes. Zircon, in contrast to ilmenite, rutile, and many other heavy minerals, is nonconductive and can be separated, along with monazite, by electrostatic methods. Monazite, which is slightly magnetic and may be slightly higher in specific gravity, can be separated from zircon by electromagnet or by gravity concentration methods.

To obtain premium-grade zircon, the zircon concentrate from the electrostatic-electromagnetic circuit is subjected again to gravity concentration to reduce the content of aluminum- and titanium-bearing minerals. Certain zircon products are leached in an acidic solution to remove iron oxide and other grain coatings.

Zircon used in foundry and certain refractory applications is graded and sized, and in many cases, ground or milled to produce zircon flour. Foundry applications generally use zircon sand and flour mixtures, which may be treated with resin coatings and binders.

Zirconia is produced directly from zircon by either plasma fusion or electric arc techniques. The plasma method for zirconia production employs heating a finely divided zircon above its dissociation temperature to form small zirconia crystallites and glassy amorphous silica. The hot zirconia and silica particles are rapidly quenched and the silica removed by leaching with sodium hydroxide, leaving insoluble zirconia crystallites.

In electric arc production, zircon is heated to temperatures of approximately 2,500° C to produce a dissociation. The silicon component is vaporized and recovered as fumed silica, leaving a residual melt that is air quenched to form zirconia. A more complex electric arc method melts a mixture of limestone and zircon to form calcium zirconate and tricalcium silicate clinker. Cooling of the mixture disintegrates the mixture into a very fine powder composed of tricalcium silicate and lime and a coarser fraction of calcium zirconate crystals. The calcium zirconate is separated from the other constituents by either air classification or flotation. The acid-soluble calcium zirconate crystals are treated with acids or other reagents to form zirconia or zirconium salts. Other compounds of zirconium, such as the hydrous or carbonated oxide, acetate, sulfate, fluoride, chloride, and organic complexes, are usually prepared from zirconia or its salts by chemical reactions.

The deBoer-van Arkel iodide process, first described in 1925, is essentially a refining process and was commercially adopted in 1945 as the first practical method for producing ductile zirconium metal. Zirconium metal is reacted with iodine vapor at 200° C to form zirconium tetraiodide, leaving most impurities except hafnium in a solid state. The gaseous halide diffuses to a heated filament where, at 1,300° C, the reaction is reversed, depositing very high-purity elemental zirconium on the filament and regenerating iodine vapor for reuse. The process yields high-purity metal but is expensive to operate. Industrial-scale plants for producing zirconium metal are based on the Kroll process in which zirconium tetrachloride is reduced with molten magnesium in an inert atmosphere. The resulting mixture of zirconium metal sponge and magnesium chloride is vacuum distilled to remove the magnesium chloride. The zirconium is crushed, sized, and compacted to form a consumable electrode. The electrode is arc melted in an inert atmosphere to give a first-melt ingot. The first-melt ingot is then used as a consumable electrode to produce a metallurgically homogeneous second-melt ingot, which is machined to give a clean surface and readied for fabrication. Zirconium tetrachloride is produced by chlorinating zircon sand in a fluidized bed containing carbon at a temperature of about 1,150° C.

Byproducts and Coproducts

Zircon is mined from deposits with a heavy-mineral grade between 2% and 20%. The associated economic heavy minerals are ilmenite, leucoxene, monazite, rutile, and the tin minerals cassiterite and stannite. Its classification as a byproduct or a coproduct depends on the fraction of zircon in relation to the other minerals. If zircon and the titanium minerals are expected to account for the majority of the revenue, it is considered a coproduct. If minerals other than zircon provide the carrying costs of the operation, then zircon is considered a byproduct. Small quantities of baddeleyite are recovered as a byproduct of copper, phosphate, and vermiculite mining in the Republic of South Africa.

ANNUAL REVIEW

Issues

Processing of some mineral sands by certain methods results in the concentration of radioactive elements in the waste or byproduct streams. Monazite and xenotime, both rare-earth, thorium phosphates, are the usual minerals of consequence because 100% separation of a heavy-minerals deposit is impossible to obtain within economic considerations. Monazite inclusions within the zircon grains and/or ionic substitution of uranium, thorium, radium, and/or actinium for the zirconium and/or hafnium within the mineral lattice result in some radioactive contamination. Monazite processing to obtain rare-earth elements results in a relatively large production of a byproduct, thorium nitrate. Because demand for thorium is greater than that for rare earths, excess thorium has been placed in low-level storage sites such as those in Barnwell, SC, and Hanford, WA. Processing of zircon and the titanium minerals are much less of a problem because of lower concentrations in the bulk product. However, some concentration does occur in the zirconium chemical and metal industries. These industries have been adhering to Federal code in the handling, storage, and disposal of the byproduct "source material." Generally, if the combined weight of uranium and thorium exceeds 0.05%, the materials are considered to be sources for these radioactive elements. Domestic requirements for licensing source material, definitions, exemptions, and other pertinent information is found in the Code of Federal Regulations, Energy, 10, Part 40 (10CFR40).

Japan enacted strict importation and industrial guidelines on June 6, 1991, as a result of the July 1990 finding of radiation levels originating from titanium dioxide pigment plant wastes dumped in the Okayama Prefecture. Basically, the policy addresses the following key areas: protection of residential areas near plants and dump sites, air quality, strict containment of ore and processing wastes, and limits on the allowable dose rates exhibited by ores.

Production

Domestic production and consumption of zircon concentrates were withheld to avoid disclosing company proprietary data. Milled zircon production increased 4% during 1993, while zirconium oxide production increased 5%. *(See table 1.)*

U.S. mine producers of zircon in 1993 were RGC (USA) Mineral Sands, Inc. and E. I. du Pont de Nemours & Co. (Du Pont). Both producers mined heavy-mineral sand deposits in Florida.

Countless other end products also were produced from zircon. High-volume production included refractory bricks and shapes, alumina-zirconia abrasives, foundry sands and investment castings, milled and micronized zircon, zirconium chemicals, and zirconia. Zirconium chemicals and zirconia are further used to produce many other products in a wide range of applications. Examples of high-value production are cubic zirconia, technical zirconia ceramics, superalloy castings, zirconia textile refractories, and specialty chemicals.

In 1993, Du Pont began dredging and mineral separation operations at its Maxville site in Florida. The new dredge was reported to have extended the mine life to the year 2010. The startup of dredging operations at Maxville coincided with a partial shutdown of the company's nearby Highland operations.[1]

Markets and Prices

Published prices for zircon- and zircon oxide-related products varied considerably by product type. The domestic list price for standard- and premium-grade zircon were unchanged, while the price for imported grades of zircon increased slightly. The published price for imported baddeleyite concentrate containing 99%+ ZrO_2 decreased 17%, and prices for zircon oxides were unchanged. Published prices for zirconium and hafnium metal products were unchanged compared to those of 1992. *(See table 2.)*

Foreign Trade

In 1993, the United States was a net importer of zirconium ores and concentrates with 99% of the imports originating in Australia and the Republic of South Africa. According to the Bureau of Census, imports of zirconium ores and concentrates increased 87% compared with those in 1992. Exports under the same classification increased 29%. *(See tables 3 and 4.)*

World Review

Australia.—Australia continued to lead the world in the production of zircon concentrates. In 1993, production of zircon by Australian producers was estimated to be 409,000 tons. Increased production corresponded to a similar increase in exports.

ISK Mineral Sands was reported to have exhausted its Waroona mineral sands deposit near Perth, Australia. Owing to poor market conditions in the titanium minerals market, ISK delayed the development of its Darndanup heavy-mineral deposit near Bunbury, Western Australia. The delay in developing Darndanup resulted in the closure of ISK's Picton mineral separation plant.[2]

Canada.—Tiomin Resources Inc. announced the completion of pilot plant gravity separation testing on heavy-mineral concentrate produced at Natashquan, Quebec. Tiomin has contracted Mineral Deposits Ltd. to establish a design for a production-scale plant and produce a capital cost estimate.[3]

South Africa, Republic of.—As part of a major corporate restructuring, the South African conglomerate Gencor increased its interest in Richards Bay Minerals (RBM) from 25% to 50%. The remaining 50% interest was held by RTZ Corp. RBM operates Tisand Ltd., a heavy-mineral producer of ilmenite, rutile, and zircon, and Richards Bay Iron and Titanium Co., the world's largest producer of titanium slag.[4] At yearend, RBM awaited a decision by the South African Government for the approval of the development of the Lake St. Lucia heavy-mineral deposit. Reserves at St. Lucia were estimated to be 276 million tons containing 9.74 million tons of ilmenite, 0.94 million tons of rutile, and 1.66 million tons of zircon.

According to industry reports, Anglo American Corp. planned to commission its Namakwa Sands project in 1994. At full production, the project will produce 195,000 tons of slag, 38,000 tons of rutile, and 140,000 tons of zircon annually.

Vietnam.—Westralian Sands Ltd. was reported to be investing in the modernization and possible expansion of a heavy-mineral operation in Ha Tinh, Vietnam. The investment represented a 60% interest in the Hah Tinh operation. The remaining interest was held by the Provincial government and the Vietnamese Ministry of Heavy Industry.[5] *(See table 5.)*

OUTLOOK

Zircon is a byproduct of heavy-mineral operations whose primary products are titanium-bearing ores and concentrates. Almost all titanium ores are consumed for producing titanium dioxide, the predominant white pigment used in most industries. Therefore, zircon supply is largely driven by demand for titanium dioxide pigments. Because global demand in the titanium pigment industry is expected to increase moderately over the next few years, the available supply of zircon is also expected to increase moderately.

The outlook for demand of zircon materials is determined by the major consuming industries, including the steel, glass, refractories, and ceramics markets. During the late 1980's, a temporary shortage of material caused prices for zircon products to soar. In reaction to rising prices and the material shortage, consuming industries developed substitute materials, which had eroded zircon demand for a period of several years. However, zircon demand is expected to increase moderately over the next few years.

Total	979,241	[r]852,012	794,824	[r]773,684	787,085

[e] Estimated. [r] Revised. W Withheld to avoid disclosing company proprietary data.

[1] Includes data available through July 15, 1994.

[2] Includes production of baddeleyite-caldasite.

[3] Reported figure.

[4] Includes production of baddeleyite.

[5] Includes production of zircon and baddeleyite.

[6] Dissolved in Dec. 1991.
