the industry that followed destruction of power plants by the retreating German forces and restriction of production to permitted power consumption under American Army regulations. Spanish production was low in 1945 chiefly because of large stocks of metal on hand in that country at the beginning of the year. Canada's recently developed mines were idle in 1945, and Mexican output was only 63 percent of that in 1944.

REVIEW BY COUNTRIES

Australia.—From time to time a small output of mercury has come from Australia, but this country depends on imports to fill internal needs for the metal. Only 12 flasks were recovered in 1944 compared with 15 in 1943 and with a peak during the war period of 37 flasks in 1940. Meanwhile imports aggregated 689 flasks in 1944, 1,323 in 1943, 1,460 in 1942, and 1,232 in 1940. Before the war mercury was imported chiefly from Italy and Spain, with Canada, New Zealand, the United States, and the Union of South Africa supplying the market after the war began.

Canada.—Recent activity in mercury mining in Canada coincided with war needs for the metal; production began to attract international attention in 1940, when 2,024 flasks were recovered, rose to a peak of 22,240 in 1943, and terminated when requirements appeared to be taken care of in 1944, ahead of the war's end. There was no production in 1945. The principal work was at the Pinchi Lake deposit, mentioned in previous reports of this series. The plant at Pinchi Lake had been enlarged from the original 50-ton unit in 1940 to the 1,200-ton daily capacity plant at the property when it closed in July 1944. Both Consolidated Mining & Smelting Co. of Canada, Ltd., which operated the Pinchi Lake deposit, and Bralorne Mines, Ltd., the other important mercury-producing company in Canada, have major interests in the production of lead, zinc, and gold, and the mercury operations represented a relatively minor activity for either company.

Germany.—Since the end of World War II, data that confirm the belief that record-breaking quantities of mercury were entering and being used in Germany have become available. The only important source of mercury in Germany is the Landsberg mine and plant at Obermoschel in the Rheinische Palatinate near Bingen. The following figures on production, imports, and exports (converted to flasks) were published [13] soon after the war's end.

Mercury produced in, imported into, and exported from Germany, 1935–44, in flasks of 76 pounds

Year	Production	Imports	Exports
1935	116	24,918	435
1936	1,102	19,958	348
1937	174	25,904	174
1938	1,363	32,866	58
1939	1,102	24,802	116
1940	870	84,326	87
1941	522	66,457	551
1942	522	49,372	435
1943		60,076	5,570
1944		24,860	1,363

[13] Bureau of Mines, Mineral Trade Notes: Vol. 21, No. 2, August 20, 1945, p. 22.

The following notes regarding mercury consumption in Germany were recently published: [14]

The war expansion of the German caustic soda and chlorine industry was in mercury cells, although existing Billeter cell installations were operated as required. The trend to mercury cells increased rapidly in 1937 at which time mercury was very cheap in Germany due to political connections with Spain. The Germans were well satisfied with the mercury cell, however, and it did eliminate expensive evaporation equipment. The largest cells under construction at the close of the war were 28,000 amp. which were believed to be the largest capacity chloride cells in the world. The usual 16,000 amp. cells required 4.5–5.0 v. and had a current efficiency of 94–95 percent.

A new and very interesting vertical rotating mercury cell was used in the most recent plant expansions. This cell required much less floor space than the conventional horizontal cells. A trend toward liquefaction of chlorine by means of higher compression followed by water cooling without artificial refrigeration was noted. A new type of rectifier, which was alleged to operate at high efficiency in the lower voltage range, was employed in at least two of the newer installations.

German chlorine practice was described in detail later, and the references are given under the section on Consumption and Uses.

It is reported [15] that American occupation forces found 51,500 flasks of mercury stored in the Mansfeld mine near Eisleben.

Italy.—Figures made available recently [16] show that the Italian mercury industry produced at new record high rates during World War II, the production peak of 94,160 flasks for 1941 surpassing the prewar peak level of 67,000 for 1937–39 by more than 40 percent. Italy's production of 94,160 flasks was the largest output for any country for any year up to the present. Production figures, including estimates for the period of occupation by Germany, are given in the foregoing world table. For 1940 to 1945 production totaled 396,000 flasks. Exports were reported as 73,680 flasks in 1940, 47,544 in 1941, 41,278 in 1942, 46,000 in 1943, none in 1944, and 4,400 in 1945, or a rounded total of 213,000 flasks for the 6-year period. Since Italian consumption of mercury is small and is reported to permit exportation of 85 to 95 percent of production and since stocks of mercury at the beginning of American occupation of Italy were small, the large difference between production and exports may have resulted from unreported requisitioning of considerable mercury by the Germans. Stocks at the end of 1945 exceeded 25,000 flasks, and the production rate at that time approximated 3,500 flasks a month.

For the period 1938–43 the Abbadia San Salvatore mine produced 46 percent of Italy's total output of mercury, Solforate del Siele 32 percent, other Tuscany mines 7 percent, and Idria 15 percent. At the end of 1945 the Idria mine was in the hands of the Yugoslavs.

Conditions at Italian mines when the Americans arrived were described briefly in the 1944 report of this series. The Abbadia San Salvatore, owned by Società Anonima Mineraria Monte Amiata, in which the Italian Government has a controlling interest, on the east slope of Monte Amiata, is developed by adits, shafts, and several levels to a depth of 165 meters below the surface. The horizontal cut-and-fill method is used to extract the ore. Waste is sorted from the ore in the stopes and used for back filling. Compressed-air rock drills and electric locomotives were temporarily replaced by hand drilling,

[14] Chemical and Metallurgical Engineering, vol. 52, No. 9, September 1945, p. 200.
[15] Bureau of Mines, Mineral Trade Notes: Vol. 21, No. 2, August 20, 1945, p. 14.
[16] Several reports prepared by C. A. Botsford, minerals attaché, Rome, Italy.

hand tramming, and animal haulage because of the power shortage, but this situation is being eased. The Siele mine, situated 7 miles south of Monte Amiata and owned by Società Anonima Stabilimento Minerario del Siele, is developed by a shaft and several levels. Mining methods are similar to those at the Abbadia mine. The Abbadia mine uses tower furnaces for the coarse ore and Cermak-Spirek furnaces (similar to the Scott furnace) for the fines. The Siele and most of the other mines use the Cermak-Spirek furnaces only.

Based on the 1940 output, the developed ore reserves in Tuscany are sufficient for about 8 years, whereas the tonnage of probable and possible reserves indicates that these mines will continue to be productive for many decades. The grade of ore mined has averaged 1.29 percent in recent years. Reserves at the Idria mine, Province of Gorizia, are said to be limited to less than a decade at a normal rate of production. Production in 1938–43 averaged 0.6 percent mercury.

Mexico.—Production of mercury in Mexico during the past few years was an important increment to the total Western Hemisphere supply when trade with European countries was difficult or impossible. United States Government mercury contracts with Mexico were terminated in 1944. Production of 26,063 flasks in that year was 20 percent below the peak for 1942, which in turn approximately equaled the total for the 5-year period 1935–39. Production of 16,443 flasks in 1945 was 37 percent less than in 1944 but continued at more than two and one-half times the prewar levels. Exports from Mexico totaled 14,968 flasks in 1945 compared with 23,525 flasks in 1944. After the beginning of World War II, exports were destined largely for the United States.

Peru.—Two furnaces, with a combined daily capacity of close to 250 tons, were under construction at the old Santa Bárbara mine a few miles south of Huancavelica in 1945. The proposed construction of the two plants was mentioned first in the report of this series for 1942, but failure to receive shipping permits to move the plants out of the United States, where they were designed, and shortage of construction materials in Peru delayed completion of the plants.

Spain.—At the outset of 1945 large stocks of mercury were held at the Almaden mine, and the mine was inoperative. Production was begun at the furnaces in May from the treatment of ores stocked in 1944. Spain's total output for the year was 40,089 flasks. The grades of ore mined in recent years have been as follows: 1940, 6.1 percent; 1941, 7.0 percent; 1942, 8.0 percent; and 1943 and 1944, 5.8 percent.

The total for 1941 was Spain's all-time production peak. Almaden has had the longest record of production and the largest production total of all mercury mines in the world. According to Hewett,[17] production probably was begun in Almaden about 400 B. C. Recorded production dates back to 1500 and is as follows:

Period	*Flasks*	*Period*	*Flasks*
1500–1699	684, 826	1875–99	1, 143, 460
1700–1799	1, 311, 693	1900–1925	737, 375
1800–1849	1, 093, 714	1926–44	937, 339
1850–74	633, 333		
			6, 540, 740

[17] Hewett, D. F., Cycles in Metal Production: Am. Inst. Min. and Met. Eng., Tech. Pub. 183, 1929, p. 21.

Turkey.—Production of mercury in Turkey declined from 815 flasks in 1936 to 97 in 1944; in both years the total came from the Ahirli and Karareis mines in the Karaburun district of Izmir.

United Kingdom.—In October 1945 control prices for mercury, which had been held at £69 to £69 15s. a flask, depending on quantity, from August 1942, were reduced £38 10s. a flask to £30 to £31 5s. a flask. The new price is equivalent to over $120 a flask and thus continued above the price in the United States. A plant for the production of the new battery that contains mercuric oxide was constructed recently at Belfast, Ireland, and was to be operated by P. R. Mallory & Co., Inc., which controls the patents for the manufacture of the batteries.

TIN

By C. E. Nighman and J. B. Umhau

SUMMARY OUTLINE

GENERAL SUMMARY

Of greatest importance to tin consumers and producers in 1945 was the unexpectedly early fall of Japan in August, which made it possible to begin reoccupation and rehabilitation of the Far East tin provinces. As the first authentic reports on the physical status of the tin mines, plants, equipment, and smelters and on economic and political conditions were received late in the year and early in 1946, it became increasingly evident that the present tin supply could not be greatly increased for 2 years or more. Because of an expected great world demand, it thus appeared requisite to continue restraints on use to avoid a run-away market and to permit equitable distribution of the apparently shrinking total world supply. However, in the light of newly available data on wartime experience, it appears that the world's basic tin requirements should be reappraised. After the United States became directly involved in the World War—that is, for 1942–45—world pig-tin consumption was, on the average, only 100,000 tons, of which at least 10,000 tons were consumed in bronzes for wartime ship construction. For that period there is at hand no evidence of the imposition of undue hardships, at least, on ultimate users of tin-bearing materials. In other words, the record shows that the inelastic portion of use is substantially lower than commonly has been assumed in recent years. To reach a 150,000-ton annual consumption level, much less than the figure of 250,000 tons forecast by the Tin Producers' Association, the future price of tin cannot greatly exceed the current price between 50 cents and 60 cents a pound.[1] As a corollary, if the tin industry is to achieve any reasonable stability there can be no room for the reintroduction of marginal or uneconomic enterprises. In view thereof and of Bolivia's peculiar position, it appears inevitable that some type of international accord for production and marketing will have to be established.

[1] In the Postwar Outlook for Tin, Minerals Yearbook, 1943, pp. 732–744, the authors had already pointed to this conclusion. See also Minerals Yearbook, 1944, p. 718.

[1] Including tin content of ores used direct to make alloys.
[2] Figures cover foreign only; domestic not separately recorded.
[3] Ceiling price, 52 cents.

No domestic production of ore or concentrates was recorded in 1945. Worthy of note was the recession of world production to or near the lowest point in 45 years. Consumption of primary tin in the United States, 55,640 long tons, was nearly 6 percent below that of 1944 and in the United Kingdom, 16,920 tons, was about 8 percent below that of the preceding year and at the lowest point for more than 10 years. Domestic reversion to the peacetime consumption pattern was most in evidence in the drop of approximately 5,000 tons or about 34 percent in the use for bronze as a result of the sharp contraction in the ship-construction program. On the other hand, tin-plate and solder uses rose 4 percent and 24 percent, respectively, compared with the previous year. A parallel change was observed in the United Kingdom. Imports of metal and concentrates, 41,967 long tons (tin content), were 14 percent below those of 1944. Slightly more than half of the decline was in the form of metal from the Belgian Congo as a result of diversions to Europe after VE-day and about 20 percent owing to a decrease in Chinese receipts. The remainder, in the form of concentrates, was mostly attributable to the drop of 1,717 tons in Bolivian receipts. Tin plate and terneplate, which were, as usual, the major exports, rose 8 percent over the 1944 level to 471,149 long tons and although about 21 percent below the 1942 peak were nevertheless the second highest of record.

The year-end tin stock position remained relatively satisfactory, although declining during the year about 15,400 tons to 95,000 tons, divided as follows: Industry pig-tin stocks (including anodes and reclaimed tin), 27,500; Government, 35,000; and in ores, 32,500 tons. Of the Government stocks, 12,140 tons of pig tin are held by the Navy and Procurement Division of the Treasury Department and are not subject to distribution. The Civilian Production Administration estimated that 18,000 tons (tin content of ore and metal) are tied up in the Longhorn-smelter working stocks. As a consequence, the actual status was much inferior to the statistical position, and in view of the probability that new supply in 1946 would not be greater than in 1945 existing use controls would have to be extended at least through 1946. Although in the United States total stocks decreased on the average about 13,000 tons a year since the end of 1941, British stocks rose at an average annual rate of about 2,300 tons to 33,200 at the end of 1945 or nearly 2 years' needs at the 1943–45 average virgin-tin consumption rate. The United Kingdom from stock and new supply will therefore furnish much of the Continental and Empire requirements as well as make some deliveries to the United States. Up to the end of 1945, the distribution of all tin supplies to the United Nations had been in the hands of the Combined Raw Materials Board. It was then succeeded by the Combined Tin Committee, which allocates all metal, including captured enemy stocks, to claimant nations. Interim allocations for the first half of 1946 made in March indicate that the United States will receive about three-eighths of the available metal.

The Government tin smelter produced nearly 41,000 long tons of tin in 1945 and at the end of the year was operating at about a 44,000-ton rate.

The domestic price of Grade A tin was held constant at 52 cents a pound, unchanged since 1942. The British internal price was maintained for the second consecutive year at £300 a long ton (53.8 cents a pound) for standard tin, delivered buyer's works. The first price break was indicated in September, when the British set a price of £375 (67.3 cents a pound) for export. At the close of the year Office of Metals Reserve announced that the price for export would be raised above the internal price and set 58 cents a pound in March 1946.

GOVERNMENT TIN OPERATIONS

In 1945 all imported metal and concentrates were again for Government account. Commitments were made for 9,440 long tons of refined tin and 67,056 long tons (gross weight) of ore and concentrates compared with 15,732 tons and 84,318 tons, respectively, in 1944. Bolivia was to furnish 90 percent of the raw material, including a substantial part of the Patiño production that was under long-term contract for delivery to the United Kingdom, the remainder to be supplied by Belgian Congo and French West Africa. Belgian Congo also supplied about 55 percent and China 34 percent of the pig tin. The remainder comprised captured German and Japanese tin. The German material contained some solder, whereas the Japanese tin, found in the Philippines, was of high quality, essentially of Banka grade. Of the Chinese tin that had been flown out to India in 1944, a portion was diverted to other destinations, and about 1,900 tons arrived in the United States. At the end of the year, 19,467 tons of ore and concentrates were afloat or awaiting shipment from foreign ports.

Operation of the Longhorn tin smelter at least into 1947 appears necessary to meet metal needs, entirely aside from the national security aspect that has attained wide acceptance. Early in 1946 the Director of War Mobilization and Reconversion, in Congressional hearings relating to the extension of Reconstruction Finance Corporation authority to purchase foreign ores, recommended that the operation be maintained, as it was essential to national defense and would otherwise benefit the Government. In March 1946 permission [2] was

[2] 79th Cong., 2d sess., Public Law 328, approved Mar. 21, 1946.

given to Reconstruction Finance Corporation to purchase ores and concentrates deemed necessary to keep the smelter running, without limit as to time, and it was freed also from the provisions of the Emergency Price Control Act of 1942, as amended, and other enactments that forbade or limited subsidized or loss sales. Under the 52-cent-a-pound price fixed by the Office of Price Administration, when the cost of tin was essentially the same and with cost of Bolivian ores delivered in the neighborhood of 65–67 cents, the indicated smelter loss was about $12,000,000 in 1945.

The original 5-year ore-purchase contract with Bolivian producers was terminated June 30, 1945. Meanwhile, negotiations for renewal had been undertaken but were not concluded until September. The new contract runs only 1 year. Under its terms, payments for "payable" tin (total less soluble tin) were set on a quarterly basis, beginning with 63.5 cents a pound for the first quarter and declining successively 1.5, 1.5, and 2.0 cents a pound to 58.5 cents a pound in the fourth, f. o. b. vessel at Antofagasta or Arica, Chile, or Mollendo, Peru. The 1½-cent production incentive bonus of the preceding amended contract was retained, as were the smelting-loss deduction, treatment charges, and penalties for impurities. The rejection point remained as before at 18 percent payable tin.[3] In the first quarter of 1946 other contracts were made for purchase of Netherlands East Indies concentrates and metal.

GOVERNMENT CONTROLS

During 1945 the use of tin was controlled principally by War Production Board Orders M–43, tin conservation, and M–81, containers. There were numerous amendments to the orders that were more in the nature of adjustments among commodity group uses to meet changing conditions as hostilities came to an end and reconversion began than actual relaxations. Of the total supply in the country, about 40,000 tons are currently tied up in smelter working stocks, in in-process materials, and in industry stocks. It is believed that this quantity is not reducible to any extent. As the remainder, available for consumption, has become progressively smaller for 4 years, while the increments to be expected from world production (unlikely to be over 110,000 tons in 1946 and 175,000 tons in 1947) would not meet the anticipated new tin needs, further drafts will have to be made on the residual accumulation. Restrictions, but on a declining scale, thus will probably extend into 1947.

The general effectiveness of the conservation measures is reflected in the 4-year war-period average of virgin-tin consumption of about 54,000 long tons, notwithstanding some extraordinary wartime needs for tin-bearing materials. The major saving of tin was again in tin plate. The output of electrotinned plate in 1945 was 860,000 short tons, an increase of one-third over that of 1944, and it was equivalent to one-third of the total tin-plate production. Change in packing quotas and modification of class of plate permissible for various packs resulted in slight increases in average tin weights per ton. Electrolytic tin plate averaged 11.9 pounds and hot-dipped plate 27.2 pounds compared with 11.82 and 26.24 pounds in the preceding year. How-

[3] The text of the agreement was published in American Metal Market, vol. 52, No. 177, Sept. 18, 1945, p. 5.

ever, as a consequence of the greater use of electrolytic plate, the average coating for all tin plate was, at 21.9 pounds, 0.4 pound less than in 1944. In the other large fields of application, a sample based on the returns of identical companies heretofore used showed essentially no change. In bronze and brass and in solder the indicated average tin content was the same as in 1944, 5 and 27 percent, respectively, whereas in babbitt it declined to 12 percent against 14 percent in 1944.

INVESTIGATION OF DOMESTIC TIN DEPOSITS

Field studies of tin occurrences were continued in 1945. The Bureau of Mines and the Geological Survey, as a part of their strategic mineral exploration programs, investigated deposits in Alaska and California. A lode deposit of tin on the Seward Peninsula of Alaska, which promises greater potentialities than any other known domestic source of tin, was tested by diamond drilling, and another deposit was explored in California. The Bureau of Mines has made a general survey of tin in California in which 37 places were visited and sampled. The survey purposed to investigate all reported tin occurrences and was not confined to the few deposits claimed to be commercial but extended to any that might yield substantial tonnages under pressure of necessity that made cost unimportant. The authors [4] in their report on the survey state:

> Although traces of tin were found in many places, nothing that suggested a tin mine was found anywhere, and it is difficult to base much hope for appreciable future tin production upon anything found thus far in California.

Page and Thayer, and Wiese and Page, of the Geological Survey, made geological reports accompanied by numerous maps of the Temescal and Gorman tin districts, California.[5]

The tin deposits of Riverside County, Calif., including the Temescal tin mine (Cajalco) owned by Tinco Corp., Richmond, have been described by Tucker and Sampson.[6]

In 1942 the Dodge Construction Co., Fallon, Nev., operating under lease from the owner, secured a Government loan for the purpose of working the Temescal tin mine. After a net expenditure of $125,000 by the Government, the project was abandoned as unsuccessful. A modern 100-ton mill was erected, and 1,400 tons of material were put through it, with a recovery of less than 1 pound of tin oxide per ton.

DOMESTIC PRODUCTION

MINE OUTPUT

The expectation that tin may be mined commercially—if at all—in the United States may well be dismissed. The Bureau of Mines received no reports of production in 1945. Results of recent organized investigations have been recited above, and preceding chapters of

[4] Bedford, R. H., and Johnson, F. T., Survey of Tin in California: Bureau of Mines Rept. of Investigations 3876, 1946, 14 pp.

[5] Page, L. R., and Thayer, T. P., Preliminary Report on the Temescal Tin Deposits of Riverside County, Calif. Wiese, J. H., and Page, L. R., Final Report on Tin Deposits of the Gorman District, Kern Co., Calif. These reports were not published but placed in open file. They may be consulted at the Geological Survey library, Washington, D. C., at its regional office, Salt Lake City, Utah, and at the office of the California Division of Mines, San Francisco.

[6] Tucker, W. B., and Sampson, R. J., Mineral Resources of Riverside County: State of California Dept. of Natural Resources, Division of Mines, California, Jour. Mines and Geology, vol. 41, No. 3, July 1945, pp. 151–154.

this series have described for 60 years or more various well-planned and misdirected efforts to find tin. The total yield has not exceeded a few hundred tons of tin—not enough to supply the country's needs for a month, even at the extremely low level of use set up in 1943.

Mine production of tin (content) in the United States, 1941–45, by States

Year	Long tons				Value
	Alaska	South Dakota	Other States [1]	Total

[2] Included in total.

SMELTER OUTPUT

Domestic tin smelters produced 40,475 long tons of tin in 1945, a peak two and a half times that recorded during World War I. This was accomplished almost wholly by the Government's Longhorn tin smelter, where output was one-third greater than in 1944. Its production rose uninterruptedly from September 1944 through July 1945 and then after 2 months continued to set new monthly records. In December it operated at a 44,000-ton annual rate and was closely approaching the program set for 1946. It thus became the world's largest single operating smelter. Maintenance of the rate of output will depend largely on the timing of receipts of high-grade material, which of late, however, has constituted only 10 to 15 percent of the charge.

Improvement in operating efficiency was noted during the year. Two reverberatories were converted into one unit. Results were as satisfactory as could be expected, giving consideration to limitations placed on design by existing construction. Among other plant betterments were the replacement of a tubular by a water-tube waste-heat boiler, which had not been procurable earlier; continuous mechanical dust removal from the main roaster flue; and improvements to the Cottrell plant. In keeping with the general industrial pattern, the work week was cut to 40 hours and pay ratio increased 18 percent in the fall. Processing costs have not been disclosed, but it has been said that on high-grade material originally treated they averaged about 2.3 cents a pound and rarely reached 3.5 cents. In the nearly 4 years of operation, the cost of labor and supplies rose greatly, while the grade and quality of ore treated declined heavily. In consequence, treatment costs have been estimated to be as much as 6.5 cents. The rise in operating expenses plus the difference between the ore costs and fixed ceiling selling price of metal indicate that the over-all Government tin operations were subsidized in 1945 to the extent of about $12,000,000.

717372—47——47

Shipments by the Longhorn smelter were 39,974 long tons (37,112 in 1944), of which 37,495 tons (32,856 in 1944) were Three Star and the remainder Grade F. Industrial users received about 25,733 tons, and the remainder was distributed to Government warehouses in Brooklyn, Chicago, St. Louis, and Texas City and to brokers or jobbers.

Only two privately owned smelters were in operation in 1945—the American Smelting & Refining Co. and the Vulcan Detinning Co.

SECONDARY TIN

Renewed efforts to bring out scrap, especially lead-base, that was acutely short, although tin-base was not neglected, resulted in an 8-percent rise in total secondary tin recovered in 1945. Detinners' recovery showed a net slight decrease. Corresponding to the greater tin-plate output, tin obtained from new clippings was up 10 percent over 1944 (2,375 long tons). The effect of the increasing component of electrolytic plate was again observed in a 13-percent rise in the tonnage treated. Tin recovered from old cans was 26 percent (about 340 tons) below that in 1944. At no time could the salvage campaign be counted a great success, and notwithstanding the deterioration in the tin-supply position it broke down seriously after termination of the war appeared imminent. In the more effective 3 years 1943–45 the recovery was about 4,000 tons annually or less than 5 percent of the total secondary tin produced. It is worthy of comment that, in the last 2 years at least, the Army, from its various camps and posts, supplied more than one-quarter of the gross weight of prepared cans returned and more than that of the tin recoverable therefrom.

Secondary tin recovered in the United States, 1925–29 (average) and 1941–45

Year	Tin recovered at detinning plants			Tin recovered from all sources			
	As metal (long tons)	In chemicals (long tons)	Total (long tons)	As metal (long tons)	In alloys and chemicals (long tons)	Total: Long tons	Total: Value
1925–29 (average)	900	2,000	2,900	7,500	23,100	30,600	$38,034,120
1941	4,500	950	5,450	5,300	32,200	37,500	43,722,700
1942	4,700	200	4,900	5,200	28,700	33,900	39,434,720
1943	3,900	200	4,100	4,700	29,100	33,800	39,332,800
1944	3,350	310	3,660	3,800	25,300	29,100	33,892,560
1945	3,150	400	3,550	3,300	28,100	31,400	36,538,320

The Government-owned detinning plant at Birmingham, Ala., continued to operate, but, as heretofore, most of the tin was recovered at privately owned plants. The 1944 chapter of this series was in error in reporting complete discontinuance of other metal-recovery operations. In 1944 the National Lead Co., as agent of the Metals Reserve Company, recovered nearly 100 long tons of tin (revised) from type metal and in 1945, 10 tons. The total auxiliary recovery through 1945 from collapsible tubes and type metal was 1,165 long tons, most of which reappeared in alloy form. The chapter in this volume, Secondary Metals—Nonferrous, contains details on secondary tin recovery.

CONSUMPTION

APPARENT CONSUMPTION

In 1945 the apparent consumption of primary tin was 11 percent higher than in 1944. Apparent consumption is computed by adding domestic smelter production to net imports. It does not take into account fluctuations in consumer, dealer, and Government stocks; consequently, it may deviate widely from actual consumption as measured in finished products, which in 1945 was 16 percent above the calculated figure. Nevertheless, the apparent consumption series is useful as an indicator of long-term trend. The data for 1939–45 are given in the subjoined table.

Apparent consumption of tin, 1939–45, in long tons [1]

1939	67, 997
1940	123, 537
1941	141, 618
1942	42, 512
1943	31, 749
1944	43, 379
1945	48, 033

[1] The series 1910–38 was published in Minerals Yearbook, 1939, p. 680. Exports of domestic tin are not included in 1931–41, inclusive. They are included in the figures for 1942–45 and are 244, 398, 405, and 708, respectively.

CONSUMPTION BY USES

Military successes, that had restored much of the freedom of the seas by the end of 1944, and the defeat of Germany, and unexpectedly early surrender of Japan in 1945 left their imprint on the use pattern of tin. Usual prewar relationships were, however, not fully in evidence. The accompanying tables, prepared from reports made to the Bureau of Mines, show actual consumption of primary and secondary tin, both where it entered process and left as finished products.

Consumption of primary and secondary tin in the United States, 1941–45, in long tons

	1941	1942	1943	1944	1945
Stocks on hand Jan. 1	56, 999	[1] 67, 421	[2] 43, 853	[3] 34, 735	[4] 27, 391

[1] Not including 2,700 tons in transit or in warehouses.
[2] Not including 78 tons in transit.
[3] Not including 316 tons in transit or in warehouses.
[4] Not including 1,941 tons in transit or in warehouses.
[5] 1941: Primary, 114,281; secondary, 6,879; terne, 1,851; scrap, 26,112. 1942: Primary, 33,126; secondary, 5,096; terne, 405; scrap, 26,941. 1943: Primary, 40,548; secondary, 4,462; terne, 188; scrap, 29,903. 1944: Primary, 55,323; secondary, 2,536; terne, 228; scrap, 28,883. 1945: Primary, 54,663; secondary, 2,623; terne, 312; scrap, 28,498.
[6] Not including 1,600 tons in transit or in warehouses.
[7] Includes small tonnage of secondary pig tin.

Continued application of conservation measures and shift in emphasis from production of war materials to those of peace resulted in 7 percent lower total consumption than in 1944, with the quantitative change shared nearly equally between primary and secondary tin. The ratio of the primary to total secondary tin, 2 : 1, compared with a 4 : 1 ratio in 1935–39, a rather striking evidence of what may be accomplished in tin conservation. As has been the case for many years, tin plate (and terneplate) holds the premier position as a user of virgin tin, taking 47 percent of the new metal. The increase of 1,100 tons or 4 percent compared with 1944 and 20 percent over the 10-year low of 1943 reflected the rise in tin-plate output as modified by the large electrolytic component. In second place was solder, up 24 percent over 1944, which accounted for nearly 20 percent of the virgin tin used and was at the 1935–39 average. In part, the large increase was due to the dearth of secondary material, permissible upgrading in tin content, and release of tin for automobile-body solders. The most-pronounced change was the drop of nearly 4,700 tons, or one-third, in the requirements for bronze. Consumption for babbitt was off about 28 percent compared with 1944, but the quantity used was close to the prewar (1935–39) and wartime (1942–45) averages. Other uses of virgin metal accounted for about 9 percent, of which nearly half was for tinning.

Consumption of tin in the United States, 1943–45, by finished products (tin content), in long tons

Product	1943			1944			1945		
	Primary	Secondary	Total	Primary	Secondary	Total	Primary	Secondary	Total

[1] Includes "Miscellaneous."
[2] Includes 5 tons of secondary for pewter.
[3] Included under "Chemicals."

In respect to the consumption of primary plus secondary tin, there was no change in order of rank compared with 1944. For the third consecutive year, bronze held first place, but by only a narrow margin over tin and terneplate. The expansion of the ship-building program that began in 1939 reached its peak in 1944. The effect of naval construction on tin needs was apparent. According to reports made to the Bureau of Mines, production of tin bronzes—that is, the five principal types having 5 percent tin or over—rose from 187,000 short tons in 1941 to 340,000 tons in 1944 and then dropped about one-quarter to 259,000 tons in 1945. In this period the ratio of output of these bronzes to total bronze and brass ingot production was fairly stable at from 62 to 68 percent. Quantitatively, however, the tin content of the bronzes varied essentially with the production, but relatively it rose from about 48 percent of the total in bronze and brass to more than 65 percent and receded in 1945 to about 58 percent. In view of the tremendous tonnage demands for bronze, it is apparent that the secondary supply usually available would be inadequate. Consequently much new metal was required, and a large part will sooner or later return as scrap, tending to cut primary tin needs even below the prewar level for bronze. The downward movement in babbitt was in response to the sharp year-end cut-back in production of white-base antifriction bearing metals.

FOREIGN TRADE [7]

Pig tin has ceased to dominate the import field since 1943, when the United States was denied access to former Asiatic sources. Previous procurement agreements abroad permitted suppliers to divert part of their shipments after VE-day from the United States to western European and other countries, while large quantities of ores were afloat or stored abroad; consequently, imports of metallic tin decreased 37 percent and ores 6 percent from 1944 levels. Metallic tin (882 tons) acquired by the Army from Germany and the Philippines and imported in 1945 has not been included. The Longhorn smelter, Texas City, Tex., was the destination of virtually all tin concentrates imported in 1945. The tin content of the material imported was 33,527 tons (35,548 in 1944). Bolivia continued to be the principal source, supplying 25,984 tons, compared with 27,701 in 1944. Imports from other sources included: Belgian Congo, 7,401 tons (7,549 in 1944); French Africa, 129 (177 in 1944); Mexico, 13 (61 in 1944); and Argentina, none in 1945 (60 in 1944).

Foreign trade of the United States in tin and tin concentrates, 1941–45

Year	Imports				Exports of tin (metal)[1] (long tons)
	Tin (metal)		Tin concentrates (tin content)		
	Long tons	Value	Long tons	Value	
1941	140,873	$149,569,328	28,670	$27,671,689	1,094
1942	26,753	29,311,113	28,933	21,422,896	[2] 165
1943	12,030	13,089,540	21,857	24,804,842	[2] 1,372
1944	13,338	15,049,200	35,548	32,346,412	[2] 438
1945	8,440	9,163,425	33,527	27,262,436	[2] 174

[1] Imported as pigs, bars, etc., and exported as such.
[2] In addition 244 tons of ingots, pigs, etc., were exported in 1942, 398 tons in 1943, 405 tons in 1944, and 708 tons in 1945; accounted for as domestic exports in "Exports of miscellaneous tin manufactures."

[7] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

Tin [1] imported for consumption in the United States, 1944–45, by countries

Country	1944		1945	
	Long tons	Value	Long tons	Value
Belgian Congo	10,000	$11,199,813	6,494	$6,853,883

Foreign trade in miscellaneous tin manufactures and tin compounds, 1941–45

Year	Miscellaneous tin manufactures		Tin compounds (pounds)	
	Imports [1]	Exports [2]	Imports	Exports
1941	$2,266	$1,456,353	7,224	137,424
1942	[3] 949	591,937		117,191
1943	[3] 2,425	666,476		25,042
1944	[3] 3,682	1,143,006		25,992
1945	[3] 1,403	1,344,477	25	35,107

[1] Includes tin manufactures, n. s. p. f., tinfoil, tin powder, flitters, and metallics.
[2] Includes tin dross and tin-bearing scrap material other than tin-plate scrap.
[3] In addition, 505,346 pounds of tin dross, skimmings, and residues valued at $63,978 were imported in 1942, 45,943 pounds valued at $4,595 in 1943, 108,296 pounds valued at $9,536 in 1944, and 127,680 pounds valued at $29 in 1945.

Exports of tin plate, terneplate, and taggers tin increased 8 percent in 1945, with substantial shipments to Europe. The principal destinations were Latin America (29 percent), Australia and New Zealand (23 percent), Canada (13 percent), and Europe (13 percent); shipments to the first two declined 1 and 19 percent, respectively, compared with 1944, whereas for the last two they rose 64 and 617 percent. Exports to Africa (10 percent of total) increased 29 percent; those to Russia (8 percent) decreased 22 percent; and those to miscellaneous countries (4 percent) were off 38 percent.

By amendment of the War Production Board Import Control Order, M–63, on November 30, 1945, importation of tin alloys (including alloy scrap) and tin bars, blocks, pig, grain, and granulated were again put under control when tin alloys were being offered in this country by foreign sellers at prices above the 52 cents a pound ceiling on tin content.

PRICES

The price of tin remained stabilized in the United States at established Government ceilings throughout 1945. The price of pig tin exported by Office of Metals Reserve was exempted from price control, effective December 31, 1945, by amendment 2 to Office of Price Administration Maximum Price Regulation 17. Metals Reserve announced on March 4, 1946, that, beginning with its March allocations, the price of pig tin for export was advanced 6 cents per pound, making Grade A brands 58 cents per pound in lots of 5 tons or more for delivery ex-dock or warehouse at United States port, or f. o. b. smelter at Texas City. In September 1945 the British export price was raised £75 above the pegged domestic price of £300, but effective

April 1, 1946, was reduced to £357. The maximum prices, by grades and brands, during 1945 were as follows:

Grade A. 99.80% or higher, meeting specifications set forth in M. P. R. No. 17 ---- 52.00c.
Following brands of pig tin will be considered as qualifying as Grade A: Longhorn 3-Star, Chempur, Pyrmont, Straits Trading, O. T. Lempriere & Co., E. S. Coy (Penang), Billiton, Mellanear (Guar. 99.9%), Hawthorne Refined, Banka, Union Min. du H. Katanga, M and T No. 1, M and T Electrolytic Refined, Vulcan American Refined, Vulcan Electrolytic, Pass No. 1.
Grade B. 99.80% or higher, not meeting specifications for Grade A, providing arsenic content does not exceed 0.05% ---- 51.87½c.
Grade C. 99.65% to 99.79% and 99.80% or higher, not meeting specifications for Grade A or Grade B ---- 51.62½c.
Grade D. 99.50% to 99.64% (includes Longhorn 2-Star) ---- 51.50c.
Grade E. 99.00% to 99.49% (includes Longhorn 1-Star) ---- 51.12½c.
Grade F. Below 99% pure (for tin content) (includes Longhorn No-Star) ---- 51.00c.

Free market prices for tin ceased to exist about the end of 1941. What might be termed the basic London and New York prices were fixed by Government decree close to the figure that ruled at that time. Although the usual price differential was increased in 1942–43, it was reversed almost the same amount in 1944–45 by the £25-a-ton increase in the internal British price, while no change was made in the American price. Outside these countries, the prices of tin, as metal or in concentrate, showed marked disparity. Recently reported prices have been: Belgian Congo and Bolivia about £350, Nigeria £300, Union of South Africa £422, Australia £A231 for 70-percent concentrate delivered Sydney. In Belgium it was 64,000 francs and in France 84,000 francs a metric ton. In 1945 Portugal and Spain set prices that, at official rates of exchange were, respectively about $2.31 and $3.31 a pound. These prices are not of moment, since the supply is inconsequential and the movement beyond the countries was limited by edict. They may, however, represent black market prices. An attempt at stabilization at an economic level in the light of war-induced increased costs of production was noted near the year end in the setting of a £300 price for Malayan tin and a repeated offer to Nigerian producers at the same figure, which is close to that to be paid Bolivian producers in the second quarter of 1946.

STOCKS

Total year-end stocks of primary tin plus tin content of the ore and concentrates in the United States in 1945 were 83,525 tons, 17 percent below those of 1944. In addition, 11,391 tons (about 1,300 tons more than in 1944) were in process in scrap and as secondary pig tin. Of the tin and concentrates, the Government held 81 percent (including sterilized stocks of 12,140 long tons of metal) and private owners the remainder. The quantity (in terms of tin content) held by the Government was divided about equally between metal and ores and concentrates. Government stocks of pig tin were depleted 12 percent and industrial stocks 17 percent. Virtually all industrial stocks were in the form of metal; only a small quantity was in ores awaiting treatment at privately owned plants. These stocks were at the lowest point since the depression of the 1930's and were about 3 months' requirements at the proposed 1946 use rate. The quantity of tin and concentrates on hand was equivalent to about 1.5 years' supply at the rate of consumption in 1945, or about 1.25 years at the proposed 1946 use rate.

Stocks of virgin pig tin in the United States, Dec. 31, 1941–45, in long tons

	1941	1942	1943	1944	1945
Location of stocks:					
Afloat to United States [1]	[2] 15,000	[2] 900	[2] 1,650	[2] 1,800

[1] As reported by Commodity Exchange, Inc.
[2] Estimated.
[3] Not available.
[4] As reported to the Bureau of Mines; do not include tin in process or secondary pig tin.
[5] Includes 2,700 tons in transit in the United States and at other warehouses not contained in figures above for "at landings" and "in licensed warehouses."
[6] Includes 78 tons in transit and 84 tons held by jobbers.
[7] Includes 316 tons in transit and at other warehouses and 50 tons held by jobbers.
[8] Includes 1,941 tons in transit and at other warehouses and 47 tons held by jobbers.
[9] Includes 1,600 tons in transit and at other warehouses and 69 tons held by jobbers.
[10] Exclusive of Government purchases delivered for stock-piling or at Texas City smelter.

The Bureau of Mines canvassed tin consumers to determine stocks and use during 1945. According to these reports, the consuming industry had 14,102 tons of primary pig tin at plants at the end of 1945, including 6,315 tons held by tin-plate manufacturers. The industry also had 1,600 tons of primary tin in transit or warehoused, in addition to 358 tons of secondary pig tin on hand at the end of the year.

WORLD ASPECTS OF THE TIN INDUSTRY

INTERNATIONAL CONTROLS

Since the beginning of the Japanese phase of World War II the International Tin Committee (ITC) has had virtually no reason for existence, nor in many minds is there justification for its continuance. Certainly, in view of the supply-demand unbalance that is likely to persist for 2 or 3 years, there is no need for production (export) control. The 5-year extension of the third control agreement that expires at the end of 1946 preserved the machinery of control and makes its further extension possible. Pursuant to the requirement that a recommendation for continuance be made not less than 12 months before the expiration date, preliminary discussions were said to have been held in London in the fall of 1945. In March 1946 the committee held a scheduled meeting to put the recommendations in final form. The recommendations are not yet known, as the committee stated, "As this recommendation is confidential to the Governments, parties to the agreement, no announcements of its contents can be made." The Mining Journal (London) of March 16, 1946, observed that "It was understood it was decided to recommend the continuance beyond the end of the current year." It is also believed that consideration was given to the readmittance of Siam and Indochina. During the period of inaction the ITC has continued to support research activities directed mainly to finding new or expanded uses for tin. No consequential developments have been reported. In February 1946 the Hague office of the International Tin Research and Development Council resumed publication of statistical bulletins.

In the place of production control, it became imperative after 1941 to parcel out existent and new supplies of tin and other commodities. This was undertaken for the Allied Nations by the Combined Raw Materials Board, which was under British and American Government auspices and was seated in Washington. This group ceased to function at the end of 1945. Without interruption the distribution of tin (metal only) to claimants, including limited quantities for vanquished countries, was carried on by its successor, the Combined Tin Committee. Belgium, France, and the Netherlands, as well as the United Kingdom and the United States, participate in the committee. About the end of the year interim allocations were made, and in March 1946 modified allocations were made for the first half of 1946. Therein the United States share was about three-eighths of the 18,300-ton total, or somewhat below the usual percentage taken by the United States, probably resulting from distribution to wartime, tin-starved nations.

Opposition to the revival of international commodity agreements typified by ITC was strengthened in 1945. At the meeting at sea of

President Roosevelt and Prime Minister Churchill in August 1941 a mutual-aid agreement was reached on measures providing for safety against the attacks of Germany and its associates. At the same time, the principles later known as the Atlantic Charter were enunciated and subscribed to by the United Kingdom and the United States. These principles were set up not only for the conduct of the war but to extend beyond the destruction of Axis power. As an adjunct thereto were expressed the hopes for freer trade—freedom of access to raw materials—and international cooperation in the economic field. In January 1943 was formed a loose aggregation of 26 nations, the United Nations Organization that in 1945 became the actively functioning United Nations. Presumably as one result of the Atlantic Charter understandings, the British Government stated late in 1942 that the tin-restriction scheme, like other commodity-regulation schemes, would be subject to postwar review. The American policy, which has the support of the British Government, has been set forth by the United States Department of State,[8] proposing the formation of an International Trade Organization, and a conference thereon by the United Nations has been requested by the summer of 1946. A major barrier to expansion of world trade is the "restrictions imposed by private combines and cartels." The proposals contemplate that countries will act individually and collectively to curb their restrictive practices. In place of international commodity arrangements, intergovernmental commodity agreements would be made under specified conditions. Membership would be open to any country, but it was especially recommended that consuming countries lacking the materials in question should have an equal voice with producing countries in consideration of any agreements as well as in their administration. Agreements should also operate to assure availability of supplies adequate at all times for world needs at reasonable prices, and requirements should be met from sources that can supply them most effectively. It was recognized that problems of trade in primary commodities differed from those connected with manufactured goods and might be serious. In respect to raw materials, intergovernmental action would be preceded by special studies in those cases where "excess supplies exist or are threatened"; where widespread unemployment has developed or is developing, and these conditions "cannot be corrected by the normal play of executive forces." The various provisions are not to apply however to effectuate "an equitable distribution of commodities in short supply." The conference should create an Industrial and Mineral Unit that "should promote by technical assistance, and other appropriate means the expansion of production and trade * * * with regard to minerals and other primary commodities" that are not under the jurisdiction of the Food and Agriculture Organization. Insofar as tin is concerned, it is likely to remain in the "short supply" class for a brief period, in which instance the Combined Tin Committee may continue to function. If that condition were to persist, the Industrial and Mineral Unit might take a hand. In any case the ITC would have a sharply constricted field in which to operate.

WORLD MINE PRODUCTION

Official reports for the war period received by the Bureau of Mines and the resumption of statistical reporting by the International Tin Research and Development Council permitted revision of the production figures heretofore tentatively presented. With the exception of 1 year, 1943, the estimates agreed closely with figures presented in the accompanying table. The wide divergence in that year was due to an underestimate of Netherlands East Indies that now is given authoritatively at 15,133 tons.

Final figures for 1945 were not fully available when this chapter was prepared, but the total was probably close to 87,000 tons or near the low point of this century. Findings of various investigational groups point to an increase of only about 20,000 to 25,000 tons in 1946, with full-scale output in 1948.

World mine production of tin (content of ore), 1925–29 (average) and 1939–45, by countries, in long tons

WORLD SMELTER PRODUCTION

The table below offers estimates of the world's smelter production, 1939–45. The United States probably held first place, followed by the United Kingdom and the Belgian Congo. Continental output approached the vanishing point in 1944–45, and in the Far East reports of an American investigator indicate that production was at an extremely low ebb.

Although damaged extensively, mostly by removal of equipment, the Billiton Co.'s modern smelter at Arnhem, Netherlands, is expected to resume work on a limited scale in 1946. Belgian smelters were repaired and furnished a small output in 1945. The Allied Control Council for Germany approved the annual use of 8,000 tons of tin; whether Germany may undertake smelting and refining was not stated. Contrary to expectations, Far Eastern smelters were not seriously damaged on the whole and can be put in operating shape well in advance of large receipts of ores. Almost all the Siamese mine output was smelted at Penang, but during the Japanese occupation 18 native smelters were erected and operated. Siam has thus become self-sufficient in smelting capacity.

REVIEW BY COUNTRIES

Australia.—Lack of manpower and drought continued to hamper tin mining in Australia in 1945. The output of Tableland Tin Dredging Co., in Queensland, was lower than normal owing to idleness of its dredge for extensive repairs in November and December. In New South Wales former important sources of tin were idle because of drafting or migration of miners. In Tasmania, Aberfoyle Tin, N. L., operated at a higher rate in 1945 than in 1944 but produced less tin, owing to a decline in grade of ore. A new crushing and screening plant was erected; and, with an improved labor supply since the termination of hostilities, delayed development has been undertaken. At Briseis Consolidated, N. L., the grade of ore continued to decrease; gravel washed in 1945 contained 0.65 pound of tin oxide per cubic yard compared with 2.5 pounds per cubic yard in 1943. Renison Associated Tin Mines, N. L., on the west coast of Tasmania, recovered a small tonnage of tin from a massive pyrrhotite and pyrite ore. After fine grinding, the classifier product is floated to remove the sulfide minerals and the cassiterite recovered by tabling. The cassiterite is fine, and the slime losses are high; average recovery was 61 percent. The Mount Bischoff properties are to be sold to the Commonwealth and State, and some exploratory work may be carried on. Working of lodes below the open-cut has not proved successful.

Belgian Congo.—It is unlikely that production of tin in the Belgian Congo in 1945 exceeded that in 1944. Exports, however, appear to have been larger in 1945, owing to shipment of carry-over from 1944. The African Metals Corp. contract for acquisition of tin from the Belgian Congo by the United States expires June 30, 1946. Under the terms of the contract, the United States paid 53 cents a pound for the tin, whether in the form of refined metal or concentrates (plus a 2-cent premium per pound if deliveries equaled or exceeded a specified tonnage) f. o. b. West African ports (Matadi). The Congo Tin Committee has been negotiating for a new contract on more favorable terms.

Total tin in metal and concentrates imported by the United States from the Belgian Congo declined 21 percent in 1945, largely owing to the resumption of shipments of metallic tin to Belgium. Metallic tin imported was 6,494 tons (10,000 in 1944) and tin in ore and concentrates 7,401 tons (7,549 in 1944).

Bolivia.—Exports of tin in concentrates and ore by Bolivia (42,465 tons) in 1945 were 10 percent more than in 1944 and were exceeded only by the 1929 peak of 46,343 tons. The United States was the destination of about 77 percent, and the remainder went to the United Kingdom. Owing to the large quantity in storage and en route at the close of the year, actual arrivals in the United States were only 25,984 tons from Bolivia. During 1945 exports of the Patiño group, amounting to 45 percent of the total, were about the same as in 1944, whereas those of the Hochschild group (28 percent) were 18 percent higher than in 1944. Those of Aramayo, with 7 percent, increased 15 percent; and the medium and small mines, with 20 percent, increased 21 percent. Exports were accelerated in the second calendar quarter because of an anticipated price reduction. A new purchase contract, important features of which are summarized in the section, Government Tin Operations, was not concluded until September and gave producers little opportunity to raise shipments to take advantage of the still unreduced price. In this, the third quarter of the year, a slight improvement in grade was noted, possibly as a result of the Banco Minero's discontinuance of purchase of concentrates carrying less than 20 percent tin. The downward trend in shipments continued into the fourth quarter.

It has been estimated that Bolivia will export the equivalent of 36,000 metric tons of fine tin in 1946; but even though this would be 17 percent below the 1945 figure producers are skeptical of its achievement, owing to higher production costs, the decline in prices, and other adverse factors. This was foreshadowed by the closing late in the year of the Huanuni mine of the Bolivian Tin & Tungsten Mines Corp. (Patiño group). This property had an output capacity of about 3,000 tons of fine tin yearly and employed about 2,000 miners. The reason assigned was the rise in costs from £334 a ton fine tin in 1944 to £402 (about 72 cents a pound) in August 1945. In the face of possible Government confiscation and operation authorized in a decree of March 29, 1945, an attempt may be made to reopen the mine. The Patiño Co. report for 1945 states that costs increased £38 14s. 1d. a long ton of tin over 1944. Apparently no new taxes were levied during the year, but use of foreign exchange proceeds from sales was limited further on a sliding-scale basis, with the greatest burden placed on exporters of the higher-grade materials. Strikes in the spring were followed by wage increases of about 15 percent, retroactive in the case of Patiño to January 1 and for Aramayo to April 1. President Villarroel warned Bolivia in November to prepare to face an acute economic crisis in 1946. Wages will not be increased, but additional taxes will be laid on industry profits. The export tax on tin already provides more than half the State's total revenue. The Banco Minero was given certain tax exemptions by the Government, which permitted purchasing the output of small mines at prices that would offset the greater penalties imposed for treatment of their low-grade output. To aid the small miners, whose tools and practices are primitive, an investment of $300,000 for a concentrating plant was planned by Banco Minero. Funds for the purpose were to be obtained through a loan from the Bolivian Development Corp. The abandoned tin-smelting venture at Oruro, which Mauricio Boni attempted in 1936, was revived. Banco Minero was empowered by a supreme resolution in April 1945 to loan B. 4,189,000 to complete the plant and bring it into operation within a year after the loan was granted. It was said that orders for some machinery had been placed in Argentina.

Production at Catavi was increased slightly by Patiño's new sink-float and Sullivan deck plants, but for a time mechanical difficulties affected performance of the sink-float plant. The Tainton volatilization plant at the Unificada mine of Hochschild has not yet proved commercially successful. Further changes in equipment were made in an effort to attain recoveries shown in laboratory tests. Anaconda round tables with concrete decks were installed at Potosi, Oploca, and Aramayo to replace buddles for the recovery of slimed tin. Additional flotation units were installed in the Colquiri mill of Cia. Minera de

Oruro. The Bolivian International Mining Corp. resumed operations in June 1945, with a new dredge replacing the one that had capsized in January 1944. The output was estimated at 30 tons of fine tin a month, but this seemingly has not been reached because of unfavorable operating conditions.

British Malaya.—After the fall of Manila to returning United States troops on February 4, 1945, Japan's already weakened lines of communication to southeast Asia virtually were cut off. Although the Japanese did not surrender Singapore and Malaya until September 14, it appears improbable that mining and smelting of tin could have been other than at a very low rate during 1945. Likewise, movement of stanniferous materials to Japan probably gave way to transport of more highly strategic goods. Up to the end of the year, according to the British Ministry of Supply, only 4,500 tons of tin had been found, whereas 17,000 tons had been reported erroneously in October. Up to the end of January 1946 only 2,300 tons of concentrates had been acquired by a tin-ore-buying agency.

In conjunction with the British Colonial Office, the Malayan Chamber of Mines appointed several committees to examine conditions in Malaya and assist in developing plans for rehabilitating the tin-mining industry and accelerating production. The Rehabilitation Committee that was to advise on the views of all sections of the industry included a representative each from Australia, China, France, and the United States. An Inspection Committee, which had an American representative,[9] arrived in Malaya in October 1945. Late in that month Arthur Notman and Charles Slaughter, American mining engineers, were selected to examine the state of mining facilities on behalf of the United States and in cooperation with the Inspection Committee. A. D. Storke, who had been appointed adviser to the Secretary of State for the Colonies on matters of rehabilitation, reached Malaya while that group was at work. At about the same time John J. Croston, assistant director of the Civilian Production Administration's Tin-Lead Division, also made an extensive survey of the far eastern tin situation as a special investigator for that agency. Summaries of their reports were published.[10]

Immediately before the war, there were 125 or 126 dredges in Malaya. In May 1941, the latest date for which information is available, 108 were in operation (about 104 in 1940), 15 idle, and the others under repair. These operations accounted for a little more than half the 1940 output of 80,651 tons tin content; about 35 percent came from gravel pumping; and most of the remainder was divided nearly evenly between hydraulicking, open-cut, and underground mines.

In general, upon reoccupation the dredges were found to be in better condition than had been anticipated. The Japanese had refloated and worked many of them while operable but apparently made no systematic effort to wreck them. Much electric and shop

[9] A. D. Hughes, resident manager of the Pacific Tin Consolidated Corp. This company, the sole American operator (Federated Malay States) had 5 dredges. At the time of evacuation in the winter of 1941–42 1 had been dismantled before moving, and 4 were sunk. These were refloated by the Japanese and were not seriously damaged. Two may be able to resume production by August 1946. The Japanese had worked 3 and some open-casts part of the time.

[10] The Storke reports appeared in American Metal Market, vol. 52, No. 235, Dec. 13, 1945, pp. 1, 5, and vol. 53, No. 24, Feb. 2, 1946, p. 1. The Notman-Slaughter statement was given in Iron Age, vol. 157, No. 1, Jan. 3, 1946, p. 202. A summary of Croston's findings appeared in American Metal Market, vol. 53, No. 145, July 30, 1946, pp. 1, 6.

equipment and many tools had been removed; repair parts and other stores had disappeared; but power plants were, for the most part, in fair shape. Official reports indicate that about one-third (41) of the dredges may begin operation by August 1946 and another third (46) by July 1947. Of the remainder, 22 are considered worthless. This group produced only about 10 percent of the dredge output, and several were obsolete before the war. The remaining 17 may come into production by 1948. This schedule assumes that repairs may be made without delay and that coal or other fuel will be available, the needed labor force recruited, and the currently highly inadequate basic food supply—rice—increased. Chinese mines that supplied about 30 percent of the prewar output, much of it by gravel pumping, suffered more severely than the dredging companies. A few were working at the time of the Japanese surrender, but out of 483 small Chinese mines only 71 are expected to resume by August 1946; output is not likely to be large until 1948. European-owned open-cast and hydraulic mines are expected to begin operation by August 1946. Hand (dulang) mining may yield 1,500 tons in 1946 and about 1,200 thereafter. Production from all categories of mining was estimated to be 12,300 tons of tin in 1946; 46,150 in 1947; 72,800 in 1948; and 73,500 in 1949. Thus, if hopes are realized, by the end of 1947, tin mining in Malaya will be restored to within 90 percent of the 53,500 tons annual average before the war broke out in Europe. Much of the recovery depends on the Government rehabilitation plan and war-damage allowances. Small companies may not be able to resume operations without Government aid. The Colonial Office has included approximately £8,000,000 for rehabilitation in Malaya in a proposal to the British Treasury. Compensation would be considered on the basis of losses due to command destruction before Japanese arrival or incident to Japanese occupation; and advances made would be paid back by the industry by 1950 at low interest rates. The Treasury, in turn, is considering whether full rehabilitation of the tin industry is necessary; how much of the total sum is to be expended on rehabilitation of tin mining against that for other commodities; and the effect of the program on general export policy. Apparently no war-damage settlement will be reached until full assessment of individual claims has been made, and it may be that amounts awarded for war damage would be credited against repayment of financial aid granted for rehabilitation.

Postwar costs are expected to exceed prewar costs substantially. The cost of new dredges has been estimated to be up at least 60 percent and smaller equipment about the same; wages are in doubt because they are related to the supply and the cost of food, much of which is now several times that of 1939. The cost of transportation has also increased more than 50 percent.

The tin smelters (formerly the largest in the world) were found to be in comparatively good condition. The Penang smelter of the Eastern Smelting Co., Ltd., had been used by the Japanese during their occupation and was ready to resume normal operation in December 1945. The prewar capacity of this smelter was 100,000 tons of tin concentrate a year. The Straits Trading Co., Ltd., smelters at Pulau Brani and Butterworth together had a little larger capacity. That at Pulau Brani, Singapore, which apparently was not used by

717372—47——48

the Japanese, was expected to begin operations on a small scale in May 1946. There has been no reference to conditions at the Butterworth and Selangor smelters. Singapore was virtually undamaged, its roads were in excellent repair, and its electric light plant was working, and shops opened within a few days of liberation. By the latter part of October 1945, American consular officers were on duty.

A tin-ore-buying agency was set up in Malaya by the British Ministry of Supply to acquire available existing supplies in all Malaya. The agency was to arrange for immediate shipment of any stocks found and will also cooperate with Chinese mine owners in solving their labor problems. The basic price to be paid for the tin was set up by the Ministry of Supply at £300 per ton Malayan port (53.87½ cents a pound or about 56 cents delivered United States). This price was in effect until February 16, 1946, when treatment charges (hitherto paid by agency) will be included among the deductions against the producer, but other charges were reported as having been substantially reduced. Concentrates purchased are expected to be smelted in Malaya. Buying seems to have been extended to include production of the smaller miners, who, however, do not seem to have responded very well to the price offered.

The British Government proposed to create a Malayan Union. It will consist of the four Federated and the four Unfederated States and of the British Settlements of Penang (Province Wellesley) and Malacca. Singapore will be constituted as a separate colony but may ultimately enter the new union.

Burma.—Preliminary observations indicate that the property of the Mawchi Mines, Ltd., was not damaged by military operations and enemy occupation as seriously as had been expected, but substantial deterioration did result from neglect. The plant for cleaning the concentrates has been entirely destroyed. Since the labor force was almost completely dispersed, the problem of recruiting another is the most urgent one facing the company. An inspection committee of the Lower Burma tin- and wolfram-mining industry is to prepare a report on conditions and requirements of the mining properties in that area. British Ministry of Supply agents on the committee will make ore and metal inventories and buy available stocks. The British Information Service has reported that the Japanese are believed to have left behind about 1,200 to 1,300 tons of tin concentrates in Lower Burma.

China.—Production of tin was probably much lower than in 1944, owing to an almost complete economic break-down, accompanied by continued civil unrest. Shortage of all goods and particularly foodstuffs is appalling, and reportedly conditions in the interior—the source of tin—are much worse than on or near the coast. The realization of postwar production plans therefore appears doubtful. The National Defense Council expected the first postwar year to show a 7,150-ton output, rising in 5 years to 14,000 tons. In an article on the Modernization of Chinese Mining,[11] T. Y. Chong said that official industrial plans called for an increase to 30,000 tons, or roughly three times the record output of prewar years. Mechanization of mining and milling would bring about the increase. The

[11] American Metal Market, vol. 53, No. 6, Jan. 9, 1946, p. 5.

Kochiu district in Yunnan Province is expected to provide about two-thirds the total and the Fuchuam, Hosien, and Chungsan districts in Kwangsi Province most of the remainder, with lesser quantities from Kiangsi and Kwantung Provinces. The National Resources Commission had already in operation a modernized smelter and mill in Yunnan and produced high-grade tin. A beginning on mine modernization had also been made, but Chong gave the impression that most of the mining, milling, and smelting was conducted as primitively as it had been several hundred years ago.

It has been reported that about 1,200 tons of tin were recovered in China from supplies taken by the Japanese.

Germany.—With the surrender of its armed forces in May 1945, Germany ceased to be a sovereign state. It had been the largest continental tin consumer for many years; except for the depression period, apparent consumption ranged from 9,000 to nearly 14,000 tons and for about 10 years was in the neighborhood of 12,000 tons, but in the period 1940–44 was reduced to about 7,125 tons. According to an announcement of the Allied Control Council from Berlin in March 1946, the permissible level of German industrial activity is set at one-half the 1938 rate. Specifically, 8,000 tons of tin may be used, but distribution in the several occupation zones was not given. Until the Arnhem smelter was constructed in the early 1930's, Germany had been the principal continental smelter and maintained several tin-processing plants through the war years. In the 1940–44 period, smelter output, including secondary tin and alloys, was reported to be 3,000 to 5,000 metric tons annually and averaged about 3,800 tons. Tin mining dates back to the Middle Ages but has been small, averaging about 150 tons a year from 1800 up to the beginning of rearmament for World War II. During 1940–44 tin-tungsten ores were mined principally in the Erzgebirge, and production was reported to have risen from 300 tons to 500 tons in 1942 and to 1,000 in each of the following 2 years. In 1945 output probably was negligible. The producing area is now in the Russian zone. During the war most of the ore supply came from Portugal and Spain, along with metal and tin-bearing materials seized in overrun countries. Germany's tin position was evidently becoming critical, for only about 3,000 tons of various brands were discovered after the surrender. In the American zone 841 tons were confiscated; but of this, 91 tons proved to be solder after arrival in the United States. Tin smelting and refining in northwestern Germany have been described.[12]

Indochina.—The tin mines of Indochina were seriously damaged during the war. Six months to a year will be required for making repairs before mining operations can be resumed. Internal political disturbances may, however, retard their rehabilitation. The tin smelter at Haiphong was reported as being intact, but reports on others are not available. A stock consisting of 560 tons of concentrates assaying 40 to 70 percent tin, and some 540 tons of metallic tin was discovered. Prewar production of tin in Indochina averaged around 1,500 tons of tin annually.

[12] Phillips, Albert J., Copper, Lead, Zinc, Tin and Antimony Smelting and Refining in Northwestern Germany: Office of Military Government for Germany (U. S.), Joint Intelligence Objectives Agency. FIAT Final Report 229, Oct. 2, 1945, 47 pp.

Japan.—Because of a large tin stock and the rapidly approaching Allied invasion it is doubtful whether tin mining and smelting were carried on to any extent in Japan in 1945. The industry was entirely disrupted by the time of the Japanese surrender on August 14. The Mitsubishi tin smelter in Osaka and the one of Toyo at Oita may have been damaged to some extent by bombing, but the tin mines in the interior probably were unharmed. Occupation authorities have directed that about 10,000 tons of the tin found in Japan are to be shipped to the United States for grading and analysis. Allocation will be determined by the Combined Tin Committee. It is believed that the Japanese may have obtained roughly 100,000 tons of tin from southeastern Asia after the fall of Singapore.

Netherlands.—The Arnhem tin smelter was being reconditioned in 1945, and production on a small scale may be resumed early in 1946. Before the war this plant was equipped to treat complex and refractory ores, as well as high-grade material. Ore supplies were usually obtained from the islands of Billiton and Singkep, Netherlands Indies; and Bolivia, Burma, and China. Only a small quantity of Banka ore was treated. The plant worked into 1943, and for a time the Germans provided Portuguese and Spanish material. In the latter part of 1944, when Arnhem was evacuated, the Germans removed virtually all the electrical equipment, ball mills, and mechanical separation and filtering plants and stripped the works' laboratory of apparatus and chemicals. However, the four blast furnaces were intact, apart from some minor damage, as were also the reverberatory and rotary furnaces, heavy machinery, and scrap-metal facilities. It has been reported that most of the equipment and many of the electric motors that the Germans removed have been located and that efforts were being made to obtain additional equipment from England.

Netherlands Indies.—The output of tin in the Netherlands Indies in 1945 was probably the smallest in almost a century. The Japanese mined and smelted tin during their occupation but on much less than the prewar scale. The sudden ending of the war in August 1945 prevented the Japanese from carrying out a scorched-earth policy. They were instrumental, however, in provoking a serious revolt among the natives against the Netherlands Government, which has had a delaying effect on restoration of tin mining. Owing to natural advantages and a higher degree of mechanization, tin production in Netherlands Indies should approach the prewar rate more rapidly than in Malaya. More than 6 of the 17 dredges on Billiton at the time of the Japanese occupation (February 1942) were found in repairable condition. Production was expected to be at the rate of not less than 10,000 tons of tin annually within 6 months. Half of the production is to go to the smelter at Texas City and the remainder to Arnhem for treatment. The Japanese are believed to have obtained about 3,800 tons of tin from Billiton in 4 years. Representatives of the Billiton Co. reached the island in October 1945 and have made some progress in restoring plant and equipment. Power plants were found to be in fair operating condition; but, as elsewhere, some of the electric apparatus, high-tension lines, and repair-shop equipment had been taken or destroyed. There had been little damage to dredges beyond removing parts, especially electric equipment, for use elsewhere. The Klappa Kampit lode mine on Billiton, which had a prewar annual output of 3,000 tons, had been thoroughly wrecked and cannot be worked for some time. A stock of 310 tons of tin was found in Billiton. Damage to mining installations on Singkep was serious, but tin production has been resumed on a small scale. Other than that tin production was progressing, there has not been much information concerning conditions on Banka, where the Indonesian rebels held control for some time. Two large dredges, which had been moved from Billiton to Banka in 1941, have been reported to be in good condition. Chinese coolies left on the island have returned to work, and by April 1946 all but 1 of the remaining 31 dredges were afloat and may be repaired. Two suction dredges had resumed operations, and 2 bucket dredges were to be in operation in May. It is understood that the smelters on Banka were in good condition and have resumed operations. Japanese on Banka reported there were almost 3,000 tons of Japanese-smelted metal and 3,500 of tin in concentrates on the island. Part of this was on its way to the United States by the end of 1945 and the first part of 1946. Progress on reconstruction work on Banka has not been as rapid as on Billiton. The Mining Equipment Corp., a Billiton Co. subsidiary in New York, has placed orders for 2 dredges and other equipment in the United States, and 6 are to be built in the Netherlands. Those from the United States are expected to be in operation early in 1947 and the others in 1947–48.

Nigeria.—Production of tin in Nigeria in 1945 about equalled that in 1944. Some of the mines were adversely affected by floods or other abnormal weather conditions, lowered ore grade, and shortage of native labor. In midsummer the movement of exports was affected by a labor strike of Government technical workers, which lasted over 6 weeks. After the fall of Malaya and the Netherlands East Indies, the British Ministry of Supply requested Nigerian producers to expand tin output to the limit. An agreement between the Ministry and the Nigerian Chamber of Mines fixed a price based on prewar costs and profits. Subsequently the producers received additional remuneration calculated on the average value of gravel worked each year compared with the average in the year before intensive operations were begun. The 100-percent excess profit tax rule was also modified. The mining companies have consistently complained that the price has been too low to compensate for the greatly increased cost of production, enforced contraction of development in favor of extraction, and the uneconomic practice of concentrating work on the higher-grade portion of the deposits.

The "cost plus" contract arrangement in force during the war expired December 31, 1945. The British Ministry of Supply has offered producers a new contract under which it would pay £300 per ton of metal f. a. s. port of shipment Nigeria, with a bonus of £25 per ton for any production exceeding the 1941 rate. The Nigerian Chamber of Mines refused to accept this price, as certain companies would operate at a loss under the terms, and presented their proposals, which the Ministry has not accepted. Under terms offered by the Ministry, the Amalgamated Tin Mines of Nigeria reports that its output would be reduced to 4,500 tons of concentrates annually, as compared to about 9,000, or half of the rate during the last 2 years.

The Geological Survey of Nigeria has been remapping the tin field on the Jos Plateau in a search for new deposits and has resurveyed a considerable area south of Bukuru.

Portugal.—Tin mining in Portugal continued to decline in 1945. Restrictions on tin sales and exports were removed, but the export of tin concentrates is not permitted. A decree of May 18, 1945, allowed tin to be sold freely in Portugal, and exports of metallic tin are allowed provided half the quantity shipped is purchased from the Government stock pile at Esc. 126 per kilo ($2.31 per pound). The only steady producer was the Gaia alluvial mine worked with a small dredge by the Portuguese American Tin Co.

Siam (Thailand).—The tin mines, including dredging equipment, in Siam fell reportedly undamaged into the Japanese hands in December 1941. The Japanese-controlled Government in December 1941 placed armed guards at the mines before the Japanese landed to prevent any destruction. Dredges taken over by the Japanese Army were later handed over to the Siamese Government, which operated them through a Government company for some time and presumably maintained others in stand-by condition. Some have been found to be in good order, while others were reported to require extensive overhauling. It is understood that numerous small smelters were set up and operated during the Japanese occupation. The British Ministry of Supply announced in London on November 3, 1945, that, according to a provisional report, 16,000 tons of tin concentrates and 4,000 of refined tin had been located in Siam. Disposition of the stocks has not been made public, but it is believed a substantial part will be made available to the United States. A British party left Singapore early in 1946 to inspect properties in Siam, and arrangements were being made to appoint a committee to inspect the Australian tin properties there.

Under terms of a peace treaty, Siam agrees to participate in any general international arrangement regarding tin which conforms with such principles regarding commodity arrangements as may be agreed to by the United Nations. Siam has also agreed to prohibit any exports of tin until September 1, 1947, except in accordance with recommendations of the Combined Boards in Washington or any successor body; to regulate trade in tin; and to stimulate production. The United States took an active part in the negotiations, although not formally a party thereto.

Spain.—The output of tin in Spain increased in 1945 following the fixing of the domestic price at 80 pesetas per kilo ($3.31 per pound). Production was mainly from small placers.

United Kingdom.—The United Kingdom ranks second both as a world smelter of tin ore and as a consumer of pig tin. It is also second among the world producers of tin plate, which usually accounts for 40 percent of its pig-tin consumption. Foreign trade in tin was greatly changed by the course of the war. From the time of the Munich agreement to the fall of Singapore imports of tin ore increased materially above the prewar level and reached 83,902 long tons (gross weight) in 1940, dropped to little more than half that in 1942, and reached a low point of 32,948 tons in 1944. Pig-tin imports fell from nearly 12,000 tons in 1938 to zero in 1941 and remained entirely negligible through 1945. Tin exports (including reexports) averaged about 18,500 tons in 1938–39, dropped sharply to 6,500 tons in 1941, and for the next 4 years averaged about 8,500. Of the 6-year (1940–45) total of 56,000 tons, a large part was sent to Russia. Stocks (tin content) gained about 20,000 tons from 1939 to 1945. In the period 1935–38 consumption of virgin tin averaged about 22,000 tons. In the following 3 years the average was roughly 30,000 tons, with an apparent peak near the 34,000 ton mark. After the loss of Malaya, consumption was cut drastically and averaged about 19,000 tons for the 1942–45 period, with the lowest point at 16,400 tons in 1945. The use pattern in this period differed from that in the United States but cannot be expressed with certainty, as the distribution between primary and secondary tin for the various product classes was not given. However, it seems to have been about as follows for primary tin: Tin plate, about 4,300 tons a year; for solder probably somewhat more; and for bearing metals—principally babbitt and bronze—possibly 60 to 80 more than for tin plate. The contrast is more striking in terms of total tin. In the United Kingdom the relative totals, in the order given, were about 1, 1.7, and 3.2, whereas in the United States they were about 1, 0.5, and 1.5. The extraordinarily subordinate position of tin plate was due largely to the transfer of export markets to the United States, already noticeable in 1940 when American exports exceeded the British.

Cornish tin mining, which began before the Christian era, is rapidly becoming extinct. Available records show that its heyday was from the middle of the Civil War to the depression of 1893 and averaged something over 9,000 tons, with a peak of closely 11,000 in 1871. In the first 2 decades of the current century, production was about half that of the 30-year period mentioned; was more than halved again (about 1,930 tons) in the succeeding 2 decades; and in 1945 was 993 tons. South Crofty, now the only property working in the Camborne-Redruth area, has encountered a new complex lode containing both coarse tin and wolfram, which may add considerably to its ore reserves. Geevor received notice of termination of its agreement with the Ministry of Supply as of June 30, 1945. It had carried out some development work but was hampered owing to labor shortage. The Ministry of Fuel and Power withdrew its support from East Pool and Agar, as the scheme for a development and diamond-drilling program was not accepted, and mining and milling operations were stopped June 2, 1945.

The output of tin plate increased to 278,700 tons in 1945 from 249,400 in 1944, and there was good demand in evidence from home consumers as the year closed. Although control remained in force throughout the year, restrictions on the use of tin plate were eased during the latter part of 1945. Export orders greatly exceeded the tonnage that South Wales could supply, and it was necessary to withhold commitment on all export inquiries for deliveries in first half of 1946. Permits for export were issued against special priorities only. Shortage of labor has made it impossible to expand export business by reopening more mills. In July 1945 less than 10,000 were employed compared with nearly 25,000 in 1939. Demobilized workers have been reluctant to return to the industry. About 200 mills could reopen within a reasonable time if labor were available and would almost double the present output in Wales. Controlled selling prices for tin plate remained in force during 1945, but under an upward revision of steel prices authorized by the British Ministry of Supply December 31, 1945, the official maximum price for the home trade has been raised from 29s. 9d. to 32s. 6d. per box, f. o. b. makers' works; and from 30s. 9d. to 35s. to 37s. f. o. b. works' port for export, varying considerably according to the country of destination.

Acceptance of the redundancy scheme by the Board of Trade was an important feature of the tin-plate industry of Wales in 1945. Tinplate Scheme, Ltd., has been formed to carry out the scheme. It will handle all financial matters involved; receive and hold the contracts from the makers whose plants are sterilized; and see that they are enforced. The cost of the plan, £420,000, is to be borne by a levy of 6d. per base box on tin-plate production since April 1, 1943.

ARSENIC

By Allan F. Matthews and R. Louise Bryson

SUMMARY OUTLINE

GENERAL STATEMENT

Domestic production of white arsenic decreased a third in 1945 compared with 1944, but a gain in imports cushioned the decline in new supply to 19 percent. Consumption receded about 12 percent; the greater decline in new supply created a deficit bridged by reductions in exports and drafts on stocks.

Arsenic was under allocation control by the War Production Board from May 22, 1942 (Order M–152 and later M–300, Schedule 46) to August 11, 1945, when control was terminated. The lead shortage during 1945 induced the WPB March 27 (Order M–384 amended) to restrict the quantity of lead available to insecticides manufacturers to 45 percent per quarter of that used in the first half of 1944 or to 1,000 pounds of lead, whichever was greater; this 10-percent cut was less than the reduction in demand for lead arsenate and thus did not hamper its manufacture. White arsenic continued to be quoted at 4 cents a pound throughout 1945, and prices of arsenical insecticides were maintained at levels fixed by the Office of Price Administration in 1943 (Maximum Price Regulation 315 as amended April 6, 1943).

Salient statistics for white arsenic in the United States, 1941–45

	1941	1942	1943	1944	1945
Production short tons	32,481	28,681	31,202	36,094	24,349

[1] Exports by producers only. [2] Apparent consumption.

DOMESTIC PRODUCTION

White arsenic production in the United States was 33 percent less in 1945 than in the peak year 1944 but was greater than in any year before the 1940's. The bulk of the output was a byproduct of copper and lead smelting by the American Smelting & Refining Co. at Tacoma, Wash., El Paso, Tex., and Murray, Utah; by the Anaconda Copper Mining Co. at Anaconda, Mont.; and by the United States Smelting, Refining & Mining Co. at Midvale, Utah.

Wartime demand for arsenic induced Government-owned Metals Reserve Company in 1943 to make five contracts for production of white arsenic from materials other than those ordinarily treated. The original objective was 65,337 short tons by 1948, but a drastic cut-back in military requirements in early 1944 resulted in subsequent cancellation of contracts, and only 42 percent of the stipulated quantity was delivered.

Production of high-arsenic ore by the United States Smelting Co. at Gold Hill, Utah, ceased January 15, 1945, but stocks continued to be treated at Midvale until later in the year. During the 16 months' operation from its reopening in September 1943, 98,784 short tons of ore were mined; treatment was principally at Midvale, but the overflow went to the smelter at Murray, Utah, which also handles flue dust from the roasting of arsenical gold ore at the property of Getchell Mine, Inc., Potosi district, Red House, Nev. No white arsenic was produced by Jardine Mining Co., Jardine, Mont., from its arsenic-gold-tungsten ores in 1945, but a stock pile of several hundred tons of material averaging about 75 percent As_2O_3 remained on hand during the year.

The Anaconda Copper Mining Co. makes metallic arsenic from a portion of its refined white arsenic output. Shepherd Chemical Co., Cincinnati, Ohio, produces sodium arsenite solution for weed killer directly from Canadian cobalt-nickel concentrates. From such concentrates the Ferro Enamel Corp., Cleveland, Ohio, formerly manufactured calcium arsenate and from Burma speiss its subsidiary, the Ferro Enamel Supply Co., from November 1943 to September 1944 likewise produced calcium arsenate, but neither company manufactured the compound in 1945.

White arsenic produced and sold by producers in the United States, 1941–45

Year	Crude			Refined			Total		
	Production (short tons) [1] [2]	Sales		Production (short tons)	Sales		Production (short tons)	Sales	
		Short tons	Value [3]		Short tons	Value [3]		Short tons	Value [3]

FOREIGN TRADE [1]

Imports of white arsenic in 1945 conformed to the 1941–44 average but equaled only two-thirds of the peak 1937 entries. Mexico and Peru are the principal sources. All the metallic arsenic was from United Kingdom. The sulfide reported by the United States Department of Commerce from Peru in 1945 is probably not pure material and may consist of concentrates or impure white arsenic.

Exports of white arsenic in 1945 were less than half of the preceding decade's average; about four-fifths went to the British Commonwealth. Calcium arsenate was exported principally to Peru (42 percent) and Colombia (29 percent), lead arsenate to Brazil (63 percent) and Argentina (13 percent); and paris green—largely for malaria control—to Colombia (36 percent), Cuba (18 percent), and Egypt (16 percent).

White arsenic [1] imported for consumption in the United States, 1941–45, by countries

Country	1941		1942		1943 [1]		1944 [1]		1945 [1]	
	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value

Lead arsenate	9,594,483	592,029	3,054,326	4,265,513	6,339,103
Paris green (cupric acetoarsenite)	[5] 224,976	171,644	1,062,640	1,138,435	456,811

[1] Arsenic trioxide (As_2O_3) content; not strictly comparable with earlier years.
[2] According to U. S. Department of Agriculture, there have been no imports of london purple since 1936.
[3] 1941-42: As reported to Bureau of Mines by the producers; 1943–45: As reported by U. S. Department of Commerce.
[4] Dealers exported an additional 1,077,244 pounds.
[5] Figures cover July to December; not separately classified before July 1.

CONSUMPTION AND USES

Apparent consumption of white arsenic in the United States in 1945 (taking into account changes in Government-owned Office of Metals Reserve stocks) was 38,100 short tons, 14 percent less than the 1941–44 average but higher than any other prior year. Cessation of

[1] Figures on imports and exports (unless otherwise indicated) compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

military demand and a less extensive boll-weevil infestation than usual were the most influential factors. Due partly to the latter factor and to the seasonal low demand for insecticides, arsenic consumption in the final 3 months of 1945 was less than half that of any of the three preceding quarters.

More than half of the arsenic supply is enlisted in the fight against insects, which destroy about 10 percent of all food and fiber crops. Lead arsenate is used primarily to protect apple trees against the codling moth and other fruit orchards, home gardens, and ornamental trees against various chewing insects. Calcium arsenate is utilized principally to combat the boll weevil in cotton fields, but a little is used with paris green in controlling potato bugs and cabbage "worms." According to one investigation,[2] the organic preparation DDT (dichloro-diphenyl-trichloroethane) is more effective than lead arsenate as a general insecticide but not so satisfactory as calcium arsenate against the boll weevil. The insecticide situation is currently described in Industry Report—Chemicals and Allied Products, issued monthly by the United States Department of Commerce.

The second-largest use of arsenic is as a weed killer, particularly on railroad rights-of-way and Hawaiian sugar plantations. Organic compounds, such as Polon (modification of 2,4-dichloro-phenoxyacetic acid),[3] are competitive where selective weed killing is required.

Production of arsenical insecticides, consumption of arsenical wood preservatives, and production of arsenical drugs in the United States, 1941–45

Year	Production of insecticides (short tons)[1]			Consumption of wood preservatives (pounds)[2]		Production of drugs (pounds)[3]
	Lead arsenate (acid and basic)	Calcium arsenate (100 percent $Ca_3(AsO_4)_2$)	Paris green (cupric aceto-arsenite)	Wolman salts (25 percent sodium arsenate)	Zinc meta-arsenite	
1941	[4] 36,656	29,684	2,073	1,656,014	268,795	(5)
1942	31,789	38,898	[6] 2,000	1,307,830	239,786	66,753
1943	40,478	34,932	1,944	769,316	53,516	83,026
1944	45,352	22,154	2,265	782,256	11,503	100,190
1945	35,596	13,920	1,950	(5)	(5)	[7] 36,759

[1] 1941, Bureau of Mines; 1942–45, U. S. Bureau of the Census. Figures for 1945 comprise 11 months actual and December estimated.

[3] War Production Board.
[4] Excludes basic lead arsenate.
[5] Data not available.
[6] Estimated.
[7] January to June, inclusive.

Arsenic is also used in the manufacture of glass, lead-base alloys, dyestuffs, cattle dip, wood preservatives, poison bait, and chemical warfare gases and in the Thylox purification of industrial gases. Demand for arsenical pharmaceuticals is declining rapidly with the advent of the penicillin treatment for venereal diseases. A fluorescent lamp shaped like an ordinary incandescent bulb and utilizing arsenic instead of mercury to produce the ultraviolet radiations[4] has been developed by Westinghouse Electric Corp.

[3] Gas purification, pharmaceuticals, cattle dip, paint, poison bait, military, and other uses.

PRICES

The quoted price for white arsenic remained at 4 cents a pound for the fifth consecutive year, according to Oil, Paint and Drug Reporter. The base price of lead arsenate in carlots was set at 11–11½ cents a pound by the Office of Price Administration February 8, 1943 (Maximum Price Regulation 315). An amendment effective April 6, 1943, fixed the base ceiling price of other insecticides as follows (cents per pound in carlots): Calcium arsenate, 7–7½ cents; paris green, 20–25 cents; and london purple, 7–8 cents.

The London price of white arsenic, 95–100 percent, 2-ton lots, was held by the British Ministry of Supply at £50–£60 per long ton from October 1943 to March 1945, according to Metal Bulletin. It was lowered to £40–£50 during April to September and £20¼–£31 for the remainder of 1945. The quotation for arsenic metal, 99-percent, was £375 per long ton in 1944 and three quarters of 1945 and reduced to £325 for the final quarter.

STOCKS

Stocks of white arsenic held by producers and Government-owned Office of Metals Reserve decreased 26 percent during 1945, largely as a result of disposal of a third of the Metals Reserve stock pile. Chemical Warfare Service of the War Department, whose need for arsenic was drastically curtailed in 1944, returned to the market enough white arsenic to reduce its stocks from 3,191 short tons on April 1, 1944, to 1,142 tons on January 1, 1945, and 732 tons on July 1, 1945. Producers' stocks of calcium and lead arsenates are believed to have remained at nearly the same high level at the end of 1945 as at the end of 1944.

[1] Arsenic is also believed to be produced in Czechoslovakia, Iran, New Zealand, Spanish Morocco, Turkey, and U. S. S. R. Production figures are not available for these countries.
[2] Data not available; in 1936 to 1940, inclusive, estimate included in total.
[3] August to December, inclusive.
[4] Arsenic content of ores mined was as follows—1936: 23,312 tons; 1937: 20,954 tons; 1938: 21,480 tons. Data not available for later years.

Argentina.—Two chemical factories in Argentina undertook the manufacture of lead arsenate in 1944. An output of 300 metric tons was anticipated for the 1944–45 spraying season.[6]

Australia.—Annual requirements of white arsenic, amounting to about 2,000 metric tons, are being met by domestic production.[7]

[6] Foreign Commerce Weekly, Lead Arsenate Production in Argentina: Vol. 20, No. 3, July 14, 1945, p. 33.
[7] Chemical and Engineering News, Australian Arsenic: Vol. 23, No. 22, Nov. 25, 1945, p. 2145.

Over 90 percent of the arsenic produced in Australia is obtained from the Wiluna district, East Murchison gold field, Western Australia. The principal sources are Wiluna Gold Mines, Ltd., and Moonlight Wiluna Mines, Ltd.[8]

Brazil.—About half the total arsenic requirements of some 1,600 metric tons have been produced domestically.[9] The largest producer is St. John del Rey Mining Co. at Morro Velho, followed by Companhia Minas de Passage, Mariana, and Companhia Brasileira de Mineracao, Caete—all gold operators in central Minas Gerais. A new Cottrell precipitator at Morro Velho and other developments underway are expected to increase white arsenic capacity to 2,000 tons annually.[10]

Canada.—Newcor Mining & Refining, Ltd., subsidiary of Wampum Gold Mines, Ltd., expects by June 1946 to begin production of gold and arsenic at Douglas Lake, Saskatchewan, 3 miles southwest of Flin Flon. The property is equipped with a 100-ton mill and a 50-ton arsenic recovery unit.[11]

France.—Production of calcium arsenate increased from less than 1,000 metric tons annually in prewar years to 15,000 tons in 1943; as a result of war damage to two factories, output dropped to 12,000 tons in 1944. Manufacture of aluminum arsenate has also expanded. Both compounds, derived from local arsenical gold ores, are used principally in the potato fields.[12]

Germany.—Arsenic produced in Germany during World War II was obtained from the arsenopyrite deposits at Reichenstein, Altenburg, and Rothenburg in Silesia, and from the Mansfeld copper mines.[13]

Iran.—Orpiment and realgar are mined at Zarah Shah at a rate of 500 to 600 metric tons of selected ore annually. The ore is transported 120 miles by camel to Zaryan station and thence by rail to the Keredj insecticide factory.[14]

Mexico.—Arsenical flue dust is recovered in Cottrell units of lead smelters of the American Smelting & Refining Co. at San Luis Potosi and the American Metal Co., Ltd., at Torreón and Monterrey. The flue dust from both smelters is sent to the lead refinery of the former company at Monterrey for extraction of white arsenic. A new chemical plant in Juarez has a scheduled daily output of 1 metric ton of calcium arsenate and about 100 kilograms of white arsenic.[15]

Peru.—The process for recovering white arsenic at the Oroya smelter of Cerro de Pasco Copper Corp. was described.[16] The corporation has begun construction of a calcium arsenate plant.[17]

Sweden.—No arsenic was refined during World War II, but appreciable quantities were sold from stock for wood preservation.[18] About 5 million cubic feet of wood are impregnated annually by the Boliden method,[19] an open-tank process utilizing arsenic acid, sodium arsenate, sodium bichromate, and zinc sulfate dissolved in water.[20] The bulk of the enormous quantity of white arsenic, reportedly exceeding 300,000 tons, stored by the Boliden Mining Co. is believed to be too low-grade in its present state for the insecticide and glass trade. Most of the several thousand tons of high-grade refined white arsenic on hand at the end of the war was exported to United Kingdom, Australia, Union of South Africa, and South America.[21]

BISMUTH

By Allan F. Matthews

SUMMARY OUTLINE

GENERAL STATEMENT

United States production and imports of refined bismuth were at the same level in 1945 as in 1944. A 12-percent increase in consumption and a rise in exports were met by withdrawals from stocks. The War Production Board relinquished allocation control of bismuth August 21, 1945, by revoking Order M-276 (effective February 1, 1943) on metallic bismuth and Schedule 88 of Order M-300 (successor to Order M-295, effective April 1, 1943) on bismuth chemicals. The prices of bismuth metal and salts remained fixed during 1945 at levels of March 1942, in accordance with the Office of Price Administration General Maximum Price Regulation, effective May 11, 1942.

DOMESTIC PRODUCTION

The quantity of refined bismuth produced in the United States in 1945 was approximately the same as in 1944 and as the average for 1935-41. Peak output was in 1942. The Bureau of Mines is not at liberty to publish data showing the domestic production of bismuth.

Three primary producers recover byproduct bismuth principally from domestic and imported lead and copper ores and from Mexican bismuth-lead bullion bars. The American Smelting & Refining Co. produces bismuth-lead alloys at its Selby, Calif., Perth Amboy, N. J., and Monterrey, Mexico, plants for refinement at Omaha, Nebr. From Montana copper and Utah lead ores the Anaconda Copper Mining Co., through its subsidiary International Smelting & Refining Co., produces bismuth-lead bullion at Tooele, Utah, and refines it at East Chicago, Ind. The United States Smelting, Refining & Mining Co. ships bismuth-lead bullion from Midvale, Utah, for refinement at East Chicago, Ind., by its subsidiary, U. S. S. Lead Refinery, Inc. The principal importer and consumer is the Cerro de Pasco Copper Corp., New York, which refines large quantities of bismuth in Peru.

Deliveries of refined bismuth by domestic producers to Government-owned Metals Reserve Company to the beginning of 1945 comprised 391,968 pounds from domestic and foreign ores and 568,020 pounds from Mexican bismuth-lead bullion. Additional deliveries during 1945 were 12,347 and 2,000 pounds, respectively. The former quantity includes 3,494 pounds from the ores of Alta United Mines Co., Little Cottonwood district, Alta, Utah. That was the total Alta bismuth delivered to Metals Reserve Company under a contract drawn up April 6, 1944, for prompt delivery of ore containing 100,000 pounds of bismuth, later modified to cover production through December 31, 1944, and then canceled August 1945.

FOREIGN TRADE[1]

Imports.—All entries of refined metallic bismuth in 1941–45 were from Peru. There were no imports of bismuth ore or concentrates in 1945. Preliminary figures for bismuth-ore imports from Bolivia, reported in Minerals Yearbook, 1944, may be assumed to be final. Almost the entire Mexican bismuth output (see world production table) is imported in the form of bismuth-lead bars for refining in the United States.

Bismuth imported for consumption in the United States, 1941–45

Year	Bismuth ore[1]			Refined metallic bismuth		Bismuth compounds and mixtures	
	Pounds		Value	Pounds	Value	Pounds	Value
	Gross weight	Bi content					
1941	(1)	(1)	(1)	223,477	$223,463	41	$744
1942	(1)	(1)	(1)	(2)	(2)	7	22
1943	138,600	48,800	$52,400	[3] 430,874	[3] 397,676	13	53
1944	118,739	51,349	60,878	363,980	345,796	40	352
1945				333,231	316,135		

[1] Figures from Foreign Economic Administration. Those for 1941–42 are not available but are believed to be negligible.
[2] No "imports for consumption"; general imports of 222,684 pounds were reexported.
[3] An additional 71,236 pounds (valued at $43,498) reported by the U. S. Department of Commerce as "bismuth" is ore and is covered by that category in this table.

Exports.—Exports of bismuth metal and alloys were 10 times greater in 1945 than in 1944 but still considerably less than in 1941. Destinations were France (96 percent), Chile (2 percent), and 12 other countries (2 percent).

Bismuth exported from the United States, 1943–45, by classes

Class	1943		1944		1945	
	Pounds	Value	Pounds	Value	Pounds	Value
Matte	10	$20	46	$74		
Metal and alloys	16,209	10,745	10,161	8,557	115,543	$149,031
Compounds and mixtures:						
Carbonate	25,795	42,055	46,761	67,725	22,197	35,178
Chloride	2,438	6,967	501	1,473	(1)	(1)
Gallate	7,278	11,515	8,429	13,302	(2)	(2)
Iodide	551	1,484	2,884	1,432	(2)	(2)
Nitrate	33,259	45,279	42,845	56,319	78,895	105,061
Oxide	345	1,226	355	1,154	(1)	(1)
Sulfate			2	20	(1)	(1)
Other	6,412	13,609	11,299	26,482	[1] 22,331	[1] 50,902

[1] Beginning January 1, 1945, included with "Other."
[2] Beginning January 1, 1945, data not available; included with "Medicinal chemicals for prescription use, n. e. s."

[1] Figures on imports and exports (unless otherwise indicated) compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

CONSUMPTION AND USES

Domestic bismuth consumption increased 12 percent in 1945 over 1944 and was greater than in any years except 1942 and 1943. Apparent consumption was 2,500,000 pounds in the peak year 1942.

Of the bismuth consumed in the United States in 1945, pharmaceuticals manufacturers utilized half, that is, some 840,000 pounds, a quantity approximating the average consumed for that purpose during the past decade. Bismuth pharmaceuticals comprise principally antisyphilitic drugs, indigestion remedies, and cosmetic powders. The demand for bismuth drugs is expected to decline as the penicillin method for treating venereal disease becomes more prevalent.

Metallurgical uses represented 49 percent of the bismuth consumption in 1945 compared with 55 percent in 1942–44 and about 25 percent in the middle 1930's. Alloys of bismuth (35–60 percent) with lead, tin, and cadmium melt at low temperatures and either expand or exhibit no appreciable volume change on solidification, promoting sharp reproduction of surfaces against which they are cast. One of these alloys, "Cerrolow 105," contains indium and has a melting point of 105° F. The group of alloys is used by the aircraft and automotive industries to prepare spotting fixtures, to make molds for electroforming, to fill thin-walled tubing during bending, to anchor fragile parts in machining or testing, to proof-cast forging dies and molds, to spray-coat wooden patterns and core boxes in foundries, and to liquid-seal bright-annealing and nitriding furnaces.[2]

Other bismuth alloys are used as solders, coatings for selenium rectifiers, and safety fuses in electrical circuits, compressed-gas cylinders, fire sprinklers, and fire-door releases. Small additions of bismuth to aluminum alloys, malleable irons, and certain steels increase machinability. The principal aluminum alloys so treated in the final year of World War II were those made into forged cylinder heads of air-cooled aviation engines. Considerable bismuth was used in the production of atomic bombs, radar equipment, and undisclosed war uses.[3]

Bismuth consumed in the United States, 1943–45, by uses

[Figures compiled by War Production Board]

Use	1943		1944		1945	
	Pounds	Percent of total	Pounds	Percent of total	Pounds	Percent of total
Pharmaceuticals	985,544	49	585,193	40	839,458	51
Fabricating alloys	652,558	33	426,894	29	371,334	23
Ammunition solders	208,632	10	211,789	14	91,250	6
Fuse alloys	40,889	2	91,096	6	77,169	5
Aluminum alloys			8,315	1	58,107	3
Other [1]	116,768	6	142,353	10	197,975	12
Total consumption	2,004,391	100	1,465,640	100	1,635,293	100

STOCKS

Stocks of bismuth metal held by producers, distributors, and consumers were reduced one-fourth in the spring of 1945. They were replenished in October, however, and by December 31 stocks were only 4 percent less than those of January 1.

Bismuth-metal inventories of Government-owned Office of Metals Reserve (successor to Metals Reserve Company July 1, 1945) gradually diminished from 958,991 pounds on January 1, 1945, to 762,829 pounds on December 31. The Government held no stocks of bismuth ore or concentrates during 1945.

PRICES

Since October 1939 and throughout 1945 metallic bismuth was quoted at $1.25 per pound, ton lots, according to E&MJ Metal and Mineral Markets. The prices of bismuth compounds were unchanged during 1942–45.

The London price of bismuth ore, 50 percent, c. i. f., per pound of contained Bi, was reduced from 4s. 6d. in January and February to 3s. 0d. for the remainder of 1945; on the other hand 30–35-percent are held at £110–£125 a long ton all year, according to the Metal Bulletin. Metallic bismuth, 99.95 percent, 5-cwt. lots, was quoted at 6s. 3d. per pound until a December raise to 6s. 8d. Bismuth matrix and bending alloys were steady at 4s. 6d. and 5s. 0d., respectively, during 1945.

TECHNOLOGY

Molybdenite was floated from bismuthinite, bismutite, and bismite by using xanthate as the collector, eucalyptus oil as the frother, and potassium bichromate as the conditioner. The feed contained 19 percent Bi and 11 percent MoS_2 and yielded concentrates of 43 percent and 93 percent, respectively.[4] The chemical reactions of bismuth and its compounds were catalogued.[5]

In-process materials at the copper-lead smelter of the Cerro de Pasco Copper Corp., Oroya, Peru, contain the following percentages of bismuth: Concentrates and byproduct roaster dusts comprising sinter feed, 0.43: finished sinter, 0.47; hot reverberatory Cottrell dust, 2.20; crude lead bullion, 1.12; and electrolytic lead refinery slimes, 13 percent. Treatment of the slimes is described by corporation engineers,[6] as follows:

> Bismuth-bearing slags from the converter and cupel operations are given a partial reduction in one of two 4- by 12-ft. oil-fired reverberatory furnaces. Partly reduced slag from this operation is returned to the converters, bismuth in slag being replaced by antimony from metal. Metal which contains 82 to 85 percent bismuth is transferred liquid to the kettle section for refining.
>
> Bismuth metal from the reverberatory operation is first given a caustic soda treatment for tellurium removal. Metal is then copper-drossed, the dross being matted with pyrite and coal. Matte is shipped to the copper circuit and metal

is returned to the kettle. After decopperizing, metal is desilverized by the Parkes process, the first or hot crusts being liquated and retorted, bismuth-bearing metal being returned to the bismuth circuit, and retort bullion entering the silver circuit. Metal is desilverized in two stages to ensure maximum purity. Lead and zinc are removed with chlorine in a cast-iron kettle. Chlorine tubes are of cast iron with pyrex glass inserts. About 24 hours is required for the operation and the end point is determined by a bar sample, which shows a distinct radial fracture when saturated with bismuth chloride; metal is then transferred into an air-sweep kettle for its removal. The metal is blown with air for about sixteen hours, the dross formed being returned to the de-leading kettle. The metal is then transferred to a casting kettle and given a final caustic soda treatment to ensure high purity. Cast bismuth assays 99.999 percent pure.

WORLD PRODUCTION

World production of bismuth approximated 1,100,000 kilograms (2,400,000 pounds) in 1945. The principal producers were United States, Peru, Canada, and Mexico.

World production of bismuth, 1940–45, by countries, in kilograms [1]

[Compiled by B. B. Waldbauer]

Country [1]	1940	1941	1942	1943	1944	1945

[1] Bismuth is believed to be produced also in Brazil, Burma, Chile, China, Germany, Japan, Norway, Rumania, Sweden, Uganda, U. S. S. R., United Kingdom, and Yugoslavia. Production figures are not available for these countries, but estimates by author are included in total.
[2] Content of ore exported to United States.
[3] Data not available. Estimate included in total.
[4] Estimate.
[5] Partly estimated. Excludes content of some bismuth-tungsten concentrates.
[6] Excludes bismuth content of tin concentrates exported.
[7] Production included in total; Bureau of Mines not at liberty to publish figure.

Australia.—Small quantities of bismuth ore have been mined as a byproduct of molybdenum and tungsten, principally at the Whipstock and Kingsgate mines, eastern New South Wales, and at the Biggenden mine, southeastern Queensland. The output was largely from Hatches Creek, central Northern Territory, in 1941–42. Since the closing of the Biggenden mine in 1937, it has been necessary to import about three quarters of Australia's bismuth requirements, and the bulk of it has been high-grade carbonate ore from China. The major lead, zinc, and copper deposits of Australia contain but minor quantities of bismuth. Lead concentrates from the Broken Hill district contain only 0.0003 percent Bi and the roasted and leached zinc concentrates only 0.0001 percent. Current annual consumption of bismuth is about 70,000 pounds, 95 percent made into medicinal salts by Bismuth Products Pty., Ltd., Sydney, and the remainder into various alloys.[7]

[7] Chace, Frederic M., The Mineral Industry of Australia: Bureau of Mines, Foreign Minerals Survey, vol. 2, No. 3, March 1945, pp. 101–102.

Germany.—German production of bismuth during World War II was typified by the rate in 1943, when 327 workmen mined 9,169 metric tons of ore and made a concentrate of 327 tons containing 17.6 percent Bi, 8.3 percent U_3O_8, 2.7 percent Co, and 0.6 percent Ni.[8]

Peru.—One of the world's largest producers of bismuth is the Cerro de Pasco Copper Corp., whose nonferrous metal properties and operations were comprehensively described in Mining and Metallurgy by officials of the corporation.[9] Their account of the refining of bismuth at Oroya is abstracted in the Technology section of this chapter.

Spain.—Production of bismuth concentrates during the first 9 months of 1945 totaled 33 metric tons compared with 39 metric tons in the corresponding period of 1944.[10] The tenor approximates 25 percent Bi.

Sweden.—The Boliden Mining Co. has resumed production of bismuth and is expected to provide Sweden's requirements of 10,000 kilograms a year.[11]

United Kingdom.—Imports of bismuth metal were 381.875 pounds in 1945 compared with 786,301 pounds in 1944 and 816,645 pounds in 1938.

MAGNESIUM

By JOHN H. WEITZ AND MARY E. TROUGHT

SUMMARY OUTLINE

SUMMARY

Production of primary magnesium in the United States in 1945 totaled 32,792 short tons—79 percent less than in 1944 (157,100 tons). Decreasing demand for war purposes resulted in curtailment of operating facilities; by the end of 1945 all Government-owned plants had ceased production, and Dow Chemical Co. remained the only commercial producer.

Salient statistics of the magnesium industry in the United States, 1941–45

	1941	1942	1943	1944	1945
Production of primary magnesium [1] short tons	16, 295	48, 963	183, 584	157, 100	32, 792
Quoted price per pound [2] cents	22. 5	22. 5	20. 5	20. 5	20. 5
Exports [3] short tons	1, 549	4, 045	35, 631	21, 001	518
World production (estimated) do	72, 100	131, 400	283, 700	264, 400	60, 600

[1] Ingot equivalent.
[2] Lowest nominal price (New York) for primary metal ingot 99.8 percent pure, carlots.
[3] Magnesium metal, 1941–42; metal and alloys, 1943–45.

Magnesium sold or used in 1945 totaled 43,496 short tons, 70 percent less than the 1944 figure of 146,585 tons. Actual consumption of magnesium (based on an incomplete canvass) in the form of primary metal and alloy (excluding secondary) was 43,987 tons (magnesium content). Exports in the form of metal and alloys totaled 518 tons; imports were negligible.

World magnesium output is estimated at 55,000 metric tons in 1945, 77 percent less than the 239,900 tons produced in 1944.

PRODUCTION

Primary.—Output of primary magnesium in the United States in 1945 totaled 32,792 short tons (ingot equivalent), a decrease of 79 percent from the 157,100 tons produced in 1944. These figures represent the magnesium ingot produced directly from Dow-type electrolytic cells plus the magnesium ingot equivalent of the raw and crystal metal obtained from other processes of manufacture which experiences some loss when melted down into ingot form. The total output of all primary magnesium in the various forms, making no allowances for melting losses, was 33,106 tons in 1945 compared with 161,935 tons in 1944.

During 1945 magnesium was produced by seven plants, four of which were Government-owned. The Government-owned plants were the New England Lime Co. ferrosilicon-process plant at Canaan, Conn.; the Magnesium Reduction Co. ferrosilicon-process plant at Luckey, Ohio; the Diamond Magnesium Co. electrolytic, Dow-type plant at Painesville, Ohio; and the Dow Magnesium Corp. electrolytic (sea-water) plant at Velasco, Tex. The three privately owned plants operating during the year were the two Dow Chemical Co. plants in Texas and the Permanente Metals Corp. at Permanente, Calif. At the end of 1945 only the Dow Chemical Co. was producing magnesium. The sole potential competition to the Dow Co. apparent at the end of the year was Henry J. Kaiser's Permanente Metals Corp. plant, where the Hansgirg carbothermal process was used during the war. Kaiser announced in December that the company had repaid in full the $28,745,000 loan extended by Reconstruction Finance Corporation for construction of the plant. Experiments are reported to have been carried on during 1945 aimed at reducing operating costs from an estimated 30 cents a pound to half that figure. Certainly without a very substantial cut in costs the plant could not hope to compete in a market in which magnesium sells for 20.5 cents and in which capacity considerably exceeds demand.

Production, sales, exports, and apparent consumption of primary magnesium in the United States, 1941–45, in short tons

	Production		Sales	Exports [1]	Apparent consumption [2]
	Raw, crude, and pure ingot	Ingot equivalent			
1941	16,295	16,295	15,528	1,549	13,979
1942	(3)	48,963	47,420	4,045	43,375
1943	190,025	183,584	170,267	14,720	155,547
1944	[4] 161,935	[4] 157,100	146,585	4,830	141,755
1945	33,106	32,792	43,496	496	43,000

[1] Primary metal only. Alloy exports in addition: 20,911 tons in 1943; 16,171 tons in 1944; and 22 tons in 1945; corresponding data for 1941–42 unavailable.
[2] Does not consider fluctuations in consumers' stocks and metal derived from scrap. Withdrawals from producers' stocks totaled 10,704 tons in 1945; additions to producers' stocks totaled 767 tons in 1941; 1,543 tons in 1942; 13,317 tons in 1943; and 10,515 tons in 1944
[3] Not available.
[4] Does not include magnesium content of incendiary mixture produced direct.

Dow Chemical Co., again in 1945 the sole producer of magnesium, owns outright 36,000,000 pounds of annual capacity at Midland, Mich., and Freeport, Tex. In addition, the company holds a right of first refusal on the Government-owned part of the Freeport plant and on the Velasco, Tex., plant, both of which are designed to process sea water.

At the end of 1945 no negotiations had been concluded for the sale of any of the Government plants, although some interest had been shown in several of them, chiefly as possible chemical-producing units.

The Surplus Property Administration recommended late in 1945 that 6 of the 13 Government-owned plants be held in operating or stand-by condition and that the remaining 7 be disposed of, perhaps through adapting them to other uses. The 6 plants recommended for stand-by lease, or sale as magnesium facilities, are the following: Freeport, Tex. (18,000 short tons annual capacity); Velasco, Tex. (36,000-ton capacity); Painesville, Ohio (18,000-ton capacity); Luckey, Ohio (5,000-ton capacity); Spokane, Wash. (24,000-ton capacity); and Canaan, Conn. (5,000-ton capacity). If this recommendation is carried out the effective magnesium-producing capacity of the United States will be approximately 136,000 short tons a year compared with a wartime peak capacity of 293,000 tons.

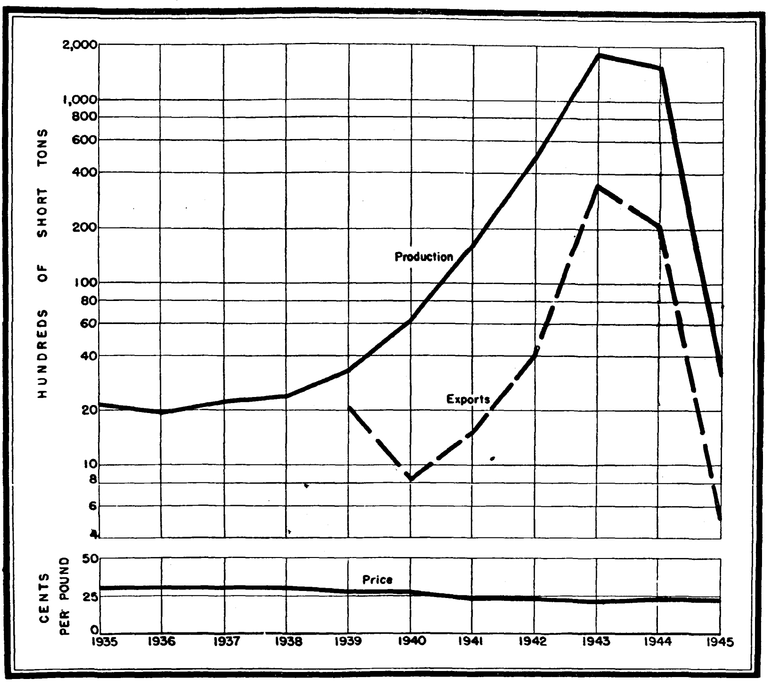

FIGURE 1.—Trends in production, exports, and quoted price of primary magnesium, 1935–45.

Secondary.—Recovery of secondary magnesium, including alloying ingredients, totaled 9,247 short tons (including secondary magnesium incorporated in primary magnesium ingot) in 1945 (14,185 tons in 1944) and required the consumption of 10,650 tons of magnesium scrap, 91 percent of which was new scrap. Of the quantity of magnesium recovered, 7,359 tons were as ingot and 496 tons went into castings, 864 tons into magnesium-alloy shapes, 274 tons into aluminum alloys, 13 tons into other alloys, and 241 tons into chemicals and incendiary products. Additional information of secondary magnesium will be found in this volume in the chapter on Secondary Metals—Nonferrous.

CONSUMPTION AND USE

The largest share of the magnesium consumed by industry during 1945 was used for war purposes—incendiaries, aircraft parts and accessories, rocket launchers, flares, and tracers. Consumption of the metal for war uses dropped sharply after the surrender of Germany and even more sharply after the Japanese capitulation; civilian uses were a very small share of total use. Apparent consumption of pure primary magnesium, calculated by subtracting exports from sales, totaled 43,000 tons in 1945 compared with 141,755 tons in 1944, a decrease of 70 percent.

A canvass measuring actual consumption was conducted in 1945, as in the preceding year; but, owing to the fact that many companies were unable to furnish the data requested, the statistics are incomplete. Actual domestic consumption totaled 43,987 short tons in 1945, a decrease of 67 percent from the 132,698 tons consumed in 1944. Of the 43,987 tons used, 31,641 tons (72 percent) were consumed in making structural products (castings, sheet, structural shapes, and forgings); and 12,346 tons or 28 percent were consumed in other products, including powder, alloys with other metals, and miscellaneous uses. Castings, largely sand and die, was the largest single use for the metal, taking 27,515 tons or 63 percent of the total. Sand castings accounted for the use of more than twice as much metal as permanent mold castings, whereas in 1944 more magnesium was used in permanent mold castings.

Actual domestic consumption of primary magnesium (ingot equivalent and magnesium content of magnesium-base alloys) in 1944–45, by uses

Product	1944	1945 [1]	Product	1944	1945 [1]
Structural products:			Other products:		
Castings:			Powder	9,080	4,769
Sand	44,773	18,405	Aluminum alloys	6,868	5,589
Die	1,165	803	Other alloys	12	24
Permanent mold	59,181	8,307	Scavenger and deoxidizer	159	228
Sheet	1,543	1,517	Chemical	156	182
Structural shapes, rods, tubing (extrusions)	4,784	2,452	Other [2]	4,633	1,554
Forgings	344	157	Total other products	20,908	12,346
Total structural	111,790	31,641	Grand total	132,698	43,987

[1] Owing to lack of returns from a number of companies, figures are incomplete.
[2] Includes primary metal consumed in making secondary alloy.

PRICES

Throughout 1945 the base price of standard four-notch primary magnesium ingot remained at 20.5 cents a pound. On August 30, 1945, the Office of Price Administration announced that price controls on primary and secondary magnesium and magnesium scrap were suspended, but this had no effect on prices during the remainder of the year. Also suspended were controls over magnesium castings, formerly subject to Maximum Price Regulation 125, which were used mainly for aircraft and other military items. Controls over magnesium strip, sheet, tube, and rod remained in effect.

FOREIGN TRADE [1]

Imports of magnesium in 1945 in all forms, all of which came from Canada, totaled 20,308 pounds (10 tons) valued at $3,768 and consisted of 14,561 pounds of metal and scrap, 15 pounds of magnesium alloy, and 5,732 pounds of powder.

Exports of magnesium from the United States, 1944–45

	1944		1945	
	Short tons	Value	Short tons	Value
Magnesium metal in primary form	[1] 21,001	$9,799,833	[2] 518	$216,793
Magnesium metal in other forms	1,597	987,048	140	292,430
Magnesium powder	1,600	2,301,293	720	579,736

[1] Includes 16,171 tons of magnesium-base alloy.
[2] Includes 22 tons of magnesium-base alloy.

Exports of magnesium in primary form decreased from 21,001 tons in 1944 to 518 tons in 1945, a drop of 98 percent; large decreases in exports of metal in other forms, and of powder, were also recorded. Of the metal in primary form, 280 tons went to U. S. S. R., 210 tons to Mexico, 22 tons to Sweden, and 2 tons or less each to nine other countries. Canada received 84 tons of the magnesium metal exported in other forms, U. S. S. R. 48 tons, and other countries 8 tons. The magnesium powder exports were distributed as follows: United Kingdom 554 tons, Canada 91 tons, Brazil 73 tons, and Mexico 2 tons.

In 1945, exports of magnesium metal in primary form were equivalent to about 2 percent of the total domestic production compared with 13 percent in 1944.

GOVERNMENT REGULATIONS

Magnesium, which was virtually free of use restrictions after revocation of War Production Board Preference Order M–2–b and the simultaneous issuance of Order M–2–c in October 1944, was made entirely free of restrictions as to use when Order M–2–c was revoked on July 24, 1945. This order had required the filing of monthly reports with WPB and had made requests for delivery of magnesium subject to the various priorities regulations.

WORLD PRODUCTION

The world output of primary magnesium declined sharply in 1945 to an estimated 55,000 metric tons, compared with 239,900 tons in 1944, a decrease of 77 percent. The largest drop from a tonnage standpoint was in the United States, but the percentage decrease was perhaps greater among the Axis nations. Data on which to base estimates for individual countries were so meager in 1945 that estimates were omitted, except for four countries in the table. As a result of cut-backs as World War II was drawing to an end, production fell to its lowest level since 1940.

Canada.—The ferrosilicon-process plant at Haley's Station was purchased from the Dominion Government in the middle of 1945 for a reported price of $1,400,000, of which $100,000 was the down pay-

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

Estimated world production of magnesium, 1940–45, by countries, in metric tons

	1940	1941	1942	1943	1944	1945
Australia		200	430	800	900	(1)
Canada [2]		5	367	3,245	4,799	3,380
France [2]	2,562	1,908	1,332	1,741	842	(1)

United Kingdom [2]	1,510	9,232	14,630	18,794	12,887	6,000
United States [2]	5,680	14,782	44,418	166,544	142,518	29,748
Total	36,500	65,400	119,200	257,400	239,900	55,000

[1] No data available. Estimates included in total.
[2] Actual production.

ment. The balance is to be retired in annual payments equal to 1 cent a pound for metal produced but not less than $50,000 a year with interest of 3¼ percent on the outstanding principal. In addition, the purchasing company has agreed to spend at least $500,000 in the next 2 years to make improvements and install additional facilities. Total capital expenditure by the Government was $3,448,062. The plant recovered over 12,000 short tons of metal from August 1942 to June 30, 1945, from the 146,913 tons of dolomite treated in that period. Substantial stocks of magnesium were reported to have been built up before the plant was closed, enabling shipments to be continued while alterations were in progress. Operations were expected to be resumed in 1946.

France.—Production of magnesium was resumed in France during 1945, and output was reported to be about 50 tons a month by the end of the year.

Germany.—Late in 1945 primary magnesium production in Germany was banned for an indefinite period by agreement among France, Great Britain, Russia, and the United States. Thus Germany, which was until 1942 the leading producer of magnesium, is no longer a factor in the industry.

United Kingdom.—Consumption of magnesium in the United Kingdom was sharply reduced in the latter half of 1945. As recorded in the Monthly Digest of Statistics, the monthly average consumption dropped from 1,160 tons in the first half of the year to 460 tons in the third quarter and to 130 tons in November. It is stated by British sources that only about 65 percent of total requirements during the war was filled by domestic production. Use of magnesium was principally in aircraft castings and incendiary bombs; only a very small percentage of the total was consumed in the production of sheet, forgings, and extrusions. By the end of 1945 only the Clifton Junction plant of Magnesium Electron, Ltd., and the Swansea plant of Magnesium Metal Corp. were in operation.

On August 1, 1945, the Government removed some of the controls over magnesium to grant licenses to users under which they were free to purchase and use the metal in any desired amount, for any purpose, and from any supplier. The price for magnesium ingot remained at £168 a long ton, which is equivalent to about 30 cents a pound.

ANTIMONY

By Thomas P. Wootton

SUMMARY OUTLINE

SUMMARY

Government control under War Production Board General Preference Order M–112 was increased, effective February 10, 1945, after antimony had been available without allocation for more than a year. This order required reports and formal allocation requests to be filed monthly by possessors or purchasers of more than 2,240 pounds of antimony contained in any commercial product. On May 12 the order was amended to require requests from consumers wanting to purchase more than 224 pounds (antimony content) at any one time, but the allowable inventory remained at 2,240 pounds. This order remained in effect throughout the year.

Domestic production of antimony contained in ores and concentrates was the lowest in 4 years. Antimony imported for consumption as metal and contained in ore increased one-third to a total of 23,270 tons. Industry-owned stocks were up slightly; but both Government and mine stocks declined sharply, leaving a net decrease of 17 percent from 26,322 tons to 21,958.

The Office of Price Administration ceiling price of American antimony metal in less than carlots remained 15.84 cents a pound for its second full year. The average price in previous years was: 1943, 15.92 cents a pound; 1942, 15.55; 1941 and 1940, 14.00. The price of antimony ores and concentrates ranged from \$2.10 to \$2.30 a short-ton unit for material ranging from 50 to 65 percent antimony.

Figure 1 is a graphic presentation, insofar as data are available, of world production, United States imports, and New York price.

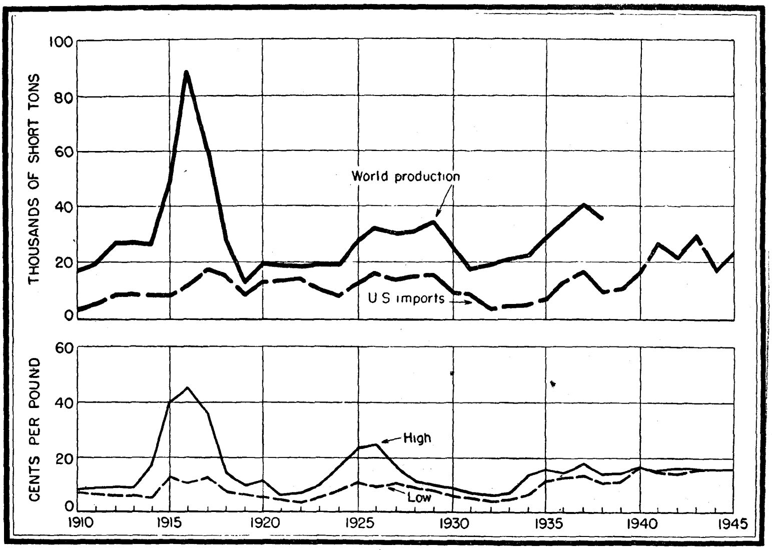

FIGURE 1.—Trends in world production, 1910–38, and United States imports and range in New York price of antimony, 1910–45.

DOMESTIC PRODUCTION

MINE PRODUCTION

In 1945 only 8 mines—3 each in Idaho and Nevada and 2 in Oregon are known to have produced antimony ores and concentrates, compared with 11 in 1944 and 17 in 1943. Although gross tonnage increased slightly from 13,501 to 14,966, antimony content dropped nearly 60 percent from 4,735 to 1,930. Most of this was contained in concentrates recovered from ores mined primarily for other metals, such as gold and tungsten. Only 32 tons of the metal were contained in ores mined solely for their antimony. Of the United States total mine production of antimony, 97 percent came from the complex ores of Shoshone and Valley Counties, Idaho.

Alaska.—No production of antimony ores or concentrates was reported from Alaska for the year 1945. Past production has come from the Stampede and Slate Creek mines in the Kantishna district.

Idaho.—As in the past, the mines of Shoshone and Valley Counties yielded most of the antimony obtained from domestic sources. The Bradley Mining Co. Yellow Pine gold-tungsten-antimony mine in Valley County produced most of the United States total mine output followed by the Sunshine Mining Co. Sunshine mine and the Coeur d' Alene Mines Corp. Mineral Point mine, both in Shoshone County.

Nevada.—Three operators in Elko, Lander, and Nye Counties produced 65 tons of antimony ore containing 22 tons of antimony, a decrease of about 25 percent in metal content from the previous year's output.

Oregon.—Only two antimony mines are known to have been operated in Oregon in 1945. Anthony Brandenthaler shipped several cars of gold-antimony ore to Midvale, Utah, from his Gray Eagle mine in Baker County, and Bert B. Lowry & Sons shipped a car of antimony ore from its property in Jackson County.

SMELTER PRODUCTION

Primary.—Smelter output of primary antimony as metal and contained in the oxide and sulfide increased 5 percent to 21,000 tons. Separate figures on these 3 primary and intermediate products cannot be published. This production came from 11 plants, including 1 new enterprise and 1 plant the output from which was previously reported with that of another plant owned by the same company. These reduction works consumed 23,200 tons of antimony in raw materials, including 18,500 tons in ores and concentrates.

The Texas Mining & Smelting Co., Laredo, Tex., continued to be the dominant factor in domestic metal production but was surpassed by one and nearly equaled by two other firms in output of the oxide. The Texas plant operates almost entirely on oxide and mixed oxide-sulfide ores imported from Mexico.

Other plants producing antimony metal in 1945 were those of the Bunker Hill & Sullivan Mining & Concentrating Co., Kellogg, Idaho; Harshaw Chemical Co., El Segundo, Calif.; and the Defense Plant Corporation, Glen Cove, Long Island, N. Y. The latter began operations in September, using imported ores supplied by the office of Metals Reserve (successor to Metals Reserve Company, November 3). The plant is operated for the Government by the Wah Chang Trading Corp. of New York. The Sunshine Mining Co.'s plant at Kellogg, Idaho, remained idle throughout the year.

Antimony oxide also was produced from ores, concentrates, and metal by the American Smelting & Refining Co., at Omaha, Nebr., and Perth Amboy, N. J.; Harshaw Chemical Co., at El Segundo, Calif., and Elyria, Ohio; McGean Chemical Co., at Cleveland, Ohio; and Metal & Thermit Corp., at Carteret, N. J.

Sulfides of antimony, including the black needle or liquated sulfide and the chemically precipitated golden and crimson material, were produced from chemical-grade sulfide ore and from the oxide by Rare Metal Products Co. at Belleville, N. J., by Harshaw at Philadelphia, and by McGean.

Production of antimonial lead in 1945 at domestic primary lead refineries declined slightly to 56,495 tons containing 4,148 tons (7.3 percent) of antimony. The contained antimony was derived as follows: From domestic ores 42 percent, from foreign ores 6 percent, and from scrap 52 percent. Details are shown in the accompanying table, and a fuller discussion will be found in the chapter of this volume on Lead.

Antimonial lead produced at primary lead refineries, 1941–45, in short tons

Year	Production	Antimony content				
		From domestic ores [1]	From foreign ores [2]	From scrap	Total	
					Quantity	Percent
1941	40,237	2,586	372	552	3,510	8.7
1942	51,762	2,396	871	257	3,524	6.8
1943	63,515	1,591	494	1,286	3,371	5.3
1944	57,902	2,015	842	1,813	4,670	8.1
1945	56,495	1,749	243	2,156	4,148	7.3

[1] Includes primary residues and small quantity of antimony ore.
[2] Includes foreign base bullion and small quantity of foreign antimony ore.

Secondary.—Recovery of antimony in antimonial lead and other alloys from scrap at secondary smelters and by remelters in 1945 amounted to 17,148 tons, an increase of 8 percent over the 15,886 tons similarly recovered in 1944. This quantity plus the 25,761 tons of antimony contained in primary materials put in process (but not necessarily recovered—see Consumption and Uses) totals 42,909 tons, which is also an increase of 8 percent over the comparable figure (39,642 tons) for 1944. Plates, grids, and sludge from discarded storage batteries continued to be the main source of secondary antimony. A detailed review will be found in the chapter of this volume on Secondary Metals—Nonferrous.

PRODUCTION BY MANUFACTURERS

It is very difficult to obtain a true picture of the total output of such metallic antimony-containing products as alloys for bearings, batteries, type, and cable coverings and such nonmetallic products as flameproofed textiles, paints, and ceramic enamels. However, due to Government controls and allocation procedures, it is possible to measure the antimony content of raw materials put in process in the manufacture of these items or in the manufacture of the intermediate products customarily used in producing them. Therefore, a discussion of the raw materials consumed in the manufacture of these metallic and nonmetallic products appears below under Consumption and Uses.

CONSUMPTION AND USES

Primary antimony content of ores and concentrates and antimony metal, oxide, and sulfides consumed in the manufacture of 10 metallic and 9 nonmetallic items for 1943–45, is shown in the accompanying table. The figures were compiled from monthly applications filed with the Civilian Production Administration by more than 400 operators asking for allocations of antimony raw materials for use in manufacturing the various items listed. No record is kept of the stocks, production, and shipments of those items, and the metallurgical losses are not reported. The table merely records the fact that 25,761 tons of antimony contained in the raw materials mentioned were consumed during the year in the process of manufacturing the 19 items.

Industrial consumption of primary antimony, 1943–45, in short tons

[Antimony content of raw materials, including ores and concentrates, metal, oxide, and sulfides, put in process]

Product	Antimony consumed in the manufacture of products listed		
	1943	1944	1945
Metal products:			
Antimonial lead	2,889	5,287	5,920
Bearing metal and bearings	1,563	2,637	2,825
Battery metal and battery parts	2,400	2,341	1,273
Type metal and type	856	841	1,243
Cable covering	447	422	275
Sheet and pipe	176	326	368
Castings	198	115	267
Collapsible tubes and foil	132	114	203
Ammunition	389	93	107
Solder	129	71	125
Total metal products	9,179	12,247	12,606
Nonmetal products:			
Flameproofed textiles	6,952	7,063	7,675
Paints and lacquers	1,859	2,490	3,062
Frits and ceramic enamels	281	501	936
Glass and pottery	537	411	304
Sodium antimonate	47	369	512
Antimony trichloride	153	289	207
Ammunition primers	97	43	66
Matches	18	10	18
Other	385	333	375
Total nonmetal products	10,329	11,509	13,155
Grand total	19,508	23,756	25,761

Consumption of antimony in the manufacture of all the major items except battery metal and parts increased sharply. The rise in consumption for making metal products was 3 percent and for nonmetal products 14 percent; the total amounted to a little more than 8 percent. Continued war demand is reflected in the increased use of antimony in producing several items, particularly paints and compounds for flameproofing textiles, and the beginning of reconversion in the last part of the year is shown by the figures on type metal, collapsible tubes and foil, ceramic materials, and matches. The use of metallic antimony and liquated antimony sulfide in making ammunition, including primers, was almost entirely for civilian sporting cartridges, inasmuch as the armed forces' small arms ammunition program was well on the way toward completion before the beginning of 1945.

STOCKS

Stocks of the antimony raw materials—ores and concentrates, metal, oxide, and sulfides—held as mine stocks, by industry and in Government stock piles, declined 17 percent from 26,332 to 21,958 short tons of contained antimony. Details, including net receipts and consumption of ores and concentrates by smelters and manufacturers, are shown in the accompanying tables.

Stocks of antimony in ores and concentrates held by smelters and manufacturers on December 31, 1945, were greater than at the end of the previous year by nearly 40 percent. Government stocks increased 11 percent, but mine stocks declined 34 percent, making a net gain of slightly more than 1 percent. Antimony content of oxide on hand increased 25 percent, due largely to cancellation of Army and Navy contracts for flameproofing compounds and fire-retardant paints, while the small stocks of antimony sulfides dropped 13 percent. The significant change, however, was the 54-percent decrease in total stocks of antimony metal. This was brought about by the heavy demand for oxide in the early months of the year, when the lack of suitable ores necessitated the production of oxide from metal, most of which was drawn from Government stocks.

Antimony ores and concentrates at smelters and manufacturers in 1945, in short tons of contained antimony

Raw materials	Stocks on [1] Dec. 31, 1944	Net receipts	Consumption	Stocks on Dec. 31, 1945
Chemical-grade sulfide ore	794	7,055	6,914	935
Metallurgical-grade sulfide ore	405	5,552	5,050	907
Mixed or oxide ore	990	9,216	9,706	500
Sulfide concentrates	855	4,123	3,074	1,904
Total ore	3,044	25,946	24,744	4,246

[1] From preceding table.

PRICES

The Office of Price Administration New York price of domestic brands of antimony metal, 99.5 percent minimum, in less than carlots remained 15.84 cents a pound and of Chinese brands (duty paid), 16.50 cents (nominal), throughout the year. Likewise, the price of domestic metal in bulk, f. o. b. Laredo, Tex., was unchanged from 14.50 cents. The London price of metal, 99 percent minimum, was lowered to £105 a long ton (from £120), effective January 1, 1945, and was unchanged at that level throughout the year.

According to E&MJ Metal and Mineral Markets, New York quotations on antimony ores and concentrates were stable at $2.10 to $2.20 a short-ton unit for the 50- to 55-percent grade; $2.15 to $2.20 for 58- to 60-percent; and $2.20 to $2.30 for 60- to 65-percent, The London price for 60-percent sulfide ore was 11s. a long-ton unit at the beginning of the year, rose to 11s. 9d. in June, and closed at 13s. 6d.

Average monthly quoted prices of antimony, prompt delivery at New York, 1941–45, in cents per pound, for less than carlots

FOREIGN TRADE[1]

The following four tables give detailed information on the imports and exports of antimony materials for 1941 through 1945.

Antimony imported for consumption in the United States, 1941–45

Year	Antimony ore			Needle or liquated antimony		Antimony metal		Antimony oxides and other compounds	
	Short tons	Antimony content: Short tons	Antimony content: Value	Short tons	Value	Short tons	Value	Short tons	Value
1941	41,662	19,386	$2,717,472	638	$126,018	7,469	$2,056,678	2	$537
1942	50,033	20,946	3,943,402	522	101,164	127	28,904	(1)	5
1943	63,187	28,755	5,351,852	1	172	932	267,916	(1)	3
1944	41,879	17,080	2,721,690			293	105,667		
1945	49,385	22,643	4,644,859			627	181,559		

[1] Less than 1 ton.

Imports of antimony metal rose to 627 tons, an increase of 114 percent over the previous year and the largest quantity received since the record year 1941, and imports of antimony contained in ore increased 33 percent to 22,643 tons.

Receipts of ore from Bolivia were nearly trebled but were still 2,500 tons below those of the record year 1943. For the first time since 1941, an appreciable quantity of metal was imported from China. Imports of ore from Mexico were the lowest recorded in several years, and no metal at all came from that country. A small shipment of metallurgical-grade ore was received from the Union of South Africa.

The gross weight of domestic antimony materials exported in 1945 was 333 tons, of which 250 tons were ores and concentrates and 83 tons metal and alloys.

Reexports of foreign metal and alloys totaled 463 tons, gross weight. There were no reexports of foreign ores and concentrates.

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

Antimony imported into the United States, 1944–45, by countries, in short tons [1]

Country	Antimony ore			Antimony metal	
	Gross weight (short tons)	Antimony content		Short tons	Value
		Short tons	Value		
1944					
Bolivia	7,235	4,450	$865,408		
Chile [2]	774	485	91,816		
China				(3)	$7
Honduras [4]	166	106	15,421		
Mexico	31,851	11,087	1,564,455	220	87,803

	41,472	16,880	2,667,891	294	105,667
1945					
Bolivia	18,970	11,348	2,292,401		
Chile [2]	2,503	1,564	313,141		
China				571	168,228
Honduras	31	17	3,676		
Mexico	25,146	8,303	1,779,770		
Peru	2,781	1,443	240,088	56	13,329
Union of South Africa	112	61	11,960		
	49,543	22,736	4,641,036	627	181,557

[1] Data include antimony imported for immediate consumption plus material entering the country under bond.
[2] Probably mined in Bolivia or Peru and shipped from a port in Chile.
[3] Less than 1 ton.
[4] Includes 77 tons of ore containing 48 tons of antimony in 1944 mined in Honduras but credited by the U. S. Department of Commerce to Guatemala.

Estimated antimony content of type metal, antimonial lead, and other alloys imported for consumption in the United States, 1941–45, in short tons [1]

Year	Type metal and antimonial lead	Other alloys [2]	Total	Year	Type metal and antimonial lead	Other alloys [2]	Total
1941	202		202	1944	388		388
1942	35		35	1945	1,379		1,379
1943	281		281				

[1] For details of gross weight and values, see imports shown in Lead chapter of this volume.
[2] Chiefly in special antimony-lead alloys containing high percentage of antimony.

Foreign antimony (regulus or metal) exported from the United States, 1941–45

Year	Short tons	Value	Year	Short tons	Value
1941	70	$19,690	1944	18	$5,445
1942	(1)	181	1945	463	141,301
1943	(1)	200			

[1] Less than 1 ton.

WORLD PRODUCTION

The accompanying table presents available data on all the important antimony-producing countries of the world. Information not obtained in time to be included in Minerals Yearbook, 1944, has been compiled for several countries, including Algeria, Australia, and Italy. Figures on the output of Chinese mines have been revised on the basis of an official report [2] recently received. The world total for 1939–44 has been estimated although information is still lacking on the output of several countries, most of them small producers.

[2] Statistical Abstract of the Republic of China, Chungking, Apr. 10, 1945, pp. 38–39.

World production of antimony, 1938–45, by countries, in metric tons [1]

REVIEW BY COUNTRIES

Australia.—The following notes on the Australian antimony industry have been abstracted from a report [3] issued by the Foreign Minerals Division of the Bureau of Mines in 1945 but classified as confidential until recently.

Antimony is recovered from high-grade ore and sulfide concentrates produced at antimony mines, from gold-antimony concentrates produced at gold mines, and from antimonial slag produced at lead refineries. This output comes from the mines of Western Australia, New South Wales, Victoria, and Queensland. Some of the metal is recovered as antimonial lead from lead concentrate and also from residues from the treatment of zinc concentrates produced from the

[3] Bureau of Mines, The Mineral Industry of Australia; Foreign Minerals Survey, vol. 2, No. 3, March 1945, p. 100.

ores of the Broken Hill district, New South Wales, and Rosebery, Tasmania. Needle or liquated antimony sulfide is produced from hand-picked stibnite by O. T. Lempriere & Co., Ltd., at its Sydney, N. S. W., plant. At the same plant, stibnite concentrates are treated for the recovery of metallic antimony, antimony oxide, and sodium antimonate.

Bolivia.—All Bolivian antimony enters world trade in the form of hand-sorted sulfide ore averaging about 60 percent antimony. It is produced by a few large and many small operators, mainly in the Departments of Oruro and Tupiza, and is marketed through Banco Minero de Bolivia.

France.—All antimony ores obtained from French mines in 1945 were used in the manufacture of antimony oxide. About one-half the domestic demand for antimony metal was met by imports, and the remainder of the metal used was smelted from ores imported from Algeria and French Morocco.

Germany.—According to a report issued by the Joint Intelligence Objectives Agency,[4] only one plant in Germany smelts antimony ore for the production of refined metallic antimony. This is the Herzog Julius Smelter at Goslar, in the Harz Mountains. It consumes annually about 2,000 tons of sulfide ores containing 40 percent antimony and 2 percent arsenic. These ores, imported from Austria, Hungary, and Slovakia, are smelted in a rotary furnace, from which 70 percent of the antimony in the charge is recovered as metal (subsequently refined in a reverberatory furnace), 20 percent in baghouse dust, and the remainder in a slag containing 10 to 12 percent antimony. Dust is returned to the furnace, and the slag is mixed with low-grade ores (8 to 10 percent antimony) and smelted in a shaft furnace. In 1944 the total recovery was 98 percent.

Honduras.—A small quantity of sulfide concentrates has been exported from Honduran mines annually, beginning in 1941. The following brief description is quoted from a recent Bureau report:[5]

> * * * Antimony is produced on a small scale in Honduras, mostly from the El Quetzal mine, near San Augustin de Copan, owned by Srs. Manuel Bueso and Rudolfo Nater. A stibnite concentrate averaging 58 to 62 percent antimony is derived from ore mined from open cuts and is exported to the United States via San Jose, Guatemala. Minor production comes from La Union mine in the Department of Olancho and at least four other small properties. * * *

Mexico.—Mexico is the second most important source of antimony in the Western Hemisphere, ranking next to Bolivia in total output in recent years but leading that country in 1944 and 1945. During the war years the entire output was exported to the United States, where most of it was treated by the Texas Mining & Smelting Co. at Laredo. The most important deposits are in the States of San Luis Potosí, Oaxaca, and Guerrero. Descriptions[6] of two of these deposits have been published in recent months.

CADMIUM

By Thomas P. Wootton

SUMMARY OUTLINE

SUMMARY

Cessation of hostilities brought little relief to cadmium consumers. Distribution of the metal had been dominated by military demand for the first half of the year; but rapid reconversion to peacetime uses, particularly plating and the production of pigments, called for the metal in quantities greater than the production rate. To help meet this demand, the Government stock pile of the metal was reduced 24 percent—from 1,190,179 pounds on December 31, 1944, to 907,425 pounds a year later. Production of primary metal declined 6 percent; and, although output of primary compounds jumped 38 percent over 1944, net decrease in total primary products amounted to nearly 5 percent.

Control by Government agencies—the War Production Board and its successor, the Civilian Production Administration—was maintained until August 20, when General Preference Order M–65 was revoked. Inventories, however, were limited to 45 days' requirements or a minimum working inventory, whichever was smaller. Control was reinstated effective February 1, 1946, by the CPA under Conservation Order M–389, which limited use of the metal by manufacturers to 90 percent of their consumption in 1941. At the same time, inventories were reduced to 30 days' supply by an amendment to table 1 of Priorities Regulation 32.

Office of Price Administration ceiling prices of 90 cents a pound for commercial sticks and 95 cents for patented shapes were unchanged in 1945.

Salient statistics of the cadmium industry in the United States, 1941–45, in pounds

	1941	1942	1943	1944	1945
Production (primary)	7,233,500	7,370,969	8,466,963	8,779,856	8,383,629

Exports	[1] 171,858	[1] 283,630	[2] 156,844	[2] 548,015	[2] 102,199
Consumption	7,766,000	7,659,000	7,381,000	8,865,000	[3] 3,753,700
Stocks (year end)	2,610,643	2,338,638	3,405,809	3,026,940	1,679,606

[1] Metal, plus cadmium content of compounds.
[2] Metal.
[3] January to June, inclusive.

DOMESTIC PRODUCTION

The entire supply of domestic primary cadmium is recovered concurrently with the treatment of ores of other metals—notably those of zinc and lead—both imported and mined in the United States. As there are no mines operated solely for the cadmium content of their ores and as many reduction plants participating in the recovery of cadmium treat both domestic and foreign materials without determining the cadmium content of either, the origin of the metal produced at United States plants is a matter of conjecture. Thus the data presented as domestic cadmium production in this chapter are not comparable to those given in other chapters for metals like copper, lead, and zinc. Most of the metal is extracted from Cottrell and bag-house dusts, the next important source being the sludges precipitated from zinc solution preliminary to the electrolytic recovery of zinc. Secondary metal is recovered from old bearings and other alloys but constitutes no great part of the total cadmium supply.

In 1945, for the first time in 7 years, domestic output of primary metallic cadmium declined, the decrease being 6 percent. Recovery of secondary metal also dropped, but the output of cadmium contained in primary compounds increased 38 percent. Labor shortage and unrest at zinc-reduction plants were largely responsible for the decrease in primary cadmium output.

Cadmium produced and shipped in the United States, 1941–45, in pounds

	1941	1942	1943	1944	1945
Production:					
Primary:					
Metallic cadmium	6,937,931	7,323,346	8,396,292	8,453,470	7,932,579
Cadmium compounds (Cd content)[1]	295,600	47,623	70,671	326,386	451,050
Total primary production	7,233,531	7,370,969	8,466,963	8,779,856	8,383,629
Secondary (metal and Cd content of compounds)[1 2]	379,500	316,345	162,424	106,850	72,473
Shipments by producers:					
Primary:					
Metallic cadmium	7,044,417	7,233,043	8,326,768	8,551,424	7,938,658
Cadmium compounds (Cd content)[1]	265,700	78,059	137,952	285,203	451,050
Total primary shipments	7,310,117	7,311,102	8,464,720	8,836,627	8,389,708
Secondary (metal and Cd content of compounds)[1 2]	376,500	304,894	187,913	106,850	67,513
Value of primary shipments:					
Metallic cadmium	$5,498,404	$5,740,082	$6,570,546	$6,435,124	$6,106,992
Cadmium compounds	207,246	61,948	108,844	213,902	347,308
Total value	5,705,650	5,802,030	6,679,390	6,649,026	6,454,300

[1] Excludes compounds made from metal.
[2] Bureau of Mines not at liberty to publish figures separately for secondary cadmium compounds.

As in the past, primary metallic cadmium was produced mainly in the Western States, 64 percent coming from four plants in three of those States. The output of six plants in five Central States (including Texas) was 28 percent of the total, and the remaining 8 percent was produced in four plants in two Eastern States. The Midvale, Utah, cadmium plant of the U. S. Smelting, Refining & Mining Co. was idle, as was also the Dumas, Tex., plant of the American

Zinc Co. of Illinois, and the Coffeyville, Kans., plant of the Sherwin-Williams Co. The Bunker Hill & Sullivan Mining & Concentrating Co. built an entirely new plant at Bradley, Idaho, which came into production in June 1945.

Primary compounds—that is, those derived directly from flue dust or from electrolytic zinc-plant residues—are made by five plants, only one of which (American Smelting & Refining Co., Denver) also produces primary metal.

Secondary cadmium metal is recovered by three plants from old bearings, cadmium-bearing alloys, skimmings, drosses, and other sources. Of the total annual output of primary and secondary metal in any one year, less than 2 percent has been recovered from material of secondary origin.

Domestic cadmium-recovery units.—There are 18 plants in the United States equipped to recover primary metallic cadmium.

The American Smelting & Refining Co. produces the metal and sulfide from imported and domestic dust and sludge and makes oxide from some of the metal in its Globe refinery at Denver; in its Corpus Christi plant only the metal, which is electrolytically deposited from zinc-plant solutions, is recovered.

The cadmium-recovery plant of the American Zinc Co. of Illinois, at Dumas, Tex., has been idle for more than a year, and its dust, as well as sponge from the Monsanto, Ill., plant, is treated in the Company's East St. Louis cadmium-recovery unit.

The Anaconda Copper Corp. is the second-largest producer of cadmium in the United States. This company, at its Great Falls, Mont., plant, not only treats cadmium-bearing material from Anaconda properties but also recovers the metal on a toll basis for the United States Government and for other companies, including the Callahan Zinc-Lead Co. and the U. S. Smelting, Refining & Mining Co.

The Bunker Hill & Sullivan Mining & Concentrating Co. completed construction on the cadmium addition to its Bunker Hill lead smelter at Bradley, Idaho, in May 1945 and cast the first refined bars in June. The metal is recovered from fume formerly treated in the nearby electrolytic zinc plant of the Sullivan Mining Co., Silver King, Idaho. The fume is broken up and leached with sulfuric acid, and the cadmium is precipitated from the leaching solution with zinc dust. The resulting sponge is filtered and briquetted, and 600-pound charges are placed in oil-fired retorts with 5 pounds of coke. The refined metal is cast into molds under candle wax to prevent oxidation and discoloration. Finished bars are 4 by 16 inches and three-quarters of an inch thick. They are packed for the market in wooden boxes containing seven bars, or approximately 100 pounds of metal. Detailed descriptions [1] of this newest domestic cadmium plant have been published.

The Eagle-Picher companies have two cadmium-recovery units, one at Galena, Kans., and one at Henryetta, Okla.

The National Zinc Co. recovers metallic cadmium at its zinc smelter at Bartlesville, Okla.

The Neo-Smelting & Refining, Inc., plant at Whitestone, N. Y., is

[1] Mining World (Seattle), How Bunker Hill Recovers Cadmium from Smelter Flue Dust: Vol. 7, No. 12, November 1945, pp. 21–24.
Huttl, John B., Bunker Hill Plant Recovers Metallic Cadmium from Fume: Eng. and Min. Jour., vol. 147, No. 4, April 1946, pp. 82–85.

the only one in the country regularly engaged in the recovery of both primary and secondary cadmium.

At the zinc-redistillation plant of the New Jersey Zinc Co. at Palmerton, Pa., cadmium (and any other impurity) is removed by fractional distillation. The cadmium is subsequently recovered from the resulting zinc-cadmium metal and cadmium dust. About half of the refined cadmium is sold to consumers and the remainder transferred to the Pigment Division, where it is manufactured into luminous paints.

The St. Joseph Lead Co. operates two cadmium-recovery units, one at its lead smelter at Herculaneum, Mo., and one at its electrothermic zinc plant at Josephtown, Pa. The company also acts as agent in distributing metallic cadmium for other producers.

The Sherwin-Williams Co. has a cadmium plant at Coffeyville, Kans., but no cadmium was recovered there in 1945.

Metallic cadmium is obtained by electrolysis at the electrolytic zinc plant of the Sullivan Mining Co. at Silver King, Idaho.

The electrolytic cadmium plant of the U. S. Smelting, Refining & Mining Co. at Midvale, Utah, was not operated in 1945, but some metal was produced for the company on a toll basis by the Anaconda Copper Corp.

At Donora, Pa., the American Steel & Wire Co., a subsidiary of the U. S. Steel Corp., recovers cadmium from purchased residues and dust and from its own residues and sludges.

The New England Chemical Works, Putnam, Conn., has facilities for recovering metallic cadmium from material of primary and secondary origin but has reported no production since July 1943.

The output of miscellaneous cadmium compounds and chemicals increased 8 percent to more than a million pounds of contained cadmium. Although the major portions of these products are made from metal and from other compounds, and from drosses and other secondary materials, appreciable quantities are derived directly from flue dust and other primary materials. In the accompanying table figures on certain compounds are grouped to avoid disclosure of confidential information.

Cadmium compounds produced in the United States, 1943–45, in pounds

Compound	1943		1944		1945	
	Gross weight	Cd content	Gross weight	Cd content	Gross weight	Cd content
Sulfide [1]	671,831	227,045	1,312,263	466,794	1,731,510	637,667
Oxide [2]	511,382	447,143	539,897	471,845	439,415	383,553
Nitrate	------	------	[3] 11,299	[3] 7,453	15,536	10,398

[1] Includes cadmium lithopone and cadmium sulfoselenide.
[2] In addition to quantities shown, cadmium oxide consumed in making other compounds shown was produced as follows: 1943, 25,975 pounds (Cd content, 22,833 pounds); 1944, 31,469 pounds (Cd content, 27,662 pounds); comparable break-down for 1945 not available.
[3] Revised.
[4] Iodide included with hydrate to avoid disclosure of confidential figures.

CONSUMPTION AND USES

The accompanying table shows the use pattern of cadmium for 1942–44 and for the first half of 1945. The WPB dropped its monthly canvass of cadmium consumers on June 30, and complete data on consumption for the year therefore are not available. It is believed however, that consumption of the metal for electroplating, for the manufacture of pigments, and possibly for the production of miscellaneous alloys increased sharply in the second half of the year. Military uses, which are included with those listed as other, virtually disappeared.

Consumption of cadmium in the United States, 1942–45 by uses

Use	1942		1943		1944		1945 [1]	
	Pounds	Percent of total	Pounds	Percent of total	Pounds	Percent of total	Pounds	Percent of total
Electroplating	6,661,000	87	6,481,000	88	5,496,000	62	2,559,500	68
Bearings	282,000	4	249,000	3	798,000	9	518,000	14
Solders	201,000	3	285,000	4	266,000	3	214,900	6
Other alloys	98,000	1	198,000	2	89,000	1	72,800	2
Pigments	367,000	4	139,000	2	177,000	2	69,700	2
Chemicals	50,000	1	29,000	1	89,000	1	17,900	(2)

[1] January to June, inclusive.
[2] Less than 0.50 percent.
[3] Includes cadmium for unspecified uses.

STOCKS

Total domestic stocks of cadmium metal and compounds, including the Government stock pile of metallic cadmium, decreased 45 percent. Details are given in the accompanying table.

Cadmium stocks at end of year, 1944–45, in pounds

	1944			1945		
	Metallic cadmium	Cadmium compounds (Cd content)	Total cadmium	Metallic cadmium	Cadmium compounds (Cd content)	Total cadmium
Producers	306,896	63,186	370,082	245,769	71,511	317,280
Compound manufacturers	11,558	63,267	74,825	17,085	31,070	48,155
Distributors [1]	358,605	62,766	421,371	380,184	26,562	406,746
Consumers [2]	924,483	46,000	970,483	(3)	(3)	(3)
Government	1,190,179		1,190,179	907,425		907,425
Total stocks	2,791,721	235,219	3,026,940	1,550,463	129,143	1,679,606

[1] Comprises principally 6 largest dealers.
[2] Partly estimated. Includes some material in process. Excludes stocks of compounds held by pigment and chemical consumers.
[3] Comparable data for 1945 not available.

PRICES

OPA ceiling prices of 90 cents a pound for metallic cadmium sticks and 95 cents a pound for patented shapes prevailed throughout the year. Average value of domestic metal, as reported to the Bureau of Mines by primary producers, was 77 cents a pound in 1945 compared with 75 cents in 1944, 79 cents in 1943 and 1942, and 78 cents in 1941. According to E&MJ Metal and Mineral Markets, producers' quotations remained 90 cents a pound.

Prices for cadmium compounds, as quoted by Oil, Paint and Drug Reporter, were $1.65 to $1.91 a pound for the bromide, $0.85 to $1.00 for red lithopone, $0.55 to $0.65 for yellow lithopone, and $1.10 for the sulfide, unchanged from the previous year.

FOREIGN TRADE [2]

In 1945 total imports for consumption of metallic cadmium and of cadmium contained in flue dust increased 27 percent in weight from 1,755,949 to 2,221,409 pounds and 13 percent in value from $898,599 to $1,018,105. Exports, data for which are presented in a table this year for the first time, decreased nearly 60 percent in total value.

Imports.—The sole source of imported flue dust in 1945 was Mexico, as has been the case since 1942. Imports from both Peru and Belgian Congo continued, but at a decrease of more than half. Although the accompanying table of imports shows only metal and dust, a very considerable additional quantity of cadmium actually comes into the United States in zinc ores and concentrates produced in several foreign countries, including Canada, Labrador, Newfoundland, Mexico, and Argentina. Much of this cadmium is recovered in the reduction of these imported materials.

Cadmium metal and flue dust imported for consumption in the United States, 1943–45, by countries

Country	1943		1944		1945	
	Pounds	Value	Pounds	Value	Pounds	Value
Metallic cadmium						
Belgian Congo	40,355	$33,325	53,082	$50,699	25,798	$22,997
Canada	------	------	------	------	672	793
Italy	------	------	8,656	7,790	------	------
Peru	8,536	7,839	4,889	4,495	2,254	2,029
	48,891	41,164	66,627	62,984	28,724	25,819
Flue dust (Cd content)						
Mexico	1,643,404	814,920	1,689,322	835,615	2,192,685	992,286
	1,692,295	856,084	1,755,949	898,599	2,221,409	1,018,105

Exports.—The total value of cadmium exported in 1945 was less than half that of the previous year, the most notable change being in metallic cadmium. This was brought about by cessation or curtailment of lend-lease shipments.

[2] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

Cadmium exported from the United States, 1943–45, gross weight, by kinds

Kind	1943		1944		1945

WORLD PRODUCTION

Available information on world production of metallic cadmium and United States production of the metal and of primary compounds during recent years is presented in the following table. Very few production data for the war period have been obtained from the defeated and liberated countries as yet, and world totals for the years since 1940 cannot be given.

World production of cadmium, 1938–45, by countries, in kilograms

[3] Exports.
[4] Data not available; in 1939 and 1940, estimate included in total.
[5] Cadmium content of flue dust exported for treatment elsewhere; represents in part shipments from stocks on hand. To avoid duplication of figures, the data are not included in the total.
[6] Figures cover January to June, inclusive.

REVIEW BY COUNTRIES

Australia (Tasmania).—The Electrolytic Zinc Co. of Australasia, Ltd., operating mines and a milling plant at Rosebery, on the west coast, and a smelter at Risdon, near Hobart, Tasmania, increased its output of cadmium 25 percent to 254 long tons of metal. The raw material consists of zinc concentrates, calcines, and flue dusts. About one-third of this comes from company operations on the island of Tasmania and the remainder from the three largest mines in the

Broken Hill district in New South Wales on the Australian mainland.

Belgian Congo.—Production of cadmium from zinc concentrates, roasted by "Sogechim," a subsidiary of Union Minière du Haut-Katanga, for the manufacture of sulfuric acid needed locally, decreased from 22 metric tons to an estimated 17 metric tons.

Canada.—Canadian output of refined metallic cadmium is derived from the zinc and lead ores of British Columbia and the zinc-copper ores of Saskatchewan and Manitoba. The Consolidated Mining & Smelting Co. of Canada, Ltd., at Tadanac (Trail), British Columbia, and the Hudson Bay Mining & Smelting Co., Ltd., at Flin Flon, Manitoba, produced approximately 80 and 20 percent, respectively, of the total Canadian output. A considerable quantity of cadmium of Canadian origin also is extracted at plants in the United States from imported zinc ores and concentrates.

Japan.—No official production figures have been received from the Japanese in many years. However, records obtained by United States armed forces after the occupation show that the Miike zinc-reduction works at Omuta on the island of Kyushu produced 9,000 kilos of cadmium in the first 7 months of 1945.

Mexico.—The 1945 exports of cadmium contained in flue dusts recovered from ores of Mexican origin were the highest on record. This material is recovered at the reduction works of the American Smelting & Refining Co. and the American Metal Co., Ltd., and all of it is exported for treatment—mostly to the United States. In addition to the cadmium contained in flue dust, an undeclared quantity of the metal is exported in zinc ores and concentrates. It is probable that, on a mine-output basis, Mexico is the world's largest producer of cadmium.

Peru.—Beginning in 1942 the Cerro de Pasco Copper Corp. added cadmium to its long list of metals recovered from Peruvian ores at the Oroya metallurgical plant. At present the output is 2 to 3 metric tons a year, all from operations of the electrolytic zinc pilot plant. An unrecorded quantity is exported to the United States with zinc concentrates from company concentrators.

PLATINUM AND ALLIED METALS

By Hubert W. Davis and Gertrude N. Greenspoon

SUMMARY OUTLINE

SUMMARY

An outstanding feature of the platinum industry in 1945 was the revocation by War Production Board on August 20 of Order M-162, which, since October 31, 1942, had prohibited use of platinum and platinum alloys in new jewelry. This was followed by a demand for platinum by the jewelry trade which quickly assumed boom proportions; as a result, sufficient metal was not available. Restrictions on use of rhodium and osmium were also removed on August 20. Limitations on use of iridium and palladium had been removed previously. During the war, ruthenium was the only metal of the platinum group not subjected to usage control at any time. Maximum prices, established by Office of Price Administration on February 1, 1943, remained in effect for all platinum metals. However, despite a ceiling price of $165 an ounce for iridium, it was quoted at $120 to $90 an ounce.

Salient statistics of platinum and allied metals in the United States, 1944–45, in troy ounces

	1944	1945		1944	1945
Production:			Stocks in hands of refiners, importers, and dealers, Dec. 31:		
Crude platinum from placers	33,625	26,551	Platinum	159,173	138,839

	[1] 119,396	96,122	Manufactures (except jewelry)	2,387	5,906

[1] Revised figures.

Although slightly more platinum was refined than in 1944, it was insufficient for domestic requirements in 1945, which were 22 percent greater than in the previous year. The refined-metal deficiency was met by release of Government stocks, by imports, and by withdrawals from refiners' and dealers' inventories. The gain in sales of platinum in 1945 over 1944 was due chiefly to much larger requirements by the chemical industry and to the boom demand by the jewelry trade; sales of platinum in 1945 were the second highest of record.

Refining of palladium was 52 percent greater than in 1944, but it again was insufficient for requirements, which established a new record. The deficit was met largely by imports of refined metal but partly by withdrawals from refiners' and dealers' inventories. With removal of the restriction on the use of platinum in jewelry, there was a decided swing from palladium to platinum for fine jewelry; nevertheless, the jewelry trade continued to absorb substantial quantities of palladium. Both refining and sales of the other platinum metals—iridium, osmium, rhodium, and ruthenium—were comparatively small in 1945; however, both refining and sales were greater than in 1944. Nevertheless, sales of each metal except rhodium substantially exceeded the quantity refined. The deficits in iridium, osmium, and ruthenium were met by imports of refined metals.

The importance of the United States as a refining center for platinum metals during the 7 years 1939–45 is reflected in its record of refining. During this period, 1,334,537 ounces of platinum metals were recovered from the refining of virgin materials; this quantity is 20 percent more than was refined during the previous 25 years 1914–38—1,112,509 ounces.

Imports of platinum metals into the United States established a new high in 1945; they were 6 percent greater than in the previous record year 1943.

The outlook for platinum has been discussed and the contribution made by the platinum metals in the war program has been reviewed by the South African Mining and Engineering Journal.[1]

* * * The war created an intensive demand for platinum, far beyond the capacity of the industry to meet in the early stages. By dint of tremendous efforts, however, the demand was met by about 1943, but so many new uses have been found for the metal that there is little doubt that world output will have to be maintained at levels quite considerably higher than those obtaining before the war. Manufacturing jewelers have been unable to secure anything like the amount of platinum they require, and consequently palladium has been used to a large extent as a substitute. The white color of palladium is used with advantage in setting gems and in two-color combinations with gold. South African jewelers have indicated that they are extremely short of platinum and are capable of using very much more than they can obtain.

The platinum metals contributed handsomely to winning the war. Use was made of their peculiar characteristics in many ways, and the industrial uses of platinum have been greatly expanded by research conducted during the war years. Large quantities were used in winning the war in the air, for magneto contacts, and spark plug electrodes were made from platinum and absorbed huge quantities of the metal. Radar required large quantities of platinum, for it was found that the metal was superior to all the others tried. One of the most notable advancements in the field of electronics generally, into which radar can be said to fall, was the development of platinum and platinum-clad grids in high frequency transmission valves. In addition, the new bomb sights developed by the United States and Britain used platinum in their construction, and the computing devices

[1] South African Mining and Engineering Journal, The Outlook for Platinum: Vol. 57, pt. I, Apr. 6, 1946, p. 127.

developed in the high-flying superfortresses, by which the defensive machine guns could be fired by remote control, needed large quantities of platinum.

The uses of platinum in the chemical industries are many. Platinum alloys are used as catalysts in the manufacture of nitric acid, one of the principal raw materials in the making of explosives. Rayon and glass fibre played an important part in the war effort, and platinum alloy spinnerets and bushings were extensively used in the production of both these products. Insoluble platinum anodes were used for the production of the perchlorates, peroxides and other chemicals obtained through anodic oxidation and were used in the production of war equipment which made use of the electrodeposition of nickel, rhodium and other metals. Measuring and recording devices were developed which made use of the corrosion and heat resisting properties of platinum, as well as of their mechanical and electrical properties.

Not the least important application of the metal has been the adaption to chemical and other appliances and equipment in increasing quantities. It has been found that platinum gives better service in many directions, with less maintenance, while the use of the metal in many chemical processes has resulted in a better product at lower cost.

* * * Platinum is no longer a metal which finds use only in luxury trades; it has taken off its white collar and put on overalls. Progress was being made in this direction before the outbreak of war, but the past six years have greatly expanded the number of industrial uses to which platinum can be put. * * *

Figure 1 shows graphically the trend in world production of platinum metals from 1914 to 1944.

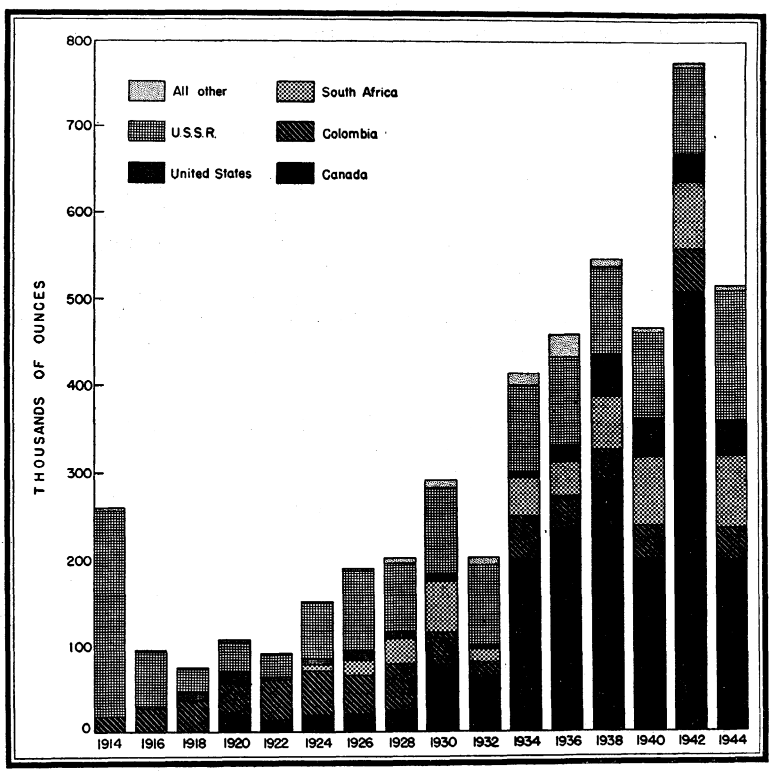

FIGURE 1.—Trend in world production of platinum metals, 1914–44.

CRUDE PLATINUM

Production.—Mine returns for 1945 show a production of 26,505 ounces of crude platinum in Alaska, 43 ounces in California, and 3 ounces in Oregon—a total of 26,551 ounces; comparable figures for 1944 are 33,616 ounces of crude platinum in Alaska and 9 ounces in Montana—a total of 33,625 ounces. Production in Alaska came from placer deposits in the Goodnews Bay district of southwestern Alaska. The output in California was a byproduct of gold placers in Trinity and Yuba Counties. Production in Oregon came from Josephine County.

Many gold and copper ores in the United States contain small quantities of platinum metals. In 1945, 4,495 ounces of platinum metals were recovered as byproducts of refining gold and copper ores compared with 6,924 ounces in 1944.

Purchases.—Buyers in the United States reported purchases of domestic crude platinum from the following sources in 1945: Alaska, 27,045 ounces and California, 25 ounces—a total of 27,070 ounces (33,841 ounces in 1944). Domestic buyers also reported purchases of 29,571 ounces (29,700 ounces in 1944) of foreign crude platinum from Colombia in 1945.

Prices.—Buyers reported purchases at $28.07 to $34.90 an ounce for domestic and foreign crude platinum in 1945. This price range resulted chiefly from variations in iridium content of crudes rather than from market fluctuations for refined platinum metals.

REFINED PLATINUM METALS

New metals recovered.—Reports from refiners of crude platinum, gold bullion, nickel, and copper indicate that 204,506 ounces of platinum metals were recovered in the United States from such sources in 1945—an increase of 34 percent over 1944. Of the new metals recovered in 1945, 84 percent was chiefly from concentrates from Canada and crude from Colombia, 14 percent from domestic crude (chiefly from Alaska), and 2 percent a byproduct of domestic gold and copper ores.

New platinum metals recovered by refiners in the United States in 1945, by sources, in troy ounces

	Platinum	Palladium	Iridium	Osmium	Rhodium	Ruthenium	Total
Domestic from—							
Crude platinum	22,923	126	4,453	845	632	118	29,097
Gold and copper refining	1,068	3,396	8		20	3	4,495
	23,991	3,522	4,461	845	652	121	33,592
Foreign from—							
Crude platinum / Nickel and copper refining	138,041	25,127	1,322		4,079	2,345	170,914
Total recovery	162,032	28,649	5,783	845	4,731	2,466	204,506

New platinum metals recovered by refiners in the United States, 1941–45, in troy ounces

Year	Platinum	Palladium	Iridium	Others	Total
1941	98,376	49,812	1,392	3,043	152,623
1942	244,226	140,262	5,102	10,737	400,327
1943	234,320	82,441	5,286	13,209	335,256
1944	132,452	10,966	4,406	5,221	153,045
1945	162,032	28,649	5,783	8,042	204,506

Secondary metals recovered.—In 1945, 96,122 ounces of secondary platinum metals were recovered from the refining of scrap metal, sweeps, and other waste products of manufacture that contain platinum metals—a 19-percent decrease from 1944.

Substantial quantities of worn-out catalysts, spinnerets, laboratory ware, and other products are returned by consumers to refiners for refining. The refined platinum metals recovered from these products (or their equivalent in refined metals) are returned to the consumers. The platinum metals so recovered are not included in the statistics of secondary metals.

Secondary platinum metals recovered in the United States, 1941–45, in troy ounces

Year	Platinum	Palladium	Iridium	Others	Total
1941	37,522	12,630	659	758	51,569
1942	56,150	16,416	1,552	2,493	76,611
1943	68,613	23,616	2,771	6,581	101,581
1944 [1]	85,942	29,684	965	2,805	119,396
1945	58,942	32,968	812	3,400	96,122

[1] Revised figures.

Prices.—Maximum prices for the six platinum metals, fixed by the Office of Price Administration on February 1, 1943, remained in effect in 1945. The maximum prices per troy ounce for refined metals of a commercial purity of at least 99.5 percent were as follows: Platinum, $35; palladium, $24; iridium, $165; osmium, $50; rhodium, $125; and ruthenium, $35.

Except for iridium, prices for the platinum-group metals remained stable in 1945. However, iridium was quoted at $120 to August 9, when it was reduced to $100; on September 13 it was lowered to $100–$90, where it remained for the rest of 1945.

Properties and uses.—Much information on the platinum metals and their alloys, particularly their physical and mechanical properties and their many and diverse uses, is given in the comprehensive book, The Platinum Metals and Their Alloys, published in 1941 by the International Nickel Co., Inc., New York, N. Y. A tabulation of uses of the platinum metals is given on page 801 of the Platinum and Allied Metals chapter in Minerals Yearbook, 1943.

Consumption.—As pure metals, combined, clad, or alloyed with other metals, the platinum metals are employed in the electrical and chemical industries, in dentistry and jewelry, and for numerous miscellaneous purposes. Sales to consumers in the United States established a new high in 1945; they were 550,045 ounces, a gain of 22 percent over 1944 and 8 percent greater than the previous record year 1943.

The most widely used metal of the group is platinum, which constituted 336,851 ounces (61 percent) of the total platinum metals sold to consumers in the United States in 1945. By taking 34.4 percent of the total platinum sold in 1945, the chemical industry was the chief buyer, displacing the electrical industry, which ranked first in 1943 and 1944. Sales of platinum to the chemical industry were 90 percent greater than in 1944. The largest outlets for platinum in the chemical industry were for chemical manufacturing equipment, catalysts, laboratory ware, and spinnerets. The electrical industry was a close second as a buyer of platinum in 1945, but its purchases were 40 percent less than in 1944; nevertheless, it bought 107,260 ounces (31.8 percent) of the total sold. The largest outlets for platinum in the electrical industry were for spark plugs, magneto and other contacts, and electronic tubes. Sales of platinum for dental and medical uses declined 11 percent from 1944 but comprised 30,871 ounces (9.2 percent) of the total sold. Because of the ban on the sale and use of platinum in the manufacture of jewelry, except for repair work, only 424 ounces were so sold in 1944. On August 20 the WPB revoked Order M-162 which, since October 31, 1942, had prohibited the sale and use of platinum and platinum alloys in new jewelry. Removal of this restriction was followed by a demand for platinum by the jewelry trade which quickly assumed boom proportions. Accordingly, the jewelry industry bought 81,305 ounces (24.1 percent) of the total platinum sold in 1945.

Next to platinum, palladium is the most extensively used metal of the group; it constituted 185,232 ounces (34 percent) of the total platinum metals sold to domestic consumers in 1945. Sales of palladium established a new high in 1945. The electrical industry displaced the jewelry industry as the chief outlet for palladium in 1945 by taking 69,300 ounces (37.4 percent) of the total palladium sold. Sales of palladium to the electrical industry established a new record in 1945 and were 64 percent greater than in 1944. Sales of palladium to the jewelry trade comprised 56,578 ounces (30.5 percent) of the total palladium sold in 1945; they were virtually the same as in 1944. With removal of the restriction on the use of platinum in jewelry, there was a decided swing from palladium to platinum for fine jewelry, The dental trade continued to be the third largest outlet for palladium, taking 42,259 ounces (22.8 percent) of the total sold in 1945. Sales of palladium to the chemical industry were 7 percent less than in 1944 and were only 8,988 ounces (4.9 percent) of the total sold in 1945. Appreciable quantities of palladium were sold to the pen and pencil trade for nibs and other parts in 1945.

Sales of the other platinum metals—iridium, osmium, rhodium, and ruthenium—were comparatively small; they made up 5 percent (27,962 ounces) of the total for the group in 1945. Iridium and ruthenium were the metals of this group most extensively used, followed in order by rhodium and osmium. Sales of iridium and rhodium were each about 50 percent greater than in 1944, but those of osmium and ruthenium were only 15 and 2 percent, respectively, more.

The following table shows sales of platinum metals by refiners, importers, dealers, and Office of Metals Reserve to consumers in the United States in 1945.

Platinum metals sold to consuming industries in the United States in 1945, in troy ounces

Industry	Platinum	Palladium	Iridium, osmium, rhodium, and ruthenium	Total
Chemical	115,816	8,988	6,182	130,986
Electrical	107,260	69,300	5,572	182,132
Dental and medical	30,871	42,259	900	74,030
Jewelry and decorative	81,305	56,578	10,026	147,909
Miscellaneous and undistributed	1,599	8,107	5,282	14,988
	336,851	185,232	27,962	550,045

Stocks.—Stocks of platinum metals in all forms in the hands of refiners, importers, and dealers totaled 301,972 ounces on December 31, 1945, compared with 322,487 ounces at the close of 1944. In addition, the Office of Metals Reserve held 63,252 ounces of refined metals and 15,251 ounces of crude platinum on December 31, 1945.

Stocks of platinum metals held by refiners, importers, and dealers in the United States, Dec. 31, 1941–45, in troy ounces

Year	Platinum	Palladium	Iridium, osmium, rhodium, and ruthenium	Total
1941	150,887	138,014	33,942	322,843
1942	160,724	107,383	35,280	303,387
1943	176,560	104,372	42,081	323,013
1944	159,173	123,448	39,866	322,487
1945	138,839	119,757	43,376	301,972

FOREIGN TRADE [2]

Imports.—Imports of platinum metals into the United States established a new high in 1945; they were 8 percent more than in 1944 and 6 percent greater than in the previous record year 1943. The principal sources of imported platinum metals in 1945 were Canada (266,534 ounces), U. S. S. R. (77,741 ounces). Colombia (31,786 ounces), and United Kingdom (7,149 ounces). Imports of unrefined materials (172,029 ounces) were 25 percent more than in 1944, but imports of refined metals (211,269 ounces) were 4 percent less. Imports of refined platinum, iridium, rhodium, and ruthenium were 4, 102, 689, and 40 percent, respectively, greater than in 1944, but imports of palladium and osmium were 14 and 31 percent, respectively, less.

[2] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

Platinum metals (unmanufactured) imported for consumption in the United States 1944–45

Material	1944		1945	
	Troy ounces	Value	Troy ounces	Value
Unrefined materials: [1]				
Ores and concentrates of platinum metals	101,747	$2,993,639	138,089	$3,955,645
Grains and nuggets (including crude, dust, and residues)	35,345	1,014,169	31,875	1,041,684
Sponge and scrap	65	1,690	2,008	63,903
Osmiridium	35	2,593	57	4,261
	137,192	4,012,091	172,029	5,065,493
Refined metals:				
Platinum	70,150	2,631,546	72,849	2,688,613
Palladium	137,496	3,116,904	118,270	2,597,815
Iridium	3,075	597,159	6,197	504,666

Rhodium	504	47,044	3,975	452,873
Ruthenium	6,450	197,890	9,053	296,804
	219,020	6,663,212	211,269	6,584,440
	356,212	10,675,303	383,298	11,649,933

[1] The concentrates and crude imported from Canada contain platinum, palladium, iridium, rhodium, and ruthenium, and the crude sponge imported from Canada contains platinum and palladium. Although the U. S. Department of Commerce records "platinum content" for these entries, the Bureau of Mines has determined from the importers of these materials that most of the entries reflect the platinum metals content. The Bureau of Mines has also determined from the largest importer of crude platinum from Colombia that the entries for his material, recorded as "platinum content" by the U. S. Department of Commerce, represent the gross weight of the material.

Platinum metals (unmanufactured) imported for consumption in the United States, 1944–45, by countries, in troy ounces

Country	Unrefined materials [1]				Refined metals					Total

Exports.—Exports of refined platinum (including scrap) increased to 7,781 ounces in 1945 (1,243 ounces in 1944), and those of the other platinum-group metals (including scrap) advanced to 10,951 ounces (5,014 ounces in 1944). The chief foreign markets for platinum were Brazil (3,909 ounces), United Kingdom (960 ounces), and Australia (523 ounces) and for the other platinum-group metals, Canada (8,996 ounces).

[1] Data not available.
[2] Recovered from nickel-copper mattes.
[3] Year ended June 30 of year stated.
[4] Produced from platinum ores.
[5] January to September, inclusive.
[6] Produced from treatment of gold ores on the Rand.
[7] New platinum metals recovered in gold and copper refining of domestic materials.

Canada.—According to the Dominion Bureau of Statistics, production of platinum metals from the nickel-copper ores of the Sudbury district, plus a very small quantity from placers in British Columbia, was 162,000 ounces of platinum and 155,600 ounces of other platinum-group metals in 1945, compared with 157,523 ounces of platinum and 42,929 ounces of other platinum-group metals in 1944. Production of platinum metals in 1945 was the second largest of record but 37 percent less than in the record year 1942. The figures on production represent the metals refined from Canadian concentrates at Acton, England, plus the platinum-metals content of concentrates sold, rather than the metals contained in the concentrates actually recovered.

The contribution made by Canada in supplying platinum metals during the 7 years 1939–45 is noteworthy. During this period the nickel-copper ores of the Sudbury district were the source of 1,206,032 ounces of platinum and 871,462 ounces of other platinum-group metals; these quantities were 38 and 15 percent, respectively, greater than supplied during the previous 19 years 1920–38—871,394 and 757,535 ounces, respectively.

Sales of platinum metals by the International Nickel Co. of Canada, Ltd., were 381,741 ounces in 1945—a new peak—compared with 303,394 and 376,604 ounces, respectively, in 1944 and 1943.

Colombia.—The South American Gold & Platinum Co. produced 20,346 ounces of crude platinum metals in 1945 (22,615 in 1944) and 52,464 ounces of crude gold (56,097 in 1944). Production of crude platinum by other operators was 14,411 ounces in 1945.

Union of South Africa.—The Union of South Africa is the third largest producer of platinum metals in the world and ranks first in production of osmiridium. Output of osmiridium, which is recovered from Rand gold ores, was first recorded in 1921 (510 ounces); it increased to 5,764 ounces in 1924 and thereafter has ranged from 5,000 to 7,000 ounces annually.

In 1926, the initial production (10,545 ounces) of platinum metals was made from the platinum ores in the Transvaal, and by 1930 output had reached 55,342 ounces. As a result of a phenomenal drop in platinum price, the general industrial depression, and the relatively high costs of reducing these complex ores, operations were suspended from April 1932 to July 1933; consequently, production declined to 9.246 and 2,386 ounces, respectively, in 1932 and 1933. Meanwhile, the various companies had ceased operations until the only survivor was the Rustenburg Platinum Mines, Ltd. This company resumed production in August 1933, and output averaged about 34,000 ounces annually during the 3 years 1934–36. Thereafter, because of the approaching exhaustion of the oxidized ore, the company plant was enlarged and altered to treat sulfide ore. As a consequence of this change and the increased demand resulting from World War II, output of platinum metals expanded markedly. The total production of platinum metals in the Waterberg, Lydenburg, Potgietersrust, and Rustenburg districts during the 20 years 1926–45 was about 889,700 ounces, of which about 497,000 ounces (56 percent) were produced during the 7 years 1939–45. Since 1931 the entire output has come from the Rustenburg district.

TITANIUM

By Allan F. Matthews and R. Louise Bryson

SUMMARY OUTLINE

GENERAL STATEMENT

Domestic output of titanium concentrates exceeded 300,000 short tons in 1945, placing the United States as the world's foremost producer. Domestic mines yielded 11 percent more ilmenite than in 1944, but imports, largely from India, had to be drawn on for 19 percent of the consumption and for building up stocks in anticipation of a 20-percent expansion in titanium-pigment-manufacturing capacity. Rutile consumption declined one-third as a result of cut-backs in demand for welding rods for ship and tank fabrication and thereby enabled a 4-percent increase in domestic output to supply about half of the demand. The remainder was imported almost exclusively from Australia; Brazil has become only a negligible source of rutile.

Sustaining a complaint by the United States Department of Justice against the National Lead Co., its subsidiary, the Titan Co., and E. I. duPont de Nemours & Co., Inc., Judge Simon H. Rifkind ruled July 11, 1945, that the companies participated in a world monopoly controlling the production and sale of titanium pigments in violation of the Sherman Antitrust Act. It was expected the court would be asked to direct the defendants to grant royalty-free licenses under all their titanium patents and, if necessary, to divest themselves of certain assets to independent competing companies.[1]

DOMESTIC PRODUCTION

Production of ilmenite in 1945 rose 11 percent above that of 1944 and output of rutile increased 4 percent, both achieving all-time highs. Ilmenite concentrate shipments in 1945 ranged from 44 to 59 percent TiO_2 and rutile concentrate shipments from 93 to 94 percent TiO_2.

[1] Engineering and Mining Journal, Court Decree Sustains Titanium Trust Charges: Vol. 146, No. 8, August 1945, p. 106.

Production and mine shipments of titanium concentrates from domestic ores in the United States, 1941–45

Year	Ilmenite				Rutile			
	Production (short tons)	Shipments			Production (short tons)	Shipments		
		Gross weight (short tons)	TiO_2 content (short tons)	Value		Gross weight (short tons)	TiO_2 content (short tons)	Value
1941	23,297	21,526	9,930	$196,522	3,130	3,431	3,192	$493,782
1942	77,208	93,397	41,328	1,805,823	2,648	2,649	2,466	410,956
1943	203,551	211,715	94,283	3,738,970	3,987	3,941	3,639	610,879

1945	308,516	308,518	141,852	7,359,170	7,179	6,837	6,414	869,920

Arkansas.—Titanium ore was not mined in Arkansas in 1945. The property of the Magnet Cove Rutile Co., Malvern, Hot Spring County, which ceased production in July 1944, was examined by the Bureau of Mines, and several churn-drill holes were put down.

Florida.—Rutile, ilmenite, and zircon were produced near Jacksonville by Humphreys Gold Corp., operating under lease from Rutile Mining Co. and its parent company, Titanium Alloy Manufacturing Co. Riz Mineral Co. mined rutile, ilmenite, and zircon from sands near Vero Beach and concentrated the product at its plant near Melbourne.

New York.—Production of ilmenite by the National Lead Co. at Tahawus, Essex County, increased 11 percent in 1945 compared with 1944. The geology of the deposit was described by Stephenson.[2] Some operational details from two other recent reports are quoted below.

The National Lead Co. at Tahawus, N. Y., operated throughout the year mining approximately 2,000,000 long tons; of this about 1,300,000 was crushed to produce more than 1,000,000 long tons of mill feed. Ilmenite production amounted to about 220,000 long tons and magnetite production to about 400,000. A portion of the magnetite (108,069 long tons) was sintered for shipment to blast furnaces. Additional shovels and trucks were purchased to facilitate stripping operations in the open-cut mine. A pilot plant was installed in the mill to confirm laboratory flotation tests for the recovery of fine ilmenite heretofore lost in the plant tailing. As during 1944, the principal problem was one of manpower. It was necessary to resort to Barbados Islanders whose contract, however, terminated at the end of the war. An agreement was then made with immigration authorities which permitted the hiring of Canadians. Without these measures it would have been impossible to keep in operation.[3]

Output in 1944 reached approximately 220,000 short tons. Plant enlargements completed during 1944 increased annual capacity to around 270,000 tons for 1945. Flotation tests indicate that improved recovery and grade of ilmenite concentrates can be obtained by flotation methods as compared to table concentration and Wetherill magnetic cleaning of the tailing from the Crockett magnetic separators. An acid circuit enhances the selective action of the collector for the ilmenite. . . . The success of the United States titaniferous magnetite mining now that the war has ended with Indian ilmenite returning to the competitive picture may depend greatly on ability to dispose of the magnetite concentrate produced in the amount of two tons for each ton of ilmenite concentrate. The magnetite concentrate is low in sulfur and practically free from phosphorus but carries nearly 10 percent TiO_2 in New York ores. Tests indicate that blending with about four

[2] Stephenson, Robert C., Titaniferous Magnetite Deposits of the Lake Sanford Area, New York: Am. Inst. Min. and Met. Eng. Min. Technol., vol. 9, No. 1, January 1945, Tech. Pub. 1789, 25 pp.
[3] Linney, J. R., Eastern Magnetite: Min. and Met., vol. 27, No. 470, February 1946, p. 85.

parts of nontitaniferous ores dilutes the titanium to a point at which no harmful effects result to smooth blast-furnace operation. Titanium from the Adirondacks and elsewhere will be needed for some time to come as protection to assure the pigment plants of the United States a source of supply and by careful management it is likely that titanium ore from American properties can be produced at a cost to compete with Indian ore.[4]

North Carolina.—The Yadkin Valley Ilmenite Co., subsidiary of the Glidden Co., at Finley, Caldwell County, produced 17,641 short tons of ilmenite (averaging 53 percent TiO_2) in 1945 compared with 14,908 tons in 1944. On January 22, 1946, the State Board of Conservation and Development approved broadening of a contract with E. I. duPont de Nemours Co., Inc., which will permit the company to prospect for ilmenite in all sounds and rivers in the State's coastal area as far south as Cape Fear River.[5]

Oregon.—Magnetometer surveys, made in 1942, of black sands along the Oregon coast were published in 1945.[6] The size, shape, magnetism, and mineral content of the sands were analyzed.[7] Efforts were made to work these deposits during World War II, and some chromite was shipped in 1943 (see Minerals Yearbook, 1943, pp. 629–630). However, due to the low grade of the products, operations were considered unsuccessful; there was no output of accessory titanium concentrates of commercial grade.

Virginia.—American Rutile Corp., subsidiary of Metal and Thermit Corp., produced rutile and ilmenite near Roseland, Nelson County. Ilmenite was produced at Piney River, Nelson County, by the Calco Chemical Division of American Cyanamid Co., which took over the mine and mill property from Virginia Chemical Co. in March 1945. The extent of the Piney River ore body was investigated in early 1944 by completing 44 drill holes to an average depth of 110 feet.[8] In June the Calco Chemical Division purchased the Gloucester City, N. J., plant of the Sherwin-Williams Co., for production of titanium dioxide.

FOREIGN TRADE[9]

Imports.—Principally as a result of increased availability of Indian concentrates, imports of ilmenite in 1945 were almost double those of 1944 and equaled 73 percent of the 1939 high. Small Norwegian entries were the first since 1936. Imports of rutile, almost exclusively from Australia, were at the same level in 1945 as in 1944. Brazilian rutile entries continued to decline. Titanium is imported from Australia only in the form of mixed zircon-rutile-ilmenite concentrates, which are separated into their component minerals by the International Titanium Corp. (subsidiary of the American Rutile Corp. and Ventures, Ltd.), Carteret, N. J.; Orefraction, Inc., Pitts-

Value of "As reported"	$306,176	$623,917	$823,624	$272,283	$98,170

[1] Classified as "ore" by the U. S. Department of Commerce.
[2] All imports of titanium from Australia in 1941–45 were in mixed zircon-rutile-ilmenite concentrates. Totals of mixed concentrates are derived by addition of the U. S. Department of Commerce figures for imports of ilmenite, rutile, and "zirconium ore" from Australia. These totals are apportioned by the Bureau of Mines (on the basis of surveys of importers) into the three component minerals. The excess quantities of ilmenite and rutile over the quantities reported by the U. S. Department of Commerce in those specific categories are entered as "In 'zirconium ore.' "
[3] Includes 309 tons not recovered from mixed concentrates.
[4] Includes quantities reported by the U. S. Department of Commerce as originating in French Equatorial Africa, from which no rutile production has been recorded.

Exports.—Titanium products valued at 2.6 million dollars were exported in 1945. Of the concentrates (probably mostly rutile) 74 percent went to Canada, 11 percent to Union of South Africa, and 8 percent to Belgium. Of the pigments, 83 percent went to Canada and 14 percent to Latin America (mainly Brazil, Cuba, Mexico, and Argentina). Most of the other compounds and ferro-alloys likewise reached the Canadian market.

Exports of titanium products from the United States, 1941–45, by classes

Year	Concentrates		Ferro-alloys [1]		Dioxide and pigments		Tetrachloride and other compounds	
	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value
1941	[2] 432	[2] $70,613	[2] 150	[2] $35,687	7,821	$1,609,071	[3] 17	[3] $5,792

[1] Includes ilmenite and rutile content of mixed zirconium-titanium concentrates.

CONSUMPTION AND USES

Consumption of ilmenite advanced 6 percent in 1945 compared with 1944 and would have shown greater gain if the needed expansion of pigment-manufacturing facilities could have been built. Consumption for pigments was 98 percent of the total, most of the remainder going into alloys and cemented carbides. Rutile, whose consumption declined one-third, was used primarily in welding-rod coatings (80 percent) and alloys and carbides (nearly 20 percent).

Consumption of ilmenite and rutile in the United States, 1944–45, by products, in short tons

Product	Ilmenite		Rutile	
	Gross weight	Estimated TiO_2 content	Gross weight	Estimated TiO_2 content
1944				
Pigments (manufactured titanium dioxide) [1]	349, 505	170, 518

Ceramics			34	30
Miscellaneous [2]	761	347	21	20
Total consumption	381, 178	187, 580	9, 791	9, 144

[1] "Pigments" include all manufactured titanium dioxide, consumption of which in welding-rod coatings was 3,900 tons in 1944 and 2,258 tons in 1945.
[2] Consists of ilmenite used as a steel flux and rutile used in lamp-electrode coatings and as a steel deoxidizer.

Titanium pigments.—Production and sales of titanium pigments climbed to another high in 1945, but demand continued greatly to exceed supply. The Bureau of Mines is not at liberty to publish pertinent figures. Distribution of pigment supplies was controlled by War Production Board Limitation Order M–353, which was revoked March 26, 1945, and replaced simultaneously by General Preference Order M–340. Under Civilian Production Administration (which succeeded War Production Board November 3, 1945) Priorities Regulation 28, manufacturers of titanium pigments January 16, 1946, were assigned CC ratings, highest obtainable for civilian goods, to enable them to expand capacity about 20 percent by late 1946. Titanium paints are noted for covering power, whiteness, and durability. Since 1939 titanium dioxide has been utilized in greater quantities than any other white pigments. Paint requirements of the Navy and Merchant Marine for maintenance of the active fleet and ships in reserve continued to be large throughout 1945. The pattern of sales distribution of titanium pigments in 1945, according to a large manufacturer, was 75 percent for paint, varnish, and lacquer, 10 percent for paper, 2 percent each for floor coverings and rubber, 1½ percent each for welding-rod coatings and textiles, and 8 percent for other uses.

Welding-rod coatings.—Production of titanium-coated welding rods was 267,000 short tons in 1945 compared with 382,000 tons in 1944. Of these rods, 46 percent were coated with manufactured titanium dioxide (extracted from ilmenite), 42 percent with natural rutile, 10 percent with both varieties of dioxide, and 2 percent with ilmenite. Decline in welding-rod output was due primarily to curtailment of fabrication of ships and tanks, particularly after cessation of war August 1945.

Titanium alloys.—Ferrocarbontitanium (15–20 percent Ti, 3–8 percent C) is a deoxidizer and scavenger in steel melts, and ferrotitanium (18–45 percent Ti, 0.1 percent C max.) inhibits intergranular corrosion and promotes hardenability of steel.[10] Recently developed titanium steels suitable for one-coat vitreous enameling can be improved in yield strength by the addition of 1.5 percent manganese and 0.5 percent each silicon, copper, and nickel.[11] The combustion chamber of some jet aircraft engines is constructed of nickel-chromium alloy containing 3 percent Ti.[12]

Other uses.—Pure titanium metal has been produced experimentally and, in view of its useful properties and the abundance of its ores, has a promising future as a structural material (see Technology section of this chapter). Sintered titanium carbide is used to tip tool steels. High-titania glasses have a refractivity comparable to lead glasses and do not have the disadvantageous high density and low resistance to abrasion of the latter.[13]

PRICES

No price changes affected any form of titanium in 1945. Ilmenite and rutile prices were fixed by the Office of Price Administration February 22, 1943 (Regulation 327), at levels prevailing in March 1942. Ilmenite, 60 percent TiO_2, was nominally quoted at \$28–\$30 a long ton, f. o. b. Atlantic seaboard, and rutile, 94 percent TiO_2, at 8–10 cents a pound. Steel quoted ferrotitanium, ton lots, at \$1.23 per pound of contained Ti for 40- to 45-percent grade and \$1.35 for 20- to 25-percent grade; and ferrocarbontitanium, 15–20 percent Ti, at \$142.50 a short ton for 6- to 8-percent carbon and \$157.50 for 3- to 5-percent carbon. Titanium metal, 96–98 percent, was listed at \$5–\$5.50 a pound. The base price of manufactured titanium dioxide remained fixed at 14½–16½ cents a pound.

TECHNOLOGY

Production, fabrication, and properties of pure titanium metal were investigated by the Bureau of Mines. The metal was prepared by the Kroll process, which involved reducing titanium tetrachloride by magnesium at about 800° C. Magnesium chloride and unreacted magnesium were leached out with cold hydrochloric acid, and the resulting granular titanium was consolidated by pressing into compacts at a pressure of 50 tons per square inch and sintering at 1,000° C. in a vacuum. These compacts were found to be ductile and suitable for fabricating into sheet and bar by commercial methods. Annealed material had a tensile strength of about 82,000 pounds per square inch, with 28 percent elongation and a Rockwell hardness of A–55. Tensile strength for 50-percent reduction by cold-working is about 126,000 pounds per square inch, with 4 percent elongation and a Rockwell hardness of A–65. The metal has excellent corrosion resistance comparable to 18–8-type stainless steel.[14] [15]

WORLD PRODUCTION

Data on world production of ilmenite and rutile in recent years are shown in the following table.

Australia.—The bulk of the Australian titanium output is in the form of mixed zircon, rutile, and ilmenite mined and concentrated on the beaches of New South Wales and Queensland and shipped to the United States for separation and consumption. An English company is planning to build near Burnie, northern Tasmania, a plant costing A£250,000 to manufacture titanium pigments from Indian ilmenite.[16]

1 Data not available.
2 Includes 26 tons of garnet-ilmenite.
3 Approximately 20 percent of ilmenite concentrates is zircon.
4 Bureau of Mines not at liberty to publish figures.
5 In addition, 98 tons of zircon-rutile-ilmenite concentrates were produced in 1938.
6 Less than 1 ton.

are hoped to result in an output of 3,500 tons of ilmenite and increased quantities of rutile in 1946.[17]

Canada.—Canadian Titanium Pigments, Ltd., of Montreal is reported to be planning construction of a plant at Cap de la Madeleine, Quebec, estimated to cost $7,000,000.[18]

India.—The two leading ilmenite producers interrupted their operations in 1945; Travancore Minerals Co., Ltd., ceased operations about the middle of the year, and Hopkins & Williams (Travancore), Ltd., shut down its plant temporarily after expiration of its mining lease September 6.[19]

United Kingdom.—British Titan Products Co., Ltd., pigment manufacturer at Billingham-on-Tees, England, has tripled its nominal capital to £1,125,000.[20] Indian ilmenite, 52–54 percent TiO_2, was quoted by Metal Bulletin at about 30s. per long ton, f. a. s., during 1945. Official prices for rutile, f. o. b. consumers' works, remained fixed throughout the year at £45–£50 a long ton for Australian concentrates, £42–£50 for Indian concentrates, and £54–£60 for Cameroun concentrates. Ferrotitanium cost £100 a long ton for the 2- to 3-percent-carbon grade (20 to 25 percent Ti) and 1s. 3½d. per pound for the carbon-free grade.

MINOR METALS

By C. E. NIGHMAN[1]

SUMMARY OUTLINE

INTRODUCTION

Literally and figuratively bringing world-wide consequences was the detonation of so-called atomic bombs on August 5, 1945, over Hiroshima and on August 8 over Nagasaki, Japan.[2] Within a few days, Japan sought peace terms and on September 2, 1945, signed an unconditional surrender that brought World War II to a close. Thus dramatically was revealed the first great result of the intense labors of an extraordinary aggregation of the world's outstanding scientists, and of an army of technicians and skilled and unskilled workers who planned, constructed, and operated the vast plants that produced the explosive elements. At a cost of over 2 billion dollars there had been produced a minute quantity—probably not over a few hundreds of pounds—of materials, the explosive power of which was virtually beyond conception. The materials, not isolated before 1940, were the isotope of uranium, U^{235}, and the hitherto unknown element plutonium, in particular the relatively stable isotope, Pu^{239}. Both were obtained or derived from ordinary uranium which, since its discovery more than one and a half centuries ago, had been considered, in terms of quantity produced or value, only a minor metal; it now stands in the front rank if not supreme among the metals.

The atomic bomb, a practical application of principles of pure science, proved to be the most revolutionary military weapon ever developed, and the means and methods of its production were an engineering triumph.[3] In the space available it is not possible to list even the more important scientific developments that followed the discovery of radio-activity at the turn of this century, with the subsequent development of modern concepts of the constitution of matter. The fantastic possibilities of destruction that appeared from application of Einstein's equation of the equivalence of energy and mass to the results of what early in 1939 was correctly recognized to be nuclear fission directed attention to the military possibilities of this phenomenon in view of the increasing certainty that another world war impended.

At the instance of a group of military officials and scientists, in-

[1] Figures on imports and exports (unless otherwise indicated) compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

[2] The first test bomb was exploded July 16, 1945, on the proving ground near Alamagordo, N. Mex.

[3] Much of the discussion in this chapter is based on what is generally called the Smyth report, an officially approved document by H. D. Smyth entitled "A General Account of the Development of Methods of Using Atomic Energy for Military Purposes Under the Auspices of the United States Government, 1940–45." This document first appeared in a limited mimeographed War Department release for use of radio commentators after 9 p. m. August 11, 1945, and for the morning papers of Sunday, August 12. It was issued subsequently in printed editions by Princeton University and by the Government Printing Office. An approved popular account by William L. Laurence appeared in the New York Times and was issued later by that newspaper in a 40-page pamphlet entitled "The Story of the Atomic Bomb." Abstracts or condensations of the Smyth report appeared in all leading technical journals, magazines, and newspapers within a few months after the original release date. Release of additional information is expected in 1946 after study by a special War Department Declassification Committee.

cluding Einstein,[4] the late President Roosevelt set up, in the fall of 1939, an advisory committee on uranium that later became part of the National Defense Research Committee and then after reorganization was incorporated in the Office of Scientific Research and Development. Contracts were concluded with several universities and the Bureau of Standards to carry out special basic research, but up to the end of 1941 commitments were only about $300,000. The attack on Pearl Harbor and knowledge that the Germans were working intensively on the atomic bomb problem made acceleration and expansion of the program imperative. In midsummer 1942 the Army Corps of Engineers set up a special organization to carry on the work. This was designated the Manhattan District and the project, for security reasons, was named the Development of Substitute Materials. In September 1942 Gen. Leslie R. Groves was placed in complete charge of all Army activities and continued so to act into 1946. After May 1, 1943, the Manhattan District was in full control of all phases of the project.

By the end of 1942 there was considerable evidence that atomic explosives could be prepared. Basic raw materials of requisite purity were becoming available. In December the first self-sustaining graphite-uranium fission pile was in operation. A microscopic quantity of the element, plutonium, had been isolated and many of its properties, including fissionability, determined. The chemistry of its separation from uranium and fission products was known. Plans for construction of full-scale plants had been drawn up. It is worthy of note that, except for a pilot uranium-graphite pile that was set up at the Clinton Engineer Works in Tennessee, the tremendous U^{235} and plutonium operating plants were constructed without recourse to the standard engineering practice of pilot-plant design and operation. In 1943–44 hundreds of square miles of land were acquired and plants erected for U^{235} separation near Knoxville, Tenn., for the plutonium production at Hanford in eastern Washington, and for the metallurgical and bomb laboratories at Los Alamos near Sante Fe, N. Mex. Although a military project, the personnel was nearly all civilian, and the construction and operation were carried out by or under the supervision of outstanding industrial organizations. In fact, a large cross-section of American industry participated directly or indirectly in the project. Its contribution, accompanied by the intensive endeavors of scientists from many lands that culminated in the atomic bombs, was one of the greatest cooperative achievements ever recorded.

Scarcely had the first joy at the cessation of conflict subsided before public attention was focused on the world-wide political and social implications of the possession of this virtually incomprehensible power. Its control became at once a matter of supreme international gravity. How could it be directed to the welfare of mankind and not to its annihilation? Interested groups made proposals concerning the revelation of still secret information that ranged from one extreme to the other. The first official pronouncement was contained in a joint declaration by the President of the United States and the Prime Ministers of the United Kingdom and Canada, signed at Washington

[4] In a letter dated August 2, 1939, Einstein wrote the President: "Some recent work by E. Fermi and L. Szilard * * * leads me to expect that the element uranium may be turned into a new and important source of energy in the immediate future. * * * This new phenomenon would also lead to the construction of bombs * * * extremely powerful bombs."

November 15, 1945. Therein was expressed a willingness to share fundamental scientific information with any fully reciprocating nation. Likewise, information on methods and processes equally applicable to humanitarian or military use would be released, but only when adequate safeguards against misuse were provided. To these ends, to eliminate atomic weapons from armaments and to establish the requisite controls a commission should be set up at once in the United Nations Organization. Such a commission was established, but it had made public no recommendations at the time this chapter was written. In the United States and in other countries atomic control legislation has been proposed. Final action has not been taken; but there is some indication in this country that controls will be vested largely, if not fully, in civilian rather than in military hands.

BARIUM AND STRONTIUM

Production of barium and strontium metals and their alloys in the United States in 1945 was slightly less than in 1944 largely because of a recession in the wartime expanded needs for radio and radionic tubes. A possible deterent to broader application has been the high price, which for barium has been above $5 a pound and for strontium about three times as much. Although barium ranks tenth in abundance among the constituents of the igneous rocks, its great affinity for fluorine, chlorine, oxygen, nitrogen, hydrogen, and sulfur has made its reduction a difficult and expensive process. In the light of recent experience in the production of magnesium by the reduction of dolomite with ferrosilicon, Kroll[5] reviewed various processes and modifications and concluded that on a large-scale operation basis metal could be produced for less than 45 cents a pound. The report contains an extensive bibliography.

Of extraordinary subsequent import was the discovery in 1939 that among the products resulting from the neutron bombardment of uranium were isotopes of barium and lanthanum, elements that lie roughly in the midsection of the periodic table. This was an entirely new development. Although nearly all the elements had been caused to disintegrate by particle bombardment, the most massive particle torn loose from a nucleus was an alpha particle or helium nucleus of atomic number 2 and atomic mass 4. It was thus established that nuclear fission (that is, a splitting into roughly equal parts) could be effected and the energy released would far surpass any theretofore observed in other atomic disintegrations.

BERYLLIUM

Consumption of beryllium ore in 1945 was nearly one-fourth less than in 1944, a large part of the drop taking place in the fourth quarter. The receipt of foreign ores was about 40 percent that of 1944, but total stocks in the United States were not greatly reduced. Residual restrictions on use of beryllium metal were lifted by revocation of War Production Board General Preference Order M–160 on May 29, 1945. Order M–160–a, covering segregation and sale of beryllium scrap, was revoked on April 23, 1945, and imports of beryllium ore, metal, and salts were removed from control on June 4, 1945, by an amendment to WPB General Imports Order M–63.

Domestic mine production.—Shipments from mines dropped sharply in 1945 from the peak level of 1944. This was to be expected when

[5] Kroll, W. J., Processes for Making Barium and Its Alloys: Bureau of Mines Inf. Circ. 7327, 1945, 16 pp.

Government purchasing at roughly three times the immediate prewar price was discontinued at the end of 1944, with the accompanying contraction in demand for beryllium products that began in 1943. It appears that domestic beryl output cannot meet requirements even with strong price support.

Beryllium ore shipped from mines in the United States, 1939–45, by States, in short tons

Foreign trade.—Imports of beryl ore were only 38 percent as great as in 1944, when the Government's foreign purchase program ceased; but a portion of the 1945 entries comprised shipments of ores actually produced in 1944. This was particularly true in Africa and Australia, and it is not expected they will be future consequential suppliers, except at very high price. Exports in 1945 were 172 pounds of ore ($130) and 103,129 pounds of metal, alloys, and scrap ($85,849). The quantity and value of salts and compounds no longer are classified separately.

[1] Less than 1 ton.

Stocks.—Consumers and dealers held only 90 tons of ore at the year end. Office of Metals Reserve held 4,497 short tons, a reduction of 187 tons during the year.

Prices.—The price of $14.50 a short-ton unit, 8–12 percent BeO content, set by the then Metals Reserve Co. in May 1944, continued to be quoted by trade journals until June 1945. Immediately after controls were lifted near midyear 1945, quoted prices dropped to $9–$10 a unit which prevailed to the year end. Beryllium-copper master alloy was quoted at $15 a pound contained Be throughout the year against a ceiling price of $17. In February 1946 the Beryllium Corp. announced a price of $14.75 and on the 5-percent Be master alloy for use in aluminum castings a price of $30 a pound contained Be in 1,000-pound lots compared with the former price of $47. Beryllium metal was priced at about $45 a pound.

Uses.—Study in 1930–32 of a highly penetrating radiation arising from the bombardment of beryllium with an alpha particle from polonium (a radium disintegration product) led to the discovery of a new, fundamental physical particle, the neutron. Its principal characteristic, the absence of electric charge, makes it an extremely effective atomic disintegration "bullet," especially with heavy, highly charged atoms. Although uranium may be disintegrated by other particles; the neutron reaction is of great moment in that a fission may provide, on the average, more than one secondary neutron which may, in turn, effect other fissions, thus establishing a continuing or chain reaction.

There is no natural neutron supply and although there are several reactions that provide neutrons the most commonly used is that of radium and beryllium. This reaction was used to measure neutron intensity at various points and with different arrangements of uranium and moderator in the experimental reaction piles, and it furnished the excess neutrons required to initiate the reaction in the first self-maintaining pile. However, contrary to some statements, the radium-beryllium mixture was not used in the later operating or production piles. In them, reaction was initiated by spontaneous uranium fission or by cosmic rays.

Beryllium was suggested for use as a moderator (see Boron section) because it has a low atomic weight and low neutron-absorption cross section, as well as being a possible source of additional neutrons that arise when it is bombarded by neutrons. Experimental use indicated that beryllium was comparable to graphite as a moderator, but in practice it found little use because it could not be procured in quantity of the requisite purity and structural form, aside from its high unit cost.

To maintain a chain reaction, more neutrons must be available than escape from the reacting mass plus those ineffective in producing fission. Escape is a surface effect and could be limited in part by enclosing the reaction piles in a reflecting material. Experimentally, at least, beryllium was so used, though graphite (carbon) appears to have been employed as a reflector in the production piles.

Beryllium enters into fabrication in several forms—as beryllium-copper alloys, as the oxide, as metal, in chemicals, and to a very minor extent as beryllium-nickel or beryllium-aluminum. Metal production was not large, at least up to 1941; the Smyth report states that in 1940 only 700 pounds were made in this country. It appears from preceding paragraphs that the special war uses probably induced a much larger output in the following years. The major metal use and a growing one because of the spreading employment of industrial radiography has been for windows on X-ray tubes,[6] where it has special value in permitting the passage of "soft" or long wave-length radiation. Beryllium oxide or zinc beryllium silicate is used as a phosphor, giving

[6] Zunick, M. J., Metallurgical Aspects of X-Ray Tube Manufacture: Iron Age, vol. 157, No. 15, Apr. 11, 1946, pp. 56–59. Several references to beryllium use are given.

a yellow-white light in fluorescent lamps. In 1945 production of fluorescent lamps was about 37 million units, with an expected output of 50 million by 1950. Another growing use of the oxide is for refractory crucibles and shapes. In the past, many commercially unsuccessful attempts were made to develop strong, light alloys with aluminum or magnesium. Recently, however, it has been found that certain binary and ternary aluminum alloys, particularly the latter, to which beryllium has been added, age-harden and are remarkably corrosion-resistant at high temperature. A new outlet for beryllium may follow. The outstanding use has remained in copper-beryllium alloys, which are finding an increasing range of applications because of unusual properties.[7]

Technologic developments.—The Bureau of Mines carried out further tests on concentration of beryl ores. Flotation patents [8] were granted Bureau of Mines technicians. A description and analysis of methods for production of beryllium and alloys, with an extensive bibliography of processes and patent literature, was published.[9] Heat-treating methods for springs and parts made from beryllium copper strip or wire were described,[10] as were schemes for surface hardening with retention of softer, tougher, and more ductile interior section of more massive bodies, such as tools, gears, and other articles.[11] A method for reduction of beryllium fluoride materials by magnesium to produce metallic beryllium of high purity was also patented.[12]

World production.—The subjoined table gives world production of beryllium ore. World output in 1945 slumped 75 percent compared with 1944; dropped 83 percent compared with the peak year 1943; and was apparently little more than the prewar 1935–39 average. The pronounced decline in 1945 was primarily the result of the termination of the war-stimulated world-wide buying program of the United States Government. The effects on production in the several producing countries is noted in the following foreign review.

World production of beryllium ore, 1938—45, by countries, in metric tons [1]

[Compiled by B. B. Waldbauer]

Foreign review.—Until 1942 reported Australian beryl production had been negligible. Based on United States imports, production in 1943–45 was about 1,075 short tons, with most of the output in the first 2 years. The Metals Reserve Co. purchase price for the last 9 months of 1944 was $8.50 a short-ton unit, f. o. b. Australian ports. Most of the Australian beryl was mined in Western Australia in the Wodgina tantalite area and in the Gascoyne River area in the vicinity of Yinnietharra. At Wodgina over several years some 500 tons had been accumulated as a byproduct of tantalite mining.[13] The ore shipped averaged 12.06 percent BeO. The deposit was believed to be nearly exhausted by the end of 1944. Pegmatites at Yinnietharra carry some beryl, and a considerable quantity was picked up at weathered outcrops. A lot of over 38 tons assayed 13.19 percent BeO. Australian deposits have been described.[14]

The Deutsche Gold und Silber Scheideanstalt at Frankfurt a. Main, known as Degussa, since the mid-1930's has been the only producer of beryllium metal and oxide in Germany. In 1938 through September 1939 its reported output was only 500 kilograms beryllia and 700 kilograms metal. From October 1939 through 1944—the plant was not operative in 1945—output rose to 18.8 metric tons of oxide and 4.1 metric tons of metal. Total Axis output for the period was 20.6 metric tons Be content. Ore supply was originally from Brazil. During the war, additional ore was obtained from Scandinavia, Portugal, and Italian stocks.[15] During the war India reached second place in world beryl production, but at the conclusion of the Metals Reserve Co. foreign purchase program mining nearly stopped. It is believed that, at highest wartime prices ($9 a long-ton unit BeO) and with reasonably stable political and economic conditions, India's production might be maintained for several years at recent peak rates. Most of the output came from Rajputana. A description of the more important mines in the several States and production and other data were published.[16] The Government, as a part of its industrialization plan has displayed much interest in the country's beryl resources and is seemingly disposed to aid development of internal manufacture of beryllium oxide, metal, and alloys. An Italian firm, Societa Anonima Processi Privative Industriale ("Sappi") in 1936 constructed and operated a beryllium plant at Chivasso near Turin. From 1940 until the Germans were driven from Italy the plant was under their control and almost the entire output was shipped to Germany. It is claimed that a secret process used was superior to any other.

BORON

Production.—Shipments of ferroboron in 1945 were 109 tons with a boron content of 16 tons, compared with 112 tons and 15 tons respectively in 1944. In view of the improved availability of the common ferro-alloys, this may indicate that boron has attained a permanent position among steel addition agents. Shippers of ferroboron were the Electro Metallurgical Co., Molybdenum Corp. of

[16] Bureau of Mines, Mineral Trade Notes: Vol. 22, No. 3, Mar. 20, 1946, pp. 4–9.

America, and Ohio Ferro-Alloys Corp. Special addition agents containing boron with other metals are made by the above-named manufacturers, as well as by the Titanium Alloy Manufacturing Co. and Vanadium Corp. of America.

Uses.—The most interesting use of boron was in the production of "atomic bomb" constituents. It has a strong tendency to absorb neutrons, and as the net number available for a self-sustaining uranium fission reaction is very small boron was not suitable as a "moderator"—that is, a mechanism for slowing neutron speeds to the range where they would be effective in disintegrating the U^{235} uranium isotope. How serious neutron loss was considered is indicated by the statement that high-purity graphite containing only about 2 parts per million of boron was undesirable as a moderator. However, the same characteristic makes boron useful in controlling the operating rate of the uranium-graphite piles used to produce the new element, plutonium. Boron as boron steel was so used. Boron trifluoride (BF_3) also was used in instruments employed for measuring neutron intensity in the piles.

The commercial use of boron in steel is essentially a wartime development. Although its use was proposed in a United States patent issued in 1924, acceptance of the proposal was slow, and in the United States the use of boron scarcely had passed the experimental stage as late as 1940 or 1941. The entrance of this country into the World War and the consequent shortage of basic steel-alloying elements greatly stimulated the use of boron, which reached a peak in 1943 at nearly eight times its 1940 consumption. The subsequent decline was in large part due to the drop in alloy-steel output and to the fact that boron's principal characteristic is to confer hardenability to steels of the medium carbon range.

In a recent review [17] on the use of boron in steel, it is reported that boron has a specific effect on hardenability that increases in proportion to total boron content to a maximum at 0.003 percent B and decreases with further additions. Although boron may displace as much as several hundred times its own weight of the commoner alloy elements it cannot eliminate their use, because there is a limit to the hardenability it affords and because the other elements furnish properties to steel that boron does not provide.

Prices.—Ferroboron, 17.5 percent minimum B, less than ton lots, was quoted at $1.30 a pound of alloy, unchanged throughout the year. F. W. Berk & Co. reduced its f. o. b. works price on 82- to 86-percent amorphous boron a pound to $15 on lots of 1 to 50 pounds, $13 on 50- to 100-pound lots, and $11 for 100- to 500-pound lots.

CALCIUM

From incomplete returns, calcium-metal production appears to have been much greater in 1945 than in the preceding year. War Production Board's calcium-metal Conservation Order M-303, with all authorizations and directions thereunder, was revoked May 2, 1945. The price for 97- to 98-percent metal was $1.85 a pound throughout the year. The principal producers of metal and hydrides were the Electro-Metallurgical Co., Metal Hydrides Co., and the New England Lime Co.

[17] Corbett, R. B., and William, A. J., Effects of Boron in Steel: Bureau of Mines Rept. of Investigations 3816; June 1945, 21 pp.

Calcium metal had been supplied by France and Germany up to 1939, and a small shipment was received in 1940, but there was no further movement until 1945, when 17,086 pounds were received from Canada. In 1945 Dominion Magnesium, Ltd., produced 29,543 pounds of calcium, the first commercial production in Canada. It was said to be exceptionally pure. The reported value, about 76 cents a pound, was less than half the quoted price in the United States.[18] In Germany during the war, production had been about 50 tons a month, of which about ¾ ton was converted to the hydride.[19]

Calcium metal and calcium-silicon imported for consumption in the United States, 1941–45 [1]

Commodity	1941		1942		1945	
	Pounds	Value	Pounds	Value	Pounds	Value
Calcium metal					17,086	$15,845
Calcium-silicon	111,994	$8,337	60,300	$10,144	164	22

[1] No transactions reported during 1943 and 1944.

Calcium has found increasing use as a deoxidizer in ferrous metallurgy and as an alloy constituent with nonferrous metals. It has been employed in the reduction of difficultly reducible metals, such as chromium, thorium, uranium, and zirconium. During the war an important calcium use was to make the hydride, which is a convenient and portable source of hydrogen for inflating weather balloons. Uranium metal had been made by reaction of calcium with the chloride or oxide and by reducing the oxide with calcium hydride; the latter was perhaps the first-applied (1941) relatively large scale production method. The uranium was, however, in the form of highly impure pyrophoric powder and was not usable in the atomic bomb project. However, by the end of 1942 acceptable metal was being turned out. Applications and uses of calcium have been reviewed and compiled in a textbook [20] that also discusses properties of the metal and production methods.

The usual methods of calcium-metal production are by electrolysis of the fused chloride or thermal reduction of the oxide, the first method having been commonly employed. In 1944 the New England Lime Co. developed, on a commercial scale, a process for calcium production by aluminothermic reduction of the oxide in vacuo.[21] The metal has an approximate composition of: Calcium, 98 to 99 percent, the principal impurities being magnesium 1.0 percent maximum and aluminum 0.2 percent maximum. The usual commercial grade is 96 to 98 percent calcium. High-purity metal may be extruded into various shapes.

COLUMBIUM AND TANTALUM

War Production Board General Preference Order M–296, Ferrocolumbium, was revoked July 9, 1945, but control of use was simul-

taneously extended under Direction 5 of General Preference Order M–21, which was revoked August 21, 1945.

Domestic production.—Domestic production of columbium ore virtually ceased in 1945, but tantalum ore output declined only 24 percent. For the third consecutive year, Arthur Montgomery of Dixon, N. Mex., was the major producer; shipments of concentrate assayed 68 to 70 percent Ta_2O_5. Until mid-1945 the ore had been shipped to a customs concentrator. Thereafter a small concentrator using the Humphreys spiral was put into operation at the mine.[22] Recovery of microlite from the tantalum-lithium ore is 95 percent.

Columbium and tantalum ores shipped from mines in the United States, 1941–45

[Compiled by R. W. Metcalf]

Year	Columbium ore		Tantalum ore	
	Pounds	Value	Pounds	Value
1941			250	$219
1942			200	175
1943	5,771	$1,465	9,411	27,621
1944	3,208	917	7,204	23,317
1945	1,149	287	5,500	13,366

Foreign trade.—Imports of columbium ores reached a new high, about 15 percent above the previous record in 1944. Tantalite imports dropped off nearly one-fourth from the 1944 peak. Details of foreign trade are shown in the subjoined table. Exports in 1945 were: Tantalum, 11 pounds ($801) compared with 5,052 pounds ($77,463) in the preceding year; columbium ore, 5,000 pounds ($188) and metal, 1,334 pounds ($3,098). There were no exports of columbium ore or metal in 1944.

Columbium and tantalum ores imported for consumption in the United States, 1943–45, by countries, in pounds

Country	Columbium ore			Tantalum ore		
	1943	1944	1945	1943	1944	1945

[1] Classified by U. S. Department of Commerce as British East Africa.

Prices.—E&MJ Metal and Mineral Markets quoted $2–$3 a pound for 60-percent tantalite concentrate, depending on source. In the

[22] Wood, John A., Spiral Concentrator Recovers Tantalum Ores at the Harding Mine: Min. Cong. Jour., vol. 32, No. 1, January 1946, pp. 44–45.

United Kingdom the nominal price for columbite remained at about 60s. a unit combined Cb_2O_5 and Ta_2O_5 on 50- to 55-percent concentrate, based on 1942 freight rates, and for 60-percent Ta_2O_5 concentrate about £10 a unit, c. i. f. Domestic prices for metals and alloys, unchanged throughout the year, were: Tantalum metal, sheet at $143 and rod at $160.60 a kilogram; ferrocolumbium, 50 to 60 percent Cb at $2.25–$2.30 a pound contained Cb; and columbium metal, sheet at $500 and rod at $560.

Stocks.—At the end of 1945, the Office of Metals Reserve held 33,991 pounds of columbite and 1,095,862 pounds of tantalite containing 452,393 pounds of tantalum oxide (Ta_2O_5).

Uses.—The principal use of columbium is to inhibit intergranular corrosion in chrome-nickel steel by preventing formation of chromium carbide. It is also used in rods for welding stainless steels. Special strong, high-temperature-resistant steels of the stainless type containing columbium are being employed in gas turbines, turbosuperchargers, and jet-propulsion motors. Only minor uses have been found for columbium metal. A wartime-developed, extraordinarily sensitive, heat-detecting device, called a bolometer, has a columbium nitride surface. Tantalum metal was first used for electric lamp filaments but was soon superseded by tungsten. It is, however, much used in various types of electronic tubes. It is much more resistant than columbium to acid corrosion. Consequently it has had extensive use in acid-resistant apparatus and notably in hydrochloric acid production. Likewise, though quantitatively small, surgical uses have been important. During the war tantalum fluoride was widely used as a catalyst in butadiene manufacture. The carbides of both columbium and tantalum are extremely hard and have melting points of about 3,500° C. and 3,900° C. respectively. They have therefore been useful as cutting-tool inserts, wire-drawing dies, and various types of nozzles. Most applications have been in conjunction with ferrous metal.

Foreign review.—Argentine production of tantalite in 1944 was about 17,000 pounds, about one-half of which was sold. Western Australia has been an important source of high-grade tantalite, some of which carried nearly 80 percent Ta_2O_5. The principal area is in the vicinity of Wodgina. Production from this area to the end of 1944 had been about 250 tons valued at £A130,000. More than 12 tons had been recovered in the Greenbushes tin area in the southwest and a small quantity from the Coolgardie gold area. Reduction of ore at Wodgina is under consideration. The Belgian Congo has become the premier producer of tantalum-columbium ores. The output in 1944 was about 200 metric tons. Brazilian shipments in 1944, virtually all to the United States, were of the same order but declined sharply in 1945. Columbite and tantalite occurrences in eastern Bolivia were described.[23] In the Canadian Northwest Territories, in the Yellowknife district, production of columbite, tantalite, and beryl was expected to begin in 1945. Two small mills were to have been built. The Jantar Nigeria Co. increased its output of columbite from 327 tons in the year ended September 30, 1944, to 375 tons in the corresponding 1945 period. Reserves were said to be 3,582 tons. A new contract for 1946 is being negotiated with Ameri-

[23] Mineria Boliviano, Minas de Mica y Columbita en el Oriente Boliviano: Vol. 2, No. 17, April 1945, pp. 16–17.

can buyers.[24] Amalgamated Tin Mines of Nigeria recovered 1,421 tons of columbite from old tailings in the year ended March 31, 1945, and 414 tons in the period April–December 1945, compared with 125 tons in the previous year. It was expected that the dumps would be exhausted early in 1946. Thereafter only a small quantity will be available from current cassiterite operations. In 1944 Nigeria produced 2,072 tons of columbite, of which about one-half was derived from old tin-mining dumps. More than 6,000 tons were produced in the past 10 years.

GALLIUM AND GERMANIUM

Gallium and germanium remain in the very rare category, largely because few, if any, mineral concentrations could be worked profitably without the concurrent recovery of other metals and because few useful applications have been found. Gallium was first discovered (1875) in certain French zinc blendes and has been determined in many others. It is almost invariably associated with aluminum and with germanium has been found in the ash of some British coals. Germanite, the only mineral that contains an appreciable amount of gallium, about 0.8 percent, was found in the complex copper ores of Mansfeld, Germany. Gallium has a very low melting point, about 30° C., and remains liquid to between 900° and 1,000° C. Because of the low melting point, the metal may find use in the development of low-melting-point alloys. Its great range in the liquid phase gives it value as filling material in direct-reading high-temperature thermometers. The price of gallium was said to be about $3 a gram. Since 1943 the Anaconda Copper Mining Co. has produced several thousand grams of gallium in connection with its indium recovery.

Germanium is generally associated with zinc ores but usually in minute percentage. In the United States the Eagle-Picher Lead Co., Cincinnati, Ohio, continued production of metal and salts. Germanium is a byproduct from cadmium recovery. About 10 pounds of germanium may be recovered from 15,000 tons of ore. The present price is about $200 a pound compared with $4,500 5 years ago. The principal use has been in radionic devices. It gives high refractive values in optical glass, and alloys with magnesium, aluminum, gold, and platinum have desirable properties. The gold-germanium alloys have aroused considerable interest because of possible uses in jewelry and in dental inlays. A study of the alloy's characteristics was published.[25]

INDIUM

Domestic production.—In 1945 the byproduct recovery of indium was substantially lower than in 1944, and there was evidently much competition for markets in view of the large price drop. The indium content of metal, alloys, and salts shipped by producers in 1945 was 57,434 troy ounces. Earlier figures are not available for publication. In 1945 producers of metal and salts were the American Smelting & Refining Co., Anaconda Copper Mining Co., National Zinc Co., Inc., and the Sherwin-Williams Co. The Cerro de Pasco Copper Mining

[24] Metal Bulletin (London), Jantar's Output: No. 3057, Jan. 1, 1946, p. 16.
[25] Jaffee, Robert I., Smith, Eugene M., and Gonser, Bruce W., The Constitution of the Gold-Germanium System: Am. Inst. Min. and Met. Eng., Metals Technol., vol. 12, No. 4, June 1945, Tech. Paper 1812, 7 pp.

Co. has carried out research on the recovery of indium from lead-refining drosses.[26]

Prices.—The year's opening price of $7.50 a troy ounce (99.9 percent indium) dropped to about $4 in March. Late in June metal was readily purchasable at $3 and in September dropped further to $2.25, with an indication that a discount might be made on bulk purchases. In less than 2 years the price cut was more than 75 percent; 10 years earlier the price had been 13 times the figure at the end of 1945.

Uses.—The major use has been in heavy-duty composite metal bearings employed extensively in airplanes, tanks, and other mobile equipment. A zinc-indium alloy was used in applying a noncorrosive plating to hollow-steel airplane propellers. Minor uses have been in solder and brazing alloys and alloyed with gold and silver for jewelry and plated articles. The first commercial use about 1927 was as a nontarnish coating on silverware. Low-melting-point alloys also have been manufactured recently. Indium foil was used as neutron indicator in the atomic bomb project uranium-graphite piles. Low-energy neutrons—about 1.5 electron-volt—are particularly effective in inducing artificial radioactivity in indium.

SELENIUM AND TELLURIUM

Domestic production.—Production of elemental selenium increased 12 percent above the 1944 level; producers' shipments rose nearly 50 percent and were about 2 percent below the record figure of 1941. Both tellurium production and sales increased substantially compared with 1944 and were approximately three-quarters and one-third, respectively, above the 1936–40 averages. At the same time the output ran ahead of market needs, resulting in a 12-percent increase in producers' stocks. On the other hand, selenium producers' stocks declined 24 percent.

Salient statistics of elemental selenium and tellurium in the United States, 1941–45

Year	Selenium					Tellurium [1]		
	Production (pounds)	Producers' sales [2] (pounds)	Producers' stocks at end of year (pounds)	Imports [3]		Production (pounds)	Producers' sales [2] (pounds)	Producers stocks at end of year (pounds)
				Pounds	Value			
1941	620,493	681,650	146,000	197,873	$288,161	224,639	239,983	20,400
1942	506,426	316,613	341,900	83,666	127,004	224,132	98,798	145,700
1943	635,581	521,779	455,677	81,720	142,032	56,174	62,260	139,403

1945	542,099	666,363	392,953	219,215	395,934	80,750	60,328	183,527

[1] Includes tellurium content of small quantity of oxide.
[2] Bureau of Mines not at liberty to publish value. Quantities for 1942–45 represent producers' shipments.
[3] Includes selenium salts.

Foreign trade.—Selenium imports, all from Canada, reached a record height at nearly 11 percent above the 1941 figure. Tellurium imports are not recorded separately. Exports of selenium, including selenium content of compounds, and tellurium in 1945, as reported by domestic producers, were 22,965 pounds and 267 pounds in comparison with 13,191 pounds and 288 pounds, respectively, in 1944. As far as known, the 1945 figures are the highest on record.

[26] Wright, T. R., The Cerro de Pasco Enterprise, Metallurgical Research: Min. and Met., vol. 26, No. 467, November 1945, pp. 559–560.

Prices.—As reported by E&MJ Metal and Mineral Markets, prices of selenium (black, powdered, 99.5 percent) and of tellurium were $1.75 a pound, nominal and unchanged in 1945. The selenium price has remained constant for at least 8 years, and tellurium changed from $2 in 1938 to $1.75 in 1939 and has been unchanged since. In London tellurium was quoted at 7s. a pound and selenium at 8s. 6d., with consistent demand.

Uses.—Important uses for selenium are in rubber compounding; as a decolorizer in glassmaking, or as a colorant for pink and with cadmium and sulfur for ruby glasses; in stainless steels to improve machinability; in alternating current rectifiers; in nonferrous alloys, especially with copper; in pigments; and as an antioxidant in lubricating oils. The use in rectifiers is growing rapidly because of their high efficiency (even at high ambient temperatures), long life, stability, and virtual absence of maintenance cost. Rectifiers are widely used in aircraft and for numerous electronic devices, battery charging, electroplating, and welding. The use of tellurium has not grown rapidly. Principally it is employed in vulcanizing rubber, to which it imparts toughness and abrasion resistance not given by sulfur; as an alloying agent with nonferrous metals, particularly lead, to which it adds corrosion resistance, fine grain, and mechanical strength; and in copper-base alloys to improve machinability and corrosion resistance. Extremely small additions to cast iron increase chill depth and hardness. The identification of selenium (atomic number 34) and tellurium isotope (atomic number 52) fragments resulting from neutron bombardment of uranium aided in establishing the certainty that the uranium nucleus could be split into roughly equal parts.

Foreign production.—Preliminary estimates of selenium and tellurium output in Canada in 1945 were, respectively, 419,000 and 42,000 pounds. Final figures for 1944 were, respectively, 298,592 and 10,661 pounds.

THALLIUM

Domestic production of thallium in 1945 declined somewhat compared with 1944. Although demand was very strong in the first half year because of rodenticide needs of the military services, the termination of hostilities in midsummer, coupled with the importation of 1,000 kilograms from France and 500 kilograms from Belgium greatly changed the supply-demand balance. The American Smelting & Refining Co., as heretofore, remained the only domestic producer. In Belgium and in France producers are Société de la Vieille Montagne and Alais Froges et Camargue, respectively. In Germany the shortage of thallium became acute because internal production was small and Algeria, the source of red squill of the best quality and in the largest volume, was cut off. Organic synthetics were substituted but were not as effective as the thallium. The Fish and Wildlife Service of the Interior Department announced the development of the most potent rodenticide yet known, "1080" or sodium fluoroacetate. Because of its extreme toxicity—an antidote has not yet been found—to man and animals other than rodents the sale to the public of this exceptional poison is currently barred. The Fish and Wildlife Service had estimated national requirements of thallium for the fiscal year ending June 30, 1947, to be about 7,500 pounds; however, as a result of the highly satisfactory field tests with "1080," thallium requirements are likely to be less than the above estimate. Another powerful thallium sulfate substitute, "Antu" or alpha-naphthyl thiourea, was reported by the Federal Public Health Service.[27] This poison is said not to be dangerous to human beings nor to many animals and though toxic to the so-called Norway rat it has apparently little effect on the black or Alexandrine rat. These two rodent poisons were listed by Science Service as eighth among the 10 most important scientific developments of 1945. E&MJ Metal and Mineral Markets reported thallium at $12.50 a pound, unchanged throughout the year.

Thallium has had little use other than as a rodenticide or insecticide. Lead-thallium alloys are said to be very highly resistant to corrosion, and use in bearing metals was early proposed. Patents on copper-thallium, copper-lead-thallium, and silver-thallium bearing metals were issued in 1945. Characteristics and certain applications of the last-named were described.[28]

URANIUM AND DERIVATIVES

General.—From the discovery of radium in uranium ore in 1898 up to about 1940 the demand for uranium was essentially a direct function of the use of radium. The several million times greater volume of residual uranium products thus became of secondary importance. In fact, in the immediate prewar years the expanding use of radium tended to create a surplus of uranium products. No exact measure of the demand for either metal is available. However, in 1939 the two outstanding producing companies agreed to share the world market because their output potential exceeded absorption capacity, without a major price reduction. About that time, radium sales were of the order of 100 grams, equivalent to something less than 500 short tons of uranium oxide (U_3O_8) yearly, and plant capacity was possibly more than double that. For at least a few years in the period 1940–45, that capacity, or the corresponding mine output, was utilized, and in addition there was a substantial domestic uranium output. The reason for the tremendous stimulation in demand is now known.

Henceforth, radium is likely to have a subordinate position because of the coming availability of a great array of uranium fission products and others that can furnish a large range of types and intensities of radiation. Not only will uranium supply these products as well as artificially radioactive materials but contemporaneously will furnish tremendous quantities of thermal energy that may prove competitive with present sources of power. The nearby needs for uranium in this country, assuming peaceful uses only, will not be large, because past uses will be considered wasteful in the light of the vastly greater economic value of the new products, as well as the enormously favorable ratio of conversion of the raw material to them. Further, in the utilization of uranium for atomic bombs, there remained considerable quantities of useful radioactive materials.

Domestic production.—A short historical survey of uranium-bearing ore production was given in the 1944 chapter of this series. It was

[27] Science News Letter, Can Kill 300,000 Rats: Vol. 48, No. 14, Oct. 6, 1945, pp. 211–212.
[28] Hensel, Franz R., Silver-Thallium Antifrication Alloys: Am. Inst. Min. and Met. Eng., Metals Technol., vol. 12, No. 7, October 1945, Tech. Pub. 1930, 14 pp.

717372—47——53

indicated therein that little uranium was available from pre-1936 vanadium-ore production. From 1937 to 1940 the expanding needs for steel-alloying elements greatly stimulated domestic vanadium-ore production. Although the total ore shipments were several hundred thousand tons, the demand for uranium was so small that only about 13,000 tons were classified as uranium ores. The average uranium content reported was less than 12 pounds a ton. Up to this time, the uranium recovered was mostly used in the ceramic field. From 1941 on data are not fully available. It has been reported that two or more uranium-recovery plants were erected in 1940 and later in Colorado. These plants treated accumulated tailings from the vanadium operations amounting to a few hundred thousand tons as well as the waste from current vanadium operations. The grade of material was probably much lower than that indicated for 1937–40, which included material chosen for its high uranium content. From 1940 on both Canada and the Belgian Congo supplied large quantities of materials, principally uranium oxide and concentrates. The total availability of uranium was therefore substantial. World production up to 1939 appears to have been of the order of 6,500 tons (U content) or 13,000,000 pounds. Inasmuch as vanadium-ore output dropped sharply after 1943 treatment plants became inactive and a Government uranium plant at Grand Junction, Colo., was dismantled, current output will be small.

Uranium metal first was made about a century ago, but it was so little known up to about 1940 that even some of its physical properties, for example, melting point, were not known with precision. For the various needs of the atomic bomb project, a large quantity of materials of extremely high purity were known to be required, but even up to the end of 1941 only a few grams of usable material were available. The difficult technical problems of large-scale output were solved in 1942, and by the end of that year production apparently attained the rate of about 1 ton a day in metal. This rate was increased and seems to have been continued well into 1945.

Data on domestic production of radium from available domestic and foreign ores are not yet available, but output is understood to have been negligible. The last reported production was 2.6 grams in 1942. Imports of radium salts in 1942–45 correspond closely to the quantities reported in preceding chapters of this series to have been put into use.

The quantities of the fissionable isotope U^{235} and of plutonium made remain a secret. The critical size for the bombs was said to lie between 2 and 100 kilograms. Both U^{235} and plutonium were used in the bombs. Four or more have been prepared, and separation plants continued in operation into 1946. Nevertheless, it is evident that several hundred kilograms may have been prepared. From the practical standpoint, production of the new element plutonium, which was begun on large scale at Hanford, Wash., in September 1944, though an intricate and difficult problem is more efficient than the uranium-isotope separation. As far as known, the plutonium production piles were still in operation when this section was being prepared (May 1946).

Byproducts production.—As yet no information is available on the quantity or exact nature of byproducts arising from the chain-reacting piles designed for plutonium manufacture. Since the sole object was to produce plutonium rapidly complete separation of the various auxiliary products does not yet appear to have been undertaken. Some 150 isotopes of about 35 elements in the atomic mass ranges 83 to 115 and 127 to 154 were created in the U^{235} Pu^{239} fission. Among them were elements 43 and 61 (masurium and illinium), whose earlier isolation has been questioned. Of these, according to the Smyth report, about 20 are in significant concentration, with the most abundant less than 10 percent of the aggregate. The half-lives (the period in which one-half disintegrates) of these intermediates range from a small fraction of a second to a year or more and for several of the more important a month or so. Some are gaseous and are wasted into the atmosphere. Others are retained in the affluents from the units in which the plutonium is extracted from the reacted uranium slugs and are held in storage basins. Presumably, a substantial quantity of relatively long-lived radioactive products will have been accumulated.

The discovery or development of two new elements of atomic numbers 95 and 96, for which the names americium and curium have been proposed, was announced by Seaborg.[29] Like neptunium and plutonium, they are radioactive. These new elements have not been found in nature, nor until 1942 had any evidence of the natural existence of neptunium and plutonium been discovered. With the knowledge of the characteristics of these elements, a careful search revealed certain alpha activity in pitchblende that corresponded to about 1 part plutonium in 10^{14} in the pitchblende.

Foreign trade.—In 1945 imports, compared with those of 1944, dropped 33 percent for radium and 5 percent in radio-active substitutes; those of uranium oxide and salts were negligible. Virtually all imports came from Canada. In 1944 exports were: Uranium salts and compounds, 100,154 grams ($1,064); radium salts and compounds, 2,600 milligrams radium content ($58,339); radium medicinal salts and compounds, 2,152 milligrams radium content ($61,747). In 1945 they comprised: Uranium salts and compounds, 68,000 grams ($993); radium, 361 milligrams radium content ($5,414); radium salts and compounds, 2,526 milligrams radium content ($49,397); and radium medicinal salts and compounds, 8,249 milligrams radium content ($180,235).

Radium salts, radioactive substitutes, and uranium ore and compounds imported for consumption in the United States, 1941–45

Year	Radium salts			Radio-active substi-tutes [1] (value)	Uranium ore		Uranium oxide and salts	
	Grams	Value						
		Total	Average per gram		Pounds	Value	Pounds	Value
1941	4.412	$110,202	$25,000	$13			387,505	$501,370
1942	23.043	377,326	16,400	50	541,307	$806,919	377,398	851,098

[29] Chemical and Engineering News, Discovery of Elements 95 and 96 Announced at Chicago A. C. S. Conference: Vol. 23, No. 22, Nov. 25, 1945, p. 2085.

Prices.—Quoted price for radium in salts continued in 1945 at $25 to $30 a milligram. Based on export valuation, prices received ranged from about $15 to $22 a milligram radium content. The Oil, Paint and Drug Reporter quoted black uranium oxide at $2.55 a pound and orange salt (sodium uranate) at $1.65 a pound, both unchanged throughout the year. Prices of other materials or products are not available. According to the Smyth report, highly purified uranium metal at first cost about $1,000 a pound; this was later reduced to about $22.

Uses.—The common nonmilitary uses have been as a ceramic colorant, in photographic chemicals, and as catalysts. From the late twenties up to World War II, except for a few years in the early thirties, consumption rarely was under 200,000 pounds (oxides and salts) and in a few years was virtually double that quantity. Control of use of uraniferous materials was made effective under WPB Conservation Order M–285 in January 1943 and is still in effect. The stringent contraction in nonmilitary use of uranium salts is shown in the accompanying table in pounds of U_3O_8.

	1943	1944	1945
Chemical and photographic	4,000	6,700	3,800
Electrical	250	800	1,000
Ceramic	7,500	100	150
Total	11,750	7,600	4,950

In recent years the use of radium in medicine has been overshadowed by its industrial use for radiography and during the war by consumption in luminous paints. From incomplete data for 1945 it is estimated that consumption for the last-named was about 23 grams compared with 50 grams in 1944 and 75 grams in 1943. Industrial and medical radiographic use was estimated to have become about 50 grams compared with about 36 grams in 1944. The National Bureau of Standards tested 2,353 preparations containing 65,937 milligrams of radium or roughly 20 percent less than in the preceding year. The special use of radium and beryllium as a source of neutrons in pilot-scale reaction piles was mentioned in the Beryllium section of this chapter.

Elsewhere it has been pointed out that, in addition to the explosive products, numerous byproducts arise. It is not improbable that subcritical quantities of U^{235} and plutonium may have important research if not industrial value. On the other hand, as a matter of international safety, it is proposed that an international control authority would not permit use outside its own laboratories of other than "denatured" materials; hence, it is from the several byproduct classes that mankind soon may benefit. In broad terms, these are thermal energy and direct radioactive products or isotopes that may be made by introducing foreign materials into reaction piles.

The heat output is enormous, but there are now many unsolved problems connected with its utilization. It is not to be expected that it soon could compete economically with the common fuels, and in the nearer future it could be developed only in massive plants because of the heavy radiation shielding required. It has been suggested that in remote desert, arctic, or other undeveloped regions such plants might attain earlier importance. The time for such development has been estimated to range from about 1 to 20 years or more. The cyclotron has been the source of many products of the other classes. Even the greatest of these machines has a minute output capacity, with very high power input. A vastly greater supply is already existent in the uranium fission plants. Enough of these virtually new products is known to indicate that the science of metals stands at a new threshold, with these materials as tools. Likewise in chemistry, biology, and therapy new vistas are opened; even the secret of photosynthesis may be unraveled. Already steps have been taken to expedite peaceful applications. Gen. Groves announced in April 1946 that the Monsanto Chemical Co. would supervise design, construction, and operation of a plant planned solely as an atomic power plant. It was stated further that other important organizations, among them the Allis-Chalmers Manufacturing Co., the General Electric Co., and the Westinghouse Electric Corp., which had so largely participated in the atomic bomb project, will likewise manage broad-scale research for or in conjunction with the Government.

Technology.—Up to about 1942 pure uranium had not been made. Details of the methods later developed have not been disclosed. Earlier schemes were reduction of uranium chloride by calcium and direct oxide reduction with calcium or calcium hydride. The last-named methods produced pyrophoric and very reactive powders of about 99.8 percent purity. Highly pure metal had been made by fluoride (KUF_5) electrolysis, but as it depended on sunlight for a photochemical reaction the method was not suited to volume production. The National Bureau of Standards then perfected an ether extraction method for treating uranyl nitrate that furnished a satisfactory, pure, brown, uranium dioxide (UO_2). This oxide was used as a base for the potassium uranium pentafluoride and the uranium hexafluoride used for isotope separation and also as a metal source. Since U^{235} is chemically identical with the major isotope U^{238}, recovery methods were physical in nature. The principal ones employed were gaseous diffusion through porous barriers, thermal diffusion, and electromagnetic separation in cyclotrons. A centrifuging process also was used but did not go beyond pilot-scale operation. The first pure chemical compound of plutonium was prepared in August 1942. This new metal results from neutron capture by U^{238} becoming the isotope U^{239}, which rapidly decays with two successive beta-particle (electron) transformations to become neptunium (Np^{239}) and then plutonium (Pu^{239}). Plutonium is an alpha particle (helium nucleus) emitter and eventually becomes U^{235}. The decay rate is, however, so low that it may be considered a stable element, but like U^{235} is readily fissionable. Separation of plutonium from uranium apparently was carried out by coprecipitation with a carrier, analogous to precipitation of radium with barium, as in the radium-uranium separation, followed by successive dissolutions of the precipitate and reprecipitations until unwanted fission products were reduced to a satisfactory level. This involved about 30 major chemical reactions and hundreds of operations, all remotely controlled because of the intense radiation. Final purification, melting, casting, and forming were conducted at the New Mexico laboratories.

Foreign notes.—As in the United States, virtually all countries that possess radioactive minerals have established controls over movements of such materials or have nationalized the deposits. In the United States, including Alaska, all public lands that contain deposits of radioactive minerals were withdrawn by Executive Order 9613, September 13, 1945.

Australia.—It was claimed that one of the world's largest uranium deposits was discovered near Stanthorpe, Queensland. The ore was said to carry up to 3 percent uranium. A small output had been obtained some years ago from the vicinity of Mount Painter and Radium Hill in South Australia. Strong efforts were made in 1944 to revive production but without notable success. Ore is low-grade and very difficult to treat.

Canada.—Field exploration was most active, especially in the Northwest Territories, in 1943-45 and is to be continued in 1946. Several strong, radioactive areas were said to have been found. Interest was revived in the Goldfields Lake, Athabaska, area from which small pitchblende shipments had been made before the war. The International Uranium Mining Co., Ltd., Great Bear Lake area, expects to reopen its mine in 1946. There has been small and intermittent production from Haliburton County, Ontario. The Canada Radium Mines plans to start milling operations there in 1946. The Canadian Government began laboratory work on uranium fission in 1942 and subsequently erected an experimental plant at Petawawa, Ontario, on the Ottawa River. A reaction pile using heavy water as a moderator is in use. Investigations on the use of thorium are also under way. Research results were exchanged with British and American project scientists. A number of workers on the Canadian project were arrested and later convicted for having divulged various secrets to a foreign power. The Eldorado mine, Great Bear Lake, and the treatment plant at Port Hope, Ontario worked at capacity.

Czechoslovakia.—The State-owned mines at Jachymov were reported to be working normally after the withdrawal of Russian troops. The Nation's Business of April 1946 states, however, that the operation was supervised by Russian troops. The German Economic Ministry reported pitchblende-concentrate production in the Sudetenland for 1939–42 to have been in metric tons: 11.5, 12, 11, and 19. The corresponding uranium oxide (U_3O_8) figures were 5.7, 5.9, 5.5, and 9.5. In 1941 radium production was 1,826 milligrams and in 1942, 2,662 milligrams. These figures are of the same order as those usual in the prewar period.

Germany.—It was known that Germany was undertaking atomic bomb development. Scant information indicates that a shortage of scientists greatly retarded development. Large quantities of heavy water were ordered, and the producing plant at Rjukan, Norway, was enlarged. The plant and accumulated stock were successfully destroyed by British and Norwegian raiders. As a part of the industrial disarmament program for Germany, the production of radioactive materials (as well as of beryllium) has been prohibited.

U. S. S. R.—Geologists are continuing to search the Urals for radioactive minerals. Uranium ores were reported to have been discovered in the central Asia's Tadzhik S. S. R. According to the Mining Journal (London),[30] a huge deposit of highly radioactive vanadium ore has been discovered at Jabagai, Kazakstan.

ZIRCONIUM

[Prepared by Allan F. Matthews]

Domestic production.—Zircon output reached several thousand tons in 1945 compared with several hundred annually in 1940–44 but was still less than the 3,646 short tons produced in 1927. The principal producer was Humphreys Gold Corp., which began recovery of zircon August 1945 as an accessory of titanium minerals from beach sands near South Jacksonville, Fla., and which was operating the property for its owner, Rutile Mining Co. of Fla. (subsidiary of Titanium Alloy Manufacturing Co.). The only other domestic producer was Riz Mineral Co., which mined black sands near Vero Beach, Indian River County, Fla., and recovered zircon, rutile, and ilmenite in its concentrator at Melbourne, Brevard County, Fla.

Foreign trade.—Imports of zircon reached a new high in 1945, but those of baddeleyite continued to decline. Exports in 1945 comprised 108 short tons ($7,126) of zirconium concentrates, 30 tons ($15,383) of metal and alloys, 203 tons ($95,792) of oxide, and 253 tons ($36,384) of other zirconium compounds.

Zirconium concentrates imported for consumption in the United States, 1941–45, by countries, in short tons [1]

Year	Zircon from—				Baddeleyite from Brazil	Accessory titanium minerals [3]	Total zirconium concentrates [4]	
	Australia	Brazil	Other [2]	Total			Short tons	Value
1941	14,689	(5)	963	15,652	[5] 5,002	7,020	27,674	$604,744
1942	11,145	----------	196	11,341	15,283	7,282	33,906	816,364
1943	11,472	110	----------	11,582	8,821	8,009	28,412	697,704
1944	11,317	(5)	----------	11,317	[5] 2,332	10,384	24,033	576,299
1945	17,138	(5)	6	17,144	[5] 792	8,534	26,470	554,400

1 Totals and country break-down by the U. S. Department of Commerce. Mineral break-down by Bureau of Mines.
2 From India, 1941–42; French West Africa (Senegal), 1945.
3 Rutile and ilmenite content of mixed zirconium-titanium concentrates imported from Australia.
4 Classified as "ore" by U. S. Department of Commerce.
5 Any zircon imports from Brazil, 1941 and 1944–45, included with baddeleyite. The 101 tons of zirconium concentrates from Brazil, shown as zircon in Minerals Yearbook, 1944, was actually baddeleyite.

Consumption and uses.—Zircon shipments to consumers reached a record level of 15,988 short tons in 1945 compared with 14,484 tons in 1944. Use distribution in 1945, according to estimates by principal shippers, was as follows, in percentages: Electrical and chemical porcelains, 34; metal and alloys, 17; refractories, 17; pottery glazes and vitreous enamels, 12 each; glass, 7; and miscellaneous, 1. The occurrence, properties, and major applications of zircon were described.[31] Baddeleyite is consumed primarily for refractories and alloys. A new producer of zirconium-copper and oxide is Beryllium Corp., Reading, Pa. The Bureau of Mines began production of ductile zirconium on a laboratory scale November 1945. The metallurgy of zirconium was reviewed.[32]

31 Thielke, N. R., and Jamison, H. W., Development of Zircon as a Versatile Ceramic Material: Bull. Am. Ceram. Soc., vol. 24, No. 12, Dec. 15, 1945, pp. 452–456.
32 Kroll, W. J., and Schlechten, A. W., Survey of Literature on the Metallurgy of Zirconium: Bureau of Mines Inf. Circ. 7341, 1946, 50 pp.

Stocks.—Producers' and distributors' stocks of zircon (including zircon content of zirconium-titanium concentrates) were 6,316 short tons at the end of 1945 compared with 4,867 (revised) in 1944. Government-owned Office of Metals Reserve stocks were 2,581 tons of zircon and 15,829 tons of baddeleyite at the end of 1945, compared with 4,840 and 15,848 tons, respectively, at the end of 1944.

Prices.—Zirconium ore, 55 percent ZrO_2, f. o. b. Atlantic seaboard, was quoted nominally at \$65–\$75 a short ton in January to November 1945 and \$60–\$70 in December, according to E&MJ Metal and Mineral Markets. Zirconium ferro-silicon was quoted throughout the year at \$102.50–\$107.50 a long ton for 12- to 15-percent Zr content and 14–16 cents a pound for 30- to 40-percent Zr and powdered zirconium metal at \$7 a pound.

Foreign production.—Most of the world's production of zircon is from Australia, which in 1944 produced 15,680 short tons (contained in zirconium-titanium concentrates) and exported 14,156 tons.[33] Brazil exported 2,372 short tons of zirconium concentrates (almost exclusively baddeleyite) in 1944 compared with 5,424 tons in 1943 and 18,865 tons in 1942. No zircon was produced in India in 1943, but output averaged 1,600 short tons annually in 1933–42.[34]

PART III. NONMETALS

BITUMINOUS COAL AND LIGNITE [1]

By W. H. Young, R. L. Anderson, and L. H. Isaac

SUMMARY OUTLINE

SURVEY OF THE BITUMINOUS-COAL AND LIGNITE INDUSTRY IN 1945

The production of soft coal in 1945—an estimated output of 576,000,000 net tons [2]—declined 7 percent from the previous all-time high of 619,576,240 tons in 1944. Although the war was over, the shortage of coal continued, and Government controls were retained. Labor difficulties caused several interruptions to production. According to the Bureau of Labor Statistics, there were 598 strikes in soft-coal mines in 1945, with 581,000 workers involved, 5,007,000 man-days lost (an average of 8.6 days per man), and an estimated loss in production of 30,000,000 tons. Difficulty in obtaining supplies and machinery and a shortage of men also caused a loss in output.

Production.—There was practically no seasonal decline in production in 1945, due largely to the Government program urging consumers to accumulate stocks during the summer. Throughout most of the year production was over 11,000,000 tons per week, except when output was reduced because of strikes or holidays.

Consumption.—All of the major classes of consumers used less coal in 1945 than in 1944 with the exception of cement mills and bunkers in foreign trade. The total consumption in 1945 was approximately 32,000,000 tons less than in 1944. Table 5 shows the trends in consumption for the major classes of consumers.

[1] Data for 1945 are preliminary; detailed statistics with final revisions will be released later. Data for 1944 are final.

[2] Throughout this chapter, "tons" refers to net tons of 2,000 pounds, unless otherwise indicated.

Changes in stocks.—The reserve supply of bituminous coal and lignite in the hands of industrial consumers and retail coal yards decreased from 57,204,000 tons at the beginning of 1945 to 45,665,000 tons at the close. The days' supply of stocks decreased from 32 to 27. Stocks on the upper Lake docks decreased 1,110,206 tons from January 1 to December 31, 1945.

Distribution.—Shipments of bituminous coal and lignite during 1945 showed decreases in most of the channels of distribution compared with 1944. Table 10 shows trends in distribution of bituminous coal and lignite for 1939–45. Changes in the monthly volume of the more important movements are shown in figure 9.

Mechanization.—The quantity of coal loaded mechanically at underground mines in the United States continued to advance during 1945. Mechanical loading increased from 53 percent of the total underground output in 1944 to an estimated 56 percent in 1945. Sales of underground loading equipment, in terms of capacity, were 25 percent greater than in 1944.

Mechanical cleaning.—The total capacity of mechanical-cleaning equipment sold for use at bituminous-coal mines in 1945 was estimated at 10,100 tons of cleaned coal per hour, an increase of 87 percent from the previous year.

Trend of employment.—An estimate of the average number of men employed at bituminous-coal and lignite mines in 1945 indicates a drop to 370,000 men from 393,347 in 1944.

Index to capacity.—The potential output upon a 308-day basis (6-day week, full-time capacity) was 686,000,000 tons in 1944. Since it is not possible for all mines to operate 308 days per year, a more conservative figure of 280 days was suggested some years ago by the coal committee of the American Institute of Mining and Metallurgical Engineers (see Minerals Yearbook, 1935, pp. 631–632). The average output per day worked in 1944 was 2,228,691 tons, which (if applied to 280 days) gives an annual potential output of 624,000,000 tons compared with the actual total production of 619,576,240 tons. For purposes of historical comparison, a capacity of 261 days, based on the 5-day week, is also shown in figure 4 and tables 12 and 13.

Trend of fuel efficiency.—For many years prior to 1942 there was a steady trend toward increased fuel efficiency. During the period 1942–45 this trend was arrested or reversed. All industries shown in table 6 exhibited decreased fuel efficiency in 1945 compared to 1944 except electric public-utility power plants, which registered no change.

Competition of oil and gas.—Shortly after the close of the war increased competition between the fuels developed, with numerous reports of conversion from coal to fuel oil.

Electric power utilities consumed 9 percent less bituminous coal, 3 percent less fuel oil, and 9 percent less gas in 1945 than in 1944.

Class I railroads decreased their consumption of coal 5 percent in 1945, and their purchases of fuel oil were decreased from 1944 purchases by 1 percent.

The manufacture of domestic coal-burning equipment is reflected in statistics published by the Bureau of the Census. Factory sales of domestic stokers for burning bituminous coal increased from 1,714 in 1944 to 89,522 in 1945. Shipments of domestic oil burners, boiler-burner units, and furnace-burner units increased from 45,752 in 1944 to 139,611 in 1945.

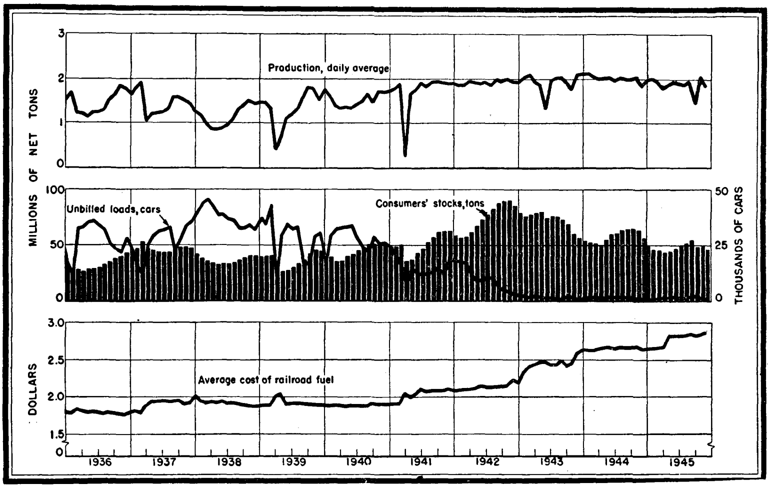

FIGURE 1.—Trends of production, stocks, and prices of bituminous coal and lignite in the United States 1936–45.

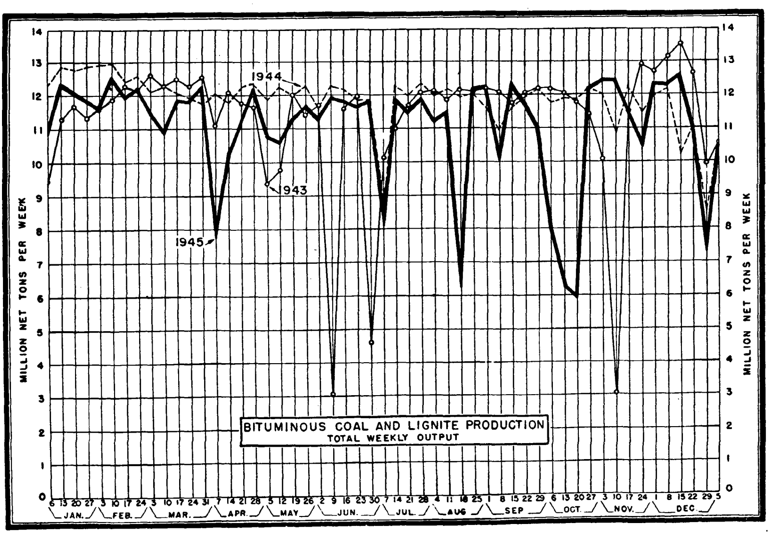

FIGURE 2.—Production of bituminous coal and lignite in the United States, by weeks, 1943–45.

SOURCES OF DATA

Bituminous-coal and lignite production statistics for 1945 are preliminary estimates based upon (1) weekly or monthly reports of railroad carloadings of coal and beehive coke by all the important carriers, (2) shipments by river as reported by the United States Army Engineers, (3) direct reports from a number of mining companies, and (4) monthly production statements compiled by a number of local operators' associations and State mine departments. In the estimates for 1945, allowance has been made for commercial truck shipments, local sales and colliery fuel, and small trucking or wagon mines producing over 1,000 tons a year.

Data for 1944 are final and are based upon detailed annual reports of production and mine operation furnished by the producers. As in previous years, all but a small percentage of the output was covered by the reports submitted. For the remaining output not directly reported—consisting chiefly of small mines—it has been possible to obtain reasonably accurate data from the records of the State mine departments, which have statutory authority to require such reports, or, in a few instances, from railroad carloadings.

Final figures of employment obtained from the annual canvass of production as shown in this report for 1944 differ slightly from the estimated total of employment based on the monthly canvass of accidents at mines accounting for approximately 70 percent of the total bituminous-coal output, as published in the chapter from Minerals Yearbook 1944 entitled "Employment and Accidents in the Mineral Industries." According to the annual canvass, the average number of men employed amounted to 393,347, whereas the monthly canvass indicated that the total average number working was 380,000. The major cause for this slight discrepancy was that the figure determined by the annual canvass represented the average number of men on the rolls per pay period while the other represented the average of men working daily.

In accordance with the practice followed by the Bureau of Mines in previous years, the statistics in this report relate to mines having an output of 1,000 tons a year or more and do not attempt to include many small mines producing less than 1,000 tons a year that sell their output by wagon or truck.

These data include, for convenience and historical comparison, the small output of anthracite and semianthracite produced outside Pennsylvania and the production of lignite.

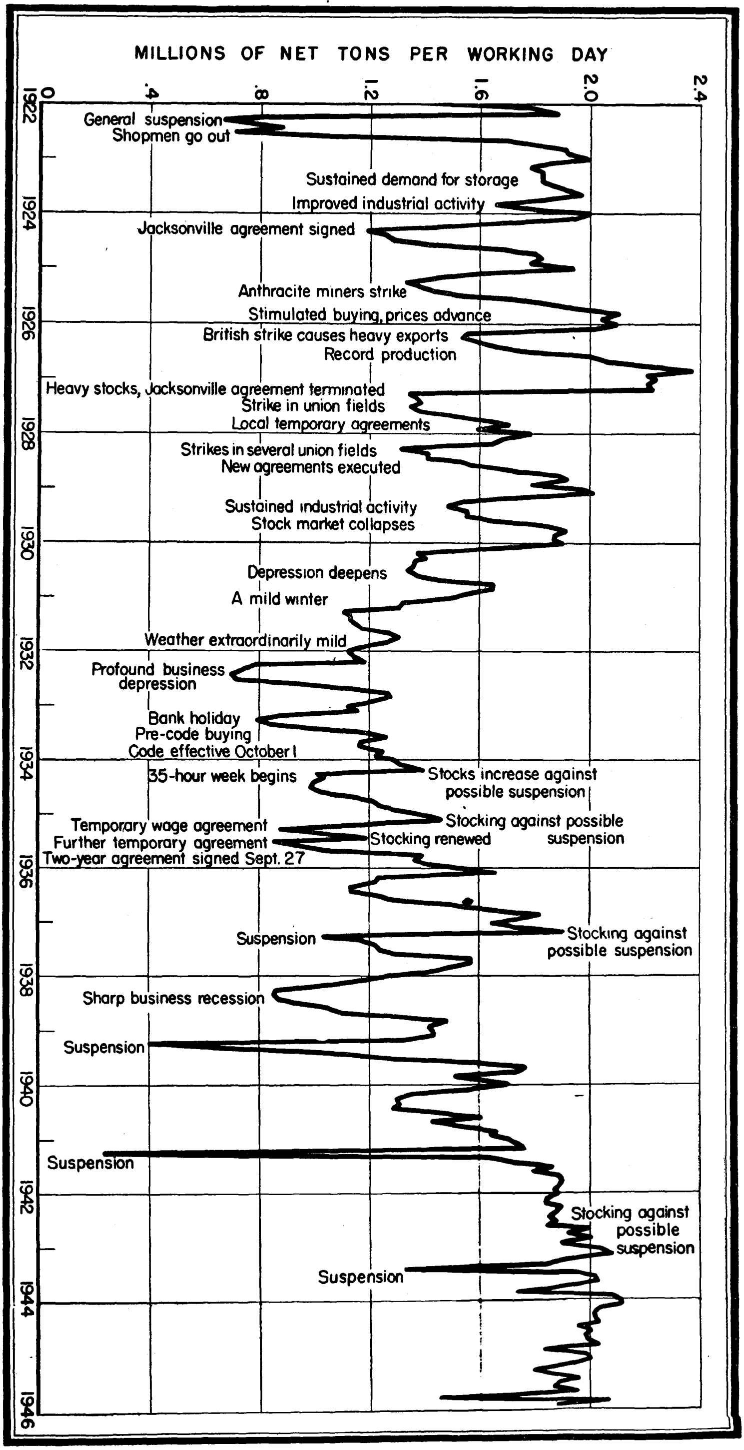

FIGURE 3.—Average production of bituminous coal and lignite in the United States per working day in each month, 1922–45.

SALIENT STATISTICS

TABLE 1.—*Salient statistics of the bituminous-coal and lignite industry in the United States, 1944–45*

[All tonnage figures represent net tons]

	1944	1945 (preliminary)	Change in 1945
			Percent
Production	619, 576, 240	576, 000, 000	−7. 0
Consumption in the United States [1]	591, 830, 000	560, 060, 000	−5. 4
Stocks at end of year:			
Industrial consumers and retail yards	57, 204, 000	45, 667, 000	−20. 2
Stocks on upper Lake docks	6, 159, 448	5, 049, 242	−18. 0
Unbilled loads, at mines or in classification yards [2]	37, 900	37, 050	−2. 2
Price indicators (average per net ton):			*Cents*
Average cost of railroad fuel purchased, f. o. b. mines [3]	$2. 65	$2. 78	+13
Average cost of coking coal at merchant byproduct ovens [4]	$5. 64	$5. 98	+34
Average retail price—35 cities [5]	$10. 27	$10. 49	+22
Average railroad freight charge per net ton [6]	$2. 21	$2. 20	−1
Underground loading machinery sold:[7]			*Percent*
Mobile loading machines (number)	282	349	+23. 8
Scrapers (number)	20	6	−70. 0
Conveyors, including those with duckbills (units)	580	738	+27. 2
"Mother" conveyors (units)	(8)	137	(8)
Surface stripping	100, 898, 376	106, 000, 000	+5. 1
Mechanically loaded underground	274, 189, 132	263, 000, 000	−4. 1
Mechanically cleaned	158, 727, 129	150, 000, 000	−5. 5
Average number of men employed at mines operating [9]	393, 347	370, 000	−5. 9
Fuel-efficiency indicators:			
Pounds of coal per kw.-hr. at electric power plants [10]	1. 30	1. 30	------------

PRODUCTION BY WEEKS AND MONTHS

The following tables summarize the preliminary statistics of weekly and monthly production of bituminous coal and lignite in 1945. The figures are estimates based upon daily and weekly statements of cars of coal and beehive coke loaded by the principal railroads and of shipments over the more important originating rivers. Allowance has been made for commercial truck shipments, local sales, and colliery fuel. The estimates given are based upon the latest information available and differ in some instances from the current figures previously published in the Weekly Coal Reports.

For method used in counting holidays, see chapter on Coal in Mineral Resources of the United States, 1930, page 631.

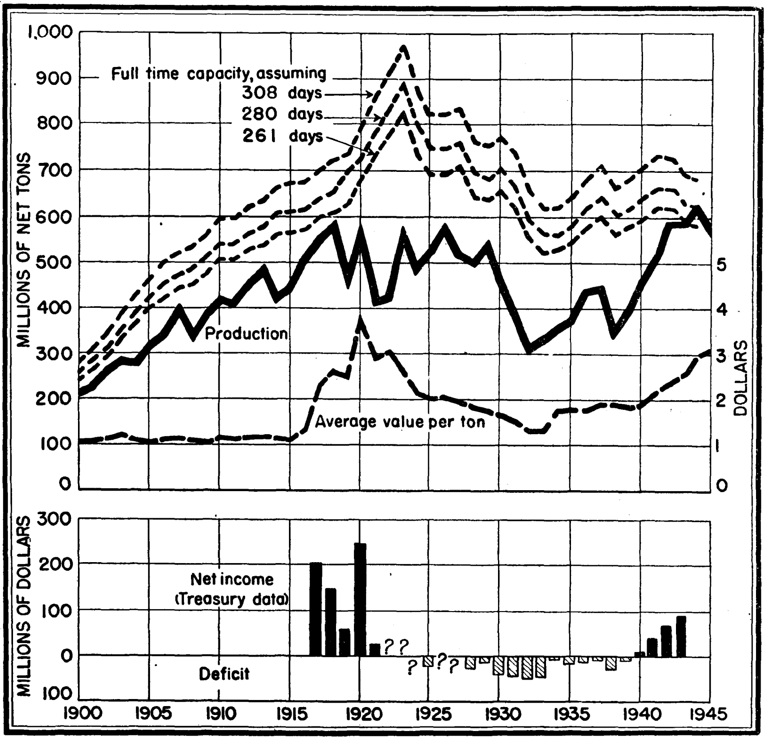

FIGURE 4.—Trends of bituminous-coal and lignite production, realization, mine capacity, and net income or deficit in the United States, 1900–1945.

TABLE 2.—*Estimated weekly production of bituminous coal and lignite in the United States in 1945*

Week ended—	Production (net tons)	Number of working days	Average production per working day (net tons)	Week ended—	Production (net tons)	Number of working days	Average production per working day (net tons)
Jan. 6	10,736,000	5.6	1,917,000	July 7	8,050,000	5	1,610,000

[1] Figures represent output and number of working days in that part of week included in calendar year shown. Total production for week of Jan. 5, 1946, was 10,255,000 tons.
[2] Average daily production for entire week and not for working days in calendar year shown.

TABLE 3.—*Estimated monthly production of bituminous coal and lignite in the United States, by States, in thousands of net tons, in 1945*

[Bituminous coal and lignite figures are preliminary estimates based on railroad carloadings and river shipments of coal and beehive coke, supplemented by direct reports from a number of mining companies, local coal operators' associations, and detailed monthly production statistics compiled by the State Mine Departments of Colorado, Illinois, Pennsylvania, Washington, and West Virginia. In making the estimates, allowance is made for commercial truck shipments, local sales, and colliery fuel, and for small trucking mines producing over 1,000 tons a year. The estimates here given differ in a few cases from the monthly figures previously published in the Weekly Coal Reports]

[1] Geological Survey and Federal Power Commission. Represents bituminous coal and lignite consumed by public-utility power plants in power generation, including a small quantity of coke amounting to approximately 100,000 tons annually.
[2] U. S. Bureau of Census.
[3] Association of American Railroads. Represents consumption of bituminous coal and lignite by class I railways for all uses, including locomotive, powerhouse, shop, and station fuel. The Interstate Commerce Commission reports that in 1944 consumption for all uses by class I line-haul railways plus purchases for class II and class III railways, plus purchases by all switching and terminal companies combined, was 136,303,060 tons of bituminous coal and lignite. Similar data from the Interstate Commerce Commission are not yet available for 1945.
[4] Includes a small amount of anthracite.
[5] Estimates based upon reports collected by the Solid Fuels Administration for War from a selected list of representative manufacturing plants and retail dealers.
[6] For the years 1939 to 1945, inclusive, the "Retail dealer deliveries" have been revised to include truck shipments from mines and "Other industrials" has been lowered accordingly. The tonnages shown for 1944 in M. M. S. 1289 under retail dealer use represent reported shipments by producers, wholesalers, sales agents, etc., via rail and water movements only.
[7] Subject to revision.
[8] Included in "Other industrials."

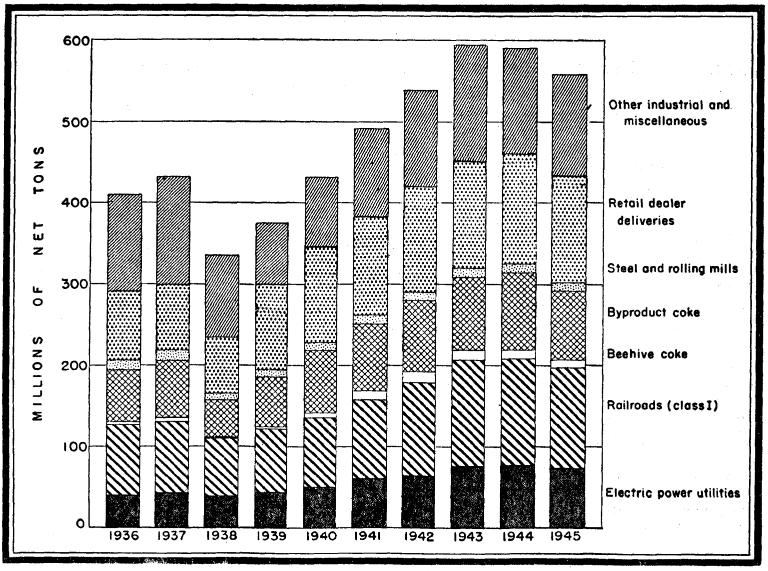

FIGURE 5.—Consumption of bituminous coal and lignite, by consumer class, with retail deliveries in the United States, 1936–45.

FUEL EFFICIENCY

TABLE 6.—*Indicators of effect of fuel economy on consumption of coal in the United States per unit of performance since the World War of 1914–18*

	Pounds	Reduction from base period (percent)
Steam railroads:		
Pounds per 1,000 gross ton-miles freight service:		
Average:		
1919–20	170	
1944	114	32.9
1945	116	31.8
Pounds per passenger-train car-mile:		
Average:		
1919–20	18.5	
1944	14.8	20.0
1945	14.9	19.5
Electric public-utility power plants:		
Pounds per kilowatt-hour:		
1919	3.2	
1944	1.3	59.4
1945	1.3	59.4
Iron and steel—pounds coking coal per net ton of pig: [1]		
1918	3,194	
1944	2,629	17.7
1945	2,635	17.5
Coke manufacture: Savings of heat values through recovery of gas, tar, light oils, and breeze by extension of byproduct in place of beehive coking, 1913–14, expressed as percent of coal used for all coke in 1945 [2]		19.7

[1] Includes only savings through higher yields of merchantable coke per ton of coal charged and lower consumption of coke per ton of iron. Excludes economies through recovery of byproducts, which are covered in next item.

[2] These byproducts are used in part for boiler fuel, in part for metallurgical purposes, in part for domestic heating and coking, and to a small extent for automotive fuel.

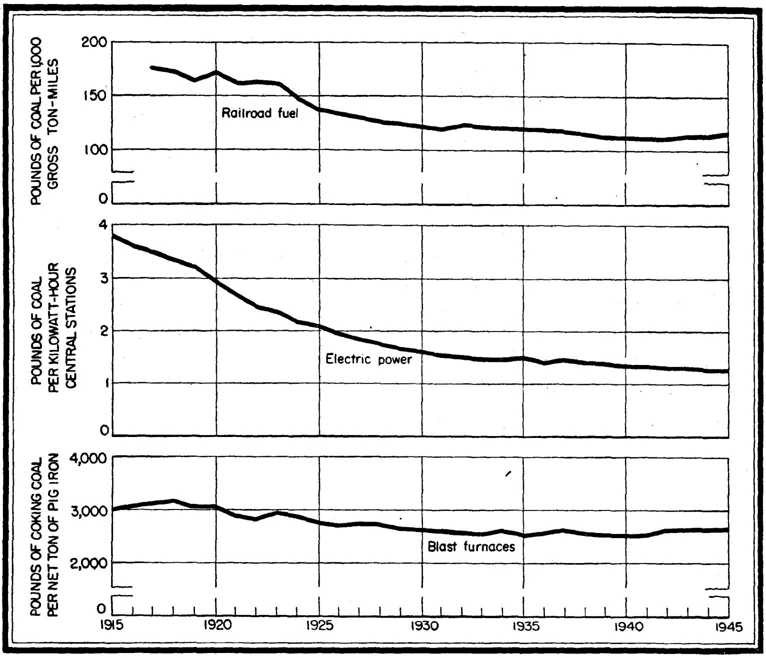

FIGURE 6.—Trends in fuel efficiency in the United States, 1915–45.

RELATIVE RATE OF GROWTH OF COAL, OIL, AND WATER POWER, 1889–1945

The total supply of available energy in the form of coal, oil, natural gas, and water power in 1945 was 35,283 trillion B. t. u.—a 3.1 percent decrease from 1944 (see fig. 7).

The figures are expressed in British thermal units because some common denominator is necessary for such unlike quantities as tons of coal, barrels of oil, and cubic feet of gas. Table 7 summarizes the equivalent of each of the fuels in trillions of British thermal units. Water power is represented by the equivalent fuel required to perform the same work. The table covers the years since 1936. Details for 1889 to 1935 are given in Minerals Yearbook, 1937, page 807.

In converting water power to its fuel equivalent, two alternative assumptions have been made. The first, as in previous issues of these tables, assumes a *constant* fuel equivalent of 4.02 pounds of coal for each kilowatt-hour of water power produced throughout the entire period from 1889 to 1945. This factor was selected because it represents, in round numbers, the average efficiency of all central stations generating steam-electric power in 1913, the base period used. The usefulness of the *constant* factor lies in showing the rate at which water power is being developed. It permits direct comparison between the relative increase (in kilowatt-hours of water power) and the corresponding increase or decrease (in tons of coal, barrels of oil, or cubic feet of gas produced). On the other hand, the *constant* factor makes no allowance for the fact that coal and other fuels produced today are used more efficiently than formerly.

To show the influence of improving fuel efficiency, a second computation of the energy equivalent of water power has therefore been made. This assumes a *prevailing* fuel equivalent, diminishing year by year, which represents the average performance of all fuel-burning central electric stations for the year in question. This average has declined from about 7.05 pounds of coal per kilowatt-hour in 1899 to 1.30 pounds in 1945. (The *prevailing* factor is thus much above the *constant* factor in 1899 and much below it in 1945.) The *prevailing* fuel equivalent indicates more nearly the quantity of fuel that would have been needed in any one year to generate the same power in a steam-electric station. It should be noted, however, that the ultimate uses to which the water power generated is put often displace fuel burned much less efficiently than in central stations and that in any instance no other important branch of fuel consumption has made advances in fuel efficiency approaching that of the central stations.

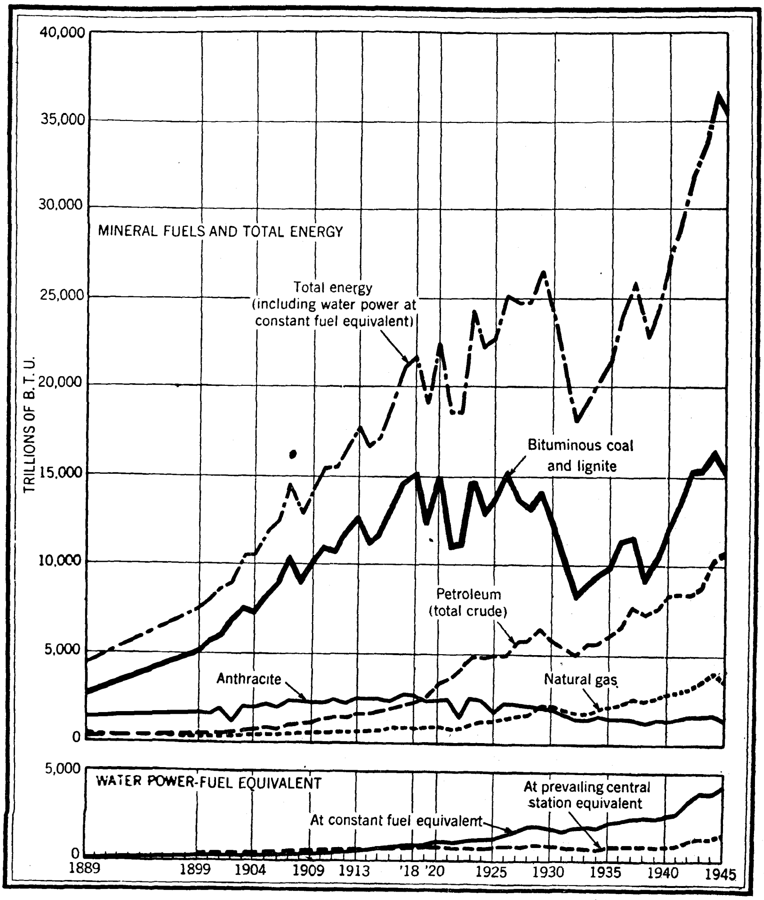

FIGURE 7.—Annual supply of energy from mineral fuels and water power in the United States, 1889–1945.

As these tables attempt to determine the total energy from all fuels and from water power, the ideal factor for converting water power into fuel equivalent would be the average efficiency of all forms of fuel consumption in each year. No basis for determining such an all-embracing average exists at present, but enough is known to make certain that it would show much less reduction from 1899 to 1945 than do the central stations. For the present, a just comparison of the changing contributions of water power and of fuel to the national energy supply would lie somewhere between the results shown by the *constant* equivalent and the *prevailing* central-station equivalent in these tables.

As in earlier issues of these tables, the figures for oil and natural gas represent the entire production of crude petroleum and of gas. Most of this production does not come into direct competition with coal. Much of the supply of both oil and gas is used in regions of the country, such as California and portions of the Southwest, where coal is available only at unusually high cost because of heavy transport charges. Nearly half of the natural gas is used in the field for drilling or operating oil and gas wells and pipe lines or for the manufacture of carbon black. More than half the oil is used in the form of gasoline, kerosine, and lubricants, for which purposes coal cannot well compete, except at very much higher levels of oil prices. Even these refined products, however, involve a certain measure of indirect competition with coal, for the energy market of the country is becoming more fluid and competitive, and a demand that cannot be met by one source of supply tends to fall back on the others.

The subject of interfuel competition is exceedingly complex, and an elaborate analysis and the accumulation of data not now available would be required to determine even approximately how much of any one fuel actually has been displaced either by other fuels or

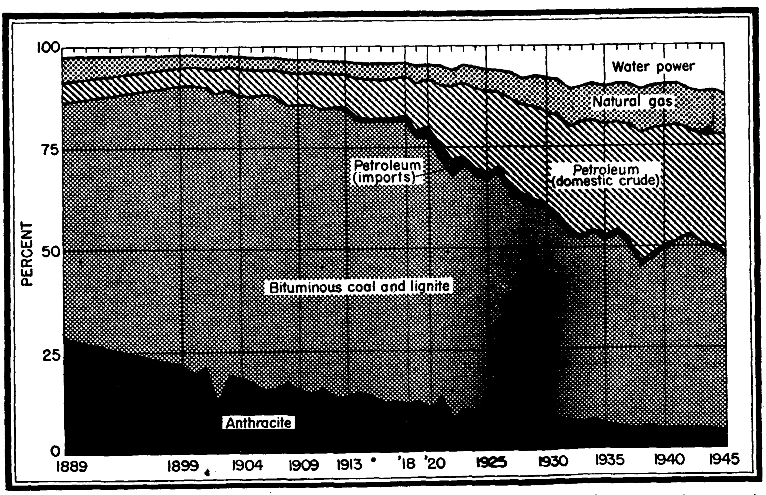

FIGURE 8.—Percentage of total B. t. u. equivalent contributed by the several sources of energy in the United States, counting water power at constant fuel equivalent, 1889–1945. If water power is counted at the prevailing fuel equivalent of central stations in each year, its proportion is 3.2 percent in 1899 and 4.3 percent in 1945, and the proportions of the other sources of energy are affected accordingly.

by water power. The present tables do not permit determination of such displacement; their purpose is rather to measure the long-time trends in the total demand for energy.

TABLE 7.—*Annual supply of energy from mineral fuels and water power in the United States, 1936–45,[1] in trillions of B. t. u.[2]*

Year	Pennsylvania anthracite	Bituminous coal and lignite	Total coal	Petroleum (total crude, including that refined)		Natural gas (total production)	Total petroleum and natural gas	Total mineral fuels	Water power (fuel equivalent)		Grand total energy	
				Domestic production	Imports				At constant fuel equivalent [3]	At prevailing central station equivalent [4]	Water power at constant fuel equivalent	Water power at prevailing central station equivalent
1936	1,485	11,504	12,989	6,598	194	2,330	9,122	22,111	2,256	812	24,367	22,923

1945 [5]	1,485	15,091	16,576	10,267	445	3,662	14,374	30,950	4,333	1,399	35,283	32,349

[1] Comparable data for earlier years in Minerals Yearbook, 1937, p. 807.

[2] The unit heat values employed are: Anthracite, 13,600 B. t. u. per pound; bituminous coal and lignite, 13,100 B. t. u. per pound; petroleum, 6,000,000 B. t. u. per barrel; natural gas, 1,075 B. t. u. per cubic foot. Water power includes installations owned by manufacturing plants and mines, as well as Government and privately owned public utilities. The fuel equivalent of water power is calculated from the kilowatt-hours of power produced wherever available, as is true of all public-utility plants since 1919. Otherwise, the fuel equivalent is calculated from the reported horsepower of installed water wheels, assuming a capacity factor of 20 percent for manufacturers and mines for the years 1936 to 1943.

[3] Assuming 4.02 pounds per kilowatt-hour, which is the average of central electric station practice in 1913, the base period used.

[4] Assuming the average central-station practice for each of the years for which data are available, which declined from about 7.05 pounds per kilowatt-hour in 1899 to 1.30 pounds in 1945.

[5] Subject to revision.

TABLE 8.—*Index numbers for relative rate of growth of coal, oil, and water power in the United States, 1936–45 [1]*

[Figures expressed as percentage of 1918 rate]

Year	Pennsylvania anthracite	Bituminous coal and lignite	Total coal	Petroleum (total crude)		Natural gas (total production)	Total petroleum and natural gas	Total mineral fuels	Water power (at constant fuel equivalent)	Grand total	
				Domestic production	Imports					With water power at constant fuel equivalent	With water power at prevailing central station equivalent
1936	55	76	73	309	86	301	291	105	270	112	106
1937	52	77	73	359	73	334	332	112	292	119	112
1938	47	60	58	341	70	318	316	97	295	104	98
1939	52	68	66	355	88	344	333	106	289	113	106
1940	52	80	75	380	113	369	358	118	313	125	118
1941	57	89	84	394	135	390	374	127	335	135	128
1942	61	101	95	390	33	423	372	136	416	147	137
1943	61	102	96	423	37	474	408	142	478	155	144
1944 [2]	64	107	101	471	119	524	459	154	481	167	155
1945 [2]	55	99	93	481	197	473	458	147	518	162	149

FINAL BITUMINOUS-COAL AND LIGNITE STATISTICS FOR 1944

Tables 12 to 53 give the final detailed statistics of bituminous-coal and lignite-mine operations in 1944. The subjects covered include production, number and size of mines, employment, value, mechanization, exports, and world production.

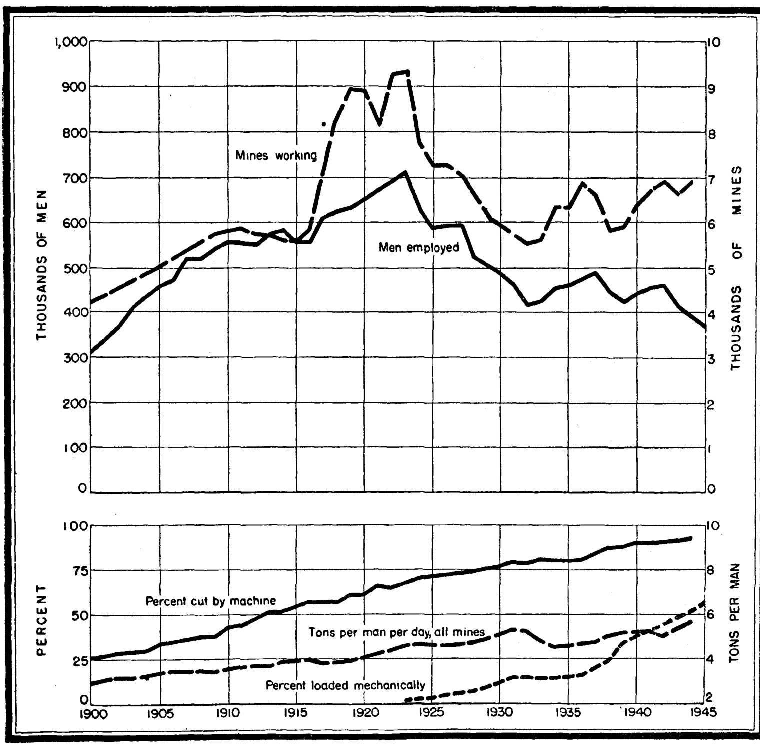

FIGURE 10.—Trends of employment, mechanization, and output per man at bituminous-coal and lignite mines in the United States, 1900–1945.

SALIENT TRENDS

TABLE 12.—*Salient trends in bituminous-coal and lignite-mining industry in the United States, 1937–44.*

	1937	1938	1939	1940	1941	1942	1943	1944
Production:								
Loaded at mine for shipment by rail ..... net tons	[1] 399, 237, 575	295, 336, 027	331, 189, 620	380, 387, 674	425, 184, 319	482, 814, 042	495, 863, 581	527, 135, 489
Loaded at mine for shipment by water ..... do	(1)	16, 902, 969	22, 229, 364	29, 493, 058	30, 240, 489	34, 018, 025	30, 188, 093	31, 518, 334
Shipped by truck or wagon ..... do	[2] 37, 762, 612	25, 592, 058	29, 533, 824	35, 540, 476	40, 055, 638	45, 154, 432	42, 432, 667	40, 123, 023
Taken by locomotive tenders at tipple ..... do	(2)	606, 857	826, 556	939, 058	1, 099, 582	920, 213	779, 154	807, 679
Shipped by conveyor or tram to point of consumption ..... do	(2)	4, 221, 671	4, 317, 465	5, 887, 994	6, 067, 697	7, 121, 116	7, 476, 717	7, 206, 392
Used by mine employees ..... do	(2)	2, 032, 289	1, 901, 408	2, 035, 201	1, 872, 026	2, 180, 077	2, 549, 775	2, 545, 343
Used at mines for power and heat ..... do	3, 052, 095	2, 493, 017	2, 565, 276	2, 442, 989	2, 488, 950	2, 708, 312	2, 701, 828	2, 713, 073
Made into beehive coke at mines ..... do	4, 884, 054	1, 359, 876	2, 089, 475	4, 045, 050	7, 140, 544	7, 776, 720	8, 185, 254	7, 526, 907
Total production ..... do	[3] 445, 531, 449	348, 544, 764	[4] 394, 855, 325	460, 771, 500	514, 149, 245	582, 692, 937	590, 177, 069	619, 576, 240
Number of active mines of commercial size:								
Class 1 (200,000 tons or more) ..... number	661	526	577	636	730	811	855	828
Class 2 (100,000 to 200,000 tons) ..... do	469	402	404	432	437	484	464	559
Class 3 (50,000 to 100,000 tons) ..... do	448	415	387	371	402	445	481	540
Class 4 (10,000 to 50,000 tons) ..... do	1, 117	1, 042	1, 065	1, 157	1, 305	1, 492	1, 544	1, 776
Class 5 (1,000 to 10,000 tons) ..... do	3, 853	3, 392	3, 387	3, 728	3, 948	3, 740	3, 276	3, 225
Total number over 1,000 tons ..... do	6, 548	5, 777	5, 820	6, 324	6, 822	6, 972	6, 620	6, 928
Average number of men employed at mines active:								
Underground ..... men	(5)	370, 004	353, 476	365, 013	376, 765	374, 654	326, 763	301, 461
Surface:								
In strip pits ..... do	(5)	7, 877	8, 791	8, 983	10, 861	12, 893	16, 643	21, 035
All others ..... do	(5)	63, 452	59, 521	65, 079	69, 355	74, 444	72, 601	70, 851

[1] In 1937, coal loaded at mine for shipment by water is included with "Loaded at mine for shipment by rail."

[2] Coal "Taken by locomotive tenders at tipple," "Shipped by conveyor or tram to point of consumption," and "Used by mine employees" included with "Shipped by truck or wagon."

[3] The total production differs from sum of items shown by amount of changes in inventory and tonnage not accounted for in distribution analysis. This amounts to 595,113 net tons.

[4] Includes 202,337 tons of coal reported as net changes in stocks at mines, Jan. 1, 1939, to Jan. 1, 1940.

[5] Data not available.

[6] Includes central washeries operated by consumers.

TABLE 13.—*Growth of the bituminous-coal and lignite-mining industry in the United States, 1890–1944*

Year	Production (net tons)	Value		Men employed	Number of mines	Calculated capacity (millions of net tons)—		
		Total [1]	Average per ton [1]			At 308 days	At 280 days	At 261 days
1890	111,302,322	$110,420,801	$0.99	192,204	(2)	152	137	129

1942	246	1	7	5.12	1,261	89.7	45.2	24.4	11.5
1943	264	(3)	(3)	5.38	1,419	90.3	48.9	24.7	13.5
1944	278	(3)	(3)	5.67	1,575	90.5	52.9	25.6	16.3

[1] Percentages for years 1890 to 1913, inclusive, are of total production, as separation of strip-mine and underground production is not available for those years.

[2] For years 1906 to 1926, inclusive, percentages are exclusive of coal cleaned at cental washeries operated by consumers; after 1926, when data became available on tonnage cleaned by consumer-operated plants, percentages include total tons cleaned at mines and at consumer-operated washeries.

[3] Data not available.

[4] One-half day or less.

TABLE 14.—*Coal produced in the United States, by States, 1934–44, with production of maximum year and cumulative production from earliest record to end of 1944, in thousands of net tons*

State	Maximum production		Production by years											Total production from earliest record to end of 1944
	Year	Quantity	1934	1935	1936	1937	1938	1939	1940	1941	1942	1943	1944

SUMMARY BY STATES AND DISTRICTS

TABLE 15.—*Number of mines, production, value, employment, days active, man-days, and output per man day at bituminous-coal and lignite mines in the United States, by States, in 1944*

[Exclusive of mines producing less than 1,000 tons]

State	Number of active mines	Disposition of coal produced (net tons)								Average value per ton [3]	Average number of employees				Average number of days mines were active	Number of man-days worked	Average tons per man per day
		Loaded at mine directly into railroad cars or river barges	Hauled by truck to railroad siding for shipment by rail and to waterway for shipment by water [1]	Shipped by truck or wagon (excluding coal used by mine employees)	Taken by locomotive tenders at tipple	Shipped by conveyor or tram to point of consumption	Used by mine employees	Used at mines for power and heat and made into beehive coke at mines [2]	Total quantity		Underground	Surface: In strip pits	Surface: All other	Total			
Alabama	352	15,635,177	1,494,621	952,186	75,964	409,120	95,221	89,876	18,752,165	$3.97	17,399	689	3,605	21,693	285	6,181,211	3.03

[1] Includes coal hauled by truck to waterway for shipment by water in following States in 1944: Illinois, 111,552 tons; Ohio, 33,398; Pennsylvania, 157,308; Tennessee, 143,264; and West Virginia, 744,689—a grand total of 1,190,211 tons.

[2] Includes coal made into beehive coke at mines in following States in 1944: Colorado, 149,908 tons; Kentucky, 92,764; Pennsylvania, 6,346,659; Utah, 15,0 2; Virginia, 397,105; and West Virginia, 525,389—a grand total of 7,526,907 tons.

[3] Value received or charged for coal f. o. b. mine, including selling cost. (Includes a value for coal not sold but used by producer, such as mine fuel and coal coked [not coke] as estimated by producer, at average prices that might have been received if such coal had been sold commercially.)

[4] As it is necessary to conceal certain items in the lignite break-down of disposition of coal, the figures are shown here in column where greater part of concealed tonnage is included.

TABLE 16.—*Number of mines, production, value, employment, days active, man-days, and output per man per day at bituminous-coal and lignite mines in the United States, by districts, in 1944*

[See Mineral Market Report 1359 for additional data by districts. Districts as defined in the Bituminous Coal Act of 1937 and modifications thereto. Exclusive of mines producing less than 1,000 tons]

Minimum price area and producing district	Number of active mines	Disposition of coal produced (net tons): Loaded at mine directly into railroad cars or river barges	Hauled by truck to railroad siding for shipment by rail and to waterway for shipment by water [1]	Shipped by truck or wagon (excluding coal used by mine employees)	Taken by locomotive tenders at tipple	Shipped by conveyor or tram to point of consumption	Used by mine employees	Used at mines for power and heat and made into beehive coke at mines [2]	Total quantity	Average value per ton [3]	Average number of employees: Underground	Surface: In strip pits	Surface: All others	Total	Average number of days mines were active	Number of man-days worked	Average tons per man per day

[1] Includes coal hauled by truck to waterway for shipment by water in following districts in 1944: District 2, 157,308 tons; district 3, 488,679; district 4, 33,398; district 6, 93,672 district 8, 162,338; district 10, 111,552; and district 13, 143,264—a grand total of 1,190,211 tons.

[2] Includes coal made into beehive coke at mines in following districts in 1944: District 1, 332,073 tons; district 2, 6,014,586; district 3, 280,542; district 7, 66,391; district 8, 668,325; district 17, 149,908; and district 20, 15,082—a grand total of 7,526,907 tons.

[3] Value received or charged for coal f. o. b. mine, including selling cost. (Includes a value for coal not sold but used by producer, such as mine fuel and coal coked [not coke] as estimated by producer at average prices that might have been received if such coal had been sold commercially.)

[4] Includes Maryland and Grant, Mineral, and Tucker Counties, West Virginia.

[5] As it is necessary to conceal certain items in the lignite break-down of disposition of coal, the figures are shown here in column where greater part of concealed tonnage is included.

[6] Includes Colfax County, New Mexico.

[7] Includes Arizona and California, but excludes Colfax County, N. Mex. No production was reported for California.

[8] Includes Idaho. No production was reported for Idaho.

[9] Includes Oregon.

[10] For purposes of historical comparison and statistical convenience, figures include output of lignite and of anthracite and semianthracite outside of Pennsylvania.

PRODUCTION BY WEEKS AND MONTHS

TABLE 17.—*Bituminous-coal and lignite production (final figures) in the United States in 1944, with estimates by weeks*

8	8,668,000	5	1,734,000				

[1] Figures represent output and number of working days in that part of week included in calendar year shown. Total production for week ended Jan. 1, 1944, was 10,515,000 net tons.
[2] Average daily production for entire week and not for working days in calendar year shown.

TABLE 18.—*Coal production in the United States, in 1944, by States (final figures), with estimates by months, in thousands of net tons*

[Totals for year are based on final complete returns from all operators known to have produced more than 1,000 tons a year. Apportionment of known yearly total among the 12 months is based upon best information available; in some States upon direct tonnage reports by operators to State mine departments; in most cases upon current records of railway carloadings and waterway shipments]

AVERAGE VALUE

Before the Bituminous Coal Act of 1937 was passed, the most valuable single index of the trend of prices at the mines was the "average value per ton, f.o.b. mines," as given in the familiar annual coal reports of the Bureau of Mines, United States Department of the Interior. This series was referred to in Bureau of Mines reports as representing "bituminous coal," and it covered all coal (other than Pennsylvania anthracite) produced in the United States. It represented the bituminous-coal industry as the term ordinarily was used in the trade and included the lignite of the Dakotas, Texas, and Montana, as well as any small tonnages of hard coal produced outside of Pennsylvania.

With the passage of the Coal Act, the Bureau of Mines relinquished the collection of statistics relating to bituminous coal, effective June 30, 1937, though continuing to compile data regarding lignite and Pennsylvania anthracite. Effective the same date, the Coal Commission became responsible for the compilation of data on bituminous coal, though not attempting to collect data regarding lignite, which was specifically exempted by the act. The records of the Commission (later the Bituminous Coal Division, United States Department of the Interior) relate to all coal other than Pennsylvania anthracite, Virginia semianthracite, and lignite.

To permit comparison of the old and new series, therefore, it is necessary to separate the lignites from the bituminous coals, though the combined average for the two is continued in a form as nearly comparable as possible to the old series (see table 20).

TABLE 20.—*Trend of average value in the United States of bituminous coal and lignite per ton, f. o. b. mines, 1929–44*

Year	Bituminous coal (subject to regulation under 1937 act) [1]	Lignite [2]	Total
Average value per ton less selling cost:			
1929	$1.782	$1.548	$1.781
1930	1.702	1.556	1.701
1931	1.542	1.410	1.541
1932	1.313	1.313	1.313
1933	1.337	1.188	1.336
1934	1.751	1.387	1.749
1935	1.772	1.120	1.767
1936	1.761	1.061	1.756
Average gross realization, selling cost not deducted:			
1936	1.831	[3] 1.061	1.826
1937	1.946	[3] 1.080	1.939
1938	1.955	[3] 1.071	1.947
1939 [4]	1.850	1.158	1.845
1940	1.913	[3] 1.156	1.908
1941	2.194	1.237	2.189
1942	2.363	1.364	2.358
1943	2.691	1.490	2.685
1944	2.929	1.487	2.923

[1] Includes all coal produced other than Pennsylvania anthracite and lignite included in second column.
[2] North Dakota, South Dakota, and lignite counties of Montana and Texas.
[3] Figures for 1936–38 and 1940 exclude selling cost as before.
[4] Producers were asked to exclude selling cost in reporting value, but a number of them included such costs.

A more important change in the two series relates to the treatment of selling expenses. The old Bureau of Mines series of "value at the mines" excluded the selling cost. Reporting operators were asked to state the "Amount received at the mines f. o. b. cars less the selling expense." No details were asked regarding the items included in the value, and no systematic effort was made to follow up the exclusion of selling expenses. It was realized at the time that some producers might find it impractical to exclude selling costs and that some part of the selling expenses of the industry might be included in the results. Nevertheless, the reports were checked for consistency from year to year, the questions were retained in the same form without change, and the results are believed to have been comparable from one year to the next. The new series of the Coal Commission represents the total or gross realization on all coal produced and specifically includes the selling cost.

The two sets of data may not be precisely comparable with respect to coal produced but not sold on the commercial market. In the Bureau of Mines series reporting operators were instructed that the "value of coal not sold but used by producer, also mine fuel and coal made into coke, should be estimated at average prices that might have been received." The instructions of the Coal Commission regarding such items were in effect similar, though given in greater detail.

A comparison of the two series is possible for 1936. In that year the average value per ton on the old (Bureau of Mines) basis amounted to $1.761 per ton for bituminous coal, excluding lignite. The average gross realization, according to data collected by the Coal Commission, was $1.831 per ton. The difference amounts to $0.07 per ton—an amount somewhat less than the average selling expenditure computed per ton of all coal produced, as reported to the Coal Commission. The comparison confirms previous indications that the great majority of operators reporting in earlier years had followed instructions and omitted selling expenses in computing the average value but that some of them had included the selling expense. The change in method of reporting should be kept in mind in comparing the two sets of data. As the reports to the Commission were submitted on a detailed accounting return and made under oath, they are to be accepted. The returns of earlier years, upon a voluntary basis and not in all instances uniform as to treatment of selling costs, seems to have been thoroughly comparable from one year to the next and afford the best available index to the rise and fall of the mine prices received by operators down to 1936.

LABOR STATISTICS

Men employed.—An average of 393,347 men was employed at bituminous-coal mines in 1944, a 5.5 percent decrease from the total of 416,007 for 1943 (see fig. 10).

The method used here in calculating employment gives an accurate measure of the working force in the coal industry, but it does not consider the time lost by men on the rolls through intermittent operations. To measure the influence of intermittency upon employment the factor of mine activity as indicated by the average number of days of plant operation was recorded separately. The average number of men on the rolls when the mines were in operation was then used, in conjunction with the average number of days of operation, as a measure of the total volume of employment in the industry.

Days operated.—The average number of days of operation at bituminous-coal mines in 1944 was 278. This represents an increase over the average of 264 days for 1943. All statistics on days of mine operation included in this report are weighted averages, in which the operating time of each mine has been weighted by the number of its employees. Several coal-mining States publish series on the number of days worked that are simple averages of the figures for each reporting mine, regardless of size. As these unweighted averages are likely to be unduly depressed by small mines, which generally operate fewer days than the larger ones, they tend to understate the working time of a typical mine employee.

Man-days of labor.—Man-days have been computed by multiplying the number of workers employed by the number of operating days. Although these computations were made for each individual mine, the combined total is necessarily only an approximation.

Data for 1944 indicate that bituminous-coal-mine employees performed 109,273,540 man-days of labor during the year. Table 15 gives a summary record of men employed, days operated, and output per man per day at bituminous-coal mines, by States, in 1944. Details by counties for 1944 are shown in table 41.

Length of working days.—Table 21 summarizes the replies of mine operators to the question, "Number of hours operated per shift."

TABLE 21.—*Number of bituminous-coal and lignite mines in the United States having established working shift of certain length and number of men employed therein in 1944*

[1] Includes mines where the day was more than 9 or less than 7 hours or was irregular.

The established working day does not of itself measure the length of time that men actually work or the time that they are underground, because of the possibility of overtime, because the mine may sometimes shut down before the full day is over, because the miner may go home before the mine stops, and because he spends a considerable time going to and from his place of work underground. These figures represent the operator's statement of the nominal operating day for the mine. They do not purport to represent the time actually worked by the men. On the one hand, they make no allowance for tonnage or piece workers who leave early; on the other hand, they make no allowance for tonnage men who continue at work after the mine as a whole is shut down or who go into the mine to work on days when the tipple is idle.

It was found that 85 percent of the men employed were in 8-hour mines and that the weighted average working shift was 7.9 hours.

BITUMINOUS COAL AND LIGNITE LOADED FOR SHIPMENT BY INDIVIDUAL RAILROADS AND WATERWAYS

Shipped by conveyor or tram to point of consumption.		7,206,392	7,206,392
Coal used by employees		2,545,343	2,545,343
Used at mine for power and heat		2,713,073	2,713,073
Made into beehive coke at mine		7,526,907	7,526,907
Total production		619,576,240	619,576,240

[1] Includes coal loaded at mine directly into railroad cars or river barges, hauled by truck to railroad siding for shipment by rail, and hauled by truck to waterway for shipment by water. In general, figures show quantity of bituminous coal and lignite originated for each railroad and waterway as reported by mine operators. It must be noted that in 1 year operator may report coal loaded on subsidiary railroad and in another year same operator may report coal loaded on parent railroad system.

[2] Tonnage from North Dakota lignite mines shipping on Minneapolis, St. Paul, & Sault Ste. Marie Railway included with that shipped on Great Northern Railway.

[3] Tonnage from Texas lignite mines shipping on Rockdale, Sandow & Southern Railroad included with that shipped on Missouri-Kansas-Texas Railroad.

MECHANICAL LOADING

Mechanical loading of coal in underground bituminous coal and lignite mines continued to advance during 1944, with a total of 274,189,132 tons loaded, as compared with 249,805,214 tons in 1943. During 1928, the first year complete data on mechanical loading were available, less than 5 percent of the underground production was mechanically loaded; this percentage has increased rapidly and 1944 marks the first year that more than one-half of the underground output was loaded mechanically.

Mechanical loading equipment used in underground coal mines is divided into two types: devices that practically eliminate hand shoveling and those that greatly reduce the labor involved in hand shoveling. Devices in the first category include mobile loaders, scrapers, and conveyors equipped with duckbills or other self-loading heads and are designated as "machines." Those in the second category include all types of hand loaded face conveyors and pit-car loaders and are designated as "conveyors."

Sales of mechanical loading equipment in 1945.—The estimated capacity of mechanical loading equipment sold for underground use in all coal mines was 25 percent more in 1945 than in 1944. Table 28 shows the sales reported, by type of equipment, and the number of manufacturers reporting for 1938–45.

Sales of conveyors to bituminous coal and lignite mines in 1945 totaled 738 units. The figures for 1942–45 exclude duckbills, which were included in all previous years. Therefore, these sales are not comparable with those for 1941 or earlier years. By excluding sales of duckbills, some of the overlapping sales of conveyors were eliminated. However, it appears that a certain amount of overlapping remains; for instance, in 1943 there were 4,417 conveyors (hand-loaded and those equipped with duckbills) in active use in bituminous-coal and lignite mines, as reported by mine operators. By adding 1943 conveyor sales of 798 units, 5,215 units appeared available for use in 1944, whereas the actual number reported in use by mine operators was 4,567, or 648 less. This difference represents idle or worn-out and obsolete equipment, duplications in reporting sales, and a small number of conveyors used in conjunction with mobile loaders.

The number of mobile loaders, scrapers, and conveyors shipped into the various States and groups of States in 1945 and the number of units in actual use in 1944 are shown in table 30.

Statistics on mechanical loading in bituminous-coal and lignite mines in 1944.—During 1944 the approximate percentage of the tonnage loaded by each type of equipment was as follows: Mobile loaders, 74; hand-loaded conveyors, 16; duckbills, 8; pit-car loaders, 1; and scrapers, 1.

Mobile loaders handle more coal than all the other types of mechanical loading devices combined. Where coal is loaded by mobile loaders it is most commonly loaded directly into mine cars, but some tonnage is loaded into shuttle cars or onto conveyors. During 1944, 77 percent of the bituminous coal and lignite handled by mobile loaders was loaded directly into mine cars, 19 percent into shuttle cars, and 4 percent onto conveyors.

During 1944 in underground bituminous coal and lignite mines 2,737 mobile loaders handled 202,875,221 net tons, an average of 74,123 tons per mobile loader per year; scrapers averaged 15,419; pit-car loaders, 7,615; duckbills, 17,403; and hand-loaded face conveyors, 13,898, per year per unit for the same period (see tables 29 and 31).

Mechanical loading by States.—West Virginia has been the leading producer of mechanically loaded coal since 1939. During 1944 West Virginia produced 79,972,476 tons of mechanically loaded coal, followed by Illinois with 50,865,235, Pennsylvania with 48,535,374, Kentucky with 23,428,629, and Ohio with 15,124,377 tons. These five States produced 80 percent of the total output of underground mechanically loaded bituminous coal in the United States in 1944.

Detailed data by States on number of mines and machines and 1944 production of mechanically loaded coal compared with total production at mines using mechanical loading devices are given in table 32. Comparative changes in underground mechanical loading in 1943–44, by States, are shown in table 33.

Table 34 shows bituminous coal and lignite mined by stripping compared with underground hand-loaded and machine-loaded tonnage, by States, for 1944.

TABLE 28.—*Units of mechanical loading equipment sold to bituminous-coal and lignite mines for underground use in the United States, as reported by manufacturers, 1938–45.*

MECHANICAL CLEANING

In 1927, the first year complete data were collected on mechanical cleaning of bituminous coal, there were 24,041,463, and 3,650,584 net tons cleaned by wet and pneumatic methods, respectively, a total of 27,692,047 net tons of clean coal or 5 percent of the total production. This percentage has increased each year and in 1944 it amounted to more than 25 percent or 158,727,129 net tons of clean coal.

Tables 35, 36, 39, and 40 include mechanical cleaning data on all coal mined in the United States except Pennsylvania anthracite. Tables 37 and 38 are upon the same basis but do not include consumer-operated plants. There are no mechanical cleaning plants at lignite mines.

Consumer-operated plants include plants owned by steel companies which receive coal from various mines (but usually from affiliated companies), clean it, and then consume it directly at the plant.

In the following tables coal cleaned at consumer-operated plants was tabulated in State or district where the plant was located. All coal cleaned at plants other than consumer-operated plants was included in State or district from which the coal was mined.

Table 35 compares bituminous coal cleaned in 1941–44, inclusive, by method of cleaning. Wet methods increased and pneumatic methods decreased in 1944 from 1943.

Mechanical cleaning by types of equipment.—The tonnage of bituminous coal cleaned by wet-washing methods reached 138,662,689 net tons in 1944—an increase of 11.5 percent over 1943. The quantity cleaned by pneumatic methods was 20,064,440 net tons—a decrease of 5.4 percent.

Table 36 compares the number of cleaning plants and the net tons of cleaned coal, by types of equipment, for 1943 and 1944. During 1944, 410 wet-washing and 82 pneumatic cleaning plants were in operation. Fifty-three tipples used both wet and dry methods at the same plants; deducting these duplications gives a net total of 439 plants that cleaned coal in 1944 compared with 432 in 1943.

Wet methods of cleaning coal include piston- or common-type jigs, Baum-type jigs, concentrating tables, launders and upward-current classifiers, and any combinations of these four methods. Baum-type jigs cleaned approximately 41 percent of the total coal cleaned by wet methods during 1944.

Pnuematic methods of coal cleaning include air tables, air flow, air sand, and any combinations of these three methods. During 1944, air tables cleaned 59 percent of the coal cleaned by pneumatic methods.

Mines served by cleaning plants, exclusive of those that ship to washeries operated by steel companies, produced a total of 232,935,780 tons, or 37.6 percent, of the total bituminous output in 1944. In this same group of mines, 148,454,987 tons were mechanically cleaned; therefore, 63.7 percent of the coal produced at mines with cleaning plants in 1944 was cleaned at the mine. The rest of the output (36.3 percent) presumably represents the larger sizes commonly picked by hand.

Table 37 shows total production of coal at mines with cleaning plants by methods of preparation in 1943 and 1944.

Coal cleaning by States.—The following States led in volume of coal mechanically cleaned in the United States in 1944: Pennsylvania, 23.5 percent of total; West Virginia, 20.8; Illinois, 20.8; Alabama, 9.1; and Indiana, 7.4 percent. These five States accounted for 81.6 percent of the total mechanically cleaned coal in 1944. Table 39 shows the number of plants in operation, tons of clean coal, and percentage of State output mechanically cleaned in 1943 and 1944.

Relation between raw coal, clean coal, and refuse.—For every 100 tons of raw coal cleaned during 1944 at the mines, 86.8 tons of clean merchantable coal, on an average, were obtained, and 13.2 tons of refuse were discarded. Table 40 shows total production of mines with cleaning plants and results of cleaning operations, by States.

Methods of mining at mines served by cleaning plants.—Mechanical loading, both in underground mines and strip pits, appears to be closely related to mechanical cleaning. Table 38 shows the mining methods at mines having cleaning plants. Production of coal from strip mines in 1944 was 100,898,376 tons (see table 34), of which 32,444,227 tons (32.2 percent) came from strip mines having mechanical cleaning tipples. Underground coal loaded mechanically in 1944 totaled 274,189,132 tons, of which 137,926,900 tons (50.3 percent) passed through tipples equipped with mechanical-cleaning devices. Hand-loaded underground coal production in 1944 totaled 244,488,732 tons, of which 25.6 percent passed through tipples equipped with cleaning plants.

TABLE 35.—*Bituminous coal mechanically cleaned by wet and pneumatic methods in the United States, in net tons of clean coal, 1941–44*

Method of cleaning	1941	1942	1943	1944	Change 1944 from 1943 (percent)
By wet methods:

[1] Based upon shipping weights and includes some marketable coal that did not pass through cleaning plants.
[2] Includes some coal mined in Pennsylvania and cleaned in Ohio.
[3] Includes some coal mined in West Virginia and cleaned in Ohio and Pennsylvania.
[4] Includes all mechanical cleaning other than washeries operated by consumer steel companies.
[5] Includes central washeries in Colorado and Pennsylvania operated by consumer steel companies.

DETAILED STATISTICS, BY STATES AND COUNTIES

Detailed production and employment statistics are given in table 41 for each coal-producing county in the United States from which three or more operators submitted reports for 1944. Statistics on counties with less than three reporting producers have been combined with data for other counties in the same State to avoid disclosing individual figures, unless permission to publish has been granted by the operators. Production of mines on the border between two States has been credited to the State from which the coal was extracted rather than to that in which the tipple was situated. If the coal is mined from lands in both States, the tonnage has been apportioned accordingly.

In this series the reported production is classified according to the principal methods of distribution or use. Beginning with 1932, the series was expanded to include data on the growing volume of coal moving from mine to consumer by truck. For 1933–36 this tonnage was shown as "Commercial sales by truck or wagon." In 1937 this tonnage was shown as "Truck deliveries, including local sales" (see Minerals Yearbook, 1939, p. 813). In 1938 the truck tonnage was shown as "Shipped by truck or wagon." The truck figures for 1933 to 1936, inclusive, and 1938 to 1944, inclusive, are reasonably comparable.

The data in the present report, as in those published for many years by the Bureau of Mines, relate only to mines with an annual output of 1,000 tons or more. That fact should be borne in mind when the statistics in this report are compared with similar data compiled by State mine departments. Differences arise largely from variations in coverage by State reports, some of which include data for all mines regardless of size and others only data for mines employing more than a specified minimum number, ranging from 2 to 10 men. To meet the administrative demand for statistics on mines with an annual output of less than 1,000 tons per year, data for the small mines are shown in table 42. The average tons per man per day at the small mines was low due to part-time employment, lack of machinery, and difficult working conditions. The production shown in table 42 is not included in the total output shown in other tables for the United States, as this would upset the comparability of the statistical series.

Because of a change in method of reporting, statistics of average production per man per day for 1932 to 1936 and 1938 to 1941 are not precisely comparable with those for other years. For other years they were based upon the calculated number of man-shifts, obtained by multiplying the average number of men employed at each mine by the number of days worked at the mine. From 1932 to 1936 and 1938 to 1941 the operators were asked to make, if possible, a special report of the number of man-shifts actually worked. The number of operators able to furnish this information was small. These reports were utilized to improve the accuracy of the record. Otherwise, the man-shifts were calculated by multiplying the number employed underground and on the surface by the number of days worked by the mine and tipple, respectively.

TABLE 41.—*Production, value, employment, days active, man-days, and output per man per day at bituminous-coal and lignite mines in the United States, by States and counties, in 1944*

[Exclusive of mines producing less than 1,000 tons]

County	Disposition of coal produced (net tons): Loaded for shipment by rail or water [1]	Disposition of coal produced (net tons): Shipped by truck or wagon (excluding coal used by mine employees)	Disposition of coal produced (net tons): Used by mine employees, taken by locomotive tenders at tipple, or other uses at mine [2]	Disposition of coal produced (net tons): Used at mine for power and heat or made into beehive coke at mine	Disposition of coal produced (net tons): Total quantity	Average value per ton [3]	Average number of employees: Underground	Average number of employees: Surface: In strip pits	Average number of employees: Surface: All others	Average number of employees: Total	Average number of days mines were active	Number of man-days worked	Average tons per man per day

[1] Includes coal loaded at mine directly into railroad cars or river barges, hauled by truck to railroad siding for shipment by rail, and hauled by truck to waterway for shipment by water.

[2] Includes coal transported from mine to point of use by conveyor or tram.

[3] Value received or charged for coal, f. o. b. mine, including selling cost. (Includes a value for coal not sold but used by producer, such as mine fuel and coal coked [not coke] as estimated by producer at average prices that might have been received if such coal had been sold commercially.)

[4] No coal was "Made into beehive coke at mine."

[5] Includes 149,908 tons "Made into beehive coke at mine" in Las Animas County.

[6] Output obtained chiefly from strip pits and by use of mechanical loading devices, in which types of operation production per man per day is large.

[7] Production of Alston Coal Co. (Alston mine) is credited to Missouri.

[8] Output obtained chiefly from strip pits in which production per man per day is large.

[9] Includes 92,764 tons "Made into beehive coke at mine" in Pike County.

[10] In Montana some lignite included in "Shipped by truck or wagon" includes "Other uses at mine." In North Dakota some lignite made into briquets is included in "Other uses at mine." In South Dakota some lignite "Loaded for shipment by rail or water" is included in "Shipped by truck or wagon." In South Dakota and Texas some lignite "Used at mine for power and heat" is included in "Used by mine employees."

[11] Includes coal "Made into beehive coke at mine" in following counties: Cambria, 47,375 tons; Fayette, 4,713,263; Indiana, 284,698; and Westmoreland, 1,301,323—grand total, 6,346,659 tons.

[12] Includes 15,082 tons "Made into beehive coke at mine" in Carbon County.

[13] Output is obtained chiefly by use of mechanical loading devices in which type of operation production per man per day is large.

[14] Includes 397,105 tons "Made into beehive coke at mine" in Wise County.

[15] Includes coal "Made into beehive coke at mine" in following counties: Fayette, 244,847 tons; Monongalia, 80,707; Nicholas, 30,358; Preston, 169,477—grand total, 525,389 tons.

STATISTICS ON LIGNITE IN 1944[3]

PRODUCTION

The production of lignite in 1944 totaled 2,554,160 net tons, exclusive of some small mines that produced less than 1,000 tons—a decrease of 7.1 percent from the 2,749,393 tons produced in 1943. The average value per ton—$1.49—is the same as in 1943. The total employees in 1944 numbered 945 against 1,165 in 1943, while the average output per man per day for the same periods, based upon calculated man-days, was 12.95 and 10.98 tons, respectively. The output per man per day is high in the lignite industry compared with other coal mining in the United States because a large part of the total production (70 percent in 1944) is recovered from strip pits where the average output per man per day is much higher than in deep mining.

As for many years in the past, North Dakota was the chief producer of lignite in 1944, followed in order by Texas, Montana, and South Dakota. The North Dakota output comprised 93 percent of the total production, that of Texas 4 percent, and that of South Dakota and Montana taken together, 3 percent.

TABLE 43.—*Summary of production, value, men employed, days operated, man-days of labor, and output per man per day at lignite mines in the United States in 1944, by States* [1]

	Montana [2]	North Dakota	South Dakota	Texas	Total
Production (net tons):					
Loaded at mine for shipment		1,864,870	(3)	106,378	1,971,248
Commercial sales by truck or wagon	[4] 51,709	411,552	[3] 26,733	1,399	491,393
Used by employees, taken by locomotives at tipple, and other uses	(4)	[5] 59,671	[6] 94	[6] 1,755	61,520
Used at mine for power and heat		29,999	(6)	(6)	29,999
Total production: 1944	51,709	2,366,092	26,827	109,532	2,554,160
1943	64,383	2,500,202	40,664	144,144	2,749,393
Value:					
Total: 1944	$113,000	$3,535,000	$55,000	$95,000	$3,798,000
1943	$139,000	$3,752,000	$78,000	$127,000	$4,096,000
Average per ton: 1944	$2.19	$1.49	$2.05	$0.87	$1.49
1943	$2.16	$1.50	$1.92	$0.88	$1.49
Number of employees:					
Underground	40	292	6	3	341
Surface (including strip pits)	15	534	22	33	604
Total employees: 1944	55	826	28	36	945
1943	66	1,002	29	68	1,165
Average number of days mines operated:					
1944	173	213	177	198	209
1943	182	223	203	129	215
Man-days of labor: 1944 [7]	9,532	175,562	4,954	7,128	197,176
Average output (tons) per man per day: 1944 [7]	5.42	13.48	5.42	15.37	12.95

[1] Includes many small mines producing less than 1,000 tons.
[2] Includes output of Custer, Dawson, McCone, Richland, Roosevelt, Sheridan, and Valley Counties.
[3] Some "Loaded at mine for shipment" included in "Commercial sales by truck or wagon."
[4] Some "Other uses" included in "Commercial sales by truck or wagon."
[5] Includes some lignite made into briquets.
[6] Some "Colliery fuel" included in "Other uses."
[7] Based upon calculated man-days.

[3] Compiled by J. A. Corgan and M. I. Cooke.

The number of lignite mines reporting production to the Bureau of Mines in 1944 totaled 108 compared with 131 in 1943 and 173 in 1942. Many of the producers indicated on their reports that the mines were closed because of insufficient labor to operate them. It is not expected that many more mines will be in operation in 1945; however, the number should increase in 1946, when it is believed that labor will be more plentiful.

According to the Federal Power Commission, 623,712 tons of lignite were consumed in the West North Central States for generating electric energy in 1944; 795 tons in the West South Central States; and 376,551 tons, a large part of which was subbituminous, in the Mountain States.

The Bureau of Mines prepared this report from an annual canvass of operators of lignite properties included in the areas mapped as "lignite" in Geological Survey Professional Paper 100-A, The Coal Fields of the United States. Subbituminous coal is not included. The data on individual operations are voluntary and confidential, as is customary in the statistical surveys of the Bureau.

TABLE 44.—*Production, value, men employed, days operated, man-days of labor, and output per man per day at lignite mines in the United States in 1944, by States and counties*

County	Total production (net tons)	Value: Total (thousand dollars)	Value: Average per ton	Total number of employees	Man-days of labor [1]	Average number of days mine operated	Average tons per man per day [1]

TEXAS							
Total Texas: Milam, Titus, and Wood	109,532	95	$0.87	36	7,128	198	15.37

[1] Based upon "calculated" man-days.
[2] Output is obtained chiefly from strip pits in which the production per man per day is large.

METHODS OF RECOVERY

TABLE 45.—*Lignite mined by different methods in the United States in 1944, by States, in net tons*

State	Mined by hand	Shot off the solid	Cut by machines [1]	From strip pits	Total
Montana and Texas	(2)	[2] 55,573		105,668	161,241
North Dakota	(2)	[2] 47,783	661,842	1,656,467	2,366,092
South Dakota	(2)	[2] 1,405		25,422	26,827
Total	(2)	[2] 104,761	661,842	1,787,557	2,554,160

[1] Total of 15 machines used—10 "permissible" and 5 other types.
[2] Small amount of "Mined by hand" included under "Shot off the solid."

NUMBER AND SIZE OF LIGNITE MINES

For 1944 the Bureau of Mines received reports from 108 lignite mines (exclusive of some mines producing less than 1,000 tons a year). Most of the operations were in North Dakota which had 84; Montana was next in order with 14 mines; and South Dakota and Texas followed, with 7 and 3, respectively. The classification by size of output in the field as a whole in 1944 is given in table 46.

TABLE 46.—*Number and production of lignite mines in the United States in 1944, classified by size of output*

Class	Mines		Production		
			Net tons		Percent of total
	Number	Percent	Total	Average per mine	
1. 200,000 tons and over	6	5.5	1,958,702	326,450	76.7
2. 100,000 and under 200,000	1	.9	104,525	104,525	4.1
3. 50,000 and under 100,000	2	1.9	161,167	80,584	6.3
4. 10,000 and under 50,000	10	9.3	193,718	19,372	7.6
5. Under 10,000 tons	89	82.4	136,048	1,529	5.3
Total	108	100.0	2,554,160	23,650	100.0

STRIPPING OPERATIONS

The production of lignite from strip pits in 1944 amounted to 1,787,557 tons—70 percent of the total output of the industry. As for many years in the past most of the stripping—that is, 93 percent of all strip-pit production and 65 percent of the total tonnage produced by the lignite industry—was done in North Dakota, where 1,656,467 tons were produced by that method. The output from stripping operations in Texas, Montana, and South Dakota was only 131,090 tons. The number of men employed in stripping operations was 596 with an average output per man per day of 17.13 tons and the average number of days worked was 199.

Detailed statistics for stripping operations in the lignite industry in 1944 are given in table 47.

TABLE 47.—*Summary of stripping operations that produced lignite in the United States in 1944, by States*

State	Number of strip pits[1]	Number of shovels, drag-line excavators, and coal-loading machines[2]	Coal produced (net tons)		Total value at mines (thousand dollars)	Average value per ton	Number of employees				Average number of days mines operated	Man-days of labor[3]	Average tons per man per day[3]
			Mined by stripping	Total at same mines			Underground	Surface		Total			
								In strip pits	All others				
Montana and Texas	4	4	105,668	105,668	88	$0.83	----	29	10	39	159	6,220	16.99
North Dakota	48	60	1,656,467	1,897,371	2,849	1.50	68	254	213	535	202	107,844	17.59
South Dakota	3	5	25,422	25,422	51	2.00	----	20	2	22	199	4,372	5.81
Total	55	69	1,787,557	2,028,461	2,988	1.47	68	303	225	596	199	118,436	17.13

[1] Includes some pits in which stripping is done by hand.
[2] In some cases same equipment was used for stripping or excavating and for loading coal; such duplication has been eliminated. In some cases coal was excavated by machine and loaded by hand.
[3] Based upon calculated man-days.

World production of coal and lignite, 1938–45, by countries, in thousands of metric tons [1]—Continued

Country [1]	1938	1939	1940	1941	1942	1943	1944	1945
Lignite (total of items shown above)	263,000	302,000	(3)	(3)	(3)	(3)	(3)	(3)
Bituminous and anthracite (by subtraction)	1,197,000	1,295,000	(3)	(3)	(3)	(3)	(3)	(3)

1 Coal is also mined in Argentina, Iran, and Italian East Africa, but production figures of those countries not available.
2 Estimate included in total.
3 Data not yet available.
4 Estimate.
5 May to December, inclusive.
6 Estimated production of Slovakia only.
7 Beginning in 1939, includes Sudetenland, Bohemia, and Moravia.
8 Beginning in 1941, also includes German-occupied Poland.
9 Fiscal year ended March 31, of year following that stated.
10 Production of less than 1,000 tons.
11 Estimated production of Croatia only.
12 January to June, inclusive.
13 Production of Government mines only.
14 Tonnage raised by Wankie colliery for year ended August 31 of year stated.
15 January to September, inclusive.

PENNSYLVANIA ANTHRACITE

By J. A. Corgan and Marian I. Cooke

SUMMARY OUTLINE

REVIEW OF 1945

The heavy demand for Pennsylvania anthracite during the war period continued throughout 1945, and the output of 54,933,909 net tons was not sufficient to meet the increased requirements created by shortages of other spaceheating fuels, the requests from Canada for large tonnages, and the expanded purchasing power of domestic consumers. The sharp decline in production—14 percent less than the output of 63,701,363 tons in 1944—is directly attributable to the scarcity of manpower, difficulty in obtaining equipment and supplies, and labor disturbances which shut down the mines completely for 3 weeks. Of the total production loss (8,767,454 tons), deep mines accounted for 79 percent, strip pits and culm banks 19 percent, and river coal 2 percent. In accordance with an arrangement made by the operators and the United Mine Workers of America in January 1943, the miners worked 6 days a week in 1945. The total days operated by the industry—269—was the highest since 1924, with the exception of the 270 and 292 days worked in 1943 and 1944, respectively.

The anthracite distribution program, inaugurated in 1943 by the Solid Fuels Administration for War, was continued through October 1945, when virtually all regulatory measures were rescinded. The Bureau of Mines worked closely with the Solid Fuels Administration for War in compiling detailed statistical data relating to production, distribution, consumption, utilization, and market requirements of anthracite, and that agency based its entire wartime program for the equitable distribution of hard coal upon those data.

From May 3 to June 23, 1945, all anthracite mines were operated under the control of the Federal Government because of unsettled labor conditions occasioned by the absence of a contract between the producers and the United Mine Workers of America to supersede the one that expired on April 30. The mines were closed entirely from May 1 to May 19, and the Bureau of Mines estimates that this stoppage of work resulted in a production loss of 3,500,000 net tons of anthracite. This loss in output added considerably to the scarcity of fuels in the New England and Middle Atlantic States.

The output of anthracite from "bootleg" holes totaled 1,026,000 net tons in 1945, a sharp decline from the record output of 6,300,000 tons reached in 1941. The decrease may be attributed largely to the efforts of the Anthracite Committee to eliminate this kind of mining, the induction of young men into the armed forces, and increased opportunities for employment in other industries.

Anthracite Industries, Inc. (now Anthracite Institute), expanded its research and promotional activities considerably, announcing improvements in the Anthratube, a new heating device for burning anthracite (see details under Anthracite Institute and Research).

Research by the Bureau of Mines on new and improved methods of mining anthracite mechanically and on the control of mine water and flood prevention was continued in 1945. It is expected that a research laboratory will be erected in the anthracite region in the near future; investigations and research to be conducted through facilities thus afforded will relate particularly to the mining, preparation, and utilization of anthracite and to safety, health, and sanitation in mining operations. The research program at the Pennsylvania State College on new and improved uses for anthracite, sponsored by the Anthracite Institute and the Commonwealth of Pennsylvania, was continued on the gasification of anthracite, the preparation of activated carbon, and the utilization of anthracite silt. Studies are also being conducted on the flow of gases through fuel beds and wall effects.

Definition of Pennsylvania anthracite.—Pennsylvania anthracite includes all nonbituminous coal mined in that State; for historical purposes data on the output of the Bernice Basin in Sullivan County are included in this chapter, although the coal of this basin has been officially classified as semianthracite. The anthracite fields are in the northeastern part of the State, and the coal is mined in the following counties: Carbon, Columbia, Dauphin, Lebanon, Lackawanna, Luzerne, Northumberland, Schuylkill, Susquehanna, and Wayne.

Statistical trends.—Tables 1 and 2 present pertinent statistical data on the Pennsylvania anthracite industry.

Anthracite Institute.—In the interest of greater efficiency and an expanded research program for the industry, the activities of Anthracite Institute and The Anthracite Industries, Inc., were consolidated under one industry organization, Anthracite Institute, at a meeting of the boards of directors of both groups on January 8, 1946. In the past, Anthracite Institute functioned mainly on problems pertaining to production, statistics, and general industry matters, while The Anthracite Industries, Inc., was responsible for research, dealer and equipment trade contracts, advertising, and public relations.

[1] Furnished by Anthracite Institute. [2] Pennsylvania Department of Mines. [3] Ore and Coal Exchange, Cleveland, Ohio.
[4] Buffalo Branch, Ore and Coal Exchange, Cleveland, Ohio. [5] U. S. Engineer Office, Duluth, Minn.
[6] Includes all commercial docks on Lake Superior and west shore of Lake Michigan as far south as Kenosha. Based on data courteously supplied by Maher Coal Bureau and direct reports to the Bureau of Mines.
[7] Association of American Railroads. [8] Furnished by Commonwealth of Massachusetts, Division on the Necessaries of Life.
[9] U. S. Department of Commerce. [10] Federal Power Commission. [11] Data not available.
[12] Anthracite Committee. Represents coal in storage closest available date to the end of the month.
[13] Computed from weekly quotations from trade journals. Figures represent circular prices quoted on white ash by leading anthracite-producing companies.
[14] Bureau of Labor Statistics.

To facilitate the administration of its increased activities, Anthracite Institute has established offices in Wilkes-Barre, Pa., to take care of all matters pertaining to production, statistics, and other general industry affairs. The research laboratory now located at Primos, Pa., will be moved to the Wilkes-Barre area. Public relations, advertising, and marketing programs will continue under the direction of the present New York office.

Anthracite Committee.—The Anthracite Committee represented producers, whose combined output comprised a large part of the total output of the industry, before the Office of Price Administration, Solid Fuels Administration for War, and other Government agencies on matters concerning the welfare of the anthracite industry. The committee kept the industry well informed on "bootleg" mining operations and was particularly active in matters requiring statistics on current production, employment, and other pertinent phases of the anthracite industry.

Standard anthracite size specifications approved and adopted by the Anthracite Committee, effective January 14, 1946, are shown in table 3.

TABLE 3.—*Standard anthracite size specifications approved and adopted by Anthracite Committee, effective Jan. 14, 1946*

	Round test mesh, inches	Percent				
		Oversize maximum	Undersize		Maximum impurities

Buckwheat No. 3 (Barley)	Through 3/16	10			[2] Ash, 15	
	Over 3/32		20	10		
Buckwheat No. 4	Through 3/32	20			[2] Ash, 15	
	Over 3/64		30	10		
Buckwheat No. 5	Through 3/64	30	No Limit		[2] Ash, 16	

[1] When slate content on Broken to Chestnut, inclusive, is less than above standards, bone content may be increased by one and one-half times the decrease in the slate content under the allowable limit, but slate content specified above shall not be exceeded in any event.
[2] Ash determinations are on a dry basis.

Labor.—Early in April 1945 the anthracite producers and the United Mine Workers of America convened to discuss a new wage agreement to supersede the one that was to expire on April 30. An agreement was not reached on the expiration date, and in the absence of a contract the miners failed to report for work on May 1. Acting under the authority of the President, the Secretary of the Interior issued an order on May 3 by which the Government took possession

717372—47——59

of mines, breakers, and other producing facilities of companies producing Pennsylvania anthracite. In his order the Secretary stressed the existing critical fuel situation and explained that the daily loss in production was only adding to the present serious shortage of anthracite, which is a principal fuel for heating the homes of war workers in the East.

Despite the Government seizure, the miners did not return to work until May 21, a new contract having been signed on May 19. The estimated production loss due to the strike totaled 3,500,000 net tons. On June 23 the Secretary of the Interior terminated Government possession of the mines and returned the properties of 354 Pennsylvania anthracite-mining companies to their private owners.

Under the new agreement, the miners received an average daily wage increase of $1.375. Wages paid for travel time accounted for $1.132 per day of the total increase; an increase in the vacation pay, overtime, and shift differentials accounted for the remaining $0.243 per day. The agreement may be renegotiated at the end of 1 year. If a significant change occurs within the year in the Government wage policy, either party shall have the right to request negotiations on general wage rates.

In accordance with an agreement between the operators and the miners made early in 1943, the mine workers continued to work 6 days a week during 1945.

Research.—The Bureau of Mines continued investigative work in the anthracite fields, started in 1944, on increasing the underground output per man per day through new and improved methods of mechanical mining. In 1945, of the total underground production, 40 percent was loaded mechanically. The coal beds in the Wyoming region are relatively flat and more adaptable to present mechanical mining methods than the pitching seams in the Lehigh and Schuylkill regions; accordingly, 52 percent of the underground output of the Wyoming region was mechanically loaded in 1945 while only 22 percent of the combined output of the last two regions was so loaded. The Bureau has done considerable research on various kinds of mechanical mining machinery that are not being utilized at present in the anthracite fields. Concurrently with the mechanical mining program, the control of mine water and flood prevention are under investigation. For many years a number of companies have carried on this work independently; however, for it to be generally successful the Federal Government, the Commonwealth of Pennsylvania, and the producers must work together, since the costs of the projects, the benefits derived, and the conservation of coal reserves concern all.

Anthracite Industries, Inc. (now Anthracite Institute), continued its enlarged scope of research activities, announcing improvements in the Anthratube, a device for utilizing an entirely new method of burning anthracite. The Anthratube principle of combustion is to burn anthracite under forced draft at a high rate of combustion in a steel tube surrounded by a water jacket from which hot water circulates to the radiators in the building to be heated. The Anthratube was released by Anthracite Institute early in 1946 to heating-equipment manufacturers for production. Details of this device are discussed on page 914 of the Pennsylvania Anthracite chapter in Minerals Yearbook, 1944.

For the past 6 years the Anthracite Institute has sponsored research on new and improved uses for anthracite at the Pennsylvania State College under an agreement whereby the institute provides a portion of the funds and the Commonwealth of Pennsylvania the remainder. The program, selected by an appointed committee, currently includes the gasification of anthracite by the use of both Broken and Egg sizes in the heavy-oil and gas-oil processes; the use of Rice and Barley in the new Wellman-Galusha agitator producer; and the production of synthesis gas from anthracite by direct gasification with oxygen and steam. A report on the preparation of activated carbon, based upon studies previously completed, was released recently for publication. This study showed that a number of anthracites could be treated to give reasonably good active carbons which may have industrial application for such uses as water and gas purification. Studies on the utilization of anthracite silt have been conducted along several lines, including the following: A critical examination of several recent developments in fine coal cleaning, such as the Humphrey's spiral concentrator, the Elmore vacuum-flotation process, and the Johnson electrostatic process; dewatering and drainage studies on various fine sizes; the use of pulverized anthracite-bituminous mixtures in firing cement kilns; the use of anthracite fines in byproduct-coke manufacture and the production of Anthra-coke; and studies on the surface and inherent properties of anthracite as related to the agglomeration of anthrafines by carbonization with various binders.

Competitive fuels in the United States and principal markets.—The principal anthracite markets are the New England States, New York, New Jersey, Pennsylvania, Maryland, Delaware, and the District of Columbia. Data on the consumption of all fuels in these markets for 1945 are not available; however, the apparent total consumption of anthracite, coke, briquets, and heating and range oils, in terms of anthracite, increased 2 percent in 1944 compared with 1943. Virtually all of the increased consumption is attributable to the gain in shipments of anthracite, which supplied 62 percent of the total equivalent fuels consumed in these States. In addition to the legitimate anthracite shipped, large quantities of "bootleg" coal are moved by truck to this area. Details on the consumption of competitive fuels are shown in table 4.

In general, the supplies of fuels commonly used for space heating in the United States increased in 1944 over 1943, a substantial gain being recorded in the consumption of anthracite, while sales of heating oils declined slightly. Details on supplies of various fuels are given in table 5.

TABLE 4.—*Apparent consumption of anthracite and selected competitive fuels in the principal anthracite markets, 1942–45*

House heating	45,200	79,600	83,686	84,766	(7)

[1] A considerable part of the smaller steam sizes is used by industries, railroads, and public utilities.
[2] U. S. Department of Commerce.
[3] Production plus imports less exports; figures for 1942–43 are corrected.
[4] Partly estimated.
[5] Data not available.
[6] An estimated one-half is used for domestic purposes.
[7] Data not yet available.
[8] Exact data not available; estimated between 55 and 77 million tons a year, including lignite.
[9] Estimated.
[10] Includes all grades of fuel oil used for heating buildings.
[11] Includes gas used for heating offices, hotels, apartments, hospitals, stores, and other large buildings, as well as houses.
[12] American Gas Association.

Distribution.—The data shown in tables 6 and 7 summarize detailed statistics on the distribution of anthracite furnished by producers and wholesalers to the Bureau of Mines in compliance with Solid Fuels Administration for War Order 7, promulgated September 28, 1943. The detailed statistics showing shipments to final destinations in the United States and Canada were published jointly by the Bureau of Mines and the Solid Fuels Administration for War in Report SFD–2, Distribution of Pennsylvania Anthracite for the Coal Year, April 1, 1943, to March 31, 1944, and were used by the Administration to insure equitable distribution of anthracite during the war period.

TABLE 6.—*Shipments of Pennsylvania anthracite, Apr. 1, 1943–Mar. 31, 1944, by States, Provinces, and countries of destination, in net tons*

[As reported by producers and wholesalers on Solid Fuels Administration for War form SFA-26]

[1] Less than 0.005 percent.
[2] Includes Alabama, Arkansas, Louisiana, Oklahoma, Tennessee, and Texas.
[3] Includes California, Montana, Nevada, New Mexico, Oregon, Utah, and Washington.
[4] Coal sold principally to over-the-road truckers for delivery outside the "local sales" area, and for which final destinations were not known.
[5] Includes Alberta, British Columbia, Manitoba, and Prince Edward Island.
[6] Shipments to final Canadian destinations as reported by American and Canadian wholesalers were as shown—3,563,465 net tons. However, the reported direct shipments by American producers and wholesalers to final Canadian destinations as well as to Canadian wholesalers was 4,071,197 net tons, broken down by size as 3,059,759 tons of domestic, 461,343 tons of Buckwheat No. 1, 438,546 tons of Rice, and 111,549 tons of all other sizes. The difference is due principally to incomplete reporting by Canadian wholesalers as to final destinations of imported coal. Official data of the United States Department of Commerce shows total exports to Canada of 4,204,740 net tons of Pennsylvania anthracite during the coal year 1943-44; this compares closely with the figure of 4,071,197 tons as reported to the Bureau of Mines by American producers and wholesalers.

Information for the 1942–43 coal year, collected in a similar manner, and published in Report SFD–1, Distribution of Pennsylvania Anthracite for the Coal Year, April 1, 1942, to March 31, 1943, was used by the Administration as the basis for its entire wartime anthracite-distribution program.

TABLE 7.—*Shipments of Pennsylvania anthracite, Apr. 1, 1943–Mar. 31, 1944 by method of movement, in net tons*

[As reported by producers and wholesalers on Solid Fuels Administration for War form SFA-26]

[1] Shipments by over-the-road trucks from the mines to destinations outside the "local sales" area.
[2] Includes shipments to industrials, utilities, railroads, institutions, etc.; this tonnage was transported by all methods of movement and was not separable by type of carrier.
[3] This tonnage was transported principally by truck.

As shown in table 6, anthracite was shipped to 43 States, the District of Columbia, the Dominion of Canada, and other foreign countries in the 1943–44 coal year. Of the total anthracite shipments, 86.3 percent was destined to the New England and Middle Atlantic States; 1.6 percent, to "unknown destinations"; 5.9 percent, to all other States; and 6.2 percent, to Canada and other countries. Inasmuch as 824,000 tons of the total listed under "unknown destinations" were shipped from the mines by truck, it may be assumed that virtually all of it was destined to New York, New Jersey, and Pennsylvania. Thus, shipments to the New England and Middle Atlantic States accounted for approximately 88 percent of the total anthracite shipped to destinations in the United States, Canada, and other countries.

As shown in table 7, 72 percent of the total shipments were made to retail dealers; 13 percent moved in the "local sales" area; and the remaining 15 percent was shipped to industries, utilities, railroads, Government agencies, and institutions, etc., outside the "local sales" area. It will be noted that of the total tonnage shipped to retailers, 90 percent, or 37,891,481 tons, was Buckwheat No. 1 and larger sizes which customarily are used almost entirely for space-heating purposes. Of the anthracite shipped to retail dealers, 73 percent moved all-rail, 9 percent by truck, 17 percent by tidewater, and 1 percent was shipped off the Lake docks. The New England and Middle Atlantic States received 83 percent of all the shipments to retail dealers in the United States and Canada in the coal year 1943–44. Nearly all of the coal moving by tidewater was shipped from the New Jersey piers to the greater New York area, while a relatively small tonnage moved by water to the New England States.

According to data compiled from records of the Pennsylvania State Department of Mines, anthracite shipments from the mine to destinations in the United States declined 14 percent in 1945 from 1944. Of the total United States shipments, 84 percent moved from the mines by rail and 16 percent by truck, whereas in 1944, 86 percent moved by rail and 14 percent by truck. Pennsylvania received 81 percent of the truck shipments in 1945; New Jersey and New York followed with 9 percent and 8 percent, respectively. Anthracite rail shipments, by destinations, for 1943–45 are shown in table 8 and truck movement in 1945, by months, and by States of destination, in table 9.

According to data compiled from records of the Massachusetts Division on the Necessaries of Life and the Anthracite Emergency Tidewater Bureau, rail receipts of Pennsylvania anthracite in 1945 in New England declined 19 percent from 1944; tidewater receipts decreased 14 percent. Details on anthracite movement to New England are given in table 10. Loadings at Lake Erie ports increased 16 percent and receipts at the Upper Lake docks, 37 percent over 1944. The substantial gains in Lake Erie loadings in 1944 and 1945 over previous years are due largely to the increased use of the smaller steam sizes of anthracite by briquet manufacturers in the Great Lakes region.

[3] Total receipts by rail and by tidewater less imports.
[4] Data not available.
[5] Less than 1,000 tons.

Shipments of anthracite from the Lehigh, Schuylkill, and Wyoming regions, 1850 to 1945, inclusive, are presented graphically in figure 1.

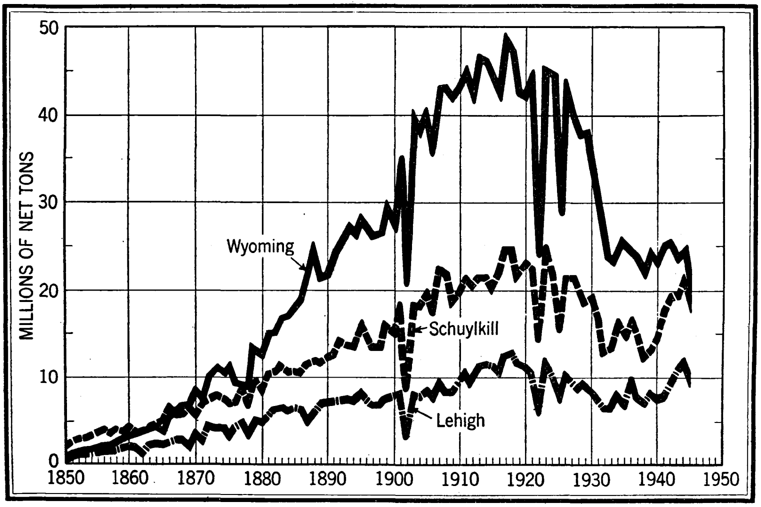

FIGURE 1.—Anthracite shipped from the Lehigh, Schuylkill, and Wyoming regions, 1850–1945.

Consumption.—Consumption of anthracite in the United States in 1945 totaled 51,600,000 net tons, compared with 59,400,000 tons in 1944. These statistics include colliery fuel and coal dredged from the streams draining the anthracite region and are based on production, imports, exports, and changes in producers' stocks but do not consider changes in stocks held by retail dealers, as data on stocks held by this group are incomplete. Owing largely to a shortage of low-volatile bituminous coal for use in the manufacture of fuel briquets and packaged fuel, the consumption of anthracite by these industries increased from 388,693 net tons in 1943 to more than 900,000 tons in 1945. The consumption of anthracite by class I railroads and electric power utilities declined 8 percent and 9 percent, respectively, in 1945 compared with 1944.

Changes in stocks.—Producers' stocks declined from 444,508 net tons in 1944 to 130,135 tons in 1945. Almost all of the coal in producers' yards was Buckwheat No. 3 and No. 4 sizes, which are ordinarily used for industrial purposes, and virtually no Buckwheat No. 1 or larger sizes of anthracite, commonly used for space heating, was available at the end of the year. Stocks held by public utilities declined 4 percent from 1944 and those held by class I railroads 42 percent. Stocks of anthracite on the Upper Lake docks in 1945 increased 64 percent over 1944. Stocks in retail dealers' yards amounted to 11 days supply in January and at the close of the year 13 days.

"Bootleg" coal.—According to the Anthracite Committee, production of "bootleg" coal in 1945 totaled 1,026,000 net tons, compared with 1,332,957 tons in 1944 and the record production of 6,300,000 tons in 1941. A survey by the committee in March 1946 revealed that 526 "bootleg" holes were being worked by 1,939 men, a substantial decrease from the 10,762 men working 3,006 holes disclosed by the committee's survey in March 1941. The decline in "bootleg" mining since 1941 is due largely to the efforts of the Anthracite Committee to decrease this kind of mining and to many of the younger "bootleg" miners entering the armed forces and nearby industries.

Early in 1945 a bill was introduced before the Pennsylvania General Assembly requiring inspections by the Pennsylvania Department of Mines of all mine openings employing two or more men. The present law requires periodic inspection only of those mines employing five or more men. The legislature adjourned without passing this measure. Had it become law, it might have been the means of drastically curtailing "bootleg" operations, since these mines would have difficulty in meeting the rigid inspection standards of the Pennsylvania Department of Mines. In 1941, 61 men were killed in the "bootleg" mining industry, and in 1945, 16 fatalities occurred. The death rate in this kind of mining in 1945 of 1 fatality for every 64,000 tons mined was much higher than the accident rate in recognized anthracite mines. Statistical details on "bootleg" mining for 1941–45 are given in table 11.

TABLE 11.—*Statistics of "bootleg" operations in the Pennsylvania anthracite industry, 1941–45*

Year	Production (net tons) [1]	Purchased for preparation by recognized operations (net tons) [2]	Number of fatalities [1]
1941	6,300,000	1,902,481	61
1942	3,931,000	2,616,839	45
1943	1,912,467	1,265,617	22
1944	1,332,957	506,842	21
1945	1,026,000	260,342	16

[1] Anthracite Committee, Harrisburg, Pa.
[2] As reported to Federal Bureau of Mines.

Trend in employment.—The number of men employed in the anthracite-mining industry declined from an average of 77,591 in 1944 to 72,842 in 1945. The shortage of labor, especially of men to work at the face, was acute; and output, no doubt, would have been much greater had enough labor been available. During the latter part of the year, many younger men returned to the mines from war service, but this did not increase materially the total number of miners employed because some of the older men who worked in the mines during the war to help out during the emergency became inactive. These figures on employment do not include men working in "bootleg" holes; for employment in this type of mining, see table 12. Data on employment in recognized operations are given in tables 28 and 29.

Sales realization.—The average sales realization on anthracite breaker shipments in 1945 was $6.26 per net ton, compared with $5.91 a ton in 1944, while the average value per ton on total anthracite output was $5.90, against $5.57 in 1944. These gains were due to increased f. o. b. mine prices granted by the Office of Price Administration to the producers to compensate them for added costs of production under the wage agreement of May 19 and for other general higher operating costs.

TABLE 12.—*Survey of "bootleg" operations in the Pennsylvania anthracite industry, 1941–46* [1]

Date of survey	Number of "bootleg" operations	Average number of men employed
Mar. 31, 1941	3,006	10,762
May 1, 1942	2,029	7,554
Dec. 15, 1942	1,363	4,967
Apr. 20, 1943	1,065	3,607
Oct. 14, 1943	791	2,725
Mar. 31, 1944	652	2,220
Mar. 7, 1945	502	1,806
Mar. 30, 1946	526	1,939

[1] Anthracite Committee, Harrisburg, Pa.

Trend in prices.—To compensate the anthracite producers for added costs of production under the wage agreement of May 19, the Office of Price Administration authorized increases in f. o. b. mine prices effective June 18 as follows: $1.00 per net ton on Broken, Egg, Stove, and Chestnut sizes; $0.85 on Pea; $0.50 on Buckwheat No. 1 and Rice; and $0.25 on Barley and smaller sizes. The increases resulted in new mine prices of $8.85 per net ton for Broken, Egg, Stove, and Chestnut sizes; $7.15 per ton for Pea; $5.15 for Buckwheat No. 1; $4.25 for Rice; $3.00 for Barley; and $2.25 for smaller sizes. On December 1, 1945, the Office of Price Administration granted additional price relief to the producers when it established different prices for groups of companies. Group 1 prices were applicable to the nine larger anthracite-producing companies, and group 2, with a few exceptions, to all other anthracite producers. The procedure of applying different prices to groups of producers was followed in World War I, when a number of the large companies were given lower prices than other producers at that time. The new prices in effect at the end of 1945 are shown in table 13.

TABLE 13.—*Maximum prices per net ton for Pennsylvania anthracite, as established by the Office of Price Administration, effective December 1, 1945*

	Broken	Egg	Stove	Chestnut	Pea	Buckwheat No. 1	Buckwheat No. 2 (Rice)	Buckwheat No. 3 (Barley)	All other sizes
Group 1: Glen Alden Coal Co.; Lehigh Valley Coal Co.; Lehigh Navigation Coal Co.; Jeddo Highland Coal Co.; Pennsylvania Coal Co.; Philadelphia & Reading Coal & Iron Co.; Susquehanna Collieries Co.; Stevens Coal Co.; Hudson Coal Co.	$9.00	$9.00	$9.00	$9.00	$7.30	$5.25	$4.30	$3.05	[1] $2.25
Group 2: All producers not included in group 1	9.50	9.50	9.50	9.50	7.80	5.70	4.60	3.35	[1] 2.25
Exceptions:									
Jeddo Highland Coal Co.: Anthracite prepared at Jeddo No. 7 and Highland No. 5 breakers. Sold under trade name "Jeddo Coal," "Highland Coal," or "Hazel Brook Coal"	9.25	9.25	9.25	9.25	7.55	5.50	4.45	3.05	2.25
Franklin-Lykens Coal Co.: Anthracite prepared at Williamstown breaker. Sold under trade name "The Only Genuine Franklin Coal of Lykens Valley"	9.75	10.00	10.25	9.50	7.80	5.70	4.60	3.35	2.25
Lehigh Naviagion Coal Co.: Anthracite sold under trade name "Old Company's Lehigh-Greenwood Premium Anthracite"	9.00	9.25	9.25	9.25	7.55	5.25	4.30	3.05	2.25

[1] If sold for fuel or sintering use, or for use in the manufacture of calcium carbide, graphite, or activated carbon, including (specifically but not exclusively) Buckwheat No. 4, river or dredge Barley, and smaller sizes.

Retail prices of anthracite, bituminous coal, coke, and heating oils in selected cities, by months, in 1945 are shown in table 14. These prices were compiled from reports of the Bureau of Labor Statistics, United States Department of Labor.

Imports and exports.—Exports of anthracite, virtually all of which were destined to Canada, declined 12 percent in 1945 from 1944. Imports were negligible, totaling only 149 net tons. For details on imports and exports see tables 36 and 37.

Mechanical stokers and oil burners.—According to the Bureau of the Census, United States Department of Commerce, factory sales of class 1 mechanical stokers for burning anthracite (capacity under 61 pounds of coal per hour) increased from 450 units in 1944 to 3,325 units in 1945. Sales of this capacity stoker totaled 17,110 units in 1941. Sales of class 2 stokers (capacity 61 to 100 pounds of anthracite per hour) totaled 1,883, a decline of 16 percent from the 2,243 units sold in 1944. Shipments of oil burners for central heating plants and industrial uses totaled 182,130 in 1945 compared with 77,081 in 1944 and 303,869 in 1941. With the lifting of Government restrictions and the settling of labor strife in plants making electric motors and other burner equipment, it is expected that sales of both stokers and oil burners will increase greatly in 1946 over the war years.

OUTLOOK

The outlook for the Pennsylvania anthracite industry in 1946 is encouraging. It is expected that production will be close to the demand and that the markets will absorb the available supply. Subsequent to 1946, competition among anthracite, heating oils, natural and manufactured gas, coke, and bituminous coal will be extremely keen, and the relative position of the industry will depend largely on its ability to develop low-cost, automatic coal-burning equipment, to find new uses for anthracite, and to reduce mining costs. Low-cost, automatic coal-burning equipment is not only a means of obtaining new business, but installations of both burners and auxiliary equipment will aid in retaining old customers. Concentrated marketing and merchandising programs should be continued; and the industry must work closely with architects, builders, and manufacturers of anthracite heating equipment to insure itself a fair share of the fuel business created by the millions of new homes which it is expected will be built during the next 10 years.

SOURCES AND ACKNOWLEDGMENTS

Final statistics of the Pennsylvania anthracite-mining industry are prepared from an annual canvass, by mail, of the producers and shippers of anthracite. About 98 percent of the tonnage is reported direct, and the remaining 2 percent is collected by personal visits or from reliable collateral evidence. The data on individual operations are furnished voluntarily by the producers and treated confidentially, as is customary in the statistical services of the Bureau of Mines.

In compiling available information, pertinent statistics prepared by the Pennsylvania Department of Mines, the Anthracite Committee, the Anthracite Institute, and the Association of American Railroads have been used to advantage. The Bureau of Mines gratefully acknowledges the cooperation of these organizations and others from whom information has been received.

PRODUCTION

The production statistics of the Pennsylvania anthracite industry contained in this chapter include coal from five sources—deep mines, strip pits, culm banks, coal purchased from "bootleg" mines, and river or creek coal recovered from the streams draining the anthracite fields. A small quantity of semianthracite produced in Sullivan County (181,315 net tons in 1945) is included also for historical comparison. The total production from these sources in 1945 was 54,933,909 net tons, a 14-percent decline from the 1944 output of 63,701,363 tons. In addition to the production of 54,933,909 net tons, the industry reported 217,363 tons of slush; that is, the settlings from the water used in cleaning anthracite. The marketing of this material, a necessity occasioned by the shortage of coal during 1945, probably will be discontinued in the postwar period. As this coal was generally unprepared, the average value received for it was only about 40 cents per ton compared with $1.78 a ton for the Buckwheat

717372—47——60

No. 4 size, and it was excluded from the tables in this chapter to avoid distortion of production statistics and keep the data comparable with those of previous years. See tables 17 to 22 for production and shipments by fields, regions, and counties.

Before 1941 "bootleg" coal was not included in the production statistics of the anthracite industry by the Bureau of Mines; however, in 1941 the Anthracite Committee inaugurated a plan whereby recognized operators purchased lawfully the run-of-mine output of "bootleg" holes for preparation at their plants and shipment to market. In 1944 these shipments totaled 506,842 net tons; in 1945 the purchases were 260,342 tons. It would be impossible to segregate this purchased "bootleg" coal from the output of the recognized industry; it is, therefore, included in the various production tables in the Minerals Yearbook chapters on Pennsylvania anthracite for 1941–45. No attempt has been made to include in the statistics "bootleg" coal other than that purchased by recognized operators. To compute the output per man per day for the anthracite industry in 1941–45 it was necessary to deduct the "bootleg" purchases from the total tonnage shipped by the recognized industry, since adequate data on man-hours required to produce the "bootleg" tonnage are not available. Details of this procedure are discussed in this chapter under Labor Statistics.

Weeks and months.—Tables 15 and 16 summarize the statistics of weekly and monthly production of anthracite. Statistics of current output are estimated from records of carloadings and from tonnage reports from trade sources. The weekly and monthly figures have been adjusted to the annual total ascertained by direct canvass of the operators.

[1] Figures represent output of working days in that part of week included in calendar year 1945. Preliminary production for week of January 5, 1946, was 737,000 tons.

Reconciliation of fresh-mined, culm-bank, and breaker product.—Anthracite is now produced from three principal sources—mines (deep, bootleg, and strip-pit), culm banks, and rivers that drain the anthracite region. As all three sources contribute to the country's supply, it is important to consider them to ascertain the total production. No difficulty is experienced in separating the figures of production by dredges, as this is a distinct industry. It is difficult, however, to make a sharp differentiation between fresh-mined and culm-bank coal, continuity of which must be maintained in the statistical history of the industry. As the best solution of this problem, the individual breaker, washery, or dredge is taken as the unit in compiling the statistics, and the producing companies are asked to supply separate statements for each. These are totaled to form the primary tables of this report to show the total quantity of breaker product, washery product, and dredge product, with related figures of value and number of employees.

TABLE 16.—*Estimated monthly production of Pennsylvania anthracite, 1938–45, in thousands of net tons* [1]

Month	1938	1939	1940	1941 [2]	1942 [2]	1943 [2]	1944 [2]	1945 [2]
January	4, 978	5, 019	5, 783	5, 162	4, 560	4, 466	4, 970	4, 219

October	4, 180	4, 985	4, 355	5, 580	5, 132	5, 359	5, 538	5, 304
November	3, 803	3, 989	3, 980	3, 974	4, 824	4, 140	5, 029	4, 559
December	4, 533	3, 914	4, 834	4, 271	4, 639	4, 996	4, 518	3, 998
	46, 099	51, 487	51, 485	56, 368	60, 328	60, 644	63, 701	54, 934

[1] Production is estimated from weekly carloadings as reported by the Association of American Railroads and includes mine fuel, coal sold locally, and dredge coal.
[2] Includes some "bootleg" coal purchased by legitimate operators and prepared at their breakers.

TABLE 17.—*Pennsylvania anthracite produced, 1941–45, by fields, in net tons*

[The figures of breaker product include a certain quantity of culm-bank coal, which amounted to 6,236,300 tons in 1945]

Field	1941	1942	1943	1944	1945

[1] Value given for shipments is value at which coal left possession of producing company and does not include margins of separately incorporated sales companies.

[2] A small amount of washery coal included with breakers.

[3] For purposes of historical comparison and statistical convenience, the mines of Sullivan County are grouped with the Pennsylvania anthracite region, although the product is classified as semianthracite according to the American Society for Testing Materials Tentative Standard.

The figures for breaker and washery product are not exactly equivalent to the fresh-mined and culm-bank coal because of the practice sometimes adopted of putting culm-bank coal through a breaker, either directly from the bank or after preliminary treatment in a washery. The tonnage of culm-bank coal prepared at the breakers is broken down by fields and shown in table 23.

Culm-bank coal.—The culm banks in the anthracite region have been a source of coal for many years. In the early days of anthracite mining, the smaller sizes of anthracite, especially Pea and under, were not used as they are today, and these sizes and larger pieces of refuse containing much good coal were piled in large banks throughout the region. In recent years, with the increased demand for the smaller sizes and more efficient preparation methods, the product of these banks is cleaned in the washery or breaker, and a prepared coal is obtained. In 1945 this source supplied 8,786,659 net tons of coal. Tables 19 and 20 give a detailed break-down of culm-bank product by regions and fields.

[1] Figures of shipments from breakers include some culm-bank coal handled in the breakers.
[2] Quantity of Lump included is insignificant.
[3] A small quantity of Pea included in Buckwheat No. 1.

TABLE 22.—*Pennsylvania anthracite produced in 1945, by counties*

County	Total shipments		Sold to local trade		Used for power and heat		Total production	
	Net tons	Value [1]	Net tons	Value	Net tons	Value	Net tons	Value [1]
Berks, Lancaster, Lebanon, Northampton, and Synder [2]	29,828	$53,063	189,530	$288,263	23	$35	219,381	$341,361
Carbon	3,660,846	20,835,066	209,369	1,504,289	91,986	261,148	3,962,201	22,600,503
Columbia	890,244	5,857,403	68,821	371,638	54,642	103,398	1,013,707	6,332,439
Dauphin	368,549	1,277,127	233,395	427,981	2,012	4,829	603,956	1,709,937
Lackawanna	6,181,663	38,935,028	1,059,713	7,076,596	385,358	854,472	7,626,734	46,866,096
Luzerne	17,636,647	118,185,649	1,641,506	10,409,670	1,284,554	2,404,448	20,562,707	130,999,767
Northumberland	4,684,731	25,430,956	261,035	1,626,859	29,747	56,229	4,975,513	27,114,044
Schuylkill	14,833,009	82,141,680	569,167	3,689,225	254,072	653,971	15,656,248	86,484,876
Sullivan	140,922	783,693	39,793	234,799	600	1,750	181,315	1,020,242
Susquehanna and Wayne	116,012	422,219	1,535	10,039	14,600	42,912	132,147	475,170
Total	48,542,451	293,921,884	4,273,864	25,639,359	2,117,594	4,383,192	54,933,909	323,944,435

[1] Value given for shipments is value at which coal left possession of producing company and does not include margins of separately incorporated sales companies.
[2] Counties producing dredge coal only.

TABLE 23.—*Culm-bank coal put through breakers, 1941–45, by fields, in net tons*

Year	Northern	Eastern Middle	Western Middle	Southern	Total
1941	113,000	57,000	519,000	387,000	1,076,000
1942	291,000	420,000	1,413,000	524,000	2,648,000
1943	[1 2] 630,000	1,088,000	2,102,000	1,208,000	[1] 5,028,000
1944	[2] 1,156,000	744,000	2,528,000	1,700,000	6,128,000
1945	[1 2] 996,000	[1] 699,000	2,335,000	2,206,000	[1] 6,236,000

[1] Includes some washery coal.
[2] A small quantity of culm-bank coal was put through breakers in Sullivan County.

Interregional variation in sizes.—The relative yield of domestic and steam sizes of anthracite in the three regions is greatly affected by geologic conditions, mining methods, and the quantity of culm-bank coal recovered.

In 1945, the breaker output of the Wyoming region consisted of 71.7 percent domestic and 28.3 percent steam sizes; of the Lehigh region, 56.7 percent domestic and 43.3 percent steam sizes; and of the Schuylkill region, 52.8 percent domestic and 47.2 percent steam sizes.

Table 21 shows shipments of anthracite, by regions and sizes. Table 24 shows percentages, by regions, of various sizes in relation to total breaker product.

Historical statistics.—Table 25 presents pertinent historical data on the Pennsylvania anthracite industry 1890–1945.

TABLE 24.—*Sizes of Pennsylvania anthracite shipped from breakers, 1943–45, by regions, in percent of total*

[Note that shipments of dredge and washery coal are not included]

[1] U. S. Department of Commerce.
[2] Prior to 1913 the figures of consumption take no account of producers' stocks, there being no data available for this item.
[3] Data first collected in 1911.
[4] Data first collected in 1915.
[5] Data first collected in 1929.
[6] As reported by the Commonwealth of Pennsylvania, Department of Mines.
[7] Data not available.
[8] Includes some "bootleg" coal purchased by legitimate operators and prepared at their breakers.
[9] Output per man per day calculated on legitimate tonnages only; "bootleg" purchases excluded.

AVERAGE VALUE AND SALES REALIZATION

The average realization figures in this study represent value at the breaker, washery, or dredge reported by the operating companies. The company is requested to "estimate value of the product not sold" and to "exclude selling expenses" in making its report. From this it will be seen that when a producing concern sells its output to a separately organized sales company the value reported will exclude the margin of the sales company and may therefore be somewhat less than the circular price at which the coal is placed on the general market. This fact should be borne in mind in considering the variations in value among different regions for the same sizes of coal, as shown in the tables.

The average sales realization per net ton on breaker shipments was $6.26 in 1945, compared with $5.91 in 1944—a 6-percent increase. (See table 26.)

With the inclusion of local sales, colliery fuel, washery coal, and dredge coal the average value per net ton of the total 1945 production is $5.90, compared with $5.57 in 1944. (See table 27.)

TABLE 26.—*Average sales realization per net ton on Pennsylvania anthracite shipments from breakers, 1943–45, by regions and sizes*

[Value does not include margins of separately incorporated sales companies]

Size	Lehigh region			Schuylkill region			Wyoming region		
	1943	1944	1945	1943	1944	1945	1943	1944	1945

[1] Quantity of Lump included is insignificant.

TABLE 27.—*Average value per ton of Pennsylvania anthracite shipments, local sales, colliery fuel, and total production, 1944–45, by regions* [1]

[Note that values in this table include washery and dredge coal]

Region	1944				1945			
	Shipments	Local sales	Colliery fuel	Total production	Shipments	Local sales	Colliery fuel	Total production
Lehigh	$5.56	$6.54	$2.85	$5.51	$5.84	$7.06	$3.15	$5.83
Schuylkill	5.14	4.78	1.99	5.08	5.52	4.74	2.14	5.42
Wyoming	6.28	5.90	1.69	5.99	6.65	6.41	1.85	6.33
Total, excluding Sullivan County	5.71	5.65	1.91	5.57	6.06	6.00	2.07	5.90
Sullivan County	5.13	5.92		5.25	5.56	5.90	2.92	5.63
Grand total	5.71	5.65	1.91	5.57	6.05	6.00	2.07	5.90

[1] Value given for shipments is value at which coal left possession of producing company and does not include margins of separately incorporated sales companies.

LABOR STATISTICS

A labor shortage of several thousand men characterized the Pennsylvania anthracite industry in 1945, when the average number of men working was 72,842—a 6-percent decrease from the 77,591 men employed in 1944. With cessation of hostilities, the labor outlook improved, and it is expected that in 1946 the average number of men employed in the industry will increase.

The employment statistics in this chapter do not include workers in "bootleg" coal mining conducted in the Southern and Western Middle fields of the anthracite regions. According to the Anthracite Committee, 10,762 men were working 3,006 "bootleg" holes in March 1941, and in March 1946 a comparable survey revealed 1,939 men employed in 526 holes. Although these workers are not included in the employment data, the coal produced by some of them was purchased (260,342 net tons) by the recognized industry for preparation and shipment to market, and coal so purchased is included in the production tables of this chapter. Complete employment data for the "bootleg" holes from which this coal was produced are not available. In calculating the output per man per day, therefore, the tons of "bootleg" coal purchased by the recognized industry were deducted from the total tonnage reported by the operators, and the resulting legitimate production was then used to calculate the output per man per day. It is true that part of the time of the men employed at the preparation plants of the recognized companies was used to prepare this purchased coal for market; however, on a per-ton basis this time is insignificant, and its omission will not detract materially from the validity of the result obtained.

See tables 28 and 29 for details on labor statistics.

TABLE 28.—*Men employed and days worked at operations producing Pennsylvania anthracite in 1945, by regions*[1]

[Includes operations of strip contractors]

EQUIPMENT AND METHODS OF MINING

Mechanical loading.—The quantity of anthracite loaded mechanically underground decreased 7 percent in 1945 from 1944, while hand-loaded tonnage declined 22 percent. Details are shown in tables 30 to 32.

Figure 2 illustrates graphically the trend of underground mechanical and hand loading and of stripping in the Pennsylvania anthracite regions, 1928–45.

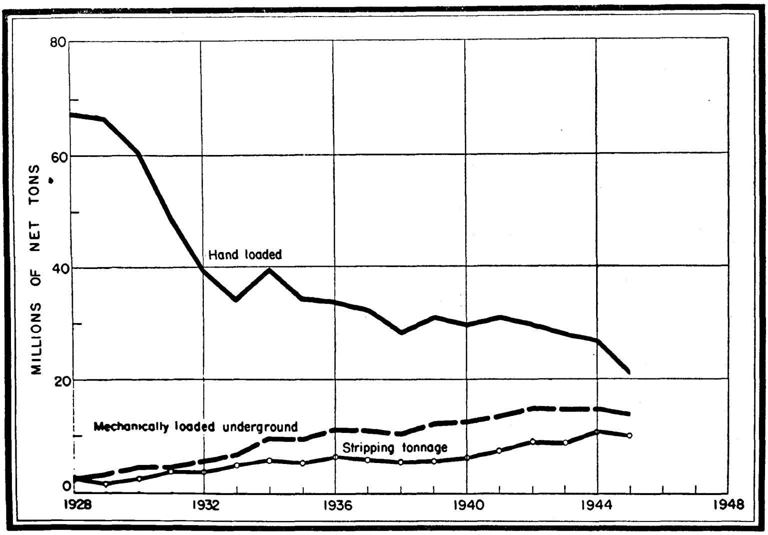

FIGURE 2.—Trend of mechanical loading, hand loading, and stripping of Pennsylvania anthracite 1928–45.

Strip-pit operations.—The heavy demand for anthracite throughout the war caused a rapid expansion of strip-pit activities, and the tonnage obtained by this method of mining increased from 14 percent of the total fresh-mined output in 1941 to 22 percent in 1945. As the output per man per day from strip mines is much larger than that in underground mines, production from this source alleviated considerably the shortage of anthracite occasioned by the scarcity of other space heating fuels. Much difficulty was experienced by the strip-pit operators in obtaining equipment, such as draglines, power shovels, trucks, and other supplies used in open-pit operations. It is expected that this condition will improve the latter part of 1946, and output from strip pits in that year should be considerably greater than production from this source in 1945. Details on strip-pit operations are given in table 33.

Figure 3 illustrates graphically the production of anthracite from strip pits, by regions, 1928–45.

Cutting machines.—The quantity of anthracite cut by machines declined 9 percent in 1945 from 1944. Details are shown in table 34.

Dredge coal.—During the war period coal recovered from the streams draining the Pennsylvania anthracite regions played an important part in alleviating shortages of industrial coal in the markets adjacent to the anthracite fields. The dredging industry reached a peak in 1941 when 1,517,563 net tons of anthracite were taken from the river and creek beds; in 1945 river coal totaled 1,205,226 tons. For details, see table 35.

TABLE 35.—*Pennsylvania anthracite produced by dredges in 1945, by rivers*

River (including tributaries)	Net tons	Value	
		Total	Average
Lehigh	41,409	$70,439	$1.70

	1,205,226	1,924,148	1.60

FOREIGN TRADE

The demand for anthracite in Canada and other foreign countries in 1945 far exceeded the supply, and exports from the United States would have been much greater had more coal been available in this country. Exports of anthracite in 1945 totaled 3,691,247 net tons, and of this total 3,393,131 tons (92 percent) were destined to Canada. (See tables 36 and 37.)

Canadian market.—Coal and lignite production in Canada in 1945 decreased 3 percent from 1944, and coke production also declined approximately 3 percent. Imports of anthracite decreased 23 percent from 1944, but imports of bituminous and subbituminous coal declined only 14 percent. Coal available for consumption in 1945 was 11 percent less than in 1944. See table 38 for coal and coke statistics in Canada.

COKE AND BYPRODUCTS

By J. A. De Carlo, J. A. Corgan, and Maxine M. Otero

SUMMARY OUTLINE

SUMMARY

The extraordinary activity in the coke industry in the United States during the period of World War II subsided markedly following the surrender of Japan in August 1945, and total output of byproduct and beehive coke for the year declined 9 percent from the record set in 1944. Production from byproduct ovens amounted to 62,094,288 net tons and from beehive ovens 5,213,893 tons, reductions of 7 percent and 25 percent, respectively, from the 1944 figures. When measured by peak 1944 wartime production output showed a severe decline, but when compared with former peacetime years it was substantially higher. The decline in 1945 was attributable not only to the abrupt transition from war to peace production following VJ-day but also to mine stoppages in October which curtailed shipments of bituminous coal to coke plants; failure of old byproduct-coke-oven batteries that had been pushed hard during the war; and the closing of a number of beehive-coke plants because of labor difficulties and lack of coal.

As coke production is geared closely to iron and steel operations, cut-backs in pig-iron requirements in 1945 naturally affected the activity of coking operations. As a consequence, byproduct-coke plants connected with iron and steel works, or "furnace" plants, operated at 83 percent of productive capacity compared with 93 percent in 1944, and nonfurnace or "merchant" plants dropped from 94 to 88 percent of capacity.

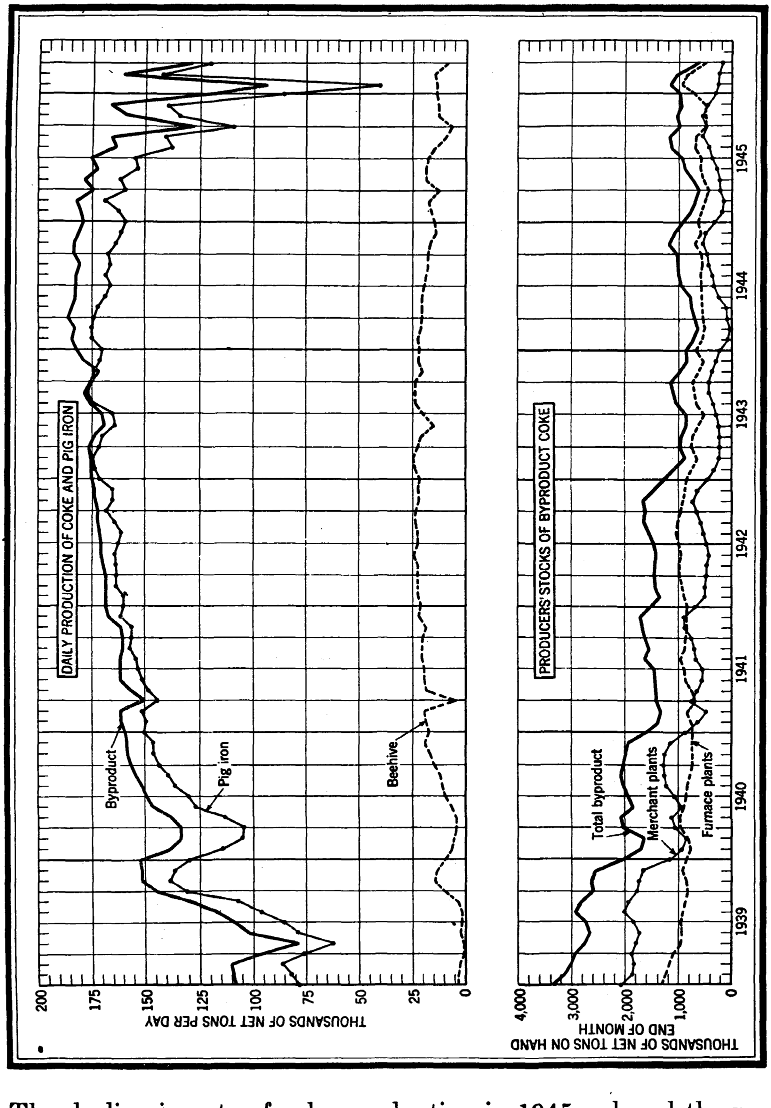

FIGURE 1.—Average daily production of beehive and byproduct coke and pig iron and producers' stocks of byproduct coke, 1939-45, by months.

The decline in rate of coke production in 1945 reduced the requirements of coking coal, and byproduct and beehive ovens carbonized 7 percent and 25 percent, respectively, less coal than in 1944. Although coking-coal requirements were substantially lower than in 1944, supplies of such coal in 1945 were inadequate, and it was necessary for the Solid Fuels Administration for War to continue regulatory measures promulgated in the war years to assure equitable distribution of byproduct-coking coal. These measures permitted that agency to divert byproduct or special purpose coal from industrial plants using this coal for steam raising and also from coke plants with adequate stock piles to coke plants with an insufficient supply to maintain maximum operation. The Bureau of Mines continued to work closely with the Solid Fuels Administration for War in collecting and compiling statistical data relating to requirements, consumption, stocks, and days' supply of coking coals at byproduct-coke plants.

The increase in Office of Price Administration maximum prices applicable to sales of bituminous coal shipped from mines in 1945 resulted in a sharp gain in the cost of coal delivered to coking plants. The average cost per net ton for bituminous coal charged into byproduct ovens advanced 4 percent over 1944 to $5.29 and approached the peak cost of $5.40 a ton in 1920. The cost of bituminous coal charged into beehive ovens soared to a new peak of $3.51 per ton, a gain of 6 percent over the previous maximum registered in 1944.

The disposal of coke for use in blast furnaces decreased 11 percent during 1945 and reflected the decline in steel-plant operations. The strong demand for coke for other purposes (for use in iron foundries, manufacturing water gas and producer gas, and miscellaneous industrial purposes) continued throughout the year, and shipments increased slightly over the 1944 total. Although coke shipments for domestic or household use increased 4 percent during the first 9 months of 1945 over the corresponding period of 1944, this gain was offset in part in the last quarter, and shipments for the entire year were less than 1 percent higher than the 1944 total (table 2).

According to data compiled by the Bureau of Mines from records of the United States Department of Commerce, export shipments of coke in 1945 increased 71 percent over 1944 and were the highest reported since 1918. This sharp increase was due primarily to the heavy shipments to Canada of reclaimed beehive coke recovered from huge waste banks in western Pennsylvania. It is estimated that shipments of reclaimed coke in 1945 constituted 20 percent of the total exports of all coke. Notwithstanding this large tonnage of reclaimed coke, export shipments of byproduct and beehive coke increased sharply and were well above those of recent years. Imports of coke were negligible and represented less than one-tenth of one percent of the total consumption of coke in the United States.

Because of the reduction in the quantity of coal carbonized compared with 1944, output of crude tar, ammonia (all forms), crude light oil, and coke-oven gas decreased 9 percent, 7 percent, 8 percent, and 10 percent, respectively, in 1945. However, yields of these byproducts per ton of coal charged varied only slightly from the 1944 figures (table 2). The value realized through their sale (excluding tar used by producers) declined 7 percent from 1944 and totaled $172,138,205. The value of all coke and breeze produced and byproducts sold decreased 5 percent from 1944 and totaled $699,216,012.

TABLE 1.—*Salient statistics of the byproduct and beehive coke industry in the United States in 1945*

	Byproduct	Beehive	Total

Value	$19,539		$19,539
For manufacture of water gas:			
Net tons	380,977		380,977
Value	$2,994,546		$2,994,546
For other purposes:			
Net tons	169,269	459	169,728
Value	$1,204,260	$3,833	$1,208,093

See footnotes at end of table.

TABLE 1.—*Salient statistics of the byproduct and beehive coke industry in the United States in 1945*—Continued

	Byproduct	Beehive	Total
Disposal of coke—Continued			
Sold to other consumers—			
For blast-furnace use:			
Net tons	2,026,012	2,126,367	4,152,379
Value	$15,937,579	$15,687,901	$31,625,480
For foundry use:			
Net tons	2,334,827	254,762	2,589,589
Value	$26,814,107	$2,155,918	$28,970,025
For manufacture of water gas:			
Net tons	1,076,144	187,697	1,263,841
Value	$8,927,407	$1,440,222	$10,367,629
For other industrial use:			
Net tons	1,852,871	433,901	2,286,772
Value	$15,517,471	$3,311,237	$18,828,708
For domestic use:			
Net tons	6,574,526	200,982	6,775,508
Value	$57,124,329	$1,461,402	$58,585,731
Disposal of screenings or breeze:			
Used by producer—			
For raising steam:			
Net tons	3,405,509	22,364	3,427,873
Value	$9,189,234	$21,492	$9,210,726
To make producer or water gas:			
Net tons	57,573		57,573
Value	$208,663		$208,663
For other purposes:			
Net tons	712,621	3,458	716,079
Value	$1,843,516	$6,355	$1,849,871
Sold:			
Net tons	1,088,890	89,505	1,178,395
Value	$2,998,426	$63,068	$3,061,494
Average receipts per ton sold (merchant sales):			
Furnace coke	$7.87	$7.38	$7.62
Foundry coke	$11.48	$8.46	$11.19
Water-gas coke	$8.30	$7.66	$8.20
Other industrial coke	$8.37	$7.63	$8.23
Domestic coke	$8.69	$7.27	$8.65
Screenings or breeze	$2.75	$0.70	$2.60
Stocks on January 1, 1946:			
Furnace net tons	425,438	2,455	427,893
Foundry do	24,509	270	24,779
Domestic and other do	477,052	2,089	479,141
Screenings or breeze do	1,022,561	20	1,022,581
Exports do	(1)	(1)	1,478,746
Imports do	(1)	(1)	51,964
Calculated consumption do	(1)	(1)	66,074,271
Byproducts produced:			
Tar gallons	696,307,311		696,307,311
Ammonium sulfate or equivalent pounds	1,749,437,753		1,749,437,753
Gas M cubic feet	904,476,118		904,476,118
Burned in coking process percent	37.27		37.27
Surplus sold or used do	61.28		61.28
Wasted do	1.45		1.45
Crude light oil gallons	245,687,253		245,687,253
Yield of byproducts per ton of coal:			
Tar do	7.95		7.95
Ammonium sulfate or equivalent pounds	20.22		20.22
Gas M cubic feet	10.33		10.33
Crude light oil gallons	2.84		2.84
Value of byproducts sold:			
Tar:			
Sold	$21,827,890		$21,827,890
Used by producer	$5,905,645		$5,905,645
Ammonium sulfate or equivalent	$22,090,179		$22,090,179
Gas (surplus)	$87,745,022		$87,745,022
Crude light oil and derivatives	$29,448,732		$29,448,732
Other byproducts [2]	$11,026,382		$11,026,382
Total value of coke and breeze produced and byproducts sold [3]	$660,769,562	$38,446,450	$699,216,012

[1] Not separated.
[2] Includes naphthalene, tar derivatives, and miscellaneous byproducts.
[3] Includes value of tar used by producer.

TABLE 2.—*Statistical trends of the byproduct and beehive coke industry in the United States, 1937 and 1942–45*

	1937	1942	1943	1944	1945
Coke produced:					
Byproduct net tons	49,210,748	62,294,909	63,742,676	67,064,795	62,094,288
Beehive do	3,164,721	8,274,035	7,933,387	6,973,022	5,213,893
Total do	52,375,469	70,568,944	71,676,063	74,037,817	67,308,181
Percent from byproduct ovens	94.0	88.3	88.9	90.6	92.3
Stocks of coke, end of year net tons	2,595,287	1,489,049	862,100	1,124,685	931,813
Exports, all coke do	526,683	839,582	994,607	866,835	1,478,746
Imports, all coke do	286,364	108,782	98,127	63,004	51,964
Consumption, calculated, all coke do	51,271,929	70,107,181	71,406,532	72,971,401	66,074,271
Disposal of coke, all coke sold or used:					
Furnace coke net tons	36,751,969	55,491,570	57,690,160	57,481,353	51,002,921
Foundry coke do	2,038,822	2,591,576	2,606,889	2,511,854	2,636,731
Other industrial (including producer and water gas) net tons	4,597,894	6,598,842	6,999,884	6,978,062	6,937,553
Domestic coke do	8,107,518	6,061,694	4,885,528	6,717,543	6,775,508
Ovens:					
Byproduct, in existence, end of year	12,718	13,303	14,253	14,580	14,510
Beehive, in existence, end of year	12,194	16,295	17,666	16,318	12,179
Byproduct, under construction, end of year	259	1,327	528	180	335
Cost of coal charged, byproduct ovens, average per ton	$3.74	$4.38	$4.75	$5.08	$5.28
Prices of coke:					
Average spot price of Connellsville furnace coke, f. o. b. ovens	$4.29	$6.01	$6.46	$7.00	$7.29
Average realization on byproduct coke sold (merchant sales):					
Furnace coke	$4.34	$6.58	$7.26	$7.59	$7.87
Foundry coke	$8.47	$10.15	$10.17	$11.03	$11.48
Other industrial (including water gas)	$6.08	$7.30	$7.43	$8.12	$8.35
Domestic	$6.53	$7.88	$8.21	$8.63	$8.69
Yield of byproducts per ton of coal charged:					
Tar gallons	8.67	8.41	8.11	8.13	7.95
Ammonium sulfate or equivalent pounds	21.84	20.85	20.32	20.29	20.22
Light oil gallons	2.86	2.88	2.83	2.87	2.84
Surplus gas sold or used M cubic feet	6.66	6.65	6.59	6.58	6.33
Average gross receipts for byproducts, per ton of coke produced:					
Tar sold and used	$0.502	$0.473	$0.463	$0.458	$0.447
Ammonia and its compounds	$0.326	$0.348	$0.355	$0.324	$0.356
Light oil and its derivatives (including naphthalene)	$0.435	$0.501	$0.546	$0.552	$0.503
Surplus gas sold or used	$1.483	$1.426	$1.390	$1.403	$1.413
Total byproducts including breeze	$2.974	$3.100	$3.123	$3.102	$3.069

WAR AGENCY REGULATIONS

Virtually all wartime allocation controls on coke and related products were rescinded by the War Production Board immediately following the surrender of Japan. This action was taken to facilitate movement of these materials to plants engaged in manufacturing civilian goods. Beginning with the revoking of allocation control on pyridine on August 1, 1945, control over coke was rescinded August 24; coal tar, benzol, toluol, xylol, naphthalene, tar-acid oil, carbolates, phenols, and substituted phenols August 31; and ammonium sulfate September 30. In October, because of the lack of coking coal, the WPB reinstated control over coke by issuing Direction 4 to Priorities Regulation 32 on October 10, 1945, effective October 15, 1945. This direction limited inventories on coke to a 20-day supply and remained in effect until November 15, 1945.

Government control over the distribution of coking coals (special purpose coals) remained under the jurisdiction of the Solid Fuels Administration for War during 1945. Regulation 24, issued January 1945, prohibited the shipment and receipt of special purpose coals during the fuel year, 1945–46, unless such coal was covered by contract entered into before February 1, 1945, and specifically approved by SFAW or pursuant to written permission or a direction issued by that agency. Coke plants in 1945 were again assured of first preference in the distribution of bituminous coal under provisions of SFAW Regulation 27, issued March 14, 1945. Control over the distribution of domestic coke within the United States was revoked on November 1, 1945, under terms of SFAW Order 27, issued October 22, 1945.

Maximum price regulations covering coke and related products in effect at the end of 1944 were continued in 1945, with several upward revisions in the ceiling prices of byproduct and beehive coke. On May 26, 1945, Amendment 5 to MPR 77 was issued by the OPA, raising the price of beehive furnace coke produced in hand-drawn and machine-drawn ovens, respectively, located in the Connellsville district,[1] \$0.25 and \$0.50 per net ton to \$8.00 and \$7.50 f. o. b. ovens. Maximum prices for beehive-oven coke, other than furnace coke, were adjusted by the same amounts.

To compensate for increased manufacturing costs of byproduct coke, the OPA issued Amendment 4 to MPR 29 on August 7, 1945, which increased the average sales price of byproduct coke \$0.40 per ton.

TECHNOLOGIC DEVELOPMENTS

Continued and expanded interest in coal carbonization in 1945 is shown by the number of new developments reported. A recent development in oven construction was the Koppers "saddle brick" designed by the Koppers Co., Inc., Pittsburgh, Pa., to increase the strength of walls. The Wilputte Coke Oven Corp., New York, N. Y., reported the following improvements in coke-oven design: Thicker oven tops, advanced equipment for the mechanical charging of coal, correct location of charging holes, reversible compensating mains to increase yields and improve the quality of byproducts,[2] and improved self-sealing oven doors and door-handling equipment.[3]

The Bureau of Mines continued to cooperate with industry in developing means to maintain and improve coke quality in the face of the coking-coal shortage. Special studies were made by Bureau engineers on the carbonization properties of low- and medium-volatile bituminous coal that might be used to increase the Nation's supply of proved coking coal, reserves of which are being depleted rapidly.[4] Studies on coal relating to carbonizing properties, plasticity, expansion, oxidation, and control of bulk density of coke-oven charges were continued.[5]

Tests on the utilization of Utah coal and blends of that coal with Oklahoma low-volatile coal and char for the production of satisfactory blast-furnace coke were conducted at Fontana, Calif.[6]

The Illinois State Geological Survey reported that an electrically heated slot-type test oven was used throughout the year in a program designed to determine suitable blends of Illinois coal for metallurgical coke production. The yields and properties of the coke and byproducts recovered from this small experimental oven compare closely with those obtained by carbonizing the same coal in commercial slot-type ovens. Because of the rapid depletion of the reserves of high-rank eastern bituminous coking coal and transportation problems, the Illinois Geological Survey, aided by the Office of Production Research and Development, WPB, initiated this research program to study the problem of substituting midwestern coals for a portion of the eastern high-volatile coals now being carbonized in midwestern coke ovens.[7]

Ammonia-recovery systems of a new type for the production of ammonium sulfate crystals of controlled size are reported by Wethly [8] and Schulte.[9] The systems consist essentially of a low-differential-classification saturator in which more than 99.8 percent of the ammonia is removed from the gas, with less seal depth. It is maintained that operating costs are lower than those for a normal saturator and that the product compares satisfactorily with the best grades of sulfate produced by synthetic ammonia plants.

A method for purifying coke-oven gas with respect to the separation and recovery of hydrogen sulfide was developed by H. A. Gollmar and is described in United States Patent 2,379,076, issued June 26, 1945, and assigned to the Koppers Co., Inc. In this sulfur-recovery process, heat from the raw coke-oven gas is used in the actification step, resulting in a substantial reduction in steam consumption and in the load of the primary coolers.

The Mellon Institute of Industrial Research, in its Thirty-third Annual Report, covering the year ended February 28, 1946,[10] summarized studies conducted on problems concerning chemicals obtained in byproduct-coking operations, including the recovery of compounds from coke-oven gas, the elimination of wastes, the improvement of quality of products, and the industrial uses of coal chemicals.

Among the new developments reported were a new process for the manufacture of sodium cyanide; a process for the separation and recovery of ammonium thiosulfate and ammonium thiocyanate from plant waste solutions; and the construction of a universal-type 3-inch fractionating column, considered the most effective device of this kind and size ever built, for use in tar distillation.

SCOPE OF REPORT

This report contains final annual data for 1945 on the production of both byproduct and beehive coke, coke breeze, coal chemicals, and city-gas-company statistics. In accordance with usual procedure, most of the tables herein include comparable data for 3 or 4 preceding years. In addition to the customary statistics on byproduct and beehive coke, there are included salient statistics on low- and medium-

[7] Reed, Frank H., Jackson, Harold W., and Henline, P. W., Coke from Illinois coal: Ind. Eng. Chem., vol. 37, No. 6, pp. 360–366.

temperature carbonization (table 3) and similar data for gas-house coke (table 4). However, since only coke made by high-temperature carbonization of coal in byproduct and beehive ovens is suitable for metallurgical purposes, statistics in this report are confined thereto unless otherwise specified. Coke is also made by other processes not included in this report, including the refining of petroleum and of crude tar. The production of petroleum coke in the United States in 1945 increased 12 percent over 1944 and totaled 2,023,000 net tons; output of coal-tar-pitch coke was 87,000 tons. Because of the extremely low ash content of petroleum and pitch coke, it is in demand as a source of comparatively pure carbon and is employed widely in the manufacture of carbon electrodes. A major proportion of petroleum coke is usually disposed of locally for miscellaneous purposes or domestic fuel.

The standard unit of measurement in the coke industry is the short or net ton of 2,000 pounds and unless otherwise specified is employed throughout this chapter.

MEDIUM- AND LOW-TEMPERATURE COKE

TABLE 3.—*Salient statistics of medium- and low-temperature carbonization plants in the United States in 1945*

Coke produced:		
Net tons		190,089
Value		$1,072,374
Screenings or breeze produced:		
Net tons		29,451
Value		$52,760
Coal carbonized:		
Net tons		327,480
Value		$577,385
Average per ton		$1.76
Average yield in percent of coal carbonized:		
Coke		58.05
Breeze		15.81
Ovens and retorts:		
In existence December 31		31
Annual coke capacity December 31	net tons	185,100
Disposal of coke:		
Sold to other consumers—		
For industrial use:		
Net tons		10,841
Value		$65,099
For domestic use:		
Net tons		118,780
Value		$729,091
Disposal of screenings or breeze:		
Sold:		
Net tons		32,462
Value		$57,745
Average receipts per ton sold:		
Industrial coke		$6.00
Domestic coke		$6.14
Screenings or breeze		$1.78
Stocks on January 1, 1946:		
Domestic and other coke	net tons	56,056
Screenings or breeze	do	33,700
Byproducts produced:		
Tar	gallons	3,200,332
Gas	M cubic feet	1,144,982
Burned in coking process	percent	55.53
Surplus sold or used	do	20.37
Wasted	do	24.10
Yield of byproducts per ton of coal:		
Tar	gallons	9.77
Gas	M cubic feet	6.15
Value of byproducts sold:		
Tar and its derivatives		$273,989
Gas (surplus)		$37,890
Total value of coke and breeze produced and byproducts sold		$1,437,013

GAS-HOUSE COKE

TABLE 4.—*Salient statistics of the coal-gas industry in the United States in 1945*

	Horizontal retorts	Vertical retorts and gas ovens	Total
Coke produced:			
Net tons	362, 381	496, 865	859, 246
Value	$2, 916, 316	$4, 365, 879	$7, 282, 195

1945	62.1	5.2	67.3	92.3	14,510	12,179	335	95.7	70.4	7.56	38	470	191	699

[1] Value for tar up to and including 1917 represented that of tar "obtained and sold," which did not always include value of tar used by producer. Beginning with 1918, tar used by producer is specifically included. Value of breeze produced at byproduct plants is included for those years for which it was reported, namely, 1916, 1917, and 1919–45. For other byproducts, only value of those sold is included. Value of breeze produced at beehive plants is not included, as it has usually been much less than a million dollars.
[2] No accurate data on value of the byproducts available.

MONTHLY AND WEEKLY PRODUCTION

TABLE 6.—*Byproduct, beehive, and total coke produced in the United States, 1937 and 1943–45, by months and average per day, in net tons* [1]

Month	1937 Total	1937 Daily average	1943 Total	1943 Daily average	1944 Total	1944 Daily average	1945 Total	1945 Daily average

[1] Before 1941 daily average production of beehive coke was calculated by subtracting Sundays and holidays in each month; 1942–45 daily average has been calculated by dividing total monthly production by total number of days in month.

TABLE 7.—*Beehive coke produced in the United States in 1945, by weeks*

[Estimated from railroad shipments]

Week ended—	Net tons	Week ended—	Net tons	Week ended—	Net tons

PRODUCTION BY FURNACE AND NONFURNACE PLANTS

The terms "furnace" and "nonfurnace" plants, as used in this report, apply to byproduct-coke plants only. Usually nearly all production of coke at "furnace" plants, which, as the name implies, are plants associated with iron and steel works, is consumed in blast furnaces near the ovens and does not enter the open market. For this reason, output of coke from this group of plants ordinarily follows closely the activity in the iron and steel industry; and, depending on the demand for metallurgical fuel, production tends to fluctuate more than that of "nonfurnace" plants. In 1945 production of coke at 53 furnace plants decreased 8 percent from the record output from the same number in 1944. Although production at furnace plants declined sharply in 1945, output was about 69 percent higher than the average output for the 1935–39 period and illustrated the impact of war on this group of plants.

"Nonfurnace" or "merchant" plants include several that are affiliated with local iron furnaces but produce more coke than the furnace can consume and therefore depend on the sale of foundry, domestic, and other coke; plants that sell their entire output on the competitive market; plants affiliated with alkali and chemical works; and a number of plants that were constructed to supply city gas, although not classed as public utilities, and sell their coke for domestic, industrial, and metallurgical use. Because of their diversified activities, output for this group is relatively stable, as illustrated in table 10. Production from 34 nonfurnace plants in 1945 declined only 5 percent from the 1944 figure and was only 14 percent higher than the 1935–39 prewar average.

TABLE 10.—*Number and production of byproduct-coke plants connected with iron furnaces and of other plants in the United States, 1913, 1918, 1937, and 1944–45*

Year	Number of active plants		Coke produced (net tons)		Percent of production	
	Furnace plants	Other plants	Furnace plants	Other plants	Furnace plants	Other plants

PRODUCTION BY STATES AND DISTRICTS

Byproduct coke.—Production of byproduct coke in 1945 declined in all but 2 of the 22 producing States, the percentage of decreases being higher in the States dominated by furnace interests. California recorded the highest relative decrease—25 percent, followed by Texas with 24 percent; Indiana, 11 percent; Pennsylvania, 10 percent; and Ohio, 9 percent. A 26-percent increase was noted in New Jersey, where new oven installations in the latter part of 1944 increased productive capacity. Tennessee showed a slight increase over 1944, with a gain of 8 percent. Notwithstanding a decline in production from 1944 of nearly 2 million tons, Pennsylvania maintained its position as the ranking coke-producing State, accounting for one-fourth of the total byproduct-coke output in 1945. Following Pennsylvania, in order of coke production, were Ohio, Indiana, New York, and Alabama. These 5 States supplied 70 percent of the total coke output, the same proportion as in 1944.

Beehive coke.—The production of beehive coke in all producing regions declined sharply in 1945. Although Pennsylvania continued its dominance in this field supplying nearly 88 percent of the total beehive-coke output in 1945, production in this State declined 26 percent from the 1944 figure and was 37 percent lower than the maximum production recorded during World War II in 1942. Production in West Virginia, the second ranking State, decreased 24 percent from 1944, and decreases of 21, 11, and 80 percent, respectively, were noted for the States of Virginia, Colorado, and Utah. Output in Kentucky, the only State recording an increase in beehive-coke production over 1944, advanced from 68,076 to 74,404 net tons, or about 9 percent.

NUMBER AND TYPE OF OVENS

Byproduct ovens.—The wartime expansion in byproduct-coking capacity that reached a peak in 1943 when 953 new byproduct-coke ovens were completed subsided sharply in 1945, when only 106 new ovens were placed in operation in December 1945, by the Jones & Laughlin Steel Corp. at its Aliquippa, Pa., steel plant. Information received by the Bureau of Mines from coke producers indicated that 335 new ovens with an annual coke capacity of 1,414,000 tons were under construction on December 31. Because the unprecedented demands for metallurgical and industrial coke during the war period made it necessary for all active plants to operate at maximum productive capacity, deterioration and oven failure, particularly among the older batteries, increased, and in December 516 ovens were idle at active plants. A recapitulation of all byproduct ovens in existence at the end of 1945 revealed that 8 percent of all ovens were more than 30 years old, 42 percent more than 20 years old, 21 percent more than 10 years old, and 29 percent 10 years old or less. As it has been generally agreed that the average life of a byproduct-coke oven is about 20 years, extensive repairs and rebuilding will be necessary, unless new ovens are constructed, to maintain adequate capacity to meet future requirements of coke.

Beehive ovens.—The effect of war-contract cancellations following VE-day and later VJ-day and other economic factors already referred to in this report is reflected in the number of beehive ovens shut down or permanently abandoned in 1945. Of the 16,318 ovens in existence on January 1, 1945, 4,505 were dismantled or permanently abandoned during the year, and at the end of the year only 12,179 were reported in existence. The average number of beehive ovens in blast during the year varied from a high of 10,281 in July to a low of 7,518 in October, when mine stoppages hampered the flow of coal to the ovens. In December the active ovens numbered 8,317, and the large requirements for metallurgical coke in the reconversion program indicate that the number of beehive ovens that will operate in 1946 will vary only slightly from this total.

CAPACITY OF BYPRODUCT-COKE PLANTS

Tables 18 and 19 show the potential maximum annual coke capacity of all byproduct ovens in existence, whether idle or active, and the relationship between capacity and production for 1937 and 1942–45. The basis upon which potential maximum capacity of a coke plant is established is the minimum coking time at which the ovens can be operated to produce coke with qualities suitable for the use for which it is intended. The operators are requested to report the potential maximum annual coke capacity of their ovens "of grades you aim to produce, that can be obtained with all conditions favorable and all ovens active." Potential maximum annual coke capacity, as thus stated, is subject to change from year to year, depending on the age and condition of the ovens, character and quality of coal charged, and economic and labor conditions.

The annual capacity of the 88 byproduct-coke plants in existence on December 31, 1945, both idle and active, decreased 1 percent from the 1944 figure (table 18). The annual capacity of "furnace" plants was 56,719,500 tons, a slight decrease from 1944, but an increase of 21 percent over the 1937 capacity. "Merchant" or nonfurnace plants ended the year with an annual capacity of 14,679,600 tons, compared with 15,344,700 tons in 1944. The operating ratio in 1945 showed an appreciable drop, especially after termination of the war in August, and for the year was 84.3 percent of capacity compared with 93.1 percent in 1944 (table 19).

TABLE 18.—*Potential maximum annual coke capacity of all byproduct-coke plants in existence in the United States, 1937 and 1942–45*

Year	Plants	Ovens	Potential maximum annual coke capacity (net tons)	Percent of change from 1937

[1] Capacity of all ovens in existence, whether active or idle, based upon maximum daily capacity times days in month.

QUANTITY AND COST OF COAL CHARGED

Tables 20 and 21 show the quantity and cost of coal charged into byproduct and beehive ovens, by months and by States, in 1945. The total quantity charged into byproduct ovens decreased 7 percent in 1945 from 1944, and for beehive ovens the decline was 25 percent. Although some slackening in the monthly consumption of coking coal was evident before VJ-day, the average rate for the first 7 months was only slightly less than for the peak in 1944. However, with the end of the war in the Pacific and subsequent labor difficulties and reconversion problems, average monthly consumption declined from 8.4 million tons for the first 7 months to 7.3 million tons for the last 5 months.

Pennsylvania's position as the leading consumer of coking coal remained unchallenged, carbonizing nearly 25 percent of all byproduct coal and more than 87 percent of the total used in beehive coking. Byproduct ovens in Ohio consumed 15 percent of the total, all of which was shipped from adjoining States; Indiana consumed 12 percent and New York and Alabama 9 percent each.

The average cost of coking coal per ton at byproduct- and beehive-coke plants advanced 4 and 6 percent, respectively, in 1945 over 1944. These increases were caused largely by the wage adjustments granted to bituminous-coal miners in the agreement concluded in April 1945. For individual States where figures can be shown, the greatest increases in the cost of coal charged into byproduct ovens were recorded in Alabama, with a gain of $0.44 per ton, followed by Ohio and West Virginia with $0.24 each, Minnesota $0.17, and Michigan and New York $0.16 each. For States producing beehive coke, the highest rise in coal costs was registered in Pennsylvania, with an increase of $0.21 per ton. The average cost of coal per ton for beehive ovens is much less than that for byproduct ovens, as the former are built at or near the producing mines and therefore benefit from the saving in transportation charges.

PREPARATION AND SOURCE OF COAL

Washed and unwashed coal.—Table 24 shows the quantity of washed and unwashed coal used in the manufacture of coke in 1945. When the coals used in the manufacture of coke contain an undue proportion of ash, sulfur, or other impurities, they are usually cleaned before being charged into coke ovens. Although the reduction of these incidental impurities by cleaning is by no means a normal adjunct to coking operations, more attention is being given to the cleaning of coal because of the rapid depletion of high-quality coking coals. Cleaning of coal to reduce its ash and sulfur content has been practiced by coke producers (according to available data) since 1890, when but 7 percent was washed. In 1945, the quantity of washed coal used in the manufacture of coke was equivalent to 27 percent of the total quantity carbonized, the same proportion as in 1944. Coal cleaned at the mines was used by 32 byproduct- and 12 beehive-coke plants in 1945, and in addition 6 byproduct-coke plants carbonized coal that was cleaned in cleaning plants near the ovens. All coal used for the manufacture of coke in Colorado and most of that in Alabama, California, Tennessee, and Texas was washed.

Sources.—In recent years more and more emphasis has been placed on the sources of high-grade coals of established coking quality in the United States because of their irregular and limited distribution and also because of the rapid rate at which our reserves of such coals are being depleted.[11] Almost any kind of clean coal can be used for ordinary fuel, but the coke industry undoubtedly has the most stringent standards of all major consuming industries, and coals used in the manufacture of coke must be carefully selected.

Coal fields in the Appalachian region, extending from Alabama to Pennsylvania, are the principal sources of coking coal in the United States and in 1945 supplied over 96 percent of all coal carbonized. The ranking States, in tonnage of coal furnished to byproduct-coke plants in 1945, were Pennsylvania, supplying 37 percent, West Virginia 35 percent, Kentucky 13 percent, and Alabama 9 percent. Other States supplying more than a million tons of byproduct coal in 1945 were Virginia and Utah. Of the 87,128,174 tons of coal purchased by coke-oven operators in 1945, more than 61 percent was received from captive mines.

[1] Low-volatile—dry V. M. 22 percent or less and more than 14 percent; medium-volatile—dry V. M. 31 percent or less and more than 22 percent; high-volatile—dry V. M. more than 31 percent.
[2] Less than 0.05 percent.

Blending.—Blending a variety of coking coals before charging into byproduct ovens is widely practiced in the coke industry and is employed primarily to produce coke economically and of a quality satisfactory for the use for which it is intended. This practice also permits the use of coals that have good coking properties but contain some objectionable impurities, such as ash, sulfur, or phosphorus, which would prohibit their use as 100-percent charge into ovens to produce coke to conform with specifications. Further, the mixing of coking coals provides a means of controlling the quality and strength of the coke and the yield of the byproducts and permits flexible operation of byproduct plants with reference to the supply of coking coals.

The majority of coke plants in the United States mix their coals before charging into ovens, and in 1945, 74 of the 87 active plants carbonized coals of different volatile content. High- and low-volatile coals were carbonized by 44 plants; high-, medium-, and low-volatile by 25 plants; high- and medium-volatile by 2 plants; and medium- and low-volatile by 3 plants. A few plants have substituted anthracite fines for low-volatile coal in recent years, and in 1945, 12 plants used anthracite in their coal mix. Of the plants that did not carbonize coals of different volatile content, 10 charged high-volatile and 3 medium-volatile. Table 27 shows the purchase, by States, of the coals used in the manufacture of byproduct coke, classified according to volatile content. In 1945, 66 percent of the total purchases of byproduct coal was high-volatile, 20 percent low-volatile, and 14 percent medium-volatile coal, compared with 67, 28, and 13 percent, respectively, in 1944.

CONSUMPTION OF COKE

The indicated consumption of coke in the United States in 1945, allowing for imports, exports, and changes in producers' stocks, declined 9 percent from the previous maximum in 1944. This decrease was due principally to the sharp reduction in coke consumed in iron furnaces, which, according to the American Iron and Steel Institute, dropped from 57,071,689 tons in 1944 to 50,653,221 tons, a decrease of 11 percent. Consumption of coke for other industrial purposes (in foundries, in nonferrous smelting, in the manufacture of water gas and producer gas, and for miscellaneous uses) and for domestic heating also decreased slightly from 1944. At the close of 1945, however, evidence pointed toward an increase in the consumption of coke for uses other than iron furnaces, particularly in the domestic-coke trade, where consumption was approximately 3 million tons lower than in 1940.

The efficiency of fuel utilization in blast-furnace operations declined for the fourth consecutive year in 1945, and the quantity of coke used per ton of pig iron and ferro-alloys reached the highest figures reported since 1927. According to data compiled by the American Iron and Steel Institute, the quantity of coke used per ton of pig iron produced in 1945 increased 30.2 pounds over 1944; and for pig iron and ferro-alloys, the gain was 29.4 pounds.

TABLE 32.—*Coke consumed in manufacture of pig iron and for other purposes in the United States, 1913, 1918, 1937, and 1944–45, in net tons*

Year	Total production	Imports	Exports	Net change in stocks	Indicated United States consumption [1]	Consumed by iron furnaces [2]		Remainder consumed in other ways	
						Quantity	Percent	Quantity	Percent
1913	46,299,530	101,212	987,395	(3)	45,413,347	37,192,287	81.9	8,221,060	18.1
1918	56,478,372	30,168	1,687,824	(3)	54,820,716	45,703,594	83.4	9,117,122	16.6
1937	52,375,469	286,364	526,683	+863,221	51,271,929	33,571,349	65.5	17,700,580	34.5

1945	67,308,181	51,964	1,478,746	−192,872	66,074,271	50,653,221	76.7	15,421,050	23.3

[1] Production plus imports minus exports, plus or minus decrease or increase, respectively, of net changes in stocks.
[2] From Report of American Iron and Steel Institute. Figures include coke consumed in manufacture of ferro-alloys.
[3] Data not available.

TABLE 33.—*Coke and coking coal consumed per net ton of pig iron made in the United States, 1913, 1918, 1937, and 1943–45*

Year	Coke per net ton of pig iron and ferro-alloys [1] (pounds)	Yield of coke from coal (percent)	Coking coal per net ton of pig iron and ferro-alloys (pounds calculated)	Year	Coke per net ton of pig iron and ferro-alloys [1] (pounds)	Yield of coke from coal (percent)	Coking coal per net ton of pig iron and ferro-alloys (pounds calculated)
1913	2,172.6	66.9	3,247.5	1943	1,834.3	70.0	2,620.4
1918	2,120.7	66.4	3,193.8	1944	1,840.6	70.3	2,618.2
1937	1,830.6	70.3	2,604.0	1945	1,870.0	70.4	2,656.3

[1] From Report of American Iron and Steel Institute; consumption per ton of pig iron only, excluding furnaces making ferro-alloys, was 2,172.6 pounds in 1913, 2,120.7 in 1918, 1,806.7 in 1937, 1,800.6 in 1943, 1,809.8 in 1944, and 1,840.0 in 1945.

FURNACE, FOUNDRY, DOMESTIC, AND OTHER COKE

Disposal, by major uses, of byproduct and beehive coke as reported by producers is shown in tables 34 and 35. As all producers, especially those that sell through middlemen, cannot furnish precise information on the ultimate use for the portion sold, the Bureau asks for a separation of sales to affiliated plants and to other purchasers into the broad classifications "furnace," "foundry," etc., and for the use to which that part of the output consumed by the producers is put. A close business relationship exists between the blast furnaces, which are the largest users of coke, and the coke plants. The proportion of the byproduct coke reported as used by the producers in integrated iron blast furnaces and sales to financially affiliated plants for blast furnace use was 72 percent of the total output, and even this high percentage does not indicate the full extent of the interrelationship of the byproduct coke and iron industry, as 78 percent of the byproduct coke produced in 1945 came from ovens associated with furnaces. Iron blast furnaces in 1945 received 46,910,622 tons of byproduct coke (76 percent of the total coke sold or used by producers), a 9-percent decrease from the record total of 1944. The second largest disposal channel for byproduct coke is the domestic market, supplied principally by "merchant" plants. Sales to this market increased slightly

[1] Comprises 43,936 tons valued at $384,697 used in foundries; 807,926 tons, $5,598,986 used to make producer gas; 1,625,879 tons, $10,998,464 to make water gas; and 325,995 tons, $2,586,805 used for other purposes.
[2] Includes 10,518,776 tons valued at $65,476,552 sold to financially affiliated plants.
[3] Includes 3,206 tons valued at $19,539 sold to financially affiliated plants.
[4] Includes 380,977 tons valued at $2,994,546 for manufacture of water gas and 169,269 tons, $1,204,260 for other industrial use sold to financially affiliated plants; and 1,076,144 tons, $8,927,407 for manufacture of water gas sold to other consumers.
[5] Included under "Undistributed."
[6] Revised figure.

over 1944 and were equivalent to 11 percent of byproduct coke production in 1945. Byproduct coke sold or used by producers for foundry use varied only slightly from 1944 and totaled 2,381,969 tons, of which 73 percent was supplied by merchant plants. Byproduct coke sold or used for other industrial purposes (including coke used in the manufacture of water gas and producer gas) constituted about 10 percent of the total production, the same proportion as in 1944.

In 1945, the producers of beehive coke reported sales of 4,929,553 tons, of which 35 percent was furnace coke sold to financially affiliated plants, 43 percent was furnace coke sold to nonaffiliated purchasers (merchant sales), 5 percent was foundry coke, 4 percent was sold for domestic use, and 13 percent was sold for other industrial purposes (including the manufacture of water gas). The quantity of beehive coke used by the producers themselves was 316,982 tons, of which all but 76,435 tons was consumed in iron blast furnaces.

[1] Includes 1,725,385 tons valued at $11,942,926 sold to financially affiliated plants for blast furnace use.
[2] Included under "Undistributed."
[3] Includes 459 tons valued at $3,833 sold to financially affiliated plants for other industrial use and 187,697 tons, $1,440,222 for manufacture of water gas sold to other consumers.

STOCKS OF COKE AND COKING COAL

Coke.—The extremely heavy demand for coke throughout 1945 made it necessary for byproduct producers to draw from stocks, and therefore total inventories at the end of the year were 15 percent lower than on January 1, 1945, and were equivalent to but 5.6 days' production at the rate prevailing in December 1945. During the same period, stocks of furnace coke declined 11 percent, and domestic and other coke 19 percent, whereas foundry-coke stocks increased 34 percent. Beehive plants carry small stocks of coke, and at the end of 1945 only 4,814 tons were in reserve. Table 36 shows the stocks of coke and breeze on hand at all plants, by States, on January 1, 1946. Table 38 shows the stocks of coke on hand at producers' plants, by months, during 1944–45.

Coal.—Because byproduct coking is a continuous process, adequate reserves of coking coal are essential to assure full-scale operations. Stocks of bituminous coal at byproduct-coke plants at the beginning of 1945 totaled 6,111,538 tons, a quantity sufficient for 24 days' average requirements at the rate of consumption prevailing in December 1944. However, because of the heavy demand for bituminous coal throughout the year, stocks at byproduct-coke plants could not be built up, and when mine stoppages in October hampered the flow of coking coal stocks were reduced to the lowest point since July 1, 1939. On an industry-wide basis the tonnage on hand on October 31, 1945, was sufficient for 14 days' supply if based on the normal average daily requirements of all plants, but inventories at many of the large steel companies' coke plants averaged less than a week's supply. Although stocks increased in November and December, the tonnage on hand at the end of the year was far short of the reserves normally carried by the operators. Table 39 shows the stocks of bituminous coal at byproduct-coke plants, by months, for 1937 and 1943–45.

TABLE 39.—*Stocks of bituminous coal at byproduct-coke plants in the United States at the end of each month, 1937 and 1943–45*

VALUE AND PRICE

The term "value" as applied to coke in this report means the value at ovens. Over 61 percent of the byproduct coke produced is made in ovens operated by corporations, which not only mine the coal they use but also operate blast furnaces that consume the bulk of the output of their ovens. This coke is not sold but is transferred by an interdepartment credit and charged on the books of the corporation owning both the coke and metallurgical plants. For the part of the output that is sold, the value is the amount received for the coke f. o. b. ovens. The total value of all byproduct coke produced in 1945, measured in this manner, decreased $8,653,833 from 1944, or less than 2 percent, and for beehive coke $10,727,631, or 22 percent (tables 34 and 35). The average value per ton of byproduct coke rose from $5.06 in 1936 to $5.16 in 1938 and after a temporary drop in 1939–40 increased steadily to $7.57 per ton in 1945. In like manner the average value of beehive coke increased from $3.91 in 1936 to $7.36 in 1945 and approached the maximum of $7.94 in 1920. The trend of the average value per ton during the last 10 years is shown in table 40.

Because of the various accounting methods used by coke operators affiliated with iron and steel plants, a better index of value changes in the market is provided by the average receipts per ton of coke sold. The average receipts from sales of byproduct coke in 1945 were $7.78 a ton, an increase of $0.32 over the average for the preceding year. The average for beehive coke rose from $6.97 in 1944 to $7.30 a ton in 1945.

The average receipts from sales represent the realization per net ton f. o. b. ovens and vary notably with the distances the coke plants are located from the mines. Thus the highest average receipts for domestic coke are those reported for Minnesota, where the coal must be hauled by rail-lake-rail from the Appalachians or even by longer all-rail routes. For details on average receipts that can be published without revealing individual operations, see table 41.

TABLE 40.—*Average value per net ton of all coke produced and average receipts per net ton from all coke sold in the United States, 1936–45*

Year	Value per ton produced			Receipts per ton sold		
	By-product	Beehive	Total	By-product	Beehive	Total

SHIPMENTS BY RAIL, WATER, AND TRUCK

As in previous years, the bulk of byproduct coke produced in the United States in 1945 was consumed in adjacent metallurgical works and but 40 percent of the total output was loaded for shipment outside the producing plants. Railroads transported 85 percent of the total byproduct-coke shipments, the same as in 1944. Truck shipments increased slightly over 1944 and represented 10 percent of the total shipments. Shipments by boat are relatively insignificant, and in 1945 less than 5 percent of the total shipments were so moved.

Unlike byproduct coke, which is mostly consumed at producing plants, beehive coke is made near the mines and is nearly all loaded at the plants for shipment to centers of consumption. In 1945, more than 94 percent of the total beehive-coke output was transported from producing plants. Shipments by rail accounted for 98 percent of all deliveries; the remaining 2 percent moved by truck and boat.

DISTRIBUTION OF BYPRODUCT AND BEEHIVE COKE

Table 44 contains data on the comparative consumption of byproduct and beehive coke and coke breeze, by States, in 1945 and shows the distribution, by major uses, of large coke in a given State. This summary table was compiled from information submitted by the coke-producing companies on the ultimate State destination of their coke and breeze. Total consumption of coke in the United States in 1945 decreased 9 percent from the peak attained in 1944 and amounted to 66,448,258 net tons. Although consumption of large coke showed a sharp decline, the quantity of coke breeze used or sold by producers increased 3 percent in the same period and totaled 5,320,257 tons. Shipments of coke and coke breeze to foreign countries registered large increases and were 31 percent and 68 percent, respectively, above the quantities exported in 1944. As shown in the summary table, distribution of coke for use in iron blast furnaces in 1945 constituted nearly 76 percent of the total deliveries from coke plants, but the tonnage involved was 11 percent below that of 1944. A slight increase was noted in shipments to iron foundries in the United States, and foreign shipments of foundry coke increased 59 percent in the same period. The domestic coke trade received approximately 10 percent of the total byproduct and beehive coke distributed in 1945, and although shipments of domestic coke within the United States dropped slightly from the 1944 deliveries, exports offset this slight decrease, and total deliveries were 57,965 tons higher than for the preceding year. The tonnage of coke used or sold by producers for the manufacture of water gas, producer gas, and other industrial purposes varied only slightly from the quantity so used in 1944 and was equivalent to 10 percent of the total coke deliveries.

TABLE 44.—*Summary of byproduct and beehive coke and breeze consumed in each State in 1945, in net tons*

[Based upon reports from all United States producers showing destination of coke used by producer or sold in 1945. Does not include imported coke which totaled 51,964 tons in 1945]

EXPORTS AND IMPORTS [12]

Shipments of coke to foreign countries in 1945 were greater than in any year since 1918. Shipments totaled 1,478,746 net tons valued at $12,600,707, an increase of 71 percent in quantity and 72 percent in value over 1944. Although foreign shipments of byproduct and beehive coke were higher than for any recent year, the large increase over 1944 was due principally to the heavy movement of reclaimed beehive coke from western Pennsylvania to Canada in the spring and summer of 1945. According to a monthly canvass of reclaimed-coke producers, conducted by the Bureau of Mines for the Solid Fuels Administration for War, monthly shipments of reclaimed coke to Canada reached a peak in July 1945, when more than 65,000 tons were destined to Canada. From information collected during the first 9 months of 1945, it is estimated that the total shipments of reclaimed coke to Canada in 1945 constituted approximately 20 percent of the total tonnage of all coke exported from the United States. Of the 1,478,746 tons of coke exported in 1945, Canada received more than 88 percent, the bulk going through the gateways of Buffalo, Michigan, and the St. Lawrence customs districts. Outside Canada, the export

[12] Figures on exports and imports compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

market for American coke is small, although Europe took 115,956 tons in 1945, while Cuba and South America received 27,971 tons and 19,061 tons, respectively.

Coke imports supply an insignificant part of the requirements of the country and totaled only 51,964 tons in 1945, all of which came from Canada.

WORLD PRODUCTION

Data on world production of coke are incomplete because of unsettled conditions throughout the world. Of the five countries whose 1945 output is reported, only Southern Rhodesia showed a gain over the preceding year. An analysis of the major coke-producing countries during the war period indicates that Germany ranked second to the United States in total output. Although figures on German coke production are not available for 1945, output is known to have been only a fraction of what it was before and during the war. Until more complete information is available, production figures for recent years on the world total are meaningless.

COKE-OVEN BYPRODUCTS

SUMMARY OF BYPRODUCTS

In the United States high-temperature carbonization of bituminous coal in byproduct ovens is one of the principal processes for recovering raw materials for the organic chemical industry. Developments in recent years in plastics, synthetic rubber, explosives, dyes, pharmaceutical preparations, and synthetic drugs have emphasized the key importance of benzol, toluol, xylol, naphthalene, phenol, cresylic acid, pyridine, and other chemicals derived from coal carbonization. To the national economy, high-temperature carbonization in byproduct-coke ovens represents an important asset in recovered products essential to the public welfare that would be lost with the use of earlier methods and equipment designed for the recovery of coke only. For example, the value at plant of the chemical raw materials recovered in 1945, which would have been wasted if the coke had been made in beehive ovens, is estimated at more than 223 million dollars; of the products recovered, gas, tar, and light oil have a combined calorific value

TABLE 47.—*Coke produced in principal countries of the world, 1929, 1938, and 1940–45, in metric tons* [1] [2]

[1] Gas-house coke not included.
[2] In addition to countries listed coke is produced in Japan, Korea (Chosen), and New Zealand, but data of production are not available.
[3] Data not available.
[4] Exports.
[5] Production includes State-operated companies only.
[6] Production of Free China.
[7] Excluding Sudetenland since October.
[8] Production of Bohemia and Moravia only.
[9] Beginning October 1939, Silesian production included.
[10] Coal year ended March 31 of year stated.
[11] In Great Britain production of gas-house coke (including breeze), not included, is especially important and was 13,049,139 tons in 1938. Data for 1940–45 not available.
[12] Figures for 1929 represent 73,616 tons of "hard" coke and 769,888 tons of "soft" coke made at collieries only. Data for other years represent total "hard" coke manufactured. In addition, "soft" coke made at collieries was as follows: 1938, 921,479; 1940, 270,135; 1941, 281,071; 1942, 246,648; 1943, 237,397 tons. Data for 1944–45 not available.
[13] Sales of coke by Wankie Colliery for year ended August 31 of year stated.
[14] Production of Urals and Siberia only.
[15] Total incomplete; represents rounded sum of figures given in table only.

equivalent to 16,835,000 tons of coal (table 49). Although the recovery of the valuable byproducts represent, to coke-plant operators, a source of additional revenue and a means of reducing to a minimum conversion costs of coal to coke, the cost of the byproducts cannot be ascertained with any degree of accuracy and, in practice, the revenue derived from them is treated as a deduction from the cost of the main product. It is of interest to note that although coal and manufacturing costs have increased during the war period, prices of the various chemicals have not increased and the values per ton of coke produced have remained relatively stable (table 50). For this reason, the ratio of the total value of byproducts sold (excluding breeze), which was equivalent to 50 percent of the value of byproduct coke produced in 1941, has declined steadily and in 1945 amounted to less than 37 percent. In general, as the recovery of the chemical raw materials necessarily accompanies the production of the main product, the decline in coke production in 1945 substantially reduced the output of all the principal byproducts.

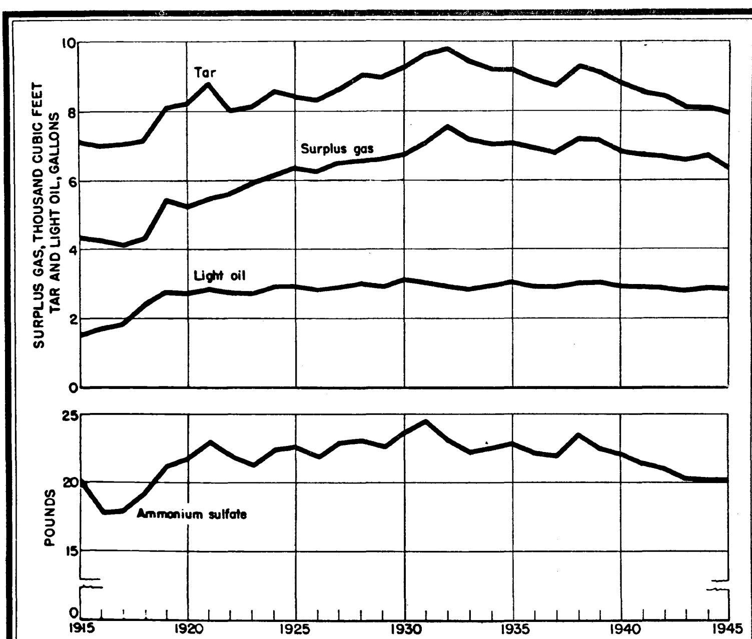

FIGURE 2.—Average yield of principal byproducts per net ton of coal carbonized in byproduct-coke ovens 1915–45. Figures for light oil represent average at plants recovering light oil.

[1] Includes products of tar distillation conducted by coke-oven operators under same corporate name.
[2] Softening point less than 110° F.
[3] Softening point over 160° F. Includes some medium pitch of tar reported by 1 producer.
[4] Includes gas used for heating ovens and gas wasted.
[5] Refined on premises to make derived products shown: 234,802,231 gallons.
[6] Total gallons of derived products.
[7] Ammonium thiocyanate, cyanogen sludge, dicyclopentadiene, hexane, phenol from sources other than tar distillation, secondary oil, sodium prussiate, sulfur, and vented vapors.
[8] Exclusive of value of breeze production, which was $12,535,373 in 1945.

TABLE 49.—*Coal equivalent of byproducts of byproduct coking in the United States, 1913, 1914, 1918, 1937, and 1944–45*

Gas.—Tables 51 and 52 show the production and disposal of coke-oven gas, by States, in 1945. After increasing continuously during the previous 6 years, production of coke-oven gas declined 10 percent below the record set in 1944. In addition to providing the fuel requirements of the byproduct-coke ovens from which it is produced, coke-oven gas supplies various other fuel needs. In 1945, 61 percent of the total output, a proportion that has changed very little in the past decade, was reported as surplus gas. Of the surplus coke-oven gas used or sold by coke-oven operators, 6 percent was used under boilers, 58 percent in integrated metallurgical works, 6 percent sold to neighboring industries, and 30 percent was sold for distribution through city mains. The quantity of surplus gas declined 11 percent from 1944, with a reduction of 7 percent in value. The average unit values of the surplus gas at plant was $0.158 per M cubic feet compared with $0.152 in 1944.

Crude tar and derivatives.—The cut-back in coke-oven operations in 1945 is reflected in the annual output of crude coal tar, which declined 9 percent below the peak established in 1944. The decreased production was accompanied by decreases in the principal outlets for crude tar. Sales of crude tar by coke-oven operators to other purchasers for refining decreased 2 percent from the 1944 total and accounted for 55 percent of the total production compared with 51 percent in 1944. The quantity processed by the coke-plant operators in integrated tar-refining facilities, which had increased steadily from 1940 to 1944, decreased 11 percent in 1945. Reduced open-hearth operations and the easing of the fuel-oil supply were in a large measure responsible for the decrease of more than 31 percent from 1944 in the quantity of crude tar used by producers in metallurgical operations. With the termination of hostilities in August 1945, Conservation Order M–297 on coal tar was revoked; however, ceiling prices on crude tar established by OPA in 1943 under MPR 447 remained in force throughout the year.

Production of creosote oil, a derivative mainly used for impregnating lumber, decreased 16 percent from 1944, and the value of creosote sold was equivalent to 55 percent of the total revenue received by coke-oven operators from the sale of all tar derivatives. Production of tar-acid oil increased 3 percent, but coal-tar pitch decreased 12 percent from the 1944 figures. Data on phenol, cresols, cresylic acid, and pitch coke cannot be shown separately without revealing individual operations. The total value, however, of sales of these commodities at producing plants amounted to $1,819,670, a decrease of 9 percent from 1944.

Ammonia.—Production of ammonia (NH_3 equivalent of all forms) decreased 7 percent from 1944, a reduction resulting from decreases of 7 and 13 percent, respectively, in output of sulfate of ammonia and ammonia liquor. All but 3 of the 87 active plants in 1945 recovered ammonia, 65 plants made ammonium sulfate, and 22 ammonia liquor (3 plants produced both sulfate and liquor). Approximately 87 percent of the ammonia produced at byproduct-coke plants was converted to ammonium sulfate, the same proportion as in 1944, and the rest recovered as ammonia liquor. Although production of ammonium sulfate decreased in 1945, sales increased 3 percent over 1944. The increase in sales was due to the action taken by the WPB in December 1944, which permitted the fertilizer manufacturers east of the Rocky Mountains an increase of one-twelfth of their original quota. This increase could be taken in January 1945 or, if the buyer preferred, distributed over the first quarter of the year. The price of ammonium sulfate, which has been governed by terms of MPR 205 since August 1942, remained unchanged through the year.

Crude light oil and light-oil derivatives.—Total production of crude light oil in 1945 decreased 22,174,731 gallons or 8 percent from the previous maximum output reported in 1944. The decrease was due in part to coal and steel strikes affecting the industry and also to the decreased yield of light oil per ton of coal carbonized from 2.87 gallons in 1944 to 2.84 gallons. The potential yield of crude light oil per ton of coal carbonized varies widely, depending upon the quality of coal charged, design and conditions of ovens, oven temperatures, coking time, and kind of scrubbing equipment and ranged from less than 2 gallons to more than 4 gallons at several plants in 1945. The bulk of the light oil produced at coke ovens is refined by operators in adjacent refining equipment, and in 1945 more than 95 percent of the total output was processed for the recovery of benzol, toluol, xylol, solvent naphtha, and naphthalene.

Benzol production (all grades), the principal constituent of light oil, decreased 6 percent from 1944 but was 17 percent higher than the prewar total in 1940. It is of interest that the production of "motor benzol," a grade of benzol normally produced for blending with gasoline for use as motor fuel, increased 55 percent over 1944, due to revocation of Conservation Order M–300, which prohibited the use of motor benzol as a motor fuel during the war. Data on the allocation of benzol for the 18-month period, January 1, 1944, to June 30, 1945, are summarized in table 57. This summary of the principal end uses of benzol was prepared by the Bureau of the Census, United States Department of Commerce, from chemical allocation records of the WPB and indicates wartime distribution of benzol. Production and sales of toluol, xylol, and solvent naphtha all decreased compared with 1944.

Foreign	88	(5)	23	20	45
	371,846	100.0	118,714	136,267	116,865

[1] Includes military aviation fuel.
[2] Blends as defined and controlled by Order M-150.
[3] Includes benzene used in the manufacture of nylon, phthalate plasticizers, maleic anhydride, camphor, anthraquinone, resorcinol, alcohol denaturant, small orders, and other miscellaneous uses not specified. Quantities used in nylon comprise a substantial part of this total. No benzene was allocated for the manufacture of automotive fuel during this period.
[4] End-use data not available.
[5] Less than 0.05 percent.

NAPHTHALENE

BYPRODUCT-COKE OVENS OWNED BY CITY-GAS COMPANIES (PUBLIC UTILITY PLANTS)

For many years the Bureau of Mines has maintained a separate classification for that group of byproduct-coke plants owned by city-gas companies (public utility plants). From the point of view of ownership and accounting these installations are part of the gas utility system; however, when considered with reference to oven design and the technique of manufacture and still more with reference to supply and demand for coke, these ovens belong to the byproduct-coke industry and are therefore included in the statistics furnished by the Bureau of Mines. This classification is maintained in the interest of those who may want to obtain information on the byproduct-coking operations of city-gas works proper.

During 1945, 15 byproduct-coke plants owned by city-gas companies operated and contributed approximately 6 percent of the total output of coke, tar, and gas of the byproduct-coke industry, 5 percent of the ammonia (NH_3 equivalent of all forms), and about 3 percent of the crude light oil. In 1945, production of coke and byproducts from this group declined for the second consecutive year, and output of coke decreased 7 percent, gas 8 percent, crude tar 9 percent, and ammonia 10 percent from the 1944 figures.

The following table presents salient statistics for 1944 and 1945 of the city-gas byproduct-coke plants in relation to the industry as a whole.

TABLE 59.—*Production of coke, breeze, gas, and byproducts in the United States at byproduct-coke plants owned by city-gas companies (public utilities* [1]*) and at all other byproduct-coke plants, 1944–45*

FUEL BRIQUETS AND PACKAGED FUEL[1]

By Gertrude S. Goodman

SUMMARY OUTLINE

SUMMARY

Despite 1945 shortages in the supply of labor, raw fuels, and other materials, the fuel-briquetting industry has continued steady expansion of its production since 1938. Output in 1945 reached a total of 2,762,204 net tons—73 percent of the total capacity of the 32 plants in operation. Packaged-fuel production, after 4 years of steadily declining output, began to recover in 1945, rising to 208,143 tons with 61 plants in operation.

Wartime controls by the War Production Board (now Civilian Production Administration)[2] were generally dropped after cessation of hostilities in August 1945; however, the Mining Division of CPA is still offering industry limited priority assistance to obtain machinery urgently needed to avoid bottlenecks in production.

The program inaugurated in 1944 by the Solid Fuels Administration for War[3] for the wider utilization of surplus anthracite fines in the manufacture of fuel briquets and packaged fuel to alleviate the shortage of scarce bituminous coals continued effective in 1945, and close to a million tons of Pennsylvania anthracite fines were used in the manufacture of fuel briquets and packaged fuel in that year. Practically all Federal restrictions on coal ordered by the Solid Fuels Administration for War were removed by April 1, 1946.[4]

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.
Data on employment and principal expenses in the manufacture of fuel briquets may be obtained from the Bureau of the Census.
Briquets made from charcoal, wood scrap, and fruit pits are not included in Bureau of Mines review.
Records on fuel briquets collected since 1907 and on packaged fuel since 1935 published in earlier reports of this series.

717372—47——65

Price control by the Office of Price Administration remained effective throughout 1945 and served to prevent repetition of the high briquet prices of World War I.[5]

Technologic developments.—Under cooperative agreement between the Bureau of Mines and the University of West Virginia, laboratories will be provided by the University at Morgantown and staffed by Bureau of Mines personnel for experiments as part of the 5-year synthetic liquid-fuels program authorized by the 78th Congress. The briquetting and coking section of the laboratory will investigate coal briquetting, carbonization, oxidation, cleaning, and other pretreatment methods in an effort to prepare a suitable low-cost fuel for generating the gases needed in the production of synthetic oil and gasoline.[6]

Work on the Piersol[7] process and press installed at the Applied Research Laboratory of the Illinois Geological Survey at Urbana, Ill., for briquetting Illinois coals was continued in 1945 with further experiments on contour of the briquet and metallurgical composition of briquetting dies.

A new development in the Piersol process consists of making briquets at room temperature from minus 10-mesh Illinois coals on the commercial-scale press without binder at approximately 30,000 pounds per square inch, followed by a 1-hour heat treatment at about 360° C. to render the briquets smokeless and weather-resistant.[8]

Illinois high-volatile bituminous coals have been successfully used in making fuel briquets since 1941 by the Coal Processing Corp. at Buckner, Ill., and were also used by the Super Heat Fuel Co., which started operations in December 1945. Tests on briquetting Illinois coals are also being conducted by several companies in the Middle West which may lead to commercial operations.

Outlook.—As the demand for fuel briquets and packaged fuel in recent years has generally exceeded the supply, it is reasonable to assume that production of these fuels will continue to increase. Two large new plants of the Reading Briquet Co.[9] in Pennsylvania expect to start operations in 1946, and interest in briquetting is spreading in other sections of the United States.

The packaged-fuel industry—relatively young and comprising many small operations—was unable to successfully weather the reverses of 4 years of shortages of labor and critical materials caused by the war. However, packaged fuel has definitely demonstrated its popularity and achieved a permanent place in the consumer fuel market. Production in 1945 has already taken an upward turn, and further expansion of the market was the objective of discussions at the meeting of the National Association of Packaged Fuel Manufacturers in Chicago on June 12, 1945.[10]

FUEL BRIQUETS

Salient statistics of the fuel-briquetting industry from 1941 to 1945 are summarized in the following table. Production and value from 1917 to 1945, inclusive, are shown graphically in figure 1.

Production.—The output of fuel briquets in 1945, continuing its upward trend, reached a total of 2,762,204 tons valued at $21,678,-886—a 12-percent increase in tonnage and an 18-percent increase in value over 1944.

Production rose to 73 percent of the capacity of the 32 plants active in 1945, reported as approximately 3,783,000 tons (see capacity

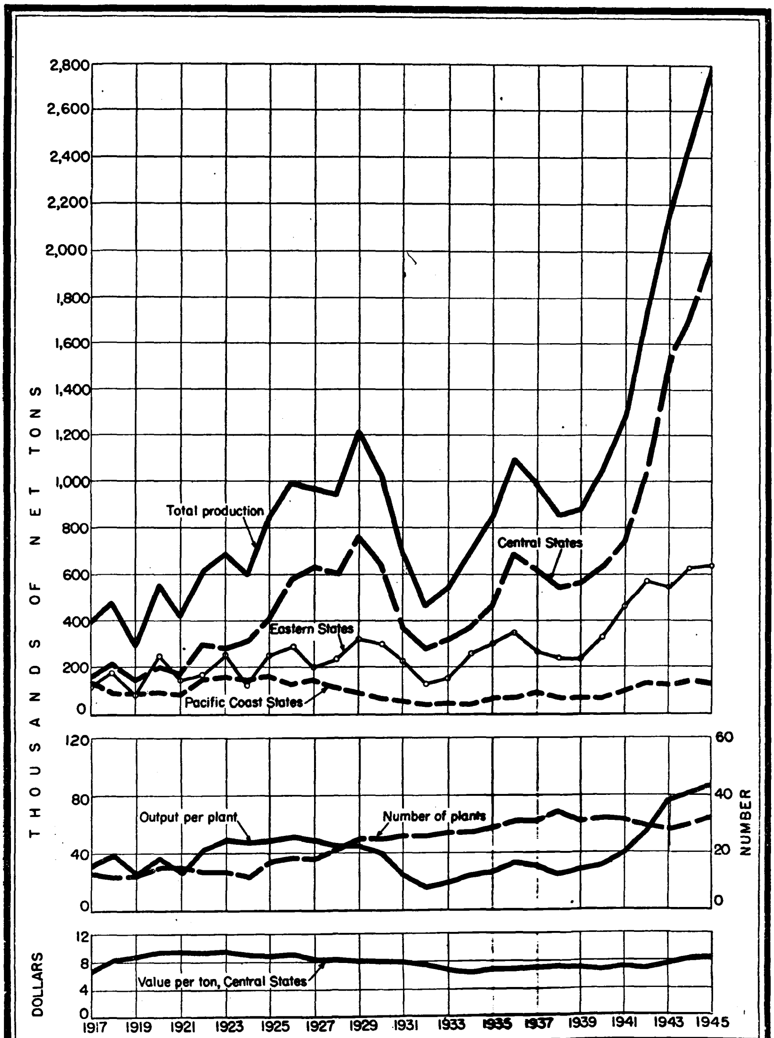

FIGURE 1.—Production of fuel briquets, output per plant, and number of plants in operation in the United States and average value per net ton, f. o. b. plant (Central States), 1917–45.

Salient statistics of the fuel-briquetting industry in the United States, 1941–45

analysis for 1944–45 in following pages). Briquets were made in 15 States in 1945, with production centered in Wisconsin (leading with 1,486,515 tons), followed by West Virginia, Pennsylvania, and Missouri, in order.

Production cannot be shown by States without revealing the operations of individual plants, except for Wisconsin, Missouri, and Illinois, as there were less than 3 plants in each of the other 12 producing States. In 1945, for the first time on record, there were 3 plants in operation in Illinois, producing 117,229 tons valued at $512,692.

Production of fuel briquets in Missouri, 1942–45

Year	Plants	Net tons	Value
1942	3	104,415	$589,466
1943	3	188,736	1,236,829
1944	3	252,286	1,910,384
1945	3	269,068	2,199,523

As briquets are used almost entirely for space heating, production is normally highly seasonal; however, since 1942 the monthly output throughout each year has been maintained at a high level. In 1945, 24 of the 32 active plants operated every month; only 3 plants operated less than 8 months and one of these was a new plant in Illinois which started operations in December. According to the Weather Bureau,[11] 1945 was notable for severe cold weather which is reflected in the increased shipments [12] to the briquet-consuming States, particularly Minnesota, Wisconsin, and the Dakotas.

Monthly production of fuel briquets in the United States, 1943–45, in net tons

Month	1943	1944	1945	Month	1943	1944	1945
January	187,201	202,234	260,340	August	204,424	222,081	235,629

March	188,500	181,137	208,337	October	205,118	239,687	259,831
April	133,531	152,725	174,613	November	179,564	240,925	257,427
May	121,027	192,944	208,452	December	204,299	233,667	256,719
June	153,854	192,427	227,892				
July	188,300	179,032	199,067		2,163,998	2,464,961	2,762,204

Packaging in cartons and bagging of bulk briquets at the plants, reported by seven operators, are merchandizing features only, used for convenience and cleanliness in the delivery of the fuel. One operator, however, reported wrapping several hundred tons of cubes—a small part of his total production—in 10-pound packages suitable for burning in the package if desired.

Value.—As sales realizations on briquets in the scattered producing centers vary considerably, an average value per ton for the entire industry has doubtful significance, because of the different conditions under which briquets are manufactured and sold. The most important factors that influence the value per ton realized at any plant are cost of raw materials and labor and prices of competing fuels; hence, the trend of fuel-briquet values in the past 5 years is indicated best in this review by the average values in the Eastern, Central,

[11] Baldwin, J. L., The Weather of 1945 in the United States: U. S. Dept. of Commerce Monthly Weather Review, vol. 73, No. 12, December 1945, pp. 201–205.
[12] See following table for "Shipments of fuel briquets of domestic manufacture in the United States, 1944–45, by States of destination, as reported by producers, in net tons."

and Pacific Coast States, as shown in the last three columns of the table of salient statistics. These are the values received by producers for the total product at the plant and should not be confused with retail prices which may include transportation costs to markets and wholesalers' margins. Retail prices paid by consumers in certain cities are shown in a separate table.

The total value of fuel briquets manufactured in 1945 was $21,678,886, f. o. b. plant—an increase of $3,244,307 or 17.6 percent over 1944.

Prices.—The following monthly fuel-briquet prices available for 15 cities for 1945 represent cash sales to household consumers for 1-ton lots (2,000 pounds) delivered at the curb or into the bin if no extra charge is made. Taxes are included when applicable. The monthly periods covered extend from the fifteenth of one month to the fifteenth of the succeeding month. The changes in prices during the year generally reflect local adjustment to ceilings allowed by OPA to partly compensate for higher costs of production including the increase in miners' wages.

Retail fuel-briquet prices per net ton in 1945, by cities and months

[1] Includes 2 percent sales tax.
[2] Includes 3 percent sales tax.
[3] Since April 1, 1945, briquets in Washington, D. C., sold on net-ton basis of 2,000 pounds; January, February, and March gross-ton price of $12.24 changed to a net-ton basis to make prices comparable throughout year.

Number of plants.—Thirty-two briquetting plants reported production in 1945; 23 of these have been active every year for periods of 7 to 37 years. Plants operating every year for more than 30 years are: Universal Coal Washing Co., Lessee, Kansas City, Mo., 37 years; Stott Briquet Co., at Superior, Wis., 37 years; Berwind Fuel Co., at Superior, Wis., 34 years; and Portland Gas & Coke Co., at Portland, Oreg., 33 years.[13]

Five plants were idle in 1945—one each in Minnesota and Connecticut, idle for 7 years or more; one each in Ohio and Texas, idle since 1941, when a small production was reported; and one in North Dakota—the plant of Western Carbon & Chemical, Inc., at Minot, reported under construction in 1944.

[13] Years other plants (active in 1945) started producing are given in the 1945 Fuel-Briquet Directory, obtainable on request from the Bureau of Mines, Washington 25, D. C.

Annual capacity and production of active briquetting plants in the United States, 1944–45

[1] 1 of these plants operated only 3 months of the year.
[2] 1 of these plants started operations in December 1945.
[3] 1 of these plants resumed operations in December 1944.

The plant of the South Chicago Coal & Dock Co., at Chicago, Ill.—active from 1937–44, inclusive—was sold to the Chicago Briquet Co., which operated at the same address in 1945.

Of the seven plants reported under construction in 1944, two started commercial production in 1945—the Super Heat Fuel Co. at Belleville, Ill., in December and the Virginia Coal & Supply Co. at Milwaukee, Wis., in February; the two Reading Briquet Co. plants [14] at Locust Summit and St. Nicholas, Pa., postponed commercial operation until spring 1946; Elmira Coal Co. at Elmira, N. Y. and the Chemi-Coal Products Co. at King City, Calif. have not yet started production; and the plant of Western Carbon & Chemical, Inc., at Minot, N. Dak., was idle in 1945.

Two additional briquetting plants were reported under construction in 1945 to start operation in 1946—the Fort Scott Briquette Co. Inc., at Fort Scott, Kans. and the United Ice & Fuel Co. at Flint, Mich. (the latter has been making packaged fuel since 1936).

Capacity of plants.[15]—The utilization of the reported total capacity of the active briquetting plants has risen from 28 percent in 1938 to 73 percent in 1945, with little change in the number of plants. Comparative data for 1944 and 1945, given in the foregoing table, show the greatest increase in production in 1945 to be concentrated at plants with annual capacities of 200,000 tons or more.

The average output per plant has more than doubled in the past 5 years, rising from 41,000 tons in 1941 to 86,000 tons in 1945. Twenty-four plants operated every month in 1945, producing 2,416,711 tons, or 87.5 percent of the total.

The largest capacities as well as the largest productions both in 1944 and 1945 were reported by the Berwind Fuel Co. and the Stott Briquet Co., Inc., for their plants at Superior, Wis.

Capacity of plants reported under construction in 1945, with plans for operation in the near future, is estimated at 700,000 tons.

Raw fuels.—Eight kinds of raw fuels entered into the manufacture of fuel briquets in 1945, and 10 types of briquets were made from these fuels (8 alone and 2 in combination). In the following tables, the quantities of raw fuels used and tonnages of each type produced are shown wherever possible without revealing operations of individual plants.

As a direct result of the program inaugurated in 1944 by the Solid Fuels Administration for War for wider utilization of surplus anthracite fines, the use of these fines rose from 389,000 tons (at 6 plants), or 19 percent of the total raw fuels in 1943, to 927,000 (at 12 plants), or 36 percent of the total in 1945. Bituminous coal, which continued tight in 1945, dropped from 65 percent of the total raw fuels used in 1943 to 47 percent in 1945. About 25,000 tons of petroleum coke, again on the market since October 24, 1944,[16] when wartime restrictions on its use as domestic fuel were rescinded, were used by 4 operators in 1945.

[1] Relatively small tonnage of petroleum coke of a type exempt from wartime allocation in 1943 (wartime restrictions rescinded Oct. 24, 1944).

[2] In 1943, 4 plants made 2 kinds of briquets; in 1944, 6 plants made 2 kinds and 1 plant 3 kinds; in 1945, 3 plants made 2 kinds; hence the sum of these items exceeds the total number of plants active in the respective years.

As indicated in the following table showing production with reference to supply of raw fuel, the greatest gain in output of briquets in 1945 over 1944 occurred at four plants at Lake Superior coal docks that used low-volatile bituminous coal in combination with Pennsylvania anthracite fines.

Production of fuel briquets, 1944–45, grouped according to location of plants with reference to supply of raw fuel

Location of plant	1944		1945		Change in 1945	
	Plants	Production (net tons)	Plants	Production (net tons)	Net tons	Percent
At or near Lake Superior, Lake Michigan, or Lake Huron coal docks:

[1] Fall River, Mass.; Jackson, Mich.; and Omaha, Nebr.

Binders.—Asphalt binders remain the preferred type in briquetting coal and coke and were used by 26 plants that produced 87 percent of the fuel briquets made in 1945. Three other plants used, respectively, asphalt and coal-tar pitch combined, asphalt and starch combined, and starch. In 1945, as in 1943 and 1944, three plants used no binder; two of these briquetted the carbon residue from the manufacture of oil gas and one used low-volatile bituminous coal.

Classification of briquetting plants in the United States, 1943–45, by percentage of binder used

Ratio of binder to raw fuel (by weight)	1943			1944			1945		
	Plants	Production		Plants	Production		Plants	Production	
		Net tons	Percent of total briquets		Net tons	Percent of total briquets		Net tons	Percent of total briquets
Less than 5 percent	4	234,747	10.8	3	58,309	2.4	4	41,333	1.5
5 and less than 7 percent	13	829,953	38.4	17	1,734,549	70.4	16	2,083,292	75.4
7 and less than 9 percent	6	983,487	45.4	4	486,366	19.7	6	475,799	17.2
9 percent or more	2			3	61,993	2.5	3	42,780	1.6
No binder	[1] 3	115,811	5.4	[1] 3	123,744	5.0	[1] 3	119,000	4.3
	28	2,163,998	100.0	30	2,464,961	100.0	32	2,762,204	100.0

[1] 2 plants use residual carbon from manufacture of oil gas, and 1 uses bituminous coal as raw fuel.

Operators reported approximately 164,000 tons of asphaltic types [17] and small quantities of starch and coal-tar pitch used as binders in 1945 in the manufacture of fuel briquets.

Seventy-five percent of the total production of fuel briquets in 1945 was made with binders ranging from 5 to 7 percent (ratio of binder to raw fuel—by weight), as compared with 31 percent of the production in 1942, 38 percent in 1943, and 70 percent in 1944.

Weight and shape.—Pillow-shaped briquets (weighing less than 5 ounces, with one exception—an 11-ounce, high-volatile bituminous pillow made by the Coal Processing Corp., at Buckner, Ill., since 1941), were made at 29 plants in 1945 and comprise approximately 70 percent of the total production. Cylindrical (barrel-shaped) briquets were made at 2 plants and 20- and 24-ounce cubes at 1 plant. Briquets weighing between 2 and 3 ounces predominate and represent 60 percent of the total production in 1945.

Prevailing weight of briquets produced in the United States, 1944–45

Weight (ounces) [1]	1944			1945		
	Plants	Production		Plants	Production	
		Net tons	Percent of total		Net tons	Percent of total
Less than 2	3	62,130	2.5	3	34,306	1.2
2 and less than 3	13	1,333,007	54.1	16	1,648,244	59.7
3 and less than 4	8	706,622	28.7	6	669,513	24.2
4 and less than 5	4	363,202	14.7	5	410,141	14.9
10 and less than 16	1			1		
16 and less than 25	2			[2] 1		
	[3] 31	2,464,961	100.0	32	2,762,204	100.0

[1] No briquets weighing between 5 and less than 10 ounces made in 1944 or 1945.
[2] This plant made cubes in 20- and 24-ounce weights.
[3] 1 plant made briquets in both 2-ounce and 3-ounce weights, and 1 made cubes in 20- and 24-ounce weights; hence the sum of these items exceeds the total number of plants.

Shipments.—Briquets are widely used in the United States; in 1945 they were shipped into 35 States and the District of Columbia and exported principally to Canada. The entire output of California, North Dakota, and Washington was consumed within those States, but the output of the other 12 producing States was also shipped to other States. States reporting the largest output in 1945 shipped their briquets as follows: From Wisconsin to 7 States and Canada; from West Virginia to 18 States, the District of Columbia, and Canada; from Pennsylvania to 16 States, the District of Columbia, and Canada; and from Missouri to 5 States.

Shipments from each producing State cannot be shown because there are only one or two producers in each of the States except Wisconsin, Missouri, and Illinois, and confidential data of individual operations would thus be revealed. However, a graphic presentation of the centers of production with corresponding States of destination for 1928 and 1936 is included in Minerals Yearbook, 1937 (p. 965, fig. 65), and since then markets have been extended still farther.

[17] Sales of briquetting asphalt as reported by the petroleum refineries to the Bureau of Mines differ slightly from the quantities reported by the briquet and packaged-fuel manufacturers as used in their processing operations.

The relatively small difference between production in 1945 (2,762,204 tons) and shipments within the United States (2,585,091) represents briquets exported, used at plants for fuel, and stocks on hand at beginning or end of 1945.

Shipments of fuel briquets of domestic manufacture in the United States, 1944–45, by States of destination, as reported by producers, in net tons [1]

[1] Includes shipments outside the United States.
[2] Includes local deliveries.
[3] An additional 27,225 tons were used by 2 producers as fuel at their plants in 1944, and 20,139 tons in 1945

Imports and exports.—Imports of briquets into the United States for the years 1941 through 1945 were small and, except for a few tons from Mexico in 1942, all from Canada. Figures for imports since 1919, first year of record, are included in annual volumes of Mineral Resources and Minerals Yearbook.[18] Exports [19] of fuel briquets made in the United States were shipped in 1945 principally to Canada and small tonnages to Switzerland, French Morocco, France, Mexico, and Cuba.

Briquets (coal and coke) and other composition coals for fuels imported for consumption in the United States, 1941–45

[1] In addition to countries listed, briquets are produced in Czechoslovakia and New Caledonia, but data on output are not available.
[2] Data not available.
[3] Data for year ended March 31 of year stated.
[4] Beginning October 1939, figures include production from East Upper Silesia.
[5] Beginning October 1938, figures include production from Sudetenland.
[6] Includes packaged fuel as follows—1938: 146,012 tons; 1939: 195,504; 1940: 258,105; 1941: 244,797; 1942: 229,560; 1943: 195,592; 1944: 159,455; 1945: 188,823 tons.
[7] Total incomplete; it represents sum of figures given in table only.

PACKAGED FUEL

Packaged fuel is the trade name applied by the industry to a combination of briquetting and packaging of screenings compressed into 3- or 4-inch cubes and wrapped (six or eight in a package) in sturdy paper and sealed with gummed tape. A study of the development of the packaged-fuel industry, from its beginning with the introduction of coal blocks made from slack coal in 1928 to the peak of packaged-fuel production in 1940, was made by V. F. Parry [21] of the Bureau of Mines; this study includes operations involved in the manufacture of packaged fuel and analysis of costs in typical plants.

The phenomenal growth in popularity of packaged fuel from 1935 through 1940, its decline from 1941–44, and the beginning of its recovery in 1945 are strikingly illustrated in figure 2.

The outstanding development in the packaged-fuel industry in 1945 is successful utilization of Pennsylvania anthracite fines combined with a smaller quantity of bituminous coal in the manufacture of packaged fuel, as demonstrated by the White Glove Packaged Fuel

[21] Parry, V. F., Technical and Economic Study of Packaged Fuel: Bureau of Mines Rept. of Investigations 3757, 1944, 45 pp. (Abs. in Mining Congress Journal, November 1944, vol. 30, No. 11, pp. 24-27, under title: Packaged Fuel—A Technical and Economic Study of a Typical American Business Effort to Sell Something Better than Formerly Used.)

Division of the Blaw-Knox Co.[22] in Philadelphia, Pa., which began commercial production in June 1945. The plan to use Pennsylvania anthracite fines was sponsored by the Federal Government at the request of the Solid Fuels Administration for War [23] in 1944, and extensive experiments were made by the Bureau of Mines [24] to test the possibilities of the project.

Processes.—In 1945, 54 of the 61 packaged-fuel manufacturers used the Eberling [25] process; 2 used Glenn-Smith [26] equipment; 2 used Leemon [27] equipment; 2 used equipment designed by the Johnson Coal Cubing Co., Inc.,[28] of Detroit, Mich., and the White Glove Packaged Fuel Division of the Blaw-Knox Co. in Philadelphia, Pa., used equipment manufactured by the Blaw-Knox Co.,[29] of Pittsburgh, Pa.

Salient statistics of the packaged-fuel industry from 1941 to 1945 are summarized in the following table.

Salient statistics of the packaged-fuel industry in the United States, 1941–45

[Data regarding fuel briquets are given separately at beginning of this chapter]

Year	Production (net tons)			Value of production	Plants in operation	Average output per plant (net tons)	Average value per net ton, f. o. b. plant	
	Eastern and Pacific Coast States	Central States	Total				Eastern and Pacific Coast States	Central States
1941	9,549	260,295	269,844	$2,471,567	103	2,620	$10.95	$9.09
1942	7,583	245,465	253,048	2,540,087	89	2,843	10.74	10.02
1943	[1] 4,970	210,635	215,605	2,366,733	72	2,995	[1] 11.55	10.96

1945	[1] 16,606	191,537	208,143	2,518,636	61	3,412	[1] 12.86	12.04

[1] Eastern States; no production in Pacific Coast States in 1943–45.

Production and value.—Notwithstanding the continued shortages in labor and materials and idleness at 29 packaged-fuel plants, production in 1945 increased for the first time since 1940, the peak year of production for the industry. The 61 plants active in 1945 produced 208,143 tons, with a value of $2,518,636, an increase of 18 percent in production and a 23-percent increase in value over 1944 (see fig. 2).

The upturn in production of packaged fuel is the result of resumption of operations at two plants (rebuilt after fires in 1944), production of the new plant of the White Glove Packaged Fuel Division of the Blaw-Knox Co., at Philadelphia, Pa. (starting in June 1945), and

general increases in production at plants in Michigan, Minnesota, and Ohio. Michigan regained its place in 1945 as the State with the highest output; and the largest producers were the Cleveland Cliffs Iron Co. at Green Bay, Wis., followed by the Johnson Coal Cubing Co., Inc.,[30] of Detroit, Mich. (whose plant, down for 4 months in 1944, has been rebuilt and operations resumed in November 1944).

Fires, damaging five plants in 1945 and resulting in shut-downs,

Production of packaged fuel in the United States, 1944–45, by States

[2] Included under "Undistributed"; Bureau of Mines not at liberty to publish figures.
[3] Includes States entered as "(2)" above.

[30] Black Diamond, Packaging Coal at the Johnson Plant at Detroit: Vol. 115, No. 2, July 21, 1945, p. 20.

point to the advisability of fireproof structures for housing equipment and care in storing raw fuels and binder materials; rebuilding these plants presents difficulties with materials, machinery, and other necessary replacements still hard to obtain.

The values, by States, represent the average per ton received by operators in 1944 and 1945 in States with three or more operators. The values do not represent the price per ton to the consumer, as many plants sell both to retailers and consumers, but rather the average per ton received by producers on the total product (exclusive of delivery charges). The value at the plant comprises cost of coal at the mine, freight rate, direct and indirect manufacturing costs, and profit.

All but three of the producing States showed increases in average realization at the plant in 1945.

Average value received per net ton of packaged fuel in the United States, 1944–45, by States

[Includes only those States where there were 3 or more plants in both years]

State	1944	1945	State	1944	1945
Michigan	$11.68	$12.06	Virginia	$11.18	$10.66
Minnesota	13.28	13.24	Wisconsin	11.46	11.65
Ohio	10.90	11.68			

Thirty-one of the 61 active plants operated each month of the year and supplied 71 percent of the total production; only 5 plants (in Michigan and Ohio) operated less than 6 months, and the output of these was small.

Monthly production of packaged fuel in the United States, 1943–45, in net tons

Month	1943	1944	1945	Month	1943	1944	1945
January	27,106	19,721	21,344	August	9,286	9,090	10,811

May	11,965	11,232	13,842	December	21,131	20,204	25,730
June	8,476	6,593	10,538				
July	7,772	5,377	7,293		215,605	175,770	208,143

Number of plants.—In 1945 the number of plants producing packaged fuel dropped further to 61. However, the record of activity among these plants is remarkable, as all but two have reported production for every year since their operations began; 44 of these plants have an unbroken record of from 6 to 11 years' activity. Twenty-two of the active plants are located in the Detroit and Cleveland areas and contribute about one-third of the national production; in addition, there were 13 idle plants in these areas in 1945.

Three plants began operating in 1945—the new large packaged-fuel plant of the White Glove Packaged Fuel Division of Blaw-Knox Co., at Philadelphia, Pa., which was under construction in 1944, began operations in June 1945; and two comparatively small plants in Monroe, Mich., and Dayton, Ohio, started operations in the fall.

Twenty-nine plants were idle in 1945 (8 of these were active in 1944, and 13 have been idle since 1943); shortages of labor and materials and inability to operate without loss under OPA price ceilings were the principal reasons given for idleness.

Two companies reported small plants under construction in 1945—one in Kansas City, Mo., and the other in Detroit, Mich. (the latter started construction in 1944).

Activity in number of packaged-fuel plants in the United States, 1940–45

Year	Active	New	Idle	Out of business	Year	Active	New	Idle	Out of business
1940	106	16	15	14	1943	72	5	23	9
1941	103	7	8	14	1944	68	4	22	7
1942	89	4	16	8	1945	61	[1] 3	[2] 29	[3] 5

[1] 1 each in Michigan, Ohio, and Pennsylvania and all active in 1945.
[2] 16 in Michigan; 3 each in Indiana, Missouri, and Ohio; 2 in Wisconsin; and 1 each in Illinois and Washington.
[3] 2 in Michigan and 1 each in Missouri, Ohio, and Pennsylvania (none of these active in 1945).

Capacity of plants.[31]—Comparative data for 1944 and 1945, given in the following table, show the greatest increase in production in 1945 to be concentrated at plants with reported capacities of 15,000 tons or more.

In 1945, 51 plants produced less than 5,000 tons each, contributing 74,719 tons (or 36 percent of the total production), utilizing 40 percent of the capacity of this group; the other 10 active plants, each producing more than 5,000 tons, contributed 133,424 tons (or 64 percent of the total production), utilizing 50 percent of their combined capacity.

The output per plant attained its highest average in 1945, rising from 2,585 tons in 1944 to 3,412 tons in 1945.

The largest annual capacities in 1945 were reported for the plants of the White Glove Packaged Fuel Division of the Blaw-Knox Co., at Philadelphia, Pa., and the Johnson Coal Co., Inc., at Detroit, Mich.

Raw fuels.—Five kinds of raw fuels entered into the manufacture of packaged fuel in 1945. The plant of the White Glove Packaged Fuel Division of the Blaw-Knox Co., in Philadelphia, Pa.[32] (using Pennsylvania anthracite fines combined with a smaller quantity of bituminous low-volatile), began operations in June 1945, but production in 1945 was not as large as anticipated. About 16,000 tons of petroleum coke—again on the market since October 24, 1944[33]—was used at eight plants in 1945.

One large operator (who makes both packaged fuel and fuel briquets and who uses only shipped-in bituminous low-volatile) reports his processing operations severely handicapped due to the wetness or frozen condition of the coal as received:

Raw fuels used in making packaged fuel in the United States, 1943–45

Raw fuel	1943		1944		1945	
	Plants	Net tons	Plants	Net tons	Plants	Net tons
Bituminous:						
Low-volatile	69	206, 059	65	156, 388	59	174, 164
High-volatile	2		3	316	3	3, 123
Pennsylvania anthracite	-----	-----	1	4, 597	1	11, 168
Semianthracite	2	6, 613	2		2	
Coke breeze	-----		1		-----	-----
Petroleum coke	[1] 2		7	12, 560	8	15, 995
	[2] 75	212, 672	[2] 79	173, 861	[2] 73	204, 450

[1] These plants reported a relatively small tonnage of petroleum coke of a type exempt from wartime allocation in 1943 (wartime restrictions rescinded Oct. 24, 1944).

[2] In 1943, 69 plants used 1 kind of fuel only, 1 used 2 kinds (separately), and 2 used mixtures of 2 kinds; in 1944, 57 plants used 1 kind of fuel only, 7 used 2 kinds (separately), and 4 used mixtures of 2 kinds; and in 1945, 50 plants used 1 kind of fuel only, 8 used 2 kinds (separately), 1 used 3 kinds (separately), and 2 used mixtures of 2 kinds. Hence the number of items exceeds the total number of active plants in the respective years.

Six types of packaged fuel, with bituminous low-volatile cubes and petroleum-coke cubes predominating, were made in 1945, as follows:

Classification of plants and production of packaged fuel in the United States in 1944–45, by kinds of raw fuel used

Raw fuel used	1944			1945		
	Plants	Packaged fuel produced		Plants	Packaged fuel produced	
		Net tons	Percent of total		Net tons	Percent of total
Bituminous:						
Low-volatile (exclusively)	61	151,626	86.3	57	167,309	80.4
High-volatile (exclusively)	2			3	3,147	1.5
Mixture of bituminous low- and high-volatile	1	12,265	7.0	---------	23,154	11.1
Mixture of bituminous low-volatile and Pennsylvania anthracite	1			1		
Mixture of bituminous low-volatile and petroleum coke	1			1		
Mixture of bituminous low-volatile and coke breeze	1			---------		
Semianthracite (exclusively)	2			2		
Petroleum coke (exclusively)	6	11,879	6.7	7	14,533	7.0
	[1] 75	175,770	100.0	[1] 71	208,143	100.0

[1] In 1944, 2 types of packaged fuel were made at 7 plants; in 1945, 3 types were made at 1 plant and 2 types at 8 plants; hence the sum of these items exceeds the total number of plants active in the respective years.

In 1945, about 158,000 tons (77 percent of the total raw fuels) were shipped-in slack from the mines and from the Lake docks. The remainder represents yard screenings. Fourteen of the 61 operators used shipped-in slack exclusively, 20 used yard screenings exclusively, and 27 used both shipped-in slack and yard screenings.

Cubes measuring 3 to 3¾ inches were made at 50 plants, and 4-inch cubes were made at 16 plants; 5 plants made cubes in two sizes.

Twenty-two plants reported wrapping the cubes by machine, 12 by hand, and 27 by a combination of machine and hand. Fifty-five plants wrapped 6 cubes to a package, 5 plants 8 to a package, and only 1 reported a package of 4 cubes.

Forty-seven plants made packages weighing 9 to 11 pounds, 18 made packages of 11 to 16 pounds, and 1 (the White Glove plant at Philadelphia) reported making packages of six 3-inch cubes weighing approximately 7 pounds; 5 plants made packages of two weights, from 10 to 15 pounds.

Only one plant reported sales of packaged fuel in bulk (unwrapped), amounting to less than 200 tons; these were made of bituminous low-volatile and asphalt binder.

Binders.—Cornstarches totaling 1,094 tons were used as binder by 59 plants, which produced 151,338 tons of packaged fuel, or 73 percent of the total production in 1945. Thirty-one plants reported using 15 pounds of starch per ton, 19 used over 15 pounds, and 9 less than 15. Asphalt[34] totaling 2,600 tons was used alone as binder by 3 plants, and 1 plant making petroleum-coke cubes used a combination of starch and asphalt. No cement was reported in 1944 or 1945.

[34] See footnote 17.

Classification of packaged-fuel plants in the United States, 1944–45, by type and percentage of binder used

Type of binder	Plants		Ratio of binder to raw fuel (by weight)	Plants	
	1944	1945		1944	1945
Starch	66	58	Less than 0.5 percent	-------	-------
Starch and asphalt	1	1	0.5 and less than 1 percent	56	52
Asphalt	2	3	1 and less than 2 percent	11	6
			2 and less than 3 percent	-------	-------
			3 and less than 5 percent	-------	1
			5 percent or more	2	2
	[1] 69	[1] 62		[1] 69	61

[1] In 1944 and 1945, 1 plant making 2 types of packaged fuel used starch binder for one and starch and asphal for the other; hence the sum of these items exceeds the number of active plants.

Shipments.—Local sales (called for by passenger car or delivered by truck) amounted to 171,621 tons and accounted for 83 percent of the 1945 total sales; other than local (shipped by truck to points in Wisconsin, Minnesota, and Michigan), 11 percent; and shipments by rail (to points in Wisconsin, Michigan, Minnesota, and Iowa), about 6 percent.

Shipments of packaged fuel in the United States by method of movement, 1943–45, in net tons

Year	Shipped by truck			Shipped by rail	Total
	Local sales [1]	Other than local sales	Total truck		
1943	167,800	33,582	201,382	14,137	215,519
1944	139,026	24,302	163,328	12,389	175,717
1945	171,621	23,381	195,002	11,713	206,715

PEAT

By J. A. Corgan and Golden V. Chiriaco

SUMMARY OUTLINE

SUMMARY

According to reports received by the Bureau of Mines, peat production in the United States in 1945 totaled 78,272 short tons with a value of $600,287 and was 73 percent of the peak United States production of 107,261 tons in 1918. In 1944 the output was 57,987 tons valued at $524,521.

Shortage of labor and equipment, a major problem in the peat industry for the past several years, continued through 1945; however, some operators expressed hope of a more favorable outlook for 1946.

Imports of peat moss, cut drastically in 1940 because of the war, have been increasing steadily since then, the quantity imported in 1945 totaling 77,673 short tons, valued at $2,393,214. These figures compare favorably with the prewar figure of 78,611 tons, valued at $1,204,883, imported in 1939. In 1944, 64,428 tons, valued at $1,916,794, were imported. As no exports are reported, the quantity of peat available for domestic consumption in 1945 amounted to 155,945 tons, an increase over the 122,415 tons available in 1944. Approximately 88 percent of the peat sales in 1945 was used for soil improvement and in mixed fertilizers.

Reserves.—Peat, an integral part of the natural resources of the country, is found in about half of the States. An estimate of 13,827,000,000 tons has been calculated as air-dried peat.[1]

Minnesota, Wisconsin, and Michigan combined contain 75 percent of the reserves; 14 percent of the country's total is in Florida, and the rest is distributed through the New England and Pacific Coast States.

PRODUCTION

Of the 104 operators reporting to the Bureau of Mines for 1945, only 44 operating in 19 States contributed to the total 1945 production of 78,272 short tons, whereas the 1944 production of 57,987 tons represents the total output of 35 producers operating in 17 States.

[1] Soper, E. K., and Osbon, C. C., The Occurrence and Uses of Peat in the United States: Geol. Survey Bull. 728, 1922, p. 92.

The increase in production in 1945 over 1944 can be attributed to a more extensive canvass made possible by the cooperation of the county agricultural agents, United States Department of Agriculture, in certain States, who, at the request of the Bureau of Mines, supplied the names and addresses of all peat producers in their respective counties. Considered on the basis of the 1944 canvass, peat production dropped slightly in 1945, as 5 plants were closed in addition to the 16 reported closed in 1944, none of which had resumed operations at the end of 1945. Of the 26 operators who produced peat both in 1944 and 1945, 13 showed a higher output for 1945; the others, with the exception of 1, produced less. Virtually all operators producing low or no tonnage cited their inability to procure sufficient labor and equipment as the chief reason.

The average value per ton in 1945 was $7.67, a decrease of 15 percent from the 1944 value of $9.05. Production and value for 1940–45 are shown in the following table.

Peat produced in the United States, 1940–45

Year	Short tons	Value		Year	Short tons	Value	
		Total	Average per ton			Total	Average per ton
1940	70,097	$516,865	$7.37	1943	60,002	$491,460	$8.19
1941	86,503	657,556	7.60	1944	57,987	524,521	9.05
1942	71,500	516,887	7.23	1945 [1]	78,272	600,287	7.67

[1] Wider coverage. See explanation under "Production."

The trend in production and value of peat from 1908 to 1926 and from 1934 to 1945 is pictured graphically in figure 1. Data for 1927 to 1933, inclusive, are not available, as the Federal Government made no canvass of the peat industry for those years.

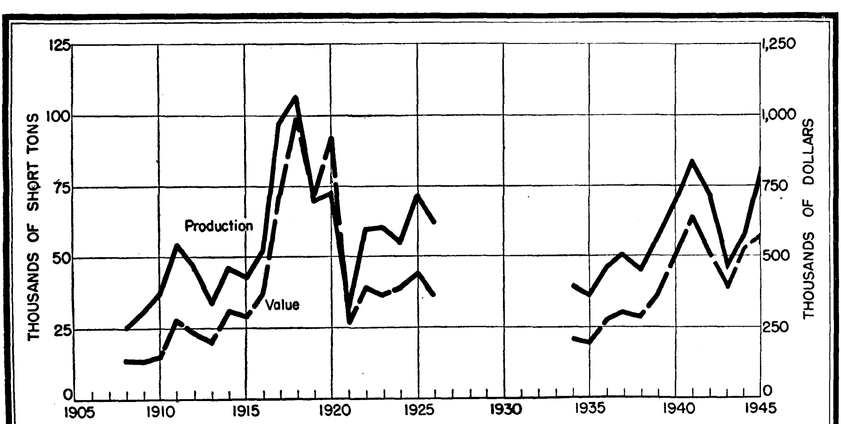

FIGURE 1.—Quantity and value of peat production in the United States, 1908–26 and 1934–45; no data available for 1927–33.

Florida ranked highest in peat production in 1945, followed in order of output by New Jersey, Illinois, Michigan, California, New York, Minnesota, Pennsylvania, Connecticut, Washington, Iowa, Wisconsin, Georgia, Ohio, Maine, Texas, Colorado, Massachusetts, and New Hampshire. In 1944 New Jersey was the highest producing State, with Illinois, Michigan, and Pennsylvania next in order, the position of the other States, except California and New Hampshire, varying also from that of 1945.

In 1945, for the first time since producers were asked to state the kinds of peat produced, peat humus failed to comprise the largest part of the production. Reed or sedge peat, produced in 11 States, comprised about 53 percent of the total production; peat humus, produced in 13 States, 33 percent; and moss peat and other, produced in 7 States, 14 percent.

USES

For many years reports have indicated that the most prevalent use of peat in this country is for soil improvement. Of the sales reported in 1945, 64 percent was sold for soil improvement; 24 percent for use in mixed fertilizers; and 12 percent for other uses, including fuel for the first time in recent years, litter for barns and poultry yards, and as a packing for bulbs, fruits, vegetables, and fragile articles. Although peat is used extensively in some European countries as fuel, it has not been used for fuel purposes in this country on a commercial scale because of plentiful supplies of higher-grade fuels. The quantity reported sold for this purpose in 1945 is negligible.

United States Government specifications.—The Federal Government purchases a certain amount of peat, provided the peat meets required specifications. These specifications may be obtained from the Procurement Division, United States Treasury Department, Washington 25, D. C.

IMPORTS [2]

Imports in 1945, all from Canada, totaled 77,673 short tons, valued at $2,393,214. Before 1939 most of the peat imported came from Germany. In 1938 Germany supplied 36,381 tons, valued at $525,564; in the same year, the Netherlands and Sweden together supplied 21,836 tons, valued at $348,252. The opportunity for increasing output, presented to producers in the United States by the decline in imports from other countries, has been thwarted to a great extent because of difficulties in obtaining necessary labor and materials.

The average value per short ton of imported peat was $30.81 in 1945 compared with $29.75 in 1944.

Peat moss imported for consumption in the United States, 1940–45

Year	Short tons	Value	Year	Short tons	Value
1940	21,689	$454,632	1943	59,427	$1,577,388
1941	30,342	704,264	1944	64,428	1,916,794
1942	49,236	1,219,473	1945	77,673	2,393,214

[2] Figures on imports compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

Peat moss imported for consumption in the United States, 1943–45, by grades

[All from Canada]

Year	Poultry and stable grade		Fertilizer grade		Total	
	Short tons	Value	Short tons	Value	Short tons	Value
1943	32,070	$910,898	27,357	$666,490	59,427	$1,577,388
1944	37,035	1,162,287	27,393	754,507	64,428	1,916,794

WORLD PRODUCTION

Because of economic chaos brought about by the war, it has been difficult to obtain data on production of peat in foreign countries. The latest available data are given in the following table.

World production of peat, 1939–45, by countries [1]

[Compiled by B. B. Waldbauer]

Country [1]	1939	1940	1941	1942	1943	1944	1945

CRUDE PETROLEUM AND PETROLEUM PRODUCTS[1]

By A. G. White, F. S. Lott, J. C. Casper, A. T. Coumbe, and A. L. Clapp

SUMMARY OUTLINE

GENERAL REVIEW

In 1945 the production of crude petroleum in the United States and the total demand for oil products exceeded all previous records. The production of crude petroleum amounted to 1,711 million barrels—a gain of 33 million barrels or about 2 percent compared with 1944. This production was 22 percent above the prewar peak of 1,402 million barrels in 1941. The total demand for all oils rose from 1,879 million barrels in 1944 to 1,952 million in 1945—a gain of 4 percent. Total exports declined from 208 million barrels in 1944 to 184 million in 1942, but domestic demand rose from 1,671 million barrels to 1,768 million.

The gain in the total demand for all oils in 1945 amounted to 73 million barrels, representing an increase of 52 million barrels in total motor-fuel demand and gains of almost 11 million barrels in residual fuel-oil demand, of 7 million barrels in distillate fuel-oil demand, of 5 million barrels in kerosine demand, and of about 1 million barrels in the demand for lubricating oils.

The total demand for motor fuel rose from 733 million barrels in 1944 to 785 million in 1945. Exports decreased from 100 million to 89 million, while domestic demand, including total deliveries from continental United States for our own military use at home and abroad, rose from 633 million barrels to 696 million. The decline in exports occurred primarily after the termination of lend-lease shipments in August, and the greatest increase in domestic demand resulted from the large military requirements in the first half of the year and the

[1] Data for 1945 are preliminary: detailed statistics with final revisions will be released later.

expansion in civilian consumption in the latter half of the year with termination of gasoline rationing in August.

The total demand for residual fuel oil rose from over 524 million barrels in 1944 to 535 million in 1945. Domestic demand increased about 11 million barrels, and there was a small decline in exports. Military, shipping, and railroad consumption remained at a high level during the year. The total demand for distillate fuel oil amounted to 253 million barrels in 1944 and 260 million in 1945. Exports declined almost 10 million barrels in 1945 and domestic demand increased about 17 million barrels. The greatest gain was in civilian consumption with termination of rationing.

Total demand for all oils in the United States, 1936–45

[Millions of barrels]

Year	Domestic demand	Exports	Total demand	Year	Domestic demand	Exports	Total demand
1936	1,092.7	132.0	1,224.7	1941	1,485.8	108.8	1,594.6
1937	1,169.7	172.8	1,342.5	1942	1,449.9	116.9	1,566.8
1938	1,137.1	193.7	1,330.8	1943	1,521.4	150.0	1,671.4
1939	1,231.1	188.9	1,420.0	1944	1,671.3	207.6	1,878.9
1940	1,326.6	130.5	1,457.1	1945 [1]	1,767.8	184.3	1,952.1

[1] Subject to revision.

The total demand for all oils in 1945 was 22 percent greater than in 1941, with gains of 13 percent in total motor-fuel demand, 35 percent in residual fuel-oil demand, 37 percent in distillate fuel-oil demand, 13 percent in kerosine demand, and 21 percent in the total demand for all other oils.

The principal changes in the supply of all oils in 1945, compared with 1944, included a gain of 33.2 million barrels in crude-oil production, an increase of 11.2 million barrels in the output of natural gasoline and cycle plants, a rise of 21.1 million barrels in total imports, and a reduction of 13.1 million barrels in total stocks. The production of crude petroleum averaged 4,584,000 barrels daily in 1944 and 4,688,000 barrels daily in 1945. Imports of crude petroleum increased from 44.8 million barrels in 1944 to 74.1 million in 1945, while imports of refined oils declined from 47.5 million barrels in 1944 to 39.3 million in 1945. Total crude stocks were reduced by 3.5 million barrels, and stocks of refined oils decreased 9.9 million barrels. Comparing 1945 with 1941, the production of all oils showed a gain of 23 percent, and imports were 17 percent larger.

In view of the fact that 1945 represented a transition from the peak of war demand in the first half of the year to unrestricted civilian consumption in the latter half, a brief review of operations, by quarters, will assist in understanding the trends of supply and demand.

In the first quarter of 1945 the total demand for all oils averaged 5,575,000 barrels daily, compared with 5,361,000 barrels daily in the fourth quarter of 1944. Exports amounted to 542,000 barrels daily, and the domestic demand—5,033,000 barrels daily—was at the highest recorded level of the war period. Crude production averaged 4,769,000 barrels daily and total crude runs to stills 4,736,000 barrels daily. Imports rose to 271,000 barrels daily, and a new supply was supplemented by a withdrawal of 102,000 barrels daily from stocks.

[1] Subject to revision.
[2] 42 gallons to the barrel.
[3] As reported to Bureau of Mines.
[4] U. S. Department of Commerce; exports include shipments to noncontiguous Territories.
[5] For comparison with succeeding year.
[6] Estimated.
[7] Figures not available.
[8] American Petroleum Institute.

In the second quarter of 1945 total demand averaged 5,576,000 barrels daily—a minor increase compared with the first quarter and a new record in total quarterly demand. Crude production of 4,842,000 barrels daily and crude runs of 4,892,000 daily represented the highest quarterly levels attained during the war. Exports of 699,000 barrels daily were the highest for the year but domestic demand declined to 4,877,000 barrels daily. Imports rose to 324,000 barrels daily, and a new supply was supplemented by withdrawal of 218,000 barrels daily from stocks.

The first and second quarters represented the highest levels of supply and demand attained during the war. With the decline in new military purchases and the termination of lend-lease shipments in August, production and total demand declined in the last two quarters of 1945.

In the third quarter of 1945 total demand declined sharply to 5,207,000 barrels daily. Exports were reduced to 422,000 barrels daily and domestic demand to 4,785,000 barrels daily. Crude production declined to 4,728,000 barrels daily, imports were reduced to 291,000 barrels daily, and 116,000 barrels daily were added to stocks

Supply and demand of all oils in the United States in 1944–45, by months

during the quarter. Crude runs to stills dropped to 4,740,000 barrels daily, and the average was decreased further by refinery shut-downs in the latter part of September due to strikes.

In the fourth quarter of 1945 total demand declined further to 5,042,000 barrels daily. Exports dropped to 360,000 barrels daily and domestic demand to 4,683,000 barrels daily. Crude production reached the lowest level of the year at 4,417,000, and crude runs declined to 4,479,000 barrels daily—affected, in part, by the continuation of refinery shut-downs in the first half of October. Imports, however, rose to 355,000 barrels daily. Even though supply was reduced, about 40,000 barrels daily were added to total stocks. The major stock increment was in gasoline, and stocks of fuel oils and kerosine were at very low levels by the end of the year.

In the first quarter of 1946 total demand for all oils amounted to 5,255,000 barrels daily—a decline of 320,000 barrels daily compared with the first quarter of 1945 but 212,000 barrels daily greater than in the last quarter of 1945. Exports rose to 405,000 barrels daily, and domestic demand increased to 4,850,000 barrels daily, with motor-fuel demand at a much higher rate than had been anticipated. Crude production rose to 4,581,000 barrels daily, imports increased to 359,000 barrels daily, and crude runs went up to 4,609,000 barrels daily. In adjusting supply to demand, by products, the yield of gasoline was reduced, and fuel-oil and kerosine yields were increased.

The total demand for all oils in 1946 probably will be 1 to 2 percent less than the war peak of 1945—a much larger total demand than was anticipated, Presumably, exports will continue to decline with cessation of war requirements abroad, the increased prices of domestic crude oil, and the problem of international exchange. Within the United States the transition from war requirements to civilian uses has been rapid.

Although the total demand for motor fuel may be somewhat less in 1946 than in 1945, domestic demand may exceed all previous records. Contemplated military purchases of motor fuel will be less than 3 percent of the total domestic demand in 1946, and the increment will be in civilian usage.

The compilation, by the Public Roads Administration, of data from State tax records furnishes the best source of information on the consumption of motor fuel for highway or automotive use. Comparative figures indicate that this automotive demand amounted to 576 million barrels in 1941, 391 million in 1944, and 456 million in 1945. Preliminary forecasts of automotive demand in 1946 were based on the assumption that the reduced number of vehicles would result in a total automotive demand considerably below the 1941 peak. Data available for the first half of the year, however, would indicate that automotive demand for motor fuel in 1946 may be considerably greater than in 1941.

The domestic demand for residual fuel oil in 1946 may be considerably less than in 1945, due to the reduction in naval purchases. The expansion in civilian demand may be retarded by difficulties in securing new oil installations and materials for reconversion. The removal of rationing restrictions should result in a return to the normal volume of light heating oils required with prospects of a rapid increase in the number of new installations.

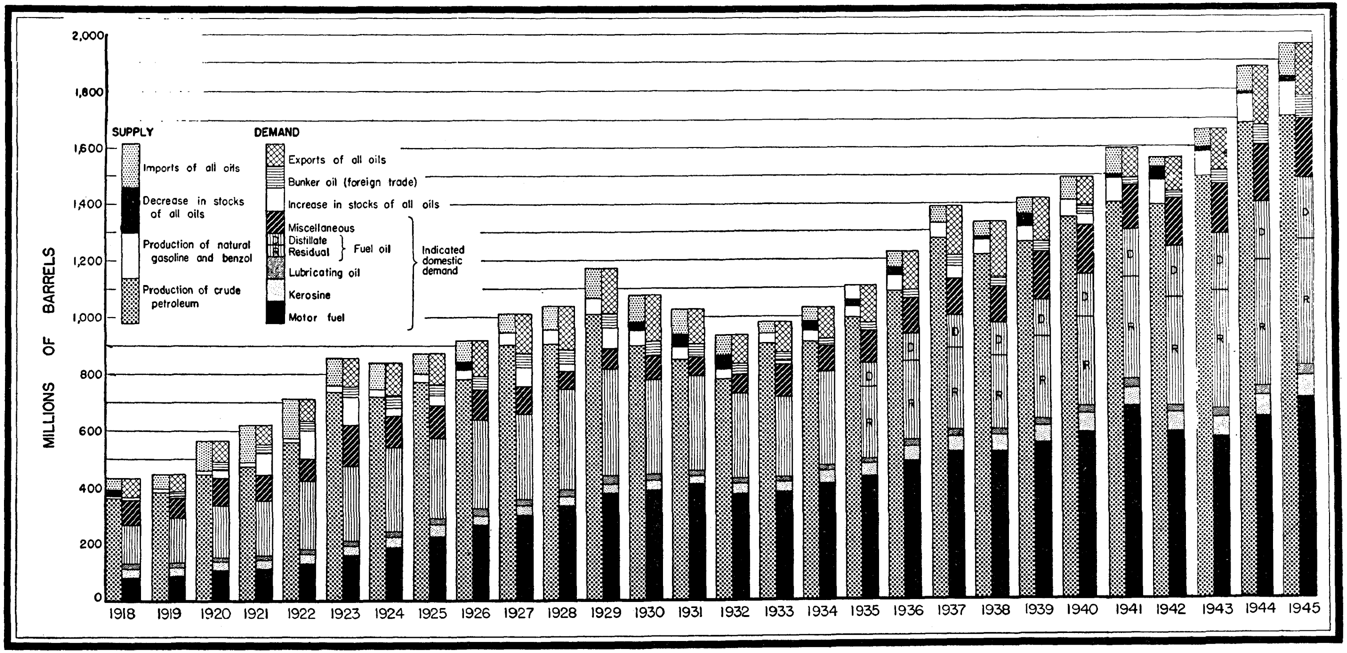

FIGURE 1.—Supply and demand of all oils in the United States, 1918–45.

ADMINISTRATION

In the early months of 1945 demand on the United States for all oils reached record levels and taxed the facilities of the Petroleum Administration for War and the petroleum industry to meet, world-wide, the urgent needs of the United Nations in the final stages of the war. With the surrender of Germany in May, a major problem of coordination of supply and transportation of petroleum and products was posed by the shift in emphasis from the European to the Asiatic theater of military operations. It was necessary to curtail the eastward movement and direct all available means to augment the rapid flow of products westward to the Pacific through the Panama Canal and overland through West coast ports until the surrender of Japan in August.

Prompt action was taken to remove controls over the petroleum industry upon the end of hostilities. The day after the surrender of Japan, August 15, 1945, rationing of gasoline and fuel oils was ended, and wartime restrictions upon gasoline quality and most refining operations were removed. On August 23 most of the distribution and marketing regulations were rescinded. Many of the controls over petroleum supply and transportation were canceled on August 27, and regulations covering well spacing in the oil and natural-gas fields expired on September 1, as did limitations on construction in all branches of the industry. By October 15 all domestic orders had been terminated and those affecting foreign operations became void by November 1.

By Executive order of the President the Petroleum Administration for War was terminated, effective May 8, 1946. Shortly thereafter, however, a new Oil and Gas Division was organized in the Department of the Interior to undertake a program, recommended by the President, of coordination of Government activities with respect to petroleum and natural gas and to serve as a liaison agency of the Federal Government in its relations with appropriate State bodies and the petroleum industry.

RESERVES

The American Petroleum Institute Committee on Petroleum Reserves estimated proved reserves of crude oil in the United States on January 1, 1946, at 20,826,813,000 barrels. These reserves include crude oil and condensate in known and proved fields recoverable under existing economic and operating conditions. Additions to reserves during 1945 totaled 2,110,299,000 barrels and represented 419,984,000 barrels from new pools discovered during the year and 1,690,315,000 barrels due to upward revisions of reserve estimates for fields discovered before 1945. The increase in total reserves amounted to 374 million barrels during 1945.

The largest gains in reserves were 171 million barrels for Colorado. 117 million for Louisiana, 95 million for Texas. 66 million for California and 58 million for Mississippi. The greatest declines in reserves were 80 million barrels for Oklahoma, 60 million for Kansas, 51 million for New Mexico, and a total of 20 million in the Appalachian States—Pennsylvania, New York, and West Virginia.

[1] From reports of Committee on Petroleum Reserves, American Petroleum Institute, of the amount of crude oil that may be extracted by present methods from fields completely developed or sufficiently explored to permit reasonably accurate calculations. The change in reserves during any year represents total new discoveries, extensions, and revisions, minus production.

WORLD OIL SUPPLY

The world production of crude petroleum exceeded all previous records in 1945, increasing from 2,614 million barrels in 1944 to 2,625 million in 1945. A gain of 2 percent in the United States more than offset a decline of 2 percent in other producing countries. The United States produced 64 percent of the total in 1944 and 65 percent in 1945.

World production was 539 million barrels greater in 1945 than in 1939. The principal changes in world production (comparing 1939 with 1945) have been a gain of 446 million barrels for the United States, 117 million barrels for Venezuela, 51 million for Iran, and 17 million barrels for Saudi Arabia. Principal declines have been in Russia, Netherlands Indies, and Rumania. In North and South America, only relatively small changes in crude-oil production have occurred outside of the United States and Venezuela. In Europe the total decline is estimated at 70 million barrels, chiefly in Russia and Rumania, with moderate gains in other small producing countries. In Asia the total increase has been about 28 million barrels, with gains in Iran and Saudi Arabia partly offset by declines in Netherlands Indies and Burma.

Net exports (exports less imports) from the United States amounted to 130 million barrels in 1939 and 71 million in 1945. In 1946 imports probably will show a material gain and exports a decline, so that the net export will be comparatively small. If this trend continues, United States production may soon reach a point where it about balances domestic requirements.

The domestic demand for all oils in the United States has increased from 1,231 million barrels in 1939 to 1,768 million in 1945 and is estimated at about the same amount in 1946—a comparative gain from 1939 to 1946 of about 44 percent.

Crude production outside of the United States increased from 821 million barrels in 1939 to 914 million barrels in 1945—a gain of only 11 percent. Crude production outside of the United States plus the net exports of all oils from the United States would indicate a net supply for the rest of the world of 951 million barrels in 1939 and 985 million in 1945, exclusive of substitute oils produced. These figures indicate only a relatively small gain in oil consumption outside the United States in 1945 compared with 1939.

CRUDE PETROLEUM

SUPPLY AND DEMAND

The total demand for crude petroleum in 1945 amounted to 1,789 million barrels and exceeded the previous record of 1944 by almost 44 million barrels. The demand for domestic crude petroleum rose from 1,701 million barrels in 1944 to 1,715 million in 1945—a gain of 14 million barrels. The demand for imported crude oil rose from 44 million barrels in 1944 to 74 million in 1945—a gain of 30 million barrels.

Compared with 1944, the production of domestic crude petroleum in 1945 increased 33 million barrels, imports of crude oil were 29 million barrels greater, and total stocks of crude oil were reduced by only 4 million barrels compared with a decrease of 22 million barrels in 1944.

The principal changes in crude-oil demand were an increase of 54 million barrels in total runs to stills, a decline of 1 million barrels in crude exports, a decline of 8 million barrels in transfers of crude oil to fuel oils, and a decline of 1 million barrels in other crude fuel and losses.

PRODUCTION

General.—The production of crude petroleum set a new record of 1,711,103,000 barrels in 1945—a gain of 33 million barrels or 2 percent compared with 1944. Production in 1945 was 309 million barrels greater than in 1941—a gain of 22 percent.

The principal gains in production in 1945 compared with 1944 were 15 million barrels for California, 13 million for Oklahoma, and 9 million for Texas. The largest declines were 3 million barrels for Kansas and 2 million for New Mexico and Illinois.

Texas and California retained their positions as the two leading States, with 44.1 and 19.1 percent of the total national output. Oklahoma ranked third in the list of producers with 8.1 percent, Louisiana fourth with 7.6 percent, Kansas fifth with 5.6 percent, and Illinois sixth with 4.4 percent.

Production in the East Texas field totaled 131,210,000 barrels in 1945—a decline of over 3 million barrels compared with 1944. In California production in the Wilmington field declined about 1 million barrels to 36,222,000 barrels in 1945, declined in the Coalinga field by 4 million barrels to 31,549,000 barrels, rose in Elk Hills 8 million barrels to 15,813,000 barrels, and increased 9 million barrels in Buena Vista Hills to 15,759,000 barrels. In Oklahoma, production in the West Edmond field rose to 26,548,000 barrels—a gain of almost 19 million barrels.

[1] Oil and Gas Journal. [2] Bureau of Mines. [3] Revised figure.

Alabama.—Continued development of the Gilbertown area, discovered in 1944, resulted in the completion in 1945 of 15 oil wells, of which 11 were in the West Gilbertown field and 4 in the East Gilbertown field, discovered in September 1945. The production increased from 43,000 barrels in 1944 to 181,000 barrels in 1945. The oil from both fields is black, asphaltic base, with A. P. I. gravity 17° to 18°.

Completions numbered 42 in 1945, of which most were wildcats, compared with 38 in 1944.

The Alabama legislature passed an oil- and gas-conservation law in 1945 and established a State oil and gas board to promulgate and enforce rules and regulations under the law.

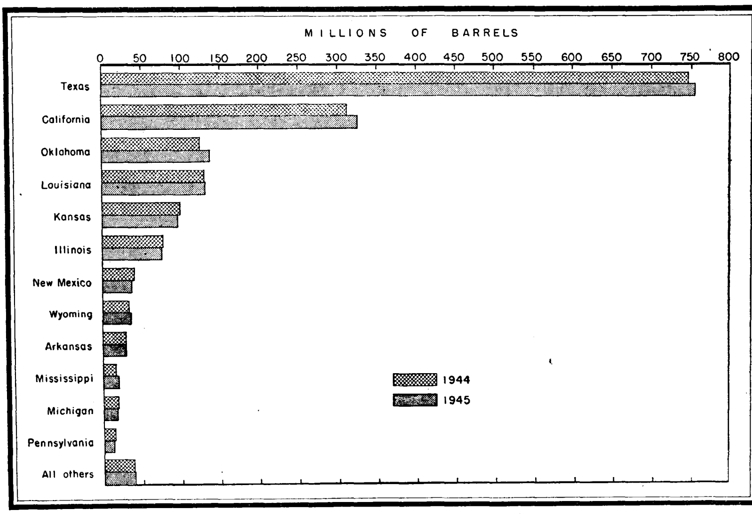

FIGURE 3.—Production of crude petroleum in the United States, 1944–45, by States.

Arkansas.—For the first time since 1936, production of crude petroleum declined in 1945 to 28,613,000 barrels from 29,418,000 barrels in 1944. Smaller output was reported from a number of fields, of which Magnolia, Dorcheat-Macedonia, and Schuler showed the greatest declines. Minor gains were reported at Midway, Stevens, and Atlanta.

Exploratory drilling declined sharply from the total of 70 wells completed in 1944 to 40 in 1945. Only 2 oil fields of small extent were discovered. These were the North Stevens field, Nevada County discovered in July by a well that pumped 50 barrels of oil daily from the Buckrange sand (Upper Cretaceous); and the Wesson field in southwestern Ouachita County, opened in September by completion of a well flowing 126 barrels per day through a ⅛-inch choke from a Lower Glenrose sand. Production from new horizons was developed in the Gum Creek (formerly New McDonald), Strong, and Stevens-Smart fields. The productive areas of several fields, including Atlanta, Fouke, McKamie, and Village, were enlarged by drilling, but none of these extensions appeared to have major importance.

Geophysical activity in exploration, as indicated by crew weeks worked, was notably higher in 1945 than in 1944 and covered many counties in central and northeastern Arkansas as well as those in the producing districts. The unproductive Desha Basin of southeastern Arkansas was extensively worked, and much of this area was leased by major oil companies.

The total number of completions declined from 215 in 1944 to 203 in 1945, of which 133 were oil wells, 8 gas wells, and 63 dry holes.

Production of crude petroleum in Arkansas, 1941–45, by fields

[1] Includes oil consumed on leases and net change in stocks held on leases for entire State.
[2] Subject to revision.
[3] Includes New London.

California.—Crude production increased from 311,793,000 barrels in 1944 to 326,482,000 barrels in 1945, a new record. Daily average output was about 915,000 barrels in the first 9 months of the year and dropped to 835,000 barrels in the last quarter as the demands of war declined. Production from the Elk Hills Naval Reserve had been sustained at a rate of 65,000 barrels daily until the end of hostilities in August, after which it was promptly cut back to about 15,000 barrels.

The San Joaquin Valley produced 161,131,000 barrels in 1945, a gain of 9 percent over 1944, owing to large increases from the Midway-Sunset and Elk Hills fields. During the emergency development at Elk Hills in 1944 and 1945, by the United States Navy, approximately 300 oil wells were completed.

The Coastal district produced 53,839,000 barrels in 1945 compared with 50,003,000 barrels in 1944. The Santa Maria Valley field output gained over 2,100,000 barrels over 1944, and smaller increases were reported from San Martinez and Ventura Avenue.

Small declines from a number of fields and the absence of large gains in any area caused production of the Los Angeles Basin to decline from 114,296,000 barrels in 1944 to 111,512,000 barrels in 1945.

The total demand for petroleum on the Pacific coast exceeded the local supply in 1945 because of the large-scale naval and military operations in the Pacific theater of war. As a result, 14,259,000 barrels of crude from Texas and Rocky Mountain fields were shipped by tank car into California in the first 11 months. This movement reached a peak in June, when 64,800 barrels daily reached the West coast.

Total well completions, surpassing the 1944 record by 5 percent, numbered 2,150, of which 1,690 were oil wells, 56 gas wells, and 404 dry holes. Exploration was heavily concentrated in Kern County, as indicated by 102 wildcat completions, of the State total of 235. Other active counties in exploration were: Los Angeles 35 completions, Solano 15, Fresno 12, Santa Barbara 12, and San Luis Obispo 10.

Seven new oil fields were discovered, as follows: McDonald, Rosedale, and Santiago, producing from Miocene formations at depths of 850 to 4,870 feet, all in Kern County. Of these, the Santiago field appears to have greatest importance. Three discoveries were made in Los Angeles County also: Hasley Canyon, Sansinena, and Ramona. The seventh new field, West Mountain in Ventura County, produced from the Sespe formation at 4,501 to 5,450 feet.

The greatest additions to reserves apparently resulted from new zones and extensions to existing fields. In Kern County important new reserves were developed at Cymric and Elk Hills and in fractured basement schist at Edison. The schist-conglomerate zone in the Wilmington field was opened to large production possibilities. Reserves were added to over 40 fields during 1945; the total additions have been estimated as about 500 million barrels.

The Conservation Committee of California Oil Producers estimated the "maximum efficient rate" of crude-oil production from California oil fields on December 31, 1945, as 824,000 barrels per day.

Colorado.—Rapid expansion of production from the Rangely field, due to intensive development and the completion of a 10-inch pipe line to transport the oil to markets, was the principal factor in raising Colorado output 61 percent in 1945 to a new record of 4,959,000 barrels. Owing to a material gain in output in 1945, Wilson Creek remained the leading field of the State in production but doubtless will be surpassed in 1946 by Rangely, whose capacity and reserves are much greater.

Oil-well completions increased from 22 in 1944 to 42 in 1945, of which 29 were at Rangely, 7 at Wilson Creek, and 3 at North McCallum. Eighteen wildcat wells were completed, of which one produced oil (Rangely), one yielded gas (Powder Wash), and 16 were dry holes.

No new field discoveries were reported in 1945, but extensions at Rangely added to proved reserves an amount many times larger than the 1945 production of Colorado. Minor extensions were reported also at Powder Wash and North McCallum.

Production of crude petroleum in Colorado, 1941–45, by fields

[1] Includes crude oil consumed on leases and net change in stocks held on leases for entire State.
[2] Subject to revision.

Florida.—A second producing well was completed in the Sunniland field, Collier County, about 1 mile north of the discovery well, in June 1945. It flowed about 200 barrels per day initially, with some salt water, from a depth of 11,597 feet in Lower Cretaceous rocks. Production of the field in 1945 was 30,000 barrels compared with 12,000 barrels in 1944.

Seventeen wells were completed in 1945 of which 16 were abandoned as dry holes. More than half the area of the State is said to be under lease for oil and gas.

Georgia.—Five exploratory wells were drilled in 1945 in the southeastern coastal plain section of the State. The deepest of these, in Atkinson County, attained a total depth of 4,296 feet and reached basement rocks, as did wells in Echols and Laurens Counties. Small shows of oil and gas were encountered, but none with promise of commercial production. Two wildcats were drilling at the end of the year.

Illinois.—Production declined 3 percent in 1945 to 75,210,000 barrels, continuing the trend that has persisted since the peak of 1940. Further declines in such leading fields as Salem, Louden, Dale-Hoodville, and New Harmony were not offset by scattered increases in output, of which the largest were at Bible Grove, Noble-Schnell, and Patoka. The latter field produced 1,574,000 barrels in 1945 under the stimulus of water-flood operations, a gain of 67 percent over 1944. Gas pressuring is practiced in a number of fields including Louden, Salem, Rural Hill, Griffen, Dahlgren and old Crawford and Laurence Counties' fields.

Oil-well completions numbered 1,079 in 1945 compared with 1,196 in 1944, amounting to 61 percent of total completions in both years. The most active fields with number of oil wells completed in 1945 were Clay City 110, Boyd 75, Mattoon 54, Bible Grove, 53, Albion 53, and Noble 40. A total of 460 wildcat wells was drilled, of which 73, or 16 percent, obtained oil production.

In all, 26 new fields were discovered, among which Brownsville, White County; Odin, Marion County; and Stamford, Clay County, were reported to have the greatest indicated reserves. Although several tests of Devonian and older formations were drilled, only one opened production in pre-Mississippian strata: Devonian production was found beneath an old Mississippian reservoir in the Woodlawn pool, Jefferson County. Late in 1945 the indicated trend of exploration was away from the active southeastern counties and toward and beyond the northern limits of the productive section of the State.

[1] Oil and Gas Journal.
[2] Includes Stoy in 1941.

Indiana.—Production amounted to 4,868,000 barrels in 1945 compared with 5,118,000 barrels in 1944 and the peak of recent years of 7,411,000 barrels in 1941. The fields of largest output in 1945 were: Griffen (1,722,000 barrels), New Harmony (464,000 barrels), and Mount Vernon (404,000 barrels): all in Posey County.

Oil-well completions declined from 144 in 1944 to 116 in 1945. Drilling was heavily concentrated in Gibson (40 oil wells) and Posey (35 oil wells) counties. Several Trenton oil wells were drilled in the Henderson field, Jay County.

Discovery of seven new pools was reported: 4 in Posey County, Crunk, Farmersville, Jeffries, and St. Wendells East; and 3 in Gibson County, Johnson West, Lysle, and Mount Carmel East. Extension of the New Harmony South pool on Mink Island in the Wabash River, and of the Owensville North pool (Gibson County) appears to have important possibilities of future development.

[1] Subject to revision.

Kansas.—Crude production declined 3 percent in 1945 to 95,997,000 barrels owing to numerous declines of which the largest were in the Silica-Raymond, Carmi, Zenith, Chase, and Burnett fields. The Trapp-Sellens area, the State's largest producer, increased its output about 1.3 million barrels over 1944, aided by an active drilling program.

Oil-well completions numbered 838 compared with 824 in 1944. Of 1,796 reported completions of all types, 385 were listed as exploratory wells. The areas of greatest development with the number of oil-wells drilled in each were: Kraft-Prusa 67, Trapp 48, Virgil and North 45, the old El Dorado field 27, and Chitwood 23. The Hugoton gas field with 164 completions was the most active area in 1945.

A total of 34 discoveries was reported, the largest indicated area and reserves being the Ryan field in Rush County, producing from the Arbuckle limestone at a depth of 3,725 feet. Before the end of 1945, 23 producing wells had been completed in this field. Other relatively important discoveries were: Carroll and Behrens in Barton County, Faulkner in Graham County, and West Ray in Norton County. All reported discoveries were on, or in the vicinity of, the great northwest trend associated with the Barton arch structure, except the Livergood field in Brown County in the northeast corner of Kansas.

Kentucky.—Production increased from 9,621,000 barrels in 1944 to a new record of 10,325,000 barrels in 1945, of which about 82 percent originated in Western Kentucky, 16 percent in Eastern Kentucky, and 2 percent in the old south-central producing area. The leading fields in production in 1945 were: Uniontown, Union County (3,091,000 barrels), Smith Mills, Henderson County (1,065,000 barrels), Poole Consolidated, Henderson County (1,006,000 barrels), and Hittesville Consolidated, Union County (636,000 barrels).

In Western Kentucky 292 oil wells were completed in 1945; 90 in Eastern Kentucky and perhaps 60 in the southern district, where activity has been increasing for several years. The most active oil fields in 1945, with the number of oil wells completed in each were: Uniontown 46, Poole 34, Waverly 32, and Dixie 27.

Eight fields were discovered, two in Union County, two in Henderson, and one each in Crittenden, Daviess, Ohio, and Todd Counties. The most important of these appear to be Dixie, Henderson County, producing chiefly from the Cypress sand at 2,300 feet; and Waverly, Union County, in which the principal producing horizon is also the Cypress at similar depth. New activity in Southern Kentucky has been encouraged by the extension of shallow Ordovician production in Clinton County.

Louisiana.—A slight gain in production in 1945 to 130,566,000 barrels exceeded the former record output of 129,645,000 barrels made in 1944. These figures do not include liquids extracted from gas at cycle and natural gasoline plants. Since 1942 declines in production of the Northern district have been offset by larger increases in the Gulf district. The largest gains in output were reported from the following Gulf fields: West Tepetate, Delta Farms, Tepetate, Vinton, and Goodhope. Among the Northern district fields, Lake St. John and Delhi had the largest increases over 1944. Haynesville declined almost 1.5 million barrels in 1945, a sharp decline similar to that in 1944, and material declines continued at Olla, Rodessa, and Nebo.

Oil-well completions in the Gulf district were 310 in 1944 and 407 in 1945, of which 24 were classed as wildcat and 383 development wells. The most active fields were Erath (24 oil wells), Delta Farms (23), Egan (20), West Tepetate (20), and Good Hope (16). In the Northern district drilling increased sharply above the level of 1944, resulting in 239 oil-well completions compared with 119 in 1944. Nine of the 1945 completions were wildcats and 230 development wells. Delhi, discovered in 1944 as the first oil field in northeastern Louisiana, was the most active field in the State in 1945, with 62 new oil wells added. Other active Northern fields in 1945 were: Bellevue with 36 new oil wells, Lake St. John 29, Big Creek 20, and Caddo 18.

The 93 exploratory wells drilled in the Northern district in 1945 discovered 5 oil fields: Big Creek and West Delhi in Richland Parish, Lamar in Franklin, North Shongaloo in Webster, and Sailes in Bienville. In the West Delhi field, 15 wells were completed by the end of 1945 flowing high-gravity oil (40°) from Tuscaloosa and Paluxy sands. Development joined this new reserve with the Delhi field. Five condensate and one dry-gas field were also discovered in 1945.

In the Gulf district 74 wildcat wells resulted in the discovery of 10 oil fields and 3 condensate fields, scattered from Beauregard and Cameron Parishes on the west to Jefferson Parish on the east. One or more dry holes were subsequently completed near several of the discoveries, tending to limit the probabilities of large reserves. Weeks Island, a condensate discovery in Iberia Parish, may have large potentialities, and two oil discoveries; Bon Air, Jefferson Davis Parish, and Oretta, Beauregard Parish, appear to have prospects of substantial reserves.

Michigan.—Production decreased for the third successive year—from 18,490,000 barrels in 1944 to 17,267,000 barrels in 1945—owing to the dearth of major new developments. Material declines in output of Reed City, Headquarters, and other fields, were not compensated by gains in the recently developed Coldwater, Deep River, Fork, and Essexville areas.

Completion of 267 oil wells in 1945 compared with 239 in 1944. A total of 770 completions was reported, of which 289 were exploratory and 481 field development wells. The most intensively developed fields, with the number of oil wells completed in 1945, were: Coldwater 46, Deep River 45, Essexville 20, Fillmore 20, and East Norwich 18.

Fifteen oil fields were discovered in 1945, none of which appears at present to be large. The more promising among them are Douglas, Montcalm County, and Harrison, Clare County, producing from the Dundee formation; and Rockford, Kent County, and Ashton, Osceola County, producing from Traverse limestone.

Seismograph and gravimeter surveys were used in 1945 in connection with the search for favorable structural conditions; in addition, 203 shallow tests were drilled through the glacial drift to determine the elevation and attitude of underlying strata that could be identified as "markers."

Mississippi.—Following 2 years of decline, production increased in 1945 to 18,775,000 barrels from 16,337,000 barrels in 1944 as the output of recently developed fields increased. Tinsley production declined from 11,803,000 barrels (72 percent of the State total) in 1944 to 9,400,000 barrels (50 percent of total) in 1945. The Cranfield and Eucutta yields, according to information supplied by the Mississippi Oil and Gas Engineering Committee, produced 2,098,000 and 2,085,000 barrels, respectively, in 1945, about four times their 1944 output. Heidelberg gained from 1,441,000 barrels in 1944 to 2,894,000 barrels in 1945. Lesser gains in 1945 were reported from several fields.

Oil-well completions were 78 in 1944 and 198 in 1945, of which 6 were exploratory and 192 development wells. Completions of oil wells in the most active fields were: Eucutta 58, Heidelberg 52, Cranfield 31, and Langsdale 16.

Three oil fields were discovered: Langsdale, Clarke County, an important reserve; Fayette, Jefferson County; and Quitman, Clarke County. The Carthage Point, Soso, and Hub condensate fields were also opened. Extensions by outpost drilling were reported at Cranfield, Baxterville, and Eucutta.

Montana.—Production declined from 8,627,000 barrels in 1944 because of the reduction of 557,000 barrels in runs from Cut Bank. This field has dominated Montana crude output for a number of years, accounting for 65 percent of the total in 1944 and 58 percent in 1945. The Montana portion of the Elk Basin field, the State's third largest source of oil, had the greatest gain in output (254,000 barrels) in 1945, as active development of the Tensleep sand continued. The comparatively small Dry Creek production increased 80 percent, apparently reflecting the 1944 discovery of oil in the Morrison formation.

Oil-well completions numbered 217, compared with 221 in 1944. The most active fields in 1945, with oil wells completed in each, were: Cut Bank 92, Kevin-Sunburst 84, Elk Basin 12, High Gravity 8, and Pondera 5. Of 35 wells classed as wildcats, 10 found oil production and 25 were dry holes.

Oil was discovered in Madison limestone at 1,650 feet, northwest of the Devon gas field, Toole County. A discovery of great potential importance was reported in the completion of the first oil well producing from Madison limestone in the Cut Bank area. The old Cat Creek field, Petroleum County, was revived by completion of a 300-barrel well in an Ellis sand, opening a new pool that was actively developed.

Nebraska.—Production in 1945 amounted to 305,000 barrels, compared with 417,000 barrels in 1944, continuing the decline that has persisted since the brief peak in output of 1941. The Falls City field accounted for 191,000 barrels of the 1945 total, Barada 106,000 barrels, and Dawson and Shubert the remainder. All producing fields are in Richardson County.

A further decline in drilling was indicated with 13 completions reported, of which 6 were in Richardson County and 3 in the northwestern section of the State. No discoveries or extensions to producing areas were made. The only producing well was completed in the Dawson field, making 30 barrels per day initially from Hunton limestone with a high percentage of water.

New Mexico.—Production declined 6 percent in 1945 to 37,281,000 barrels, as output from all leading fields was reduced. Monument, Eunice, Vacuum, and Hobbs continued to be the major sources of production.

The number of oil-well completions changed only from 283 in 1944 to 279 in 1945. All of the 1945 wells were in the southeastern part of the State, 10 being classed as wildcats in Lea County and 269 field-development wells. Oil wells added in the most active fields were as follows: Grayburg-Jackson 35, Lovington West 24, Square Lake 23, Red Lake 17, and Caprock 16. The average depth of wells drilled was greater in 1945 than in 1944 and previous years, influenced by development of deeper production, chiefly in lower Permian horizons, in several fields. The deepest test ever drilled in New Mexico was abandoned as a dry hole at total depth of 13,998 feet in Pennsylvanian formation. It was located 1 mile from the Maljamar field, Lea County.

A major discovery was indicated by opening of the Paddock pool in April, 4 miles north of the important Drinkard pool, a 1944 discovery. Production was obtained from Glorietta and Yeso limestones of Permian age. In the Drinkard field substantial additions to reserves were made by development of new production from Clearfork and Wichita-Albany formations.

New Mexico's second Ellenburger limestone discovery was made in September, in the Skelly-Penrose area, by a large well that produced from a depth of 8,059 to 8,140 feet. Apparently, it is an important discovery. In the same area, new reserves in producing formations of Permian age were discovered.

New York.—The declining trend of production in 1943 and 1944 appears to have been arrested, at least temporarily, in 1945 as total output amounted to 4,648,000 barrels, compared with 4,697,000 barrels in 1944.

Drilling in 1945 was moderately below the 1944 rate. Oil-well completions numbered 723, or 65 fewer than in 1944, and water-input wells declined to 408 from 446 in 1944. A few unsuccessful attempts were made to enlarge productive areas of old fields in Allegany and Cattaraugus Counties, and some wildcatting activity was reported in southeastern Chautauqua County.

A deep well at Arcade, Wyoming County, reached a depth of over 7,100 feet in early 1946, having penetrated the Potsdam sandstone and encountered below it previously unknown dolomite and sandstone formations of probable Cambrian age.

Ohio.—In common with the other eastern producing States whose output is from stripper wells and secondary recovery operations, Ohio registered a peak in output in 1942 that has been followed by a declining trend. In 1945 production of 2,828,000 barrels was 4 percent below 1944 and 20 percent below 1942. Most of the 1945 production decline was in the Pennsylvania Grade oil.

Oil-well completions gained from 210 in 1944 to 248 in 1945, according to the Oil Weekly. Almost half the new oil wells produced from the Clinton sand, about one-quarter from sands above the Berea sand, and about one-fifth from the Berea. Oil development was most active in the following counties, in order: Muskingum, Perry, Washington, Meigs, Monroe, and Ashland.

No discoveries of new oil were reported in 1945, but a number of extensions to proved fields were made, notably to Clinton production in Muskingum and Perry Counties and to Berea production in Meigs County. A small Big Injun sand pool was opened at Stafford, Monroe County.

Oklahoma.—The upward trend in production, begun in 1944, continued through 1945, when the total output (138,036,000 barrels) was 11 percent above 1944. Output of the West Edmond field, north of Oklahoma City, increased from 7,752,000 barrels in 1944 to 26,548,000 barrels in 1945, or more than the State as a whole. Gains of about 1 million barrels each at Cement and Moore were accompanied by losses of over 3 million barrels at Oklahoma City and 1 million in the old Hewitt field. Principal fields in the Seminole district continued slow declines.

Oil-well completions were sharply higher for the second year, increasing from 1,031 in 1944 to 1,426 in 1945, influenced by concentrated drilling at West Edmond, which resulted in a gain from 256 to 390 oil wells in that great field. At the end of 1945, West Edmond had approximately 700 oil wells in a productive area of 31,500 acres, producing over 80,000 barrels daily of pipe-line oil (41° A. P. I. gravity). Of 471 exploratory completions in 1945, 86 were commercial oil wells, located in the following leading counties: Oklahoma 10, Logan 7, Stephens 7, and Garvin 5. After West Edmond, the fields with greatest number of oil completions were: Paul's Valley 59, Velma 45, Spaulding 37, Cement 37, Stroud 37, Cheyarha 36, Loco 36, and Lone Grove 27.

Much of the exploratory effort was directed toward structures in the eastern part of the great Anadarko Basin and resulted in several discoveries. The outstanding new field, on the basis of early indications, was North Lindsay, McClain County, in which production was found from the Wilcox sand below 10,950 feet. Other 1945 discoveries in the Anadarko Basin included the Chitwood pool, Grady County, producing condensate from a Pennsylvania sand at 10,880 feet; Northwest Cashion, Kingfisher County, producing from the Bois d'Arc section of the Hunton limestone at 7,064 to 7,095 feet; Bethany pool, Oklahoma County, producing condensate from the Bois d'Arc at 7,154 to 7,220 feet.

Of particular interest was the discovery of commercial oil production near Keyes, Cimarron County, west of the Hugoton gas production. The discovery well produced initially 140 barrels daily of 38° gravity oil from sand at 4,800 to 4,840 feet in the Cherokee formation.

Approximately 25 percent of the oil produced in 1945 qualified for payments under the OPA stripper-well program, which have been estimated to average about 31 cents a barrel. Seismograph activity was directed chiefly toward Western and South Central Oklahoma and is reported to have totaled 367 crew months of work, a 3-percent decline from the 1944 peak.

Although no new water-flood operations were reported in 1945, an increase in this type of secondary recovery is anticipated as materials and labor become less difficult to obtain and as a result of the provisions of the 1945 Compulsory Unitization Bill which fosters unit operation of oil and gas pools.

Pennsylvania.—Production declined in 1945 for the third successive year to 12,515,000 barrels, 11 percent below the 1944 total and 30 percent below 1942. The Bradford-field production dropped 11 percent to 10,793,000 barrels, of which 963,000 barrels were produced in the New York State portion of the field.

According to the Oil Weekly, oil-well completions numbered 1,400, a reduction of 10 below 1944, and 1,227 water input wells were drilled, compared with 1,268 in 1944.

Two small oil fields were discovered in 1945. One, in Kent Hollow, Keating Township, McKean County, produced from Haskell sand. An area of about 600 productive acres was indicated by the 12 oil wells. The other oil pool, discovered in early 1945 in North Strabane Township, Washington County, produced from the Gordon sand and appeared to be about 150 acres in areal extent.

Tennessee.—About 8,000 barrels of oil were produced in 1945, most of which was from Mississippi lime wells in Scott and Morgan Counties. Two wells each in Clay and Fentress Counties accounted for the remainder.

Six completions were reported in 1945, three in Fentress and one each in Cumberland, Jackson, and Haywood Counties. All were dry holes.

Texas.—Production increased 1 percent above the 1944 record to 755,533,000 barrels, although a sharp cut-back occurred after the end of hostilities in August. The principal gains in output were almost 15 million barrels in West Texas and 7 million in South Texas. Minor declines were recorded in the Gulf Coast, East Texas, and Panhandle districts where production from most major fields was reduced.

Oil-well completions increased from 3,526 in 1944 to 4,036 in 1945, or 15 percent, owing principally to greater activity in West Texas, the Gulf Coast and North and West Central districts. A total of 1,552 wildcat completions resulted in 228 oil discoveries concentrated heavily in the Gulf Coast, West, and North Texas.

Moderately reduced output characterized most Gulf Coast fields in 1945, the principal exceptions being Fannette, Stowell, Old Ocean, and Withers-Magnet, which continued upward trends of several years duration.

Oil-well completions increased 26 percent over 1944 to 1,013, the rate of completions tending to increase in the late months of the year. The most active fields with oil wells added in each were Seeligson 106, Willamar 69, Stratton 42, Tijerina 40, and Livingston 35.

Over 50 new fields were discovered in 1945, of which about one-third produced from the Wilcox formation, a smaller proportion from the Frio, and a few from Cockfield-Yegua horizons. In addition, a number of new pays and extensions to productive acreage were developed. Several deep tests in old fields were drilled to explore possibilities below formations currently producing. Indications were found of porous sand bodies and limestone strata at depth that are expected to encourage further prospecting. One of these holes, on Millican dome, Brazos County, reached a record depth of 16,655 feet.

The gain in West Texas production to a new record of 175,727,000 barrels in 1945 was influenced by Andrews County, which doubled its output to 14,383,000 barrels through intensive development at Fullerton, Means, and other fields; and Winkler County, where the Keystone area contributed materially to a gain of 4 million barrels of production.

West Texas oil-well completions were 1,309 in 1945 compared with 1,323 in 1944. The following were the most active fields and the number of oil wells completed in each: Fullerton 208, Slaughter 165, Keystone 87, North Ward 47, TXL 41, and Cowden 41.

Exploratory drilling resulted in the discovery of 26 new fields, of which 7 produced from Devonian, 2 from Ellenburger limestone, 1 from Waddell sand (Ordovician), and the remaining 16 from Permian formations. Most of the important recent discoveries produce from rocks of greater age than the Permian, and this is expected to be generally true of new discoveries in this area for a number of years. Large new reserves were developed in the Ellenburger limestone by deep drilling in the Todd Deep field, Crockett County; TXL field, Ector County; and Fullerton field, Andrews County. Field extensions of major importance were reported at TXL (Devonian), Slaughter (San Andres), Fullerton (Devonian), and Mabel (San Andres), among others. The deepest producing well in West Texas was completed in November as the discovery well of the Jones Ranch field, Gaines County, 4½ miles southwest of the Wasson field. The well produces from Devonian formation at 11,422 feet.

Production of the East Texas district declined about 5 million barrels in 1945 to 179,124,000 barrels, as output of the East Texas field was reduced almost 4 million barrels to 131,315,000 barrels. Gains in output of the relatively young New Hope and Quitman fields failed to offset declines in other areas.

Oil-well completions totaled 157, an increase of 33 over 1944, owing in part to the drilling of 42 wells in the Hawkins field. Sixteen oil wells at New Hope, 11 at Pickton, and 8 at Sand Flat indicated the other active development areas, except the great Carthage field, which had 2 oil wells and 91 condensate wells added.

Only two small oil fields and four condensate fields were discovered in 1945. Myrtle Springs, Van Zant County, a January discovery, produces oil from the Travis Peak below 8,500 feet. The other oil field, La Rue in Henderson County, was discovered also in January by a well that produced initially 260 barrels from the Bacon sand of the lower Glen Rose. The four condensate fields are Fairfield and Teague in Freestone County, producing from Travis Peak sand and Pettit limestone, respectively; and Whelan and Marshall in Harrison County, producing from Dees sand and Pettit limestone of the lower Glen Rose formation.

Production in North and Central Texas continued in 1945 the upward trend of recent years. Drilling activity increased about 15 percent in 1945 and resulted in completion of over 1,000 oil wells. Oil-well completions in most active fields were: Electra 85, K. M. A. 66, Thornberry 49, Ellis 48, and Hildreth 39.

Active exploration discovered over 40 new fields, many of which were in Jones, Shackelford, Young, Archer, and Jack Counties. The most promising discoveries appeared to be National, Wilbarger County; Johnson, Montague County; and Belcherville, Montague County. Much of the exploratory effort in recent years has been directed toward horizons in Mississippian and Ordovician rocks at greater depths than the older producing reservoirs in strata of Pennsylvanian age.

Panhandle production declined 5 percent in 1945 to 31,726,000 barrels. Oil-well completions numbered 176 compared with 227 in 1944. Only 7 wildcats, all dry holes, were reported, scattered in 6 counties. Emphasis in drilling was upon developing gas-productive capacity.

Production of crude petroleum in Texas, 1941–45, by districts and fields

[5] Includes the fields in and between Wilbarger, Wichita, Clay, Montague, and Cooke Counties on the north and Runnels, Coleman, Brown, and Comanche Counties on the south.
[6] Includes crude oil consumed on leases and net change in stocks held on leases for East (exclusive of East Texas proper) Central, North, and South Texas.
[7] Carson, Gray, Hutchinson, Moore, and Wheeler Counties.
[8] Includes fields in Brooks, Duval, Hidalgo, Jim Hogg, Jim Wells, La Salle, Live Oak, McMullen, Starr, Webb, and Zapata Counties.
[9] Includes the part of Jordan pool in Crane County.

West Virginia.—Production of 2,879,000 barrels of crude petroleum was 6 percent below 1944 and 19 percent below the 1942 peak.

According to a report by David B. Reger, Morgantown, W. Va., oil-well completions were 80 in 1945 and 71 in 1944. The most active counties with number of new oil wells in each were: Calhoun 23, Ritchie 10, Roane 9, Kanawha 8, Wood and Pleasants 5 each.

No discoveries of new oil were made, but the limits of 4 oil fields were extended. The most important extension was apparently to the Sycamore pool, Calhoun County, to which 15 Big Injun oil wells were added.

Production of crude petroleum in West Virginia, 1941–45, by months

Wyoming.—Production increased from 33,356,000 barrels in 1944 to 35,359,000 barrels in 1945, the highest figure since 1924. Chief production gains were at Byron-Garland, Hamilton Dome, Frannie, and Steamboat Butte. The output of Lance Creek decreased over 1 million barrels.

Oil-well completions numbered 162, compared with 167 in 1944. The oil wells added in active fields in 1945 were: Elk Basin 35, Oregon Basin 13, Garland 12, Lance Creek 12, and Salt Creek 10.

Three oil fields were discovered in 1945. South Elk Basin, in Park County, produced oil from the Tensleep sand at 6,975 feet and appears to be a relatively important discovery; Zimmerman Butte, in Hot Springs County, produced from the Embar formation at 4,313 feet; and Oil Mountain, in Natrona County, produced from Tensleep sand at 2,620 feet. Deeper oil-producing zones were developed at Bailey, Half Moon, and Lamb fields in the Tensleep sand, Golden Eagle in the Lakota sand, North Baxter Basin in the Nugget sand, and Sheldon in the Embar formation. Noteworthy additions to known crude reserves were made by extensions to the Steamboat Butte, Lost Soldier, and Little Buffalo Basin fields.

Seismograph field studies were actively pushed in 1945 with a high concentration of activity in the Green River and Powder River Basins. Less effort was directed toward surface geological work and magnetometer and core-drill prospecting.

Negotiations were pending in 1945 for unitization of several important oil fields, including Elk Basin, Grass Creek, La Barge, and Oregon Basin, but no agreements appear to have been reached.

WELLS

The number of wells drilled in the United States in 1945, including oil and gas wells and dry holes, increased from 23,106 in 1944 to 24,667 in 1945. This represents a 7-percent increase in 1945 compared with the 29-percent increase in 1944.

Oil-well completions rose 10 percent from 13,029 in 1944 to 14,297 in 1945, and dry holes increased from 7,010 in 1944 to 7,471 in 1945, but the number of gas wells completed dropped 5 percent from 3,067 in 1944 to 2,899 in 1945. The number of oil wells completed in 1945 represented 58 percent of the total wells drilled compared with 56.4 percent in 1944. Dry holes remained at 30.3 percent of the total, and gas-well completions accounted for 11.7 percent of the total in 1945 compared with 13.3 percent in 1944.

Oil and Gas Journal east of California; American Petroleum Institute in California.

The total completions in Texas accounted for 29 percent of all wells drilled in the United States in 1945. This Texas total of 7,184 in 1945 represented a 25-percent increase over the 5,729 completions in 1944. The number of oil wells drilled in Texas rose from 3,526 in 1944 to 4,036 in 1945, gas-well completions increased from 268 in 1944 to 714 in 1945, and the number of dry holes increased from 1,935 in 1944 to 2,434 in 1945. Active drilling continued in Oklahoma, where the total completions rose from 1,890 in 1944 to 2,509 in 1945. This drilling produced 1,426 oil wells in 1945 compared with 1,031 in 1944. Louisiana had a drilling gain of 305 wells for the year and Mississippi an increase of 206 wells. The greatest decline in total completions was in the area comprising Pennsylvania, New York, Ohio, and West Virginia, where the total completions dropped from 5,410 in 1944 to 4,710 in 1945. The increase in the number of oil wells drilled in this area was more than offset by a sharp decline in gas-well and dry-hole completions. Other declines in total drilling were reported for Kentucky, Illinois, Montana, Kansas, and Arkansas.

STOCKS

Total stocks of crude petroleum amounted to 223,259,000 barrels on December 31, 1945, compared with 226,770,000 barrels on January 1, 1945. Stocks of foreign crude oil increased by 0.5 million barrels during the year, and stocks of domestic origin declined by 4 million barrels. The principal changes in stocks of domestic crude by States or origin were declines of 9.5 million barrels for Texas crude and 3 million barrels for all grades of California crude and increases of 3.9 million barrels in stocks of Oklahoma origin, 2.2 million for Illinois crude, 1.3 million for Mississippi crude, and 1.1 million for Louisiana crude.

Total stocks of crude petroleum on December 31, 1945, were about 51 million barrels less than on December 31, 1940. The major decreases during this 5-year period, by States of origin, have been 29 million barrels for Oklahoma, 22 million for California, 8 million for Wyoming, and 5 million for Illinois. The principal increase has been about 16 million barrels in stocks of Texas origin.

Stocks of crude petroleum, natural gasoline, and refined products in the United States at end of year, 1941–45

[1] Final figures.
[2] For comparison with succeeding years.
[3] Includes equivalents for wax, coke, and asphalt in barrels.

The relative significance of the volume of crude oil in storage has changed materially, considering the fact that the total demand for crude petroleum was about 22 percent greater in 1945 than in 1941, and that the available shut-in production declined greatly during the war period. The stocks of crude oil also must be considered in relation to the stocks of refined products. Total stocks of refined products have declined from 281 million barrels at the end of 1940 to 236 million barrels at the end of 1945. Stocks of refined declined 18 million barrels in 1943, increased 17 million barrels in 1944, and declined about 10 million barrels in 1945.

Stocks of crude petroleum in the United States in 1945, by States of location and by months [1]

[1] Excludes stocks of California heavy crude.
[2] New basis to compare with subsequent months; a transfer of 199,000 barrels of California condensate from crude-oil stocks.
[3] Final figures.

CONSUMPTION AND DISTRIBUTION

Runs to stills.—Total crude runs to stills amounted to 1,720 million barrels in 1945, a gain of 54 million barrels compared with 1944. Runs of foreign crude amounted to 74 million barrels, and runs of domestic crude were 1,646 million. The principal changes in refinery operations, by districts, in 1945 were gains of 19 million barrels in crude runs in California, 17 million in the East Coast district, 15 million in the Louisiana Gulf Coast district, 6 million in the Oklahoma-Kansas district, and 5 million in the Rocky Mountain district. The principal decreases in crude runs were 6 million barrels in the Texas Gulf Coast district and 3 million in the Indiana-Illinois district.

Distribution.—The total demand for domestic crude petroleum rose from 1,701 million barrels in 1944 to a new record of 1,715 million barrels in 1945—a gain of 14 million barrels, or less than 1 percent. The larger demand was met by an increase of 33 million barrels in crude production and a withdrawal of only 4 million barrels from stocks of domestic crude oil compared with a reduction in such stocks of 24 million barrels in 1944. The supply of domestic crude petroleum was supplemented by an increase in the imports of foreign crude oil from 45 million barrels in 1944 to 74 million in 1945. Imports of refined oils were 8 million barrels less than in 1944, and total stocks of refined oils were reduced by 10 million barrels during the year compared with a gain of almost 17 million barrels in 1944.

Receipts of domestic and foreign crude petroleum at United States refineries totaled 1,724 million barrels in 1945 compared with 1,669 million in 1944. In 1945 receipts of foreign crude petroleum were 74 million barrels, or 4.3 percent of the total; interstate receipts of domestic crude were 627 million, or 36.4 percent of the total; and intrastate receipts were 1,023 million, or 59.3 percent of the total.

Refinery receipts of crude in 1945, by methods of transportation, indicated that 79.4 percent of the total was delivered by pipe lines, compared with 83.3 percent in 1944; that 4.3 percent was delivered by tank car and truck, compared with 6.8 percent in 1944; and that 16.3 percent was delivered by boat, compared with 9.9 percent in 1944. These figures reflect the increase in the tanker movement from Gulf ports to East Coast refineries in the latter half of 1945, the increase in receipts of foreign crude by boat, and the reduction in war emergency movements by tank car and pipe line.

The principal changes in the market demand for crude petroleum by States of origin (computed from production and changes in crude stocks by origin) in 1945 compared with 1944 were gains of about 12 million barrels for Texas, 9 million for Oklahoma, and 7 million for California. The largest decreases were 4 million barrels for Illinois and 3 million for Kansas. Thirteen States had a market demand exceeding 10 million barrels in 1945 and contributed over 98 percent of the total supply.

The demand for Texas crude oil rose from 753 million barrels in 1944 to 765 million in 1945. The record production of 756 million barrels was supplemented by a withdrawal of over 9 million barrels from stocks of Texas origin. The relative contribution of Texas to the national demand rose from 44.2 percent in 1944 to 44.6 percent in 1945.

Runs to stills of crude petroleum in the United States in 1945, by districts and months [1]

[1] Subject to revision.

Approximately 56 percent of Texas crude was delivered to refineries within the State, and the remainder represented shipments to other States and exports. The largest interstate shipments were to refineries in the East Coast and Indiana-Illinois districts.

[1] Subject to revision.

California ranked second as a source of crude supply in the United States and supplied 18.9 percent of the total market demand for domestic crude oil in 1944 and 19.2 percent in 1945. The demand for California crude oil amounted to over 322 million barrels in 1944 and exceeded 329 million in 1945. Production was supplemented by a withdrawal of 3 million barrels from stocks of California origin in 1945. About 308 million barrels of California oil were delivered to refineries within the State in 1945, 4 million barrels were exported to Canada, and 17 million barrels represented crude used direct for fuel and losses.

The demand for Oklahoma crude oil amounted to 134 million barrels in 1945 compared with over 125 million in 1944. Production rose from almost 125 million barrels in 1924 to 138 million in 1945, but about 4 million barrels were added to storage in 1945. This increase in production and demand gave Oklahoma third place as a source of national oil supply in 1945. About 57 million barrels of Oklahoma crude were delivered to refineries within the State in 1945. The largest outside market is in the Indiana-Illinois refinery district, with Kansas and the Appalachian refineries as the largest secondary markets.

Louisiana was the fourth largest source of domestic crude-oil supply in 1945. Production approximated 131 million barrels, about 1 million barrels were added to storage, and demand was almost 130 million barrels or 1 million barrels less than in 1944. Of the total deliveries to refineries in the United States, about 57 percent were intrastate, and the largest interstate shipments went to Texas.

Daily average demand for domestic crude petroleum in the United States in 1945, by States of origin and by months [1]

[1] Subject to revision.
[2] Includes Washington.
[3] Includes Minnesota and Wisconsin.
[4] Includes Idaho.

The demand for Kansas crude oil declined from 98 million barrels in 1944 to 95 million in 1945. Almost 1 million barrels were added to stocks of Kansas origin during the year. Shipments to refineries in Kansas amounted to over 44 million barrels, and the major outside market was in the Indiana-Illinois refinery district.

Illinois ranked sixth in the national supply of domestic crude oil. The demand for crude of Illinois origin declined from 77 million barrels in 1944 to 73 million in 1945. Production declined from over 77 million barrels in 1944 to 75 million in 1945, and about 2 million barrels were added to storage during the year. About 23 million barrels of Illinois oil were delivered to refineries within the State. The largest outside market for Illinois oil was in Ohio, and there was a substantial export to Canada.

The demand for New Mexico crude declined from 40 million barrels in 1944 to 38 million in 1945. The major part of New Mexico crude was shipped to refineries in Texas. The demand for Wyoming crude declined from 38 million barrels in 1944 to about 35 million in 1935. About 21 million barrels were shipped to refineries within the State, 12 million barrels were sent to other Mountain States, and about 2 million barrels were marketed in Illinois, Indiana, and Missouri. The increase in the demand for Colorado crude—from 3 million barrels in 1944 to almost 5 million in 1945—partly offset the decline in the demand for Wyoming crude oil.

The demand for Arkansas crude oil amounted to 29 million barrels in 1945, with virtually no change compared with 1944. About 15 million barrels were delivered to refineries in the State, and the major part of the remainder went to refineries in Louisiana.

The demand for Mississippi crude oil gained over 1 million barrels in 1945, while the demand for Michigan crude declined over 1 million barrels, and the supply of Pennsylvania crude was almost 2 million barrels less than in 1944.

Receipts of crude petroleum at refineries in the United States, 1941–45, by methods of transportation

PRICES AND VALUE

Since there were no general increases in posted crude prices in 1945, the only important change in the value of crude oil at the well resulted from the stripper-well subsidy plan. The subsidy plan, effective August 1, 1944, was in operation for the full year 1945, compared with 5 months in 1944. This plan provided for Federal payments of 35 cents per barrel for fields with average production of less than 5 barrels daily per well; of 25 cents per barrel for fields averaging 5 barrels and less than 7 barrels daily per well; and of 20 cents per barrel for fields averaging 7 barrels and less than 9 barrels daily per well. The plan also authorized payment of 75 cents per barrel for all Pennsylvania Grade oil produced in Pennsylvania, New York, West Virginia, and Ohio. A number of other stripper pools were added to the list in 1945 because of high production costs.

These subsidy payments are supplemental to posted crude prices and are included in the Bureau of Mines figures for average value of crude oil at the well.

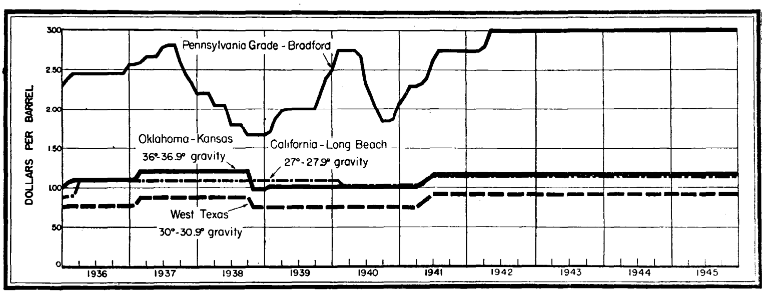

FIGURE 5.—Posted prices of selected grades of crude petroleum in the United States, 1936–45, by months.

Complete data on values in 1945 are not yet available, but the preliminary estimate for all crude produced in 1945 is $1.22 per barrel, compared with the average of $1.21 per barrel in 1944. This increase of 1 cent per barrel is slightly less than would be expected from subsidy payments for 12 months in 1945, compared with the increase from subsidy payments for only 5 months in 1944, but the increased production of lower-value crudes in 1945 tended to offset the effects of subsidy payments upon the national average.

Value of crude petroleum at wells in the United States, 1943–44, by States [1]

REFINED PRODUCTS

GENERAL REVIEW

The demand for refined products in 1945 reflects the shift from a peak wartime basis to a period of readjustment involving the removal of wartime controls, the termination of lend-lease exports, a rapid decline in military purchases with a draft on surplus stocks in military custody, and a substantial increase in civilian consumption. The interpretation of these trends was obscured by the shut-down of a substantial part of refinery capacity in the last half of September and the first half of October. Estimates of probable demand for the early part of 1946 proved to be materially below actual requirements and necessitated a sharp upward revision of forecasts for demand during 1946.

The total demand for all oils rose from 1,879 million barrels in 1944, to 1,952 million in 1945—a gain of 73 million barrels or about 4 percent. Exports of refined products declined from 173 million barrels in 1944 to 151 million in 1945. Domestic demand for all oils, including military consumption in the United States and shipments to our armed forces abroad, rose from 1,671 million barrels in 1944 to 1,768 million in 1945. The domestic demand for motor fuel showed a gain of 64 million barrels, the demand for distillate fuel oils increased about 16 million barrels, and the domestic demand for residual fuel oil gained 11 million barrels compared with 1944.

[3] Negative quantity; represents net excess of unfinished rerun over unfinished produced.
[4] Not available.

Imports of refined products amounted to about 9 million barrels less in 1945 than in 1944, with the largest decline in residual fuel oils.

Crude runs to stills rose from about 1,666 million barrels in 1944 to 1,720 million in 1945—a gain of 54 million barrels. On a daily average basis these runs amounted to 4,551,000 barrels in 1944 and 4,711,000 barrels in 1945—a gain of 3.5 percent.

Changes in the relative demand for products have been reflected in the refinery yields from crude oil. The total gasoline yield declined to a low of 37.1 percent in 1943, rose to 39.4 percent in 1944, and increased to 40.9 percent in 1945. The yield of distillate fuel oil remained fairly constant during the war years and amounted to 14.4 percent in 1944 and 14.5 percent in 1945. The yield of residual fuel oil reached a peak of 27.7 percent in 1944 and declined to 27.3 percent in 1945.

[1] Subject to revision. [2] Less than 0.1 percent.
[3] Negative percentage; represents excess percentage rerun over percentage produced.

Stocks of refined oils declined from 246 million barrels at the end of 1944 to 236 million at the end of 1945, compared with 294 million at the end of 1941. The principal changes in 1945 were an increase of 15.8 million barrels in stocks of finished gasoline, a decrease of 13.2 million in residual fuel-oil stocks, a decline of 2.5 million in stocks of distillate fuel oil, and a reduction of 4.9 million in stocks of unfinished gasoline. In view of actual demand in the first quarter of 1946, stocks of gasoline were relatively high, and stocks of fuel oils and kerosine were low, necessitating an abnormal readjustment of yields to meet requirements.

[3] Negative quantity (overage).
[4] Subject to revision.

The representative prices of refined products in 1945 showed no changes in the first half of the year, but some readjustments were made beginning with August. The price of Regular Grade gasoline at Oklahoma refineries was 5.88 cents per gallon for the first 8 months of the year, rose to 5.99 cents in September and 6 cents in October, and declined to 5.92 cents in November and 5.81 cents in December. The tank-wagon price of kerosine at Chicago remained 10.60 cents per gallon through July, declined to 10.50 cents in August and to 10.30 cents in September and October, and rose to 10.55 cents in November and 10.60 cents in December. The price of bright stock at Oklahoma refineries remained at 22.75 cents per gallon during the year. The price of Bunker "C" fuel oil at New York was \$1.77 per barrel for the first 8 months of the year and declined to \$1.55 in September and October, to \$1.54 in November, and to \$1.51 in December.

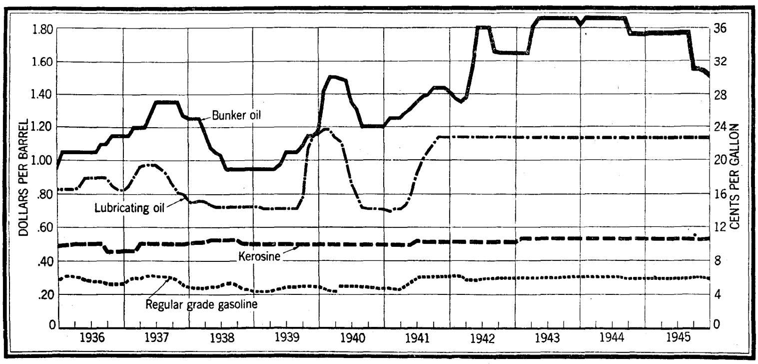

FIGURE 7.—Prices of Bunker "C" oil at New York, bright stock at Oklahoma refineries, tank-wagon price of kerosine at Chicago, and Regular Grade gasoline at refineries in Oklahoma, 1936–45, by months.

Summary of refinery capacity in the United States, January 1, 1940–45

AVIATION GASOLINE

The wartime expansion in the production and use of aviation gasoline was much greater than the increase in demand for other petroleum products because of the growth of the use of air power in war. The total demand for aviation gasoline (domestic demand plus exports) rose from a daily average of 49,000 barrels in 1941 to a peak of 701,000 barrels daily in April 1945. Since these requirements follow a war-use pattern, it is necessary to divide the months of 1945 into two parts

[1] Includes some 98 and 99 octane.
[2] Exports of 80–87 octane aviation gasoline (Census classification—medium octane aviation) have not been included for 1943–44, since the only available figures include large but indeterminate amounts of automotive gasoline.
[3] Subject to revision.

to get a picture of the changes within the year. Total demand dropped from a daily average of 560,000 barrels for the first 8 months to 123,000 barrels for the last 4 months, with 37,000 barrels daily in December.

The production of all aviation grades increased from an average of 58,000 barrels daily in 1941 to an average of 537,000 barrels daily in 1944 and 620,000 barrels daily in the peak month of March 1945. The average production for the first 8 months of 1945 was 578,000 barrels daily compared with 99,000 barrels daily for the last 4 months. The greatest monthly decrease came between the August daily average production of 425,000 barrels and the 133,000-barrel average in September.

As a result of the abrupt curtailment of military demand in the last 4 months of 1945, the total quantity of aviation gasoline, including components, transferred to other products was abnormally large, amounting to 57 percent of production compared with 3 percent in the first 8 months. These transfers in the last 4 months plus total demand exceeded production by 81,000 barrels daily, causing a drop in stocks from 15 million barrels on August 31 to 5 million at the end of the year.

Exports of all grades of aviation gasoline averaged 135,000 barrels daily in the first 8 months of 1945, with 244,000 barrels daily in April, and dropped to an average of 7,000 barrels daily in the last 4 months of the year, with a low of only 2,000 barrels daily in September. Almost all of the wartime exports went to other Allied Nations.

Domestic demand (including military use in the continental United States and shipments to our armed forces abroad) amounted to 117 million barrels in 1945, a decline of 15 million barrels from the peak year 1944. However, the daily average for the first 8 months in 1945 was 424,000 barrels, compared with 362,000 barrels in 1944. Domestic demand was reduced each month after the end of the war, reaching a low of 28,000 barrels daily in December. The average for the last 4 months of 1945 was 116,000 barrels daily. Improvements in quality of product accompanied the gains made in the quantity of aviation gasoline produced in the war years. The production of 100-octane or above constituted about 40 percent of the total production in 1941 and rose to 85 percent of the total produced in the first 8 months of 1945.

MOTOR FUEL

The total demand for motor fuel in 1945 was 785 million barrels or 52 million above the previous high in 1944. In the 24-year period from 1918 through 1941, this total demand for motor fuel rose from less than 100 million barrels per year to 695 million barrels, with very little deviation from the general trend, except in the depression years 1930–34. War conditions in 1942 caused a decrease in the total number of motor vehicles, a tire shortage, a decline in the normal transportation of gasoline by tankers, and gasoline rationing. The result was a drop in civilian gasoline demand for the first time in 10 years. Since military requirements were still relatively low in 1942 and since exports showed only small gains over 1941, the final result was a drop of 70 million barrels in total motor-fuel demand for the year. There was a further decline of 4 million barrels in 1943. The 113-million-barrel increase in 1944 was an all-time record for yearly gains, and the total motor-fuel demand was higher than in any previous year. Several factors caused this demand for 733 million barrels of motor fuel.

Decreased tanker losses made it possible to supply the growing wartime needs of the other Allied Nations; as a result, motor-fuel exports (including shipments to noncontiguous territories) were almost twice as large as in 1943. The planned program, designed to satisfy the growing military demand for aviation gasoline, was on schedule. Mechanized warfare had created a peak military demand for automotive-type gasoline, and essential transportation at home was using more motor fuel to keep war production at the necessary level. These same conditions existed in the wartime portion of 1945. The peak of this year came in August, when the average total motor-fuel demand was 2,355,000 barrels per day. Military and export demands dropped after the end of the war, but the removal of gasoline rationing at home caused an increase in civilian consumption. The high wartime requirements in the first part of 1945 and the increased civilian demand in the latter part of the year resulted in a gain of 52 million barrels or a total yearly demand of 785 million barrels, another all-time high.

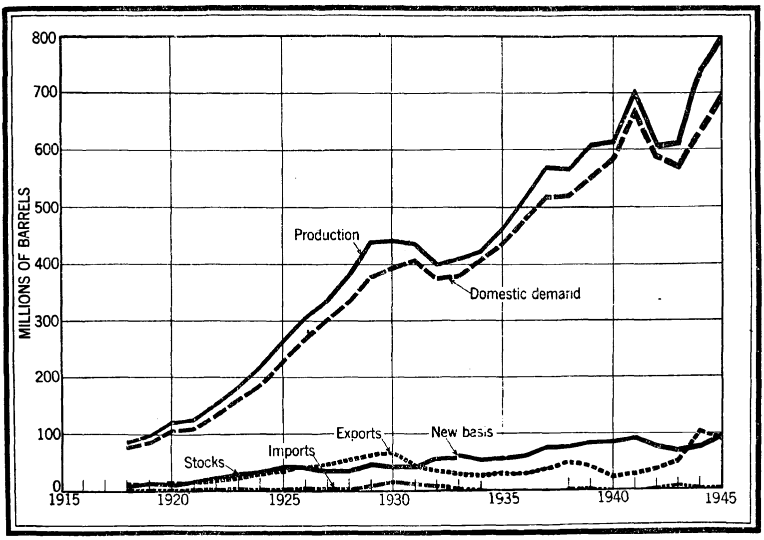

FIGURE 8.—Trends of production, domestic demand, exports, imports, and stocks of motor fuel in the United States, 1918–45.

Exports.—Exports of motor fuel (including shipments to noncontiguous Territories) averaged 141,000 barrels daily in 1943, increased to 275,000 barrels daily in 1944, were 337,000 barrels daily in the first 7 months of 1945, and dropped to 114,000 barrels daily in the last 5 months of the year. The total for 1945 was 89 million barrels, compared with 101 million in 1944. The peak month of 1945 was April, with a daily average of 419,000 barrels. Shipments to noncontiguous Territories were 1.8 million barrels in 1945, compared with 2.3 million in 1944. These shipments do not include military liftings of gasoline for the Territories. The major part of total exports of motor fuel went to other Allied Nations. Exports to the United Kingdom were 62.1 million barrels or 70 percent of the total in 1945, compared with 75.9 million or 75 percent in 1944.

[1] Subject to revision.
[2] Includes L. P. G. sales for fuel and chemical uses.
[3] New basis to compare with subsequent months; a transfer of 199,000 barrels of California condensate from crude-oil stocks.

Domestic demand.—Domestic demand for motor fuel (including military consumption in continental United States and all shipments to our armed forces abroad) increased 63.9 million barrels in 1945 to reach a total of 696,407,000 barrels for the year. This gain, combined with the 1944 increase, produced a total gain of 128 million barrels in the last 2 years, compared with the decline of 99 million in the 2 years 1942–43 and a net gain of 29 million for 1945 over 1941. Although it is not possible to divide domestic demand into military and civilian requirements, we do know that most of the demand for aviation gasoline was military, either for our armed forces or those of other Allied Nations. The daily average domestic demand for all grades of aviation gasoline dropped 58 percent in the last 5 months of 1945, compared with the daily average for the first 7 months, while other gasolines included in motor fuel increased 18 percent for the same period. Military demands for motor fuel were reduced by the end of the European War and more automotive gasoline was available for civilian use. The end of the Pacific War caused further declines in military requirements, but the removal of all civilian gasoline rationing brought sharp increases in automotive demand to more than offset the gradual reduction of military purchases. This resulted in high domestic demands for motor fuel in August and September and produced a small net increase in the daily average for the last 5 months of the year compared with the daily average for the first 7 months.

Production.—The total production of motor fuel in 1945 was 799,059,000 barrels, a gain of 59,719,000 barrels over the previous record set in 1944. This 1945 production comprised 401,789,000 barrels of cracked gasoline, 302,347,000 barrels of straight-run gasoline, 92,043,000 barrels of net natural gasoline and cycle-plant products (after deducting transfers and sales of liquefied gases for fuel and chemical purposes), and 2,880,000 barrels of benzol. The gain in production of straight-run gasoline was 32 million barrels compared with a 16-million-barrel increase in cracked gasoline. Peak production of motor fuel came in July, when the daily average rose to 2,339,000 barrels. Decreased refinery operations in September and October caused production to drop to an average of 1,978,000 barrels daily for the 2-month period, compared with an average of 2,179,000 barrels daily in November and December.

Yields.—The yield of straight-run gasoline from crude petroleum rose from 15.1 percent in 1943 to 16.2 percent in 1944 and to 17.6 percent in 1945, while the yield of cracked gasoline increased from 22.0 percent in 1943 to 23.2 percent in 1944 and to 23.3 percent in 1945. The total gasoline yield from crude was 37.1 percent in 1943 and 39.4 percent in 1944, compared with 40.9 percent in 1945, and the average yield for November and December in 1945 was 41.9 percent compared with 40.4 percent for the same period in 1944. These high yields in the last 2 months of 1945 contributed to a production surplus that was above normal and gave a very large stock increase for the period.

Production of gasoline in the United States in 1945, by methods of manufacture, districts, and months [1]

[1] Subject to revision.

[2] Based upon crude runs to stills.

Prices.—Gasoline prices showed a very slight downward trend in 1945, most of the decreases coming near the end of the year.

The average group 3 refinery price for Regular-Grade gasoline dropped from a yearly average of 5.95 cents per gallon in 1944 to 5.90 cents per gallon in 1945. The price was constant for all months through August, rose slightly, and then dropped near the close of the year.

The average 50-city dealers' net price, exclusive of all taxes, dropped from an average of 10.49 cents per gallon in 1944 to 10.33 cents per gallon in 1945. The average price was constant at 10.46 cents per gallon through August and dropped to 10.07 cents for the remaining months of the year.

Average monthly prices of gasoline in the United States, 1944–45, in cents per gallon

[1] National Petroleum News.
[2] American Petroleum Institute; compiled by The Texas Co.

The average 50-city service-station price, including State and local taxes but excluding Federal tax, was 19.09 cents per gallon in 1944 and declined to 19.00 cents in 1945. The monthly averages remained constant at 19.05 cents per gallon in the first quarter of 1945, rose until they reached 19.13 cents in August and September, then dropped to 18.74 cents for the months of the last quarter.

There was no change in the average tax rates in 1945 compared with 1944. The average local tax rate remained at 0.05 cent per gallon, the State tax at 4.42 cents per gallon, and the Federal tax at 1.50 cents per gallon for a total average tax rate of 5.97 cents per gallon.

Stocks.—Stocks of finished and unfinished gasoline amounted to 98 million barrels at the end of 1945, compared with 87 million at the close of 1944. This 11-million-barrel increase in gasoline stock comprised a 16-million-barrel gain in finished gasoline and a 5-million-barrel decrease in unfinished. In the first quarter of the year, stocks of finished and unfinished gasoline increased 11 million barrels, and this gain was balanced by a stock draft of 11 million in the second quarter. Most of the third quarter's drop of 12 million barrels came in September, when refinery production was low and the total gasoline demand was almost 150,000 barrels daily above the average for the year. Although both domestic demand and exports decreased in October, the daily average production of motor fuel was at the low point of the year to give a net increase in stocks of only 2 million

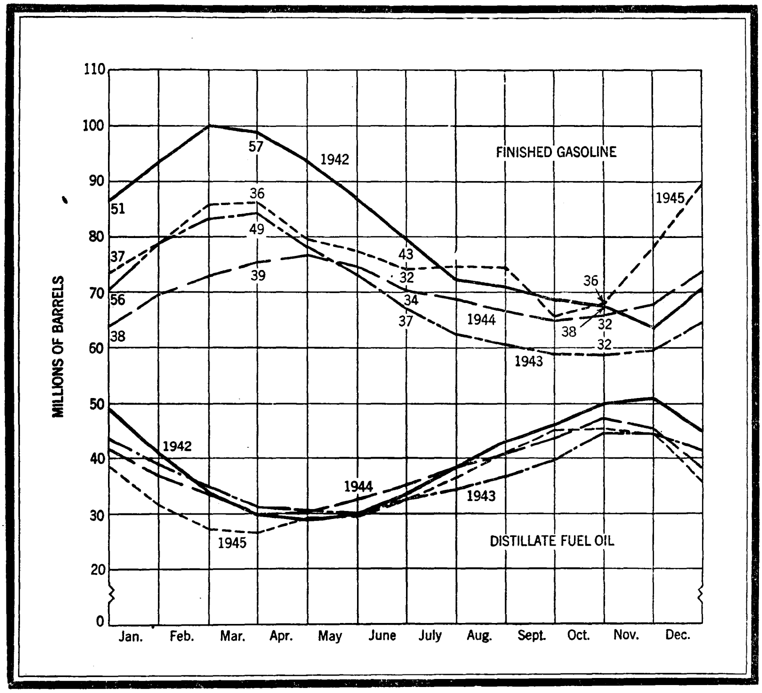

FIGURE 9.—Stocks of finished gasoline in the United States, 1942–45, by months, with figures representing days' supply at certain periods; also stocks of distillate fuel oil, 1942–45, by months.

[2] Includes stocks of finished gasoline at refineries, bulk terminals, and in pipe lines.

barrels. Full refinery operation in November and December, combined with high percentage yields of gasoline and lower total motor-fuel demand, added 21 million barrels to gasoline inventories in the 2 months' period. If the November–December period in 1945 is compared with the same period in 1944, we find motor-fuel production up 3 million barrels in the 1945 period, while domestic demand was down 3.5 million and exports down 7.5 million. These factors produced the 21-million-barrel stock increase in the last 2 months of 1945 compared with the 8.6-million-barrel increase in the same period of 1944.

Gasoline stocks may be expressed in terms of days' supply by dividing the stocks at the end of the month by the daily average total demand for the succeeding month. Upon this basis the days' supply represented by finished gasoline stocks on December 31 was 51 days at the end of 1941 compared with 36.9 days at the end of 1944 and 48.9 days at the close of 1945. However, the closing inventory for 1945 came after a heavy 2-month stock build-up. Stocks of finished gasoline at the end of October represented only 36.1 days' supply.

The stocks included in these figures represent gasoline held at refineries and bulk terminals and by pipe lines but do not include gasoline that has passed into the custody of the armed forces.

Production and consumption by States.—The refinery production of gasoline in 1945 was 774,460,000 barrels, compared with 722,718,000 barrels in 1944. Texas again led all States, with a production of 234,703,000 barrels or 30 percent of the total, compared with 220,758,000 barrels or 31 percent of the total in 1944. California refinery production (including some production in Washington) increased from 109,867,000 barrels in 1944 to 121,094,000 barrels or 16 percent of the total in 1945. Only four States produced less gasoline at refineries in 1945 than in 1944, and the only important producing State showing a decline was Ohio, where the drop was from 36,001,000 barrels in 1944 to 34,691,000 in 1945.

The lack of information on military consumption at home and abroad makes it extremely difficult to compute total consumption of gasoline by States, since, in some cases, sales to the Government within a State ultimately may be shipped abroad.

Distribution.—Gasoline transportation changed in 1945 from wartime movements to more nearly normal distribution. Tanker and barge movements of commercial gasoline from the Gulf coast to East coast ports rose from 1,931,000 barrels in February to 9,813,000 barrels in November. The high-cost, but necessary, wartime movements by tank cars declined rapidly after the end of the war. The total motor fuel delivered by pipe lines increased in 1945, but the monthly deliveries ranged from 29,593,000 barrels in May to 14,897,000 barrels in December. The greatest drop came with the closing of the 20-inch war emergency pipe line, when deliveries declined from 25,826,000 barrels in August to 18,491,000 in September. Some other wartime lines and extensions were closed; and a few lines, where changes had been made in direction of flow to meet war needs, were again reversed to conform to normal patterns of distribution.

Shipments of motor fuel by pipe lines in the United States in 1945, by months

KEROSINE AND RANGE OIL

A heavier domestic and foreign demand for kerosine in 1945 was practically all supplied from increased production, as the quantity taken from storage was negligible, and furthermore there were no imports.

Petroleum refiners produced 81,024,000 barrels of kerosine in 1945, a new record and a quantity of 3 percent above the 1944 total of 78,344,000 barrels. The yield of kerosine remained at 4.7 percent for both 1944 and 1945, so the expanded output must be credited entirely to an increase (3 percent) in the volume of crude runs to stills. It should be added that the percentage yield of kerosine and other petroleum products was kept down in 1945 as well as in 1944, so that more gasoline could be made to satisfy the unusual demand for motor fuel at the time.

The increased production of kerosine in 1945 resulted mostly from important gains reported for the East Coast and Louisiana Gulf Coast refinery districts. Petroleum companies operating in the East Coast area produced 14 percent more kerosine in 1945 than in 1944, while the output for the Louisiana Gulf Coast for 1945 was nearly 16 percent above the 1944 quantity. Over a quarter of the kerosine manufactured in the country originates in the Texas Gulf Coast district; however, the output there for 1945 was only slightly above the 1944 total, while the production reported for the Indiana-Illinois-Kentucky area, which ranks second as a source of this fuel, declined by 7 percent in 1945 compared with 1944. Petroleum refineries operating in the Oklahoma-Kansas-Missouri district produce about one-tenth of the total kerosine manufactured, and the output in those States in 1945 was about 4 percent over the 1944 yield. Relatively less important quantities of kerosine are produced in the other refinery districts of the country, and these latter areas all showed gains in output in 1945, except the Appalachian area, where the kerosine total reported was approximately 16 percent below the 1944 quantity.

Comparative analyses of statistics for kerosine in the United States, 1944–45, by months and districts

Month and district	Production (thousands of barrels)		Yield (percent)		Domestic demand (thousands of barrels)		Stocks (thousands of barrels)

[1] Subject to revision.
[2] Figures not available.

A rising domestic demand for kerosine noted in 1944 continued into 1945, when requirements of 75,595,000 barrels were 5 percent over the 1944 total of 71,812,000 barrels. It should be added that this expanding market for kerosine was also evident in the first quarter of 1946, as monthly figures indicate an increase of 24 percent over the corresponding period of 1945. The domestic demand for kerosine by refinery districts cannot be determined definitely as several factors, such as the intermovement between the different areas and the imports and exports for each district, are not readily available.

Exports of kerosine, which varied very little in 1944 compared with 1943, mounted noticeably in 1945, when the foreign demand totaled 6,158,000 barrels, a gain of 26 percent over 1944 requirements of 4,888,000 barrels. Most of the kerosine sent abroad went to the United Kingdom, and the total of these shipments increased from 4,168,000 barrels in 1944 to 4,984,000 in 1945. Comparative lesser quantities of kerosine were also exported, principally to Canada, Mexico, the Netherlands and to France in 1945. No kerosine was imported into the United States in 1945 and only 147,000 barrels were reported for 1944 compared with 375,000 in 1943.

Stocks of kerosine, which gained in 1944, declined slightly in 1945, when the year-end total of 10,421,000 barrels was approximately 7 percent below the comparative item of 11,150,000 for 1944. The shrinkage of kerosine stocks in 1945 was limited to those held at bulk terminal points, which dropped by 22 percent from 5,385,000 barrels in 1944 to 4,209,000 at the close of 1945. Conversely, supplies of kerosine reported as stored at refineries increased from 5,765,000 barrels in 1944 to 6,212,000 in 1945, a gain of 8 percent. The number of days supply of kerosine stocks on hand at the year end, which incidentally has shown a sharp downward trend in recent years, was arrested slightly in 1944 at 39 days compared with 38 days for 1943; however, it again dropped noticeably in 1945 to quantity sufficient for only 33 days.

Broadly speaking, year-end stocks of kerosine in areas of large consumption, the East coast and the North Central States, showed a pronounced shrinkage in 1945 compared with 1944, while inventories in the heavy producing States, Texas and Louisiana, mounted noticeably. The pattern of stock changes in 1945 indicated a lack of adequate transportation facilities to move supplies from main producing centers to the more important markets; furthermore, it differed from that of 1944, when kerosine-stock increases were recorded for the East Coast and North Central areas, and there was a loss for the principal producing section—the Texas Gulf Coast district. Kerosine inventories in the East Coast, where about 60 percent of this fuel is marketed, declined by 11 percent—from 4,359,000 barrels in 1944 to 3,894,000 at the close of 1945. Furthermore, supplies in the area dropped from 39 percent of the national total in 1944 to a 37-percent share in 1945. Even more pronounced percentage losses in year-end kerosine stocks were recorded for the Appalachian (a 46-percent decline) and the Oklahoma-Kansas-Missouri (a 17-percent loss) refinery districts, and the inventory for the Indiana-Illinois-Kentucky area declined from 2,362,000 barrels in 1944 to 1,769,000 in 1945, a 25-percent shrinkage. The more important gains in kerosine stocks in 1945 were noted for the Texas Gulf district, where there was a 51-percent increase and for the Arkansas-Louisiana Inland district, where supplies mounted by 49 percent. Stock increases for the Texas Inland and Louisiana Gulf areas in 1945 were less pronounced, while losses were registered for relatively unimportant quantities stored in the Rocky Mountain and California refinery districts.

Annual sales of kerosine have remained at a fairly constant level in recent years, however, the total of 71,214,000 barrels shown in the 1944 survey by the Bureau of Mines was 5 percent above 1943 deliveries of 67,815,000 barrels. All sections of the country except the Pacific coast reported nominal gains in sales of kerosine in 1944 compared with 1943. Requirements in the important East Coast area, which registered a sharp decline in 1943 due to the rationing and other difficulties, were reported as 41,458,000 barrels, an increase of 6 percent over the 1943 total of 39,202,000 barrels. An upturn in the quantity of kerosine handled was evident in all parts of the Atlantic Coast market; however, a 7-percent gain indicated for the Middle Atlantic States in 1944 was above the average for the area as a whole. Sales of kerosine in 1944 in the North Central States, another important consuming area, were 7 percent over 1943 deliveries, and a 6-percent gain was also noted in the 1944 deliveries in the South Central States. Relative little kerosine is sold on the Pacific coast, and the 1944 total of 2,454,000 barrels was 15 percent below 1943 requirements.

Sales of kerosine in the United States, 1943–44, by regions, States, and uses [1]

[Thousands of barrels]

[1] Figures for 1945 by States not yet available.

The larger share (56 percent in 1943 and 58 percent in 1944) of kerosine sales is reported as range oil or fuel used for cooking or for water and room heating, and the total under that general classification increased from 38,221,000 barrels in 1943 to 41,017,000 in 1944, a 7-percent gain. Some kerosine (about 9 percent of the total) is consumed as tractor fuel, and the annual sales survey showed that the demand increased by 5 percent from 5,869,000 barrels in 1943 to 6,143,000 in 1944. All other uses of kerosine, 24,054,000 barrels in 1944, was little above 1943 requirements of 23,725,000 barrels.

Sales of range oil in the United States, 1942–44, by States [1]

[1] Figures for 1945 by States not yet available.

There was very little fluctuation in representative kerosine prices in 1945. The quotation on 41°–43° gravity, water-white kerosine at refineries in Oklahoma dropped from 4.38 cents a gallon to an average of 4.31 cents on November 30, and this changed the weighted average for that month to 4.37 cents a gallon. The price was again increased to 4.38 cents a gallon on December 26, resulting in an average of 4.33 cents for the closing month of 1945 and an average of 4.37 cents a gallon for the year compared with 4.38 cents in 1944. The tankwagon price for kerosine at Chicago dropped from 10.6 cents a gallon to 10.3 cents on August 20; however, the higher quotation was restored on November 5, 1945.

FUEL OIL

The domestic demand for fuel oil set a new record in 1945; however, with the cessation of hostilities, exports dropped sharply. An increase of 4 percent in demand for fuel oil on the home market compares with an expansion of 7 percent in 1944 over 1943, while the pronounced shrinkage in the foreign trade is indicated by an 18-percent decline in 1945 in contrast to a 41-percent gain in 1944. It was necessary to draw heavily on stocks in 1945 to satisfy all demands, as a slight increase in production (3 percent over 1944) was not sufficient to offset a 17-percent drop in imports and a 25-percent decline in transfers of crude oil to the fuel-oil account. The indicated domestic demand for fuel oil increased from 721,340,000 barrels in 1944 to 748,835,000 in 1945. The market for the heavier fuel oils showed the greater expansion in 1944—10 percent over 1943 compared with less than a 1-percent gain for the distillate grades—however, this was reversed in 1945, when the demand for the lighter fuel oils of 225,753,000 barrels was 8 percent above the 1944 total of 209,320,000 and the volume for residuals—523,082,000 barrels in 1945—was only 2 percent over 1944 domestic requirements of 512,020,000 barrels. Exports of fuel oil declined from 56,027,000 barrels in 1944 to 45,746,000 in 1945. Foreign shipments of both light and heavy fuel oils were lower in 1945, when the total for distillate grades dropped by 22 percent from 43,491,000 barrels in 1944 to 33,827,000 in 1945, and the overseas demand for residuals (11,919,000 barrels) was 5 percent below 1944 requirements of 12,536,000 barrels. The downward trend in the foreign trade in fuel oils in 1945 compares with a net gain of 41 percent in 1944 over 1943, resulting from a 74-percent rise in exports of light fuel oils and a 16-percent decline for the heavier grades in the same year.

The peak demand for fuel oil was reached in the first quarter of 1945, when requirements of 213,160,000 barrels were 8 percent above the comparative 1944 total of 197,669,000 barrels. Most of this increase was limited to the heavier grades—important fuel in the war effort—of which the quarterly total increased 11 percent from 131,098,000 barrels in 1944 to 144,879,000 in the opening months of 1945, while the first-quarter gain for the distillate fuel oils was less than 3 percent—68,281,000 barrels in 1945 compared with 66,571,000 in 1944. It should be added that warmer weather in the initial months of 1945 was a factor and undoubtedly tended to soften the market for light heating oils.

The ending of hostilities in Europe in May and in the Pacific area in August and the resulting cancellation of numerous war contracts, the fading of peak transportation activities, and the slack period for heating oils were all reflected in declining domestic fuel-oil needs in the second and third quarters of 1945 and an actual drop in the fourth-quarter volume of 1945 compared with 1944. The demand in the second quarter of 180,524,000 barrels was 6 percent above the corresponding 1944 item—170,234,000 barrels—and the gain shrank to 4 percent in the third quarter (161,811,000 barrels in 1945 compared with 155,561,000 in 1944), when the heating load was at its lowest ebb. The rising seasonal demand for heating oils in the final quarter of 1945 was not sufficient to offset dwindling military and industrial requirements and the total for the period—193,340,000 barrels—was 2 percent below the comparative 1944 quantity of 197,876,000 barrels.

When the quarterly demands for light and heavy fuel oils are reviewed separately, it is found that the market for distillate grades—important for space heating—tended to maintain a higher relative volume in 1945 than in 1944, while the demand for residual fuel oils—used principally for industrial and transportation fuels—contracted sharply. The requirements for light fuel oils was up 10 percent in the second quarter of 1945 over 1944, 13 percent in the third quarter, and 9 percent in the closing months of the year, while demand for the residual grades slumped steadily as military activities were terminated or from a 6-percent gain in the second quarter of 1945 over the corresponding 1944 total to less than a 1-percent increment in the third quarter and to an actual decline of 7 percent in the closing 3 months of 1945. Colder weather in the final three quarters of 1945 as well as the cancellation of all rationing of oil supplies as of August 15, 1945, were factors that helped to keep the domestic demand for light fuel oils at expanded levels.

Available statistics show that the domestic demand for fuel oil (201,145,000 barrels) in the first quarter of 1946 was 6 percent below the total (213,160,000 barrels) for the comparative period of 1945. The decline in the market, however, was limited to the heavier grades, which dropped by 13 percent from 144,879,000 barrels in the initial quarter of 1945 to 126,527,000 for the same quarter of 1946. Conversely, the requirements for distillate fuel oil during the first 3 months of 1946 (74,618,000 barrels) was 9 percent over the comparative 1945 total of 68,281,000 barrels.

Detailed statistics covering sales of fuel oil by principal uses in 1945 as reported in the annual survey are not ready at this time; however, some estimates based on monthly figures and other data from various sources can be presented. It is evident that the railroads required about 126,800,000 barrels of fuel oil in 1945 compared with 125,162,000 in 1944. Monthly totals compiled by the Interstate Commerce Commission covering purchases of fuel oil by class I railroads for locomotives and rail motor cars show a slight drop for residual grades from 113,314,000 barrels in 1944 to 111,966,000 in 1945, while the Diesel-fuel item was up sharply from 7,880,000 barrels in 1944 to 10,811,000 in 1945. Fuel oil delivered for the bunkering of vessels probably reached 121,000,000 barrels in 1945 compared with 105,256,000 in 1944. Records by the Bureau of the Census, United States Department of Commerce, show that vessels engaged in foreign trade loaded 79,611,000 barrels of bunker oil at continental United States ports in 1945—a gain of 14 percent over the 1944 total of 70,061,000 barrels. It is estimated that bunker-oil requirements for

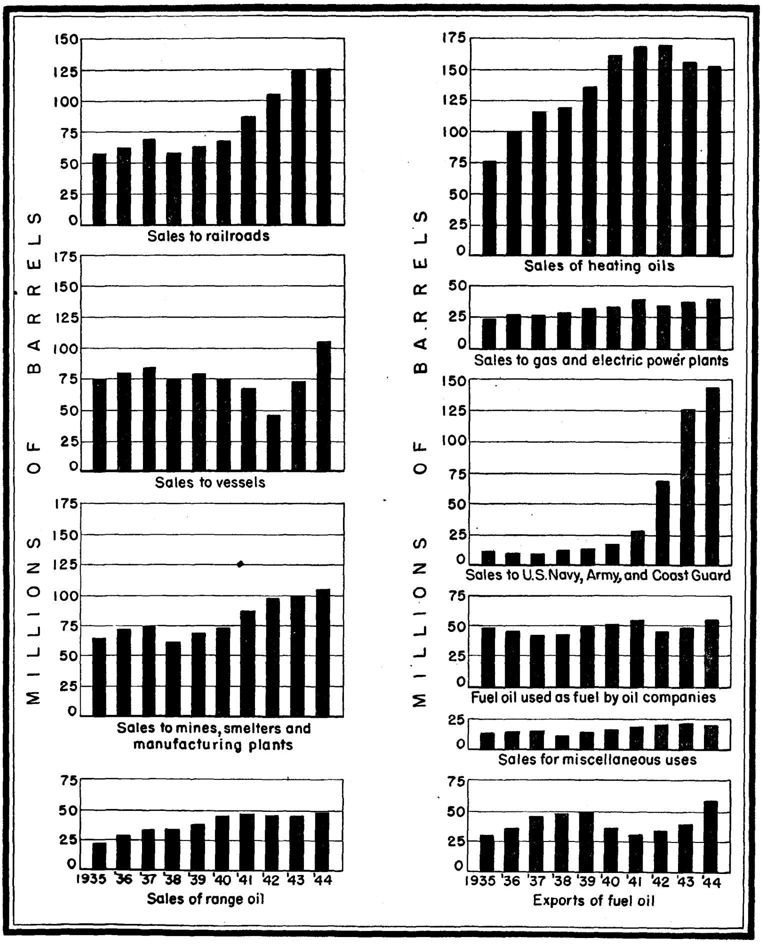

FIGURE 10.—Sales of fuel oil and range oil in the United States, 1935–44, by uses.

vessels operating along the coasts and on inland waterways expanded from approximately 35,000,000 barrels in 1944 to 41,000,000 in 1945.

The consumption of fuel oil by the electric-power and manufactured-gas industries was evidently about 41,500,000 barrels in 1945, a total 3 percent above 1944 requirements of 40,313,000 barrels. Statistics released by the Federal Power Commission indicate 20,183,000 barrels of fuel oil used for the production of electric energy in 1945 (compared with 20,866,000 barrels in 1944), while it is thought that quantities delivered to manufactured-gas companies will approximate 21,300,000 barrels in 1945—a moderate increase over the 1944 quantity of 19,921,000 barrels.

The rationing of fuel oil up to August 15, 1945, and the difficulties of obtaining supplies and equipment probably prevented any expansion in the use of fuel oil by manufacturing industries, and it is estimated that requirements for the year—103,400,000 barrels—were about the same as in 1944. Nearly three-fourths of the fuel oil used for space heating is distillate, and it is estimated that the demand for this grade increased somewhat after the end of rationing to a 1945 total of 122,000,000 barrels, compared with deliveries of 111,729,000 in 1944. Heavy fuel oil used in heating probably rose to 45,500,000 barrels in 1945, advancing the total for all grades to 167,500,000 barrels against 152,203,000 in 1944. It is believed that No. 1 fuel oil consumed as range oil totaled about 7,800,000 barrels in 1945, compared with 6,619,000 in 1944.

Sales of fuel oil [1] and of range oil in the United States, 1940–44 by uses [2]

[1] Includes Diesel fuel.
[2] Figures for 1945 not yet available.
[3] This total involve some duplication due to rehandling of fuel oil initially sold to the Government

Oil companies produced and refined slightly more crude petroleum in 1945 than in 1944 and therefore probably used additional fuel oil in their operations— about 57,500,000 barrels compared with 56,344,000 in 1944. The balance of the fuel oil available in 1945—about 123,000,000 barrels—must be credited to military and miscellaneous uses.

Sales of residual fuel oil [1] *in the United States, 1940–44, by uses* [2]

[1] Includes Navy grade and crude oil burned as fuel.
[2] Figures for 1945 not yet available.
[3] These totals involve some duplication due to rehandling of fuel oil initially sold to the Government.

The trend in the demand for fuel oil for different uses during the years 1935–44 as reported to the Bureau in the annual survey of sales is indicated by a series of columns in figure 10. Light and heavy fuel oils as well as kerosine sold as range oil, are included.

Fuel-oil exports (including shipments to noncontiguous Territories) declined by 18 percent from 56,027,000 barrels in 1944 to 45,746,000 in 1945. Exports of distillate fuel oil were unusually high in 1944 due to lend-lease requirements, however, this demand was not repeated in 1945, when the total of 33,827,000 barrels was 22 percent below the 1944 volume of 43,491,000 barrels. It should be added, however, that the 1945 export total for distillate fuel oil was still above the prewar level of these shipments. Export of residual fuel oil have not varied greatly during the war years—the 1945 total of 11,919,000 barrels was 5 percent below the 1944 item of 12,536,000 barrels.

Virtually all the loss in exports of distillate fuel oil in 1945 is found in the lower shipments to the United Kingdom, which declined from 37,640,000 barrels in 1944 to 26,913,000 in 1945. The Canadian demand for American light fuel oil also dropped from 1,714,000 barrels in 1944 to 826,000 in 1945. Conversely, exports of distillate to U. S. S. R. continued to show an upward trend, from 264,000 barrels in 1943 to 312,000 in 1944 and to 1,052,000 in 1945.

Lend-lease shipments of heavy fuel oil to the United Kingdom declined from 6,059,000 barrels in 1944 to 4,360,000 in 1945, while exports to Canada, which have dropped in the 2 previous years, turned upward in 1945 to 734,000 barrels compared with requirements of 496,000 in 1944. Greatly expanded movements of heavy fuel oil to Cuba reported in 1944—2,245,000 barrels—were not repeated in 1945, as the total shipped to that country, mostly for reexport, declined to 1,005,000 barrels. Relatively important quantities of residual fuel oil are sent to Mexico; however, the volume for 1945—583,000 barrels—was below the 1944 item of 627,000 barrels. A small quantity of heavy fuel oil was credited to U. S. S. R. in 1945—159,000 barrels—and none in 1944.

The production of fuel oil rose from 700,607,000 barrels in 1944 to 718,716,000 in 1945—an increase of less than 3 percent compared with gains of 13 percent realized in 1943 and 11 percent in 1944.

The output of distillate fuel oil expanded from 239,152,000 barrels in 1944 to 249,224,000 in 1945—a gain of over 4 percent—while the increment for residual grades was less than 2 percent—469,492,000 barrels in 1945 compared with 461,455,000 in 1944. In 1944 and 1945 the larger production of fuel oil as a whole must be attributed solely to the greater volume of crude runs, as the percentage yield dropped from 44.0 percent in 1943 to 42.1 percent in 1944 and then to 41.8 percent in 1945. This shrinkage in the yield of fuel oil resulted largely from the effort of refiners to produce a maximum quantity of gasoline (straight-run and cracked), and this is reflected in the rising percentage yield of the latter product, which has increased from about 37 percent in 1943 to nearly 41 percent in 1945. In other words, some potential production of fuel oil was sacrificed to make more gasoline—a product greatly needed in the war as well as a more profitable one. The refining program had a greater effect on the output of residual grades of fuel oil, the percentage yield of which declined from 29.2 percent in 1943 to 27.3 percent in 1945; and the gain in production of 16 percent realized in 1943 dropped to an 11-percent increment for 1944 and to less than a 2-percent increase in 1945, while the yield of light fuel oils was maintained at an average of 14.5 percent for the same years and the annual increases in production (8 percent for 1943, 13 percent for 1944, and over 4 percent for 1945) have not fallen so drastically as for the residual grades.

Variations in fuel-oil production in the several refinery districts in 1945 compared with 1944 can be attributed to both fluctuations in crude runs and modified percentage yields. In the Atlantic Coast district, where about one-fifth of the fuel oil of the country is produced, the output of both distillate (50,243,000 barrels in 1945 compared with 46,763,000 in 1944) and residual (85,352,000 barrels in 1945 compared with 79,964,000 in 1944) expanded by about 7 percent in 1945. The gain in production for the area in 1945 was mostly due to higher crude runs (7 percent over 1944), as the percentage yields for both light and heavy fuel oils were only fractionally higher than in 1944. The foreign crude refined on the Atlantic coast usually has a high residual fuel-oil content, and the volume of this crude processed in 1945 (71 percent over 1944) was also a factor in the increased output of heavy fuel oil.

About 30 percent of all distillate and 20 percent of the heavy fuel oil is produced in the Texas Gulf Coast district. The output of residual there declined by 9 percent from 97,683,000 barrels in 1944 to 88,617,000 in 1945—a loss resulting not only from smaller crude runs but also from a considerably lower yield, which declined from 23.9 percent in 1944 to 22.0 percent in 1945, a downward change caused by the higher production of gasoline in the area. The percentage yield of distillate was up fractionally (18.3 percent in 1945 compared with 18.1 percent in 1944), so even with the smaller quantity of crude petroleum run to stills the production of 73,677,000 barrels in 1945 differed little from the 1944 total of 73,935,000 barrels.

A very large volume of residual fuel oil—about one-third of the national total—is produced in the Pacific Coast area, and the quantity increased by nearly 10 percent from 135,946,000 barrels in 1944 to 148,976,000 in 1945. The gain in the residual output on the Pacific coast in 1945 was not only due to expanded runs (6 percent over 1944), but also to the kind of crude processed—a heavy petroleum which yielded 47.5 percent of heavy fuel oil in 1945 compared with 46.1 percent in 1944. It should be added that this larger quantity of residual fuel oil was made in 1945, even though the production and percentage yield of gasoline were also increased. The distillate fuel-oil content of California crude is fairly low (10.0 percent yield in 1944 and 9.5 percent in 1945); and the production of 29,702,000 barrels in 1945 was only 1 percent over the 1944 total of 29,382,000 even though runs were higher in 1945.

Sales of fuel oil [1] in the United States, 1940–44, by regions and States [2]

[1] Includes distillate fuel oil, residual fuel oil, and some crude oil burned as fuel.
[2] Figures for 1945 not yet available.
[3] These totals involve some duplication due to rehandling of fuel oil initially sold to the Government.

The Indiana-Illinois-Kentucky refinery district is a fairly important source of both light and heavy fuel oil. The refineries in the area not only ran slightly less crude petroleum in 1945 than in 1944, but they also reduced the percentage yield of residual to turn out more gasoline. The result was that the output of heavy fuel oil dropped by 6 percent—from 56,890,000 barrels in 1944 to 53,494,000 in 1945. However, there was little change in the production of light fuel oil—34,601,000 barrels in 1945 compared with 34,544,000 in 1944—even considering the lower runs—as the yield of this lighter product—12.4 percent in 1944 and 12.5 percent in 1945—was slightly improved.

Refiners operating in the Oklahoma-Kansas-Missouri district ran about 5 percent more crude in 1945 than in 1944; and with only minor changes in the percentage yields for fuel oils, they were enabled to increase the output of distillate by 6 percent from 19,281,000 barrels in 1944 to 20,500,000 in 1945, while the production of the heavier grades—24,764,000 barrels in 1945 compared with 23,984,000 in 1944—represented an expansion of 3 percent. These higher outputs of fuel oil in 1945 apparently did not affect the production of gasoline, as that priority product also showed a gain both in volume and percentage yield.

An 18-percent increase in the volume of crude petroleum refined in the Louisiana Gulf Coast area and a higher yield (19.8 percent in 1945 compared with 18.4 percent in 1944) for distillates resulted in a 27-percent gain in the output for these light fuel oils—19,710,000 barrels in 1945 against 15,572,000 in 1944. However, the yield for heavier grades was cut rather drastically (17.2 percent in 1945 compared with 19.3 percent in 1944) to make more gasoline; as a result, the production of 17,062,000 barrels in 1945 was only about 5 percent over the 1944 total of 16,322,000, even though the runs were much higher in 1945.

Relatively smaller quantities of distillate fuel oil are produced in the remaining refinery districts. Gains in the output for 1945 were reported for the Texas Inland and Rocky Mountain areas owing to increased runs and higher percentage yields, while conversely the lower production of light fuel oils in the Appalachian and Arkansas and Louisiana Inland districts was the result of opposite operating conditions—reduced runs and scaled-down yields. The Texas Inland area produces an appreciable amount of heavy fuel oil (about 5 percent of the national total); however, although runs were greater, the volume of this grade of fuel oil dropped by 6 percent, as the percentage yield was cut heavily from 28.8 percent in 1944 to 26.6 percent in 1945. The Rocky Mountain refinery district produced 18 percent more residual fuel oil in 1945 than in 1944, as both the runs and the percentage yield were substantially higher in 1945. Small quantities of heavy fuel oil originate in the Appalachian and Arkansas and Louisiana Inland districts, and the respective totals for 1945 were nominally lower than those for 1944.

Crude oil is sometimes used directly as fuel, and when so used it is credited to the fuel-oil account and appears in fuel-oil statistics under the general heading of "transfers." Light crude oil consumed as fuel by pipe line companies is transferred to the distillate fuel-oil total, while heavy crude petroleum used directly as fuel on leases or for

717372—47——72

general industrial purposes is covered in transfers as part of the residual fuel-oil supply.

Transfers classed as distillate fuel oil decreased from 3,242,000 barrels in 1944 to 3,047,000 in 1945, and the quantities for both years represented only about 1 percent of the total light fuel-oil supply for all purposes. Transfers to the residual fuel-oil supply, which have increased steadily in volume during the war years, declined by 27 percent from 28,515,000 barrels in 1944 to 20,727,000 in 1945; and incidentally, the total in 1945 represented less than 4 percent of the heavy fuel-oil supply for all uses compared with over a 5-percent share in 1944. Most of the residual transfers are reported from California, and there the quantity declined from 23,177,000 barrels in 1944 to 16,039,000 in 1945—a 31-percent shrinkage. This drop in transfers to the residual fuel-oil account in California was undoubtedly due in part to a lower production of nongasoline-bearing crude in that area in 1945. Transfers to residual fuel oils east of California of 4,688,000 barrels in 1945 were about 13 percent below the 1944 total of 5,338,000 barrels.

Very little light crude oil is credited to the distillate fuel-oil account in California, and the quantity has ranged from 19,000 barrels in 1943 to 79,000 in 1944 and then down to 3,000 in 1945. Light crude oil added to distillate fuel oils in areas east of California totaled 3,044,000 barrels in 1945 compared with 3,163,000 in 1944.

The high imports of fuel oil recorded in 1943 and 1944 were not repeated in 1945, when total receipts from foreign sources—36,311,000 barrels—were about 17 percent below the 1944 level (43,507,000 barrels). Furthermore, imported fuel oil supplied only about 5 percent of the demand for all purposes in 1945 compared with a 6-percent share in 1944. The drop in imports of residual grades from 36,485,000 barrels in 1944 to 31,557,000 in 1945 (a 14-percent shrinkage) was not as pronounced as that for the light fuel oils, which declined by a third from 7,022,000 barrels in 1944 to 4,754,000 in 1945. Several factors, such as an increased percentage yield, greater percentage increase in production, a relative lower drop in transfers, greatly curtailed exports, and a relatively favorable stock position resulted in a better supply situation for distillate fuel oils in 1945; consequently, there was not a great pressure for imports. However, in the case of residual grades, all the above-mentioned factors were statistically less favorable in 1945, and therefore, there was an incentive to maintain imports at a relatively high level to satisfy the market. Imports supplied less than 2 percent of all demands for distillate fuel oil in 1945, compared with a 3-percent share in 1944, while the percentage of residual fuel oil of foreign origin in the marketed total was 7 percent in 1944 and 6 percent in 1945.

Most of the fuel oil imported into the United States is credited to Curacao, a refining center on an island in the Netherlands West Indies, which runs on crude from Venezuelan fields. Less important quantities are also received from Venezuela, Trinidad, Mexico, and Canada.

An improved fuel-oil stock situation evident in 1944 was not repeated in 1945, when the year-end total (72,936,000 barrels), was about 18 percent below the comparative 1944 item (88,716,000 barrels). The heavy fuel-oil inventory showed some improvement in 1944 (4 percent over 1943); however, it declined sharply in 1945 to 37,158,000 barrels, a total 26 percent below 1944 year-end stocks of 50,383,000 barrels. Distillate fuel oils held in storage totaled 35,778,000 barrels at the close of 1945 compared with 38,333,000 for 1944—a drop of about 7 percent and a percentage decline similar to those reported for 1944 and 1943.

The heavy liquidation of residual fuel-oil stocks in 1945 was due to a combination of several factors. The percentage yield was lowered in 1945 to make more gasoline, with the result that production of heavy fuel oils showed only a slight gain (less than 2 percent) even though crude runs were increased over 3 percent. Furthermore, additional supplies of residual fuel oil from both "transfers" and imports were down sharply in 1945, compared with 1944, and hence there was added pressure to force large quantities from storage. Exports showed a small decline (5 percent) in 1945; however, there was an active domestic demand, and consequently a large volume of heavy fuel oil from inventory was diverted to the market. The same factors influencing the flow of distillate fuel oil into consumption were statistically more favorable, and therefore the draft on stocks was less critical in 1945 than for the heavy grades.

Fuel oil held in storage at refineries dropped 20 percent—from 65,426,000 barrels in 1944 to 52,591,000 at the end of 1945—and compared with a 2-percent shrinkage in 1944 over 1943. The liquidation of fuel oils held at bulk storage plants was less pronounced; however, there was a decline of about 13 percent (20,345,000 barrels at the end of 1945 against 23,290,000 in 1944) compared with a drop of only 1 percent in 1944. Residual fuel oils stored at refineries (28,749,000 barrels at the end of 1945) were 29 percent below the comparative 1944 total of 40,356,000; this loss is in contrast to a gain of 4 percent for these stocks reported in 1944. The heavy-fuel-oil inventory at bulk terminals (8,409,000 barrels at the end of 1945) was 16 percent below the 1944 total (10,027,000 barrels). This shrinkage in volume of residual fuel oil stored at bulk plants in 1945 compares with a 4-percent gain realized in 1944. The quantity of distillate fuel oil carried at refineries has continued to drop since 1941, although at a diminishing percentage rate of decline for each year. The year-end total for 1945 (23,842,000 barrels) was 5 percent below the 1944 quantity (25,070,000 barrels), which in turn was 10 percent less than the comparative 1943 item. Light fuel oil held at bulk plants at the close of 1945 (11,936,000 barrels) was 10 percent less than the 1944 inventory (13,263,000 barrels) and compares with a loss of 5 percent reported for 1944 and a gain of 13 percent in 1943 over 1942.

Distillate fuel oil withdrawn from storage satisfied about 1 percent of the total domestic and export demand for both 1944 and 1945, while in the case of residual grades over 2 percent of total requirements came from inventory in 1945 in contrast to none in 1944. Light fuel oil in storage at the end of 1945 represented a 39-day supply at the December daily rate of domestic demand and compares with stock reserves of 47 days at the close of 1944 and 59 days for 1943. The final 1945 inventory for residual fuel oil was adequate for 25 days at the then current rate of domestic demand and contrasts with a 31-day supply represented by year-end heavy-oil stocks of 1944 and 33 days for 1943.

Comparative analyses of statistics for distillate fuel oil in the United States, 1944–45, by months and districts

[1] Figures represent crude oil used as fuel on pipe lines.
[2] Subject to revision.
[3] Figures not available.

Distillate fuel-oil stocks reported for the east coast increased by 9 percent from 9,621,000 barrels at the end of 1944 to 10,515,000 for 1945. The 1945 quantity represented 29 percent of the national inventory and compared with a 25-percent share in 1944. Residual fuel-oil stocks in the same area increased by 3 percent—from 6,831,000 barrels in 1944 to 7,057,000 in December 1945. The 1945 quantity was second in volume only to supplies held in California, covered 19 percent of total heavy fuel-oil stocks, and was in contrast to a 14-percent share reported on the Atlantic coast at the end of 1944.

Approximately half of the residual fuel-oil stocks of the country are carried in the California refinery area; however, the proportion declined from nearly 52 percent of the national total in 1944 to 48 percent in 1945. The year-end total for California dropped by 32 percent from 26,047,000 barrels in 1944 to 17,832,000 in 1945 and reflects the tightness of supplies in that area in the latter year. The California refinery district rates second only to the East Coast as a storage area for distillate fuel oils; however, inventories there declined from 24 percent of the national total in 1944 to 22 percent in 1945, and the volume at the end of 1945 of 7,868,000 barrels was 15 percent below comparative 1944 stocks of 9,259,000 barrels.

Important quantities of fuel oil are stored on the Texas Gulf coast; however, the total dropped 37 percent from 17,523,000 barrels in 1944 to 11,078,000 in December 1945. The larger share of this shrinkage was confined to the residual grades, which declined by nearly half from 9,974,000 barrels in 1944 to 5,051,000 at the close of 1945. This heavy draft on residual fuel-oil stocks in that area in 1945 was due to several factors, such as lower runs to stills and a reduced yield, which cut down production by nearly 10 percent. This tightness in the supply in 1945 came at a time of an active market; consequently, unusual liquidation of stocks resulted. Although production of distillate fuel oil was sustained in the Texas Gulf coast in 1945, the heavy demand for supplies lowered stocks 20 percent from 7,549,000 barrels in 1944 to 6,027,000 by the end of 1945.

The fuel-oil inventory in the Indiana-Illinois-Kentucky refinery district was reduced from 9,479,000 barrels in 1944 to 8,360,000 at the end of 1945. Light fuel-oil stocks were lower by 10 percent, from 6,419,000 barrels in 1944 to 5,773,000 in December 1945, as production from reduced crude runs in 1945 was not sufficient to meet requirements. The supply of residual fuel oil in the area was similarly affected; as a result, quantities held in storage were liquidated by 16 percent—from 3,060,000 barrels in 1944 to 2,587,000 at the end of 1945.

Fuel-oil stocks reported in the remaining refinery districts are relatively unimportant. Quantities of distillate stored in the Appalachian, Louisiana Gulf Coast, and Rocky Mountain districts gained in 1945 over 1944. The most important increase was in the Louisiana Gulf area, where the light fuel-oil inventory increased from 1,292,000 barrels in 1944 to 1,766,000 in December 1945. Lower distillate fuel-oil stocks were reported for the Oklahoma-Kansas-Missouri, Texas Inland, and Arkansas and Louisiana Inland refinery districts at the close of 1945 compared with 1944. The 1945 liquidation of light fuel-oil stock was trivial in the Texas Inland area; however, it amounted to a 14-percent reduction for the Oklahoma-Kansas-Missouri district

Comparative analyses of statistics for residual fuel oil in the United States, 1944–45, by months and districts

and a 21-percent decline for the Arkansas-Louisiana Inland area. Relative important percentage gains in heavy fuel-oil stocks were realized in the Louisiana Gulf, Arkansas and Louisiana Inland, and Rocky Mountain refinery districts in 1945 over 1944, while inventory losses were indicated for the same period in the Appalachian, Oklahoma-Kansas-Missouri, and Texas Inland areas.

During 1945 there were no tanker movements of fuel oil from California to eastern markets. The California refinery district (California, Oregon, Washington, Arizona, and Nevada), however, does make some fuel-oil shipments to other Western States by railroad tank car and trucks. Distillate fuel oil handled in these land movements totaled 636,000 barrels in 1945 compared with 492,000 in 1944, while the quantity of residual grades involved declined from 182,000 barrels in 1944 to 158,000 in 1945. The California refinery area in turn receives some small amounts of fuel oil from other States, namely, 251,000 barrels of light fuel oils in 1945, compared with 275,000 in 1944 and 773,000 barrels of heavy grades in 1945 against 571,000 in 1944.

With the ending of the war in late 1945, the tanker and barge movement of fuel oils from the Gulf refinery districts to the East Coast area showed great improvement, although the traffic is still well below normal volume. Light fuel oils handled over this water route more than doubled—from 13,123,000 barrels in 1944 to 28,175,000 in 1945, yet this latter quantity is much less than the 1941 total of 42,-620,000 barrels. Most of the distillate fuel oil shipped out of the Gulf Coast area to eastern markets is credited to Texas—11,976,000 barrels in 1944 and 24,883,000 in 1945. The balance—1,147,000 barrels in 1944 and 3,292,000 in 1945—originated in Louisiana. Tanker movements of heavy fuel oils over the Gulf-East Coast route increased from 20,453,000 barrels in 1944 to 37,193,000 in 1945. It should be added that the 1945 volume for residuals was only about one-half the comparative 1941 item of 75,923,000 barrels. Texas supplied 18,927,000 barrels of the 1944 quantity and 34,409,000 barrels in 1945. Louisiana furnished the balance of the heavy fuel oil making up this traffic—1,526,000 barrels in 1944 and 2,784,000 in 1945.

The Gulf Coast region makes some barge shipments of fuel oil to points on the Mississippi River. The quantity of distillate fuel oil involved in this movement increased from 2,881,000 barrels in 1944 to 4,352,000 in 1945, while residual grades declined slightly—from 1,182,000 barrels in 1944 to 1,042,000 in 1945. Practically all the fuel oil handled in this barge movement is credited to Louisiana; very little of it comes from Texas. In addition to the above-mentioned quantities, Arkansas also ships fuel oil by barge to Mississippi River ports. All of the oil moved was distillate grade and declined from 3,398,000 barrels in 1944 to 2,980,000 in 1945.

The reporting of rail shipments of petroleum products to the Joint Tank Car Subcommittee was discontinued after August 31, 1945. Available records for the first 8 months of 1945 indicate, however, a pronounced drop in the movement of fuel oils for civilian consumption by rail from districts 2 and 3 into the East Coast area (district 1). Tank-car shipments of distillate fuel oil from district 2 to district 1 declined from 10,614,000 barrels for 1944 to 6,203,000 in the January-August period of 1945, while the total from district 3 into the East

Coast dropped from 18,300,000 barrels in 1944 to 9,078,000 in the first 8 months of 1945. Heavy grades of fuel oil entering district 1 by tank car and credited to district 2 totaled 4,150,000 barrels through August 1945 compared with 8,418,000 in all of 1944. Rail shipments of the same grades from district 3 into the Atlantic Coast area were 43,554,000 barrels in 1944 and 12,251,000 through August 1945. The revival of the tanker traffic between Gulf and East Coast ports and the diverting of railroad tank cars from eastern to western areas to relieve a serious shortage of petroleum products in the Pacific Northwest were the two main factors which adversely affected the rail movement of fuel oils into district 1.

[1] Platt's Oil Price Handbook.

The War Shipping Administration ordered two important changes regarding tanker rates in 1945. The surcharge of 200 percent to cover wartime risks and expenses, dating from April 6, 1942, was discontinued by Rate Order 378, as of September 1, 1945. Tanker rates in the past have been on a barrel basis and differed for the several petroleum products. The Gulf to Atlantic coast (not east of New York) charge on No. 2 fuel oil was 42 cents a barrel, dating from January 19, 1942, through October 14, 1945, and the rate for crude and heavy fuel oil (10°–19.9° gravity) was 48 cents a barrel over the same period. Effective October 15, 1945, tanker rates were put on a long-ton (2,240 pounds) basis for all petroleum products. The freight charge from Gulf ports to New York harbor was placed at $2.85 a ton, and as the average gravities vary for the different products the new rate is about 38 cents a barrel for No. 2 distillate and 43.8 cents for heavy fuel oil.

There were no changes in representative wholesale or bulk fuel-oil prices in 1945, except for some downward adjustments in the Atlantic Coast area at the close of the War. The Office of Price Administration, in its Amendment 32 to Maximum Price Regulation 88, effective September 1, 1945, reduced the wholesale price of petroleum products in the Atlantic Coast marketing area "to restore normal prices based on the return of tankers to coastwise petroleum movements." As a result of this change, the price of bunker C at New York Harbor was reduced from $1.77 to $1.55 a barrel, and the quotation for Diesel fuel for ships' bunkers was lowered from $2.78 to $2.15 a barrel. The difference between the old and the new prices represented, broadly speaking, the added cost of tanker transportation under war conditions. Heavy fuel oil, including bunker C, was reduced further, because of lower tanker rates up to 5 cents a barrel at Atlantic Coast ports by OPA Amendment 37 to M. P. R. 88, effective November 28, 1945. The price of bunker C at New York Harbor under this order was dropped to $1.51 a barrel or 4 cents below the former quotation.

As with wholesale fuel-oil prices, there were some after-the-war price adjustments in representative retail prices, as shown in average monthly quotations for various cities compiled by Bureau of Labor Statistics, United States Department of Labor. The consumer prices of fuel oil and other petroleum products sold on the eastern seaboard were reduced in line with lower wholesale prices put into effect on September 1, 1945. The average retail price of No. 2 fuel oil in the New York area (9.09 cents a gallon dating from December 1942) was dropped to 7.58 cents a gallon on September 17, 1945, by OPA Amendment 13 R. M. P. R. 137. The 17-day lag between the wholesale and retail price changes was made to allow dealers to dispose of stocks bought at the higher level. Because of a shortage in supplies, the OPA allowed shippers of fuel oil from PAW district 3 to district 1 a temporary increase in the price of light fuel oils up to 2 cents a gallon—Amendment 38, M. P. R. 88, effective December 19, 1945, and ending April 30, 1946. As a result of this allowance the average retail quotation of No. 2 at New York advanced to 7.60 cents a gallon. The average retail price of No. 2 fuel oil in Chicago (7.45 cents a gallon, dating from September 1944) declined to 7.19 cents in September 1945. There was an advance to 7.40 cents in November and then again to 7.45 cents a gallon in December 1945. These changes were the result of prevailing market conditions, as the OPA issued no new price regulations for the Chicago area during the final months of 1945.

LUBRICATING OIL

The demand for lubricating oil totaled 41.1 million barrels in 1944 and rose to 41.9 million in 1945. Exports declined from 8.7 million barrels to 6.6 million, while domestic demand increased from 32.4 million barrels to 35.3 million.

The yield of lubricating oil from crude has declined from 2.8 percent in 1941 to 2.5 percent in 1944 and 2.4 percent in 1945. Refinery stocks of lubricating oil amounted to 7,773,000 barrels at the end of 1945, showing a minor decline during the year.

The refinery production of lubricating oil amounted to 41,867,000 barrels in 1945, compared with 41,106,000 barrels in 1944. Production in the Appalachian district was 4,891,000 barrels in 1945, compared with 5,278,000 barrels in 1944. The principal increases in production in 1945 were in the Oklahoma-Kansas and Texas Gulf Coast districts.

Under present abnormal conditions, it has not been possible to estimate the relative consumption of lubricants for automotive and nonautomotive purposes.

OTHER PRODUCTS

Wax.—The total demand for wax has increased from 737 million pounds in 1941 to 796 million in 1944 and 831 million in 1945. Exports have been substantially below the prewar level. Domestic demand totaled 524 million pounds in 1941 and rose to 633 million in 1944 and 673 million in 1945.

The refinery production of wax was 818 million pounds in 1945. About 38 percent of the total was produced in the East Coast district, 15 percent in the Texas Gulf Coast district, and 12 percent in the Appalachian district.

Coke.—The production of petroleum coke amounted to 2,023,000 short tons in 1945 compared with 1,803,000 tons in 1944. Exports declined from 187,000 tons to 158,000 tons and domestic demand rose from 1,665,000 tons in 1944 to 1,841,000 tons in 1945. With the termination of wartime requirements, petroleum coke has become available for domestic heating purposes.

The principal refinery districts producing petroleum coke in 1945 were Indiana-Illinois and Texas Gulf Coast. The Indiana-Illinois district produced 56 percent of the total in 1945, compared with over 61 percent in 1944.

Asphalt and road oil.—The domestic demand for asphalt declined from 6,932,500 short tons in 1944 to 6,698,200 tons in 1945, while exports increased from 127,100 tons to 224,800 tons. The consumption of road oil. however, showed a material gain—from 1,560,000 barrels in 1944 to 2,505,000 barrels in 1945. Owing to wartime restrictions, consumption was curtailed, so that a large gain in demand may be expected in 1946. The demand for road oil in 1941 totaled 8,980,000 barrels.

Detailed statistics for asphalt and road oil appear in the chapter of this volume on Asphalt and Related Bitumens.

Still gas.—The output of still gas increased from 368,061 million cubic feet in 1944 to 372,449 million cubic feet in 1945. The largest production of still gas, by refinery districts, in 1945 was 108 billion cubic feet in the Texas Gulf Coast, 63 billion in the Indiana-Illinois district, 50 billion in the East Coast, and 48 billion in California. The major part of this still gas is used for fuel at refineries.

Miscellaneous oils.—The domestic demand for this group of products has risen steadily—from 11,862,000 barrels in 1941 to 36,291,000 barrels in 1945. The major products in this group are liquefied gases for fuel uses and for chemical and rubber manufacture. The supply of miscellaneous oils is derived from natural gasoline and cycle plants and from refinery production. Transfers of liquefied gases from natural gasoline and cycle plants have increased from 6,281,000 barrels in 1941 to 18,383,000 barrels in 1945. Refinery production of miscellaneous oils has risen from 6,266,000 barrels in 1941 to 19,080,000 barrels in 1945. These figures indicate that the supply from the two sources is approximately the same. No detailed break-down of the refinery output of miscellaneous oils in 1944 and 1945 is available.

WORLD PRODUCTION [2]

The world production of crude petroleum continued its steadily rising trend (interrupted only in 1930–32, 1938, and 1942). A 2-percent gain in the output of the United States from 1944 to 1945 was more than sufficient to offset a decrease of 2 percent in the rest of the world.

The Western Hemisphere contributed 83 percent of the total world petroleum production in 1945. The United States alone supplied 65 percent of the world output and Venezuela 12 percent. In the Eastern Hemisphere, the U. S. S. R. furnished 6 percent of the world total, so far as incomplete statistics would indicate.

In the United States, military demands during the first 7 months of 1945 and the removal of restrictions on civilian consumption during the last 5 months were reflected in an increase in demand of 6 percent and an increase in production of 2 percent. In Mexico increasing industrialization and growing home consumption promoted a 14-percent increase in the production of crude petroleum.

[2] By A. H. Redfield, Petroleum Economics Division, Bureau of Mines.

In Venezuela a decline in the output of the old Cabimas field from 1944 to 1945 was more than made up by increased production at Tia Juana and Lagunillas, as well as in minor fields of the Maracaibo Basin. In eastern Venezuela the Jusepin, Mulata, Quiriquire, and Guara fields led the general advance. Colombia produced 3 percent more petroleum in 1945 than in 1944. In Peru, declines in the older La Brea-Parinas and Lobitos fields were reflected in a general 5-percent decrease in output. In Argentina, both Government and private production were less, resulting in an output 6 percent lower in 1945 than in 1944.

Petroleum production in Europe suffered considerably from the effects of war, so far as incomplete and unofficial statistics permit a judgment. Only Rumania appears to have increased its production in 1945 over 1944.

In the Middle East, the removal of the submarine threat from the seas permitted petroleum production to expand, even beyond its prewar levels, in Iran, Bahrein Island, Saudi Arabia, and probably Iraq.

Crude petroleum produced in principal countries of the world, 1940–45, in thousands of barrels

FOREIGN TRADE [3]

IMPORTS

Imports of mineral oils, crude and refined, into continental United States increased 23 percent from 1944 to 1945. They constituted 6 percent of the total new supply in continental United States in 1945 compared with 5 percent in 1944.

Crude petroleum, residual fuel oil, and distillate fuel oil together made up 96 percent of the total mineral-oil imports in 1944 and 97 percent in 1945. Virtually all these imports came from ports of the Caribbean Sea and the Gulf of Mexico. Venezuela supplied 82 percent of the crude petroleum imported in 1944 and 85 percent in 1945, Colombia 17 percent in 1944 and 11 percent in 1945, and Mexico 1 percent in 1944 and 3 percent in 1945. Of the residual fuel oil imported, the Netherlands West Indies furnished 98 percent in 1944 and 97 percent in 1945. Minor amounts were imported in both years from Trinidad, Mexico, Canada, Colombia, and Venezuela.

Of the distillate fuel oil imported into the United States, the Netherlands West Indies was the principal source, supplying 69 percent in 1944 and 87 percent in 1945. The share of Mexico in this trade decreased from 14 percent in 1944 to 5 percent in 1945; that of Venezuela from 12 percent in 1944 to 2 percent in 1945; and that of Trinidad from 6 percent in 1944 to 4 percent in 1945.

Of all mineral oils, crude and refined, imported into the United States, the Netherlands West Indies supplied 51 percent in 1944 and 41 percent in 1945, Venezuela 38 percent in 1944 and 48 percent in 1945, Colombia 7 percent in 1944 and 6 percent in 1945, Mexico 2 percent in 1944 and 3 percent in 1945, and Trinidad 1 percent in both 1944 and 1945.

EXPORTS

Continental United States continued to be a net exporter of mineral oils. The excess of all petroleum exports over all petroleum imports decreased from 115 million barrels (revised figure) in 1944 to 71 million barrels in 1945. In crude petroleum, however, imports were larger than exports in both years. The excess of crude imports decreased from 10.6 million barrels in 1944 to 6 million barrels in 1945. On the other hand, exports of refined oils exceeded imports of refined oils, with the exception of residual fuel oil. This excess decreased from 126 million barrels (revised figure) in 1944 to 112 million barrels in 1945. Imports of residual fuel oil exceeded exports by 24 million barrels (revised figure) in 1944 and by 20 million barrels in 1945.

Exports and Territorial shipments of crude petroleum from continental United States decreased 4 percent from 1944 to 1945. Canada received 97 percent of these outgoing shipments in 1944 and 93 percent in 1945; the United Kingdom 1 percent in 1944 and 4 percent in 1945; and Cuba 2 percent in both years.

In absolute amounts, exports and Territorial shipments of refined mineral oils were 13 percent less in 1945 than in 1944. The decreases were general among the major refined oils.

Of the exports of major refined oils, 78 percent in 1944 and 77 percent in 1945 went to Europe. The United Kingdom received 75 percent of the total in 1944 and 69 percent in 1945, and the U. S. S. R. 3 percent in 1944 and 4 percent in 1945.

Other North American countries received 6 percent of the total exports both in 1944 and in 1945. Canada's share of the whole decreased from 4 percent (revised figure) in 1944 to 3 percent in 1945.

Exports of major refined mineral oils from the United States to Oceania amounted to 5 percent of the total outward shipments from the United States in 1944 and to 1½ percent in 1945. Australia received 3 percent of the whole in 1944 and 1½ percent in 1945.

Mineral oils, crude and refined, shipped from continental United States, including shipments to noncontiguous territories, 1944–45, by classes and months [1]

[1] Compiled from the records of the U. S. Department of Commerce.
[2] Includes natural gasoline, naphtha, benzol, and antiknock compounds.
[3] Less than 1,000 barrels.
[4] Less than 1,000 pounds.

INTERCOASTAL SHIPMENTS [4]

Receipts of mineral oils, crude and refined, on the East coast from Gulf Coast ports were 2.7 times as large in 1945 as in 1944 but still were less than half as large as in 1940 and 1941. Crude petroleum was the largest single item in these 1945 shipments; it constituted 36 percent of the total shipments in 1945, compared with 19 percent in 1944. Shipments of gasoline and of distillate fuel oil were more than twice as large in 1945 than in 1944; shipments of kerosine more than 2½ times as large; and shipments of residual fuel oil nearly twice as large.

Mineral oils, crude and refined, shipped commercially from Gulf coast to east coast ports of the United States, 1944–45, by classes [1]

NATURAL GAS [1]

By F. S. Lott and H. Backus

SUMMARY OUTLINE

SUMMARY

The volume of business handled by the natural-gas industry continued to expand to new record levels in 1945, as in other years since 1938. Marketed production is estimated to have increased 4 percent over 1944 to 3,875,172 million cubic feet. All consuming groups consumed more than in 1944, except the miscellaneous industrial classification, which required slightly (3 percent) less gas in 1945, owing to the sharp curtailment of industrial activity after the first quarter of that year.

The most significant effects of lessened use of gas for some industrial purposes, during and after the final stages of the war, were noted in regions dependent, in part at least, upon supplies of gas from remote sources. In these regions many of the transporting companies were able for the first time in 3 years to feel adequately prepared for the stresses of approaching peak winter demands. The segments of industrial consumption that continued to grow to new record volumes in 1945 were: Oil- and gas-field use, carbon-black manufacture, and petroleum-refinery fuel. These types of consumption tend to occur relatively close to gas-producing fields and to have flat seasonal demand curves. They therefore seldom involve complex or costly problems of transport.

The average value of natural gas at the wells was 5.1 cents per thousand cubic feet in 1944 and is thought to have remained unchanged in 1945. Although an upward trend in field values of gas is evident in most producing districts, the United States average has changed very little in recent years because of the growing proportion of gas marketed from southwestern producing States where low well-head values prevail. For example, Texas, Louisiana, and New Mexico increased their share of United States marketed production from 51 percent in 1937 to 58 percent in 1944.

[1] In this report the term "billion" is equivalent to 1,000,000,000 and "trillion" to 1,000,000,000,000, according to United States usage.

The average value of natural gas at points of consumption is estimated to have declined from 21.5 cents per thousand cubic feet in 1944 to 21.2 cents in 1945 (see fig. 1), influenced by lower averages for domestic, commercial, and industrial gas. Domestic and commercial values have been declining for 6 years as average consumption per meter has increased.

The volume of gas exported to Mexico increased from 14,433 million cubic feet in 1944 to about 17,000 million cubic feet in 1945, and the small movement to Canada from New York State increased from 143 million cubic feet to 172 million. No imports of natural gas into the United States have been reported since 1939, when piping of gas from an Alberta field into Montana was discontinued.

Salient statistics of natural gas in the United States, 1941–45

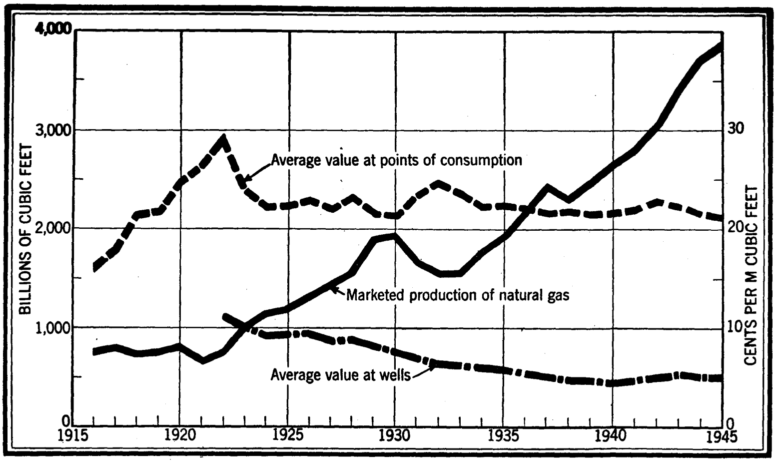

FIGURE 1.—Production and value of natural gas in the United States, 1916–45.

At the end of 1945 the number of domestic meters was about 10,850,000, an increase of 2 percent over 1944 and 47 percent in 10 years. Similarly, commercial meters increased 4 percent over 1944 to about 875,000, a gain of 43 percent in 10 years.

OUTLOOK

The probability of a vigorous growth trend in natural-gas sales during at least the early postwar years, has been more clearly defined by developments of recent months.

Of great potential significance as regards political economy may be the testimony presented before the Federal Power Commission in its natural gas investigation, to which wide publicity was accorded. In the record of natural gas, strong emphasis was placed upon (1) the great and growing magnitude of available reserves; (2) the past record of relatively trouble free service to the public; (3) stable or declining costs to most consumers; (4) opposition of consuming groups to restriction upon supply or utilization; and (5) the great developments anticipated from the fruits of recent research affecting the future, not only of natural gas, but of coal and other fuels.

Wider public appreciation of these factors will tend to strengthen the position of natural gas in competition with other fuels and develop the conditions for sound expansion. Greater demand from consumers in established marketing areas as well as from communities not currently served with natural gas is concretely expressed in numerous projects for expanding facilities for transmission and distribution. An aggregate investment for these purposes of over 150 million dollars of new money is indicated by gas company proposals for the near future.

Recent developments affecting long distance gas transmission indicate that a materially higher efficiency and attendant lower unit cost of operations have been attained than in the past. In delivering southwestern gas to the Appalachian region cost reductions have been possible through using major lines at practically 100-percent load factor and by taking advantage of record low interest rates in financing capital expenditures. As the cost of money is an important element of gas pipe-line expense, the saving from this source has been appreciable. On the other hand, because labor expense represents a relatively small component of the total cost of natural-gas transmission or production, the effect of increased wage scales has been small.

These cost trends have, of course, been improving the competitive position of natural gas, particularly as regards coal with its inherently high labor cost per unit of output and relatively low capital investment. It is well to remember also that price levels in general and wage rates are far above prewar levels and are expected to remain on a "high plateau" indefinitely. The effect of these changes will be more severe upon other fuels than upon natural gas, which, after the "shafts" have been dug, practically "mines itself" in condition for market.

It is often said that technology has caused the world to shrink drastically in recent years. Similarly, the economic and physical barriers to long-distance gas transmission have crumbled rapidly, and markets have thereby been brought significantly closer to major sources of supply.

LAW AND ADMINISTRATION

Unusually cold weather in the first days of February 1945 caused a crisis in gas supply in the Appalachian region. The Office of War Utilities, a division of the War Production Board, appealed to all consumers of natural gas to curtail their use of gas during the emergency, supplies of many war plants were cut off, and restrictions were placed upon heating of places of amusement, schools, libraries, and similar establishments. These measures were taken to prevent a collapse of gas pressures in the major pipeline networks, which would have seriously delayed the war effort and caused great public loss and suffering. The curtailment orders were in force February 2 to 5, inclusive, and were reinstated during a second cold spell on February 19 to 21.

As a result of these experiences, top priorities were authorized for two major pipe-line construction projects to bring an additional 110 million cubic feet daily of gas from southwestern producing States to the eastern industrial area.

A comprehensive investigation of the natural-gas industry was conducted by the Federal Power Commission in a series of eight public hearings in the late months of 1945 and early 1946. Voluminous testimony was placed in the record by witnesses for the industry, State and local governments, consumers, competing fuel and transportation interests, and the Federal Government. It is understood that a report of findings will be submitted by the Commission to the Congress early in 1947.

HISTORY OF GAS STATISTICS

A discussion of the nature and development of Bureau of Mines statistics on the production and use of natural gas was presented at the final hearing before the Federal Power Commission in June 1946. Because it is believed this discussion will interest and assist users of the gas data in the long series of Natural-Gas chapters in the Minerals

Yearbooks and preceding Mineral Resources volumes, most of it is reproduced here.

The primary purposes of the statistics on natural gas compiled by the Bureau of Mines are to measure the quantities produced and utilized, by States and the United States, and to indicate the corresponding dollar values.

Basic data are obtained from operators in the industry who report the required information on annual questionnaire forms and mail them direct to the Bureau of Mines. Effective participation by the industry involves considerable effort and expense and is essential to the success of the project. This cooperation of the industry and Government is logical because it produces information of recognized value to each and to the general public.

The year 1906 may be regarded as the birthdate of natural-gas statistics, for in that year an effective measure of the volume of natural gas produced and utilized in the United States was developed by the Geological Survey. Its canvass of the industry was the first in which comprehensive volume data were reported. In earlier years only the value of gas at points of consumption was recorded, or its value in terms of the cost of coal, wood, or other equivalent fuel displaced.

The business of selling natural gas for fuel was carried on for a number of years before a satisfactory means was devised for measuring large movements of gas through pipe lines. Hence, in this period statistics of actual volume were unobtainable. The nearest approach to such statistics for years before 1906 was probably the calculated estimates of production made by F. G. Tryon, formerly with the Geological Survey and later with the Bureau of Mines. These were based upon contemporary estimates of the quantity of coal displaced by gas or of the value of the gas sold and they covered annually the period from 1882 to 1905, inclusive.[2]

The 1906 survey provided statistics, by States, of the volume of production and consumption of natural gas, the number of consumers, and the values at points of consumption. It was noted in the first report that many producers kept no record of the quantity of gas produced, and this rendered the collection of a complete record of production very difficult. However, most of the gas marketed by small producers was, and is today, sold to larger organizations for transport to markets.

As a result of this situation, an indirect approach to production figures was developed. After the data of consumption had been organized as a starting point, the movement of gas was traced backward through intercompany receipts and deliveries to its point of origin. In this way, much of the production for which no adequate reports from producers could be obtained was traced to its source through transporting-company reports and credited to the proper producing area. Through this procedure, the figure obtained for production represents essentially the amount of gas usefully consumed and has been termed "marketed production." It does not measure the total volume of gas withdrawn from natural reservoirs for it takes no account of losses and waste. For most individual States, marketed production and consumption differ over wide limits because of the

[2] Burns, A. F., Production Trends in the United States: Nat. Bureau of Econ. Research, 1934, p. 292.

extensive transportation of gas across State lines; for the United States as a whole, however, they differ only by the small net balance of trade with Mexico and Canada.

The indirect method has been an essential tool in the compilation of natural-gas statistics through the years. Although, under present operating conditions, gas usually is metered at some point near the producing wells, a complete annual coverage of production from producers' reports has not been feasible, for a canvass of the several thousand small, scattered units engaged in production involves heavy expense and has not in the past produced a complete coverage because a minority failed to report.

As the industry grew in economic stature and geographic extent, its activities commanded wider interest that was often expressed in requests to the Bureau of Mines for more, or new types of, statistical information. Compilation of the natural-gas and other mineral statistics was transferred by Executive order from the Geological Survey to the Bureau of Mines on July 1, 1925. Hence, the Bureau figures reflected these demands as facilities would permit, increasing in scope and, from time to time, adding to the detailed information shown. At the beginning, consumption of natural gas comprised two classes, domestic and industrial. In later years, the industrial class was successively divided by industry groups into the present six parts. The domestic class, which had included such consumers as stores, theaters, cleaning plants, and the like, was divided in 1930 into two parts. The new domestic class was limited to dwellings or household consumers, and the remainder were designated commercial consumers. These changes enhanced the usefulness of the gas statistics by providing specific yardsticks for measuring segments of the market.

The importance of interstate gas transportation was indicated in 1921 with publication of a table defining these movements, by State of production and State to which piped. These operations have increased about sevenfold since 1921, and the table has expanded to include States traversed by long-distance transportation and those to which service to consumers has since been extended.

Before 1922 published values of natural gas referred to values at points of consumption and therefore reflected all costs from the producing fields to points of delivery to consumers. A value of gas production at the wells was first compiled for 1922 and provided an index of the producers' average realization for their product in the field.

The number of consumers of natural gas mixed with manufactured gas increased very rapidly after 1930, as a result of the growth in long-distance gas transmission through major pipe lines built in the 1925–32 period. Many of the market areas to which natural gas was made available for the first time had been served with manufactured gas, and distributing companies often chose to use natural gas as an agent of enrichment for manufactured gas rather than to convert to 100-percent or "straight" natural gas. Beginning with 1931, the Bureau of Mines published data indicating, by States, the quantity of natural gas mixed for consumption with manufactured gas, the corresponding numbers of domestic and commercial consumers, and the value of natural gas consumed. These data are included in the general tables of consumption of natural gas. They provide a means of segregating straight natural-gas consumption for those who may desire this information.

Beginning with 1935, an attempt was made to indicate more completely than in the past the order of magnitude of total withdrawals of natural gas from reservoirs. A table was compiled under the title, "Gross production of natural gas in the United States, by States," in which the difference between marketed production, as published for many years by the Bureau of Mines, and estimated gross production was shown.

Gross production was estimated by summation of four columns: Marketed production, gas used for repressuring, gas stored underground, and losses and waste. In compiling the last column, information from reports to the Bureau of Mines was supplemented by available data from State, Government, industry, and other sources deemed to be reliable. Because of the lack of complete information on gas withdrawals in many producing areas, the estimate of gross production must be regarded as a conservative approximation of actual output that probably does not include significant volumes of gas produced in some States. The gas shown as used for repressuring and stored in the ground is returned to underground reservoirs and is therefore generally available as a reserve for future use. In separating gross production by source between gas wells and oil wells, condensate wells have been classed as gas wells.

The natural-gasoline and carbon-black industries are, of course, closely related to natural gas, which is the raw material from which the products of both are derived. The Bureau of Mines compiles and publishes statistics of production and primary distribution for these two industries. Data from producers, particularly in the natural-gasoline group, interlock with information reported by the natural-gas companies at many points where the gas is transferred from one type of property to another. Thus, a cross check of many transactions can be made to improve the accuracy of the gas figures.

It may be proper here to mention two problems common to the production of most statistical information, because they have been mentioned frequently in recent years with reference to the natural-gas data compiled by the Bureau of Mines. The first is: What should be the time interval between statistical benchmarks? The Bureau's gas data have been on an annual basis for over 40 years. The second is: To what degree should the statistics be classified to show segments of supply, or distribution and use? The trend toward more detailed classification of the gas statistics has been sketched briefly above, as they have been adapted to a progressively broader field of usefulness.

These two problems have no final solutions; but it has been the purpose of the Bureau of Mines, in its natural-gas statistics, so far as possible, to provide dependable information of a character to reflect current needs of industry and government. It is evident that interest in all phases of the natural-gas industry has greatly increased since the end of hostilities last year, and the importance of natural gas is recognized more widely than ever before. A desire for more complete monthly natural-gas data has been expressed in the southwestern producing States, and in other quarters a need is felt for more complete segregation of natural-gas consumption. These inquiries are a natural result of analysis and study of available information on gas, through which the limitations as well as the utility of the data are revealed.

GROSS PRODUCTION

The gross withdrawal of natural gas from gas and oil wells is estimated to have increased from the revised total of 5,160,560 million cubic feet in 1943 to 5,614,220 million in 1944 (9 percent), of which about half was from Texas fields. Principal gains were in the leading States—Texas, Louisiana, and California. Material declines in New

[1] Marketed production plus quantities used in repressuring, stored in ground, lost, and wasted (see footnote 2).
[2] Includes gas (mostly residue gas) blown to the air and transportation losses but does not include direct waste on producing properties, except where data are available.
[3] Includes gas transported from other States.
[4] Revised figures.
[5] Florida, North Dakota, South Dakota, Tennessee, Utah, and Virginia.

Mexico and Illinois were related to smaller gas production from oil wells. In West Virginia withdrawals from gas wells were reduced from the unusually high rates of 1943.

Growing concern, on the part of State officials and the industry, with regard to waste of oil-field gas caused the procurement and publication, particularly in Texas, of more complete data on these activities than had been available in the years before 1943. Hence, the indication of an upward trend in losses and waste in 1943 and 1944 is largely the result of more complete coverage in those years. The actual trend has been obscured to an indeterminate degree.

Storage of gas in natural reservoirs below ground decreased in 1944 to 9,917 million cubic feet (net) from 18,953 million in 1943 as withdrawals to meet peak loads more nearly balanced summer input. In three States—Kansas, Kentucky, and West Virginia—heavy winter requirements caused a net reduction in the quantity of gas in storage reservoirs.

MARKETED PRODUCTION

In 1944 the marketed production of natural gas reached a record volume of 3,711,039 million cubic feet, 9 percent above 1943. Texas supplied the largest gain in output (202 billion cubic feet) over 1943 and by so doing increased its share of United States marketed production from 38.8 to 41.1 percent. West Virginia production dropped sharply (19 percent) to the lowest level since 1939.

Although the average value at the wells declined to 5.1 cents per thousand cubic feet in 1944 from 5.2 cents in 1943, it is interesting to observe that this average declined in only three States of large production—California, Montana, and Michigan. States in which the average value of gas at the wells was less than 5.0 cents produced 70 percent of the total marketed production in 1944 compared with 72 percent in 1943.

1 Less than 0.05 percent.
2 Less than $500.
3 Includes 1,474 millions of cubic feet piped to Mexico.
4 Includes 31 millions of cubic feet piped to Canada.
5 Includes 112 millions of cubic feet piped to Canada.
6 Includes 12,959 millions of cubic feet piped to Mexico.

WELLS

Gas-well completions numbered 3,227 in 1945, compared with 3,069 in 1944. Gas development in southwestern fields was greatly stimulated by heavy demand, particularly from the long-distance transmission systems. On the other hand, drilling in the Appalachian region declined, apparently under the influence of increasing costs and the scarcity of undeveloped but high-grade productive acreage, such as the Oriskany sand fields provided for a few years. In the 5 Appalachian States 20 percent fewer gas wells (426) were completed in 1945, and in 5 southwestern producing States 94 percent more gas wells (628) were completed. Remarkable gains in Texas and Kansas reflected intensive development of the Panhandle, Carthage, and Hugoton areas.

The total number of producing gas wells increased by 1,580 during 1944 to 58,780 on December 31. In all, 1,489 gas wells were abandoned or shut in.

TECHNOLOGIC DEVELOPMENTS

Commercial-scale production of liquid and solid products from dry natural gas by chemical synthesis techniques moved a step closer to realization with the projection of a large plant near Brownsville in south Texas. Construction of the plant, which will cost about $20,000,000, is scheduled to begin early in 1947. With availability of natural gas on a long-term basis at 5 cents or less a thousand cubic feet, it is confidently believed that production costs will be at competitive levels with products obtained from crude petroleum.

Adaptations of the process may open interesting prospects also to the producers of coal and manufactured gas. It has been stated that a 1,000-B. t. u. gas may be made from coal at costs not far above those for producing an equivalent quantity of manufactured gas, on a heat unit basis, by conventional methods.

It is apparent that the efficiency of long-distance gas transmission has increased notably in recent years, with attendant savings in the unit cost of gas moved. Perhaps the best example of coordinated activities on a broad scale for the most advantageous use of varied facilities is the arrangement by which gas from Texas is integrated into the supply-demand balance of the Appalachian region. Seasonal fluctuations in demand for natural gas are effectively met by extensive use of underground storage and control of local production in a manner to permit full utilization of capacity to transport southwestern gas into the region.

In a number of market areas, supplemental installations for meeting peak-load gas requirements with liquefied petroleum gases have been constructed in the last 2 years. This type of equipment is expected to add significantly to markets for these liquid products.

A more systematic and comprehensive coverage than in the past of the reserves of natural gas in the United States is promised by plans of the American Gas Association. A Committee on Natural-Gas Reserves has been organized to present estimates annually of the magnitude of reserves of natural gas and, in cooperation with the American Petroleum Institute, the quantity of recoverable hydrocarbon liquids associated therewith.

REVIEW OF DEVELOPMENTS, BY STATES

Arkansas.—Data from L. L. Jordan, Arkansas Oil and Gas Commission, indicate that gas production from controlled fields in south Arkansas declined from 61,028 million cubic feet in 1944 to 58,085 million in 1945, and output of uncontrolled fields declined from 14,809 to 11,824 million cubic feet. Output of the dry-gas fields in the northwestern district increased from 4,830 million cubic feet to 5,132 million.

The only gas discovery in 1945 was the Bloomer field on the Big Creek anticline in northern Sebastian County. The discovery well encountered gas in the Atoka formation at 2,730 feet, with initial rock pressure of 250 pounds and open flow capacity of 431,000 cubic feet. Five gas wells completed in the White Oak field, Franklin County, extended the productive area 3 miles to the southwest and 1 mile to the north and opened a new gas sand below (3,600 feet) the older producing horizons (3,000 feet and less).

The Columbia and Texarkana pools remained shut-in during 1945 for lack of a market. These gas deposits in southwest Arkansas contain a high percentage of nitrogen.

An active campaign of leasing for oil and gas was conducted in southeastern Arkansas.

California.—According to a report of the California Railroad Commission, supplied by E. F. McNaughton, the natural-gas reserves of California, as of January 1, 1946, approximated 11.4 trillion cubic feet, of which 6.8 trillion were oil-well gas and 4.6 trillion dry gas. The Rio Vista field is credited with 3.5 trillion of the dry-gas total.

Extensions of the Rio Vista and Kirby Hills fields were reported, in addition to discovery of the Cache Slough field 1¼ miles north of the nearest Rio Vista well but separated from it by two dry holes. A well at Maine Prairie produced 7 million cubic feet of gas from 4,790 feet to open a new area or an extension to the Millar field north of it.

The capacity to deliver gas from the storage reservoirs at La Goleta and Playa del Ray was materially increased in 1945 to aid further in meeting winter peak demands.

Data furnished by R. M. Bauer, Southern California Gas Co., indicate that gas production in 1945 totaled 554,486 million cubic feet (a gain of 1 percent over 1944), exclusive of 93,030 million cubic feet used for repressuring. Of the total, 187,846 million cubic feet were produced from dry-gas pools, including 159,580 from Rio Vista. Dry-gas production in California has increased rapidly in recent years to a cumulative total to January 1, 1946, of 980 billion cubic feet.

Colorado.—No gas discoveries and only one new gas well (at Powder Wash) were indicated in a report from J. R. Schwabrow, Geological Survey, United States Department of the Interior, Casper, Wyo. Two oil wells, however, were recompleted as gas wells in the Powder Wash field, with an initial capacity of about 16 million cubic feet a day.

The pressure-maintenance plant in the North McCallum field in 1945 handled 11 billion cubic feet of carbon dioxide gas not included in natural-gas statistics. About 58 percent of this gas was returned to the oil-producing sand, 31 percent lost, and 11 percent used in dry-ice manufacture.

About 400 million cubic feet of natural gas were produced with oil at Rangely and 560 million at Wilson Creek in 1945, part of which was used in the field and the balance lost to the air. In the Hiawatha field 513 million cubic feet of gas were returned to oil sands for pressure maintenance.

Marketed production continued to decline to 4,247 million cubic feet in 1945 from 4,872 million in 1944. Production, by fields, in millions of cubic feet, in 1945 was: Hiawatha 2,355, Powder Wash 1,616, Thornburg 234, Berthoud 39, and Craig 2.

Illinois.—Gas data for 1945 are taken from a report by Alfred H. Bell and Virginia Kline of the Illinois State Geological Survey.

Although more than 1,000 oil wells were drilled, no gas-well completion was reported. Total gas production is estimated at 50 billion cubic feet in 1945, of which only 477,600,000 cubic feet were dry gas, from the Russellville and Ayers gas fields and from gas wells in the Louden oil field.

The gas produced from oil wells is largely unmetered, and therefore information as to its utilization is estimated. Approximately 21 billion cubic feet of gas were processed at natural-gasoline plants. Over half of 15 billion cubic feet of residue gas was returned to oil sands and about 5 billion were used in oil-field operations. Of the Louden field residue gas, 578 million cubic feet were sold for distribution to domestic and commercial consumers. Over half of the casinghead gas produced in fields with no processing plants is estimated to have been used in the oil fields and a small amount injected into producing sands.

Indiana.—A report by Charles F. Deiss and A. C. Colby, State geologist, and assistant, respectively, of Indiana, states that three gas pools were discovered in 1945: The French pool in Spencer County, Friendship in Ripley County, and Oliver in Posey County.

Gas-well completions increased from 28 in 1944 to 36 in 1945, of which 11 were in Decatur County, 6 in Jay, 5 in Rush, and 4 in Harrison.

Production in the old Trenton field, scattered over 20 counties, was estimated in 1945 at about 37 million cubic feet. The output of other fields was not shown.

Kansas.—A report by Doris Bush Leonard, geologist, Kansas Geological Survey, and a letter from L. B. Taylor, State Corporation Commission, supplied the following information:

Completion of 215 gas wells in 1945 was reported, of which 181 were in the Hugoton field, anticipating future increased pipe-line takings. Although only 7 of the total were indicated for eastern Kansas, more were doubtless drilled but not reported.

Gas production declined to 124,100 million cubic feet in 1945 from 134,703 million in 1944. Principal fields produced as follows, in millions of cubic feet: Hugoton 80,705, Medicine Lodge 13,656, Otis 6,022, Cunningham 3,423, and eastern Kansas (estimated) 5,130.

Six gas discoveries were made in 1945, among which the Adams Ranch pool, Meade County, was the most important. The other discoveries were: Fairmont in Leavenworth County, Medicine Lodge Northeast pool in Barber, Dundee pool in Barton, Shady pool in Pawnee, and Loretta in Rush.

Kentucky.—Gas-well completions numbered 229 in 1945, of which 218 were in eastern Kentucky fields, 5 in western, and 6 in south central Kentucky.

Only one gas discovery was reported. A well near Hyden, Leslie County, tested 133,000 cubic feet of gas initially from "Big 6" sand of Silurian age at about 2,790 feet. Closest production is in the Oneida gas pool in Clay County, 17 miles to the northwest. In the latter field 8 gas wells producing from the "Big 6" sand were drilled in 1945.

Louisiana.—Completions of gas and condensate wells increased from 82 in 1944 to 147 in 1945, of which 85 were in the Northern district and 62 in the Gulf district.

The discovery of one dry-gas and eight condensate fields was reported. Northern Louisiana discoveries were as follows: Chatham in Jackson Parish (dry gas), East Haynesville in Claiborne, Knowles in Lincoln, Sicily Island in Catahoula, Southwest Delhi in Franklin, and Vixon in Caldwell. In south Louisiana three condensate fields were opened to production from sands of Miocene age: Houma in Terrebonne Parish, Mud Lake in Cameron, and Weeks Island in Iberia. The latter produced at the record depth for condensate production of 13,505 feet.

Casinghead-gas production decreased 6 percent below 1944 to 178,690 million cubic feet, and gas production from gas and condensate wells increased about 1 percent to 617,456 million cubic feet.

Michigan.—According to F. R. Frye, Michigan Department of Conservation, 63 gas wells were completed in 1945 compared with 64 in 1944. The discovery of 8 gas fields and 4 new producing formations was reported in 1945. None of these, however, appeared to be of major size; therefore, added reserves may not have offset withdrawals during the year.

Total gas production in 1945 increased about 10 percent over 1944 to 23,299 million cubic feet.

The Marion and Cranberry Lake gas fields were purchased for use as gas-storage facilities.

Mississippi.—Information from H. M. Morse, supervisor, Mississippi State Oil and Gas Board, is the basis of the following summary.

Total gas production in 1945 was 8,354 million cubic feet from 18 fields, led by Cranfield with 3,783 million cubic feet, Gwinville with

1,331 million, Jackson with 632 million and Baxterville with 618 million.

A conservative estimate of gas reserves indicated 860 billion cubic feet as of January 1, 1946, of which about 75 billion is oil-field gas. The largest reserves, in billions of cubic feet, were at Cranfield 442, Gwinville 259, and Baxterville 103.

Missouri.—Seventeen gas wells were drilled in Missouri in 1945, according to a report from Frank C. Greene, Missouri Geological Survey. Several were shallow private wells drilled by farmers in the New Ballard area, Bates County. Gas completions by counties were: Bates 7, Cass 3, Jackson 4, and Platte 3.

Production in 1945 was 77.6 million cubic feet from 36 commercially produced gas wells.

Montana.—Information in a report from J. R. Schwabrow, Geological Survey, Casper, Wyo., indicates that 49 gas wells were completed in 1945 compared with 81 in 1944. The gas completions were distributed by fields as follows: Bears Den 1, Bowdoin 6, Cedar Creek 11 (not including 7 in North Dakota), Cut Bank 9, Devon 8, Hardin 8, Kevin-Sunburst 5, and Whitlash 1.

No discoveries were reported. The Marias River field was abandoned in August 1945 after less than 2 years of production.

Production by leading fields, in millions of cubic feet, was: Bowdoin 5,067, Cedar Creek 5,375, Cut Bank 14,730, Dry Creek 1,149, Kevin-Sunburst 2,282. Marketed production decreased from 31,549 million cubic feet in 1944 to 31,064 million in 1945, exclusive of 1,100 million used in field operations.

New Mexico.—Information on developments has been supplied by Foster Morrell, supervisor, Geological Survey, Roswell, N. Mex.

Gas completions in 1945 in southeast New Mexico were six in Lea County and four in Eddy County. No large gas reserves were discovered, but the Sims No. 1 well in sec. 24, T. 22S, R. 37 E., Lea County, which opened production from the Upper Yeso formation at 5,460 feet, may be potentially important.

In northwestern New Mexico, 11 gas completions were reported (all in San Juan County), and 2 discoveries were made. An important gas reserve was indicated in the Paradox formation (Pennsylvania) by Ute No. 1 well, which made 42 million cubic feet of gas initially from 8,420 to 8,650 feet. A discovery, of perhaps minor importance, was made 3 miles east of the Kutz Canyon gas field in the Farmington sand at 1,350 feet.

Production in the southeastern district amounted to 108.7 billion cubic feet in 1945, of which 105.3 were processed at gasoline plants. Residue gas from these plants was distributed as follows: Domestic, commercial, and miscellaneous industrial, 44.1 billion cubic feet; carbon-black manufacture, 16.1 billion; plant and lease fuel, 9.9 billion; shrinkage, 7.1 billion; vented at plants, 23.9 billion; returned to oil reservoirs, 2.8 billion.

New York.—Of 20 wells drilled in 1945, mostly to the Oriskany sand, 7 were gas producers with a total daily open-flow capacity of 64 million cubic feet, according to information from E. T. Heck, geologist, New York State Museum. Six of the seven producers were in the Tuscarora Township pool, Steuben County, mentioned in the preceding gas chapter as a 1944 discovery.

The seventh gas well was completed in Independence Township, Allegany County, with a flow of 8 million cubic feet from Oriskany sand at 4,746 feet.

A deep test well in Arcade Township, Wyoming County, found small shows of gas at 6,030 and 6,182 feet, salt water at 6,391 feet. It had reached 7,126 feet in March 1946.

North Dakota.—Gas production increased from 200,105,000 cubic feet in 1944 to 216,733,000 cubic feet in 1945, according to a report from Wilson M. Laird, State geologist, Grand Forks, N. Dak.

All production was from 13 small gas wells on the southeastern part of the Cedar Creek anticline, Bowman County. Seven of these were drilled in 1945.

Ohio.—During 1945, about 7,000 acres were added to new gas pools, according to a report by Kenneth C. Cottingham, chief geologist, Ohio Fuel Gas Co., Columbus, Ohio. Clinton sand discoveries were reported in Lorain, Stark, Coshocton, Perry, and Ashland Counties; and an Oriskany-sand wildcat produced 3.9 million cubic feet initially from a depth of 3,632 feet in Goshen Township, Mahoning County.

Gas-well completions declined from 478 in 1944 to 429 in 1945, of which 247 were Clinton-sand, 89 Berea-sand, 55 shallow-sand, and 24 Oriskany-sand producers.

Natural-gas production amounted to 51,724 million cubic feet in 1944 and is estimated to have declined to about 47,000 million in 1945.

Oklahoma.—The following information is taken from a report by Elmer Capshaw, gas engineer, Oklahoma Corporation Commission, and other sources.

Although no major gas reserves were proved in 1945, the discovery of two condensate fields—Chitwood in Grady County and Bethany in Oklahoma County—suggests the probability of important additions with further development.

Gas-well completions numbered 277, of which 15 were reported as discoveries. Drilling for gas was most active in the Guymon-Hugoton area in Texas County, where 110 wells were drilled with average open-flow potentials of 15 million cubic feet each per day. The Oklahoma portion of this great field had 215 producing gas wells at the end of 1945.

Gas production increased 44.2 billion cubic feet in 1945 to 385.9 billion, of which 244.3 billion were dry gas and 141.6 billion from oil wells. New processing facilities permitted greatly increased marketing of casinghead gas from West Edmond and Crescent oil fields in the form of residue from natural-gasoline plants. Withdrawals from the Guymon-Hugoton area increased from 42.1 billion cubic feet in 1944 to 85.4 billion in 1945, nearly all of which was piped to other States. Consumption of natural gas within Oklahoma is thought to have declined in 1945 less than had been anticipated.

Pennsylvania.—Information from J. G. Montgomery, Jr., vice president, United Natural Gas Co., indicates that in 1945, 691 wells were drilled for gas in shallow sands. Of these, 292 were completed as gas wells in southwestern Pennsylvania, with total capacity of 99.7 million cubic feet, and 228 in the northern and middle districts, with a total capacity of 49.0 million cubic feet.

Ten deep tests failed to find new gas reserves. Dry holes through the Medina sands were drilled in Elk, McKean, Warren, and Mercer Counties. Oriskany sand failures were drilled in Washington (two), Fayette, and Erie Counties. A test in Worth Township, Mercer County, encountered salt water in dolomite (Beckmantown) below the Trenton limestone. Nine wells to test lower horizons were drilling at the year end.

Gas production was 92,987 million cubic feet in 1944 and is estimated to have declined to about 82,000 million in 1945.

South Dakota.—About 9,937,000 cubic feet of gas were produced at Pierre in 1945, according to data received from J. R. Schwabrow, Geological Survey, Casper, Wyo. No gas-well completions were reported.

Tennessee.—Information is taken from a report by Kendall E. Born, assistant State geologist, Nashville, Tenn.

The 1945 gas production was about 40 million cubic feet, of which 30 million were produced with oil in the Boone Camp pool near Sunbright, Morgan County (15 wells), and the remainder from the Jamestown field (5 wells) in Fentress County.

A 4-inch line was built in 1945 to take gas from the Sunbright area, a distance of 25 miles to Huntsville in Scott County.

Texas.—Marketed production was 1,525,515 million cubic feet in 1944 and is estimated to have increased to about 1,680,000 in 1945.

Gas-well completions increased remarkably, from 270 in 1944 to 714 in 1945, owing primarily to intensive drilling in the major gas-producing areas in anticipation of expanding gas requirements of the major pipe-line systems, both existing lines and new ones that are planned. Perhaps every important pipe-line system taking gas from Texas fields to distant markets is involved in projected increases in its carrying capacity. In addition, new lines, such as that to California from Texas and New Mexico and those planned to north-central and eastern markets, are expected to build up demand on Texas fields.

In the Panhandle field, 341 gas wells were drilled in 1945, compared with 51 in 1944. In the eastern Texas region the Carthage field had 92 gas-condensate completions, compared with 20 in 1944, adding about 22,000 acres to the field to bring proved acreage to approximately 212,000.

Discoveries in 1945 included 22 condensate fields, of which 17 were in the Gulf coast area, and 35 dry-gas fields, of which 16 were in the Gulf coast. These figures suggest the future importance of the coastal fields as a tremendous source of gas.

A number of important projects were announced during 1945 to increase the recovery of oil through processing of casinghead gas and returning the dry gas to petroleum reservoirs below ground for repressuring or pressure maintenance. In addition to materially increasing the efficiency of oil recovery from natural reservoirs, the benefits will include a substantial production of light liquids from the natural gas and the retention in underground formations of significant quantities of natural gas for future use, both of which would otherwise be dissipated to the atmosphere.

Utah.—A report from J. R. Schwabrow indicates that production of natural gas (all from the Clay Basin field) was 6,671 million cubic feet in 1945, of which 6,652 million were marketed outside the field, 18 million used in field operations, and 1 million cubic feet lost.

A shallow well drilled at South Cisco is reported to have found 1 million cubic feet of gas a day—a discovery of possible commercial value.

At Farnham 140 million cubic feet of carbon-dioxide gas were produced and used in dry-ice manufacture.

Virginia.—No drilling for gas was done in 1945, according to a report from William M. McGill, assistant State geologist, Charlottesville, Va.

Gas production was 56,104,000 cubic feet in 1945, compared with 57,340,000 in 1944, all from the Early Grove field.

The Brooks well, 2 miles west of the Rose Hill oil field, Lee County, was deepened to 4,079 feet through the Trenton limestone without finding new production.

West Virginia.—Of 28 wildcat wells drilled in 1945, 16 resulted in discoveries of gas compared with 25 in 1944, according to a report by David B. Reger, consulting geologist, Morgantown, W. Va.

Proved gas territory added in 1945 in at least six new gas pools and many extensions to existing fields totaled about 58,000 acres. Important additions to gas reserves were made in Wyoming and adjacent southern counties. The development of Oriskany sand gas at Canaan Valley, Dry Fork district, Tucker County, extends significantly to the east the limits of the Appalachian gas province on a long northeast-southwest front. The second well, completed in 1945 on a large structure, produced 5 million cubic feet a day initially from a depth of 8,404 feet, with rock pressure of 3,200 pounds.

Gas-well completions declined from 577 in 1944 to 499 in 1945, distributed by most active counties as follows: Lincoln 78, Kanawah 48, Wayne 45, Boone 39, Upshur 34, and Gilmer 27. Oriskany sand development was less in 1945 than in 1944. Twenty-nine wells were completed, 14 being commercial gas wells. Eleven of the latter extended the old Charleston field to the north and south. Two small producers in Boone County and one in Putnam completed the list.

Marketed production in 1944 was 181,452 million cubic feet and in 1945 is estimated to have declined to 160,000 million cubic feet.

Wyoming.—Thirteen gas wells were completed in 1945 with total open-flow capacity of 80 million cubic feet, according to information received from J. R. Schwabrow, Geological Survey, Casper, Wyo. Only about 37 gas wells have been drilled in Wyoming during the last 5 years. No new gas pipe lines were reported in 1945.

East Muskrat was the only gas field discovered in 1945. New gas zones were found at Big Piney, North Baxter Basin, and South Elk Basin. Gas with condensate was found at 7,242 feet depth in the River dome and a heavy gas flow at Neiber dome demolished the drilling rig after catching fire.

Gross gas production was 51,673 million cubic feet in 1945, compared with 51,602 million in 1944. Repressuring and field use declined slightly to 11,736 and 1,067 million cubic feet, respectively; marketed production and losses increased comparably to 36,357 and

2,512 million cubic feet. Production by leading fields in 1945 was: Baxter Basin, 9,597 million cubic feet; Big Sand Draw, 5,094 million; Garland, 3,685 million; Lance Creek, 2,923 million; and Salt Creek, 2,792 million. Beaver Creek, a 1938 discovery, was produced for the first time in November 1944 and produced a total of 1,017 million cubic feet in 1945.

CONSUMPTION

In 1944 the consumption of natural gas in the United States increased 9 percent over 1943 to a new record of 3,696,463 million cubic feet. As peak-load demand for gas in some important market areas continued to exceed currently available supplies, the consumption was less than would have been normal in the absence of war-imposed restrictions on the use of gas and utility operations.

Major consuming groups increased their use of gas over 1943 as follows: Domestic, 6 percent; commercial, 8 percent; and total industrial, 9 percent. All types of industrial consumers except cement manufacturers used more natural gas in 1944 than in 1943.

The largest consuming States accounted for the following percentages of the United States total in 1944: Texas, 33; California, 14; Louisiana, 8; and Oklahoma, 7. Collectively, they consumed 62 percent in 1944, compared with 66 percent in 1934.

Natural gas consumed in the United States, 1940–44

Year	Domestic and commercial consumption							
	Consumers (thousands) [1]			Billions of cubic feet			Average number of M cubic feet used per domestic and commercial consumer	Average value at points of consumption per M cubic feet (cents)
	Domestic	Commercial	Total	Domestic	Commercial	Total		
1940	9, 245	741	9, 986	444	134	578	57. 9	65. 7
1941	9, 730	767	10, 497	442	145	587	55. 9	65. 9
1942	10, 135	779	10, 914	498	184	682	62. 5	63. 4
1943	10, 354	811	11, 165	529	205	734	65. 8	62. 4

Treated for natural gasoline.—Natural-gasoline and cycle plants processed an estimated 3,300,000 million cubic feet of natural gas in 1944, an increase of 9 percent over 1943. In both years the quantity of gas processed equaled 89 percent of total consumption.

In six States in 1944 the quantity of gas treated exceeded total marketed production. This condition often occurs when a large volume of the gas treated is either blown to the air or returned to underground formations after treatment and thus is not a part of marketed production. In a few States—for example, Kansas and West Virginia—a material portion of the gas processed is produced in other States.

Natural gas treated at natural-gasoline and cycle plants in the United States, 1940–44, by States, in millions of cubic feet

[1] Estimated.

Domestic and commercial.—Consumption of 562,183 million cubic feet of natural gas by domestic users in 1944 exceeded the 1943 record by 6 percent. Since 1938, the domestic consumption has expanded 53 percent as the average annual consumption per domestic meter has increased from 42,900 cubic feet to 52,700 cubic feet, or 23 percent. The average value at points of domestic consumption was 69.1 cents a thousand cubic feet in 1944, compared with 70.0 cents in 1943 and 74.2 cents in 1938.

Commercial consumption increased 8 percent over 1943 to 220,747 million cubic feet. This represents a gain of 93 percent over 1938 as the average yearly consumption per meter increased from 164,600 cubic feet to 261,200 cubic feet, or 59 percent. The average value of this gas at points of consumption was 41.7 cents a thousand cubic feet in 1944, compared with 42.8 cents in 1943 and 49.2 cents in 1938.

[1] Includes natural gas used with manufactured gas. [2] Maryland includes District of Columbia and Virginia. [3] Utah includes North Dakota and South Dakota.

Field.—Consumption in oil- and gas-field operations increased 10 percent in 1944 to 855,180 million cubic feet and amounted to 23 percent of consumption for all purposes. Four States accounted for 87 percent of the United States total field use in 1944, as follows: Texas, 48; California, 15; Oklahoma, 14; and Louisiana, 10. The same States provided these percentages of United States production of crude petroleum and light liquid products from natural-gas processing plants in 1944: Texas, 45; California, 19; Oklahoma, 8; and Louisiana, 8.

Carbon-black manufacture.—The quantity of gas consumed for this purpose increased 13 percent over 1943 as production of carbon black increased 35 percent. The average value of gas used at the plants increased from 1.47 cents a thousand cubic feet in 1943 to 1.62 cents in 1944, reflecting firmer trends in field values of gas that have continued through 1945 and early 1946.

Petroleum refineries.—A gain of 24 percent to a total of 301,026 million cubic feet in 1944 reflected the continued rapid expansion in use of natural gas as fuel at petroleum refineries that has tripled since 1939. Apparently, the strong demand and firm price tendencies in recent years for fuel oils have made it profitable, particularly in the Southwest and California, to bring gas to refineries for use as a source of processing heat.

Electric public-utility power plants.—The Federal Power Commission reports the use of 359,745 million cubic feet of natural gas (including insignificant amounts of manufactured gas) as fuel at electric power plants in 1944, compared with 305,576 million in 1943. Minor gains were indicated in nearly all consuming States, of which there were 30. Texas, California, and Louisiana used 59 percent of the United States total in 1944.

Portland-cement plants.—Further sharp curtailment in production of portland cement in 1944 reduced consumption of natural gas at these plants to 35,588 million cubic feet, the lowest since 1935. Increases in consumption of principal fuels in 1944 over 1934 were as follows: Coal, 7 percent; natural gas, 30 percent; and fuel oil, 38 percent.

Other industrial.—Miscellaneous industrial utilization of natural gas, including fuel at electric public-utility power plants, increased 7 percent over 1943 to a record of 1,365,969 million cubic feet. More than half of this gain is attributable to the power plants. Declines in general industrial use in the Appalachian region, owing in part to curtailment orders, were offset by larger use in Western States, where transportation factors were not controlling.

Industrial consumption of natural gas in the United States in 1944, by States and uses

[1] Federal Power Commission: Figures include gas other than natural, impossible to segregate; therefore shown separately from main table.

[2] Gas used in portland-cement plants included under "Miscellaneous" for United States total and under "Other industrial" for State total to avoid disclosing figures of individual operators.

[3] Gas used in carbon-black manufacture included under "Miscellaneous" for United States total and under "Other industrial" for State total to avoid disclosing figures of individual operators.

[4] Maryland includes District of Columbia and Virginia.

[5] Less than $500.

[6] Utah includes North Dakota and South Dakota.

Mixed gas.—In the adjacent table showing consumption of natural gas used with manufactured gas, the quantity figures refer only to the natural-gas component of mixed gas. They do not measure the total volume of gas sold in the form of mixed gas.

Fewer mixed-gas consumers in the District of Columbia, Pennsylvania, and Maryland caused the total number of reported consumers to decline, but natural gas used in mixtures increased from 84,853 million cubic feet in 1943 to 89,645 million in 1944.

Consumption of natural gas used with manufactured gas in the United States in 1944, by States

INTERSTATE SHIPMENTS AND EXPORTS

The upward trend in interstate shipments (including exports) continued in 1944 as the total movement expanded 4 percent to 1,029,758 million cubic feet.

Among States that market more gas than they consume, the largest gains in outward shipments were from Texas (38 billion cubic feet), Kansas (17 billion), Louisiana (10 billion), and Oklahoma (9 billion). A large decline in West Virginia shipments (29 billion cubic feet) accompanied declining output of the great Oriskany-sand field near Charleston, W. Va.

PIPE-LINE DEVELOPMENTS

Much of the new construction of gas-transmission facilities in 1945 was directed toward the provision of larger capacity for major pipe-line systems. Among the transmission companies that made substantial investments in added compressor horsepower, loop or connecting lines, or field gathering systems were: Memphis Natural Gas Co., Northern Natural Gas Co., Cities Service Gas Co., Panhandle Eastern Pipe Line Co., Interstate Natural Gas Co., United Gas Pipe Line Co., Kansas-Nebraska Natural Gas Co., Natural Gas Pipe Line Co. of America.

In addition to the project to bring gas from western Texas and New Mexico to southern California, on which contracts have already been signed, several proposals have been made to lay new pipe lines to carry gas to Michigan, Wisconsin, Ohio, and adjacent markets from Texas fields. These interstate projects are of course subject to approval of the Federal Power Commission, and some may be affected by the disposition to be made of the two war-emergency pipe lines—Big Inch and Little Inch—running from Texas to the New York-Philadelphia area. No decision has yet been made with respect to the permanent disposal of these large lines, although bids from private interests have been received for both oil and natural-gas transportation.

NATURAL GASOLINE

AND LIQUEFIED PETROLEUM GASES[1]

By F. S. Lott[2] and A. T. Coumbe

SUMMARY OUTLINE

NATURAL GASOLINE

SUMMARY

Total production of the natural-gasoline industry in 1945 reached a new record of 4,673,507 thousand gallons, a gain of 11 percent over 1944. The estimated value at plants of all liquid products was $196,000,000, compared with $182,500,000 in 1944. Until the end of hostilities in August 1945, the demand for all products was strong. In succeeding months demand and production were temporarily reduced as a result of curtailment of operations at petroleum refineries, incident to decreased war demands and shut-downs due to strikes in September and October.

Prices were generally firm until the latter months of 1945, when lower tendencies appeared. The Mid-Continent (Group 3) spot price for 26–70 grade natural gasoline averaged 4.75 cents per gallon in 1944 and 4.56 cents in 1945.

Total stocks of light products changed only from 186,942 thousand gallons on January 1, 1945, to 181,513 thousand gallons on December 31. Refinery stocks declined about 30 million gallons, and those at plants and terminals increased 24 million gallons. Nearly all of this increase was at installations east of California.

[1] Data for 1945 are preliminary; detailed statistics with final revisions will be released later.
[2] Tables compiled by E. M. Seeley, Petroleum Economics Division, Bureau of Mines.

[7] Revised.
[8] Figures from data compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

A total of 62,833,000 gallons of light products was exported in 1945, an increase of 47 percent over 1944. Fourth quarter shipments more than doubled those in the comparable 1944 period.

The table of salient statistics in this chapter has been arranged to reflect the balance of supply and demand at natural-gasoline and cycle plants. It, therefore, omits the item "Benzol" shown in preceding chapters of this series and uses shipments to refineries as reported by the plant operators instead of quantities of light products utilized at refineries as reported by petroleum refineries. The form is similar to the table on page 2 of the Monthly Natural Gasoline Report, as first published in the issue of January 1945. The item "Receipts from outside sources" represents light end products of crude petroleum origin, shipped from petroleum refineries to plants for processing or blending with natural-gas liquids. "Exports from plants" covers reported shipments for export from plants and terminals. They differ from "Total exports," shown at the bottom of the table, by the quantity of similar products exported from refineries. The item "Losses" represents only reported losses at plants.

PRICES AND MARKET CONDITIONS

After selling at the ceiling price of 4.75 cents a gallon since October 8, 1943, the 26–70 grade of natural gasoline in Oklahoma dropped ¼ cent to 4.50 cents on April 3, 1945, and held at that level to the end of the year, except for a few sales at 4.25 cents early in December. This grade of natural gasoline f. o. b. Breckenridge, Tex., however, reflected softening markets after March 31 and declined by successive stages from 4.375 cents a gallons to 3.5 cents on December 31, 1945. These declines forecast the weak markets experienced in early 1946, when the Oklahoma and Breckenridge prices fell to 2.75 and 2.25 cents, respectively, as the end of the high seasonal demand from refineries approached.

Although price ceilings on light products were unchanged in 1945, they became ineffectual later in the year because products generally

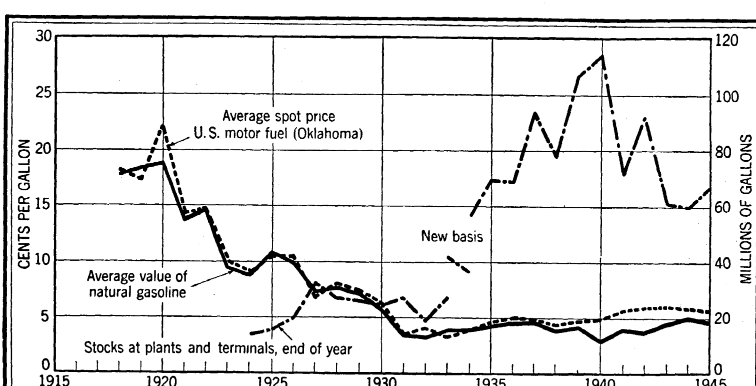

FIGURE 1.—Trends in average value of natural gasoline, spot price of gasoline, and stocks of natural gasoline, 1918–45.

sold below them. Quotations on sales of liquefied petroleum gases are not available, but average prices undoubtedly declined as a result of the curtailment of aviation-gasoline production after August 1.

The octane rating of U. S. motor fuel was changed on September 1, 1945, from 70–74 to 73–75. The average spot price for this grade at Oklahoma refineries declined from 5.95 cents a gallon in 1944 to 5.89 cents in 1945, owing in part to price shading in November and December 1945.

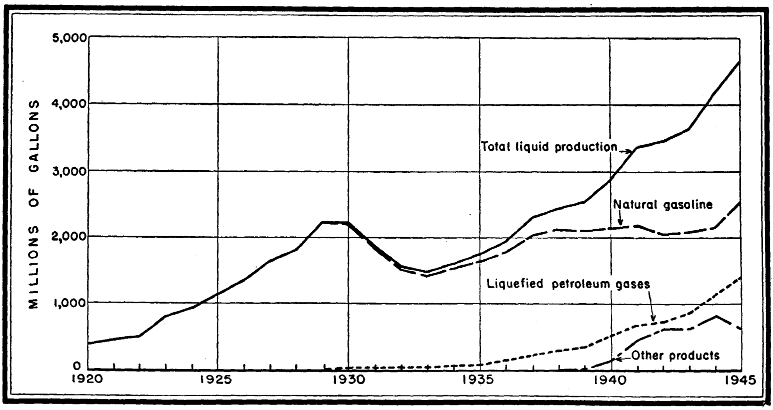

FIGURE 2.—Annual production of the natural-gasoline industry, 1920–45.

PRODUCTION

Trends in total output.—Total liquid production of the industry averaged 13,011,000 gallons daily in January 1945, rose to a peak of 13,151,000 gallons in May, and, after an autumn decline, returned to 13,048,000 gallons in December. Although the output of liquefied petroleum gases in December remained 9 percent below the January rate, natural-gasoline output increased 10 percent.

Figure 2 shows graphically the trends of production at natural-gasoline and cycle plants since 1920. The output of liquefied petroleum gases prior to 1941 has been estimated, chiefly on the basis of early surveys of sales for fuel. Total production of light products in 1945 was 38 percent above 1941. Liquefied petroleum gases—the component having the largest growth factor—gained 101 percent in the same period. For comparison, the increase in production of domestic crude petroleum in 1945 over 1941 was 22 percent.

California.—Total output of light products at plants was 889.5 million gallons in 1945, an increase of 15 percent over 1944. After August, production was reduced about 8 percent below the rate of earlier months. Gains of 3 percent in natural gasoline and 19 percent in liquefied-petroleum-gas output were supplemented by inclusion of the production of other products (70.8 million gallons), chiefly condensate, for the first time. In 1944 this material was reported as a part of crude petroleum production.

Natural gasoline and allied products produced and natural gas treated in the United States, 1944–45, by States

State	Number of operators [2]	Natural gasoline		Liquefied petroleum gases		Other products [1]		Natural gas treated		
		Thousands of gallons	Thousands of dollars [3]	Thousands of gallons	Thousands of dollars [3]	Thousands of gallons	Thousands of dollars [3]	Millions of cubic feet [4]	Average yield (gallons per M cubic feet): Light products except L. P. G.	Average yield (gallons per M cubic feet): All light products

[1] Other products include finished gasoline, condensate, kerosine, distillate fuel, "Special" naphtha, toluene, etc.
[2] A producer operating in more than 1 State is counted but once in arriving at total for United States.
[3] Estimated.
[4] Partly estimated.
[5] Drip gasoline produced in Colorado and Utah combined with Wyoming.
[6] Subject to revision.
[7] Drip gasoline produced in Colorado combined with Wyoming.
[8] Less than $500.
[9] Not available.

Kettleman Hills plants produced 170 million gallons of light products in 1945 compared with 171 million in 1944, and Ventura Avenue increased from 86 to 90 million gallons. The largest gain in 1945 was in the Paloma field, where cycling operations were begun in June 1944.

Louisiana.—An increase of 11 percent in production over 1944 to 548.9 million gallons resulted from a gain of 30 percent in the Gulf and a loss of 7 percent in the Inland district. Indicated gains of 88 percent in natural gasoline and 47 percent in liquefied-petroleum-gas production accompanied a decline of 30 percent in other products in 1945. The figures for natural gasoline and the "Other products" group in 1945 are not directly comparable with 1944 because a reclassification of output in 1945 increased the proportion of natural gasoline and reduced that of other products, relative to earlier years.

Oklahoma.—Production in 1945 totaled 416.8 million gallons compared with 421.8 million in 1944, hence the slow decline that began in 1942 continued. A 10 percent reduction in natural-gasoline output in 1945 to 272,028 thousand gallons was offset in part by an increase of 13 percent in liquefied petroleum gases to 136,224 thousand gallons. The Oklahoma City field produced 65 million gallons of light products in 1945, compared with 53 million gallons in 1944; Osage County declined to 73 from 75 million gallons in 1944.

Monthly production of natural gasoline and allied products in the United States, 1944–45, by States and districts, in millions of gallons

[1] Subject to revision.

Texas.—The output of light products continued in 1945 its upward trend, gaining 15 percent over 1944 to 2,159.0 million gallons. Increases of 35 percent in natural gasoline and 32 percent in liquefied petroleum gases were accompanied by an apparent decline of 28 percent in other products output. As in Louisiana, the first and third items above were affected in 1945 by a reclassification of plant output. Several new plants commenced operations in 1945, of which the largest was at Sheridan, Colorado County.

Other States.—Production of New Mexico and Arkansas increased 20 and 12 percent, respectively, in 1945 to new records. The volume of light products produced in Michigan continued to increase and approached in 1945 that of New York-Pennsylvania, which declined. Illinois production decreased 10 percent from its 1944 peak. All producing States, except the four leading ones, accounted for 14 percent of total United States output of light products in 1945, compared with 15 percent in 1941.

TRANSITION

In the months following the end of hostilities in August, production of light products declined 11 percent and then followed an upward trend to new record levels early in 1946. The demand for natural gasoline at refineries remained high through the winter months, influenced by the seasonal need for "volatility" in gasoline.

Total shipments to refineries of liquefied petroleum gases dropped abruptly from about 70 million gallons monthly to 42 million in September and were below a 35-million-gallon monthly rate in early 1946, a decline of more than 50 percent from a year earlier. Refinery demand for isobutane held up relatively well, as takings of isopentane contracted 80 percent. These changes resulted primarily from alterations in refinery processing incident to curtailment of aviation-gasoline production and expansion of commercial motor-fuel output.

Sales of liquefied petroleum gases for fuel and chemical purposes expanded vigorously through the fall and winter months, as expected, following release of these materials from wartime controls. Such sales in January 1946 were 24 million gallons (35 percent) above a year earlier and compensated in large part, from a volume standpoint, for the loss of markets at refineries.

Stocks did not change significantly until the first quarter of 1946, when they rose 54 percent to a total of 279,656,000 gallons. The major increment was in stocks of natural gasoline at plants and terminals east of California.

The severe decline in price quotations for natural gasoline between March 1945 and February 1946 (42 percent in Oklahoma and 49 percent at Breckenridge, Tex.), emphasized the arrival of a buyer's market in products of the natural-gasoline industry east of California. The material excess of potential supply over prospective markets under early peacetime conditions (discussed in the 1944 Natural Gasoline chapter) had its logical effect upon prices. However, there is little doubt that low prices will act promptly as a stimulant to sales for export and to jobbers and in some degree to refiners. Relative firmness in costs of competing fuels will aid this process. In the development of new markets for the liquefied gases, stress is being placed upon an increase in the summer load as a means of reducing the amplitude of seasonal fluctuations in consumption.

An important expansion in productive capacity of the industry over the next year or two is indicated by the large number of projects planned or already under construction. In view of the expected increase in output it is evident that, unless more of the products are absorbed by refiners, they will seek consuming markets directly and thus will provide increased competition for refinery gasoline and other commodities.

MARKET DEMAND

The total demand for products at natural-gasoline and cycle plants reached a new peak of 4,769,442 thousand gallons in 1945, an increase of 11 percent over 1944 and 35 percent over 1941.

The adjacent supply and distribution table is similar in form to the salient statistics table commented upon in the opening summary of this chapter. Liquefied-refinery-gas production and use are excluded, because this material originates at petroleum refineries. It will be noted that a more complete segregation by products is available for 1945.

Supply and distribution at plants of natural gasoline and allied products in the United States, 1944–45, by months, in thousands of gallons

[1] Subject to revision.

Shipments to refineries.—Reported shipments to refineries amounted to 3,599,112 thousand gallons in 1945, or 12 percent more than in 1944. Of the total demand at plants, refinery shipments, either direct or through brokers, accounted for 75 percent in 1945 and 1944, compared with 77 percent in 1941. Although shipments of liquefied petroleum gases were 35 percent greater in 1945 than in 1944, they declined so rapidly with liquidation of the aviation-gasoline program that in the fourth quarter they averaged over 13 million gallons a month (25 percent) below the comparable 1944 period.

"Direct" sales.—Sales to jobbers and trade outlets expanded in the spring of 1945 and remained at relatively high levels for the remainder of the year. Such sales totaled 314,888 thousand gallons in 1945 compared with 253,218 thousand in 1944.

Percentage of natural gasoline and allied products in refinery gasoline in the United States, 1941–45, by districts

Year	East Coast	Appalachian	Indiana, Illinois, Kentucky	Oklahoma, Kansas, Missouri	Texas Inland	Texas Gulf Coast	Louisiana Gulf Coast	Arkansas and Louisiana Inland	Rocky Mountain	California	Total
1941	2.3	1.9	5.3	6.6	17.6	5.6	3.7	6.1	4.4	16.1	7.1
1942 [1]	1.4	2.1	5.8	6.3	16.0	13.9	13.1	11.6	4.8	16.7	9.6
1943 [1]	1.1	1.9	6.0	8.6	21.2	14.2	18.3	12.9	4.0	15.0	10.3
1944 [1]	2.3	1.7	6.3	7.1	17.8	11.6	12.6	16.5	5.7	13.6	9.3
1945 [1] [2]	1.7	1.7	5.8	7.3	20.5	10.9	7.5	19.3	6.9	14.2	9.1

[1] 1942–45: Not comparable with prior years because relatively more liquefied petroleum gas is included.
[2] Subject to revision.

Sales of liquefied petroleum gases for fuel use in the first 9 months of 1945 were smaller than in the same 1944 period, but in the fourth quarter exceeded the 1944 rate by 9 percent. The most conspicuous growth was shown in sales for use as raw material in chemical manufacture. The rate in December 1945 was more than double that of a year earlier, and the total of 155,889 thousand gallons for 1945 was 61 percent above 1944. The manufacture of chemicals from liquefied petroleum gases is expected to increase very greatly in the next few years as the results of wartime and later research are applied to commercial operations.

Exports.—An expansion in exports, chiefly in the last 5 months, raised the total in 1945 to 62,833,000 gallons, an increase of 47 percent over 1944. Natural-gasoline exports increased from 28,222,000 gallons valued at $2,082,000 in 1944 to 36,912,000 gallons valued at $2,293,000 in 1945. Liquefied-petroleum-gas shipments almost doubled, rising from 14,480,000 gallons valued at $783,753 in 1944 to 25,921,000 gallons valued at $1,589,000 in 1945.

The principal countries of destination in 1945 and amounts received were: Canada 49,860,000 gallons, Mexico 12,556,000, Portugal 97,000, and Brazil 63,000.

STOCKS

Total stocks of products were relatively stable in 1945, decreasing only from 186,942 thousand gallons on January 1 to 181,513 thousand gallons on December 31. Inventories at refineries, however, declined

717372—47——76

almost 30 million gallons, continuing the 1944 trend, as holdings at plants and terminals rose 24 million gallons.

Year-end inventories of natural gasoline at refineries were the lowest in recent years, amounting to only half of such stocks in 1943 and about one-third of the quantity held at the end of 1941. Liquefied petroleum gases at refineries declined more than 50 percent after reaching a peak of 41,622 thousand gallons on May 31, 1945. Stocks of all types of light products at plants and terminals increased during 1945.

Stocks of natural gasoline and allied products in the United States, 1941–44 and 1945, by months, in thousands of gallons

[3] New basis for comparison with 1945.

TECHNOLOGIC DEVELOPMENTS

Cycle plants.—Total liquid production at cycle plants in 1945 was about 1,221 million gallons (29 million barrels), or 26 percent of the entire natural-gasoline industry. As a great many condensate fields exist to which cycling has not yet been applied, a large increase in these operations may be anticipated when economic conditions permit. A large new cycle plant in the Sheridan field, Colorado County, Tex., was in the final stage of construction late in 1945.

Yields.—As the average yield of all light products has increased from 1.22 gallons per thousand cubic feet of gas processed in 1942 and 1943 to 1.27 gallons in 1944 and 1.32 gallons in 1945, the yield of natural gasoline and "other products" has remained at 0.92 gallon since 1942. The recovery of liquefied petroleum gases has therefore progressively grown from 0.27 gallon per thousand cubic feet in 1942 to 0.40 gallon in 1945, reflecting the operation of added facilities for recovery and fractionation of light ends.

Production by processes.—The total number of operating plants wa 610 in 1944 compared with 642 in 1943, continuing the long-term trend toward fewer active plants. Compression plants numbered 190, a net loss of 25 since 1943 (including 11 in Illinois and 8 in Pennsylvania). Eleven absorption plants (5 in California) ceased operating and 4 were added, resulting in a net loss of 7. Three cycle plants were added in Louisiana, and 1 was removed from the active list in Texas.

The average liquid production per plant in 1944 was 6,888 thousand gallons, compared with 5,738 thousand in 1943 and 5,024 thousand in 1941. Average plant production by type of plant in 1944, in thousands of gallons, was: Compression 1,124, absorption 7,755, cycle 29,201.

The Paloma cycle plant in California commenced operation in June 1944 but is not included in the table of plants because until 1945 its production of debutanized condensate was reported as crude petroleum.

[1] Figures for 1945 not yet available.
[2] Includes 18 plants manufacturing liquefied petroleum gases.
[3] Includes combination of absorption process with compression and charcoal processes.
[4] Includes 163 plants manufacturing liquefied petroleum gases.
[5] Includes 3 charcoal plants in West Virginia with 3,770,000 gallons production in 1944 and 5 charcoal plants (1 in Pennsylvania and 4 in West Virginia) with 2,324,000 gallons production in 1943.
[6] Includes 21 plants manufacturing liquefied petroleum gases.
[7] Drip gasoline.

Technical trends.—Recent emphasis upon conservation of natural gas produced with oil, stimulated by the current investigation of the natural-gas industry by the Federal Power Commission, indicates that increasing amounts of casinghead gas will be processed for extraction of liquids and returned to petroleum reservoirs, primarily to improve the efficiency of oil recovery.

The most revolutionary development in imminent prospect will be tested commercially in a plant now under construction at Brownsville in South Texas. This plant is designed to convert dry natural gas into a variety of petroleum products by chemical reorganization, at costs that are claimed to be competitive with those of petroleum refineries. The production from coal, at low cost, of a gas comparable in quality to natural gas is also indicated as a possibility of the process. Because commercial application of these new techniques and discoveries could profoundly influence the future of the fuel industries, they will be studied closely and with keen interest by all concerned.

LIQUEFIED PETROLEUM GASES; SALES SURVEY

Sales of liquefied petroleum gases increased from a revised total of 1,060,156,000 gallons in 1944 to 1,276,766,000 in 1945—a gain of over 20 percent. If material delivered for synthetic rubber components is omitted in order to arrive at totals comparable with those of former years, the gain in sales was about 19 percent in 1945 (1,067,979,000 gallons in 1945 and 898,071,000 in 1944) compared with increases of 33 percent in 1944 and 15 percent in 1943. The ending of the war in the latter part of 1945 released some liquefied petroleum gases for civilian consumption; however, shortages of equipment for transportation and use of these gases continued, and consequently potential markets were not fully supplied.

Sales of liquefied petroleum gases in the United States, 1938–45, in thousands of gallons

Year	Butane	Propane	Butane-propane mixtures	Pentane	Total	
					Quantity	Percent of increase over preceding year
1938	52,768	54,130	56,050	2,253	165,201	16.8
1939	71,351	79,323	69,020	3,886	223,580	35.3
1940	77,056	109,216	123,348	3,836	313,456	40.2

[1] Without synthetic rubber components for comparison with 1943.
[2] Revised. [3] Not available. [4] Includes material delivered for synthetic rubber components.
[5] Subject to revision.

All uses of liquefied petroleum gases showed substantial gains in 1945 over 1944 except quantities reported for industrial consumption and internal-combustion-engine fuel. Distributors delivered 533,262,000 gallons for domestic use (household consumption) in 1945—a 20-percent gain over the 1944 demand of 445,617,000 gallons. It should be noted that the 1945 rate of expansion for domestic requirements was somewhat below that recorded for 1944—29 percent; furthermore, the annual percentage of increase is again headed downward, as it was in 1942 and 1943. Incidentally, deliveries of liquefied petroleum gases for domestic fuel represented about 42 percent of total sales for all purposes in both 1944 and 1945. Quantities of liquefied petroleum gases credited to manufactured-gas companies—constituting about 4 percent of all demands—have been trending upward steadily in recent years, and the 1945 total (53,849,000 gallons) was 17 percent above 1944 requirements (45,879,000 gallons) and more than double the 1941 item (25,255,000 gallons).

Liquefied petroleum gases diverted for the manufacture of synthetic rubber increased from 162,085,000 gallons in 1944 to 208,787,000 in 1945—a 29-percent gain. The 1945 quantity represented about 16 percent of all deliveries of liquefied petroleum gases compared with a 15-percent share in 1944. Chemical-manufacturing plants use liquefied petroleum gases as raw material, and the requirements have mounted to important items in the late war years—increasing from 151,985,000 gallons in 1944 to 224,291,000 in 1945—a 48-percent increment. Sales of liquefied petroleum gases credited to chemical plants forged ahead of the synthetic rubber total in 1945; furthermore, the proportionate share to be used for chemical raw material rose to about 18 percent of all deliveries in 1945 compared with 14 percent of the total in 1944.

Sales of liquefied petroleum gases for industrial fuel in 1945—163,121,000 gallons—differed little from 1944 requirements—162,018,000 gallons. The small increase in this demand in 1945 reflects not only the sudden tapering off in the war industries toward the close of the year but is also partly the result of transportation and equipment difficulties connected with the distribution and use of this fuel. It can be added that liquefied petroleum gases sold to industrial plants dropped from 15 percent of total market deliveries in 1944 to a 13-percent proportion in 1945. Distributors reported 93,340,000 gallons of liquefied petroleum gases diverted for internal-combustion-engine fuel in 1945—a 1-percent gain over 1944 requirements of 92,495,000 gallons. This small increase is well below the gains of 7 and 5 percent indicated, respectively, for 1943 and 1944. Butane-propane mixtures are used predominantly for internal-combustion-engine fuel, and the strong competitive demands for these "mixtures" for domestic fuel and chemical raw material were evidently factors that tended to limit quantities available for engine fuel. Lack of internal-combustion-engine equipment and maintenance difficulties also retarded the increase in demand for liquefied petroleum gases as fuel.

The proportionate share of butane in the annual sales of liquefied petroleum gases has declined steadily in recent years owing to war restrictions and the diversion of important quantities for the manufacture of motor fuel and synthetic rubber. Butane, not including quantities reported as synthetic rubber components, represented less than 14 percent of all sales of liquefied petroleum gases in 1944 and 1945, as compared with a 24-percent share in 1941 and a 22-percent share in 1942. If material sold to rubber plants is included, the butane item increases to about 26 percent of total sales in both 1944 and 1945. Fuel uses formerly satisfied with butane have been shifted largely to propane and to a lesser extent to butane-propane mixtures. The relative quantity of propane in the annual sales has expanded steadily from a 26-percent share in 1942 to a 39-percent proportion in 1945, while the percentage for "mixtures" has fluctuated during the same interval but has averaged about 50 percent of annual requirements for these liquid gases. Incidentally, the percentage for "mixtures" dropped from 50 percent of total sales in 1944 to 47 percent of the comparative 1945 item. When liquefied petroleum gases used as raw material for the manufacture of synthetic rubber are added to the totals, propane made up 32 percent of all deliveries in 1944 and 35 percent in 1945, while for the "mixtures" the proportion dropped from about 43 percent in 1944 to 40 percent in 1945.

The demand for butane, including synthetic rubber components, increased by 19 percent from 273,116,000 gallons in 1944 to 325,-140,000 in 1945. If sales of butane to rubber plants are omitted, the 1945 total is 143,283,000 gallons, a 17-percent gain over 1944 requirements of 122,870,000 gallons. Although less butane was used as industrial fuel in 1945 than in 1944, all other uses made gains as restrictions pertaining to this fuel were lifted or modified. Butane reported for domestic fuel, which has declined steadily in quantity since 1942, rebounded to a record volume in 1945, when the total—52,866,000 gallons—was nearly double 1944 deliveries—27,565,000 gallons—and well above the previous record of 45,028,000 gallons sold in 1942. Sales of butane for domestic fuel uses represented 16 percent of the butane total in 1945 compared with a 10-percent share in 1944. During recent years butane has become an important raw material for making synthetic rubber, and this one use alone has accounted for about 55 percent of total butane sales. Quantitatively, requirements for this purpose have increased from 150,246,000 gallons in 1944 to 181,857,000 in 1945—a 21-percent gain. Butane reported as raw material for chemical plants has also shown a steady increase in recent years and has expanded from 5,256,000 gallons in 1942 to 23,475,000 in 1944 and to 26,227,000 in 1945.

Sales of butane to manufactured-gas companies dropped noticeably in 1944, yet they recovered somewhat in 1945, when requirements (15,637,000 gallons) were 5 percent over the 1944 total—14,900,000 gallons; however, the 1945 quantity is still well below the 1943 item—21,829,000 gallons. The industrial demand for butane in 1945 was the only principal use to show a shrinkage, when requirements (42,-043,000 gallons) were about 21 percent below the 1944 total (52,-890,000 gallons). The growing use of propane as an industrial fuel, competitive demands for butane as a raw material and a domestic fuel, and the slow-down in activities in the latter part of 1945 were all factors that tended to reduce the quantity of butane sold as an industrial fuel. The quantities of butane reported as internal-combustion-engine fuel have dwindled noticeably during the war years; however, a gain was indicated in 1945, when deliveries for direct use as motor fuel increased to 6,469,000 gallons compared with 4,030,000 in 1944.

Distributors sold 418,055,000 gallons of propane in 1945, a 29-percent gain over the 1944 quantity (324,355,000 gallons). When the propane delivered to rubber plants is added, the 1945 propane total is 444,581,000 gallons or 32 percent over the comparative 1944 demand—335,884,000 gallons. All uses of propane showed important gains in 1945. About half of the propane is reported as domestic fuel, and these deliveries increased by 29 percent from 167,450,000 gallons in 1944 to 216,415,000 in 1945. The use of propane as an industrial fuel has expanded greatly in recent years, replacing butane and "mixtures," which in turn were diverted to other uses. Sales of propane to industrial plants expanded from 20,601,000 gallons in

1942 to 105,040,000 in 1945. It should be added that the 1945 demand was 13 percent above the 1944 total—93,040,000 gallons.

Chemical plants are using greatly increased quantities of propane as raw material, as indicated by purchases of 4,455,000 gallons in 1943, 40,666,000 in 1944, and 66,776,000 in 1945. The 1945 quantity was a 64-percent gain over the 1944 total and from another angle the 1945 chemical item represented 16 percent of the total demand for propane compared with a 13-percent share in 1944. The volume of propane diverted to synthetic rubber plants for use as raw material is not relatively important; however, the total more than doubled from 11,529,000 gallons in 1944 to 26,526,000 in 1945.

Sales of propane to manufactured-gas companies have expanded rapidly in recent years, and the 1945 total (22,323,000 gallons) is 31 percent above the 1944 demand (17,103,000 gallons) and over four times 1942 requirements—4,957,000 gallons. Relatively little propane—about 2 percent of the annual total—is reported as fuel for internal-combustion engines; however, this particular use mounted by 23 percent from 6,085,000 gallons in 1944 to 7,453,000 in 1945.

Deliveries of butane-propane mixtures, including negligible amounts sold to synthetic rubber plants, increased from 451,156,000 gallons in 1944 to 507,045,000 in 1945—a gain of 12 percent. More than half of these totals (56 percent in 1944 and 52 percent in 1945) were reported as domestic fuel, which rose quantitatively from 250,602,000 gallons in 1944 to 263,981,000 in 1945—an increase of 5 percent. Chemical plants use important volumes of "mixtures" in their processes, and their purchases of this raw material have skyrocketed from 38,325,000 gallons in 1942 to 131,288,000 in 1945. Incidentally, the latter quantity was nearly 50 percent over the 1944 demand of 87,844,000 gallons. The use of "mixtures" as fuel for internal-combustion engines ranks third in relative volume; however, deliveries for this purpose have fluctuated from 64,470,000 gallons in 1942 to 82,380,000 in 1944 and down to 79,418,000 in 1945—a loss of 4 percent for the last year.

Sales of "mixtures" for industrial fuel, totaling 16,038,000 gallons in 1945, differed little from the 1944 quantity—16,088,000 gallons. Butane-propane mixtures, as an industrial fuel, have lost ground to propane in recent years, and present demands are well below peak requirements of 43,011,000 gallons reported for 1942. "Mixtures" delivered to manufactured-gas companies reached a "high" of 15,889,000 gallons in 1945—a 15-percent gain over the 1944 total—13,876,000 gallons.

In recent years large quantities of butane were diverted from normal markets to plants for the manufacture of aviation gasoline, synthetic rubber, and chemical products. The effect of this shift of butane to other channels is clearly indicated if the relative proportions of the various liquid gases reported for the principal uses are reviewed. Butane delivered for domestic fuel declined from 15 percent of the total demand in 1941 to a 6-percent share in 1944. The pressure for butane for use as raw material and industrial fuel was lightened in the latter part of 1945, and with this change in the market it is noticed that the butane share in the domestic fuel total rose to 10 percent. The percentage of propane sold for household

Sales of liquefied petroleum gases in the United States, 1944–45, by uses, methods of transportation, and regional distribution, in thousands of gallons

[2] Subject to revision.

consumption dropped from 44 percent in 1941 to about 37 percent in 1943, and there was a corresponding rise in the relative percentage of "mixtures" sold for this particular purpose. There was a slight increase (to 38 percent) in the relative proportion of propane reported as domestic fuel in 1944; this upward trend continued into 1945 to a 41-percent share. The declining percentages for butane and propane in the domestic-fuel market in the war years were counteracted by a pronounced rise for "mixtures," which went from about 40 percent of the total demand in 1941 to 56 percent in 1944. The percentage gains for butane and propane in the 1945 domestic requirement were reflected in a drop to a 50-percent share for butane-propane mixtures.

The relative percentages for the liquefied gases sold to gas-manufacturing companies have fluctuated for several years; however, over this time there has been a net drop for butane from 48 percent of the 1941 total to a 29-percent share of the 1945 demand. The propane reported for gas-company use dropped sharply from 27 percent in 1941 to 16 percent in 1942. Nevertheless, there has been a steady increase since that year to a 42-percent proportion in 1945. The percentage for butane-propane mixtures in the manufactured-gas-company total has mounted from 25 percent in 1941 to 30 percent in 1945. However, the percentage share for "mixtures" reached about 45 percent in 1942;

the proportions for both butane and propane were down sharply in that particular year.

In recent years industrial plants using liquefied petroleum gases for fuel purposes have made a pronounced shift from butane and butane-propane mixtures to propane. In 1941 nearly half (47 percent) of the fuel for this principal use was reported as butane; however, this proportion has steadily shrunk to a 26-percent share in 1945 because of changed market conditions prevailing during the interval. The relative proportion of butane-propane mixtures consumed by industrial plants has likewise dwindled from 36 percent of the total demand in 1941 to 10 percent of the requirements in both 1944 and 1945. Conversely, propane delivered for industrial fuel has jumped from 17 percent of the total in 1941 to over a 64-percent share in 1945.

Most of the liquefied petroleum gases delivered as raw material for making synthetic rubber were reported as butane—93 percent of the total demand in 1944 and 87 percent in 1945—while propane made up all of the balance, except for insignificant quantities of "mixtures." In 1941 butane-propane mixtures comprised nearly 90 percent of the total liquefied petroleum gases used as raw material by chemical plants. Pentane satisfied about 7 percent of this particular market at the time, while butane and propane were unimportant. There have been some changes during recent years, as butane and propane have become more in demand for use as chemical raw material at the expense of "mixtures." As a result, butane was reported as making up about 12 percent of the 1945 demand, and propane mounted to a 30-percent share for the same period, while the relative proportion for butane-propane mixtures slumped to 58 percent of total requirements for both 1944 and 1945.

There were restrictions on the use of butane as internal-combustion-engine fuel during the war period; consequently, its proportionate utilization for this purpose declined from 28 percent in 1941 to 4 percent in 1944. As regulations were modified in late 1945, butane rose to 7 percent of the total for that year. On the other hand, as butane became less available for direct motor-fuel use, the demand was shifted to butane-propane mixtures, the proportion of which went from 70 percent in 1941 to 89 percent in 1944. The percentage for "mixtures" in the motor-fuel total dropped to 85 percent in 1945, as more butane became available. Propane has never been an important fuel for internal-combustion engines; however, the percentage for this liquid gas expanded from 2 percent of the 1941 total demand to 8 percent in 1945.

E. T. Knudsen of the Los Angeles office of the Bureau of Mines reported the distribution of 187,211,000 gallons of liquefied petroleum gases in the Pacific Coast marketing area (California, Oregon, Washington, Arizona, and Nevada) in 1945—a 12-percent gain over a revised total of 166,913,000 for 1944. The liquefied petroleum gases delivered in the Pacific Coast area represented 15 percent of the national total in 1945 compared with a 16-percent share in 1944. Marketers in all other parts of the country sold 1,089,555,000 gallons of liquefied petroleum gases in 1945, an increase of 22 percent over the 1944 demand—893,243,000 gallons.

CARBON BLACK

By F. S. LOTT AND H. BACKUS

SUMMARY OUTLINE

SUMMARY

Production and sales of carbon black rose to new peaks above 1 billion pounds in 1945. The 31-percent gain in production to 1,052,-798,000 pounds sufficed to exceed the demand for the first time since 1942, as sales increased only 9 percent over 1944 to 1,020,035,000 pounds. Producers' stocks continued at minimum levels until the end of hostilities in August, subsequently rising to 102,005,000 pounds on December 31, 1945, compared with 69,243,000 at the end of 1944.

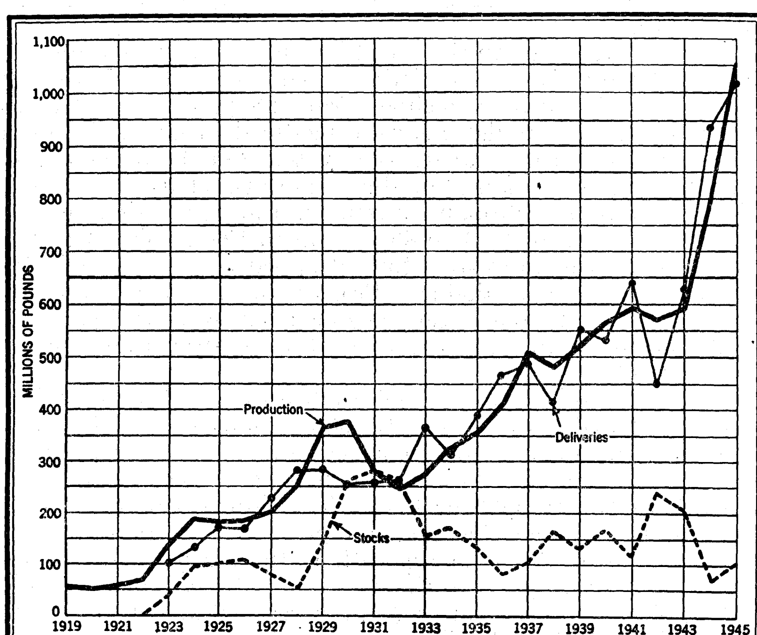

FIGURE 1.—Production, stocks, and deliveries of carbon black, 1919–45.

Demand in the early months of 1945 was so large in comparison with current supply that stringent measures were required to restrict consumption through tighter allocation controls and reduction by about 10 percent below current practice of the quantity of black permitted per tire manufactured. Price increases to high-cost plants were allowed in March and April to encourage larger output. In May, production and demand were in balance for the first time in many months, and thereafter a progressively easier situation made possible removal of restrictions upon consumption, beginning in June.

Salient statistics of carbon black produced from natural gas in the United States, 1941–45

[1] Principally channel. [2] Figures not available. [3] Revised figures.

A reduction in requirements for military tires was followed in June by a downward adjustment in scheduled production of tires, and consumption of carbon black was temporarily curtailed by widespread strikes at rubber-processing plants in October. Shortages of drying oils and resins throughout 1945 tended to limit the use of carbon black by the paint and ink trades. Reconversion of the automotive industry to civilian products created in November a large demand for high-color-type blacks for use in automobile coatings that continued into 1946. The total demand for carbon black appeared to be running above 100 million pounds per month early in 1946 and increasing to cause a renewed decline in producers' stocks, particularly of channel types.

The production of contact-process blacks increased 30 percent over 1944 to a new record of 538,539,000 pounds, 8 percent above the former peak of 1940. A gain of 33 percent in furnace-black output to 514,259,000 pounds in 1945, or 49 percent of total black production, failed to surpass the expanded output of contact types.

Sales to rubber companies continued to dominate the domestic market, amounting to 95 percent of domestic sales in 1944 and 1945. Exports of 173,773,000 pounds in 1945 were 11 percent above 1944, owing to increased shipments after the surrender of Japan.

RECONVERSION

Reconversion of the carbon-black industry to normal peace conditions will be slow compared to many other segments of the economy because of delays in availability of natural rubber in quantity and the many technical, economic, and political problems that will impinge upon the future course of the rubber industry, the largest consumer of carbon black. Few industries have experienced such revolutionary changes in technical background in a brief period of years, or have been so effectively impressed upon public and official minds as an essential part of our industrial organization in peace and war, as the rubber industry. The wartime research in rubber and carbon black and appraisal of the industries' needs and public functions will fundamentally influence the future selection of raw materials and the scope of productive activity. The pattern, however, is intricate; many of its lines must be drawn by the industries themselves, others by the Federal Government, and still others by events in foreign countries.

According to the Civilian Production Administration, United States consumption of rubber in 1945 increased 8 percent over 1944 to 1,040,045 tons, of which 105,429 tons were natural rubber, 693,580 tons synthetic, and 241,036 tons reclaimed. Carbon-black sales to rubber companies, after deducting an estimate of 100 million pounds for use in reclaimed rubber, were 898 pounds per ton of virgin rubber consumed in 1944 and 882 pounds in 1945, although a higher percentage of synthetic rubber was used in 1945. Assuming a 1946 consumption of 600,000 tons of synthetic and 300,000 tons of natural rubber in the United States, domestic requirements of carbon black for rubber manufacture would approximate 800 million pounds. The expectation of a record volume of exports in 1946 seems justified, and an expansion of carbon-black consumption by other domestic trades than rubber processing.

Development of a light-colored substitute for carbon black was announced by the B. F. Goodrich Co. in May 1946. The material is produced by processing silica and alcohol and is particularly adaptable to the manufacture of colored rubber articles, in which the pigmentation of carbon black is undesirable. Present costs are much above those of carbon black, but volume production is expected to reduce costs to a competitive level, for at least some purposes.

Summary of statistics for carbon black produced from natural gas in the United States, 1941–45

Year	Production (thousands of pounds)	Value (thousands of dollars)	Stocks at end of year (thousands of pounds)	Sales (thousands of pounds)		Average yield (pounds per M cubic feet of gas)
				Domestic	Export	
1941	594,065	19,341	118,847	496,579	148,165	1.63
1942	574,006	19,547	242,755	334,296	115,635	1.71
1943	593,421	20,248	205,215	524,388	104,912	1.88
1944	801,860	29,411	69,243	[1] 780,439	156,991	2.20
1945	1,052,798	42,323	102,005	846,262	173,773	2.32

[1] Revised figures.

PRODUCTION

By States.—Production of 721,438,000 pounds of carbon black in Texas in 1945 exceeded the 1944 record by 44 percent. The Panhandle output gained 35 percent over 1944 and the remainder of the State 81 percent, reflecting new capacity, chiefly in West Texas. Of the total output of carbon black, Texas supplied 69 percent in 1945, compared with 62 percent in 1944, reversing a 6-year decline in this proportion.

Louisiana production increased 5 percent over the 1944 record to 168,229,000 pounds, although one less plant operated than in 1944. Although one new plant began to produce in Oklahoma, output declined from 53,887,000 pounds in 1944 to 53,192,000 pounds in 1945. Larger operations in New Mexico raised the output of the California-Kansas-New Mexico group 27 percent to 109,939,000 pounds in 1945.

Referring to the production graph in figure 2, the curve for "Other Texas" includes a small output from Oklahoma and Wyoming in 1932–35, inclusive.

Carbon black produced from natural gas in the United States in 1945, by States and by major producing districts

State and district	Producers reporting [1]	Number of plants	Production: Pounds	Production: Value at plant: Total	Production: Value at plant: Average (cents)	Natural gas used: M cubic feet	Natural gas used: Average yield per M cubic feet of gas (pounds)	Natural gas used: Value: Total	Natural gas used: Value: Average per M cubic feet (cents)
California	1	1							
Kansas	2	2	109,939,000	$4,216,000	3.83	28,734,000	3.83	$1,039,000	3.62

Total United States	[1] 21	59	[2] 1,052,798,000	42,323,000	4.02	431,830,000	2.32	9,854,000	2.28

[1] In counting the total number of producers reporting, a producer operating in more than 1 State, district, or county is counted but once.
[2] Includes carbon black made from liquid hydrocarbons.

Methods and yields.—The average yield of all carbon blacks continued to increase to 2.32 pounds per thousand cubic feet of gas burned in 1945 from 2.20 pounds in 1944. Significant gains were reported in Texas and Louisiana; declines in Oklahoma and the California-Kansas-New Mexico group were apparently caused by greater channel-black output in those areas.

The 1945 gain in furnace-black production (33 percent) was less rapid than in the other war years, suggesting the approach of a temporary peak in output of these grades. Semireinforcing (SRF) blacks constituted over 50 percent of the 1945 furnace-process blacks and high-modulus (HMF) blacks over 30 percent. Furnace plants consumed approximately 51,700 million cubic feet of natural gas and over 15 million gallons of liquid hydrocarbons in 1945.

The yield at contact-type plants increased from 1.32 pounds of black per thousand cubic feet of natural gas consumed in 1944 to 1.42 pounds in 1945. Data on production by principal grades in 1945 are not available, but the easy-processing grade in 1944 amounted to almost 80 percent of total contact-black production. The channel and other contact-type plants utilized 380,144 million cubic feet of natural gas in 1945.

Number and capacity of plants.—Of the six new channel-black plants that began to produce in 1945—all owned by the Defense Plant Corporation and operated by private companies—three are in Texas, two in New Mexico, and one in Oklahoma. One new furnace plant, owned by the Columbian Carbon Co., commenced operating at Seagraves, West Texas.

Two plants were shut down in 1944 and did not operate during 1945. They are the roller-type plant of the United Carbon Co., at Ryus, Kan., and the channel plant of Chas. E. Johnson & Co., at Bastrop, Morehouse Parish, La.

The total number of operating plants was thus increased from 54 in 1944 to 59 in 1945, of which 43 were contact-type plants and 16 furnace (including 1 "Thermatomic").

Plans for construction of two Government plants at McCoy, La., and Eunice, N. Mex., were abandoned in 1945. A third project, at South Eunice, N. Mex., for which only the engineering work had been done, was sold in July 1946 to a new company.

The total reported capacity of all plants that produced in 1945 was 3,633,600 pounds per day, an increase of 41 percent over 1944. The capacity of contact-type plants increased from 1,347,710 to 1,770,600 pounds daily (31 percent) and that of furnace plants from 1,237,706 to 1,863,000 pounds (51 percent). The ratio of production to total capacity at the year end was 79 percent in 1945 and 85 percent in 1944.

Producers.—The number of producing companies was reduced to 21 in 1945 from 22 in 1944 by elimination of the Crescent Carbon Co. whose channel plant at Borger, Tex. was acquired by the United Carbon Co. in June 1944.

DEMAND

Total deliveries.—Producers' total sales increased 9 percent over the 1944 record to 1,020,035,000 pounds, of which 83 percent were to domestic users and 17 percent to foreign countries. Exports accounted for 37 percent of total deliveries in the 1936–39 period and domestic sales for 63 percent. On September 30, 1945, the Government abandoned the wartime practice of purchasing carbon black from producers for resale to consumers, and distribution returned to normal trade channels.

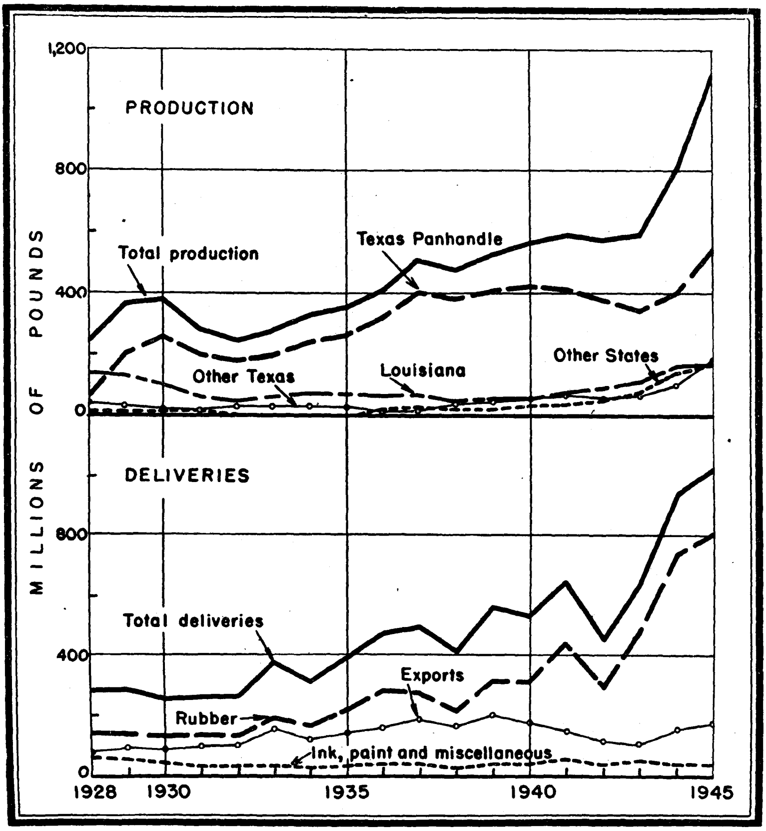

FIGURE 2.—Production and deliveries of carbon black 1928–45. Production in "Other Texas" includes Oklahoma and Wyoming in 1932–35.

Domestic demand.—Domestic deliveries amounted to 846,262,000 pounds in 1945—8 percent more than in 1944.

Sales of 804,386,000 pounds to rubber companies were 9 percent above 1944 and constituted 95 percent of all domestic deliveries. Demand for rubber grades of black in the third quarter of 1945 was below production but was at record levels at the end of the year.

Restraints upon the consumption of carbon black by the ink and paint trades were imposed by Government controls in the first half of the year and by scarcities of drying oils and resins needed in manufacture of inks and paints throughout 1945. Deliveries of 22,824,000 pounds to ink companies in 1945 were 7 percent below 1944. The apparent consumption of newsprint in the United States was 3,507,000 short tons in 1945 and 3,243,000 in 1944, according to the American Newspaper Publishers Association. Deliveries to paint manufacturers in 1945 increased 40 percent over 1944 to 7,421,000 pounds, stimulated by strong demand for high-color blacks late in the year, particularly for automotive enamels and lacquers.

717372—47——77

Exports and imports.[1]—The rise in exports that began in 1944, continued in 1945 with particularly large movements in the last quarter. The total of 173,772,618 pounds shipped in 1945 compared with 156,990,520 pounds in 1944 and approximated the prewar annual rate.

Exports to Belgium and France were resumed after liberation of those countries, and larger shipments were made to most importing countries. The only notable declines were in shipments to India and the U. S. S. R., countries that imported unusually large amounts of carbon black from the United States during the war.

Carbon black exported in 1945 was valued at an average of 5.66 cents per pound compared with 4.75 cents in 1944.

Imports of "gas black and carbon black" from Canada gained sharply in 1945 to 1,526,758 pounds, with an average value of 9.7 cents a pound, compared with 267,158 pounds in 1944, valued at 9.8 cents. Imports of acetylene black from Canada declined to 7,583,370 pounds with an average value of 9.76 cents a pound in 1945 from 8,574,693 pounds valued at 9.81 cents a pound in 1944.

STOCKS

Producers' stocks of contact blacks began the year at 58,036,000 pounds, were depleted rapidly to about 22 million pounds in April, then were gradually built up to 64,956,000 pounds on December 31, 1945. Furnace-black inventories varied similarly. Beginning at 11,207,000 pounds, the pressure of urgent demand kept them very low until July, after which an easier supply-demand position permitted accumulation to 37,049,000 pounds at the year end.

[1] Figures on exports and imports compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

PRICES AND VALUES

Liberalization of price-ceiling regulations during 1945 contributed to the rise in average value of carbon black at the plants from 3.67 cents a pound in 1944 to 4.02 cents in 1945. The average value of contact process blacks was 3.50 and 4.11 cents a pound in 1944 and 1945, respectively, and comparable furnace black values were 3.84 and 3.93 cents.

In March the Office of Price Administration permitted an increase in ceiling prices on all rubber grades of channel black produced under emergency high-cost conditions from 3.3 cents a pound in bulk for uncompressed beads to 5.0 cents a pound and 5.5 cents for compressed beads. This action was taken to stimulate production.

With the return of carbon-black marketing to normal trade channels on September 30 (purchases by Defense Supplies Corporation were discontinued), price ceilings for blacks from low-cost producing facilities were adjusted to conform to the higher-cost ceilings, resulting in uniform ceilings for each grade of channel black. Ceiling prices on channel black for use in paint and inks were raised 1.7 cents a pound in October to compensate for higher costs of natural gas.

ASPHALT AND RELATED BITUMENS

By A. H. Redfield[1]

SUMMARY OUTLINE

SUMMARY

Domestic demand for petroleum asphalt was 1 percent higher, and export demand 79 percent higher in 1945 than in 1944. Export demand, however, was only 3 percent of the total demand, domestic and foreign, so that the total demand increased 2 percent in 1945 over 1944. To meet the greater demand, domestic and foreign, petroleum refineries in the United States enlarged their output 2 percent from 1944 to 1945; and more petroleum asphalt was imported. Stocks, however, were 11 percent higher at the end of 1945 than at the beginning of the year. In numerical terms, an increase of 54,590 short tons in domestic demand and of 93,746 tons in foreign demand, as well as a rise of 66,500 in inventories during 1945, were made possible by increases of 130,500 tons in refinery production and of 17,436 tons in imports and by the addition during 1944 of 66,900 tons to inventories.

Bituminous rock did not share in the continued demand which maintained sales of paving asphalt at their 1944 level; its sales were 13 percent less in 1945 than in 1944. On the other hand, sales of gilsonite were 25 percent more in 1945 than in 1944. Exports of natural asphalt, unmanufactured, increased 27 percent in 1945 over 1944.

NATIVE ASPHALT AND BITUMENS

Bituminous rock.—Although highway construction and maintenance were apparently more active in 1945 than in 1944, sales of bituminous rock by producers in the United States decreased from 740,454 short tons valued at $2,771,925 in 1944 to 642,600 tons valued at $2,565,925 in 1945. The decline was greater west of the Mississippi River. Sales by producers in Texas and Oklahoma decreased from 479,745 tons valued at $1,214,329 in 1944 to 413,021 tons valued at $1,054,380 in 1945. Smaller sales were made in California in 1945 than in 1944, but larger sales in Missouri and Utah—all three small producers. In Kentucky and Alabama, however, the decrease was less—from 226,190

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

tons valued at $1,315,234 in 1944 to 192,381 tons valued at $1,235,928 in 1945.

Gilsonite and wurtzilite.—Sales of gilsonite by producers in northeastern Utah increased materially—from 49,051 short tons valued at $918,480 in 1944 to 61,273 tons valued at $1,250,546 in 1945. The average sales price per ton at the mine or railhead increased from $18.73 in 1944 to $20.41 in 1945.

No wurtzilite was sold in 1945. Sales of wurtzilite in 1944 amounted to 11 tons valued at $874.

Exports.—The tonnage of natural asphalt, unmanufactured, exported from the United States increased from 37,210 short tons valued at $729,765 in 1944 to 47,094 tons valued at $1,207,147 in 1945. In spite of a decrease in shipments to Australia and New Zealand (the principal area of foreign demand) and to South America, enlarged exports to Europe, as well as smaller increases in exports to India and to Canada, raised the total exports of natural asphalt 26 percent over the corresponding exports of 1944. Of the 1945 exports 44 percent went to Australia and New Zealand, 35 percent to Europe, principally to Norway, Sweden, France, and the United Kingdom, 14 percent to India, and 3 percent to Canada and Mexico.

MANUFACTURED OR PETROLEUM ASPHALT

Production.—Production of asphalt by petroleum refineries in the United States increased 2 percent from 1944 to 1945. The principal gains in tonnage were in the East Coast district, where 15 percent more asphalt was made in 1945 than in 1944. East of the Mississippi River and in interior United States the production of asphalt gained,

Production, receipts, stocks, consumption, transfers, losses, exports, and domestic sales of asphalt (exclusive of road oil) at petroleum refineries in the United States in 1945, by districts, in short tons

District	Production	Receipts from other sources	Stocks		Consumption by companies, transfers, losses, and exports	Sales to domestic consumers
			Dec. 31, 1944	Dec. 31, 1945		
East Coast	1,602,200	253,500	100,200	125,300	187,000	1,643,600

Indiana, Illinois, Kentucky, etc	1,450,700	109,200	115,100	140,500	246,600	1,287,900
Oklahoma, Kansas, and Missouri	671,500	119,600	96,900	79,100	77,900	731,000
Texas:						
Gulf Coast	314,700		20,900	24,700	92,300	218,600
Inland	315,200	7,000	21,100	37,100	66,200	240,000
Total Texas	629,900	7,000	42,000	61,800	158,500	458,600
Louisiana-Arkansas:						
Louisiana Gulf Coast	409,000		51,100	53,100	50,100	356,900
Arkansas and Louisiana Inland	403,000	57,200	42,900	43,400	49,900	409,800
Total Louisiana-Arkansas	812,000	57,200	94,000	96,500	100,000	766,700
Rocky Mountain	289,900	65,200	40,600	46,700	79,000	270,000
California	1,355,400	12,800	104,000	107,500		1,364,700
Total United States:						
1945	7,126,600	651,500	626,200	692,700	860,600	6,851,000
1944	6,996,100	302,500	563,300	626,200	500,500	6,735,200

except in the Appalachian district. On the Gulf coast, increased output of asphalt in coastal Louisiana more than offset a decline in coastal Texas. In the Rocky Mountain district, however, asphalt production decreased 9 percent from 1944 to 1945; and in California it decreased 11 percent.

Stocks.—Stocks of petroleum asphalt held at refineries were 11 percent higher on December 31, 1945, than on December 31, 1944. The most marked increase in tonnage of inventories during 1945 occurred in the Indiana, Illinois, Kentucky, etc., district, closely followed by the East Coast district. Asphalt stocks in the Texas Inland district were considerably larger at the end of 1945 than 1 year previously. Except in the Oklahoma-Kansas-Missouri district, increases in asphalt inventories were general over the United States during 1945.

Sales.—Sales of petroleum asphalt to domestic consumers increased 2 percent in quantity and 4 percent in value from 1944 to 1945. The average value at the refinery increased from $11.24 in 1944 to $11.51 in 1945.

Of the total sold, 15.8 percent was manufactured from foreign petroleum (imported chiefly from Venezuela, Colombia, and Mexico) in 1945 compared with 10.6 percent in 1944. Although runs of foreign crude to stills increased 71 percent from 1944 to 1945, sales of petroleum asphalt from this source increased only 52 percent. Of the foreign crude processed, 9 percent was converted into asphalt in 1944 and 8 percent in 1945. East Coast refineries sold 99 percent of the total asphalt made from foreign crude in 1944 and all of that sold in 1945.

Sales of asphalt (exclusive of road oil) at petroleum refineries to domestic consumers in the United States, 1944–45, by districts

1944	6,022,954	66,109,282	712,222	9,605,382	6,735,176	75,714,664

News-Record, showed an increase of 16 percent in value—from 195.7 million dollars in 1944 to 227.3 million dollars in 1945—and of 12.7 percent in indicated volume if the values are adjusted by the Engineering News-Record index of construction costs. The increases were greatest in the 14 States west of the Mississippi River and east of the Rocky Mountain front and in the 5 Middle Atlantic States lying north of the Potomac River. Smaller increases occurred in the 10 Southeastern States lying east of the Mississippi River and south of the Ohio and Potomac Rivers, as well as in Louisiana and the District of Columbia; and in the 6 New England States. On the other hand, the recorded contracts indicated decreased road and street construction in the 7 Pacific and Rocky Mountain States and in the 5 States east of the Mississippi between the Ohio River and the Great Lakes.

Although the available statistics indicate greater activity in highway construction and maintenance in 1945 than in 1944, sales of paving asphalt used for high-type surfacing increased less than 1 percent—from 1,889,966 short tons in 1944 to 1,904,002 tons in 1945. Sales of cut-back asphalts suitable for surfacing lighter-type highways were 9 percent lower in 1945 than in 1944. The popularity of medium-curing cut-backs suffered a set-back; 14 percent less of this type of cut-back was sold in 1945 than in 1944, but sales of rapid-curing cut-backs increased slightly.

The quantity of emulsified asphalt sold in 1945 was less than in 1944, but the value was higher. Petroleum refineries sold 97,389 short tons (22,946,747 gallons) valued at $1,113,781 in 1944 and 69,943 tons (16,479,935 gallons) valued at $711,770 in 1945. In addition, 65,726,027 gallons valued at $5,970,053 in 1944 and 68,747,092 gallons valued at $6,493,043 in 1945 were sold by major industrial companies that purchased asphalt from petroleum refineries and manufactured it into emulsions. Accordingly, total known sales of emulsified asphalts and fluxes decreased 3.9 percent in quantity—from 88,672,774 gallons in 1944 to 85,227,027 gallons in 1945—but increased 1.8 percent in value—from $7,083,834 in 1944 to $7,204,813 in 1945.

Roofing manufacture made the second-largest demand for asphalt, absorbing 26 percent of the total sales to domestic consumers in 1944 and 30 percent in 1945. Although shipments of prepared roofing reported to the Bureau of the Census increased only 1 percent—from 48,691,000 squares in 1944 to 49,156,000 squares in 1945—domestic sales of roofing asphalt and roofing flux combined increased 16 percent—from 1,763,552 short tons in 1944 to 2,049,685 in 1945. These figures do not include roofing asphalt and flux consumed by the companies in factories of prepared roofing owned by themselves or by affiliated companies.

DOMESTIC DEMAND

The indicated average monthly domestic demand for petroleum asphalt (including small quantities of imported lake asphalt and grahamite) increased less than 1 percent—from 578,708 short tons in 1944 to 583,258 tons in 1945.

The period of high demand that had characterized 1940–44 continued into 1945. In terms of the long-term trend, the indicated demand was 41 percent above the expected demand for 1944 and 38 percent above that for 1945; that is, if the national demand had continued the average growth it manifested from 1908 to 1944, it would have averaged 412,072 tons a month in 1944 and 423,173 tons in 1945. If these averages are used as a standard of comparison the indicated demand of 578,708 tons a month in 1944 was 141 percent of the expected demand (412,072 tons) in 1944, and the indicated demand of 583,258 tons a month in 1945 was 138 percent of the expected demand (423,193 tons).

On a monthly basis, demand was slightly higher during the first 3 months of both 1944 and 1945 than the normal seasonal trend would warrant. From January to March 1944 demand amounted to 15 percent of the annual total and during the corresponding months of 1945 to 15.6 percent of the total, compared to a statistical "normal" of 13.9 percent. On the other hand, during the 6 months from May 1 to October 30, 1944, 66.5 percent of the total demand for the year occurred and during the corresponding months of 1945, 65.3 percent of the annual demand, compared with a statistical "normal" of 67 percent during those 6 months.

Relation of indicated asphalt demand to basic trend, multiplied by seasonal factors, 1944–45, by months

Months	1944			1945		
	Indicated monthly demand	Trend, multiplied by seasonal factors	Relation of indicated monthly demand to trend	Indicated monthly demand	Trend, multiplied by seasonal factors	Relation of indicated monthly demand to trend

DISTRIBUTION BY RAIL

The tonnage of asphalt (natural, byproduct, or petroleum) terminated by class I railroads in the United States increased from 5,145,677 short tons in 1944 to 5,379,418 tons in 1945, according to freight-commodity statistics compiled by the Interstate Commerce Commission. Of the total deliveries during the 2 years, 56 percent was set down in the populous area north of the Potomac and Ohio Rivers and east of the Mississippi River, although this area comprised only 14 percent of the area of continental United States. Increased deliveries in central and southern United States more than offset decreases in New England, the Middle Atlantic States, the Rocky Mountain States, and the Pacific States.

FOREIGN TRADE

Imports.—Imports of natural asphalt and bitumen into the United States in 1945 totaled 5,148 short tons valued at $122,207, compared with 8,235 tons valued at $254,135 in 1944. Imports of lake asphalt from Trinidad decreased from 8,062 short tons valued at $249,866 in 1944 to 4,926 tons valued at $116,219 in 1945; and imports of grahamite from Cuba decreased from 999 short tons valued at $17,900 to 222 tons valued at $5,927.

Imports of solid petroleum asphalt increased from 123,938 short tons valued at $705,133 in 1944 to 142,802 tons valued at $798,667 in 1945. Of the 1944 and 1945 imports, virtually all came from the Netherlands West Indies.

In addition, 13,033 barrels (2,370 tons) of liquid petroleum asphalt valued at $20,801 were imported in 1944 and 22,161 barrels (4,029 tons) valued at $43,028 in 1945. The Netherlands West Indies supplied virtually all the liquid petroleum asphalt imported into the United States in 1944 and 1945.

Petroleum asphalt exported from the United States, 1943–45, by countries

Exports.—Exports of petroleum asphalt from the United States in 1945 were 79 percent larger than in 1944 and approximated the prewar average. The most marked increase was in shipments to Europe, especially to Sweden and to Spain; to Asia, notably to British India; and to Africa, chiefly the Union of South Africa. Asphalt exports to South America increased slightly. On the other hand, exports to Australia and New Zealand decreased considerably, and shipments to other North American countries were generally less in 1945 than in 1944.

ROAD OIL

Reported sales of road oil by refineries in the United States increased 26 percent in quantity—from 2,031,000 barrels in 1944 to 2,567,000 barrels in 1945—but decreased 6 percent in value—from $3,783,000 in 1944 to $3,561,000 in 1945. What was sold in 1944 and for nearly 9 months of 1945 as road oil might better have been described as liquid asphalt, as the use of petroleum residues having a penetration greater than 350 after distillation to 680° for highway purposes was officially forbidden until August 22, 1945.

Production, receipts, stocks, consumption, transfers, losses, exports, and domestic sales of road oil in the United States in 1945, by districts, in thousands of barrels

District	Production	Receipts from other sources	Stocks		Consumption by companies, transfers, losses, and exports	Sales to domestic consumers
			Dec. 31, 1944	Dec. 31, 1945		
East Coast	289	8	19	17	283	16
Indiana, Illinois, Kentucky, etc	539	37	2	17	201	360
Oklahoma, Kansas, and Missouri	298	72	5	6	11	358

Total: 1945	2,686	1,074	189	370	1,012	2,567
1944	1,556	1,104	193	189	633	2,031

Road oil sold by petroleum refineries to domestic consumers in the United States, 1944–45, by districts

District	1944		1945	
	Thousands of barrels	Thousands of dollars	Thousands of barrels	Thousands of dollars
East Coast	78	214	16	36
Indiana, Illinois, Kentucky, etc	3	6	360	595
Oklahoma, Kansas, and Missouri	40	78	358	450
Texas	948	1,553	682	878
Louisiana-Arkansas	4	7	12	20
Rocky Mountain	157	245	616	876
California	801	1,680	523	706
Total United States	2,031	3,783	2,567	3,561

In 1944 three refining districts—Texas, California, and Rocky Mountain—together supplied 94 percent of the road oil sold in the United States in 1944. In 1945, however, production and sales of road oil had extended to central United States; Indiana, Illinois, Kentucky, etc., and Oklahoma, Kansas, Missouri, together sold 28 percent of the total and Texas, California, and Rocky Mountain 56 percent.

CEMENT

By Oliver Bowles and Esther V. Balser

SUMMARY OUTLINE

SUMMARY

The cement industry experienced a substantial recovery in 1945. The total production of 104,288,647 barrels of hydraulic cements was 13 percent higher than in 1944; but, with the exception of that year, it was lower than in any year since 1935. The gains were shared by portland cement and by the subsidiary group of natural, masonry, and puzzolan cements. The portland-cement industry operated at 43 percent and the "All other" group at 46 percent of productive capacity in 1945. Mill shipments of portland cement, which totaled 106,353,595 barrels, were 13 percent greater than in 1944. Shipments of the "All other" group gained 12 percent. Stocks of all hydraulic cements at mills on December 31, 1945, were 16,575,139 barrels, 18 percent less than at the close of 1944.

The average net mill realization per barrel of portland cement increased 4 cents from the 1944 price, reaching $1.63 per barrel. "All other hydraulic cements," as a group, gained 18 cents a barrel to $1.42.

The decline in the long-term trend of finished cement, which had continued since February 1943, was halted early in 1945, and in April it began an upward movement at a gradually accelerating rate.

Monthly production of cement diverged considerably from the usual peacetime seasonal pattern. The decline in January and February was less than normal, and from March to October the gains were more gradual and uniform than in prewar years. The decline in output during the last 3 months of the year, which is usually quite pronounced, was decidedly moderate in 1945, reflecting the growing demand of the construction industries for cement following the suspension of hostilities. As in 1944, peak production was attained in October.

The following table presents the principal statistics of the cement industry over a 5-year period.

Salient statistics of the cement industry in the United States, 1941–45

	1941	1942	1943	1944	1945 [1]
Production of finished cement:

[1] Includes new mill in Hawaii, completed late in 1944.
[2] Compiled from monthly reports by producers.
[3] Value received f. o. b. mill, excluding cost of containers.
[4] Revised figures.
[5] Subject to revision.

Shipments from mills, which were less than 5 million barrels per month in January and February, increased rapidly to a maximum of 13,303,000 barrels in October. A sharp seasonal decline characterized November and particularly December.

In 1945, as in 1944, the Middle States comprised the leading cement-consuming region in continental United States. (See fig. 1.) States in the regions shown in figure 1 are as follows: Northeastern—Connecticut, Delaware, District of Columbia, Maine, Maryland, Massachusetts, New Hampshire, New Jersey, New York, Pennsylvania, Rhode Island, and Vermont; Southern—Alabama, Arkansas, Florida, Georgia, Kentucky, Louisiana, Mississippi, North Carolina, Oklahoma, South Carolina, Tennessee, Texas, Virginia, and West Virginia; Middle—Illinois, Indiana, Iowa, Kansas, Michigan, Minnesota, Missouri, Nebraska, North Dakota, Ohio, South Dakota, and Wisconsin; Rocky Mountain—Arizona, Colorado, Idaho, Montana, Nevada, New Mexico, Utah, and Wyoming; Pacific—California, Oregon, and Washington.

A marked gain in output and mill shipments of cement in 1945 was to be expected in view of the increase of approximately 20 percent in total new construction compared with 1944, as determined by the United States Department of Commerce. The gain in building construction was partly offset by the continued decline in area of new concrete pavements, which dropped from a monthly average of 2,723 thousand square yards in 1944 to 1,751 thousand in 1945.

Maximum Price Regulation Order 224 of the Office of Price Administration was amended three times during 1944 to allow price increases in several areas. Five additional amendments were promulgated in 1945, one of which, however, was merely to clarify a previous amendment. Increases of 20 cents a barrel were allowed in amendments as follows: Effective January 8, 1945, for Wisconsin, Illinois, Indiana, Western Kentucky, North Dakota, South Dakota, Minnesota, Iowa, and Eastern Missouri; effective August 31, 1945, for Ohio, West Virginia, Michigan, Western Pennsylvania, Western Virginia, and Eastern Kentucky; and effective December 11, 1945, for Nebraska, Kansas, Oklahoma, Arkansas, and Western Missouri. Effective November 10, 1945, an increase of 10 cents a barrel was authorized for Georgia, Alabama, Tennessee, Louisiana, Mississippi, North Carolina, South Carolina, Florida, and Eastern Virginia.

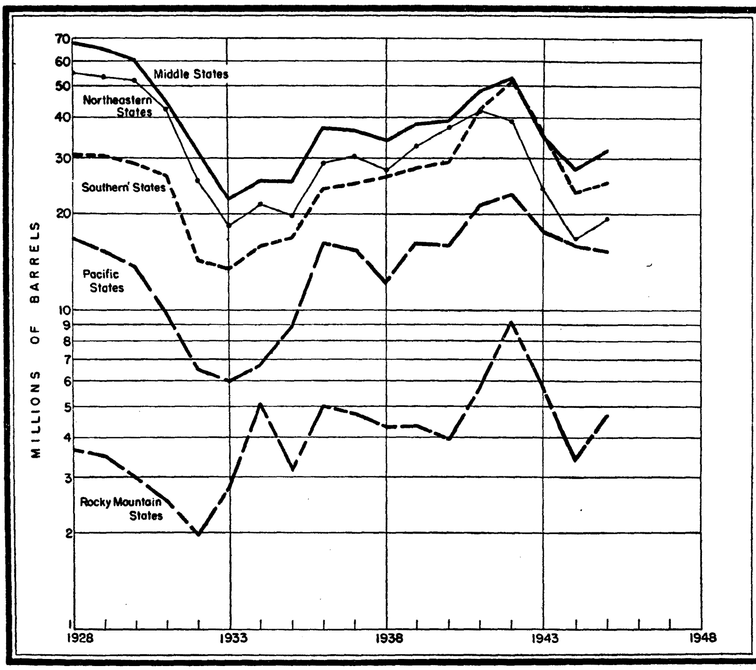

FIGURE 1.—Trends of indicated consumption of portland cement in continental United States, 1928–45, by regions.

PORTLAND CEMENT

PRODUCTION, SHIPMENTS, AND STOCKS

Portland cement constituted 99 percent of the total output of hydraulic cements in 1945. Thus, the general conditions affecting the activity of the portland-cement industry during 1945 were largely those given in the preceding summary.

In 1945 portland cement was manufactured at 141 plants, and shipments were made from 145 plants in 34 States, Hawaii, and

Finished portland cement produced, shipped, and in stock in the United States, 1944–45, by districts

[1] New mill.

[2] Figures not available by months prior to May.

[3] Revised figure.

Puerto Rico. Four plants shipped from stocks. The leading States, in order of production, were California, Pennsylvania, Texas, Michigan, and Alabama.

Production in 1945 was higher in all but three of the Bureau of Mines' districts in continental United States than in 1944; the increases ranged from 3 percent in the Virginia-Georgia-Florida-Louisiana district to 38 percent in Illinois. Production was lower than in 1944 in Tennessee (25 percent), Iowa (6 percent), and Oregon-Washington (23 percent). Hawaii first reported production in May 1945.

Shipments were greater than in 1944 in all but three districts. The largest gains were in Puerto Rico (49 percent) and Texas (34 percent). Shipments declined 1 percent in the Western Pennsylvania-West Virginia district, 24 percent in Tennessee, and 23 percent in Oregon-Washington.

Stocks of finished cement were 18 percent lower on December 31, 1945, than on the same date in 1944. Declines were registered in all districts except Illinois, Virginia-Georgia-Florida-Louisiana, California, and Oregon-Washington. They followed the same trend as in 1944, reaching a maximum in February and a minimum in October. Stocks of clinker were at reasonably high levels during the first quarter but became progressively smaller, reaching a minimum in November.

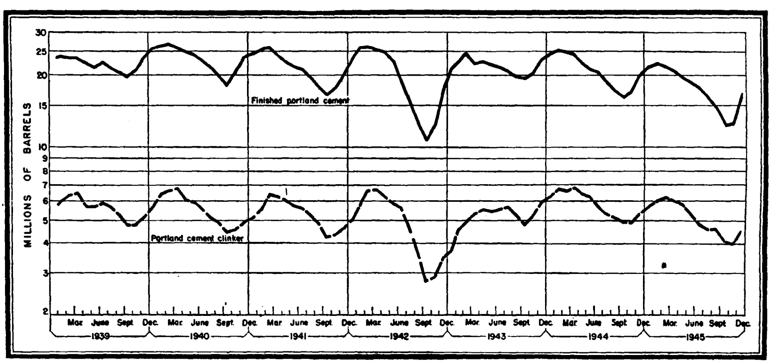

FIGURE 2.—Trends in end-of-month stocks of finished portland cement and portland-cement clinker, 1939–45.

Stocks of finished portland cement and portland-cement clinker at mills in the United States on December 31, and yearly range in end-of-month stocks, 1941–45

	Dec. 31 (barrels)	Range: Low Month	Range: Low Barrels	Range: High Month	Range: High Barrels

[1] Revised figures. [2] Includes new mill in Hawaii.

DOMESTIC CONSUMPTION

The following table shows that the indicated consumption of portland cement in 1945 gained in all but 11 States. The changes in regional consumption are illustrated in figure 1.

Destination of shipments of finished portland cement from mills in the United States, 1943–45, by States

Destination	1943 (barrels)	1944 (barrels)	1945 Barrels	1945 Percent of change from 1944
Continental:				
Alabama	2,354,265	1,193,825	1,912,267	+60.2
Arizona [1]	997,273	577,030	740,332	+28.3
Arkansas	1,280,188	728,357	974,515	+33.8
California	13,157,805	12,047,681	11,791,720	−2.1
Colorado	951,031	694,058	1,134,256	+63.4
Connecticut [1]	1,094,609	863,538	996,729	+15.4
Delaware [1]	531,444	212,109	210,283	−.9
District of Columbia [1]	1,314,305	667,007	765,140	+14.7
Florida	2,997,035	1,712,942	2,067,746	+20.7

[1] Shipments by producers to foreign countries and to noncontiguous Territories of the United States (Alaska, Hawaii, Puerto Rico, etc.), including distribution from Puerto Rican mills.

[2] Includes distribution from new mill in Hawaii.

LOCAL SUPPLIES

The following table compares the shipments from mills within a State or group of States with the estimated consumption (State receipts of mill shipments) and indicates the surplus or deficiency in the supply of cement locally available. Consumption in the States that do not produce cement is indicated in a preceding table showing shipments into each State. The total surplus of producing States in 1945 was distributed as follows: 11,698,119 barrels to non-cement-producing States; 7,996,682 barrels to destinations outside continental United States (excluding local consumption of Puerto Rican and Hawaiian production); and 490,825 barrels to unspecified destinations.

Estimated surplus or deficiency in local supply of portland cement in cement-producing States, 1944–45, in barrels

[1] New mill.

TRANSPORTATION

The proportion of cement shipped by each of the major methods of transportation for 1945 is indicated in the following table. The proportions of total cement shipped by truck, railroad, and boat in 1945 differed little from the proportions recorded for 1944. Railroad shipments account for approximately 80 percent of the total.

Bulk shipments of cement continued to decline. The percentage shipped in bulk in 1943 was 42.2, in 1944, 34.5, and in 1945, only 30 percent. The use of paper bags is increasing, while the percentage shipped in cloth bags shows a steady decline.

Shipments of portland cement from mills in the United States (including Puerto Rico), 1943–45, in bulk and in containers, by types of carriers

[Barrels of 376 pounds]

[1] Includes steel drums and iron and wood barrels.
[2] Includes cement used at mills by producers as follows—1943: 153,337 barrels; 1944: 112,593 barrels; 1945: 217,968 barrels.
[3] Less than 0.05 percent.
[4] Includes new mill in Hawaii; product shipped in paper bags by truck and railroad

MILL VALUES

The average net mill realization of all portland cement shipped from mills in 1945 advanced to $1.63 per barrel from $1.59 in 1944. The gain in average mill return resulted from the increases in ceiling prices allowed for certain areas, to which reference has been made on a preceding page.

The composite wholesale price of portland cement, f. o. b. destination, according to the Bureau of Labor Statistics index (1926=100), was 99.4 in 1945; in 1944 it was 95.8.

Average mill value per barrel, in bulk, of portland cement in the United States, 1941–45

1941	$1.47	1944	$1.59
1942	1.53	1945	1.63
1943	1.57		

CAPACITY OF PLANTS

The aggregate annual capacity of all portland-cement plants in 1945 increased 1,100,000 barrels over 1944. The increase was due chiefly to extensions and improvements at old plants and includes approximately 75,000 barrels capacity for finished portland cement of 1 new plant that began operating during the year. The capacity of

1 plant reported dismantled late in 1944 has been excluded from the figures for 1945. Data for 1945 are based on 154 mills, including 1 new mill (Hawaii). The over-all rate of operation in 1945 was at 43 percent of total capacity. As indicated in the following table, the percentage of capacity utilized in 1945 gained in all districts except Tennessee, Virginia-Georgia-Florida-Louisiana, Iowa, and Oregon-Washington.

Portland-cement-manufacturing capacity of the United States, 1944–45, by producing districts

District	Estimated capacity (barrels)		Percent of capacity utilized	
	1944	1945	1944	1945
Eastern Pennsylvania and Maryland	41,608,420	42,567,325	28.5	34.1

California	28,640,000	26,490,000	51.2	60.2
Oregon and Washington	7,363,288	7,350,000	59.8	45.9
Puerto Rico	1,620,000	1,620,000	63.1	89.0
Hawaii (new mill)		75,000		29.4
	240,531,601	241,631,390	37.8	42.5

The percentage of capacity used in each month of 1945 was higher than in the corresponding month of 1944, except in February, when they were the same. The monthly rate was lowest in January, February, and March 1945. It increased steadily thereafter until October. The recessions in November and December were much smaller than the average seasonal declines. In the following table, cement plants are grouped according to size.

Distribution of portland-cement plants in the United States in 1945, according to annual capacity

Estimated annual capacity, barrels:	*Number of plants*
Less than 1,000,000	38
1,000,000 to 1,999,000	84
2,000,000 to 2,999,000	21
Between 2,999,000 and 10,000,000	11
	154

Percent of capacity used in the finished portland-cement industry in the United States, 1944–45

The total capacity of wet-process mills was higher than that of dry-process mills, and wet-process capacity gained slightly over the dry-mill capacity in 1945, as indicated in the accompanying table; however, the percentage of total cement produced by the wet process in 1945 was lower than in 1944.

Capacity of portland-cement plants in the United States (including Puerto Rico), 1943–45, by processes

Process	Capacity: Thousands of barrels 1943	1944	1945[1]	Capacity: Percent of total 1943	1944	1945[1]	Percent of capacity utilized 1943	1944	1945[1]	Percent of total finished cement produced 1943	1944	1945[1]

[1] Includes new dry-process mill in Hawaii.

CLINKER PRODUCTION

The output of clinker, the intermediate product of the industry, was 13 percent greater in 1945 than in 1944. The growing demand for cement is reflected in the 16-percent decline in stocks of clinker as of December 31, 1945, compared with those on hand a year earlier.

[1] Compiled from monthly estimates of the producers.
[2] Includes new dry-process mill in Hawaii.
[3] Revised figures.
[4] Subject to revision.

PRODUCTION ACCORDING TO RAW MATERIALS

A combination of limestone with clay or shale is the predominant raw material for making portland cement. In 1945, 71.4 percent of the output was made from this combination of raw materials, compared with 72.0 percent in 1944. Cement rock and limestone, which in the early days of the industry were the leading raw materials, now have secondary importance. This combination furnished raw material for 19.8 percent of the cement output in 1945, which was slightly higher than in 1944. Marl, which was used in substantial quantities before 1906, is now of minor importance, supplying raw material for only 2.0 percent of the cement made in 1945. The combination of blast-furnace slag and limestone accounted for 6.8 percent of the output in 1945, compared with 6.3 percent in 1944.

Production and percentage of total output of portland cement in the United States, 1898–1914, 1926, 1929, 1933, 1935, and 1941–45, according to raw materials

Year	Cement rock and pure limestone		Limestone and clay or shale		Marl and clay		Blast-furnace slag and limestone

[1] Includes output of 2 plants using oystershells and clay in 1926; 3 plants in 1929, 1933, and 1935; and 4 plants in 1941–45.

RAW MATERIALS

The tonnages of raw materials (exclusive of fuels and explosives) required for the production of portland cement during recent years are given in the following table.

Raw materials used in producing portland cement in the United States, 1943–45

Raw material	1943	1944	1945
	Short tons	*Short tons*	*Short tons*
Cement rock	8, 564, 458	5, 119, 318	5, 656, 390
Limestone [1]	28, 598, 436	19, 958, 151	22, 747, 654
Marl	699, 456	643, 412	646, 391
Clay and shale [2]	4, 004, 316	2, 822, 881	3, 162, 458
Blast-furnace slag	544, 084	278, 998	380, 970
Gypsum	850, 660	597, 297	683, 158
Sand and sandstone [3]	350, 941	230, 288	272, 077
Iron materials [4]	188, 096	123, 079	128, 312
Miscellaneous [5]	38, 542	22, 442	36, 100
Total	43, 838, 989	29, 795, 866	33, 713, 510
Average total weight required per barrel (376 pounds) of finished cement	*Pounds* 657	*Pounds* 656	*Pounds* 656

[1] Includes oystershells.
[2] Includes bentonite, diatomaceous shale, fuller's earth, and other clays.
[3] Includes silica and quartz.
[4] Includes iron ore, pyrite cinders and ore, and mill scale.
[5] Includes diatomite, fluorspar, pumicite, flue dust, pitch, red mud and rock, hydrated lime, tufa, cinders, calcium chloride, sludge, grinding aids, and air-entraining compound.

FUELS AND POWER

In consonance with the increasing tempo of cement production in 1945, consumption of all types of fuel increased. Stocks of fuels were generally low. They were sufficient for only 1½ to 2 months' operations at the average rate of consumption throughout the year.

Finished portland cement produced and fuel consumed by the portland-cement industry in the United States, 1944–45, by processes

Process	Finished cement produced			Fuel consumed [1]		
	Plants	Barrels of 376 pounds	Percent of total	Coal (short tons)	Oil (barrels of 42 gallons)	Natural gas (M cubic feet)
1944						
Wet	[2] 83	[2] 52, 157, 819	[2] 57.4	[2] 2, 001, 165	1, 525, 242	23, 476, 342

[1] Includes new dry-process mill in Hawaii.

TYPES OF CEMENT

A breakdown of total production of portland cement in 1945, by various types, is presented in the following table. The drop in sales of low-heat type IV to less than one-tenth of the 1944 figure is noteworthy. Sales of all other types increased.

Prepared masonry mortars.—Production of these mixed materials in 1945 from 70 plants totaled 4,017,531 barrels, and shipments 3,929,710 barrels, valued at $6,545,218, an average mill realization of $1.67 a barrel. These data are not included in the statistics of this chapter, but the portland cement used in producing the mixtures is included.

Portland cement produced and shipped in the United States, 1941–45, by types

Kind and year	Active plants	Production (barrels)	Shipments		
			Barrels	Value	
				Total	Average
General use and moderate heat (types I and II):					
1943 [1]	153	123,490,667	118,347,297	$182,682,614	$1.54
1944 [2]	151	83,576,685	86,933,387	135,564,313	1.56
1945 [2 3]	145	94,998,226	98,282,835	156,427,366	1.59
High-early-strength (type III):					
1941	90	6,063,638	6,123,224	11,443,792	1.87
1942	87	7,523,647	7,065,700	13,683,665	1.94
1943	95	6,816,671	6,299,190	12,040,467	1.91

1945	11	409,131	420,483	822,651	1.96

[1] Figures reported separately for the first time in 1943.
[2] Includes air-entrained and Vinsol resin cements classed as modified cements by producers.
[3] Includes new mill in Hawaii.
[4] 1941–42: Includes hydroplastic portland cements; 1943–45: Includes hydroplastic, plastic, and waterproofed cements.

NEW DEVELOPMENTS

A new use for cement that may be extended greatly in the future is for grouting railroad ballast. Quite a number of railroad companies in the United States are using the process to some extent in treating water pockets and soft spots in road beds. Two methods of pressure grouting are used. By the earlier method, pneumatic pressure was applied to neat cement or very rich mixtures. Today the most popular method is to use lean mixtures injected by hydraulic pressure. The cement is applied through "grouting points" driven into the ballast a few feet apart and to depths of 5 or 6 feet. Grouting increases stability and reduces track maintenance expense.

Lining new oil-field pipe with cement is not new, but during the war the process was used extensively for reconditioning used pipe that would otherwise be discarded as scrap. The incentive behind this movement was the acute shortage of iron and steel for pipe manufacture. Many used pipes were relined with cement in the Illinois, Oklahoma, Kansas, and Texas oil fields.

Interest grows in air-entrained cements used in highway construction because of their superior resistance to freezing and thawing. Much research has been conducted during the past year to determine optimum percentages of reagent additions and the behavior of reagents under varying conditions. It was found that the heat generated in clinker grinding might be high enough to volatilize a considerable part of a commonly used reagent—vinsol resin. Air entraining has recently been extended to concrete-block manufacture.

Recent significant trends in the cement industry are toward increasing the length of kilns and adding clinker-cooling equipment or improving that already in use.

The scarcity of lumber and the high price levels attained for it compared with prices of other building materials have stimulated a much wider use of cement blocks as substitutes for lumber. This use of cement has therefore experienced a substantial growth.

The Bureau of Mines has recently published a report [1] describing the cement industry in Mexico, South and Central America, and the adjacent islands.

NATURAL, MASONRY (NATURAL), AND PUZZOLAN CEMENTS

Production and shipments of the group of hydraulic cements other than portland in 1945 increased 19 and 12 percent, respectively, from the previous year. Stocks increased 3 percent. Producers reported a consumption of 23,944 short tons of coal and of gas equivalent to approximately 265 short tons of coal.

[2] Subject to revision.

TRENDS IN EMPLOYMENT AND OUTPUT PER MAN

In Minerals Yearbooks, 1935 (pp. 891–905) and 1940, Review of 1939 (pp. 1141–1153), trends in employment and output per man in the cement industry were traced from 1928 to 1938. Similar data for 1939 and 1940 appeared in Minerals Yearbook, 1941 (pp. 1215–1222), and for 1941 and 1942 in Minerals Yearbook, 1943 (pp. 1265–1273). The study is continued herein through 1943 and 1944.

Employment in the portland-cement industry, finished cement produced at mills included in study, and average output per man in the United States, 1940–44 (excluding Puerto Rico)

Year	Employment					Production			Percent of industry represented [1]
	Average number of men	Time employed				Finished portland cement (barrels)	Average per man (barrels)		
		Average number of days	Total man-shifts	Man-hours					
				Average per man per day	Total		Per shift	Per hour	
1940	26,038	279	7,276,469	7.4	54,116,153	129,830,687	17.84	2.40	99.7
1941	28,409	303	8,600,572	7.4	63,636,617	163,567,931	19.02	2.57	99.7
1942	29,768	315	9,374,851	7.5	70,203,687	182,114,486	19.43	2.59	99.6
1943	25,453	300	7,626,376	7.7	58,737,442	132,445,838	17.37	2.25	99.3
1944	20,376	278	5,670,147	8.0	45,236,906	89,883,262	15.85	1.99	98.9

[1] Calculated for each year by dividing quantity of finished cement produced at mills included in study by total production.

MILL EMPLOYMENT

A large percentage of the total employees in the cement industry is employed in the mills.

Mill employees in the portland-cement industry, finished cement produced at mills included in study, and average output per man in the United States, 1940–44 (excluding Puerto Rico)

Year	Employment—cement mill only					Production			Percent of industry represented [1]
	Average number of men	Time employed				Finished portland cement (barrels)	Average per man (barrels)		
		Average number of days	Total man-shifts	Man-hours			Per shift	Per hour	
				Average per man per day	Total				
1940	20,692	287	5,930,723	7.4	43,967,729	129,830,687	21.89	2.95	99.7
1941	22,205	311	6,904,905	7.3	50,616,860	163,567,931	23.69	3.23	99.7
1942	23,492	323	7,589,439	7.4	56,345,160	182,114,486	24.00	3.23	99.6
1943	19,958	308	6,156,775	7.6	47,004,631	132,445,838	21.51	2.82	99.3
1944	15,566	289	4,501,364	8.0	35,826,375	89,883,262	19.97	2.51	98.9

[1] Calculated for each year by dividing quantity of finished cement produced at mills included in study by total production.

QUARRY AND CRUSHER EMPLOYMENT

The number of quarry and crusher employees is generally less than 20 percent of the total number of workers in the industry.

Quarry and crusher employees in the portland-cement industry, material (quarry rock and overburden) handled at quarries included in study, and average output of material per man in the United States, 1940–44 (excluding Puerto Rico)

Year	Employment—quarry and crusher only					Material handled—quarry rock and overburden				Percent of industry represented [1]
	Average number of men	Time employed				Short tons	Percent of overburden included	Average per man (short tons)		
		Average number of days	Total man-shifts	Man-hours				Per shift	Per hour	
				Average per man per day	Total					
1940 [2]	4,394	244	1,070,881	7.6	8,171,104	33,804,500	2.6	31.57	4.14	82.6
1941 [2]	4,858	269	1,307,370	7.7	10,088,738	44,361,943	4.1	33.93	4.40	91.2
1942 [2]	5,090	280	1,423,290	7.8	11,089,206	50,959,664	10.4	35.80	4.60	90.9
1943 [3]	4,403	262	1,152,041	8.0	9,231,784	39,191,018	--------	34.02	4.25	92.1
1944 [3]	3,489	245	855,934	8.2	7,001,742	28,307,328	--------	33.07	4.04	91.6

[1] Calculated for each year by dividing quantity of finished cement produced at mills included in study by total production.
[2] Includes tonnage of quarry rock and overburden.
[3] Excludes overburden.

HOURS PER DAY

Employment data indicate a general trend toward a shorter working day.

Number of men employed in the portland-cement industry in the United States [1] and output per man-hour, 1942–44, classified according to hours of labor per day

Hours per day	1942			1943			1944		
	Men employed		Production per man-hour (barrels)	Men employed		Production per man-hour (barrels)	Men employed		Production per man-hour (barrels)
	Number	Percent of total		Number	Percent of total		Number	Percent of total	
Less than 6	1,395	4.7	2.77						
6 and less than 7	6,043	20.3	2.54	4,172	16.4	2.30	694	3.4	1.92
7 and less than 8	8,427	28.3	2.75	3,538	13.9	2.16	1,920	9.4	1.73
8 and less than 9	13,672	45.9	2.50	17,606	69.2	2.26	17,045	83.7	2.04
9 and less than 10	231	.8	2.60				494	2.4	1.42
10 and less than 11							92	.5	1.34
11 and less than 12				137	.5	2.16	131	.6	1.97
	29,768	100.0	2.59	25,453	100.0	2.25	20,376	100.0	1.99

[1] Exclusive of Puerto Rico.

EMPLOYMENT BY DISTRICTS

Employment by geographic areas is indicated in the following tables.

Employment in the portland-cement industry, finished cement produced at mills included in study, and average output per man in the United States, 1943–44, by districts (excluding Puerto Rico)

District	Employment					Production			Percent of industry represented[1]
	Average number of men	Time employed		Man-hours		Finished portland cement (barrels)	Average per man (barrels)		
		Average number of days	Total man-shifts	Average per man per day	Total		Per shift	Per hour	
1943									
Eastern Pennsylvania and Maryland	4,330	276	1,195,258	7.5	8,963,677	18,318,790	15.33	2.04	100.0

[1] Calculated for each year by dividing quantity of finished cement produced at mills included in study by total production.

FOREIGN TRADE [2]

Imports.—As indicated in the following table, imports of cement have been very small during recent years. Imports by country of origin are listed in the second table following.

Hydraulic cement imported for consumption in the United States, 1941–45

Year	Barrels	Value	Year	Barrels	Value
1941	43,466	$59,048	1944	169	$418
1942	644	2,020	1945	323	700
1943	13,658	55,560			

Roman, portland, and other hydraulic cements imported for consumption in the United States, 1943–45, by countries [1]

Country	1943		1944		1945	
	Barrels	Value	Barrels	Value	Barrels	Value
Canada	13,652	$55,536	169	$417	320	$685
Chile					(2)	2
Dominican Republic					3	13
Egypt	5	10				
Guatemala			(2)	1		
Mexico	1	2				
	13,658	55,548	169	418	323	700

[1] Excludes "white, nonstaining, and other special cement."
[2] Less than 1 barrel

Exports.—Exports of nearly 6½ million barrels of cement in 1945 were far greater than the average of prewar years. The Latin-American countries are the principal foreign markets, particularly Mexico, Brazil, and Venezuela. Although the production capacity of the southern republics has increased greatly during recent years, it is apparent that market requirements are growing even more rapidly.

Hydraulic cement exported from the United States, 1941–45

Year	Barrels	Value	Percent of total shipments from mills
1941	2,556,234	$5,663,037	1.5
1942	1,100,826	2,707,217	.6
1943	1,731,956	4,654,862	1.3
1944	4,040,405	10,044,838	4.2
1945	6,476,333	15,570,610	6.0

[2] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

WORLD PRODUCTION

Insofar as figures are available, a general upward trend is indicated throughout the world in the production of cement in 1945.

World production of hydraulic cements, 1939–45, by countries, in metric tons [1]

[1] Data cover all hydraulic cements.
[2] Data not available; estimate included in total, except for 1944 and 1945.
[3] Estimate.
[4] Excludes portland cement data, which are not yet available.
[5] Slovakia only.
[6] Includes Sudetenland.
[7] January to September, inclusive.
[8] Shipments.
[9] Year ended March 31 of year stated.
[10] Cement is also produced in Queensland and South Australia, but data are not released.
[11] Year ended June 30 of year stated.

STONE

By Oliver Bowles and Nan C. Jensen

SUMMARY OUTLINE

GENERAL CONDITIONS

Sales of crushed and dimension stone combined (153,405,210 tons) were 1 percent less in 1945 than in 1944 and 22 percent less than the all-time high record of 1942. The total value of sales ($179,307,902) was, however, 2 percent greater than in 1944. Sales of crushed and broken stone declined 2 percent, although the total value of sales was a little higher than in 1944. Dimension stone, on the other hand, experienced a strong recovery, the quantity sold gaining 71 percent and the value 20 percent compared with 1944. However, the industry was still far below its prewar level. The lower average unit values in 1945 of both monumental stone and cut stone for building purposes compared with 1944 is noteworthy.

This chapter follows the general plan introduced in 1938, whereby crushed stone and dimension stone are considered separately, except in the introductory general tables.

The tables of this report give the quantities sold or used by producers and the values f. o. b. quarries and mills. Stone quarried and used by producers is considered as sold and is included in the statistics of sales. The data, however, do not include stone made into abrasives (such as grindstones) or that used in making lime and cement. These materials are reported in terms of finished products in the Abrasive Materials, Lime, and Cement chapters of this volume. The following tables show the total sales of stone by kinds, uses, and States.

Stone sold or used by producers in the United States, 1941–45, by kinds

[Quantities approximate]

Year	Granite		Basalt and related rocks (trap rock)		Marble		Limestone	
	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value
1941	14, 298, 750	$24, 968, 489	17, 936, 950	$18, 641, 852	176, 460	$4, 785, 710	133, 163, 600	$127, 585, 118
1942	14, 064, 780	23, 794, 514	17, 626, 660	21, 005, 943	169, 500	3, 910, 203	142, 487, 600	138, 578, 027
1943	9, 240, 280	18, 217, 064	14, 385, 260	17, 699, 907	168, 790	3, 610, 035	128, 980, 270	127, 296, 872

DIMENSION STONE

Dimension stone includes blocks or slabs of natural stone that are cut or trimmed to definite shapes and sizes. Materials classed as crushed and broken stone, on the other hand, comprise irregular fragments or grains sized chiefly by screening or air separation. Crushed and broken stone is covered in a later section of this chapter.

Dimension-stone producers may be divided into three main groups upon the basis of plant operation. The first group quarries stone and sells it as rough blocks or slabs; the second quarries stone and also manufactures it into finished products; and the third buys sawed slabs or rough blocks of stone and manufactures them into finished products but does not operate quarries. The Bureau of Mines statistical canvass covers the first and second but not the third group. Bureau of Mines statistics are compiled from reports of quantities and values of original sales, hence they include some material sold as rough blocks and some sold as finished products.

Total sales of dimension stone in 1945 increased 66 percent in quantity and 20 percent in value compared with 1944. These over-all figures include slate, but detailed statistics of this branch of the industry are given in the separate chapter on Slate.

The following table presents salient statistics for 1944 and 1945.

Dimension stone sold or used by producers in the United States, 1944–45, by kinds and uses

Kind and use	1944	1945	
		Total	Percent of change
Granite:			
Building stone:

[1] Includes soapstone, mica schist, volcanic rocks, argillite, and other varieties that cannot be classified in the principal groups.
[2] Details of production, by uses, are given in the chapter on Slate in this volume.

BUILDING STONE

Stone is the most ancient building material used in more or less permanent structures of which we have historic records. Natural caves protected by overhanging rock probably furnished the earliest human shelter. Stone has always occupied an important place in the construction of historic buildings and monuments, but its use has been greatly limited under conditions prevailing throughout the world during recent years. In 1945, however, sales of building stone were almost double both in quantity and value those of the all-time low of 1944.

The following table gives the quantity and value of each kind of building stone sold in 1945.

Building stone sold or used by producers in the United States in 1945, by kinds

Kind	Rough: Construction: Cubic feet	Rough: Construction: Value	Rough: Architectural: Cubic feet	Rough: Architectural: Value
Granite	183,890	$56,314	61,120	$71,898

Marble	54,300	203,061	127,070	1,195,116	265,500	1,573,148
Limestone	748,480	585,288	426,370	1,104,178	3,411,730	2,406,326
Sandstone	[2] 270,590	[2] 357,776	(2)	(2)	439,810	424,870
Miscellaneous					373,530	676,285
	[2] 1,114,270	[2] 1,226,117	[2] 602,670	[2] 2,475,770	4,913,600	5,485,011

[1] For granite, sawed stone corresponds to dressed stone for construction work (walls, foundations, bridges) and cut stone to architectural stone for high-class buildings.
[2] A small quantity of cut sandstone is included under sawed stone.

GRANITE

Sales of granite in the form of blocks and slabs gained 27 percent in quantity but declined 2 percent in value in 1945 compared with 1944. Unit prices were lower in all but one of the important categories—that of rough architectural stone. The unit values of paving blocks and curbing were also higher, but those products have become a quite unimportant branch of the industry. The greatest gains were in the building-stone branch of the industry, rough construction stone sales gaining 73 percent and cut stone 45 percent in quantity compared with 1944. Monumental stone gained 4 percent in quantity but declined 4 percent in value. Paving block and curbing sales declined greatly from the low levels of 1944. Details by States are indicated in the following table.

Granite (dimension stone) sold or used by producers in the United States in 1945, by States and uses

Estimated value of dark stock	1,008,146	1,069,449	1,109,936
Estimated polishing cost	365,794	129,347	1,441,128
Estimated sawing cost	121,931	388,038	1,127,839
Total value of granite	6,623,625	7,473,768	10,731,361

[1] Through the kindness of the Granite Manufacturers' Association, Barre, figures covering the entire granite industry of the Barre district are given in this table to supplement figures of sales reported by quarrymen.

BASALT AND RELATED ROCKS (TRAP ROCK)

Basalt and related rocks are used only in a small way as building stone. Sales in 1945 were much higher than in 1944, particularly of the products classed as rubble, the crudest form of building stone. Basalt and related rocks are used to some extent for memorials, but such stones are classed in trade as black granite and are therefore included with the figures for monumental granite.

Basalt and related rocks (trap rock) (dimension stone) sold or used by producers in the United States in 1945, by States and uses

State	Active plants	Building stone: Rough construction: Short tons	Building stone: Rough construction: Value	Building stone: Rubble: Short tons	Building stone: Rubble: Value	Total: Short tons	Total: Value
Alaska	1			(1)	(1)	(1)	(1)
California	1			(1)	(1)	(1)	(1)
Connecticut	1	(1)	(1)			(1)	(1)

Average unit value			$2.64		$1.07		$1.13

[1] Included under "Undistributed." [2] 87,890 cubic feet (approximate).

MARBLE

Marble sales continued their gains of 1944. Value of sales was higher than in any year since 1940. The gains were greatest in building marble, sales of which were 49 percent greater in quantity and 48 percent in value than in 1944. Sales of exterior finished marble registered the most striking gain. The average value per cubic foot of building marble declined 1 percent, while that of monumental marble advanced 10 percent.

The substantial gains in sales of building marble are forerunners of much larger advances that are to be expected when activity attains momentum in public-building construction, which has been almost stagnant for several years. Both depressions and wars have a detrimental effect on the construction of permanent public buildings; accordingly, very few such buildings have been erected since 1930, and the accumulated need offers a large potential market for marble for both interior and exterior work.

Marble (dimension stone) sold by producers in the United States, 1944–45, by uses

Use	1944		1945

[3] Average value per cubic foot.

LIMESTONE

Limestone, in the form of dimension stone, is used almost exclusively for building purposes. Under normal conditions limestone is the most widely used building stone. During the war the demands for stone were so small that many firms oriented their well-equipped mills to the production of munitions, and they made a substantial contribution of materials that were necessary to winning the war. Now that the war is won, they are reconverting the mills to their accustomed functions and reopening quarries that have been idle. The reconversion problem is simple, and resumption of stone dressing will take place as rapidly as market demands will justify. Already, striking gains have been made. Production of cut stone was more than three times as great and the value per cubic foot of sales was 50 percent higher than in 1944. Sales of rough-construction stone were nearly double those of 1944, while rubble sales gained 29 percent. The total quantity of building limestone sold in 1945 was more than double that of 1944, and the sales value was more than four times as great. Even with these large gains the value of sales in 1945 was only 12 percent of the 1929 figure.

The most productive area in the United States is centered in the vicinity of Bedford and Bloomington, Ind. This area supplied 91 percent of the rough architectural and finished (sawed and cut) limestone sold in 1945.

Limestone (dimension stone) sold or used by producers in the United States in 1945, by States and uses

SANDSTONE

Sandstone as dimension stone is used principally for building purposes. Sandstone was the only major branch of the dimension-stone industry to show a decline in the quantity sold in 1945. However, this decrease was predominantly in the rough-construction stone, which sells at a relatively low price per ton. Sales of cut stone, slabs, and mill blocks gained 53 percent in quantity and 35 percent in value. Flagging sales gained moderately, but rubble and curbing output fell below that of 1944. No sales of paving stones were reported in 1945.

The total quantity of sandstone sold in 1945 was 13 percent less than in 1944; however, as the declines were chiefly in the lower-priced products and cut-stone sales made substantial gains, the overall value of sales was 12 percent greater than in 1944.

As in previous years, Ohio was the principal producer. Its quarries produced 65 percent of the total value of output in 1945. Other producing States, in order of sales value, were New York, Tennessee, Pennsylvania, and California.

The second table following presents a 23-year history of the bluestone industry. Bluestone is a type of sandstone that splits readily into thin, uniform sheets. It is particularly well-adapted for flagging but is used also for building stone and curbing. The industry has declined greatly because concrete is now used extensively for purposes for which flagstones were employed many years ago.

Sandstone (dimension stone) sold or used by producers in the United States in 1945, by States and uses

[1] New York and Pennsylvania are the only States that produce bluestone.

MISCELLANEOUS STONE

Types of stone other than those included in the major groups already discussed are covered in the following table. The principal varieties are mica schist, argillite, light-color volcanic rocks, soapstone, and greenstone. The quantity sold in 1945 increased 22 percent and the value 23 percent compared with 1944.

Miscellaneous varieties of stone (dimension stone) sold or used by producers in the United States in 1945, by States and uses

State	Active plants	Building				Flagging		Total

[2] Building stone (rough and dressed), approximately 373,530 cubic feet; flagging, approximately 9,290 cubic feet.

TRENDS IN USE OF DIMENSION STONE

A 30-year history of production of dimension stone by kinds is depicted in figure 1. Wars and depressions affect these industries adversely, as may be judged from the graph covering 1917 to 1922 and 1931 to 1945.

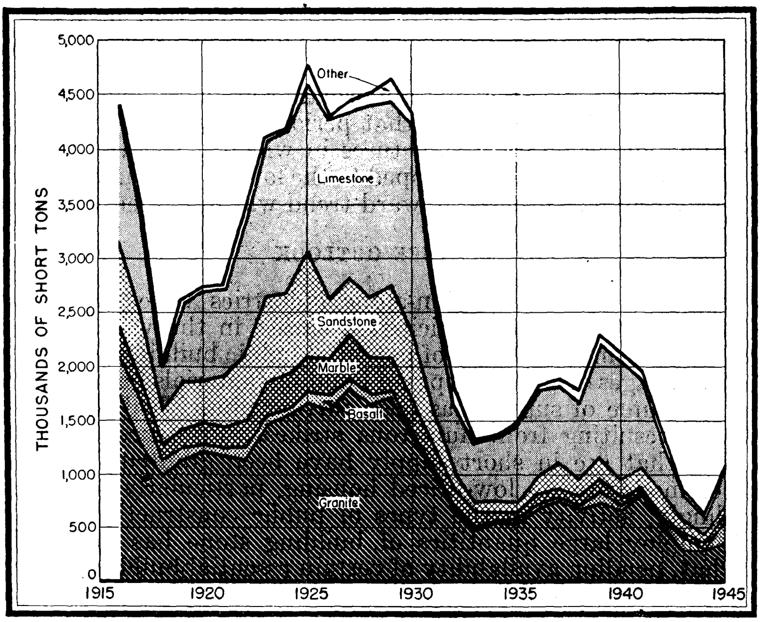

FIGURE 1.—Sales of dimension stone in the United States, by kinds, 1916–45.

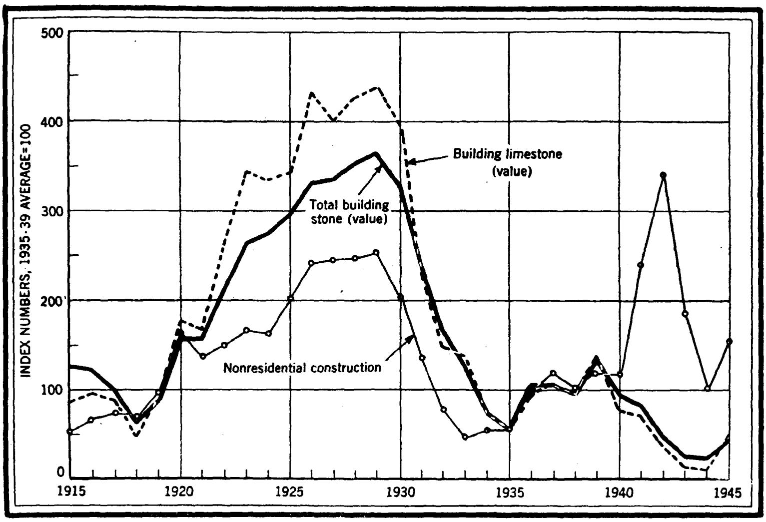

FIGURE 2.—Sales of all building stone and building limestone compared with nonresidential construction (public and private), 1915–45. Data on nonresidential building construction from Bureau of Foreign and Domestic Commerce.

Figure 2 traces for 31 years the history of production of all building stone and of the principal variety—limestone—in their relation to nonresidential building, the class of construction that normally uses stone most extensively. In general, building stone follows the trend of nonresidential construction, but since 1940 there has been no such correspondence. Because of abnormal wartime conditions nonresidential construction during that period consisted mainly of more or less temporary military structures in which very little stone was used. Building-stone sales dropped to the lowest point in their history in 1944, but an encouraging upward trend was in evidence in 1945.

FUTURE OUTLOOK

Prospects for the dimension-stone industries were not as bright late in 1945 as had been anticipated earlier in the year. Although there is an enormous backlog of potential public building construction, serious shortages of certain types of building materials have developed, and the volume of supply has been further diminished by industrial inactivity resulting from numerous strikes. Priorities for building materials that are in short supply have been granted favoring the needs of moderate- to low-priced housing, particularly for veterans. Accordingly, activity in the types of public construction that ordinarily employ large quantities of building stone has been delayed somewhat, pending availability of certain essential building materials. In nonresidential building, preference will be given to enlarging existing industrial plants or constructing new ones. Even though these various handicaps exist, a substantial increase during 1946 in educational, religious, recreational, and Government building is anticipated; thus a growing demand for dimension stone may be expected. The year 1946 will be essentially a transition period, and because of its uncertainties all forecasts must be qualified.

CRUSHED AND BROKEN STONE

About 152 million short tons of crushed and broken stone were sold in 1945, exclusive of that used for making cement and lime. Sales decreased 2 percent in quantity but gained slightly in value compared with 1944. The average value at the quarry increased 2 cents a ton.

The accompanying table of salient statistics shows the quantity sold and the value of sales during 1944 and 1945, by uses. Detailed data on asphaltic stone and slate granules and flour are given in the chapters on Asphalt and Slate.

Crushed and broken stone sold or used by producers in the United States, 1944–45, by principal uses

Use	1944			1945

[1] Included under "Undistributed."
[2] To avoid disclosing confidential information, certain totals are somewhat incomplete, the figures not included being combined under "Undistributed."

COMMERCIAL AND NONCOMMERCIAL OPERATIONS

The accompanying table shows the production of crushed stone for concrete and road metal during recent years by Government agencies of various kinds, contrasted with that by commercial enterprises. For several years prior to 1940, Government-sponsored enterprises produced 29 to 46 percent of the total output. They consisted principally of make-work organizations designed to meet unemployment and, to a lesser extent, State, county, and city highway boards or commissions. War conditions brought about a radical change in the situation. Unemployment ceased to be a problem. Highway construction, except for military roads, was virtually suspended; consequently the output of stone by State and county organizations was very small. Noncommercial production dropped to only 9 percent of the total in 1943, increased to 12 percent in 1944, and dropped to only 7 percent in 1945. This is the lowest percentage recorded for many years.

Concrete and road metal sold or used by commercial and noncommercial operators in the United States, 1941–45

[Figures for "noncommercial operations" represent tonnages reported by States, counties, municipalities, and other Government agencies, produced either by themselves or by contractors expressly for their consumption, often with publicly owned equipment; they do not include purchases from commercial producers. Figures for "commercial operations" represent tonnages reported by all other producers]

Year	Commercial operations				Noncommercial operations				Total	
	Short tons	Average value per ton	Percent of change in quantity from preceding year	Percent of total quantity	Short tons	Average value per ton	Percent of change in quantity from preceding year	Percent of total quantity	Short tons	Percent of change in quantity from preceding year
1941	75,588,820	$0.94	+36	69	34,603,790	$1.04	−7	31	110,192,610	+19

1945	59,347,220	1.01	+4	93	4,760,970	1.12	−40	7	64,108,190	−1

GRANULES

Beginning with 1942, the coverage of granules for roofing purposes has been more complete than in former years. The following table shows total production for the past 4 years. Separate figures for slate granules are given in the chapter on Slate.

Roofing granules [1] sold or used in the United States, 1942–45, by kinds

Year	Natural		Artificially colored		Brick		Total	
	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value
1942	352,320	$2,650,503	538,310	$7,594,174	43,230	$636,961	933,860	$10,881,638
1943	287,090	2,190,143	543,870	7,745,452	47,650	716,685	878,610	10,652,280
1944	287,080	2,210,379	637,090	9,313,356	65,830	1,005,964	990,000	12,529,699
1945	355,840	2,628,052	628,220	9,124,891	61,220	947,637	1,045,280	12,700,580

[1] Manufactured from stone, slate, slag, and brick.

SIZE OF PLANTS

The production of stone according to size of plants and number of plants in each size group has now been covered for 4 years—1941 to 1944. Figures for 1941 appear on page 1241 of the Minerals Yearbook 1942 and for 1942 on page 1300 of the volume for 1943. Figures for 1943 and 1944 are given in the following table.

The general trend during recent years has been toward an increase in the number of plants in the larger size groups and a larger percentage of total production by those groups. For instance, in 1941 there were 41 plants producing 500,000 tons or more a year, and they produced 34 percent of the total output. During the following 3 years the number of plants in that size range numbered 51 to 61, and they produced between 40 and 41 percent of the total.

Number and production of commercial crushed-stone [1] plants in 1943–44, by sizes of output

Range of output	1943				1944			
	Number of plants	Total production of plants (short tons)	Percent of total	Cumulative total (short tons)	Number of plants	Total production of plants (short tons)	Percent of total	Cumulative tota (short tons)
Less than 1,000 tons	101	44, 820	0. 03	44, 820	93	43, 330	0. 03	43, 330

[1] Exclusive of marble, which is primarily a dimension-stone industry.

METHODS OF TRANSPORTATION

The following table shows the quantities of commercial crushed stone for concrete and road metal conveyed during 1944 and 1945 by each of the principal methods of transportation. The percentage hauled by truck declined in 1945, while that hauled by rail increased correspondingly.

Stone for concrete and road metal sold or used by commercial producers in the United States, 1944–45, by methods of transportation [1]

Method of transportation	1944		1945	
	Short tons	Percent of total	Short tons	Percent of total
Truck	36,835,560	65	37,091,440	62
Rail	15,593,350	27	17,719,460	30
Waterway	1,813,980	3	2,355,590	4
Unspecified	2,573,060	5	2,180,730	4
	56,815,950	100	59,347,220	100

[1] For practical purposes the entire output of noncommercial operations commonly is moved by truck. Including noncommercial production, crushed stone for concrete and road metal moved as follows—1944: Truck 69 percent, rail 24 percent, water 3 percent, and unspecified 4 percent; 1945: Truck 65 percent, rail 28 percent, water 4 percent, and unspecified 3 percent.

GRANITE

Sales of crushed and broken granite increased 4 percent in quantity in 1945, but the total value of sales was almost identical with that of 1944. The average sales value per ton declined 4 cents. Sales of riprap declined considerably, and the value per ton was much lower than in 1944. Crushed granite for concrete and road metal registered a small gain, and the average value per ton was 1 cent lower than in 1944. The most decisive gain was in granite sold as railroad ballast, which advanced 48 percent in quantity and 45 percent in value. The unusually heavy rail traffic has created an urgent need of maintaining roadbeds in adequate condition. The average sales value of ballast declined 2 cents a ton.

The number of individual operations supplying noncommercial crushed stone cannot be determined with any degree of accuracy from the reports submitted. Therefore, in the accompanying tables covering granite and other kinds of crushed and broken stone, the number of active plants is not given. For many years before 1939, when noncommercial production was less important, such figures appeared in the tables.

Granite (crushed and broken stone) sold or used by producers in the United States in 1945, by States and uses

BASALT AND RELATED ROCKS (TRAP ROCK)

Sales of crushed and broken trap rock were 5 percent greater in quantity and 1 percent greater in value in 1945 than in 1944. This classification includes the dark igneous rocks—basalt, gabbro, and diorite. The value per ton declined from $1.22 to $1.18.

Basalt and related rocks (trap rock) (crushed and broken stone) sold or used by producers in the United States in 1945, by States and uses

[1] Includes stone sold for base course, fill material, roofing granules, waste, and unspecified uses. [2] Included under "Undistributed."

MARBLE

In the manufacture of marble blocks, much waste accumulates. Some of it is marketed as terrazzo or marble flour, and it also finds outlets for the same uses as those to which limestone is applied. It may be sold as agricultural limestone, as a filler, or as road stone or concrete aggregate. The great variation in unit value in different States, as indicated in the accompanying table, is due to the diversity in price among highly refined or commonplace uses.

Marble (crushed and broken stone) sold by producers in the United States in 1945, by States [1]

State	Active plants	Short tons	Value	State	Active plants	Short tons	Value
Alabama	2	(2)	(2)	Utah	1	5,640	$61,386
California	1	(2)	(2)	Virginia	1	1,230	9,818

Tennessee	4	20,420	41,124	Average unit value			$5.19
Texas	1	7,000	90,000				

[1] Includes stone used for agriculture, asphalt filler, cast stone, composition flooring, crushed stone, flux, magnesia, mineral food, poultry grit, riprap, shingles, spalls, terrazzo, tile, whiting (excluding marble whiting made by companies that purchase their marble), and unspecified uses.
[2] Included under "Undistributed."

LIMESTONE

Sales of limestone were reported to the Bureau of Mines from 44 States and 2 Territories in 1945. Because of its wide distribution and relatively low cost of production, it is used more extensively than other types of stone in the United States. In 1945 limestone constituted 74 percent of all crushed and broken stone sold (excluding that used for making cement and lime), the same percentage as in 1944. Fluxing-stone sales dropped nearly 3½ million tons but were still far in advance of prewar levels. Agricultural limestone sales declined 8 percent but were still higher than in any previous year except 1944. The strong world-wide demand for agricultural products and the high buying power of farmers bear promise of a continuing heavy demand for agricultural limestone. The sales value of agricultural limestone averaged 15 cents a ton higher than in 1944. Reflecting the upward trend in building and highway construction, sales of crushed stone as concrete and road metal gained 6 percent compared with 1944. Sales of limestone as railroad ballast show little change. Sales for miscellaneous uses, which, as a whole, declined moderately, are indicated in the second table following.

Limestone (crushed and broken stone) sold or used by producers in the United States in 1945, by States and uses

[1] Includes stone for filler for calcimine, caulking compounds, crayons, explosives, foundry facing powder, leather goods, linoleum, paint, paper, phonograph records, plastics, pottery, putty, roofing, rubber, tanning, tooth paste, wire coating, and unspecified uses.
[2] Included under "Other uses."
[3] Includes stone for refractory magnesia.
[4] Includes stone for acid neutralization, athletic-field marking, carbon dioxide, chemicals (unspecified), concrete blocks and pipes, electric products, fill material, oil-well drilling, rayon, rice milling, spalls, spray, waste rock, water treatment, and (1945) magnesium metal.

Dolomite (calcium-magnesium carbonate) has a variety of uses, some of which are quite distinct from those of high-calcium limestone. Dead-burned dolomite is used as a refractory lining for metallurgical furnaces, and statistical data on this product (which is closely allied to lime) are given in the chapter of this volume on Lime. Raw dolomite is also used as a refractory, particularly for patching furnace floors. Dolomite is also used as a source of magnesia (MgO), which may be applied to refractory use, employed for heat insulation, or used in various other ways. In 1943, for the first time, dolomite was used extensively as a source of magnesium metal. This use has declined owing to the cut-back in the metal program.

Sales of dolomite and its primary product of calcination—dolomitic lime—for certain uses are covered in the following table.

Dolomite and dolomitic lime sold or used by producers in the United States for specified purposes, 1944–45

	1944	1945
Dolomite for—		
Basic magnesium carbonate: [1]		
Short tons	220,160	295,540
Value	$450,328	$373,919
Magnesium metal:		
Short tons	652,610	(2)
Value	$983,359	(2)
Refractory uses:		
Short tons	1,075,050	1,027,090
Value	$1,130,022	$1,120,136
Dolomitic lime for—		
Refractory (dead-burned dolomite):		
Short tons	1,290,790	1,187,330
Value	$11,441,612	$10,613,711
Paper mills:		
Short tons	46,000	52,000
Value	$347,000	$413,000
Total (calculated as raw stone) short tons	4,621,000	3,801,000

[1] Includes dolomite for refractory magnesia. [2] Bureau of Mines not at liberty to publish figures.

The use of limestone as a fluxing agent in metallurgical furnaces has attained such importance that a special table has been prepared showing the quantity and value of fluxing stone applied to various uses.

Sales of fluxing limestone, 1941–45, by uses

Year	Blast furnaces		Open-hearth plants		Other smelters [1]		Other metallurgical [2]		Total	
	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value
1941	20,244,510	$14,832,938	6,332,210	$4,469,838	481,100	$398,839	374,700	$362,544	27,432,520	$20,064,159
1942	23,663,630	18,523,158	5,843,820	4,886,157	494,720	460,270	257,080	277,728	30,259,250	24,147,313
1943	24,755,920	18,785,578	5,932,900	4,899,369	671,990	581,325	209,840	239,295	31,570,650	24,505,567
1944	24,045,890	18,954,798	6,158,870	5,251,987	557,830	547,277	317,740	376,051	31,080,330	25,130,113
1945	21,901,820	17,111,472	5,038,140	4,286,889	502,230	491,178	197,330	186,854	27,639,520	22,076,393

[1] Includes flux for copper, gold, lead, zinc, and unspecified smelters.
[2] Includes flux for foundries and for cupola and electric furnaces.

Limestone is employed not only raw but also for the manufacture of cement and lime. The latter industries are covered in separate chapters of the Minerals Yearbook. It is of interest, however, to show in one table, as follows, the total tonnage of limestone consumed for all purposes.

Limestone sold or used for all purposes in the United States, 1943–45, in short tons

Use	1943	1944	1945
Limestone (as given in this report) (approximate)	128,980,000	115,506,000	112,240,000
Portland cement (including "cement rock") [1] Natural cement ("cement rock") [1]	35,867,000	24,148,000	27,332,000
Lime [2]	13,193,000	12,947,000	11,841,000
	178,040,000	152,601,000	151,413,000

[1] Reported in terms of cement in chapter on Cement.
[2] Reported in terms of lime in chapter on Lime.

SANDSTONE

Sandstone was the only major commodity in the crushed stone industry to show a loss in sales value in 1945 compared with 1944. The quantity sold declined 32 percent and the value 23 percent. The most striking recession (55 percent) was in stone sold for concrete and road metal, and for this use the average value per ton declined from $1.14 to only 81 cents. Quartzite (ganister) sold for the manufacture of silica brick gained 22 percent in quantity and 23 percent in value. A gain was also recorded for sales of railroad ballast, but production of sandstone for riprap and "other uses" declined.

Sandstone (crushed and broken stone) sold or used by producers in the United States in 1945, by States and uses

State	Refractory stone (ganister)		Riprap		Crushed stone: Concrete and road metal		Crushed stone: Railroad ballast		Other uses [1]		Total

Average unit value		$2.27		$0.92		$0.81		$0.96		$6.25		$1.84

[1] Includes sandstone for chemical use, concrete blocks, poultry grit, rock wool, roofing granules, spalls, stone sand, waste, and unspecified uses.
[2] Included under "Undistributed."

MISCELLANEOUS STONE

Crushed and broken stone, other than the five principal varieties already discussed, includes light-color volcanic rocks, schists, boulders from river beds, serpentine, and flint. The following table shows sales of stone of these types, by States and uses, in 1945; such sales increased 13 percent in quantity and 26 percent in value over 1944.

Miscellaneous varieties of stone (crushed and broken stone) sold or used by producers in the United States in 1945, by States and uses

[1] Includes stone used for ornamental concrete, refractory, road base, roofing granules, and spalls.
[2] Included under "Undistributed."
[3] Chats; figures collected by Joplin, Mo., office of the Bureau of Mines.
[4] A small quantity of stone included with chats.

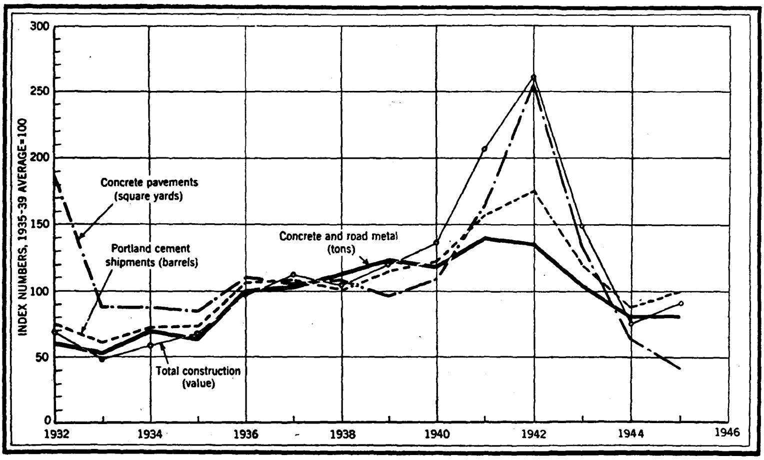

FIGURE 3.—Crushed-stone aggregates (concrete and road metal) sold or used in the United States compared with shipments of portland cement, total construction (value), and concrete pavements (contract awards, thousands of square yards), 1932–45. Data on construction and concrete pavements from Bureau of Foreign and Domestic Commerce.

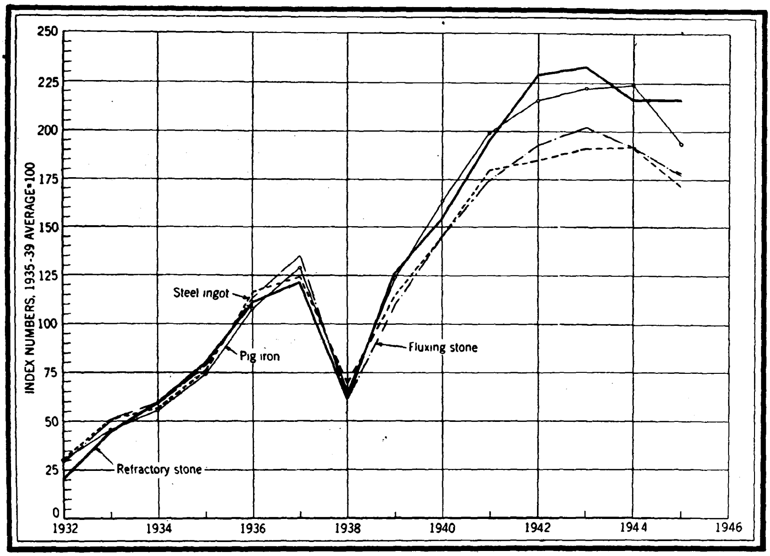

FIGURE 4.—Sales (tons) of fluxing stone and refractory stone, including that used in making lime, as recorded in the chapter on Lime, compared with production of steel ingot and pig iron, 1932–45. Statistics of steel-ingot production compiled by American Iron and Steel Institute.

MARKETS

The principal use of crushed stone is as aggregate in concrete for both highway and building construction. It is natural, therefore, that crushed-stone sales should follow the trends of portland-cement shipments, the area of new concrete pavements, and value of new construction. These relationships are indicated in figure 3. Concrete-pavement construction continued its downtrend in 1945—a drop of 36 percent compared with 1944, which, in turn, was less than half as great as in 1943. As this decline was offset to a large extent by the 20-percent increase in value of total construction, the decline in crushed-stone sales was very small. Cement shipments made substantial gains.

The metallurgical industries operated at high capacity during most of 1945. Pig-iron production of over 53 million tons was 13 percent lower than the all-time high record of 1944. Steel production of nearly 80 million tons was 10 percent below the all-high time of 1944. The market for fluxing stone was, therefore, strong until the last quarter of 1945.

A high rate of furnace production not only demands abundant supplies of fluxing stone but also large quantities of refractories to line the furnaces and keep them in repair. The principal refractories so used are dead-burned dolomite and silica brick. Ganister (quartzite) is the chief constituent of the latter. The close relationships of fluxing-stone output to pig-iron production and of refractory stone to steel-ingot manufacture over a period of years are indicated in figure 4.

OUTLOOK

The principal use of crushed stone is as aggregate for concrete in building construction and highways. The vast accumulated need for reconditioning and widening existing streets and highways, building new roads, public and private building construction, reclamation projects, and other public works furnishes an enormous potential market for aggregates. The volume of the market will depend primarily on the ability of industry and Government (Federal, State, and local) to set these innumerable projects in motion. It is to be expected, therefore, that the output of aggregates will expand steadily throughout 1946 and attain large proportions in 1947.

Production of fluxing stone and of stone for the chemical and processing industries is an important feature of the limestone industry, and demands for these products will probably be strong in consonance with the anticipated high level of industrial activity.

FOREIGN TRADE[1]

Imports of stone, which were reduced greatly during the war, showed substantial increases in 1945. Marble imports were about three times as great as in 1944 but were still quite small. Granite imports were larger than in any year since 1939. Imports of quartzite, which originate in Canada, maintained a high level. Larger imports of dimension stone are to be expected as trade is resumed with many foreign countries that were cut off during the war.

Exports of stone are never large. They show a moderate gain in 1945.

Stone imported for consumption in the United States, 1944–45, by classes

Class	1944		1945	
	Quantity	Value	Quantity	Value
Marble, breccia, and onyx:

SLATE

By Oliver Bowles and M. G. Downey

SUMMARY OUTLINE

SUMMARY

Sales of slate as a whole gained 16 percent in quantity and 13 percent in value in 1945 compared with 1944. Slate sold as dimension stone (that is, in the form of roofing slate, mill stock, etc.) gained 14 percent in quantity and 15 percent in value.

Roofing-slate sales increased 14 percent in quantity and 22 percent in value but were still abnormally low because in 1944 they reached the lowest point in the history of the industry. The average value per square in 1945 was $9.64, whereas in 1944 it was $9.00. In the Pennsylvania area sales were 8 percent higher in quantity and 15 percent higher in value than in 1944. Total roofing slate sales of New York, Vermont, and Maine, although still at a very low level, were nearly twice as great as in 1944. In the Buckingham region, Virginia, sales increased moderately.

Sales of mill stock gained only 3 percent in quantity and 4 percent in value, and sales of electrical slate, blackboards and bulletin boards, and school slates all registered gains. On the other hand, sales of structural and sanitary slate, vaults and covers, and billiard-table tops suffered substantial losses. The continued decline in sales of structural and sanitary slate reflects the low level of public building construction. Sales of flagstones, stepping stones, and similar products gained 34 percent in quantity and 25 percent in value.

Statistics on slate granules and flour are included in this chapter although they have little in common with the slate products already mentioned. Granules are, in fact, used in making roofing products that compete in the roofing-slate market, but most of the slate used in the manufacture of granules and flour is unsuited for other slate products. The gains of 16 percent in quantity and 12 percent in value for 1945 compared with 1944 probably reflect an increasing volume of reroofing rather than the demands of new construction. In 1945 the average sales value of granules f. o. b. mill was $8.80 and of flour $3.61 per short ton compared with $9.25 and $3.92, respectively, in 1944. These products therefore reversed the almost universal uptrend in unit values in 1945. Figures for sales of granules of all kinds, including slate, are given in the chapter of this volume on Stone.

The following table presents the principal statistical data for the slate industry in 1944 and 1945.

Salient statistics of the slate industry in the United States, 1944–45

	1944			1945				
	Quantity			Quantity			Percent of changes in—

[1] Square feet approximate. Number of pieces: 1944, 479,030; 1945, 353,400.
[2] Includes slate used for walkways, stepping stones, and miscellaneous uses.

SALES

Dimension slate.—The term "dimension slate" is applied to blocks or slabs of specified sizes and shapes. It includes all slate products except granules and flour. The following table shows sales of dimension slate for a 5-year period.

Slate (other than granules and flour) sold by producers in the United States, 1941–45

Year	Roofing			Mill stock		Other[1]		Total	
	Squares	Approximate equivalent short tons	Value	Approximate short tons	Value	Approximate short tons	Value	Approximate short tons	Value
1941	378,980	140,830	$3,180,766	18,680	$1,076,814	21,480	$152,254	180,990	$4,409,834

1945	101,300	38,240	976,122	11,520	742,345	19,900	253,273	69,660	1,971,740

[1] Includes flagstones, walkways, stepping stones, and miscellaneous slate.

As roofing slate is used chiefly in residential building it is interesting to follow the trend of roofing-slate sales compared with the number of new dwelling units built. This relationship is indicated in figure 1. From 1929 to 1938 slate sales compared favorably with the normally expected requirements of the very small building programs of those years, but since 1938 they have fallen far below the normal demands of new dwelling units erected. This condition is probably due to the prevalence during war years of housing construction so low-priced or so temporary in character that slate was not a suitable material.

Mill-stock slate is used most widely in nonresidential building, and sales of mill stock have followed rather closely the trend of such construction since 1925. During the war years both nonresidential building and mill-stock sales were at a low level. The relationships are shown in figure 1.

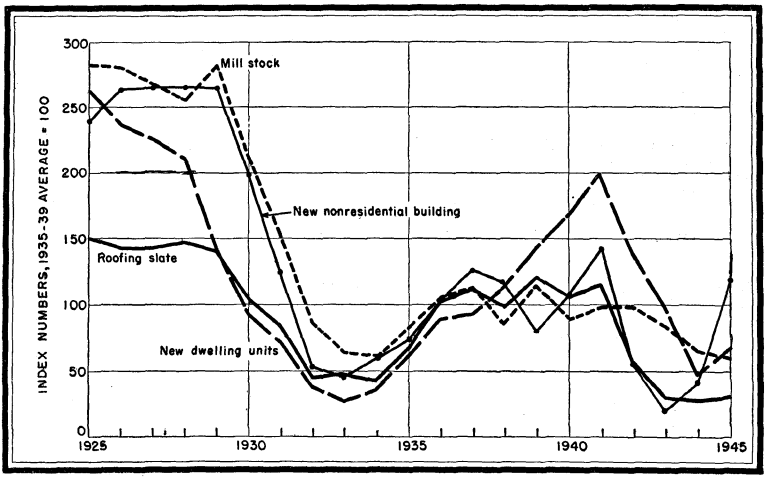

FIGURE 1.—Sales of roofing slate and mill stock compared with number of new dwelling units and value of new nonresidential building, 1925–45. Data on new nonresidential building from Bureau of Foreign and Domestic Commerce, on new dwelling units from Bureau of Labor Statistics.

Figure 2 presents graphically a statistical history of slate over a 31-year period, by uses. The chart illustrates the relative inactivity in the slate industry, brought about by both wars and depressions.

Figure 3 presents the history of slate production, by uses, on a quantity basis. The large-tonnage products that have a relatively low unit value assume greater prominence in this chart than in figure 2.

Granules and flour.—Granules are used chiefly in surfacing prepared roofing. Flour, most of which is recovered as a byproduct of the granule industry, is used as a filler in road-asphalt surface mixtures, paints, roofing mastic, linoleum, and various other products. The substantial gain in sales of granules in 1945 is remarkable in view of the low level of building construction. Maintenance and repair evidently consumed a large part of it. Sales for a 5-year period are indicated in the accompanying table.

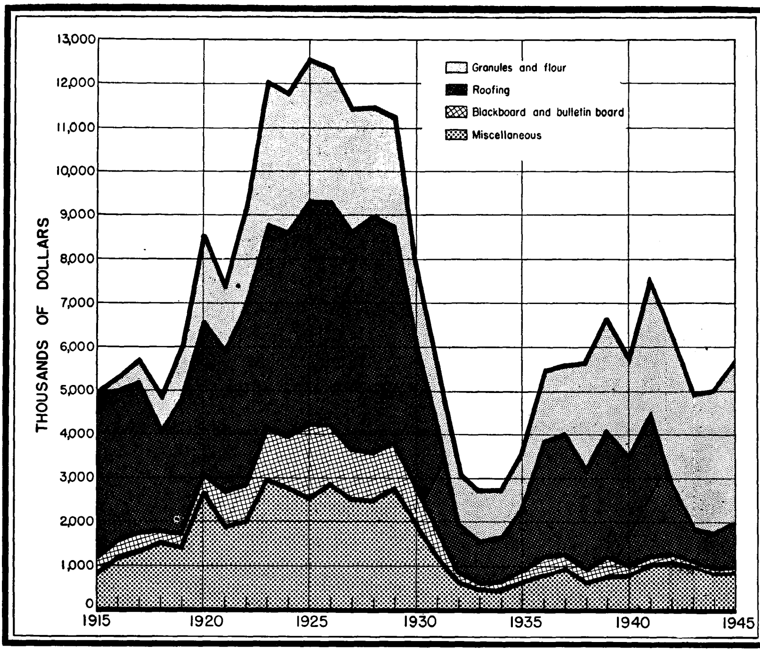

Figure 2.—Value of slate sold in the United States, 1915–45, by uses.

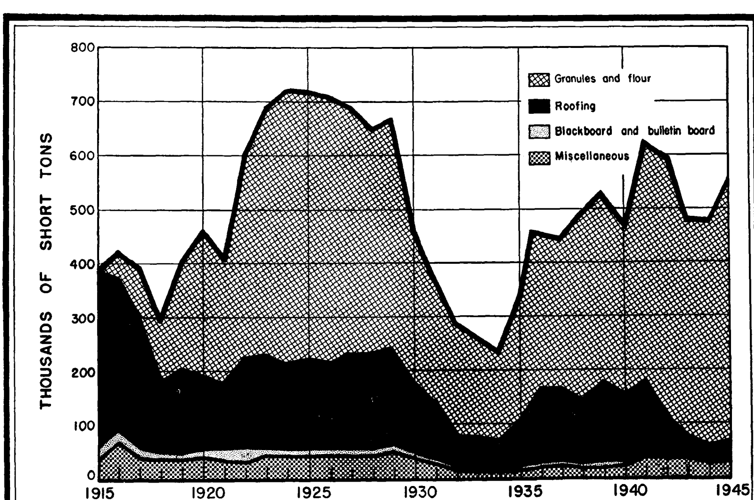

Figure 3.—Quantity of slate sold in the United States, 1915–45, by uses.

Crushed slate (granules and flour) sold by producers in the United States, 1941–45

Year	Granules		Flour		Total	
	Short tons	Value	Short tons	Value	Short tons	Value
1941	323,740	$2,708,246	113,930	$397,554	437,670	$3,105,800
1942	356,510	2,955,562	127,230	448,854	483,740	3,404,416
1943	292,330	2,547,399	103,220	376,489	395,550	2,923,888
1944	309,170	2,861,014	107,720	422,223	416,890	3,283,237
1945	374,800	3,299,593	107,430	387,580	482,230	3,687,173

PRICES

The average price of roofing slate, f. o. b. quarry or mill, as reported to the Bureau of Mines increased 64 cents a square in 1945 compared with 1944. In Pennsylvania it increased 52 cents a square, in Virginia 51 cents, and in the New York-Vermont and Maine areas $1.06.

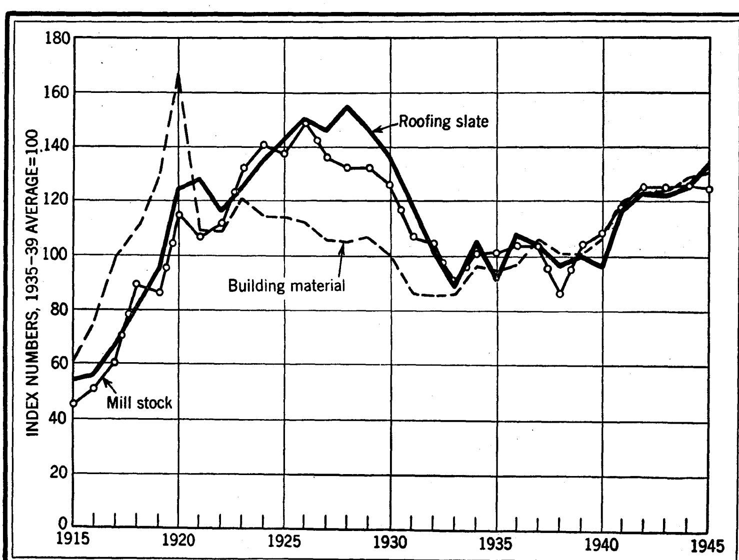

FIGURE 4.—Prices of slate compared with wholesale prices of building materials in general, 1915–45. Wholesale prices from Bureau of Labor Statistics.

The average value of mill stock remained unchanged at 35 cents per square foot. The average value of electrical slate increased 2 cents, structural and sanitary slate 4 cents, blackboards and bulletin boards 2 cents, and billiard-table tops 1 cent per square foot compared with 1944. The average value per square foot of vaults and covers declined 2 cents. The sales value of granules declined 45 cents and of slate flour 31 cents a short ton.

Price history.—Figure 4 shows the trend of slate prices compared with prices of all building materials over a 31-year period. During recent years they have been in remarkably close accord.

REVIEW BY STATES AND DISTRICTS

The following table gives sales of slate in 1945, by States and uses.

Slate sold by producers in the United States in 1945, by States and uses

State	Operators	Roofing		Mill stock		Other uses (value) [1]	Total value
		Squares (100 square feet)	Value	Square feet	Value		
Arkansas	1					$50,000	$50,000
California	1					(2)	(2)
Georgia	1					(2)	(2)
Maryland	1					(2)	(2)
New York	6	(3)	(3)			857,465	[3] 857,465
Pennsylvania [4]	17	75,970	$704,061	1,767,530	$462,432	763,248	1,929,741
Vermont and Maine	14	[3] 16,020	[3] 170,594	340,250	279,913	1,466,469	[3] 1,916,976
Virginia	5	9,310	101,467			(2)	(2)
Undistributed						803,264	904,731
Total: 1945	46	101,300	976,122	2,107,780	742,345	3,940,446	5,658,913
1944	44	89,090	802,179	2,041,210	715,689	3,486,327	5,004,195

[1] Flagging and similar products, granules, and flour.
[2] Included under "Undistributed."
[3] Roofing slate in New York included with Vermont and Maine.
[4] For details of production in Pennsylvania, see following table.

Maine.—The principal product of the quarries near Monson is electrical slate. As in 1944, only one company was active.

New York-Vermont.—In order that the output of an individual firm may not be revealed, Maine has been included with Vermont in the accompanying table. The total value of slate products sold in Vermont and Maine was approximately 21 percent greater in 1945 than in 1944, although the figures are not quite comparable because roofing-slate production in New York is included with Vermont and Maine in 1945 but not in 1944. Roofing-slate production in Vermont increased substantially in 1945, and sales of the colored slates of this area may be expected to increase greatly when moderate- to high-priced residential building construction revives. Production in New York, which consisted chiefly of granules, was considerably higher than in 1944.

Peach Bottom district.—The slate quarries in the area near Cardiff, Md., and Delta, Pa., produced only granules and flour in 1945, although they are potential producers of high-quality roofing slate.

Lehigh district.—The quarries of Lehigh and Northampton Counties, Pa., furnish all types of slate products and comprise the most productive slate area in the United States. As separate figures may not be shown for York County, which includes part of the Peach Bottom district, it is included with Northampton County in the accompanying table showing detailed figures for Pennsylvania.

The total value of all slate products sold in the Lehigh district in 1945 was 6 percent higher than in 1944. Roofing-slate sales were 8 percent higher in quantity and 15 percent higher in value. Mill-stock products are more important than roofing in this district. The total value of mill products sold was less than 1 percent greater than in 1944. Sales of blackboards and bulletin boards gained 29 percent in quantity and 41 percent in value, and school slates 20 percent in quantity and 18 percent in value. On the other hand, sales of the following mill-stock products declined decidedly: Electrical (23 percent in quantity and 22 percent in value), structural and sanitary (21 percent in quantity and 12 percent in value), vaults and covers (10 percent in quantity and 16 percent in value), and billiard-table tops (16 percent in quantity and 15 percent in value). The value of miscellaneous products (chiefly granules and flour) gained 1 percent. Most of the slate in this area is a blue-black "soft-vein" well-adapted for structural products as well as for roofing. Detailed figures for production in Pennsylvania are given in the following table.

Slate sold by producers in Pennsylvania in 1945, by counties and uses

County	Operators	Roofing slate		Mill stock					
				Electrical		Structural and sanitary		Vaults and covers	
		Squares (100 square feet)	Value	Square feet	Value	Square feet	Value	Square feet	Value
Lehigh	5	4,720	$44,320	31,320	$12,882	1,650	$634	180	$54
Northampton and York [1]	12	71,250	659,741	20,920	8,168	297,140	125,539	307,920	84,904
Total:									
1945	17	75,970	704,061	52,240	21,050	298,790	126,173	308,100	84,958
1944	18	70,220	614,077	67,530	26,985	380,180	142,981	341,420	101,679

County	Mill stock—Continued						Other uses (value)	Total value
	Blackboards and bulletin boards		Billiard-table tops		School slates			
	Square feet	Value	Square feet	Value	Square feet	Value		
Lehigh	106,850	$22,852			307,570	$8,033	$7	$88,782
Northampton and York [1]	542,620	147,507	151,360	$51,859			763,241	1,840,959
Total:								
1945	649,470	170,359	151,360	51,859	307,570	8,033	763,248	1,929,741
1944	502,730	121,030	179,800	61,069	256,280	6,815	753,260	1,827,896

[1] York County produced granules and flour only.

Virginia.—The principal product of the Buckingham County quarries is roofing slate. Output gained 4 percent in quantity and 9 percent in value in 1945 compared with 1944. Because of the small number of operators, sales of granules and flour may not be shown.

Other districts.—Slate products, chiefly granules and flour, were produced in Montgomery County, Ark., near Glenwood; near Placerville, El Dorado County, Calif.; and in Bartow County, Ga., near Fair Mount.

NEW DEVELOPMENTS

Pennsylvania State College is conducting a research program in which emphasis is placed on the development of new products from waste slate. The manufacture of expanded aggregates for use in lightweight concrete is among the most promising. Preliminary tests indicate favorable strength-to-weight ratios. In 1945 a 31-ton sample of waste slate was shipped to Ironton, Ohio, where the Alpha Portland Cement Co. passed it through one of its cement kilns. A satisfactory aggregate that would float on water was obtained at a calcination temperature of about 2,100° F. Progress has also been made toward evaluating the microscopic, X-ray, and chemical characteristics of slate.

OUTLOOK FOR THE FUTURE

The degree of prosperity in the slate industry depends primarily on the volume of residential construction. The shortage of housing that resulted first from the prolonged depression of the 1930's, and intensified by the war conditions that followed, had reached such proportions that it became a leading national problem early in 1946. A need exists for millions of homes, and a building program of large proportions will undoubtedly get under way when manpower shortages in the building-material-supply industries are relieved and some solution is found for the difficult labor-relations problems. Slate should benefit greatly from an enlarged program of residential building. There is, however, a possibility that the urgency of the need for human shelter will stimulate a type of construction so low in unit cost that slate will be used sparingly. Such a contingency looms large only so long as building materials are in such short supply that a large proportion will be allocated to low-priced housing. When the raw materials of construction become plentiful, homes of the better class will doubtless be built in large numbers because the need for them exists and the funds to finance them are available. A great revival in slate sales is definitely in view; when it will materialize is problematical; but the strong uptrend in residential building early in 1946 is encouraging. The greatest handicap to increased slate production early in 1946 was manpower shortage.

FOREIGN TRADE [1]

Imports.—As indicated in the following table, slate imports have been very small during recent years.

Slate imported for consumption in the United States 1939–45, by countries [1]

Country	1939	1940	1941	1942	1944
Canada	$570		$189	$177	
China	26	$21	45		
Hong Kong	4		26		
Italy	356	324			
Japan	61	175	7		
Mexico					$50
United Kingdom			1,381		1
	1,017	520	1,648	177	51

[1] No imports during 1943 and 1945.

[1] Figures on imports and exports (unless otherwise indicated) compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

Exports.—The following table lists the value of exports of slate products for a 5-year period as reported to the Bureau of Mines by shippers. The gain of 36 percent in value of exports in 1945 over 1944 is encouraging.

Slate exported from the United States, 1941–45, by uses [1]

SAND AND GRAVEL

By G. W. Josephson and G. E. Tucker

SUMMARY OUTLINE

SUMMARY

In the first half of 1945 the sand and gravel industry marked time, but after the end of hostilities sales for building construction increased rapidly. On the other hand, sales of industrial sands decreased in the latter part of the year as industry was reconverted to peacetime production. Highway construction was slow in starting, so little postwar activity was noticeable in paving material figures in 1945. Over-all production was slightly higher in 1945 than in 1944. Prices increased, as did wages and many other costs.

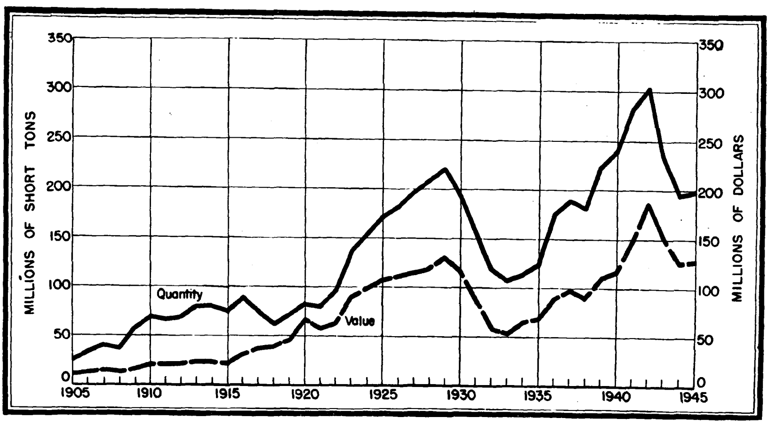

Figure 1.—Total production of sand and gravel in the United States, 1905–45.

FUTURE OUTLOOK

The predicted boom in building construction was well on the way to realization by the end of 1945. Home-construction needs of the country are of a magnitude that can keep the building industry busy for years, and this demand is supplemented by substantial needs for commercial buildings. At present there appears to be enough savings and credit available to finance the program if neither runaway inflation nor deflation destroys the purchasing power of the people who intend to own the homes.

Some funds for highway construction are now available; and, although Government agencies are reluctant to appropriate money for huge programs, road-building activity is expected to increase.

As the prospects of the manufacturing industries are generally conceded to be favorable, demand for industrial sand should likewise be active in the immediate future.

Sand and gravel sold or used by producers in the United States, 1944–45, by commercial and Government-and-contractor operations and by uses

[1] Includes blast sand as follows—1944: 482,293 tons valued at $1,228,744; 1945: 318,390 tons, $766,013.
[2] Includes ballast sand produced by railroads for their own use as follows—1944: 40,486 tons valued at $10,263; 1945: 17,792 tons, $2,429.
[3] Includes some sand used by railroads for fills and similar purposes as follows—1944: 286,965 tons valued at $57,060; 1945: 220,244 tons, $44,356.
[4] Includes ballast gravel produced by railroads for their own use as follows—1944: 9,097,590 tons valued at $2,896,111; 1945: 8,587,465 tons, $2,987,940.
[5] Includes some gravel used by railroads for fills and similar purposes as follows—1944: 1,605,789 tons valued at $308,780; 1945: 843,969 tons, $133,494.
[6] Approximate figures for States, counties, municipalities, and other Government agencies directly or under lease.

PRODUCTION

After reaching a record total of over 304,000,000 tons in 1942, production of sand and gravel declined in the following 2 years, but in 1945 the trend was reversed—output was 0.4 percent greater than in 1944. The increase was principally in the production of building sand and gravel. With the exception of glass sand, the tonnage of the industrial sands declined substantially, and postwar highway construction programs had not yet shown their full effect on paving materials. As stocks of sand and gravel are relatively small and constant from year to year, production virtually equals sales. The terms are used interchangeably in this report.

Sand and gravel sold or used by commercial and Government-and-contractor producers in the United States, 1941–45

Year	Sand		Gravel (including railroad ballast)		Total	
	Short tons	Value	Short tons	Value	Short tons	Value
1941	103, 835, 000	$62, 152, 000	184, 880, 000	$85, 055, 000	288, 715, 000	$147, 207, 000
1942	107, 371, 000	74, 443, 000	196, 975, 000	114, 057, 000	304, 346, 000	188, 500, 000
1943	82, 053, 000	62, 263, 000	152, 011, 000	90, 530, 000	234, 064, 000	152, 793, 000
1944	68, 978, 000	54, 054, 000	125, 805, 000	71, 110, 000	194, 783, 000	125, 164, 000
1945	71, 726, 000	54, 856, 000	123, 798, 000	73, 981, 000	195, 524, 000	128, 837, 000

California produced more than any other State, and Illinois, Michigan, and Texas followed in that order. In only these four States did output total more than 10,000,000 tons. The following tables show details of production, by States and uses, in 1945.

Sand and gravel sold or used by commercial and Government-and-contractor producers in the United States in 1945, by States

State	Short tons	Value	State	Short tons	Value

[1] Included under "Undistributed."
[2] Includes items entered as "1."
[3] Includes 318,390 tons of blast sand valued at $766,013.
[4] Includes 17,792 tons of ballast sand valued at $2,429, produced by railroads for their own use.
[5] Includes 220,244 tons of sand valued at $44,356, used by railroads for fills and similar purposes.
[6] Includes 8,587,465 tons of ballast gravel valued at $2,987,940, produced by railroads for their own use.
[7] Includes 843,969 tons of gravel valued at $133,494, used by railroads for fills and similar purposes.

Government-and-contractor production.—As shown in the accompanying chart, output of sand and gravel from "noncommercial" or Government-and-contractor operations accounted for nearly half the total tonnage in 1939. By 1942 it had declined to less than a quarter and in 1945 it was only 22 percent of the total production.

States reported 37 percent of the total in 1945, counties 44, municipalities 3, and other agencies 16.

In 1945 contractors furnished 32 percent of the Government-and-contractor tonnage, which compares with 56 percent in 1943. The average value increased 5 cents per ton in 1945.

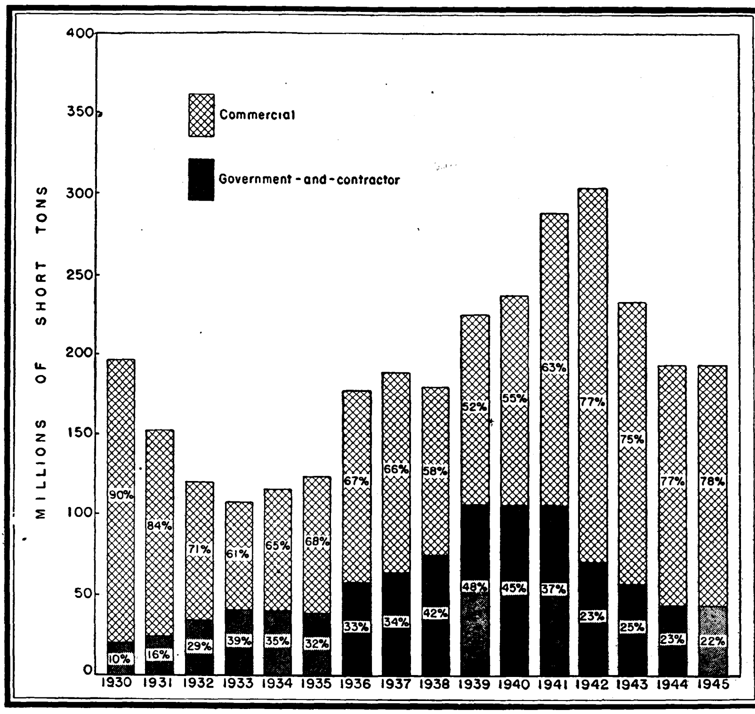

FIGURE 2.—Sand and gravel sold or used in the United States by commercial and Government-and-contractor producers, 1930–45.

Other agencies	27,827,000	.63	23,824,000	.54	5,727,000	.59	7,161,000	.73
	71,399,000	.41	57,595,000	.43	44,150,000	.37	43,386,000	.42

METHOD OF TRANSPORTATION

As more tires, trucks, and repair parts became available in 1945 and railroad cars were often scarce, a greater proportion of sand and gravel shipments moved by truck. Waterways handle a minor portion of the national total, but in some areas they are dominant. As shown in the accompanying table, trucks and railroads handle nearly equal tonnages from the commercial plants; but, taking Government-and-contractor output into consideration, truck transportation dominates the industry as a whole.

Sand and gravel sold or used by commercial producers in the United States, 1944–45, by methods of transportation [1]

Method of transportation	1944		1945	
	Short tons	Percent of total reported	Short tons	Percent of total reported
Truck	58,210,087	42.4	61,439,488	43.5
Rail	68,899,663	50.1	69,456,386	49.2
Waterway	10,359,959	7.5	10,389,771	7.3
Total reported	137,469,709	100.0	141,285,645	100.0
Percent of total commercial production covered		91.0		92.9

[1] For practical purposes the entire output of Government-and-contractor operations commonly is moved by truck. Including Government-and-contractor production, sand and gravel moved as follows—1944: Truck 56 percent, rail 38 percent, and waterway 6 percent; 1945: truck 57 percent, rail 37 percent, and waterway 6 percent.

DEGREE OF PREPARATION

Whereas Government-and-contractor sand and gravel commonly includes a high proportion of unprepared material, the reverse is true of commercial plants. As preparation adds substantially to production costs commercial output has a higher average value. The accompanying table shows this relationship in the past 2 years. Of the total sand and gravel production in 1945, 71 percent was classified as prepared.

Sand and gravel (prepared or unprepared) sold or used by producers in the United States, 1944–45, by commercial and Government-and-contractor operations

	1944			1945		
	Quantity		Average value per ton	Quantity		Average value per ton
	Short tons	Percent		Short tons	Percent

SIZE OF PLANTS

After reaching 87,000 tons in 1942, the average plant output declined to 62,000 tons in 1944—almost as low as before the war. In 1945 average plant production increased to 68,000 tons. The plants producing over 500,000 tons decreased from 30 to 28 and supplied only 15.2 percent of the tonnage as compared with 17.1 percent in 1944; but, as shown in the accompanying table, the contributions of the small plants (less than 25,000 tons) also decreased. However, the middle-size plants, producing 50,000 to 400,000 tons, increased in number. Details of output, by size groups, are given in the following table.

Comparison of number and output of commercial sand and gravel plants in the United States, 1944–45, by size groups [1]

Size group, in short tons	1944				1945			
	Plants [2]		Production		Plants [2]		Production	
	Number	Percent of total	Short tons	Percent of total	Number	Percent of total	Short tons	Percent of total

[1] Plants operated by or for States, counties, municipalities, and other Government agencies are not included; also not included are approximately 180 railroad plants with an output of 11,031,000 tons of sand and gravel in 1944 and 165 plants with an output of 9,669,000 tons in 1945.
[2] Includes a few companies operating more than 1 plant but not submitting separate returns for individual plants.

PRINCIPAL TRENDS

Sand and gravel for construction.—When hostilities ended the demand for home and other building construction, accumulated during the war and the depression, made itself felt. As this demand

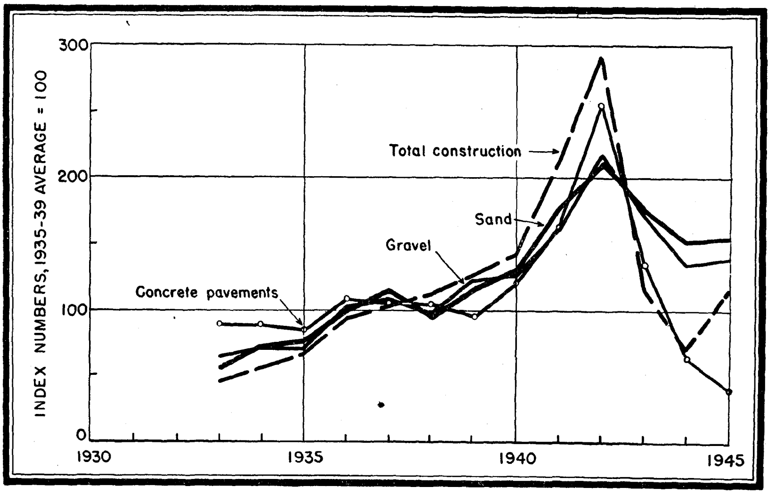

FIGURE 3.—Value of sand and gravel production compared with total construction (contract awards, value) and concrete pavements (contract awards, thousands of square yards) in the United States 1933-45. Data on construction and concrete pavements from Bureau of Foreign and Domestic Commerce.

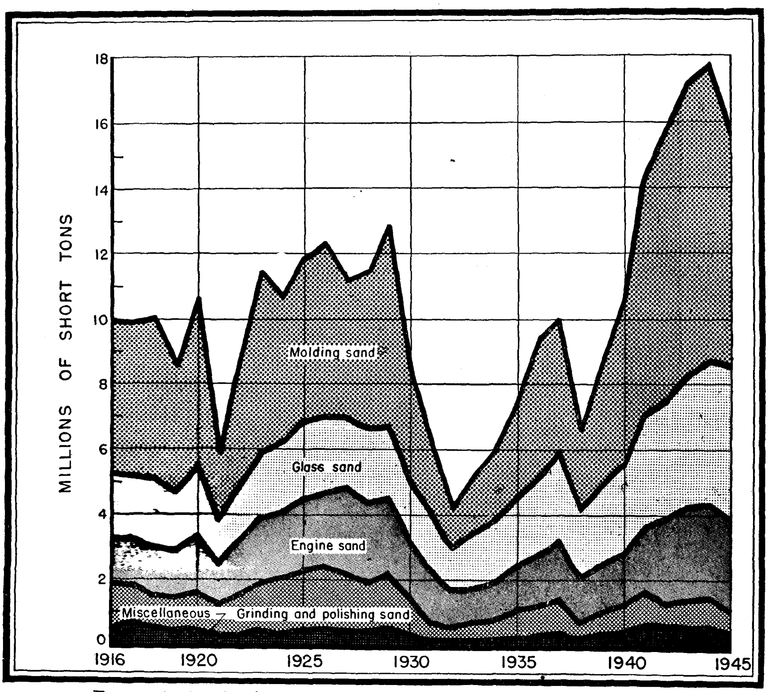

FIGURE 4.—Production of industrial sands in the United States, 1916-45.

is supported by substantial private savings and easy credit, it should continue at a high level for a number of years. Similarly, highway construction has been neglected during the war and is likely to increase substantially as public funds are made available.

Industrial sands.—Although output of most industrial sands declined considerably in 1945 owing to reconversion problems, their prospects are far from dark. Their volume depends upon the level of industrial production; and, barring major financial dislocation, industry is likely to be busy in the immediate future producing goods that are now in great demand.

EMPLOYMENT AND PRODUCTIVITY

Although more men became available in the latter half of the year, manpower was scarce in 1945. Total employment declined to an average of somewhat less than 22,000 men. As shown in the following table the average number of hours worked per day also decreased, and productivity improved.

Employment in the commercial sand and gravel industry, sand and gravel produced at plants included in the study, and average output per man in the United States, 1939–45 [1]

[1] Excludes plants operated by or directly for States, counties, municipalities, and other Government agencies.

PRICES

In 1945 the average value, reflecting the rise in labor and other costs, increased for most classes of sand and gravel. However, the rise was a comparatively modest 3.1 percent for the whole, and for commercial plants it averaged only 1.4 percent. Details of valuation are shown in the summary table at the beginning of this chapter. Sand and gravel prices were controlled by the provisions of Maximum Price Regulation 188 of the Office of Price Administration.

NEW DEVELOPMENTS

Although it is difficult to point out any spectacular technical developments in 1945, progress was being made. Plants that had been overworked during the years of record production needed rehabilitation. In renewing their equipment, many operators were incorporating improvements of all kinds that have become available in recent years. This will raise the general level of efficiency and quality and enable producers to meet the trend toward increasingly stringent specifications. For example, trade journals published descriptions of installations designed to deliver a product containing more fines.[1 2 3]

The widespread demand for more fines in concrete aggregates led to a Nation-wide study of past grading analyses by the National Sand and Gravel Association. This showed that 61 percent of the 214 sources had less than 2 percent of minus 100-mesh material in their product and 90 percent had less than 3½ percent. With speci-

fications of over 2 percent becoming routine, the majority of sand producers are finding it necessary to modify their practice.

Geophysical exploration for gravel deposits is not common, but sometimes it may be effective and inexpensive. A paper outlining use of earth resistivity method by the Public Roads Administration was published in 1945.[4]

FOREIGN TRADE

Imports of sand and gravel are small when compared with the total domestic production—0.14 percent in 1945; however, the tonnage is relatively large. The accompanying table shows imports during the past 10 years. In 1945 Canada furnished 200,280 short tons of sand valued at $126,097 and 78,863 tons of gravel worth $42,015. The United Kingdom and Bermuda furnished less than 1 ton each. Exports are not now separately classified by the United States Department of Commerce, but before 1939 they ranged from 25,000 to 100,000 tons a year.

Sand and gravel imported for consumption in the United States, 1936–45, by classes

Year	Sand				Gravel		Total	
	Glass sand [1]		Other sand [2]					
	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value
1936	52,944	$117,706	124,013	$62,193	201,398	$38,142	378,355	$218,041

1945	(3)	148	200,280	126,102	78,863	42,015	279,143	168,265

[1] Classification reads "Sand containing 95 percent silica and not more than 0.6 percent oxide of iron and suitable for manufacture of glass."
[2] Classification reads "Sand, n. s. p. f."
[3] Less than 1 ton.

BLAST-FURNACE SLAG

In 1945 output of commercialized blast-furnace slag totaled 12,635,868 tons, 2 percent more than the 12,405,992 tons reported in 1944. Sales of air-cooled slag increased 3 percent. These statistics are based on a canvass, conducted by the National Slag Association, of the 32 companies that prepared blast-furnace slag for commercial use.

Practically all of the commercial production is east of the Mississippi River, chiefly at steel centers in Ohio, Alabama, Pennsylvania, and Illinois. Shipments, however, are made into all States east of the Mississippi except some of the New England States outside the economic range of sources of supply. Shipments of slag are made by rail-

[4] Moore, W., Prospecting for Gravel Deposits by Resistivity Methods: Pit and Quarry, vol. 38, No. 3, September 1945, pp. 77-80.

road, truck, and waterway. The accompanying tabulations show the pattern of distribution during the past 4 years.

The average shipping range of blast-furnace slag in 1945 was 63 miles by rail, 15 by truck, and 125 by waterway. In most instances shipments did not exceed 100 miles by railroad, 30 by truck, and 250 by waterway.

Shipments of commercial slag in the United States, 1941–45, by methods of transportation [1]

[Percent of total]

Method of transportation	1941	1942	1943	1944	1945
Rail	55	52	56	56	67
Truck	43	47	44	44	33
Waterway	2	1	(2)	(2)	(2)

[1] National Slag Association. [2] Less than 0.5 percent.

Details of the tonnage and value of slag consumed in the various uses are shown in an accompanying table. An outstanding development is the increased production of lightweight slag for use in building construction. To service the seemingly insatiable demand for building materials in the latter part of 1945, installation of concrete-block plants reached a record rate. As they began to operate, demand for aggregates grew in proportion. Tests and experience both in this country and in Europe indicate that properly expanded slag is particularly valuable for this use. Most foamed slag is produced with the Brosius and Caldwell machines in the United States, but other methods are under investigation also.

In 1945, slag processors reported that 158,186 tons of iron were recovered—approximately 24 pounds per ton of slag handled.

Not including those assigned to administrative, office, and sales activities, 1,414 plant and yard employees were engaged in the production of commercial slag in 1945.

Air-cooled blast-furnace slag sold or used by producers in the United States, 1944–45, by States [1]

GYPSUM

By Charles L. Harness and M. G. Downey

SUMMARY OUTLINE

SUMMARY

Despite price difficulties and shortages of labor and materials, the gypsum industry as a whole recovered in 1945 from the wartime low of 1944. Small increases were recorded for both mined and calcined gypsum, the generally accepted barometers of the industry. Receipts of Canadian gypsum, for use in plaster and wallboard plants on the Atlantic seaboard and for peanut fertilizer in the Southeast, were the highest since 1941, although still much below prewar levels. Sales of most gypsum building products showed increases, although sales of some low-profit items (including lath) and temporary structural materials (sheathing and laminated board) declined.

When the War Production Board on October 15, 1945, abolished Conservation Order L-41, which had controlled construction since April 1942, rapid improvement in the availability of most construction items was expected. These expectations were not borne out. Accordingly, the Civilian Production Administration issued Priorities Regulation 33 on December 20, 1945, effective January 15, 1946, requiring that dealers in construction materials set aside certain percentages of their sales for veterans and low-cost reconversion housing. The commodities affected included gypsum board and lath. The CPA estimated that the material set aside would be adequate for 400,000 dwelling units and that the remainder would supply the needs of 100,000 additional units. That some such action in the case of gypsum board was necessary is shown by the gradual increase in producers' unfilled orders, which amounted on January 1, 1945, to about 30 days' production but by the end of 1945 had increased to 3 or 4 months' production.

It soon became apparent that the construction industry would require additional assistance and that the 500,000 houses originally aimed at by Priorities Regulation 33 were inadequate. A bill (H. R. 4761) was introduced in Congress to amend the National Housing Act, placing wide powers of price control and priorities under the control of the National Housing Administration. Under the system of controls provided in the bill, Housing Expediter Wilson W. Wyatt proposed to allocate construction materials to 700,000 conventional houses, 250,000 temporary units, and 250,000 permanent prefabricated houses in 1946, followed by 600,000 prefabricated houses and 900,000 conventional houses in 1947.

Salient statistics of the gypsum industry in the United States, 1941–45

[1] Each mine, plant, or combination mine and plant is counted as 1 establishment.
[2] Excludes byproduct gypsum.
[3] Made from domestic, imported, and byproduct crude gypsum.

The United States Department of Commerce [1] estimated that 2,101 million square feet of gypsum board (including lath) would be required for the 1,200,000 houses contemplated for 1946 and that 3,431 million square feet would be needed for all construction during 1946.

H. R. 4761 passed the House of Representatives March 7, 1946, and the Senate in amended form April 10. A conference, to follow reconvening of the House on April 30, was agreed on by both Houses of Congress.

The bill provided for subsidies to encourage production of construction materials whenever necessary and to assist financially the installation of new production capacity. In view of the new and enlarged board mill capacity under construction in many parts of the country during 1945 and 1946 there is some doubt as to whether further development will be needed.

In early 1945 the gypsum products industry experienced the severest labor shortage in its history. It was not until the fall of the year that relief was felt. According to the United States Department of Labor, 4,900 persons were employed in gypsum-product plants in February 1946 compared with 4,000 in February 1945, 4,600 in February 1944, and 4,300 in February 1943.

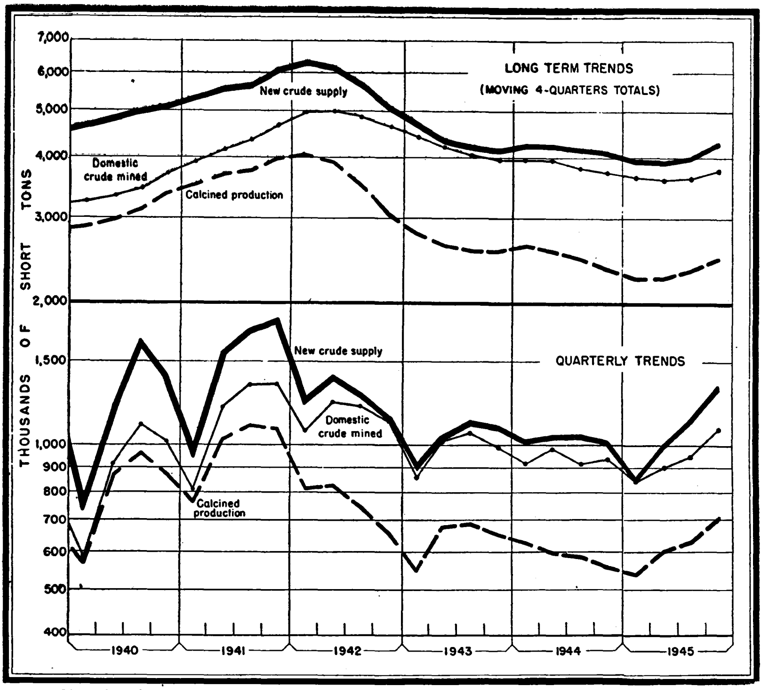

FIGURE 1.—Trends of new crude supply, domestic crude mined, and production of calcined gypsum 1940–45 by quarters.

DOMESTIC PRODUCTION

Increased output of crude gypsum in Texas, Iowa, and Michigan overcame by a small margin decreases in California, Nevada, and New York, resulting in a 1-percent gain in 1945 production over 1944, the wartime low.

Active operations totaled 49, comprising 22 underground mines, 19 open quarries, and 8 mine-quarry combinations.

Crude gypsum mined in the United States, 1943–45, by States

State	1943			1944			1945		
	Active mines	Short tons	Value	Active mines	Short tons	Value	Active mines	Short tons	Value

[1] By groups of States as follows—1943: Arkansas (1), Kansas (2), and Oklahoma (2)—371,893 tons valued at $501,203; Colorado (3), Montana (2), South Dakota (1), Utah (2), and Wyoming (1)—166,547 tons, $235,628; Ohio (2) and Virginia (2)—470,064 tons, $814,645. 1944: Arkansas (1), Kansas (2), and Oklahoma (2)—295,604 tons, $472,789; Colorado (2), Montana (2), South Dakota (1), Utah (2) and Wyoming (1)—165,360 tons, $296,033; Ohio (2) and Virginia (2)—515,075 tons, $1,023,140. 1945: Arizona (1), Arkansas (1), and Kansas (2)—120,422 tons, $160,156; Colorado (3), Montana (2), South Dakota (1), and Wyoming (1)—129,587 tons, $243,214; Ohio (2) and Virginia (2)—477,595 tons, $1,356,592; Oklahoma (2), and Utah (2)—223,983 tons. $317,752.

CALCINED PRODUCTION AND PROCESSING EQUIPMENT

The calcined production in 1945 was obtained from 44 active plants distributed through 19 States. Active calcining equipment in these plants comprised 176 units. The average mill value of calcined gypsum, which is a "transfer value" assigned by producers, was $5.82 per short ton, a drop of 4 cents from the 1944 value.

Calcined gypsum produced in the United States, 1944–45, by districts [1]

District	1944		1945	
	Short tons	Value	Short tons	Value
New Hampshire, Vermont, Massachusetts, and Connecticut	39,084	$288,714	50,102	$394,764

[1] 1943: Includes rotary and beehive kilns and grinding-calcining units; 1944–45: Includes rotary and beehive kilns, grinding-calcining units, and hydrocal cylinders.
[2] 1943: 1 calcining plant each in Connecticut, Florida, Georgia, Indiana, Massachusetts, New Hampshire, Oklahoma, South Dakota, Vermont, and Wyoming; 2 each in Colorado, Kansas, Montana, Nevada, New Jersey, Ohio, Utah, and Virginia. 1944: 1 calcining plant each in Connecticut, Florida, Indiana, Massachusetts, Oklahoma, South Dakota, and Vermont; 2 each in Colorado, Kansas, Montana, Nevada, New Jersey, Ohio, Utah, and Virginia. 1945: 1 calcining plant each in Connecticut, Georgia, Indiana, Massachusetts, New Jersey, Oklahoma, and South Dakota; 2 each in Colorado, Kansas, Montana, Nevada, Ohio, Utah, and Virginia.

DISTRIBUTION OF SALES, BY USES

Industrial plaster requirements eased even before the war's end, making more plaster available for the Nation-wide construction which began immediately after WPB Limitation Order L–41 was dropped. Sales of uncalcined gypsum were higher than in 1944, as the decrease in shipments of agricultural gypsum was more than compensated by a sharp recovery in portland-cement retarder sales.

Figure 3, correlating sales of lath and other gypsum board with floor area of construction, shows that the gypsum industry failed to get its share of the new construction in 1945. This was due to no lack of demand but to shortages of labor in mines and mills and to lack of shipping facilities from Nova Scotia.

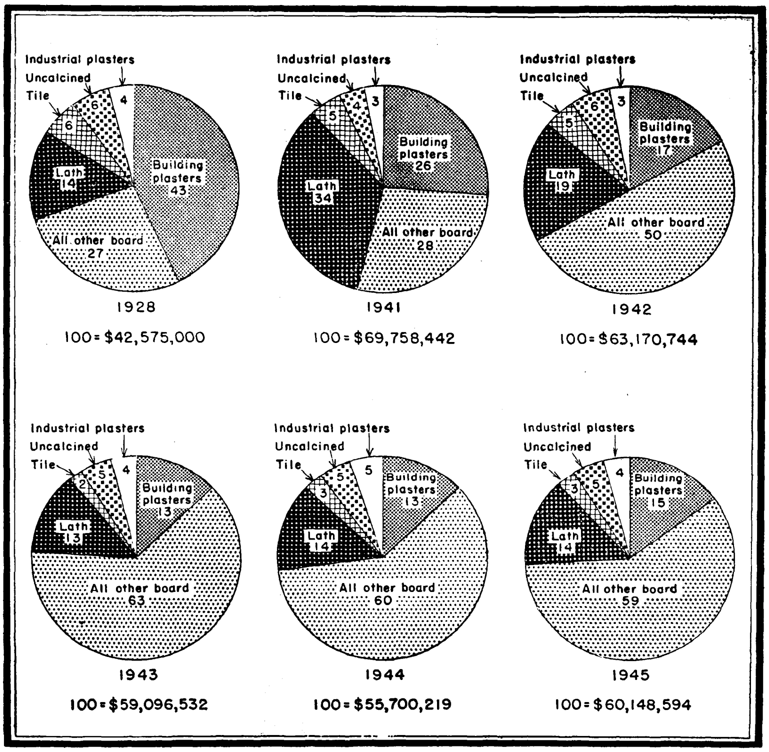

FIGURE 2.—Percentage distribution of total sales value, f. o. b. plant, of gypsum products in 1928 and 1941-45, by groups of products.

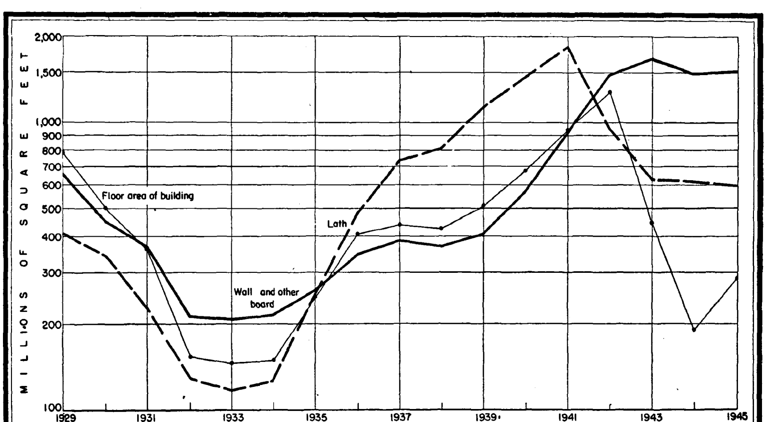

FIGURE 3.—Trends in sales of gypsum lath and wallboard and other board (includes wallboard, laminated board in terms of component board, and sheathing) compared with Dodge Corp. figures on floor area of residential and nonresidential building, 1929-45.

Shipping space from Nova Scotia continued to be restricted during 1945, although less so than in 1944, and Nova Scotia anhydrite available for dusting the peanut crops in Florida, Georgia, and Virginia was in very short supply. Considerable agricultural gypsum was shipped from Plasterco and Saltville, Va., but not enough to meet all demands of peanut growers. Nova Scotia anhydrite commonly analyzes 80 to 85 percent calcium sulfate, but, as it is an anhydrous sulfate its sulfur content is higher than that of gypsum, which contains 21 percent water.

Gypsum products (made from domestic, imported, and byproduct crude gypsum) sold or used in the United States, 1944–45, by uses

[1] Per M square feet, f. o. b. producing plant.
[2] New product first marketed in 1942.
[3] Includes partition, roof, floor, soffit, shoe, and all other gypsum tiles and planks.
[4] Per M square feet, f. o. b. producing plant, of partition tile only.
[5] Reported as area of component board and not of finished product.

PRICES

Except for certain modifications discussed hereafter, the prices of gypsum products continued "frozen" in 1945 under Maximum Price Regulation 188 of the Office of Price Administration, based on March 1942 levels. Amendment 70 to Order A–1, February 15, 1945, permitted board mills in Indiana, Iowa, Michigan, Ohio, New York, Massachusetts, Pennsylvania, and Virginia to add actual transportation costs to their f. o. b. plant ceilings for wallboard, lath, sheathing, and laminated gypsum products destined for export from Atlantic ports on Government or Lend-Lease orders. Under Amendment 85 to Order A–1, July 3, 1945, producers of gypsum lath were permitted to add freight costs to lath shipped to Florida, Georgia, Alabama, South Carolina, and part of North Carolina, provided the additional cost should not exceed freight from Plasterco, Va. On August 21 the OPA increased ceiling prices of gypsum lath 3.82 cents and 2.5 cents per square yard, respectively, in the eastern seaboard and the California-Nevada marketing areas, and on September 14 it raised the ceiling price of calcined gypsum "bag goods" in the eastern seaboard area by $2.40 a short ton from a previous ceiling of about $12. The increase could be passed on by resellers, it was stated.

On November 15 a ceiling of $25 per M square feet was placed on water-repellent sheathing, in Order 5 to Maximum Price Regulation 592.

About three-quarters of the gypsum produced in the United States is calcined by the producer and does not enter the open market. The remainder is sold largely as portland-cement retarder and agricultural gypsum. The average value for retarder sales in 1945 was $2.26 per short ton and for agricultural sales $3.71.

The average value reported for crude gypsum mined was $1.83. Most producers presumably report the cost of mining as their value of crude gypsum. Some, however, report the actual value of sales. Some who sell part of their crude and calcine the rest assign the selling price as the value for their entire output, whereas others in this category use mining cost for that calcined and selling price for that sold. For these reasons, the value of gypsum reported for a certain State may represent neither the market value nor the cost of mining but probably an intermediate.

PLANT EXPANSIONS

Increased gypsum facilities are being installed in many parts of the country. The National Gypsum Co. is making a notable addition to East coast capacity by erecting a $2,500,000 board and plaster plant in Baltimore with rated capacity 25 percent greater than its Bronx plant. The installation will have six kettles. The Baltimore Port Development Commission is building pier and rock storage facilities for the plant, which will use gypsum imported from its mines at Walton, Dingwall, and Cheticamp, Nova Scotia. The firm's Savannah, Ga., board plant is being expanded 25 percent at a cost of $350,000, and the Portsmouth, N. H., board plant, shut down in 1944 owing to inability to import gypsum, is being reopened. Improvements are being made in the Niles, Ohio, metal lath plant; a new quarry is being opened at Fort Dodge, Iowa; and $300,000 is being spent on the Rotan, Tex., plant. Two ships were purchased to import Nova Scotia gypsum, and a third was to be acquired in May 1946. The company expects to increase its over-all capacity by 25 percent, it is said.

On the West coast the Kaiser interests are readying the wallboard plant at Long Beach, Calif., leased from Standard Gypsum Co. in 1944, and it is reported that the plant will offer agricultural gypsum, wallboard, and lath by the middle of 1946. The firm has completed negotiations with the Mexican Government for access to an estimated half-billion-ton deposit of gypsum on San Marcus Island on the Gulf of Lower California. The plant was formerly leased and operated by Pacific Portland Cement Co. The latter firm is reported to have sold its Plaster City, Calif., plant to the United States Gypsum Co.

The Blue Diamond Corp., Los Angeles, Calif., is augmenting its open-pit production at Blue Diamond, Nev., by adding underground operations. The firm has ordered new grinding equipment and contemplates enlarging its entire gypsum operation. Sulfur Springs Gypsum Co. has opened a new mine at Thermopolis, Wyo., for gypsum fertilizer. Monterey Gypsum Co. has reopened a deposit near King

City, Calif., which has been worked intermittently since 1898. The plant, which is producing agricultural gypsum, has a capacity of 200 tons per 8 hours. The Arizona Gypsum Co., Phoenix, Ariz., has begun the production of agricultural gypsum.

The Texas Cement Plaster Co. sold its assets, including its open-pit gypsum quarry at Longworth, Tex., and its plaster and board plant at Hamlin, Tex., to the Celotex Corp. of Chicago.

RECENT TECHNICAL DEVELOPMENTS

Resin-impregnated plasters [2] were introduced in 1945.

They offer increased temperature and moisture resistance to contour blocks, check patterns, and mock-ups in foundry and machine shop. The form is rendered tougher if glass wool is added to the plaster mix before it is poured. Resin is added in two ways, either as a slurry mixed with the plaster or as a slurry applied to the set, dried plaster. In the latter application the resin is taken up by capillary action.

Mechanization of gypsum mines received further impetus during the war, owing to the labor shortage. The use of caterpillar-mounted loading machines with battery-operated, rubber-tired shuttle cars in mines of the Certainteed Products Corp. has been described.[3]

RECONVERSION PROBLEMS

As gypsum was an essential war commodity in virtually all of its uses, reconversion to peacetime production in general involves making greater quantities of the same products that were made during the war. Many of the larger producers complain of labor shortages and therefore they welcome the return of war veterans. The manpower lack is perhaps felt more keenly in the mines than in the plants, for underground work is generally less appealing to the inexperienced applicant. The smaller producers appear to be better off as regards manpower than the larger organizations. A potent factor in board production is the shortage of paper liner, which is expected to ease somewhat during 1946.

FOREIGN TRADE [4]

Of the 502,530 short tons of gypsum and anhydrite imported from Canada, 309,980 tons was landed in the New York customs district, 66,507 in the Georgia district, 56,776 in the Massachusetts district, and 32,564 in the Virginia district. The imports from Newfoundland were landed in the Virginia district, and the receipts reported from the Dominican Republic were shipped to Puerto Rico for consumption there.

WORLD PRODUCTION

As shown in the accompanying table, gypsum is mined in many countries. Owing to the late war, output has been generally curtailed the world over and recent figures are lacking for many of the principal producers. World production probably attained nearly 10,000,000 metric tons in 1937 but has been nowhere near that figure in recent years. Among the leading foreign producers in normal times are

France, Germany, Great Britain, Spain, and the Soviet Union. The famous Paris Basin of France is well known for its Tertiary gypsum deposits, many 60 feet thick. German deposits in the Harz Mountains, Thuringia, Saxony, and other areas, were mined not only for building purposes but as a raw material for sulfuric acid and other sulfur chemicals of commerce. Such German data as are available are incomplete, as captive tonnage mined and consumed by cement plants is not counted in the totals. In 1935 (latest available) a production of 855,000 metric tons was reported. Russian figures have not been available since 1934, when output was announced as 688,000 metric tons. Before the Spanish Civil War about 700,000 metric tons were mined in Spain annually; the latest available figures (see table) show about one-tenth that amount, or less.

World production of gypsum, 1938–45 by countries, in metric tons [1]

[3] Rail and river shipments.
[4] Approximate production.
[5] Production of one company only.
[6] Sales.

CANADA

Preliminary figures of the Dominion Bureau of Statistics show sales of 822,380 short tons of gypsum for 1945 compared with 596,164 tons for 1944. The Canadian gypsum industry is reviving. New deposits are being opened and new calcining and other equipment installed. Gypsum, Lime & Alabastine, Ltd., Toronto, placed in operation a new plaster, wallboard, and lath plant at New Westminister, B. C. A permit has been granted to Western Gypsum Products, Ltd., for the construction of a gypsum plant in Alberta costing $250,000. The crude rock will be hauled by rail from the Crows Nest Pass in southwestern Alberta. The same firm is constructing a board plant at Calgary, Alberta, which when completed will employ 50 people. Gypsum mined at Maynook, B. C., will be used.[5] Plans were drawn up to replace the buildings of Canadian Gypsum Co., Ltd., destroyed by fire at Weston, Ont., in February 1945, the program calling for an expenditure of $400,000.[6]

LIME

By Oliver Bowles and F. D. Gradijan

SUMMARY OUTLINE

SUMMARY

The lime industry experienced a moderate decline in 1945. Sales of "open-market" lime totaled 5,920,579 short tons—a decline of 9 percent from 1944 and 10 percent from the all-time high of 1943. The average price per ton increased 24 cents. Quicklime represented 77 percent and hydrated lime 23 percent of the total, whereas in 1944 the percentages were 80 and 20, respectively. Sales of agricultural lime declined 20 percent. The upward trend in the construction industries was reflected in a 6-percent gain in sales of building lime. The decline in production of war materials without a corresponding gain in peacetime manufacturing industries led to a 9-percent drop in sales of chemical and industrial lime and an 8-percent drop in sales of dead-burned dolomite.

The supply situation with respect to chemical and industrial lime continued to be somewhat critical throughout the year. Threatened shortages were due primarily to unavailability of labor.

The permitted maximum prices of building and chemical lime were, except for certain amendments and individual adjustments, continued through 1945 at the March 1942 level as fixed by Maximum Price Regulation 188. Even though Regulation 188 was superseded by Maximum Price Regulation 592 on August 1, 1945, the price freeze, as of March 1942, was not altered. Amendments permitted an upward revision of prices as follows: Effective April 13, 1945, an increase of 45 cents a ton for lime produced in Clark, Delaware, Franklin, and Preble Counties, Ohio; effective May 12, 1945, an increase of 65 cents a ton for lime produced in Virginia, North Carolina, South Carolina, Georgia, Alabama, Tennessee, Mississippi, and Louisiana; effective June 21, 1945, an increase of 75 cents a ton for

Salient statistics of the lime industry in the United States, 1925–29 (average), 1935–39 (average), and 1943–45

[1] Selling value, f. o. b. plant, excluding cost of containers.

lime produced in Arkansas, Kansas, Nebraska, Oklahoma, and that part of Missouri west of the 93d meridian; and effective August 13, 1945, an increase of $1.20 a ton for lime produced in Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, Connecticut, and that part of New York east of the 77th meridian. In addition to these regional authorizations, many individual price adjustments were granted to lime producers in States not covered by the regional amendments.

The regional authorizations did not affect prices of agricultural lime, which were controlled by Maximum Price Regulation 386. However, numerous individual price adjustments were granted producers of agricultural lime.

PRODUCTION

Production in 1945 increased for building uses but declined in all other categories. As stocks of lime are small, the sales given in the following table are regarded as equivalent to production of "open-market" lime.

Lime sold by producers in the United States, 1944–45, by types and major uses

	1944				1945				Percent of change in—

[1] Selling value, f. o. b. plant, excluding cost of containers.
[2] Includes lime used by producers (captive tonnage) as follows—1944: 432,166 tons, valued at $2,570,544; 1945: 368,572 tons, $2,216,373.

CAPTIVE TONNAGE

The reader is referred to the chapter on Lime of Minerals Yearbook, 1944, for a somewhat detailed discussion of the interpretation of captive tonnage as applied to the lime industry by the Bureau of Mines. It is evident that the statistics of greatest interest and value to the lime industry and to others who may be following economic trends are those of the "open-market" lime that freely enters trade. Accordingly, the captive tonnage lime—that is, the lime used in the plant where it is made—is excluded from the statistical tables of this chapter. The only exception is the inclusion of a moderate tonnage of captive lime applied to special uses for which complete coverage was obtained from the lime reports.

The captive tonnage reported to the Bureau as limestone is included in the statistics on limestone in the chapter on Stone of this volume. If reported as lime, it is generally converted to its equivalent of limestone and also included in the statistics of stone.

PRODUCTION BY STATES

In 1945 lime was produced at 189 plants in 36 States and 2 Territories. Production by States and Territories insofar as figures may be segregated, is indicated in the following table.

Lime sold by producers in the United States, 1944–45, by States

State or Territory	1944			1945		
	Active plants	Short tons	Value	Active plants	Short tons	Value

Hydrated lime included in above distribution	1,323,018	10,642,644	8.04	1,355,028	11,422,254	8.43

[1] Included under "Undistributed."
[2] Excludes bleach used in paper mills.
[3] Includes chocolate, cocoa, fruit juices, phosphate baking powders, and unspecified food products.
[4] Includes flotation, cyanidation, bauxite purification, and magnesium manufacture.
[5] Includes mold coating and unspecified.
[6] Includes bleach used in paper mills.
[7] Includes acid neutralization, alcohol, calcium carbonate (precipitated), cement manufacture, polishing compounds, retarder, sulfur, textiles, tobacco, and wool pullers.
[8] Includes lime used by producers (captive tonnage) as follows—1944: 432,166 tons, valued at $2,570,544; 1945: 368,572 tons, $2,216,373.

PRODUCTION BY USES

The use pattern of lime changes from year to year, according to circumstances. Direct and indirect war uses have characterized recent years, and war was the principal controlling influence during most of 1945. A drift to peacetime uses was under way during the last quarter of the year, but reconversion had made too little progress by the end of the year to have any marked effect on the lime industry.

Lime and other liming materials used in agriculture.—The total effective lime content of all agricultural liming materials sold in 1945 decreased 9 percent from 1944.

Building lime.—As building construction of types that use mortar or plaster was at a low level throughout 1945 sales of building lime were correspondingly low, but a 6-percent gain in sales of building lime indicate an upward trend.

Agricultural lime and other liming materials sold by producers in the United States, 1944–45, by kinds

Kind	1944				1945			
	Short tons		Value		Short tons		Value	
	Gross	Effective lime content[1]	Total	Average	Gross	Effective lime content[1]	Total	Average
Lime:

[1] Effective lime contents as follows: Quicklime, 85 percent; hydrated lime, 70 percent; limestone and oystershells, 47 percent; calcareous marl, 42 percent.
[2] Figures supplied by Fish and Wildlife Service.
[3] Preliminary figure.

Chemical and industrial lime.—Although there was a general overall decline of 9 percent in the quantity of lime sold for chemical and industrial uses, the quantities used in several industries increased. Large increases were recorded for water purification, petroleum refining, bleach, sand-lime and slag brick, and paints. The large decline in sales for calcium carbide and cyanamide manufacture was to be expected because of a diminishing need for acetylene gas in welding and in the manufacture of synthetic rubber. The quantities of lime sold for ore concentration and explosives also declined greatly. Further details are indicated in the accompanying table.

HYDRATED LIME

Production of hydrated lime, which gained 2 percent in 1945, represented 23 percent of the total output compared with 20 percent in both 1943 and 1944. Active hydrating plants numbered 125 and were distributed in 34 States and 2 Territories. The following table shows production by States.

Hydrated lime sold by producers in the United States, 1944–45, by States

State or Territory	1944			1945

TRENDS IN PRINCIPAL USES

Building-lime sales, which generally follow the trend of total new construction, failed to keep pace with it since 1939, as indicated in figure 1. Since that year war construction dominated all building activities, and the types of construction that prevailed required relatively little lime. It is apparent from the same figure that refractory lime (dead-burned dolomite) used for furnace linings and lime employed in the chemical and manufacturing industries follow closely the volume of industrial production.

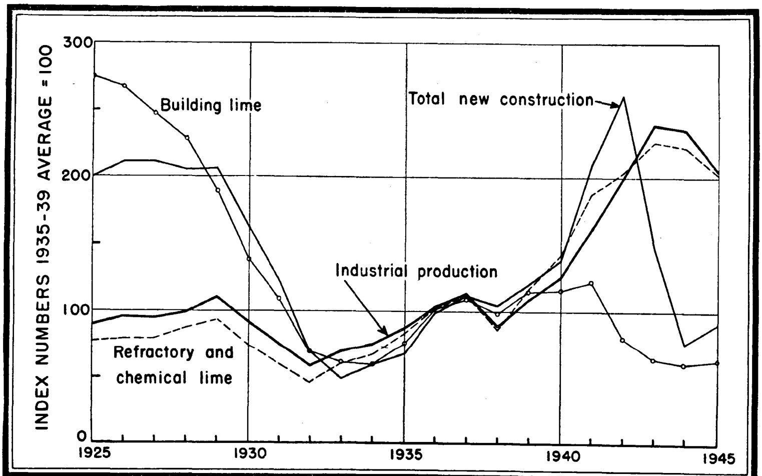

FIGURE 1.—Sales of refractory and building lime compared with total new construction and industrial production, 1925–45. Units are reduced to percentages of the 1935–39 average. Statistics on value of construction from the Bureau of Foreign and Domestic Commerce and on industrial production from the Federal Reserve Board.

Trends in sales of "open-market" lime for its principal uses during the past 21 years are indicated in figure 2. Chemical lime has continued the downward trend begun in 1944. Sales of refractory lime (dead-burned dolomite) have since 1925 followed a course closely

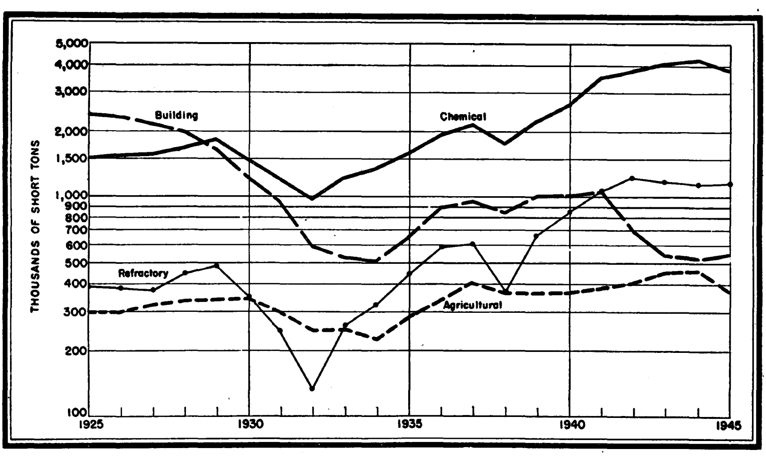

FIGURE 2.—Trends in major uses of lime, 1925–45.

paralleling that of chemical lime. Building lime has reversed its downward course. The volume of sales of agricultural lime was appreciably lower in 1945.

SHIPMENTS

Total shipments.—Output exceeded apparent consumption in 13 of the 36 lime-producing States in 1945. The excess of out-of-State over into-State movements was large only in Missouri, Ohio, Tennessee, and West Virginia.

Sales, shipments, and supplies of lime available for consumption in continental United States, by States and groups of States, are listed in the two following tables.

Lime supplies available in continental United States in 1945, by States, in short tons

MILL VALUES

The net mill realization (excluding container cost) per ton of lime sold in the open market in 1945 averaged $7.76, a gain of 24 cents over 1944 and 49 cents over 1942. The gain in 1945 reflects the various upward price adjustments authorized by the OPA, as recorded in the introductory paragraphs of this report. As in 1944, the largest increase was in agricultural lime.

NEW DEVELOPMENTS

A new type of calcining unit, known as the "Nelson," that has been used in two lime plants in Mexico, was introduced in a lime plant at Provo, Utah, in 1945. This is the first installation on record of such equipment in the United States. The unit is an inclined stationary furnace having a 35° slope. It is said to require little power or supervision and to be economical of fuel. Operating records show that in experimental runs before all mechanical difficulties were overcome the oil consumption per ton of lime was little more than half of the average consumption in United States oil-burning kilns.

The National Lime Association is sponsoring a fellowship at the National Bureau of Standards for continued research on masonry mortars, formerly conducted at the Massachusetts Institute of Technology. These studies are gradually establishing the fundamental characteristics of a mortar that will furnish a strong, permanent, waterproof bond.

SIZE OF PLANTS

The following table presents a grouping of lime plants according to size. The progressive decline in the number of plants operating continued in 1945. The 189 producers in 1945 contrast strikingly with the 450 in 1925, when production was only about three-fourths as great. The decline in the number of active plants is most pronounced in the groups of smaller operations, particularly in the group producing 1,000 to 5,000 tons a year.

Distribution of lime (including refractory) plants, 1943–45, according to size of production

CLAYS

By G. W. Josephson and A. Linn [1]

SUMMARY OUTLINE

GENERAL SUMMARY

Coming as it did in the middle of the year, the effect of the end of the war was only partly visible in the statistics of the clay industry in 1945. Sales of some types, such as rubber clay, increased sharply, but more time will be required to fully reveal the reactions of others. Total output of clay in 1945 was 9 percent greater than in 1944.

Output of kaolin, ball clay, fuller's earth, bentonite, and the common clays increased from 1 to 20 percent; a new record was attained by bentonite. Kaolin benefited from the sudden demand for rubber clay that developed immediately after the end of hostilities. Increased demand from the pottery industry bolstered ball-clay sales. Fuller's earth was still on an upward trend, supported by good demand in the oil industries and expansion of the new uses as absorbents. With the revival of building construction, the production of the common clays began to rise from the low levels reached during the war.

During the early part of the year clay producers held a relatively low priority position, but they were given special consideration by the War Production Board during the latter part.

Prices were under the control of the Office of Price Administration during 1945. In certain cases price increases were authorized for specific products and areas, and a general increase was approved for brick and tile.

Care must be exercised in correlating the clay statistics recorded in this chapter with those published in Minerals Yearbooks prior to 1944. The relationship of the present figures to the previous series is outlined in the clays chapter of Minerals Yearbook, 1944.

[1] Not separately classified prior to Jan. 1, 1945; included with "Other clays."

FUTURE OUTLOOK

During the last few months of 1945 the predicted postwar demand for building construction became a reality. The need for more adequate housing unquestionably exists, and the means of satisfying it are being provided by personal savings, credit, and huge Government appropriations. As it will take years to complete the program, the output of common clays will probably be high for an extended period. Competition with other materials is a factor that may become serious, but it appears that in the immediate future the market will absorb virtual capacity production of structural clay products.

On the other hand, output of fire clay is likely to remain between the wartime and prewar levels. Probably fewer new furnaces will be constructed than during the war, but maintenance should provide a good market.

Bentonite has established so many consecutive new records that further growth seems the only logical conclusion. However, such a large portion of total sales is for use in foundries and rotary drilling that any substantial decline in those activities can interrupt the current rise in bentonite output.

Kaolin and ball clay have good peacetime markets, so sales should be large for some time to come, particularly if competition from foreign clays does not reach serious proportions.

The trend of output of fuller's earth is less predictable. Sales to oil refiners have been relatively stable, and the expansion has been in uses as absorbents. This market is in an early stage of development, so will probably grow; however, there may be a limited period of recession, if machine-shop activity declines, until promotion of wider use in industry is successful.

CONSUMPTION AND USES

The tonnages shown in the accompanying table were compiled from reports of sales by producers for consumption in the various uses indicated. These figures are comparable with similar statistics published in Minerals Yearbook, 1944, and those of kaolin, ball clay, bentonite, and fuller's earth are comparable for previous years as well. Some of the fire clay and miscellaneous clay figures are not comparable with those published prior to 1944, owing to exclusion of captive tonnage in the earlier years. The relationship is outlined in greater detail in the Clays chapter of Minerals Yearbook, 1944.

Clay sold or used by producers in the United States in 1945, by kinds and uses, in short tons

Use	Kaolin	Ball clay	Fire clay and stoneware clay	Bentonite	Fuller's earth	Miscellaneous clay including slip clay	Total

CHINA CLAY OR KAOLIN

As shown on the accompanying chart, the output of kaolin reached a record of 1,087,848 short tons in 1941 and then declined gradually during the following 3 years. In 1945 the trend was reversed, and kaolin output was 8 percent larger than in 1944.

Production was reported from 10 States in 1945, but 92 percent of the total came from 2. Georgia furnished 75 percent and South Carolina 17; most of the remainder came from North Carolina, Florida, and Pennsylvania.

Kaolin has a wide variety of use. Its principal markets are in the paper, rubber, refractory, and pottery industries. In 1945, 59 percent of the total was used as paper filler and coating, 12 in rubber, 10 in refractories, and 8 in pottery.

Consumption of paper clays declined during the war owing to high production of the darker types of paper, but in 1945 sales increased by nearly 34,000 tons and were within 9 percent of the record set in 1941.

When the Japanese cut off our supply of natural rubber, the consumption of rubber clay dropped from 127,055 tons in 1941 to 50,964 in 1943. Part of the decline was due to actual shortage of rubber and later to the fact that the compounding of synthetic rubber requires more carbon black and relatively smaller amounts of kaolin than does natural rubber. But equally important were the wartime restrictions on the manufacture of some nonessential types of mechanical goods and emphasis on high strength rather than attractive appearance for all rubber goods.

At the end of the war manufacturers again turned their attention to the civilian market. The output of mechanical goods increased. In addition, in order to produce rubber goods in the attractive light colors that enhance sales appeal, more clay was added to those that had been in production throughout the war. Consequently, sales of rubber clay increased greatly in the latter part of 1945, and the total for the year exceeded that of 1944 by 84 percent.

The tonnage of kaolin used for refractories totaled 159,886 in 1942, but by 1945 it had declined to 90,703. There is less new furnace construction than in 1942, but maintenance still offers a substantial market.

Consumption of kaolin in pottery in 1945 was 12 percent lower than in 1944.

Prices of kaolin quoted in trade journals were stable during 1945. Sagger clays sell for as little as $2.50 per ton, but most of the processed types are priced between $6 and $25. A few sell as high as $40. English china clay was quoted at $19 to $28 for lump and from $40 up for powdered. The national average value, as reported by producers to the Bureau of Mines, was $9.65 per ton in 1945—substantially higher than the $9 reported in 1944.

Imports of china clay increased 25 percent in 1945, but were less than half as large as the 122,232 tons averaged in 1935–39. A total of less than 3 tons was reported from Canada, Liberia, and Union of South Africa and the rest came from England. Strong competition from English china clay had not yet developed owing to labor shortages and good demand in Britain, but a vigorous effort by the English producers to recapture their American market can be expected. During the war their output was restricted by diversion of manpower to direct war production, and some mines were closed. Many of these have been reopened, operators furnished with equipment, and representatives sent overseas. Britain greatly needs foreign exchange, and as kaolin has ranked second only to coal as a raw material export, the British Government is encouraging this trade as well as assisting the expansion of her pottery industry.

Before January 1, 1945, exports of kaolin from the United States were not separately classified, but the United States Department of Commerce reports that 12,402 short tons of kaolin or china clay valued at $130,977 were exported in 1945.

BALL CLAY

The highest output of ball clay in the United States was attained in 1941, when sales totaled 198,445 short tons. After 2 years of decline, volume increased moderately in 1944, and this upward trend continued in 1945. Sales in 1945 were 12 percent greater than in 1944 and were the second highest on record.

Almost equal quantities of ball clay were produced in Tennessee and Kentucky, and together they comprised 93 percent of the total output in the United States in 1945.

Prices of domestic ball clay quoted in trade journals ranged from $3 to $18.25, depending upon quality and degree of preparation. The average value reported by producers to the Bureau of Mines has been increasing gradually during the past few years and in 1945 was $9.11 per short ton, which compares with $8.84 in 1944.

Although relatively small quantities are consumed in refractories, tile, and other uses, 91 percent of total sales are reported to be consigned to the producers of pottery.

Imports under the classification of "common blue and ball clays" totaled 17,824 short tons valued at $183,717—approximately the same quantity as in 1944. It was all "unwrought and unmanufactured" English ball clay. Foreign ball clays still enjoy a good reputation in the United States, but domestic substitutes have served satisfactorily during the war. Although English ball-clay producers desire to regain their prewar volume of sales in the United States, they have encountered difficulties. The English ball-clay mines are not highly mechanized, and consequently output can be expanded rapidly only by increasing the working force. Labor was scarce in England in 1945, so clay production was limited. Local demand was high, and rehabilitation programs that have been planned by the British Government probably will take even greater quantities in the future. Studies were made of the possibilities of mechanization, and German methods were investigated by a team consisting of mine owners and technicians.

Similarly, German producers of Vallendar clay would like to regain the market they once served in the United States. These mines, located near Coblenz, also are worked by selective methods, principally in open pits, but they have more mechanical equipment than is commonly employed in the English ball-clay mines. The deposits, which may be as much as 100 feet thick, are stripped with a bucket excavator, and the clay is mined by cutting it into blocks with spades or a plowlike cutter. These blocks usually are shipped immediately or dried in racks in an open-walled shed. Only a very small percentage is dried artificially. When the territory was overrun by our troops, production stopped and remained virtually at a standstill during the remainder of the year. Some mines were maintained but some became flooded. Efforts were being made to resume production because the clay was needed in neighboring countries, but at the end of the year the operating program for these mines was uncertain.

FIRE CLAY

The output of fire clay declined 4 percent in 1945 and totaled about three-fourths as much as was produced in the record year of 1942. Before the war the refractories industry operated at less than

50 percent of capacity; but, as the demand for new furnaces grew, by 1942 it was producing virtually at capacity. Since then volume has declined as building programs were completed. However, the market has not decreased to the prewar level, because high industrial activity requires a large quantity of refractories for maintenance and normal expansion.

Fire-clay deposits are widely distributed, but market and quality considerations concentrate activity in a comparatively few States. In 1945 Ohio supplied 26 percent of the total, Pennsylvania 22, and Missouri 18; the remaining 34 percent was reported from 26 States. A map showing locations of fire-clay mines in the United States was published in the Clays chapter of Minerals Yearbook, 1941.

As shown in the table in the Consumption and Uses section of this chapter, fire clays have a wide variety of uses. In 1945, 73 percent of the total tonnage was used in refractories and 22 percent in heavy-clay products. Refractory use declined 10 percent, whereas consumption in heavy-clay products increased 21 percent.

The average value of fire clay sold on the open market in 1945 was $2.52, as compared with $2.48 reported in 1944. Producers estimated the average value of captive tonnage at $2.58, considerably higher than in 1944 ($2.12). It is difficult to account for this increase, but it probably reflects higher operating costs.

Exports of fire clay totaled 94,602 short tons in 1945—approximately the level maintained during the past several years. Imports were limited to 28 tons valued at $837 from Brazil; they are reported to have been Gross Almerode clay.

BENTONITE

Breaking sales records has become virtually a habit of bentonite producers. In 1945, for the seventh consecutive year, more bentonite was sold or used by producers than in any previous year. Output in 1945 exceeded the 1944 tonnage by 5 percent and tripled that of 1938.

The major markets for bentonite have been developed in the foundry and petroleum industries. Sales for use as a foundry-sand bond increased steadily during the war but declined 11 percent in 1945, when reconversion reduced foundry activity.

On the other hand, sales to the petroleum industry for use in drilling muds, required to control gas pressures, increased 34 percent in 1945, more than compensating for the loss of foundry business. Approximately 28 percent of the total output was used for drilling mud and the same percentage for foundries. A little over 25 percent was used for oil filtering and decolorizing and the remainder in a wide variety of uses.

Almost 66 percent of the total output comes from the Wyoming-South Dakota area; 35 percent was produced in Wyoming and 31 percent in South Dakota.

In crude form bentonite may not sell for more than $2 to $3 per ton, but most of it is sold in prepared form at higher prices. Trade-journal quotations are: Dried and crushed, in bulk, $7.50; pulverized, 200 mesh, bagged, $9.50 to $11; pulverized 325 mesh, bagged, $16. The average value, as reported by producers to the Bureau of Mines, declined slightly, from $6.60 in 1944 to $6.57 in 1945. The average value of the material that is sold by producers has declined from $7.50 in 1943 to $7.29 in 1945.

At one time the American market was served by foreign as well as domestic bentonite, but this is no longer true. No imports were recorded by the United States Department of Commerce in 1945. Exports of bentonite are not recorded separately; producers reported to the Bureau of Mines, however, that they exported 14,684 tons to Canada, Mexico, Britain, Australia, Switzerland, Belgium, Africa, and various South American countries. This figure does not include dealer exports or acid-treated bentonite shipped to foreign oil refineries.

FULLER'S EARTH

The upward trend in output of fuller's earth that began in 1941 continued through 1945, but the rate of increase was reduced. In 1945 approximately 1 percent more fuller's earth was sold or used than in 1944.

As shown in the accompanying chart, wartime demand has doubled the use of fuller's earth since the low year 1940. Expansion in consumption of filtering, decolorizing, and catalyzing materials by the oil industries was helpful, but the greatest increase in demand came from a newly developed market—as an absorbent.

The floors of machine shops are notoriously oily and slippery, and this condition is a constant source of accidents. As fuller's earth was known to have exceptional oil-absorbing properties it was applied experimentally to such floors, with very good results. Not only will it remove the free oil on the surface, but when left on as a floor covering it will even draw accumulated oil out of the floor itself by capillary action. In addition to providing an anti-skid floor that prevents accidents, it reduces the fire hazard and improves visibility in the plant by serving as a light-colored nonglare carpet.

The product was offered in about 1942 and was an immediate success. Sales increased steadily to 57,700 tons in 1945. The market has been expanded by finding a variety of new applications. Not only is it effective on oil and grease, but also syrups, solvents, acids, and other liquids are absorbed. It is even claimed to have virtue as

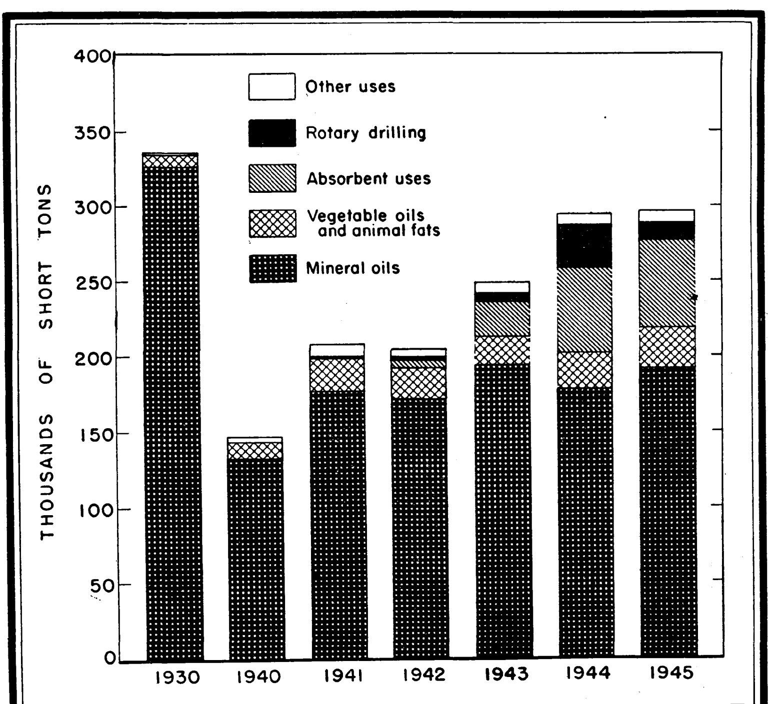

FIGURE 3.—Fuller's earth sold or used by producers for specified uses, 1930 and 1940–45.

a deodorant. The potential market is large. By 1945, uses as an absorbent accounted for 19 percent of total sales of fuller's earth. The petroleum industry took 65 percent for filtering and decolorizing oils and greases, and 9 percent was used for vegetable- and animal-oil processing.

The high quality of fuller's earth from the Georgia-Florida district is indicated by its relatively high value. In 1945, Georgia-Florida reported 45 percent of the total tonnage and 56 percent of the value. Texas, with 35 percent of the total, reported more output than any other State.

Trade-journal quotations of fuller's earth prices were as follows: Georgia and Florida, 30- to 60-mesh, $14.50 per short ton; 15- to 30-, $14; 200- up, $10; and 100- up, $7. Texas material is listed at $12.50 per ton at the mine, but most of it is sold for less than this figure. Imported earth was quoted at $30 to $40 per ton.

The United States Department of Commerce reports that 336 short tons of fuller's earth valued at $4,647 were imported from the United Kingdom in 1945. Exports are not classified separately, but producers reported to the Bureau of Mines that in 1945 they shipped 6,753 short tons valued at $72,135 to Canada, Belgium, Sweden, England, Persian Gulf, and various countries in South America.

MISCELLANEOUS CLAYS

The various types of clay in the foregoing sections of this chapter are classified according to a practical pattern of composition and use that has grown up over a period of years. There remains a very large tonnage of clay and shale of uncertain or divergent specifications that is used in making heavy-clay products and portland cement. With these are grouped, in this "Miscellaneous" section, relatively minor quantities of slip clay, oil-well drilling mud, pottery clay, and small tonnages that find other special uses.

As demand for cement and heavy-clay products by the building industry began to grow following the cessation of hostilities, the production of miscellaneous clays increased, with output for 1945 reaching a total 19 percent above that for 1944.

Most of these clays are dug mechanically in open pits, and their value as raw clay at captive operations is usually less than $1 per ton. On the other hand, the merchant clay sold for an average of $2.30 a ton. Some of the specialties, such as drilling mud, vary from as low as $2 to over $10 a ton.

CLAY PRODUCTS

Although in a few areas, where war construction was active, producers of heavy-clay products had a good market, the industry as a whole declined steadily during the war. Construction was restricted by the War Production Board, labor was scarce, wages and other costs increased, and price adjustments were hard to obtain. Many plants were closed for the duration.

With the end of hostilities, however, the outlook changed. During past years house construction had fallen far short of the needs of the country. This demand, backed by wartime savings and easy credit, was expected to assist the reconversion to a peacetime economy, so construction was encouraged by Government agencies. Consequently the need for clay products mushroomed, and the industry revived as rapidly as it could reopen plants and obtain labor to expand production.

Under Amendment 9 to Order 1 of MPR 592 the OPA approved a general price increase of about 10 percent for brick and tile produced in OPA regions 1 to 12 to assist the industry to obtain labor and increase production.

In the past, heavy-clay-products manufacture has included much hand labor, and the industry has been criticized for not adopting new methods more rapidly. However, the industry has been handicapped financially, and purchase of radically new equipment was difficult. Even so, considerable progress has been made. Power shovels, scoops, and planers have mechanized the pit. Machinery handles the various raw-material processing operations, including the forming of the simpler or more common shapes. But the drying, burning, storing, and shipping operations have used a great deal of hand labor. The scarcity and increasing cost of labor during the past few years have stimulated installation of labor-saving equipment. More and more tunnel kilns are being built to replace other types. Coupling the drier to the tunnel kiln reduces heat losses and rehandling costs still further. Various types of trucks and cranes pick up, carry, and place heavy loads, using pallets or clamps to hold the brick. Belt conveyors are used to advantage in handling both raw materials and brick. Numerous articles describing novel devices and recommended practice have appeared in trade publications.[2]

For example, portable hoppers holding 1,600 pounds of coal, filled daily and placed by a lift truck to feed stokers, will reduce the firing crew substantially.[3]

One factor limiting clay-products output may be a shortage of brick masons. There is said to be an accumulated shortage of over 60,000 bricklayers, and there were relatively few apprentices in 1945. This situation is being corrected as young men return from military service, but training of new men will take time even under intensive training programs. In some localities, schools for apprentices and premium wages while learning on the job have begun to reduce the shortage.[4]

The great increase in popularity of concrete block for building construction during the past year gives the clay-products producer some food for thought. It cannot be said that these concrete units have the durability, water resistance, or attractiveness of structural clay products; but they are being improved, and their competition must be considered seriously. Some structural-clay-products plants have installed concrete-block machines and are then able to supply building contractors with either type of product.

The accompanying table shows shipments of the principal structural clay products during the past 3 years.

Quantity and value of shipments of the principal classes of structural clay products in the United States, 1943–45 [1]

TECHNOLOGIC DEVELOPMENTS

Research is gradually increasing our knowledge of the physical characteristics of clay. A paper outlining a study of the effect of water on the sand-bonding and plastic characteristics of clays was published in 1945. Water is said to be held rigidly on the surface of clay minerals up to a specified thickness. When this is exceeded, plasticity develops on the addition of a relatively small amount of water. Each type of clay seems to have a characteristic ability to

stabilize water, and some require more time than others to reach maximum. More complete understanding of these relationships may lead to better choice and handling of clays for specific uses.[5]

The Research Committee of the Whitewares Division of the American Ceramic Society has initiated an investigation of ball clays. The objective is to increase "knowledge and insight into the reasons for the characteristic nature of clays." The project is cooperative in nature, in that test work is done in many widely distributed laboratories and supervised by a committee representative of all phases of the industry. A symposium containing detailed description and analysis of test methods, as well as a discussion of objectives and line of procedure, was published by the American Ceramic Society in April 1945. This type of collective research promises to reveal fundamental information that can be of real value in the technology of other clays, as well as ball clay.[6]

During the war clay received its first serious consideration as an ore of aluminum. Many processes were developed and tested through the pilot plant, and two reached the commercial-plant stage. However, as enemy interference with our transportation of bauxite from Guiana declined, the immediate need for domestic ore was reduced. At the end of the war support for alumina-from-clay projects became weaker. The operating companies felt that the plants were not yet ready to compete commercially without Government subsidy. Operation continued through 1945, but at the end of the year the future program was uncertain.

In the vicinity of Munich, in the American zone, Germany has a highly developed bleaching-clay industry. The natural bleaching clays found in Germany are of relatively low quality, but it was found that the bentonite clays in the Munich area could be acid-activated. Between the wars, this industry developed a great variety of high-quality products and distributed them to a world-wide market. As the specifications, production methods, and uses of these materials are of interest to American industry the Field Information Agency, Technical, of the War Department, investigated these plants, and a report will be published sometime in 1946.

ABRASIVE MATERIALS

By Robert W. Metcalf and A. B. Holleman

SUMMARY OUTLINE

GENERAL CONDITIONS

Diatomite, pumice and pumicite, and metallic abrasives production rose to new records in 1945. The output of natural abrasives in 1945 totaled 980,780 short tons valued at $9,801,988, an increase of 3 percent in tonnage and 2 percent in value compared with 1944. Artificial abrasives, however, declined 10 percent in tonnage and 12 percent in value compared with 1944, owing principally to the 21-percent drop in output of aluminum oxide. Domestic production of natural abrasives in 1945 constituted 74 and 31 percent, respectively, of the total tonnage and value of artificial and natural abrasives combined, compared with 71 and 28 percent in 1944. Marketed production of emery in 1945 was the highest since 1918, and that of garnet was the highest since 1928. Output of grindstones, pulpstones (for which figures cannot be shown), and grinding pebbles also were larger in 1945 than in 1944. Domestic production of most of the other natural and artificial abrasive products herein discussed, for which data may be shown, registered only moderate declines in 1945 compared with 1944.

The total value of imports of natural abrasive materials in 1945 dropped 43 percent, to $13,493,381. Imports of bort (glaziers' and engravers' diamonds, unset, and miners') accounted for most of this decrease with a 15-percent decline in quantity and a 44-percent decline in value. The lowered receipts probably were due largely to the change in industrial activity because of the close of the war and partly to the more general consumption of smaller, less perfect stones for many industrial purposes. Imports of corundum ore in 1945 continued large and were only 2 percent below the very active year 1944. No imports of crude or prepared pumice were reported in

1945, and only small amounts of garnet, burrstones, grindstones, sharpening stones and tripoli, rottenstone, or diatomite. "Flint, flints, and flintstones" were at more than twice the 1944 level, although much below prewar imports. Natural abrasive materials exported in 1945 were valued at $2,087,598, compared with $2,091,675 in 1944. The value of emery and corundum wheels declined sharply to $144,589, although that of grindstones increased over 60 percent, and that of all other natural abrasive exports showed a moderate gain.

Salient statistics of the abrasives industries in the United States, 1944–45

	1944		1945		Percent of change in 1945	
	Short tons	Value	Short tons	Value	Short tons	Value

[1] Average annual figure for 1942–44. Bureau of Mines not at liberty to publish 1945 data.
[2] Data included in total, Bureau of Mines not at liberty to publish figures.
[3] Data for oilstones and related products in 1944 and 1945 and corundum in 1944 not included in totals; Bureau of Mines not at liberty to publish figures.
[4] Tonnage of millstones not recorded.
[5] Includes Canadian production.
[6] Weight cannot be reported because of varying units.

This chapter includes data for most of the materials used chiefly as abrasives, although certain clays, oxides, and substances mentioned later under Miscellaneous Mineral Abrasive Materials are not included in the statistics presented herein. On the other hand, certain of the abrasive materials for which figures are shown also have important nonabrasive uses.

In the mechanical finishing of aluminum articles, the finer abrasives and reduced wheel speeds are essential to obtain the most attractive finish.[1] Recommendations are made for the proper abrasives and wheels used in roughing, greasing or oiling, buffing, and coloring aluminum products. Tripoli, soft silica, emery flour, and lime are

[1] Aluminum Company of Canada, Ltd., Aluminum Surface Finishes: Montreal, Canada, 1945, 75 pp.

among the abrasive materials employed. The ingredients and composition of abrasive cleaners and their behavior and efficiency for various purposes were outlined by Lesser.[2] Definitions, specifications and description of coated abrasive products such as silicon carbide, aluminum oxide, flint, emery and garnet paper, and belts of various types, and their application to specific industrial operations were published in 1945.[3]

An evaluation of the hardness and other properties of sintered carbides and nitrides indicates that with constant binder volume and grain size the hardness of a sintered alloy depends solely on chemical and physical properties of the materials used.[4] Tests were made of various methods of measuring the hardness of abrasive particles,[5] such as by sand-blast, ball penetration, needle penetration, impact, torsion, and rolling. The sand-blasting, rolling, and impact methods were claimed to be of the greatest practical significance. An Australian handbook recently published by McPhersons, Ltd., Melbourne, contains valuable information on the types and uses of industrial abrasives and operating data and methods of various kinds of grinding equipment.[6]

A treatment has been devised that coats individual abrasive grains with a shell of isotropic vitrescent carbon which, under pressure and heat of grinding, changes to an extremely hard substance claimed to have a cutting power similar to that of diamonds.[7]

NATURAL SILICA ABRASIVES

Diatomite.—The Bureau of Mines has not been at liberty to publish annual production statistics since 1926. Total output (sales) for 3-year periods, however, may be shown. Total sales for the three most recent such periods were as follows: 1936–38, 279,645 short tons valued at $4,377,353; 1939–41, 360,502 tons valued at $5,746,216; and 1942–44, 524,872 tons valued at $9,894,534. The high level of output indicated in the 1942–44 period was exceeded in 1945, although the actual figures cannot be shown.

The principal producing States in 1945, as for many years, were California and Oregon. Increased output was reported in 1945 from Nevada and Washington. No production was made from Florida or Idaho. Other States mining diatomaceous earth in 1945 were Arizona and New York. Statistics of uses of diatomite cannot be shown. It is possible to indicate roughly the relative proportions of shipments for filtration, insulation, and fillers, the principal uses. Filtration accounted for somewhat over half of the total shipments. Fillers took over one-fifth of sales, and insulation about one-eighth. Miscellaneous uses, including small amounts for fine abrasives, comprised the rest.

Quotations on diatomite at the beginning of 1945 were reported in E&MJ Metal and Mineral Markets as follows (prices are per ton on an f. o. b. mill, Nevada, basis): Crude, in bulk, dried, $7, nominal; 98- to 100-mesh, $20; low-temperature insulation, $19; high-temperature insulation, $30; fine abrasive, 2 cents per pound. (Bags extra.) These quotations were changed in February to the following: Crude, in bulk, dried, $10 per ton; 98- to 100-mesh, $25; low-temperature insulation, $25; high-temperature insulation, $40; fine abrasive, 2 to 3 cents per pound. (Bags extra.) In March, filtration grades of California diatomite were quoted by the same journal at $20 to $50 per ton, f. o. b. mill. No other changes were reported during the year.

The Great Lakes Carbon Corp., 333 N. Michigan Ave., Chicago, Ill., on December 1, 1944, acquired the assets and properties of the Dicalite Co., at Walteria, Calif., and Terrebonne, Oreg. This company, trading as the Great Lakes Carbon Corp., Dicalite Division, 756 S. Broadway, Los Angeles, Calif., also took over, on April 1, 1945, the U. S. Diatom property near Basalt, Nev., which had been operated for part of 1944 by the Consolidated Feldspar Corp., Trenton, N. J. Later in 1945 the Dicalite Division acquired the properties of the Kittitas Diatomite Co., Ellensburg, Wash., with plant at Kittitas, thus giving that firm producing facilities in four States. According to trade-journal reports, expansion programs were projected for each of these operations. The American Diatomite Corp., Clermont, Fla., and the Fowler-Reeves Corp., Mina, Nev., have ceased operations. Certain companies reported no or curtailed output on account of scarcity of labor and difficulty of obtaining supplies.

Fresh-water deposits of diatomite in the High Plains region of West Texas in Armstrong, Crosby, and other counties were investigated by Evans.[8] Diatomaceous earth was shipped during 1945 from a large deposit in Digby County, Nova Scotia, Canada; other occurrences in this area are being investigated.[9] Diatomite has been produced in Tarapaca Province in Chile for many years. Large deposits also are said to exist near Mejillones and in Antofagasta Province.[10] Brazil's diatomite industry is claimed to be large and well-developed. This mineral in Brazil largely has been used for building purposes, particularly the manufacture of lightweight roofing tiles, and also as a filtering medium in the refining of sugar.[11] Kenya, in Africa, possesses a small diatomite industry, which markets cleaning powder and metal polishes.[12] An occurrence of diatomite near Carew Peak, New Zealand, was investigated.[13] The revival of the Scottish diatomite industry in the Isle of Skye has been the subject of much discussion. The diatomite there is of a moderately good grade, regarded as especially suited for insulation or possibly as a filler in plastics. Modernization of recovery methods is being contemplated in the revival of this dormant industry.[14]

Occurrence, production, and importance of kieselguhr or diatomaceous earth in Finland's national economy were detailed by Molder.[15] Uses listed include the manufacture of water glass, glazes, enamels, and ultramarine, cement, light brick, and paving materials. It was also used as filtering agent, catalyzer, as a filler in paper, rubber, and paint, and as a heat-insulator.

The mechanics and advantages of the cooling and filtration of wort were discussed by Dietz.[16] Experiments on the use of diatomite as a filler for newsprint resulted in improved stock, according to Hoffner and Kobe.[17] The activation of diatomite was covered by a Russian patent.[18] A practical study of insulating materials in the petroleum industry by Searle [19] included considerable excellent material on the favorable and unfavorable factors when using diatomite either alone or mixed with clay as an insulating medium in stills and cracking furnaces.

Tripoli.—Production of tripoli, amorphous silica, and rottenstone in 1945 totaled 18,247 short tons valued at $306,829, or 1 percent less in quantity and 2 percent more in value than in 1944. Output in Illinois, which was valued at $184,189 and totaled 11,144 short tons, was 7 percent less than in 1944. Other States marketing these materials in 1945 were Missouri and Pennsylvania.

The principal uses of tripoli are as abrasives—chiefly as a constituent of polishing and buffing compounds—and as filler. Tonnages reported as sold for abrasive use were about one-sixth less in 1945 than in 1944, and the quantity reported sold for fillers increased 16 percent. Tripoli sold for "other uses," including foundry facings, more than doubled. A brief discussion of the mining, preparation, and marketing of tripoli is in process of publication and probably will be released by the Bureau of Mines about the middle of 1946. A description of the plant and products of the Barnsdall Tripoli Co., Seneca, Mo., was published in the early part of 1946.[20]

Tripoli (including Pennsylvania rottenstone) sold or used by producers in the United States, 1941–45

Year	Illinois		Other States [1]		Total

As reported in E&MJ Metal and Mineral Markets, quotations on tripoli in 1945 remained unchanged compared with 1944 and other recent years. Prices are per short ton, f. o. b. Missouri, in paper-lined burlap bags, minimum carlot 30 tons: Once ground, through 40-mesh, rose- or cream-colored, $14.50; double-ground, through 110-mesh, rose or cream, $16; air-floated, through 200-mesh, $26. Quotations on rottenstone in 1945, as given in Oil, Paint and Drug Reporter, were the same as in 1944: Carlots, in bags, at mines, $25.50 per short ton; less than carlots, $37.50 per ton.

Firms actively producing tripoli, amorphous silica, and rottenstone in 1945 were: Illinois (amorphous silica)—Tamms Silica Co., 228 N. LaSalle St., Chicago, Ill., with plant at Olive Branch, and Ozark Minerals Co., Cairo; Oklahoma (mine) and Missouri (mill)—Barnsdall Tripoli Corp., Seneca, Mo.; and Pennsylvania (rottenstone)—Penn Paint & Filler Co., Antes Fort, and Keystone Filler & Mfg. Co., Muncy.

Quartz.—Sales of crude, crushed, and ground quartz from pegmatite veins or dikes and from quartzite in 1945 dropped 30 percent in quantity and 17 percent in value compared with 1944. Crude quartz sold in 1945 rose 60 percent compared with 1944, to 24,392 short tons, the highest figure since 1920. Sales of crushed quartz in 1945 were about half those in 1944. Ground material also showed a substantial decline. The average value per ton of all quartz sold in 1945, however, increased to $4.10, compared with $3.48 in 1944 and 1943.

Quartz (crude, crushed, and ground)[1] *sold or used by producers in the United States, 1941–45*

Year	Crude		Crushed		Ground		Total	
	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value
1941	8,977	$39,247	24,101	$94,913	8,607	$94,427	41,685	$228,587
1942	2,043	7,937	45,747	144,808	18,088	178,749	65,878	331,494
1943	6,134	55,600	84,233	183,507	9,078	107,451	99,445	346,558
1944	15,222	35,279	61,823	170,325	5,334	80,874	82,379	286,478
1945	24,392	72,392	28,718	93,631	4,654	70,780	57,764	236,803

[1] To avoid duplication, the ground material shown here is only that ground by the original producers of the crude quartz or by grinders who purchase from small miners not reporting their production.

Sales of quartz in 1945 were reported from 12 States, one more than reported in 1944. The greater part of the output came from Western States, and the decrease in output was due largely to the smaller production of ferrosilicon in Pacific Coast States as a result of the cessation of hostilities. South Dakota and Massachusetts were listed as producers in 1945, but no output was reported from Tennessee.

Quotations on ground "hard quartz" silica, as given in Oil, Paint and Drug Reporter, remained unchanged throughout 1945 at the following levels: 325-mesh (99½-percent grade), carlots in bags, $15.50 per ton, and less than carlots, $18.50; 140-mesh (99½-percent grade), carlots in bags, $11 per ton, and less than carlots, $16.

Quartz (crude, crushed, and ground) [1] *sold or used by producers in the United States, 1943–45, by States*

State	1943		1944		1945

Ground sand and sandstone.—Sales of ground sand and sandstone in 1945 continued at a high level but were 4 percent less in tonnage and 7 percent less in value than in 1944. Sales in 1945 were higher than for any years except 1944 and 1943 and totaled 533,656 short tons valued at $3,709,597. Average value per ton in 1945 declined to $6.95, compared with $7.14 in 1944 and $7.27 in 1943. Production by States or groups of States for which comparable data can be presented indicates a large percent of increase in Georgia in 1945, although New Jersey-Pennsylvania had a greater absolute gain in output. Illinois, Massachusetts, Ohio-Virginia-West Virginia, and "Other States" showed moderate decreases in 1945 compared with 1944. The principal States producing sizable tonnages of ground sand and sandstone are Illinois, New Jersey, Ohio, and Pennsylvania.

Ground sand and sandstone sold or used by producers in the United States, 1941–45

Distribution of sales of ground sand and sandstone by uses, as reported by firms producing 90 percent of the total sales, indicates that over a period of years the chief consumers for these products, in order of total quantity consumed, are the pottery, porcelain, and tile industries, foundries, and manufacturers of cleaning and scouring compounds or other abrasive products. Glass manufacture, enamel, and fillers account for most of the remaining tonnage for which uses are reported.

Ground sand and sandstone sold or used by producers in the United States in 1945, by uses [1]

Use	Short tons	Value	
		Total	Average per ton
Abrasive:			
Cleansing and scouring compound	93,064	$534,156	$5.74
Other	665	4,533	6.82
Enamel	16,783	122,149	7.28

Total reported by uses	479,727	3,320,214	6.92

[1] Data represent 90 percent of the industry.

Abrasive sands.—Natural sands with a high silica content are employed for sand blasting, stone polishing, glass grinding, coating sandpaper, or other abrasive uses. Sales of such grinding and polishing sand in 1945 totaled 642,511 short tons valued at $1,029,501. Included in these data were 318,390 tons of blast sand valued at $766,013. Information with respect to tonnages produced in each State, where these data may be published, appears in the chapter on Sand and Gravel in this volume. Sales of blast sand and total abrasive sands from 1936 to 1945 are shown in an accompanying table. The figures stress the increasing importance of sand blasting operations in modern industry, and particularly their expanding employment in wartime.

Abrasive sands sold or used by producers in the United States, 1936–45, in short tons

Year	Blast sand			Total abrasive sands		
	Short tons	Value		Short tons	Value	
		Total	Average per ton		Total	Average per ton
1936	(1)	(1)	(1)	934,059	$1,306,871	$1.40
1937	(1)	(1)	(1)	1,067,178	1,440,736	1.35
1938	205,753	$509,178	$2.47	502,328	754,805	1.50
1939	220,240	542,915	2.47	668,027	895,989	1.34

[1] Not separately reported.

SPECIAL SILICA-STONE PRODUCTS

Grindstones and pulpstones.—Production of grindstones in 1945 was 7 percent larger in tonnage and 12 percent greater in value than in 1944 but slightly less in tonnage than in 1943. Sales of pulpstones in 1945 increased substantially compared with 1944, although the Bureau of Mines is not at liberty to publish actual data. As in 1944, grindstones were produced in Ohio and West Virginia and pulpstones in West Virginia only.

Grindstones and pulpstones sold by producers in the United States, 1941–45

Year	Grindstones		Pulpstones		
	Short tons	Value	Quantity		Value
			Pieces	Equivalent short tons	
1941	13,573	$434,208	685	1,963	$111,348
1942	12,763	422,763	528	1,918	116,976
1943	10,732	392,296	323	1,891	95,909
1944	9,373	356,106	(1)	(1)	(1)
1945	10,033	399,565	(1)	(1)	(1)

[1] Bureau of Mines not at liberty to publish figures.

Oilstones and related products.—Sales of natural sharpening stones, including oilstones, whetstones, scythestones, and rubbing stones, were somewhat higher in 1945 than in 1944. The Bureau of Mines, however, has not been at liberty to publish sales data since 1939. Producing States in 1945 and the type of abrasive stone reported from each were: Arkansas—oilstones and whetstones; Indiana—rubbing stones and whetstones; New Hampshire—scythestones; and Ohio—scythestones, whetstones, and "other" sharpening stones, including lathestones.

Millstones.—The value of sales of millstones in 1945 totaled $15,018, 55 percent greater than in 1944 and the highest value since 1941. Marketed production of millstones in 1945 was reported by the following: Jasper Stone Co., Sioux City, Iowa, deposit in Rock County, Minn.; George Coddingham, Accord, N. Y., deposit in Ulster County; Gardner Granite Works, Salisbury, N. C., deposit in Rowan County; Interstate Millstone Co., Christiansburg, Va., deposit in Montgomery County.

Value of millstones and chasers sold by producers in the United States, 1941–45 [1]

Year	Producers	Value	Year	Producers	Value
1941	8	$15,579	1944	3	$9,700
1942	5	10,391	1945	4	15,018
1943	4	9,240			

[1] 1941: New York, North Carolina, Virginia, and West Virginia; 1942–44: New York, North Carolina and Virginia; 1945: Minnesota, New York, North Carolina, and Virginia.

Grinding pebbles and tube-mill liners.—Marketed production of grinding pebbles and tube-mill liners combined rose 5 percent in tonnage and 17 percent in value in 1945 compared with 1944 and totaled 10,597 short tons valued at $247,739. Sales of grinding pebbles in 1945 increased 8 percent in quantity and 17 percent in value compared with 1944. The value of tube-mill liners increased 18 percent, although the tonnage sold showed a small decrease of 4 percent. The Bureau of Mines has not been free to publish totals for grinding pebbles and tube-mill liners from 1933 through 1940. Current production levels, although considerably under 1941 and 1942 figures, nevertheless are generally 2 to 4 times those reported to the Bureau of Mines in most years since 1920. During the last two months of 1945, small shipments of flint pebbles were received from Belgium and Denmark, the first since the end of the war.

Grinding pebbles and tube-mill liners sold or used by producers in the United States, 1941–45

Year	Grinding pebbles		Tube-mill liners		Total	
	Short tons	Value	Short tons	Value	Short tons	Value
1941	13,561	$22,826	3,411	$54,216	16,972	$276,042
1942	15,487	245,794	2,576	49,967	18,063	295,761
1943	9,924	157,778	2,585	46,071	12,509	203,849
1944	8,012	172,418	2,063	38,833	10,075	211,251
1945	8,615	201,806	1,982	45,933	10,597	247,739

Grinding pebbles and tube-mill liners in 1945 were produced in the same States as in 1944—grinding pebbles in California, Minnesota, North Carolina, Texas, Washington, and Wisconsin and tube-mill liners in Minnesota, North Carolina, and Wisconsin.

The following firms in 1945 produced for sale the products indicated: John T. Momand, Carlsbad, Calif., beach pebbles; Jasper Stone Co., Sioux City, Iowa, quartzite liners and artificially rounded quartzite grinding pebbles (quarries at Jasper, Minn.); Southern Products & Silica Co., Lilesville, N. C., silica grinding pebbles; Harris Granite

Quarries Co., Salisbury, N. C., rounded granite cubes and liners; Peeler & McCombs, Faith, N. C., rounded granite cubes and liners; Dezendorf Marble Co., Austin, Tex., flint pebbles; Mineral Products Co., Seattle, Wash., grinding pebbles; and Baraboo Quartzite Co., Baraboo, Wis., quartzite pebbles and granite liners.

Comparative grinding tests on hard and fibrous materials using flint, Jasper adamant, zircon, and porcelain balls were described by Metz.[21] Grinding in connection with flotation separation and auxiliary control equipment were high-lighted.

NATURAL SILICATE ABRASIVES

Pumice and pumicite.—Production of pumice and pumicite (or volcanic ash) broke all records in 1945, and rose to 157,011 short tons valued at $1,051,307, 24 percent larger in tonnage and 49 percent higher in value than 1942, the previous peak year. The quantity marketed in 1945 surpassed that sold in 1944 by 77 percent.

Pumice or pumicite was reported from eight States in 1945, the same States as in 1944, with the addition of a small output from Idaho. California replaced Kansas as the chief producing State and accounted for 48 percent of the total production, compared with 30 percent of the total for Kansas. All States for which comparisons are possible showed substantial increases in 1945 compared with 1944, ranging from 10 and 11 percent, respectively, for Kansas and Nebraska to 140 percent for California and a much larger percent of increase for Washington (464 percent).

Pumice and pumicite sold or used by producers in the United States, 1941–45

Year	Short tons	Value	Year	Short tons	Value
1941	117,310	$669,514	1944	88,757	$704,110

Pumice and pumicite sold for concrete admixture and concrete aggregate in 1945 totaled 72,901 short tons, slightly more than the total reported used for all abrasive purposes—71,011 tons—but very much less in value. The increase in output for acoustic plaster and for concrete aggregate and mixtures resulted from the greater use of pumice or pumicite-containing lightweight block and tile in construction, especially in California and Washington. Cleaning and scouring compounds, hand soaps, and other abrasives rose 11 percent in quantity in 1945 compared with 1944 and accounted for 45 percent of the total tonnage marketed. Quantities sold for "other uses" also increased sharply and in 1945 included sales for use in insecticides, insulation, plastics, and solvents.

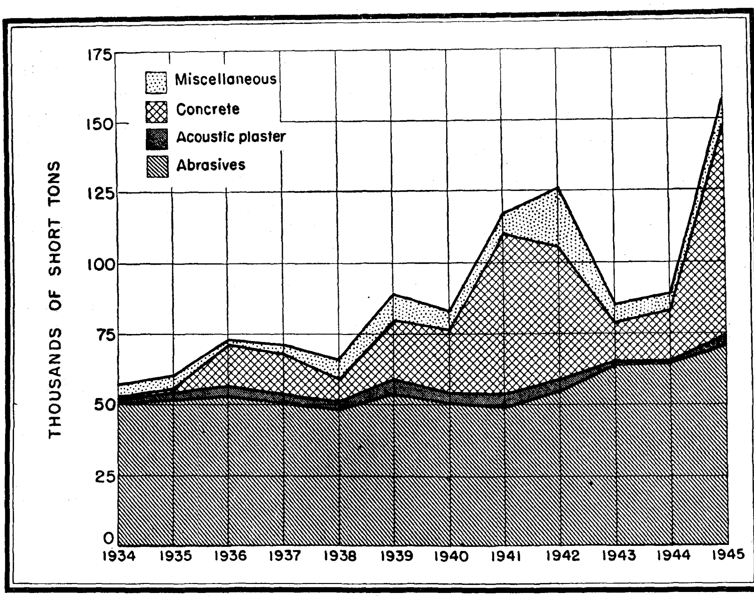

FIGURE 1.—Trends, by uses, of pumice and pumicite sold or used by producers in the United States, 1934–45.

Pumice and pumicite sold or used by producers in the United States, 1943–45, by uses

Use	1943		1944		1945	
	Short tons	Value	Short tons	Value	Short tons	Value

Cleansing and scouring compounds and hand soaps	59, 247	$354, 242	57, 833	$375, 310	63, 704	$434, 928
Other abrasive uses	4, 216	64, 988	6, 094	136, 753	7, 307	229, 212
Acoustic plaster	1, 617	29, 860	938	29, 144	3, 693	78, 278
Concrete admixture and concrete aggregate	13, 794	52, 718	17, 511	90, 136	72, 901	176, 920
Other uses [1]	6, 276	109, 687	6, 381	72, 767	9, 406	131, 699
	85, 150	611, 495	88, 757	704, 110	157, 011	1, 051, 037

[1] 1943: Asphalt, insecticide, paint filler, brick manufacture, filtration, solvents, and unspecified; 1944: Insecticide, insulation, brick manufacture, filtration, solvents, and unspecified; 1945: Insecticide, insulation, solvents, plastics, and unspecified.

Quotations on pumice in 1945, as reported by E&MJ Metal and Mineral Markets, remained unchanged from 1944 figures and were as follows: F. o. b. New York or Chicago, in barrels—lump, 5 @ 7½ cents per lb., and powdered, 2½ @ 4½ cents per lb.

Garnet.—Output of garnet in 1945 rose to 6,306 short tons valued at $375,198, the highest tonnage since 1928 and 6 percent greater than in 1943. The trend in garnet production in the last quarter century is shown in figure 2. Producers in 1945 were the following: Barton Mines Corp., North Creek, N. Y.; Estate of John Burnham, Essex, N. Y.; Garnet Mines, Inc., 725 Paulson Bldg., Spokane, Wash.; and Spokane Garnet Sand & Sales Co., P. O. Box 1452, Spokane, Wash., and its successor, Idaho Garnet Abrasive Co., of the same address. The last three firms all recovered garnet sand from stream beds in western Idaho. A description of the Gore Mountain garnet quarry, operated by Barton Mines Corp., North Creek, N. Y., appeared in 1945.[22] Trade reports indicate possible production in California.[23]

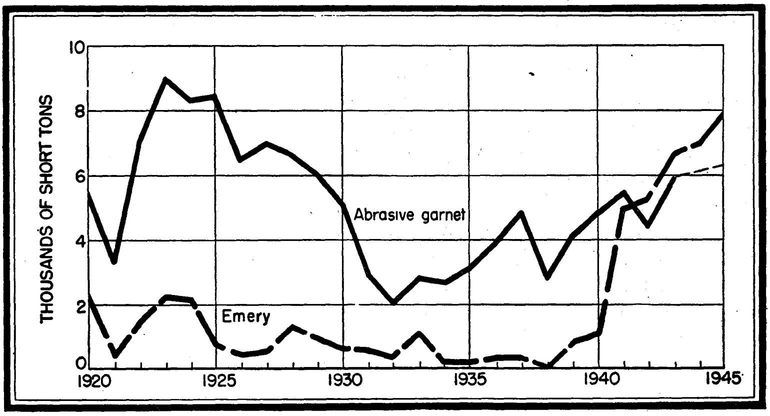

FIGURE 2.—Marketed production in the United States of abrasive garnet and domestic emery, 1920–45.

Quotations on domestic garnet in 1945 as reported by E&MJ Metal and Mineral Markets were the same as in 1944 and immediately preceding years: New York Adirondack garnet concentrates, grain—$85 per short ton.

Abrasive garnet sold or used by producers in the United States, 1941–45

Year	Short tons	Value	Year	Short tons	Value

NATURAL ALUMINA ABRASIVES

Corundum.—Corundum, a natural alumina abrasive, Al_2O_3, was especially needed during the war for use in snagging wheels by companies making tanks, guns, and other heavy military equipment and for polishing highly essential precision lenses.

Efforts to establish and foster a domestic corundum industry resulted only in a small, almost negligible output, which was consumed largely for experimental purposes. Tests were undertaken principally in South Carolina, North Carolina, and Montana. Although considerable tunneling and development work was carried forward, particularly in Montana, activity in each of these States finally was discontinued.

Most of the corundum consumed in the United States for many years originated in the Union of South Africa, particularly in the Transvaal. In normal years this source furnished a fairly steady supply despite the handicaps of distance and transportation difficulties. Production in South Africa during the war was stimulated in every way possible by the Foreign Economic Administration and other agencies. Although imports for consumption in the United States rose considerably during the war years, the receipts were hardly adequate to satisfy the stepped-up demand for production of optical equipment and heavy matériel needed by the Army and Navy. The supply of corundum still is somewhat short of demand. Imports in 1945, however, were maintained at a high level throughout the year and were only slightly under the figure reported in 1944, which was the highest year since 1910. Supplementing receipts from the Union of South Africa, shipments from other countries occasionally have been received, including Canadian material recovered from tailings dumps at now long-abandoned mines.

A study of the control activities of the Government in relation to corundum supplies during the war was published.[24] Efforts to establish a grinding-wheel industry based upon Indian corundum were reported by Rao.[25] Locally compounded bonds were used. The test wheels were said to be satisfactory except for the uneven surface wear due to hand molding.

Quotations on crude corundum imported into the United States are not given in domestic trade journals. Corundum grain throughout 1945 was quoted in E&MJ Metal and Mineral Markets as follows: Per pound, sizes 8 to 60, inclusive, 8¾ cents; 70 to 275, inclusive, 9¾ cents; 500, 30 cents; 850 to 1,000, inclusive, 45 cents; 1,200 to 1,600, inclusive, 60 cents; and 2,600, 70 cents.

Emery.—Sales of domestic emery in 1945 were the largest since 1918, reaching 7,856 short tons valued at $75,977 (see fig. 2), 13 percent higher in tonnage and 17 percent higher in value than in 1944, an active year. The entire output, as in other recent years, was mined in and near Peekskill, N. Y., by Joe DeLuca and DiRubbo & Ellis. Emery is shipped largely as crude rock to manufacturers of grinding wheels, abrasive sticks, polishing compositions, and similar materials. It also is marketed as grain to other makers of abrasive products.

[25] Raja Rao, P. S., High-Speed Grinding Wheels from Mysore Corundum: Trans. Indian Ceram. Soc., vol. 3, No. 1, 1944, pp. 42–48; Am. Ceram. Soc., Ceram. Abs. and Bull., vol. 24, No. 10, Oct. 15, 1945, p. 175.

Considerable amounts are employed as a nonslip, wear-resistant component in concrete floors.

According to E&MJ Metal and Mineral Markets, quotations on crude domestic emery ore remained unchanged in 1945, compared with 1944: $10 per ton for first-grade emery, f. o. b. New York. Grain emery was quoted by the same source as follows (prices are per pound, in 350-lb. kegs, f. o. b. Pennsylvania): Turkish and Naxos, 7 cents; Khasia, 6 cents; and American, 5 cents. The quotation for Indian emery grain (Khasia) was discontinued in July.

NATURAL CARBON ABRASIVES [26]

Abrasive or industrial diamonds.—Industrial diamonds are produced chiefly in the Belgian Congo, and most of the rest of the world's supply is obtained from Gold Coast, Sierra Leone, and Angola. Total sales of industrials in 1944 were placed at £3,800,000, compared with the record figure of about £5,500,000 in 1943. Sales during the war years have exceeded production by large margins, and the war demands for this product have been met only by very heavy withdrawals from accumulated stocks of the Diamond Trading Co. For the most part, these stocks now have been virtually exhausted, particularly in certain classifications. Certain South African mines have been reopened in order to supply, at least partly, the expected demand. Although postwar industrial activity undoubtedly will be somewhat less than during the war, a steady if smaller market for industrial diamonds will continue. The wider use of diamond grinding wheels, used in finish grinding of carbide tools and of hard metals and alloys and other substances, the expansion and greater standardization of diamond-cutting tools, the growing employment of diamonds in blast-hole drilling, and the use of diamond dies for making the fine wires needed in the expected growth of the electronics industry are all indicative of a continued active demand.

Reflecting the curtailment of military production and the resultant current slackening in volume of industrial production, receipts in 1945 of "bort (glaziers' and engravers' diamonds, unset, and miners')"—roughly corresponding to so-called "industrial grades"—dropped to 10,726,372 carats, the smallest year's imports since 1941, but much exceeding quantities received in 1941 and immediately preceding years.

A comprehensive review of all phases of the diamond industry was published.[27] When the shortage of high-quality stones became acute during the war, intense study was devoted to the possibility of

[26] See also chapter on Gem Stones of this volume.
[27] Ball, Sydney H., The Diamond Industry in 1944: Jewelers' Circular—Keystone, New York, 1945, 24 pp.

using lower-grade material for certain uses. In this connection, Whittaker[28] reported, after exhaustive tests, that the lower-quality stones may be substituted for the better grades heretofore employed in dresser tools, provided the stones are selected with suitable care. Criteria and methods of selecting industrial diamonds for specific uses were described by Grodzinski.[29]

The uses and modern applications of diamond dust in industrial operations were summarized in 1945.[30] Conditions in the diamond-cutting industries of the United States and Puerto Rico were investigated.[31] An account of the development of a diamond-die industry in the United States was published.[32] Descriptions of diamond deposits and discoveries in Brazil,[33] Venezuela,[34] and Russia (U. S. S. R.)[35] were given in the trade press.

A large electrical company has undertaken the manufacture of artificial sapphires for use as bearings in navigation instruments.[36] Grodzinski[37] described the use of sapphire plug and ring gages and other types of sapphire gages and workpieces and their much longer life compared to high-quality steel gages. Differences between natural and artificial sapphires were clearly outlined.[38] The manufacture of artificial sapphires for jewel bearings in Great Britain supplied a wartime demand.[39]

ARTIFICIAL ABRASIVES

Production of artificial abrasives (silicon carbide, aluminum oxide, and metallic abrasives) continued at a higher level in 1945, although, except for steel shot and grit (metallic abrasives), tonnages were somewhat less than in 1944. The total tonnage of these three abrasive materials in 1945 was 347,560 short tons valued at $21,892,821, or 10 percent in quantity and 12 percent in value less than in 1944. Shipments of metallic abrasives (steel shot and grit) in 1945 totaled 146,771 short tons valued at $8,524,073, a new high in both quantity and value. Operation was only at 70 percent of capacity, owing to new plants starting in the industry. Production of silicon carbide in 1945 was 4 percent less in quantity and 10 percent less in value than in 1944. Output of aluminum oxide in 1945 decreased 21 percent in tonnage and 22 percent in value to the lowest point since 1940. Production of silicon carbide and aluminum oxide in 1945 was at 75 per-

[1] Production; Bureau of Mines not at liberty to publish data for United States separately. Figures include material used for refractories and other nonabrasive purposes.
[2] Figures include only shipments from United States plants.

Production of silicon carbide and aluminum oxide largely is concentrated in the Niagara Falls region of Canada and the United States; some aluminum oxide, however, also is manufactured in Quebec, Canada, and in Alabama. The same companies that produced aluminum oxide and silicon carbide in 1944 and other recent years were active in 1945. The total for aluminum oxide in 1945 included 18,804 short tons of "white high-purity or special material" valued at $2,065,350, a decline of 27 percent in both tonnage and value compared with 1944. Silicon carbide consumed in refractory or nonabrasive uses in 1945 was estimated at 44 percent of the total production, and aluminum oxide consumed for similar purposes in 1945 was estimated at 4 percent.

Stocks of crude artificial abrasives and capacity of manufacturing plants, as reported by producers, 1936–45, in short tons

Year	Silicon carbide		Aluminum oxide		Metallic abrasives	
	Stocks at end of year	Capacity	Stocks at end of year	Capacity	Stocks at end of year	Capacity
1936	6,613	(1)	14,101	(1)	2,198	(1)
1937	6,074	(1)	17,966	(1)	3,012	(1)
1938	12,568	(1)	32,121	(1)	4,944	(1)
1939	7,475	(1)	21,528	(1)	4,389	(1)
1940	3,621	(1)	18,372	(1)	5,042	(1)
1941	2,640	44,960	19,546	150,146	3,708	136,750

1945	4,347	72,000	31,933	233,300	10,433	209,360

[1] Data not available.

Statistics for metallic abrasives cover steel shot and grit (including figures for one firm that manufactures a similar product from salvaged wire clippings) but not steel wool. The principal producing States in 1945, in order of production, were Ohio, Michigan, and Pennsylvania. Other States in which metallic abrasives were manufactured in 1945 were Illinois, Massachusetts, New Hampshire, and New York. Fifteen firms with 16 plants reported shipments in 1945, compared with 13 companies and 14 plants in 1944.

Producers of metallic abrasives in 1945 were the following:

Western Metal Abrasives Co., 2547 East 79th St., Cleveland 4, Ohio—plant at Chicago Heights, Ill.
Holden & Norris, Inc., Eames St., Wilmington, Mass.
Industrial Metal Abrasives Co., 1603 Wildwood Ave., Jackson, Mich.
Erwin Foundry & Mfg. Co., 1018 East Michigan St., Adrian, Mich.
Cleveland Metal Abrasive Co., 887 East 87th St., Cleveland 8, Ohio—plant at Howell, Mich.
Clayton-Sherman Abrasives Co., 3896 Lanyo Road, Detroit 10, Mich.
Harrison Abrasive Corp., 887 Chestnut St., Manchester, N. H.
Abrasive Shot & Grit Co., 1 Carolina St., Springville, N. Y.
American Steel Abrasives Co., Sherman, East & Charles St., Galion, Ohio.
Cleveland Metal Abrasive Co., 887 E. 67th St., Cleveland 8, Ohio—plant at Cleveland.
National Metal Abrasive Co., 3560 Norton Road, Cleveland 11, Ohio.
Steelblast Abrasives Co., 6536–40 Carnegie Ave., Cleveland 3, Ohio.
Cut Steel Abrasives, Inc., P. O. Box 394, 1609 Wilson Ave., Youngstown 1, Ohio.
Globe Steel Abrasive Co., 238 First Ave., Mansfield, Ohio.
Pittsburgh Crushed Steel Co., 4839 Harrison St., Pittsburgh 1, Pa.
Philadelphia Steel Abrasive Co., Vandalia & McKean Sts., Philadelphia 48, Pa.

Manufacture of alumina abrasives of modified grain size was described by Bauman and Benner.[40] Alumina is sintered at about 1,800° with small amounts of TiO_2 and either Cr_2O_3 or V_2O_3 to obtain a solid solution of the other oxides in the alumina. Zirconium and vanadium oxides in amounts up to 2 percent reduce grain size, whereas manganese, iron, chromium, and titanium oxides increase it. The making of boron carbide, B_4C, in the electric furnace at temperatures exceeding 5,000° F. was outlined in the technical press.[41] The uses of boron carbide include the lining of compressed-air nozzles used in pressure blasting, because of its extreme resistance to abrasion, and the lapping or polishing of metal parts.[42]

Production of smooth surfaces has been claimed for an abrasive product made by cementing finely divided SiC, B_4C, or diamond dust to granules of quartz, gravel, or Al_2O_3.[43]

MISCELLANEOUS MINERAL ABRASIVE MATERIALS

In addition to the natural and manufactured abrasive materials for which data are included herein, many other mineral substances are used for abrasive purposes. Various oxides, such as tin oxide, rouge, crocus, chromium oxide, magnesium, and manganese oxides, are utilized as polishing agents. Cerium oxide also recently has been

[40] Bauman, Jr., Henry N., and Benner, Raymond C. (assigned to the Carborundum Co.), Modified Alumina Abrasive: United States Patent 2,369,709, Feb. 20, 1945; Chem. Abs., vol. 39, No. 20, Oct. 20, 1945, p. 4736.

[42] Compressed Air Magazine, Only a Diamond is Harder: Vol. 50, No. 7, July 1945, p. 192.
[43] Fruth, Hal F. (assigned to Galvin Mfg. Co.), Abrasive Material: United States Patent 2,378,399, July 19, 1945; Chem. Abs., vol. 39, No. 18, Sept. 20, 1945, p. 4208.

favored especially for glass polishing because of its cleanliness and efficiency. Among manufactured or artificially prepared products used as abrasives are boron carbide and a periclase abrasive derived from magnesite. Another series of abrasive products valuable for their durability and hardness comprise the so-called cemented carbides, including tungsten carbide, tantalum carbide, titanium carbide, etc. Natural materials with specialized abrasive applications include finely pulverized and calcined clays (china clays, ball clays, fire clays), high-grade lime (Vienna and Sheffield lime), talc, ground feldspar, river salt, slate flour, whiting, and other substances.

FOREIGN TRADE [44]

The total value of imports of abrasive materials in 1945 decreased 43 percent compared with 1944, owing almost wholly to the drop in value of bort (glaziers' and engravers' diamonds, unset, and miners'). This classification, comprising largely what are known as industrial grades, dropped 15 percent in quantity (carats) and 44 percent in value, but was much higher than in the years immediately preceding 1941. Imports of corundum ore remained at a high level, almost equaling the tonnage of 1944, the highest since 1910. Imports of garnet, though small in aggregate, increased considerably in 1945 compared with 1944. "Flint, flints, and flint stones, unground," which includes grinding pebbles, were over twice 1944 imports in tonnage and 262 percent greater in value, although much below prewar receipts. No crude or prepared pumice was imported in 1945 and only small quantities of burrstones, grindstones, sharpening stones (hones, oilstones, and whetstones) and tripoli, rottenstone, and diatomaceous earth.

Reflecting not only increased costs in South Africa and strong efforts to stimulate output there but also the continuing demand for industrial uses, the average value (foreign market value) of corundum ore in 1945 rose to $73.12 per short ton, compared with $68.31 in 1944 and $58.60 in 1943. Average value per carat of imports of "industrial diamonds" or bort (unmanufactured) dropped to $1.19, compared with $1.80 in 1944 and 1943, such decrease probably due partly, at least, to the more prevalent use of smaller diamonds for bonded cutting and grinding tools and other abrasive purposes.

The total value of exports of natural abrasive materials in 1945 was $2,087,598, or only slightly less than that reported in 1944. The value of export shipments of emery and corundum abrasive wheels dropped 58 percent, although the value of grindstones exported increased over 60 percent. The classification including all other natural abrasives registered a moderate gain.

[44] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

Abrasive materials imported for consumption in the United States, 1943–45, by kinds

Kind	1943		1944		1945	
	Quantity	Value	Quantity	Value	Quantity	Value

SULFUR AND PYRITES

By G. W. Josephson and M. G. Downey [1]

SUMMARY OUTLINE

GENERAL SUMMARY

The Axis countries surrendered in 1945, and by the end of the year the world's sulfur industry was progressing slowly toward peacetime operation.

In Germany, Italy, and other countries that had been overrun, production halted; and in the succeeding period of reorganization, revival by the military governments was retarded by physical shortages, destruction of facilities, and purely economic barriers, such as unfavorable rates of exchange.

Conditions in Europe were too chaotic to allow full-scale reestablishment of the export trade of Spain, Portugal, and other large pyrites producers.

Although the end of hostilities removes much of the immediate need for development of domestic sulfur resources by importing countries, sulfur is so vital to modern industry that efforts to attain self-sufficiency continued in many countries.

As the pyrites group of minerals is the principal source of sulfur in the Eastern Hemisphere and native sulfur in the Western, the course of the war is reflected in the production figures. Official statistics are not yet available for many countries, but it is known that world production of pyrites sank to a low level in 1945, whereas native sulfur reached a new high.

As Italy was going through a difficult period of transition, its output of sulfur was small, but in the United States the industry established new records in production, consumption, and even in exports. Substantial tonnages were drawn from stocks to help meet the demands, but the stocks were never depleted to a danger point. Sales declined moderately after the end of the war.

Production and consumption of pyrites in the United States declined slightly in 1945, and imports from Spain remained relatively low.

Allocation of sulfuric acid by the War Production Board was found to be necessary in a few areas, but not of sulfur. Neither was pricing a problem for Government agencies as the price of sulfur, under the provisions of the General Maximum Price Regulation, remained stable.

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

[1] Revised figures. [2] Stocks held at mines only. [3] Nominal.

FUTURE OUTLOOK

Having weathered the war and the first months of the reconversion period, the native sulfur industry in the United States looks forward with confidence.[2] It has a product unexcelled in quality, an established and growing market, large production capacity, ample stocks above ground, large reserves, low production costs, and few serious competitors. Sales were lower at the end of the year, but volume is likely to be large while American industry satisfies the current demand for consumers' goods.

Domestic pyrites are relatively well established where currently mined and used, but its opportunities for expansion appear to be very limited. Prices are unfavorably low.

SULFUR

DOMESTIC PRODUCTION

Increasing demands for acid during the last year of the war stimulated a record production of sulfur in 1945—8 percent greater than the previous high, set in 1942. Although sales declined after the end of the war, production continued at a high level throughout the year. Shipments from the mines were 9 percent greater than in 1944 and larger than in any previous year. In addition to the sulfur from Frasch-process mines, a small tonnage of sulfur-bearing ore is mined in Colorado and Texas for agricultural use.

REVIEW BY STATES

Texas furnished over 79 percent and Louisiana almost 21 percent of the native sulfur output of the United States in 1945.

Sulfur produced and shipped in the United States, 1941–45

Year	Produced (long tons)				Shipped	
	Texas	Louisiana	Other States [1]	Total	Long tons	Approximate value
1941	2, 596, 731	533, 620	8, 902	3, 139, 253	3, 401, 410	$54, 400, 000
1942	2, 885, 621	570, 345	4, 720	3, 460, 686	3, 128, 559	50, 100, 000

[1] 1941: California; 1942: California and Utah.

Colorado.—Thomas Sulphur Co. mined sulfur ore in Delta County.

Louisiana.—Output from the Grande Ecaille mine of the Freeport Sulphur Co. in Plaquemines Parish increased to 783,410 long tons in 1945.

Texas.—The following companies operated in Texas in 1945: Duval Texas Sulphur Co. at Orchard Dome, Fort Bend County; Freeport Sulphur Co., at Hoskins Mound, Brazoria County; Jefferson Lake Sulphur Co., Inc., at Clemens Dome, Brazoria County; Texas Gulf Sulphur Co., at Boling Dome, Wharton County; and the Pecos Orla Sulphur Co., at the Michigan claims in Culberson County. At the year end, construction and installation of facilities at the Long Point Dome property of Jefferson Lake Sulphur Co. were well advanced. The company expects to bring this mine into production in 1946. The following table was compiled from information supplied by the Texas State Comptroller's Office.

[2] Claiborne J. T., No Reconversion Problems for Sulfur: Min. Cong. Jour., vol. 32, No. 2, February 1946, pp. 67–68.

Sulfur produced in Texas in 1945, by companies, in long tons

Company	First quarter	Second quarter	Third quarter	Fourth quarter	Total
Texas Gulf Sulphur Co	492,640	536,573	596,531	577,673	2,203,417

Total	680,002	735,090	782,045	772,641	2,969,778

RECOVERY AS BYPRODUCT

In the United States native sulfur serves as our principal source of sulfur, and some deposits of pyrites are also mined primarily for the sulfur that can be derived from them. In addition to these, we obtain substantial quantities as byproducts of other commodities.

Copper and zinc ores yield large tonnages of pyrites that are recovered as flotation concentrates in milling. Some of our domestic coals contain massive "coal brasses" that can be easily separated by washing and jigging. These are included in the Pyrites section of this chapter.

Smelting of copper, zinc, and lead ores liberates voluminous sulfur oxide fumes that are a nuisance if released to the atmosphere. For the dual purpose of eliminating this nuisance and recovering a salable byproduct, smelter fumes are converted to sulfuric acid or sulfur. The equivalent of 275,000 long tons of sulfur was recovered from this source in 1945. The following table shows the output of acid at smelters during the past 5 years.

Byproduct sulfuric acid [1] (expressed as 60° B.) produced at copper and zinc plants in the United States, 1941–45, in short tons

	1941	1942	1943	1944	1945
Copper plants [1]	243,812	265,522	348,832	320,572	298,309
Zinc plants	672,177	695,242	[2] 879,266	[2] 839,451	786,582
	915,989	960,764	[2] 1,228,098	[2] 1,160,023	1,084,891

[1] Includes sulfuric acid produced as byproduct at a lead smelter.
[2] Revised figures.

Elemental sulfur is also obtained from coke-oven, refinery, natural, and other industrial gases by the Thylox, Ferrox, and Nickel processes. Elemental sulfur recovery plants are located in 11 States and in 1945 produced 25,184 long tons (calculated as 100 percent sulfur), of which 11,691 tons were shipped. Some of this material is marketed as a paste containing 35 to 50 percent of sulfur, but 79 percent is sold as brimstone.

Fuel gases also yield sulfur in the form of hydrogen sulfide through the Phenolate, Phosphate, and Girbotol processes. The product is usually converted to sulfuric acid or burned as fuel. Hydrogen sulfide, recovered in three States in 1945, contained 19,308 long tons of sulfur.

STOCKS

Notwithstanding the high rate of output in 1945, producers' stocks declined steadily during the first 7 months of the year, and after the surrender of Japan they increased. For the year as a whole, total stocks decreased 2 percent to 4,003,917 long tons, of which 3,459,609 were held at the mines.

PRICES

Throughout 1945 crude sulfur was quoted by trade journals at $16 per long ton f. o. b. mines.

CONSUMPTION AND USES

Although available statistics and estimates indicate that consumption of native sulfur in the United States attained a new record in 1945, the quantity appears to have been very little more than in 1944. Total sales, including exports, apparently were about 9 percent greater than in 1944.

Apparent consumption of sulfur in the United States, 1941–45, in long tons

	1941	1942	1943	1944	1945
Shipments [1]	3,076,038	3,032,043	3,191,051	3,580,058	3,849,591
Imports	28,631	25,632	16,658	32	33
Total	3,104,669	3,057,675	3,207,709	3,580,090	3,849,624
Exports:					
Crude	729,464	568,249	657,393	653,686	918,691
Refined	31,312	17,030	25,079	21,546	23,971
Total	760,776	585,279	682,472	675,232	942,662
Apparent consumption	2,343,893	2,472,396	[2] 2,525,237	2,904,858	2,906,962

[1] Apparent shipments to consumers. [2] Revised figure.

The pattern of sulfur consumption, by industry, has been estimated by Chemical and Metallurgical Engineering as follows:

Sulfur consumed in the United States, 1941–45, by uses, in long tons

Use	1941	1942	1943	1944	1945
Chemicals [1]	1,060,000	1,260,000	1,320,000	1,585,000	1,605,000
Fertilizer and insecticides	450,000	475,000	580,000	580,000	600,000
Pulp and paper	360,000	365,000	305,000	300,000	297,000
Explosives [1]	83,000	90,000	90,000	88,000	90,000
Dyes and coal-tar products	65,000	60,000	65,000	75,000	75,000
Rubber	55,000	35,000	45,000	55,000	58,000
Paint and varnish	65,000	70,000	80,000	90,000	94,000
Food products	6,000	6,000	7,000	7,000	7,000
Miscellaneous	95,000	110,000	120,000	140,000	135,000
Total	2,239,000	2,471,000	2,532,000	2,920,000	2,961,000

[1] To avoid disclosing estimated consumption of sulfur in direct defense applications, such as military explosives, sulfur so used is included under "Chemicals."

Sulfur is used in elemental form in a wide variety of products, including rubber and insecticides, and a large tonnage is oxidized for use in papermaking. About three-fourths of the total sulfur, from all sources, is burned and converted into sulfuric acid—the inexpensive and highly effective acid that serves virtually every industry. Chemical and Metallurgical Engineering has estimated the consumption of sulfuric acid, by industries, from 1943 through 1945 as follows:

Sulfuric acid (basis, 100 percent) consumed in the United States, 1943–45, by industries, in short tons

Industry	1943	1944	1945
Fertilizer	2,500,000	2,620,000	2,800,000
Petroleum refining	940,000	1,020,000	1,070,000
Chemicals and defense [1]	2,285,000	2,425,000	2,240,000
Coal products	580,000	620,000	585,000
Iron and steel	535,000	560,000	580,000
Other metallurgical	360,000	340,000	320,000
Paints and pigments	495,000	530,000	545,000
Industrial explosives	115,000	110,000	115,000
Rayon and cellulose film	415,000	450,000	495,000
Textiles	85,000	75,000	70,000
Miscellaneous	350,000	340,000	310,000
Total	8,660,000	9,090,000	9,130,000

[1] To avoid disclosing estimated consumption of acid in direct defense applications, such as military explosives, acid so used is combined with "Chemicals."

Less than 1 percent more acid was consumed in 1945 than in 1944. Consumption in fertilizers continued to increase, and the "Chemicals and defense" total declined. Throughout the war, shortages persisted in some areas, particularly in the West, but they never reached a critical stage for the essential requirements. Reuse and regeneration of spent acids, construction of a comparatively moderate number of new acid plants, and operation of many plants at well over their rated capacities all combined to keep pace with requirements.[3] During the war new construction increased sulfuric acid capacity approximately 2,380,000 tons to a total of about 10,500,000.[4] Conversion problems were not nearly as acute as in many other essential industries. Although consumption for military explosives declined, the effect was relatively small, owing to the high percentage of salvage of ordnance acid. The major consuming industries, such as fertilizer, petroleum, chemicals, steel, paper, rubber, and fibers, can be as active in prosperous peacetime as in wartime, and some are more so.

FOREIGN TRADE

Unlike most of the domestic nonmetallic minerals, a substantial proportion of our sulfur production is sold to foreign consumers. In 1945 nearly a million tons—25 percent of the quantity produced—were exported. The accompanying table shows the world-wide distribution of these shipments. With the end of the war substantial quantities have begun to move into Europe. Imports have been negligible during the past 2 years.

The Federal Trade Commission conducted hearings to determine whether the operations of the Sulphur Export Corporation were conforming to the provisions of the export trade laws.

Sulfur exported from the United States, 1944–45, by countries

[1] No imports of sulfur ore reported 1941–45, but processors state that in 1945 at least 2,000 tons of sulfur ore were imported from Mexico.

WORLD PRODUCTION

Although deposits of sulfur are distributed rather widely, most of them are small, low-grade, or inaccessible. Most of the output is concentrated in a few countries. Production statistics from many countries are not yet available for the past few years; but it is estimated that world production of elemental sulfur, including that derived from gases, totaled about 4,300,000 long tons in 1945.

World production of native sulfur, 1938–45, by countries, in long tons [1]

[1] Native sulfur believed to be produced also in China, Cuba, Egypt, India, Iran, Taiwan, and U. S. S. R., but complete data not available.
[2] Data not available.
[3] Estimate.
[4] In addition, following quantities of sulfur rock reported—1938, 16,545 tons; 1939, 19,568. Similar data not available for later years.
[5] Production of Sicily for fiscal year ended July 31 of year stated.
[6] The incomplete data cited is crude sulfur ore; total production and sulfur content are unknown.
[7] Estimated sulfur content of ore, excluding sulfur made from pyrites.

Argentina.—Under difficult mountain conditions Argentina is continuing to develop a substantial deposit of volcanic sulfur south of Socompa. Although sulfur from this operation is unlikely to become an active competitor in the world market, it can eventually supply domestic needs. With present equipment it can probably furnish not over half of Argentina's requirements; but planned improvements in machinery, transportation, and construction of living quarters for workmen may expand output to over 30,000 metric tons a year, approximately the level of Argentine consumption.

Chile.—Sulfur output in Chile was limited to the level of domestic consumption plus sales, totaling somewhat over 10,000 tons, to Argentina. Competition in the world market is restricted by the cost of production—about $35.00 per ton—and by increases in freight rates and handling costs at the port.

Ecuador.—In the Parish of Tixan, Canton Alausi, Chimborazo Province, are deposits of high-grade sulfur near a railroad. Production is negligible, but the Government is attempting to establish an industry.

Egypt.—Development of two small deposits on the coast of the Red Sea, at Jemsa and Ranga, Egypt, has been reported. Production increased from 130 tons in 1942 to 860 tons in 1944.[5]

Italy.—The Italian sulfur industry has been badly disrupted by the war. From 1937–41 Italian production averaged 340,000 tons a year, of which 65 percent was exported. Owing to the invasion, production was suspended in August 1943. Although output was resumed on a minor scale in December 1943, a combination of military restrictions, power, and supply shortages, and economic difficulties has depressed the industry since that time. Production in 1944 totaled 38,000 metric tons and in 1945 approximately 81,000. This somewhat exceeds domestic consumption, which is currently smaller than before the war. Over 50,000 tons of accumulated stock were available for export early in 1946. As most of the mines are relatively undamaged, they could soon be brought into full production if sufficient supplies, power, and market were available. Before the war European consumers took a large fraction of Italy's sulfur output, but reestablishment of this trade is delayed by monetary and political disturbances. Inflation within Italy has multiplied costs of production 13 to 15 times since 1943. This has been partly counterbalanced by adjustments in the rates of exchange, but with American sulfur delivered in Europe at about $30.00 per ton and Sicilian sulfur priced at 9,500 lire f. o. b. Sicilian ports a ratio of over 300 lire per dollar would be required to make them competitive, assuming other currencies are in relative balance. In 1945 the rate of exchange was 100 lire per dollar, and shortly after the end of the year it was raised to 225.

Characteristically the Italian industry is organized and to some degree controlled by trade and marketing associations. In 1945 Ente Zolfi Italiani and Ente Zolfi Siciliani were dissolved and replaced by voluntary groups named Unione Nazionale Zolfi, in Rome, and Consorzio Zolfifero Siciliano in Palermo. Through these organizations producers hope to develop and apportion the internal and export markets. From 1935–39 output was distributed as follows: Calabria produced 0.2 percent; Benevento area 3.6; Ancorria, Pesaro, and Flori Provinces 41.3; and Sicily 54.9 percent.[6]

Near East.—Sulfur is known to exist in many deposits in the Near East. Some of them have been worked, but the operations are on a small scale. During the past year there have been reports of activity in various localities.[7] A volcanic deposit is said to exist on the island of Gebel Tier, Aden. Oil prospect drilling has penetrated sulfur in Kuweit, Arabia. A small quantity is found in the overburden of pyrite ore bodies in Cyprus. Deposits are known in the Semnan and the Bandar Abbas areas of Iran and in the Tigris Gorge in Iraq.

[5] Mining Journal, vol. 226, No. 5768, Mar. 9, 1946, p. 187.
[6] Botsford, C. A., Sulfur Industry of Italy: Bureau of Mines Mineral Trade Notes, vol. 21, No. 6, Dec. 20, 1945, pp. 41–47.
[7] Chemical Age (London), vol. 54, No. 1395, Mar. 23, 1946, p. 322.

In the Ghaza district of Palestine output of 1,248 tons was reported in 1940, but the easily available reserves are said to have been depleted. In the Palmyra Grottos in Syria and Lebanon sulfur is found associated with gypsum.[8]

Turkey.—Two mines, one at Keciburlu, Isparta, and the other at Saraykoy, Teketirkaz, Denizli, supply over half of Turkey's requirements for elemental sulfur. Keciburlu produced 3,327 metric tons in 1944 and Saraykoy 75. Exploration has revealed new deposits near Keciburlu that are expected to increase production in the future. A reserve of 500,000 tons of ore averaging 33 percent sulfur has been revealed.[9]

PYRITES

DOMESTIC PRODUCTION

Production of pyrites in the United States declined 8 percent in 1945; 91 percent of the total was classified as fines and the remainder as lump.

Pyrites (ores and concentrates) produced in the United States, 1941–45

Year	Quantity		Value	Year	Quantity		Value
	Gross weight (long tons)	Sulfur content (percent)			Gross weight (long tons)	Sulfur content (percent)	
1941	645, 257	41. 9	$2, 009, 000	1944	788, 530	42. 2	$2, 598, 000
1942	720, 363	42. 6	2, 464, 000	1945	722, 596	41. 0	2, 700, 000
1943	802, 384	42. 0	2, 844, 000				

Owing to the strong competition of native sulfur a comparatively small fraction of the output of pyrites is sold on the open market. Most of it is converted to acid by the producing companies in areas that have a market nearby. In 1945, 587,899 tons were consumed by the producing companies, and 130,763 tons were sold.

REVIEW BY STATES

California.—Virtually all the pyrites recovered in California in 1945 came from the Hornet mine of the Mountain Copper Co. in Shasta County.

Colorado.—Only the Rico Argentine Mining Co. reported pyrites output in Colorado in 1945. Its mine is in Dolores County.

Illinois.—The Midland Electric Coal Corp. separated 6,861 long tons of "coal brasses" as a salable byproduct at its coal-washing plant in Henry County in 1945.

Indiana.—Pyrites (coal brasses) were recovered and sold by the Snow Hill Coal Corp. from its Talleydale mine in Vigo County.

Montana.—Pyrites were recovered as a flotation-concentrate byproduct of copper plant operations by the Anaconda Copper Mining Co. in Deer Lodge County.

New York.—In 1945 the St. Joseph Lead Co. mined pyrites at the Balmat mine in St. Lawrence County.

Pennsylvania.—Pyrites were produced by the Bethlehem Steel Co. in Lebanon County.

---

[8] Work cited in footnote 5.
[9] Bureau of Mines, Mineral Trade Notes: Vol. 21, No. 6, Dec. 20, 1945, p. 46.

Tennessee.—Owing to the large output by the Tennessee Copper Co. in Polk County, Tennessee was the leading pyrites-producing State in 1945.

Virginia.—The General Chemical Co. mined pyrites at the Gossan mine in Carroll County and converted it to acid at Pulaski.

Wisconsin.—Pyrites were recovered and converted into acid by the Vinegar Hill Zinc Co. in Grant County.

FOREIGN TRADE

Restrictions in the supply of pyrites during the war have reduced the American market for foreign pyrites. As shown in the accompanying table, movement from Spain was nearly cut off. Increased shipments from Canadian producers to East coast plants satisfied part of the demand for a time, but exhaustion of the Aldermac mine limited this supply. Canada has many other potential sources of byproduct pyrites; but transportation costs were relatively high and prospective prices were so unattractive that all of the needed tonnage did not appear. Consequently, native sulfur replaced the missing pyrites. Recapture of the American market has been made more difficult for pyrites by the abandonment of older pyrites-consuming acid units in favor of new plants designed to use native sulfur.

Imports from Canada have been declining since 1942, and those from Spain are still relatively small. The total tonnage of foreign pyrites imported into the United States in 1945 was slightly greater than in 1944 but was only 39 percent as large as the 482,336 tons that entered in 1939.

Such factors as low production costs and favorable rates of monetary exchange may again furnish foreign pyrites with advantages in its future competition with native sulfur, but at present it appears to be at a disadvantage in the United States.

Spanish pyrites have been variously quoted in trade journals at 12 to 20 cents per unit of sulfur; one well-informed company in the trade reports that 14 cents closely approximates the actual market value of foreign pyrites delivered to the East coast.

Pyrites, containing more than 25 percent sulfur, imported for consumption in the United States, 1941–45, by countries

Country	1941		1942		1943		1944		1945

WORLD PRODUCTION

In the United States native sulfur can be produced so inexpensively that it dominates the market. On the other hand, in most of Europe and in many other areas pyrites have a competitive advantage. As shown in the accompanying table, statistics of production are still far from complete for the past few years, but from available information it seems doubtful that world output of pyrites greatly exceeded 6,000,000 tons in 1945.

Brazil.—A total of 3,000 to 4,000 metric tons of pyrite are mined annually by three companies in the Ouro Preto area of Minas Gerais.[10]

Canada.—Byproduct pyrites are recovered at the Waite Amulet and Noranda mines in Quebec and the Britannia mine in British Columbia. Mine shipments totaled 227,733 short tons in 1945. Sulfur in smelter gas is recovered in elemental form at Trail, British Columbia, and as sulfuric acid at Copper Cliff, Ontario.[11]

France.—Production of pyrite in France in 1940–44 averaged about 200,000 metric tons annually. Approximately 150,000 tons came from the Sain-Bel mine near Lyon, Department of Rhone. From 20,000 to 40,000 tons were produced by the Chizeuil mine near Chalmoux, Department of Saone-et-Loire. Both mines are operated by Société des Manufactures de Glacés et Produits Chimiques de Saint-Gobain, Chauny et Cirey. The remainder (20,000–25,000 tons) came from the Soulier mine near Saint-Martin-de-Valgalgues, Department of Gard. It is owned by Compagnie d'Alais, Froges et Camargue.

Germany.—A report by the Office of Military Government (United States) indicates that production of pyrites in Germany increased from an average of 201,000 metric tons in 1932–34 to 1,397,000 in 1943. This expansion came principally from the Meggen mine of Sachtleben A. G. in Westphalia. This mine alone contributed 1,052,608 tons in 1943, from an unusually large and high-grade vein of sedimentary origin. Reserves are estimated to be at least 5 million tons and possibly up to 23,000,000. The mine suffered no war damage, and it has been put back into limited operation by the

[6] Average sulfur content of pyrites was 42 percent in 1931, latest year for which such information was available.
[7] Incomplete data.
[8] January to September, inclusive.

British Military Government. The Waldsassen, Bavaria, mine of Bergbau G. m. b. H. supplied about 60,000 tons, and virtually all of the remainder came from coal-washing operations and as a byproduct from lead-zinc ores. In 1943 imports totaled 792,273 tons, about 450,000 of which came from Norway, 150,000 from Italy, and 90,000 from Yugoslavia.

In addition to sulfur derived from pyrites, Germany obtained a large tonnage from other sources. According to a German report, total recovery of sulfur (or its compounds) in 1943 was equivalent to 3,675,000 tons of sulfur trioxide. The sources were as follows: 1,900,000 tons from domestic and imported pyrites; 650,000 from regeneration of spent sulfuric acid; 240,000 as acid from copper and lead smelting, fuel and other industrial gases; 80,000 as acid from spent oxide; 95,000 as acid from gypsum; 250,000 as acid from zinc ores; 210,000 from imported elemental sulfur; and 250,000 tons from domestically produced elemental sulfur.

Italy.—Ordinarily Italy produces close to a million tons of pyrites a year, but in 1945 military activity forced the mines to suspend operation for long periods, and output was of the order of 100,000 tons. Owing to power shortages, many mines were flooded; but only one, the Niccioleta, was subjected to systematic destruction by the retreating forces. As power became available in the summer of 1945, pumping was begun, and in July and August the Boccheggiano, Niccioleta, and Gimigliano mines started producing on a small scale. Output can be brought up to normal in a few months when adequate supplies, power, and transportation become available. Italy consumes most of its pyrites—exports range from 50,000 to 200,000 tons a year.

Deposits are found in many Provinces. Their relative commercial importance is shown by production statistics for 1938. In that year Grossetto Province contributed 792,467 metric tons; Belluno Province, 43,586; Aosta, 40,496; Trento, 38,649; and others, 15,114. The principal mines in Grossetto Province are the Gavoranno (capacity, 30,000 tons of ore per month), the Boccheggiano (12,000 tons), the Niccioleta (20,000 tons), and the Ravi Marchi (5,000 tons). In Trento Province are the Andreolle mine and the Calceranica (rated at 5,000 tons per month). Belluno Province has the Agordo mine, which at present has a capacity of 3,000 tons per month. In Aosta are the Bore and Baoio, which produced 2,500 tons per month in 1943; the Herin mine (1,000 tons); and the Traversella (2,200 tons). In addition, pyrites have been prospected or mined on a small scale in the Provinces of Novara, Vercelli, Genova, and Sasseri, but output has been insignificant. Over 90 percent of the production comes from mines owned by Societa Montecatini.[12]

Portugal.—Foreign trade in Portuguese pyrites did not revive substantially in 1945; but output, principally for domestic fertilizer acid, increased to 170,967 metric tons—less than one-third capacity.

Spain.—As Spain's foreign markets had not fully reopened in 1945, its pyrites industry continued to coast along at a small fraction of its prewar volume.

PHOSPHATE ROCK

By Bertrand L. Johnson and E. M. Tucker [1]

SUMMARY OUTLINE

GENERAL CONDITIONS

Several new records were made in the domestic phosphate-rock industry in 1945. Total mined production reached a new high at 5,399,739 long tons, and the quantity mined in Florida (3,814,935 tons) and the Western States (323,955 tons) also set new records. Phosphate rock sold or used by producers in 1945 also made a new peak of 5,806,723 tons (see fig. 1), over 400,000 tons greater than in 1944, with a value of $23,951,077, in turn about 3 million dollars above the 1944 value. The marketed production from Florida and also the Western States was greater than ever before. Sales of Tennessee rock were less. Imports again increased markedly, reaching 141,658 long tons. Exports were greater by about 50,000 tons. Apparent domestic consumption reached nearly 5½ million tons. Stocks at the end of 1945 had decreased about one-third, the decline being chiefly in

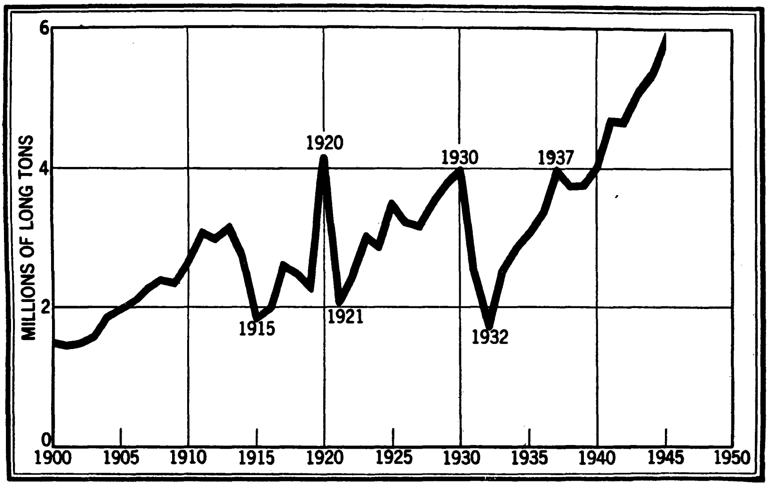

Figure 1.—Marketed production of domestic phosphate rock, 1900–1945.

[1] Figures on imports and exports (unless otherwise indicated) compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

Florida. The P_2O_5 content of the domestic phosphate rock sold or used in 1945 was at a new high—1,884,035 long tons.

OUTLOOK

Unsatisfactory conditions still prevail in the world's phosphate-rock industry and appear likely to continue for a considerable time. Rehabilitation of the industry in the former major producing countries in Africa and the Far East has been slow. The situation resulting from the shortage of phosphate supplies due to these delays is aggravated by the threat of famine in many countries. In the United States the production of phosphate rock is still supported by the Government guaranty of 90 percent parity to farmers, together with the demand for export crops and fertilizer for export. The abnormal domestic production and consumption of phosphate rock may be expected to continue pending recovery in other producing areas, satisfaction of demands from nonproducing, phosphate-consuming countries, disappearance of the famine threat, or major financial difficulties.

PRODUCTION

A new high record was made in 1945 in the quantity of phosphate rock mined in the United States, with a total of 5,399,739 long tons. The increase was due largely to the much greater quantity mined in Florida and to a smaller extent to the increase in the mined production of the Western States. These more than counterbalanced the considerable decline in Tennessee. Phosphate rock was mined in 1945 in Florida, Tennessee, Montana, and Idaho and apatite in Virginia.

Phosphate rock mined in the United States, 1935–45, by States, in long tons

Year	Florida	Tennessee [1]	Western States	United States	Year	Florida	Tennessee [1]	Western States	United States

[2] Includes small quantity of phosphate rock from South Carolina.
[3] Includes some matrix of washer grade.

SALES

A new high record in the quantity of domestic phosphate rock sold or used by producers—5,806,723 long tons—was made in 1945 and exceeded the previous maximum, that of 1944, by 430,080 tons. The total value was over 3 million dollars more than that of 1944, owing partly to the increased sales and partly to a higher average value, which rose from $3.88 in 1944 to $4.12 in 1945.

Phosphate rock sold or used by producers in the United States, 1941–45

Year	Long tons	Value at mines		Year	Long tons	Value at mines	
		Total	Average			Total	Average
1941	4,689,652	$15,596,273	$3.33	1944	5,376,643	$20,856,429	$3.88
1942	4,644,240	16,597,492	3.57	1945	5,806,723	23,951,077	4.12
1943	5,126,232	18,962,021	3.70				

DISTRIBUTION OF SALES

As in 1944, the most popular grades of phosphate rock sold or used by producers in the United States in 1945, according to reports from them, were the 72- and the 75/74-percent B. P. L. grades, although marked increases are to be noted in the 70- and the 68/66-percent B. P. L. grades. Over 72 percent of the domestic phosphate rock sold or used by producers in 1945 was of 70-percent B. P. L. or higher grades. The quantity of phosphate rock containing less than 60 percent B. P. L. sold or used declined in 1945, comprising in that year but 9 percent of the total.

The quantity of domestic phosphate sold or used by producers in the United States for the production of superphosphates is reported to have been nearly 300,000 tons greater in 1945 than in 1944, although its percentage of the total declined slightly. Increases were also registered in the amounts for direct application to the soil and stock and poultry feed. Less is reported to have gone into the chemical uses in 1945 than in 1944. The quantity used for direct application to the soil is now over 400,000 tons a year and forms 7 percent of total uses.

[4] 0.5 percent or less.
[5] Includes phosphate rock used in pig-iron blast furnaces, parting compounds, research, defluorinated phosphate fertilizers, refractories, and other uses.
[6] As reported to Bureau of Mines by domestic producers.

CONSUMPTION

An increase of about 400,000 tons in the apparent domestic consumption of phosphate rock in the United States in 1945 extended the war-time expansion of the domestic demand for that commodity. As indicated on the curve (see fig. 2) the consumption was far above the normal prewar figure and widened still further the great, abnormal, upward fluctuation across the general growth line.

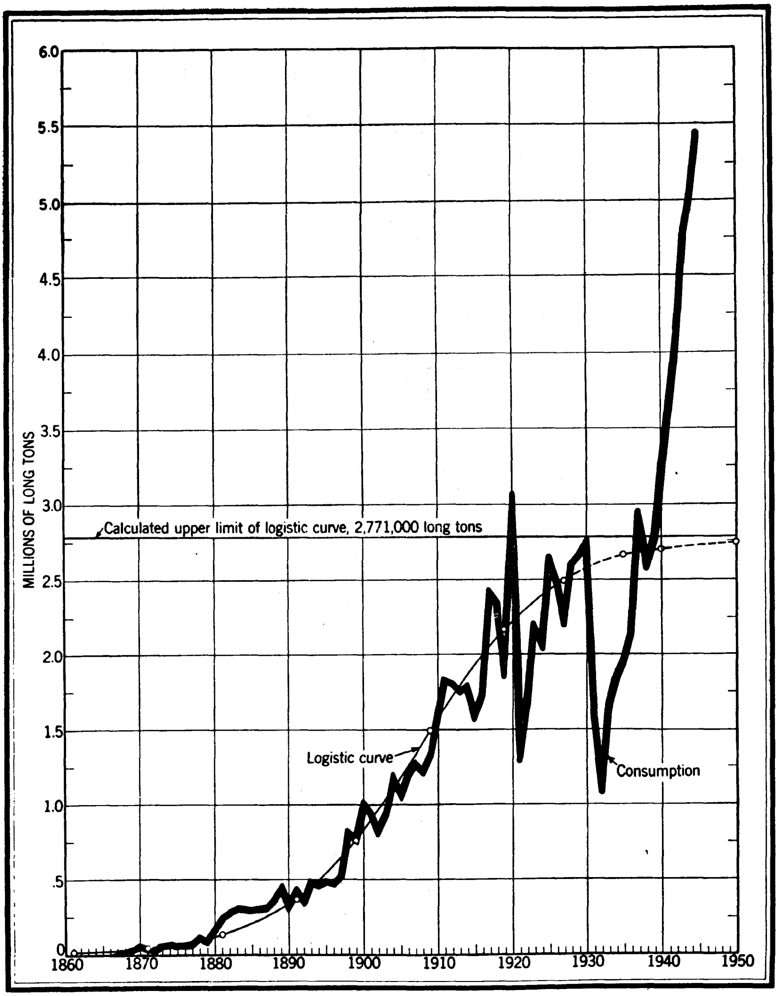

FIGURE 2.—Consumption of phosphate rock in the United States, 1867–1945.

PRICES

Maximum prices of Florida land-pebble phosphate rock, Florida hard-rock phosphate, and Tennessee brown-rock phosphate for sales by miners are covered by Revised Maximum Price Regulation 240 of July 1, 1944, effective July 6, 1944, and the later amendments. No changes were made in unground Florida land-pebble or hard-rock prices during 1945, but in February 1945 (amendment 1) and again in October 1945 (amendment 4) price ceilings for unground Tennessee brown-rock phosphate were raised. The latter increase, effective October 15, 1945, amounts to the approximate cost to the industry of an increase in wages for labor engaged in mining and processing Tennessee phosphate rock. The wage increase was ordered by the War Labor Board and is the amount considered the minimum requirement to keep all essential producers in operation. Manufacturers will be required to absorb the increase, and the price of fertilizer to the farmer will not be affected, according to the Office of Price Administration. These various prices are shown in the accompanying table.

Ceiling prices per long ton of Florida and Tennessee unground phosphate rock, f. o. b cars at mines, by grades, in 1945 [1]

Grades—B. P. L.[2] content (percent)	Prices				
	Florida		Tennessee		
			Brown rock		
	Land pebble	Hard rock	Jan. 1–Feb. 16	Feb. 17–Oct. 14	Oct. 15–Dec. 31
68/66	$2.20		$4.50	$4.60	$4.80
70/68	2.60		5.00	5.10	5.30
72/70	3.20	$7.10	5.50	5.60	5.80
75/74	4.20	7.85			
77/76	5.20	8.60			

[1] Office of Price Administration Revised Maximum Price Regulation 240 and amendments.
[2] Bone phosphate of lime.

Sales of Western States phosphate rock are under the general maximum price regulation at individual ceilings.[2] The Anaconda Copper Mining Co. has established ceiling prices for Idaho phosphate rock, basis f. o. b. cars at Conda, Idaho, guaranteed average 32 percent P_2O_5 (about 70 percent B. P. L.) with no adjustment for grade, as follows:

Sales to superphosphate manufacturers

	Per net ton
Mine-run bulk	$4.75
Crushed undried bulk	5.00
Crushed and dried bulk	5.25
Pulverized bulk	5.90

Sales to fertilizer mixers and dealers

Pulverized bulk	$6.75
Pulverized, in 100-lb. bags	9.25

Sales to consumers

Pulverized bulk	$7.75
Pulverized in 100-lb. bags	10.25

It is reported that the Mountain Copper Co., Ltd., has established the same prices.

[2] C. C. Gran (head, Agricultural Chemicals Section, Food Price Division, Office of Price Administration), Letter, Apr. 22, 1946.

The International Minerals & Chemical Corp. has established maximum prices for Montana phosphate rock, basis f. o. b. cars at Drummond or Hall, Mont., as follows:

Sales to fertilizer manufacturers

Mine run undried.—

$5.75 per net ton, basis 70 percent B. P. L., with 10 cents per unit rise and fall.

Milled and dried, 72/70 percent B. P. L.—

$6.50 per net ton, basis 72 percent B. P. L., with 10 cents per unit rise to 74 percent maximum and fall to 70 percent minimum.

Milled and dried, 75/74 percent B. P. L.—

$7 per net ton, basis 75 percent B. P. L., with 15 cents per unit rise to 76 percent maximum and fall to 74 percent minimum.

Milled and dried, 77/76 percent B. P. L.—

$7.50 per net ton, basis 77 percent B. P. L., with 20 cents per unit rise and fall to 76 percent minimum.

REVIEW BY STATES

Florida.—A new record for the total quantity of Florida phosphate rock sold or used in any one year—4,238,228 long tons, 485,433 tons greater than in 1944—was set in 1945. (See fig. 3.) The total value of this rock, $16,298,474, was nearly 3 million dollars greater than that of the phosphate rock sold or used in 1944 but was still much below the record value of 1920 ($19,464,362). Increases in the quantities sold or used and the values of all the component types of Florida rock—hard rock, land pebble, and soft rock—were recorded in 1945 over 1944. The total average value per ton and the average values for hard rock and land pebble were higher in 1945 than 1944, but the average value per ton of soft rock, as reported by the producers, was less in 1945 than in the preceding year.

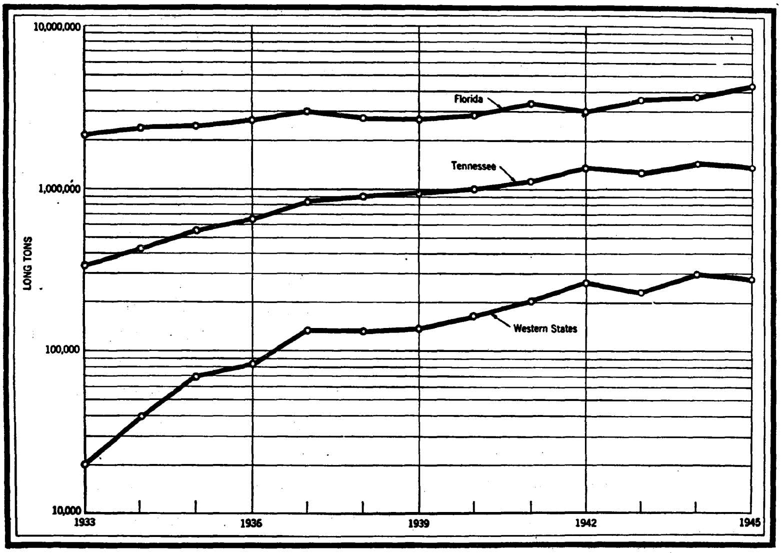

FIGURE 3.—Rate of growth of phosphate rock sold or used by producers, 1933–45, by States.

Three companies were operating in the hard-rock phosphate field in 1945, although mining was being carried on only at the Section 12 mine, operated jointly by C. & J. Camp, Inc. (P. O. Box 608, Ocala, Fla.), and J. Buttgenbach & Co. (P. O. Box 67, Lakeland, Fla.), about 3 miles southeast of Dunnellon. The other company, the Dunnellon Phosphate Mining Co. (P. O. Box 157, Savannah, Ga.) did not operate its mine in Citrus County, near Hernando, which it reports is shut down for an indefinite period, but made some shipments from stock for export. At the Section 12 mine the overburden is removed by hydraulicking, and the underlying phosphate matrix is then mined with a 3-cubic-yard Monighan dragline, which loads it into a 7-cubic-yard skip car for delivery to the washing plant. Later it is expected that an electric shovel will be used for digging the matrix and loading it into Koering Dumptors for hauling to the skip cars. That part of the deposit which is below water level will be mined with a dragline. Detailed descriptions of the plant by Felton [3] and Avery [4] were published during the year.

During the fiscal year ended June 30, 1945, the Federal Trade Commission completed its investigation of the Florida Hard Rock Phosphate Export Association, which it had ordered in 1944 under the Webb-Pomerene law (Export Trade Act), and issued recommendations for readjustment of the business of the association. These recommendations, listed in detail in the annual report of the Commission,[5] are to the effect that the association should withdraw from and rescind certain cartel agreements with foreign producers and with the Phosphate Export Association and other agreements with domestic hard-rock-phosphate producers restricting the use of the Fernandina terminal at Fernandina, Fla., because these divers agreements have been found to have a tendency to restrain trade within the United States.

The investigation of the Phosphate Export Association by the Federal Trade Commission, instituted in August 1944 under the provisions of the Export Trade Act (Webb-Pomerene law), was completed early in 1946, and its recommendations to the Phosphate Export Association were released March 12, 1946.[6] The Commission recommended to the Phosphate Export Association that it withdraw from and rescind certain cartel agreements with foreign producers of phosphate rock requiring it to be responsible in its quotas for all exports from this country, including those of nonmembers. This provision was found by the Commission to be in restraint of the export trade of domestic competitors or potential competitors. The Federal Trade Commission also recommended that the Phosphate Export Association cease the following: (1) Deterring or preventing importation of phosphate rock into the United States; (2) restricting the right of members to withdraw from the association by requiring that their

[6] Federal Trade Commission, FTC Makes Recommendations for Readjustment of Business of Phosphate Export Association: Press Release, Mar. 12, 1946, 3 pp.

Federal Trade Commission, United States of America Before Federal Trade Commission; Docket 202-3, In the Matter of Phosphate Export Association et al. Conclusions. [Contains the Commission's conclusions on which its recommendations to the association are based.]

export trade continue to be handled by the association; (3) requiring members who dispose of mineral deposits to arrange for the successor to continue agreements with the association; (4) restricting the licensing of patents to association members; and (5) restricting the use of the Fernandina terminal, Fernandina, Fla., through an agreement with the Florida Hard Rock Phosphate Association.

On October 12, 1945, the Phosphate Export Association announced its dissolution on October 11, 1945, and stated that each of the following member companies would thereafter conduct its own export business in phosphate rock—The American Agricultural Chemical Co., American Cyanamid Co., Coronet Phosphate Co., International Minerals & Chemical Corp., The Phosphate Mining Co., Southern Phosphate Corp., and Swift & Co.

Seven companies were mining and shipping land-pebble phosphate rock in 1945. These were the American Cyanamid Co. (Brewster), American Agricultural Chemical Co. (Pierce), Coronet Phosphate Co. (Plant City), International Minerals & Chemical Corp. (Mulberry), Phosphate Mining Co. (Nichols), Southern Phosphate Co. (Ridgewood), and Swift & Co. Fertilizer Works (Agricola). The Pembroke Chemical Corp. (Pembroke, Fla.) did not mine any land pebble in 1945 but did dry material from its wet-rock stocks, which it exported with previously dried rock. The Virginia-Carolina Chemical Corp. purchased, as of June 1, 1945, practically all the capital stock of the Phosphate Mining Co. The New York office of the latter company was discontinued, and the head office moved to Richmond, Va., to the executive offices of the new parent corporation.

The entire capital stock (2,000 shares of preferred and 2,000 shares of common) of the Ore & Chemical Corp., of New York, owner of 355 shares of the Pembroke Chemical Corp. or 39.44 percent of the 900 issued and outstanding shares, was vested by the Alien Property Custodian under and by virtue of Vesting Order 2587, executed on November 17, 1943, and Supplemental Vesting Order 4818, executed on April 14, 1945, under the authority of the Trading With the Enemy Act, as amended, and Executive Order 9095, Metalgesellschaft, A. G., Frankfurt, Germany, being indicated to have held directly or indirectly a dominant interest in the Ore & Chemical Corp. All the shares of the Ore & Chemical Corp. were sold in 1945 to B. R. Armour, Englewood, N. J. Thirty-five additional shares of the Pembroke Chemical Corp. (3.89 percent of the outstanding capital stock) were vested by the Alien Property Custodian under and by virtue of Vesting Order 4159, executed on September 22, 1944, under the authority of the Trading With the Enemy Act, as amended, and Executive Order 9095, as amended. These shares were sold to the Ore & Chemical Corp. early in 1946.

The Victor Chemical Works, already a large producer of elemental phosphorus in the Tennessee brown-rock-phosphate field, has announced expansion of its elemental phosphorus-producing facilities by the proposed erection of a new electric furnace plant on tidewater on Anclote River, near Tarpon Springs, northwest of Tampa, Fla.. Phosphate rock from the land-pebble field will be used as the source of the phosphorus.

Some of the recent developments in the land-pebble field were described by Barr [7] in a review of the phosphate-rock industry in 1945. He also states that no new mining methods were introduced in this field during the year, although excavation of matrix by electric dragline before hydraulic transport to the washer plant continued to gain favor. Flotation is reported to continue as the dominant factor in the field, and Barr states that most of the deposits left or now being mined could not be practically operated without this process.

Florida phosphate rock sold or used by producers, 1941–45, by kinds

[1] Includes material from waste-pond operations.

Tennessee.—The tonnage of phosphate rock sold or used by Tennessee producers in 1945 (plus a small quantity of apatite from Virginia) was about 30,000 tons less than in 1944, according to reports from the producing companies. The phosphate rock sold or used was brown rock, except for the Virginia apatite, and a small tonnage of Tennessee blue rock. Although the tonnage sold or used decreased in 1945, the total value was greater than in 1944, the average value increasing from $4.51 in 1944 to $4.68 in 1945.

Tennessee brown-rock phosphate was mined in 1945 by the Tennessee Valley Authority (Columbia, Tenn.) and by several private companies: Armour Fertilizer Works (Room 350, Hurt Building, Atlanta, Ga.), Federal Chemical Co. (634 Starks Building, Louisville, Ky.), Harsh Phosphate Co. (Route 4, Murfreesboro Road, Nashville, Tenn.), Hoover & Mason Phosphate Co. (8 South Michigan Avenue, Chicago, Ill.), International Minerals & Chemical Corp. (20 North Wacker Drive, Chicago, Ill.), Monsanto Chemical Co. (1700 South Second Street, St. Louis, Mo.), and Virginia-Carolina Chemical Corp. (Richmond, Va.). Sales of blue rock are reported to have been made by George E. Sloan, Columbia, Tenn.

Barr [8] states that there were no new mine or plant installations in

[7] Barr, J. A., Potash and Phosphate: Min. Cong. Jour., vol. 32, No. 2, February 1946, pp. 69–72.
[8] Barr, J. A., Work cited in footnote 7.

the Tennessee phosphate fields in 1945, although some old equipment was replaced by new and more modern types, such as Diesel machines for the old steam dragline excavators. The nominal grade of phosphate rock for electric-furnace consumption is given as 55 percent B. P. L. while that for the manufacture of superphosphate is said to average 70 percent B. P. L.

The series of articles on the treatment of phosphate rock by Wustrack, begun in 1944, was continued by the appearance of the fifth article—on sampling and analysis.[9]

A brief summary of the Tennessee phosphate-rock deposits and industry appeared in 1945 in a report of the Tennessee State Planning Commission.[10]

According to the annual published report of the Tennessee Valley Authority for the fiscal year ended June 30, 1945, approximately 517,000 tons of phosphate matrix was mined during the year. More than 525,000 tons of matrix, containing 20.6 percent P_2O_5, were processed in the Godwin washing plant, and about 242,000 tons of phosphate sands, averaging 26.2 percent P_2O_5, were recovered. This was nearly 20 percent more than the total of washed sands produced in 1944. Nearly 60,000 tons of lump sinter were produced and shipped to Muscle Shoals, together with over 7,300 tons of sinter fines, which were reprocessed in the nodulizing kilns at Muscle Shoals. Purchases of phosphatic materials, comprising sinter from the Monsanto Chemical Co. and washed sands from the International Minerals & Chemical Corp., declined to 121,000 tons or about 79 percent of 1944 purchases, as a result of the increase in field plant operations of TVA. Additional phosphate reserves were acquired during the year through the purchase in fee simple of three tracts in Williamson County, Tenn., containing an estimated 1,309,000 tons of matrix, and purchase of the mineral rights on another tract in Maury County, estimated to contain about 323,000 tons.

Total production of elemental phosphorus for the fiscal year reached 29,800 tons as compared with 24,400 tons in the 1944 fiscal year. More than four-fifths of this output—about 24,000 tons—was shipped to satisfy requests of the Chemical Warfare Service. Only about 4,000 tons of elemental phosphorus were available for use in manufacturing concentrated phosphatic fertilizers, chiefly during the latter part of the year. The increased production of elemental phosphorus was achieved despite major repairs and construction involving all five electric furnaces. This included replacement of one of the units, previously constructed to produce phosphoric acid direct, with an enlarged furnace producing elemental phosphorus. A second furnace was dismantled because of obsolescence and deterioration and was replaced with a larger unit. Major repairs were made to the crucibles of the other three furnaces. Construction of a 13,000-kilowatt phosphorus furnace was begun during the year at the request of WPB and was half-completed at the close of the year.

A small experimental plant for the production of red phosphorus suitable for small arms primer compositions was operated during the year, and 3,800 pounds of primer-grade material were sent to the

[9] Wustrack, O. H., Phosphate Production Problems; Article 5. Sampling and Analysis: Rock Products, vol. 48, No. 4, April 1945, pp. 71,138, 140, 142.

[10] Whitlatch, G. I. (compiler), Industrial Resources of Tennessee: Tennessee State Planning Commission, Nashville, Tenn., 1945, 210 pp. (See pp. 35–37.)

Frankford Arsenal. Forty 4.2-inch mortar shells were filled with mixtures of red and white phosphorus for testing by the Chemical Warfare Service. A laboratory study was also carried out on metallic phosphides to determine their possible usefulness in incendiary bullets.

About 22,400 tons of concentrated superphosphate were produced during the year, about half as much as during the previous year. The production of calcium metaphosphate was a little over 4,000 tons, but shipments totaled about 6,000 tons. Production of this material was about 42 percent above that of the 1944 fiscal year. Construction of the new fused tricalcium phosphate plant at Godwin, Tenn., was completed, and one of the two furnace units was placed in operation late in May. The plant has a designed capacity of 120 tons a day of fertilizer-grade material or 70 tons of feed-grade material. Production up to June 30, 1945, was 1,050 tons of fertilizer-grade, fused tricalcium phosphate.

Over 6,400 tons of feed-grade dicalcium phosphate were produced for use as animal feed supplements in the absence of importations of bonemeal during the war. Production was started in the previous fiscal year at the request of the War Food Administration and as authorized by the War Production Board. Largely because of the demand for elemental phosphorus for military use, 1945 production was only about 72 percent of that of the previous year.

With the large wartime expansion in phosphorus capacity, the limiting factor in fertilizer production was in the acid plant, where owing to deterioration during the year one unit became inoperable. A new improved unit was placed in operation, and plans were completed for the construction of two new units, each capable of burning 24 tons of phosphorus per day. One of these is an entirely new experimental installation for producing superphosphoric acid.

In small-scale tests, diammonium phosphate was produced, containing a high concentration of plant food. Experimental work resulted in development of a continuous process which was under test at the end of the year.

About 612 tons of TVA triple-superphosphate were sold commercially for the first time through Associated Cooperatives. The sales were made at wholesale ceiling prices to several Mississippi Valley cooperatives.

Tennessee phosphate rock (including sintered matrix) sold or used by producers, 1941–45

[Includes apatite from Virginia]

Year	Long tons	Value at mines: Total	Value at mines: Average	Year	Long tons	Value at mines: Total	Value at mines: Average

[1] Includes small quantity of blue rock.

Virginia.—In 1945 apatite was produced from the Piney River nelsonite deposit by the Calco Chemical Division of the American Cyanamid Co. The company became a shipper in February 1945 after the superphosphate plant was shut down and dismantled.

The drill sampling is described and evaluation of this Piney River ilmenite-apatite lode in 1944 is given by Davidson in a paper published early in 1946.[11] The ore body is the upper weathered part of a tabular mass of a basic rock (a mixture of feldspar, ilmenite, and apatite) occurring in a large area of pre-Cambrian granite-gneiss. The ore-bearing section is about 3,000 feet long, strikes northeasterly, and has an average dip of 45° SE. The weathered outcrop of the ore body is now being exploited by open-cut.

Western States.—A new high record for the value of the marketed production of phosphate rock featured the Western States phosphate-rock industry in 1945, when the total value of that sold or used exceeded 1½ million dollars ($1,589,915). This, an increase of 18 percent over the 1944 figure, reflects a higher average value per ton of rock. The tonnage marketed, however (274,198 long tons with a P_2O_5 content of 88,052 tons), was less in 1945 than in 1944 when 298,999 tons, containing 95,767 tons P_2O_5, were sold or used. This was a decrease of 8 percent from the record high of the previous year, but it still remained greater than for any other year. The production in 1945 came from Idaho and Montana; only development work was reported in Wyoming, and Utah remained inactive. The average P_2O_5 content of the Western States phosphate rock sold or used in 1945 is reported to have been 32.11 percent, a little above that of 1944 (32.03 percent).

Montana continued to be the largest phosphate-rock producer of the Western States group in 1945 as in other recent years; its lead over Idaho, however, dropped to only 27,518 long tons. (See fig. 4.) Its total in 1945 (150,858 long tons, with a P_2O_5 content of 49,068 tons) was a decrease of 19 percent from 1944. The average P_2O_5 content was 32.53 percent, slightly higher than that of 1944 (32.16 percent). The Montana Phosphate Products Co., of Trail, British Columbia, still the largest producer in the Western States in 1945, in spite of a marked decrease in production in 1945, operated its Anderson, Anaconda, and Graveley mines as well as several Government leases. Most of the mined product was exported to the plant of the Consolidated Mining & Smelting Co., of Canada, Ltd., at Trail, but a considerable quantity was sold in the United States. Gilbert's description [12] of the operations of this company was published early in 1945. The International Minerals & Chemical Corp. operated its property in the Douglas Creek area, Granite County, during the early months of 1945. Considerable phosphate rock was mined. The crude ore was taken to its concentrating plant at Sherryl on the Phillipsburg branch of the Northern Pacific Railway, and the concentrates produced were shipped. Lee H. Skeels, trustee for and leasee of the Soluble Phosphates, Ltd., Maxville, Granite County, Mont., mined a small tonnage at the Master Key mine near Maxville in 1945, ground, and shipped the product for direct application to the soil. Tests on phosphate rock from this property for radioactivity and uranium minerals with a Geiger-Muller counter at the Bureau of Mines laboratory, College Park, Md., in 1945, did not show the presence of either.

[11] Davidson, D. M., Diamond-Drill Sludge Sampling and Appraisal of a Weathered Ilmenite Ore Body, Piney River, Va.: Am. Inst. Min. and Met. Eng., Tech. Pub. 1951, Min. Technol., vol. 10, No. 1, January 1946, 5 pp.

[12] Gilbert, Geoffrey, Mining Operations of the Montana Phosphate Products Co.: Am. Inst. Min. and Met. Eng. Tech. Pub. 1824, Min. Technol., vol. 9, No. 3, May 1945, 5 pp.

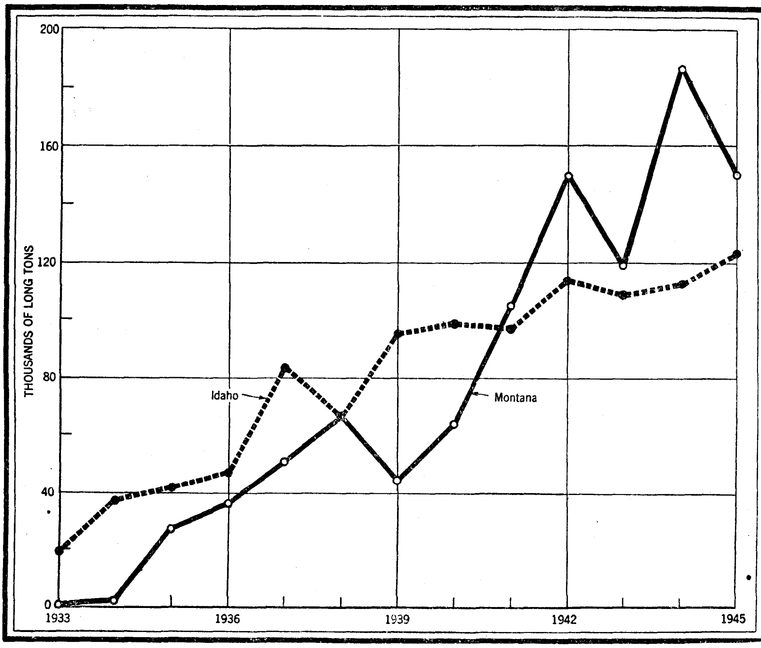

FIGURE 4.—Idaho and Montana phosphate rock sold or used by producers, 1933–45.

A record marketed production of Idaho phosphate rock was made in 1945 (123,340 long tons containing 38,984 tons P_2O_5 content). This was an increase of 8 percent over the previous record made in 1942 (114,079 tons). The average P_2O_5 content was 31.61 percent, a little below that of 1944 (31.80 percent). There were three phosphate-rock-producing companies in Idaho in 1945. By far the largest of these, the Anaconda Copper Mining Co., operated its No. 3 mine at Conda, Caribou County. Most of the shipments in 1945, as in prior years, went to the company plant at Anaconda, Mont., for conversion to superphosphate and phosphate chemicals. A considerable quantity was sold to other domestic consumers. The San Francisco Chemical Co., 216 Pine Street, San Francisco 4, Calif., started operations again at its Waterloo mine near Montpelier, Bear Lake County, Idaho, during 1945, and mined a sizable quantity, part of which was sold for the manufacture of superphosphate and the remainder retained in stock. The Teton Phosphate Co., Montpelier, Idaho, mined phosphate rock from its Bennington mine near Bennington, Bear Lake County, Idaho. This was ground in the company plant and sold for direct application to the soil.

No phosphate rock was produced in either Utah or Wyoming in 1945. The Garfield Chemical & Manufacturing Corp., Salt Lake City, Utah, which mined and shipped phosphate rock in 1942 from a Federal lease near Spanish Fork, Utah County, Utah, made no production in 1943, 1944, or 1945. John M. Thomas reported only development work at his property near Cokeville, Lincoln County, Wyo.

The average value per ton of the Western States phosphate rock sold or used, as reported by the producers to the Bureau of Mines, increased sharply in 1945—$1.30 per ton—or from $4.50 in 1944 to $5.80 per ton in 1945. There was an increase of only 27 cents per ton in Idaho, but one of $1.98 in Montana.

Papers by Gale [13] and the Mining World [14] describing the recovery of lithium phosphate from the brines of Searles Lake, Calif., appeared during the year.

TALC, PYROPHYLLITE, AND GROUND SOAPSTONE[1]

By Bertrand L. Johnson and Dorothy I. Marsh

SUMMARY OUTLINE

GENERAL CONDITIONS

Mined production of talc, pyrophyllite, and ground soapstone in 1945 continued its decline from the high levels of 1943, according to reports from producers. Sales increased slightly in quantity, but declined in value. (See fig. 1.) Sales of the ground materials were

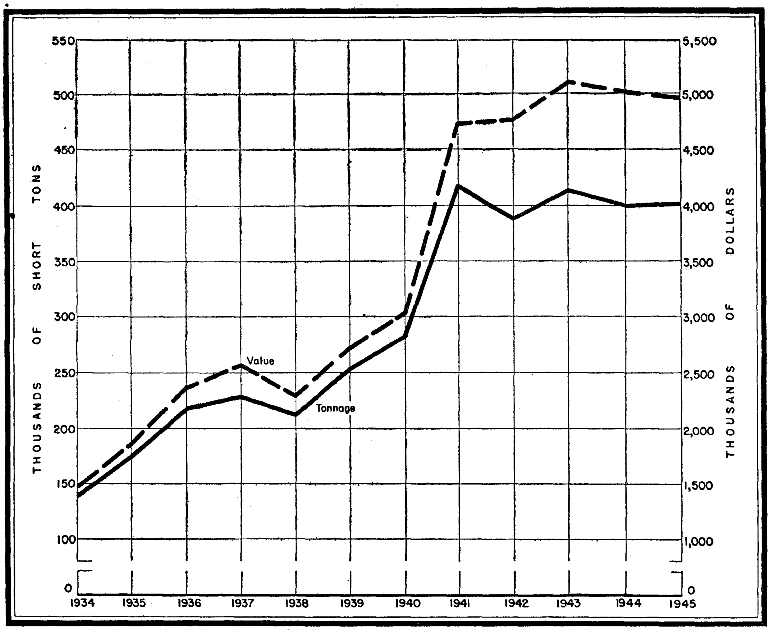

FIGURE 1.—Sales of domestic talc, pyrophyllite, and ground soapstone, 1934–45.

[1] Soapstone sold in slabs or blocks is included in the chapter on Stone.

larger in both quantity and value in 1945 than in 1944. Sales of crude were less in both categories. Total imports in 1945 were less in both quantity and value than in 1944, as were also the imports of all classes of these materials. Exports of "talc, steatite, soapstone, and pyrophyllite, crude and ground" increased in 1945 both in quantity and value. Exports of "powder—talcum (in packages), face, and compact," increased greatly in value.

Production and sales figures of pyrophyllite are now available for 4 years and are given in the footnotes of the salient statistics table. Pyrophyllite is included with talc in this chapter because of its resemblance to talc in certain physical properties and because it is interchangeable with talc in some uses, although certain specialized uses for pyrophyllite have been developed in recent years. It is a hydrous aluminum silicate, whereas talc is a hydrous magnesium silicate.

Salient statistics of the talc, pyrophyllite,[1] and ground-soapstone industries in the United States, 1944–45

	1944		1945	
	Short tons	Value	Short tons	Value

[1] In 1944: Mined, 67,252 short tons. Sold—crude, 5,683 tons, $52,343; ground, 60,560 tons, $504,739; total, 66,243 tons, $557,082. In 1945: Mined, 77,716 short tons. Sold—crude, 5,949 tons, $33,910; ground and other manufactures, 71,645 tons, $617,290; total, 77,594 tons, $651,200 (exclusive of pinite).
[2] Data not available.
[3] Includes pinite from Nevada.
[4] Exclusive of "Manufactures, n. s. p. f., except toilet preparations," as follows: 1944: $25; 1945: $63. Quantities not available.
[5] Quantity not recorded.

Thirteen States reported sales of talc, pyrophyllite, or ground soapstone in 1945, the same as in 1944. The greater part of the total sales was made by the Eastern States in 1945, and most of the remainder came from the Southwest—southeastern California and southwestern Nevada.

A downward trend in the production of talc reflected in a drop in average inventories to about a 6-week supply prompted the War Production Board to issue, on April 9, 1945, the amended Conservation Order M–239, Talc, effective April 23, 1945. This channeled the critical grades into the most essential war needs, such as paint for the

Army, Navy, Marine Corps, Coast Guard, Maritime Commission, War Shipping Administration, Office of Scientific Research and Development, or the government of any country whose defense the President considered vital to the defense of the United States, or for use in the manufacture of rubber tires, or for the packaging of synthetic rubber. The order was revoked August 20, 1945. (Federal Register, August 21, 1945, p. 10180.)

A series of maps of the Waterbury and Johnson talc mines in Washington and Lamoille Counties, Vt., prepared by the Geological Survey, became available in 1945. The Eastern Magnesia Talc Co. operates both of these mines. The deposits consist of irregular, lenticular bodies in schist. The maps include a surface map of each mine, as well as a geologic map of the 200-foot level and five structure sections of the Johnson mine. A geologic map of the International No. 4 mine and parts of the No. 3 and No. 5 mines, St. Lawrence County, N. Y., prepared by the Geological Survey, also is ready for distribution.

A summary description of talc deposits and industry of New York is included in a study of the mineral industries of the Adirondacks by Otte.[2]

The Palen Mountains talc deposit in eastern Riverside County, Calif., was described by Tucker and Sampson [3] in a report on the mineral resources of Riverside County, and the geology, chemistry, and utility of California talcs has recently been discussed by Lamar.[4]

OUTLOOK

The growth of the talc, pyrophyllite, and ground soapstone industry in evidence in the prewar years was halted during the war at around the 400,000-tons-a-year level. (See fig. 1.) The lessened immediate postwar demand for these commodities, with the decline in the needs for war usages, is expected to be reflected in a smaller domestic production. Some newly developed wartime uses that may find application in a peacetime economy may cushion the expected decline. Moreover, the need for these commodities in paint and roofing materials for postwar building programs may counterbalance the decline in painting and roofing activities by the Army and Navy. Increased demands from the ceramic, rubber, paper, and other industries may later revive the pre-war upward trend in sales.

The importation of high-grade talcs from various European countries as well as from Manchuria and other Asiatic regions is expected to revive. Foreign cosmetic-grade talcs have already returned to the domestic market.

SALES

In 1945 the quantity of domestic talc, pyrophyllite, and ground soapstone sold or used was slightly greater than in 1944, according to reports of the producers to the Bureau of Mines, but was less than in either 1943 or 1941. The total value reported was less than in 1944 or 1943. The average value per ton in 1945 was only $12.36, which was lower than in either 1943 or 1944.

[1] In 1944: Crude, 5,683 tons, $52,343; ground, 60,560 tons, $504,739; total, 66,243 tons, $557,082 (exclusive of pinite). In 1945: Crude, 5,949 tons, $33,910; ground and other manufactures, 71,645 tons, $617,290; total, 77,594 tons, $651,200 (exclusive of pinite).
[2] Includes pinite from Nevada.

Sales by States.—In 1945 New York remained the leading producer by a considerable margin, although sales were again less than in the preceding year. In California, Georgia, North Carolina, and Vermont sales increased in 1945 over 1944. The quantities reported as sold in California and North Carolina in 1945 were the highest ever recorded. The greater part of the pyrophyllite marketed comes from North Carolina.

Talc, pyrophyllite, and ground soapstone sold by producers in the United States, 1944–45, by States

State	1944: Short tons	1944: Value	1945: Short tons	1945: Value
California	65,191	$1,054,312	75,564	$1,098,936
Georgia	30,425	363,342	32,433	296,163
Maryland	17,130	161,222	14,707	149,170

	398,863	5,017,462	401,080	4,956,901

[1] Includes pinite.
[2] Montana, New Mexico, New York, Pennsylvania, Texas and Virginia.

MARKETS

Seven industries—paint, ceramics, rubber, roofing, paper, toilet preparations, and insecticides—consumed 79 percent of the domestic sales of talc, pyrophyllite, and ground soapstone in 1945, according to reports from the producers. Increases were reported in sales to the ceramic, rubber, roofing, toilet preparations, and insecticide industries. Those in the rubber and insecticide industries were especially noticeable. Use in insecticides now ranks fourth in quantity consumed and takes 9 percent of total sales. There was a marked decline in the quantity used for paints.

Talc, pyrophyllite, and ground soapstone sold by producers in the United States, 1944–45, by uses

Use	1944		1945	
	Short tons	Percent of total	Short tons	Percent of total

[1] Less than 0.50 percent.
[2] 1944: Chemical war service, refractory, plaster, plastics, bleaching, textile, and other minor uses. 1945: Refractory, plaster, plastics, textile, agriculture, and other minor uses.
[3] Includes pinite.

PRICES

Quoted prices on ground domestic talc per ton, carlots, bags, f. o. b. works, have remained constant for several years. According to the Oil, Paint & Drug Reporter of June 10, 1946, these prices are per ton:

Talc, domestic, ordinary, ground	$14.50–$24.50
California	17.50– 43.00
New York, fibrous, ground, off color, coarse	13.00
New York, fine, 325 mesh—93–94 percent	13.00– 18.00
New York, fine, 325 mesh—98–99.5 percent	15.25– 19.25
New York, fine, 325 mesh—99.85–99.95 percent	17.00– 21.00
Pennsylvania	11.00– 13.50
Vermont	14.00
Talc, imported, Canadian	24.00– 30.00

The prices on pyrophyllite were the same in 1945 and the first half of 1946 as in 1944. According to the same journal these were, in June 1946: Standard, 200-mesh, carlots, bulk, mines, per ton, $10 to $11.50; 325-mesh, same basis, $13.00 to $13.90; No. 3, 200-mesh, carlots, mines, $9.50; 325-mesh, same basis, $11.50. Pyrophyllite in paper bags was $1.50 per ton extra.

The average values of all grades of talc, pyrophyllite, and ground soapstone in the past 5 years, as reported to the Bureau of Mines by producers, are given in the table under "Sales."

On July 23, 1945, the Office of Price Administration issued MPR 592, Specified Construction Materials and Refractories, which superseded the General Maximum Price Regulation and Maximum Price Regulation 188 with respect to transactions covered by this regulation. It became effective July 30, 1945. Prices of talc (including steatite), pyrophyllite, and ground soapstone and of talc crayons, natural sawed and pressed or extruded, formerly covered by MPR 188 and amendments were accordingly placed under MPR 592.

MPR 592, Order 1, Modification of Maximum Prices, of the same effective date, which brings together, restates, and reclassifies the modifications of maximum prices previously contained in Order A–1 under MPR 188 insofar as they applied to commodities now covered by this regulation, restates (sec. 7.2) the maximum prices for specified grades of crude talc produced in Esmeralda County, Nev., and in section 7.3 states that

> The manufacturers' maximum prices for pyrophyllite established pursuant to Maximum Price Regulation No. 592 may be increased by adding an amount not in excess of $0.40 per net ton to the f. o. b. factory prices.

In October 1945 the OPA suspended the above price control on industrial talc, pyrophyllite, and ground soapstone. Agricultural grades, which form only a very small percentage of the total consumption of these materials, were not included in this suspension but were later (May 1946) removed from control.

DEVELOPMENTS IN THE INDUSTRY

The results of the Bureau of Mines investigation of domestic talcs was published early in 1945.[5] This investigation, begun in December 1941 and recessed in 1943, was a general survey of domestic talcs to determine those suitable for the production of radio ceramic or "steatite" insulators. About 200 samples from 46 mines, 26 prospects, and 24 uncertain sources were examined. Samples of a grade satisfactory without beneficiation were obtained from 17 mines and 5 prospects in Inyo County, Calif., and Esmeralda County, Nev. The talcs obtained from the Smith-Dillon and Clark-Teutsch mines in Montana were likewise of satisfactory grade. Reserves of satisfactory-grade material have been tentatively estimated at about 115,000 tons, or a 4 to 5 years' supply at the present rate of consumption. The deposits in the Western States have been supplying the required grade of material. Originally the material came almost exclusively from the Talc City mine of the Sierra Talc Co., Inyo County, Calif. Other mines in that county and in Esmeralda County, Nev., now supply part of the market. Some also comes from Montana and New Mexico.

Most talcs produced in the eastern region—New York and the Appalachians from Vermont to Alabama—are stated to be unsuitable for use in high-frequency insulators, as they are either too refractory, or contain too much iron oxide, or have high linear shrinkage. Talcs

[5] Klinefelter, T. A., Speil, Sidney, and Gottlieb, Sidney, Survey of the Suitability of Domestic Talcs for High-Frequency Insulators: Bureau of Mines Rept. of Investigations 3804, 1945, 58 pp.

from some of these desposits show a possibility of furnishing by beneficiation products that would meet the requirements for high frequency ceramics. The largest reserves of this type are in New York and Alabama. At present, the eastern deposits are not considered usable reserves, however.

Trauffer [6] has described the operations of the International Talc Co. in the Gouverneur district, northern New York.

Steatite ceramic blocks with radio circuits printed on them have been used in radio and electronic apparatus.[7]

Several papers on steatite ceramics have been published recently.[8]

FOREIGN TRADE [9]

Imports.—The reversal in 1944 of the declining trends in the quantity and value of total imports of talc, steatite or soapstone, and French chalk, was only temporary, and in 1945 a decline occurred nearly to the 1943 level in total quantity imported and almost to the 1942 level in total value. Declines occurred in quantities and values of all classes. As usual, the imports were largely of materials "ground, washed, powdered or pulverized, except toilet preparations." Canada was the only source of the ground material and India the chief source of the other classes. (See fig. 2.)

Exports.—The quantity of "talc, steatite, soapstone, and pyrophyllite, crude and ground" exported from the United States in 1945 was a new record, surpassing the previous all-time record of 1941 by 252 short tons. The total value of these exports in 1945 was likewise a record—$279,178. A large increase, nearly a million dollars, occurred in 1945 in the value of "powders—talcum (in packages), face, and compact" over that of 1944, the value exceeding 2¼ million dollars.

Talcum and other powders exported from the United States, 1941–45

Year	Talc, steatite, soapstone, and pyrophyllite, crude and ground		Powders—talcum (in packages), face, and compact (value)
	Short tons	Value	
1941	10,889	$216,440	$1,229,280
1942	9,246	191,900	678,313

[1] In addition to countries listed, talc or pyrophyllite is reported produced in Brazil, Bulgaria, Chile, Finland, France, Kenya, and U. S. S. R., but data on production are not available.
[2] Data not available.
[3] Excludes soapstone, which is reported only by value and was as follows: 1938, $35,038; 1939, $41,471. Soapstone is sold in the form of both blocks and powder.
[4] January to September, inclusive.
[5] Less than 1 ton.
[6] Includes steatite, as follows—1938: 3,480 tons; 1939: 5,545; 1940: 17,191; 1941: 18,948; 1942: 24,859; 1943: 9,741; 1944: 7,369.
[7] Talc, pyrophyllite, and ground soapstone sold by producers; includes also pinite in 1940, 1941, 1942, and 1944.
[8] Estimate.

Canada.—The Canadian talc and soapstone industry in 1944 was described in official reports as follows:[10]

The value of crude and refined talc and soapstone sold by Canadian producers of these minerals totalled $357,249 in 1944 compared with $266,685 in 1943. Mine shipments of soapstone and talc reported in 1944 by operators in the Province of Quebec amounted to 19,013 short tons valued at $205,127. Production of the higher grades of talc in Canada is confined chiefly to the Province of Ontario, and in 1944 shipments totalling 13,584 tons worth $153,122 were made entirely from a deposit located near Madoc, Hastings County. In British Columbia, crude talc imported from the United States is treated in a mill at Vancouver. Canadian Wartime Metals Corporation discontinued operations on February 29, 1944, at its Lava Talc project located at the Red Mountain and Gold Dollar claims in the Golden mining division of British Columbia; approximately

[10] Canada Department of Trade and Commerce, Dominion Bureau of Statistics, Mining, Metallurgical, and Chemical Branch, The Talc and Soapstone Industry, 1944: Ottawa, Canada, 1945, 7 pp.

seven tons of sawn talc blocks were shipped to the United States for experimental purposes.

Imports of talc and soapstone into Canada during 1944 totalled 6,094 short tons valued at $130,603; they came entirely from the United States. Exports of talc from Canada in 1944 amounted to 11,920 short tons worth $157,178.

During 1944 there were 6 firms reported as active in the industry, 4 in the Province of Quebec, 1 in Ontario, and 1 in British Columbia. * * *

The following information is from a report prepared by the Bureau of Mines, Ottawa:

Ontario supplies all of the prime white powdered talc produced, Quebec furnishing off-color ground talc (in part made from soapstone waste), sawn dimension soapstone, and talc crayons. In recent years, the total output of ground talc of all grades has been about equally divided between these two provinces, with annual shipments averaging between 12,000 and 15,000 tons each.

Canada is self-sufficient in respect to most of the grades of ground talc needed for its industrial requirements, and there is a considerable surplus for export. It also produces most of the sawn dimension soapstone and talc crayons used, but is dependent on imports, obtained mainly from the United States, for certain special qualities of ground talc demanded by the ceramic, paint, and cosmetic trades. Imports of such talc in 1942 and 1943 amounted to approximately one-third of the total domestic consumption of about 15,000 tons.

Following the outbreak of war, a substantial demand for Canadian talc developed in the British market, to supply deficiencies caused by cutting off imports from France, Italy, and Norway. In 1943, all forms of talc, soapstone, and pyrophyllite were placed under strict control and allocation by the British Government, with all purchases and imports to be made for Ministry of Supply account.

In Ontario, all the output comes from the Madoc area, in Hastings County, where production commenced some 40 years ago.

In Quebec, the entire production is obtained from the Eastern Townships, mainly from the Thetford Mines area, and there are also a mine and mill at Highwater, close to the Vermont boundary. All of Canada's output of sawn soapstone blocks comes from the Thetford Mines area.

Owing to the critical need for additional sources of massive, steatitic talc, investigations were made during 1943 and 1944 by Wartime Metals Corporation, a Crown company, of an occurrence of such material near Red Earth Creek in Kootenay Park, British Columbia, but it was decided that the recovery of usable material was too low to justify further work. Samples of yellow steatite from a deposit at the base of Mt. Whymper, several miles south of the above occurrence, were forwarded to the United States for test, but the material proved to be too badly flawed to be usable.

* * * * * * *

The Canadian consumption of ground talc in 1943, as reported by users, totalled 17,201 tons, distribution, by industries, being as follows: paints, 34 percent; roofing products, 23 percent; rubber, 11 percent; pulp and paper, 9 percent; cosmetic and pharmaceutical preparations, 7 percent; insecticides, 5 percent; soaps and cleaners, 3 percent; miscellaneous, 8 percent. Consumption of soapstone furnace blocks by Canadian pulp and paper mills in the same year was 1,076 tons, equivalent to 11,956 cubic feet.

* * * * * * *

Ground talc has a wide price range. * * * Roofing and foundry talcs are the cheapest grades, the users being satisfied with coarser, grey or off-colour material, often soapstone powder or sawing dust, which sells for about $5 to $7 a ton f. o. b. rail. Domestic grey talc, suitable for roofing, rubber, and paper use, sold in 1944 for $8 to $11.75 a ton according to fineness. White talc from Madoc, Ontario, was quoted at $8 to $10 for the coarser grades, $12 to $18 for finer mesh sizes, and $44 for minus 400-mesh material.

FLUORSPAR AND CRYOLITE

By Hubert W. Davis and Gertrude N. Greenspoon [1]

SUMMARY OUTLINE

FLUORSPAR

SUMMARY

Fluorspar production in the United States, which reached an all-time high of 413,700 short tons in 1944 after an unbroken 6-year upward trend, declined to 325,200 tons in 1945. The smaller output was caused largely by suspension of operations at some mines and downward adjustment in operating schedules at many others to conform to the lessened demand for fluorspar that followed the ending of hostilities with Japan on August 14. Also contributing to the drop in output was the Ohio River flood in March, which forced all mines and mills in the Rosiclare district of Illinois to stop operating for about 2 weeks, and heavy rains, which necessitated extra pumping at mines in the Cave in Rock district of Illinois and at some mines in western Kentucky. A number of mines, including the Rosiclare in Illinois and the Keystone, Old Silver, and Ellis in Kentucky, were flooded and put out of production for some time.

Shipments of fluorspar likewise declined to 323,961 tons (413,781 tons in 1944). Despite the loss of output because of the flood and extra pumping, Illinois maintained its rank as the chief producer in 1945 by supplying 45 percent of the domestic shipments.

Consumption of fluorspar, which in 1944 for the first time exceeded 400,000 tons, declined to 356,090 tons in 1945. The drop was due chiefly to severe curtailments at steel and hydrofluoric acid plants after VJ-day owing to war-contract terminations and to production stoppages at steel mills during the mid-August victory celebrations.

Receipts of foreign fluorspar (100,725 tons) in 1945 established a new record, exceeding by 9 percent the previous peak of 1944. As in 1944, the bulk of the fluorspar imported was delivered to the Govern-

[1] Figures on imports (unless otherwise indicated) compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce; those on exports of fluorspar supplied by the producers.

ment stock pile. Exports—usually small—were again insignificant and totaled only 1,420 tons in 1945.

The Government stock-pile objective of 260,000 tons of fluorspar was nearly attained, as 245,728 tons of finished fluorspar had been delivered toward it at the close of 1945; however, of this amount, 46,872 tons have been disposed of, leaving a balance of 198,856 tons of finished fluorspar stocked in the United States on December 31. In addition, 12,600 tons belonging to the United States Government were stored in Spain. All contracts for the purchase of fluorspar for the Government stock pile were terminated during 1945. The finished fluorspar remaining in the Government stock pile when declared surplus will be transferred to the Treasury Procurement Division in accordance with the Surplus Property Act of 1944, Public No. 457, 78th Congress, sec. 22 (a), approved October 3, 1944.

Production of metallurgical-grade and ceramic-grade fluorspar was ample for requirements throughout 1945; because of the satisfactory supply-and-demand relationship in these grades, there were no restrictions on their delivery or use. On the other hand, acid-grade fluorspar was in short supply until VJ-day, and the restriction on its use for nonessential purposes continued in effect until that time. During the first 7 months of 1945, consumption of acid-grade fluorspar averaged about 11,600 tons monthly, whereas domestic production averaged only 8,700 tons.

Salient statistics of fluorspar in the United States, 1936–45, in short tons

Year	Shipments from domestic mines	Foreign trade		Consumption	Stocks at end of year

[1] Finished fluorspar only.
[2] Revised figure.

The shortage in domestic production was met by milling to acid grade a substantial tonnage of Mexican fluorspar and by the use (after drying) of an appreciable quantity of flotation concentrates from Newfoundland; these tonnages were from the Government stock pile. The Mexican fluorspar, being of much higher grade than domestic milling ore, lends itself to higher recovery.

The greatly increased demand for acid-grade fluorspar during the war resulted from its expanded use in both anhydrous and aqueous hydrofluoric acid. Anhydrous hydrofluoric acid has three major uses—as a catalyst for producing aviation alkylate (widely used in high-octane aviation blends), as a raw material in the production of Freon (which gained new prominence when it began to be used as the propellant in the aerosol insecticide bomb), and for certain secret military uses, including the atom bomb. The bulk of the aqueous hydrofluoric acid is employed in producing fluorine chemicals—aluminum fluoride, sodium aluminum fluoride, sodium fluoride, and others. The little-publicized fluorine chemicals and their contribution to the war program are discussed in an article by Callaham.[2] The aerosol insecticide bomb is described in much detail in Steel.[3]

With the end of the war with Japan, consumption of acid-grade fluorspar declined phenomenally to an average of about 4,800 tons monthly during the last 4 months of 1945. The postwar outlook for acid-grade fluorspar, as well as other grades, has been discussed by Waggaman and Ralston.[4]

Deliveries of fluorspar to consumers in the United States totaled 357,624 short tons in 1945 (313,092 tons from domestic mines and 44,532 tons from foreign sources); in addition, 9,449 tons of finished fluorspar from domestic mines were delivered to Government stock piles. In 1944 deliveries to consumers totaled 398,916 tons (387,405 tons from domestic mines, 3,696 tons from Government stock piles, and 7,815 tons from foreign sources); in addition, 24,396 tons of finished fluorspar from domestic mines were delivered to Government stock piles. Total deliveries to steel plants in the United States decreased to 207,100 tons from 221,000 tons in 1944 and those to hydrofluoric acid plants dropped to 102,734 tons from 126,991 tons in 1944; sales to glass and enamel plants advanced to 36,508 tons from 29,859 tons in 1944.

The average composite selling price ($30.72 a short ton) of all grades of fluorspar (both domestic and foreign) delivered to consumers in the United States was $0.12 more than in 1944 ($30.60). The average selling price of all grades of domestic fluorspar shipped in 1945 ($30.55) established a new peak and was $0.33 greater than the previous high of 1944. The average selling price f. o. b. Illinois-Kentucky mines of metallurgical-grade fluorspar shipped to domestic steel plants was $29.94 a ton ($29.73 in 1944) and of that shipped to domestic manufacturers of hydrofluoric acid $37.72 ($36.51 in 1944).

The total quantity of fluorspar shipped in and imported into the United States from about 1870 through 1945 was approximately 7,648,000 short tons, comprising about 83 percent from domestic mines and 17 percent from foreign sources.

The total shipments since commercial production was begun (around 1870) in the United States through 1945 were approximately 6,353,000 tons, of which Illinois and Kentucky contributed 53 and 35 percent, respectively. Imports of fluorspar into the United States from 1910 through 1945 were about 1,138,000 short tons, and imports before 1910 are estimated at 157,000 tons—a total of about 1,295,000 tons, of which the United Kingdom and Germany contributed 41 and 16 percent, respectively.

It is noteworthy that, of the total domestic shipments, 2,241,114 tons (35 percent) were shipped during the past 7 years (1939–45). Despite the drain on resources of fluorspar during these years,

[2] Callaham, J. R., Fluorine Industry Molds a Postwar Career from Wartime Service: Chem. and Met. Eng., vol. 52, No. 3, March 1945, pp. 94–99.
[3] Steel, Bug Bombs: Vol. 116, No. 26, June 25, 1945, pp. 118–119, 156, 160.
[4] Waggaman, W. H., and Ralston, O. C., Postwar Prospects for Fluorspar are Bright: Min. and Met., vol. 26, No. 462, June 1945, pp. 295–299.

Pehrson[5] states that, as of December 31, 1944, about 60 percent of the total known domestic reserves, as estimated by the Federal Geological Survey and the Bureau of Mines, remained, and that commercial reserves as of that date would be sufficient for 40 years at the 1935–39 annual rate of use of domestic fluorspar.

Fluorspar shipped[1] from mines in the United States, 1880–1945, by States, in short tons[2]

Year	Arizona	Colorado	Illinois	Kentucky	Nevada	New Mexico	Other States[3]	Total

[1] Imports Aug. 1 to Dec. 31, 1909, totaled 6,971 tons. Earlier imports not separately recorded but estimated at 150,000 tons and virtually all from United Kingdom.
[2] Argentina, Australia, Austria-Hungary, Belgium, China, Czechoslovakia, Italy, Netherlands, Norway, Tunisia, and Soviet Russia in Asia.
[3] Figures, by years, for 1910–39 are given in Minerals Yearbook, Review of 1940, p. 1298.
[4] Less than 1 ton.
[5] Bureau of Mines has determined that 1,691 tons credited to Canada by the U. S. Department of Commerce originated in Newfoundland.

PRODUCTION AND SHIPMENTS

Production of finished fluorspar totaled 325,200 short tons in 1945, including 121,670 tons of flotation concentrates. In addition, about 34,000 tons of crude ore, equivalent to 16,300 tons of finished fluorspar, were mined but not milled in 1945. Thus, total mine production (expressed in terms of finished fluorspar) was 341,500 tons in 1945 compared with 396,000 tons in 1944. Of the mine production in 1945,

[5] Pehrson, E. W., The Mineral Position of the United States and the Outlook for the Future: Paper presented before the New York Section, Am. Inst. Min. and Met. Eng., Feb. 19, 1945, 18 pp.

10 mines producing over 10,000 tons each supplied 161,000 tons or 47.2 percent, 10 mines producing 5,000 to 10,000 tons each supplied 76,000 tons or 22.3 percent, 30 mines producing 1,000 to 5,000 tons each supplied 80,000 tons or 23.4 percent, and 13 mines producing 500 to 1,000 tons each supplied 9,000 tons or 2.6 percent; thus, 63 mines produced 326,000 tons or 95.5 percent of the total. The remainder (15,500 tons or 4.5 percent) of the production, in quantities ranging from a few tons to 500 tons, came from an undetermined number of small mines, prospects, waste dumps, and old workings of abandoned mines.

Fluorspar shipments from domestic mines in 1945 aggregated 323,961 short tons valued at $9,896,879, decreases of 22 percent in quantity and 21 percent in total value from the all-time high of 1944. Of the 1945 total, 52,718 tons were shipped by river or river-rail for delivery to consumers as compared with 69,536 tons in 1944.

Illinois (45.4 percent) and Kentucky (29.4 percent) supplied 74.8 percent of the fluorspar shipped in 1945 compared with 69.9 percent in 1944. Shipments from Illinois and Kentucky were 16 percent less than in 1944 compared with a loss of 35 percent from other producing States.

The average value of all grades of finished fluorspar shipped in 1945 was $30.55 a short ton ($0.33 more than the 1944 average).

The following table shows shipments of fluorspar, by States, in 1944 and 1945.

Fluorspar shipped from mines in the United States, 1944–45, by States

State	1944			1945		
	Short tons	Value		Short tons	Value	
		Total	Average		Total	Average
Illinois	176,259	$5,954,991	$33.79	147,251	$5,014,807	$34.06
Kentucky	112,791	3,363,788	29.82	95,142	2,832,945	29.78
Colorado	65,209	1,604,043	24.60	52,437	1,333,735	25.43
New Mexico	42,973	1,205,830	28.06	14,449	390,331	27.01
Nevada	7,293	251,421	23.37	7,038		
Utah	3,466			2,973	304,045	22.43
Texas	4,769	100,381	21.05	3,413		
Washington				132		
Arizona	976	21,983	22.52	1,126	21,016	18.66
California	26	650	25.00			
Wyoming	19	400	21.05			
	413,781	12,503,487	30.22	323,961	9,896,879	30.55

Shipments of fluorspar in 1945 comprised 193,524 tons of fluxing gravel (including 4,182 tons of flotation concentrates which were blended with fluxing gravel) and foundry lump, 129,806 tons of ground and flotation concentrates, and 631 tons of acid lump. The bulk of the fluxing-gravel and foundry-lump fluorspar was shipped to steel plants and iron foundries; but a comparatively small tonnage moved to plants making cement, ferro-alloys, nickel, basic refractories, and fluxing compounds, to smelters of secondary metals, and to the Government stock pile. Of the ground and flotation concentrates shipped in 1945, hydrofluoric acid plants took 61 percent; the remainder went to aluminum- and magnesium-reduction works, to manufacturers of ferro-alloys, steel, glass, enamel, and welding rod, to smelters of secondary metals, and to the Government stock pile. Except for 36 tons to steel plants and 2 tons to nonferrous smelters, all the acid-lump fluorspar was shipped to hydrofluoric acid plants.

The next table shows shipments of fluorspar, by grades and industries, in 1944 and 1945.

Fluorspar shipped from mines in the United States, 1944–45, by grades and industries, in short tons

Grade and industry	1944	1945
Fluxing gravel and foundry lump:		
Ferrous	210,930	[1] 184,645
Nonferrous	1,264	1,170

Glass and enamel	29,859	35,960
Hydrofluoric acid	121,084	80,155
Miscellaneous	2,730	1,796
Government stock pile	24,396	9,449
Exported	1,980	1,420
	413,781	323,961

[1] Includes 4,182 tons of flotation concentrates, which were blended with fluxing gravel.
[2] Includes pelletized gravel.
[3] Excludes 4,182 tons of flotation concentrates, which were blended with fluxing gravel.

SHIPMENTS, BY USES

As is evident from the following table and figure 1, the predominant purchaser of fluorspar is the steel industry, which also consumes substantial quantities of hydrofluoric acid and sodium fluoride, in which fluorspar is the basic material.

Fluorspar shipped from mines in the United States, 1944–45, by uses

Use	1944				1945			
	Quantity		Value		Quantity		Value

	410,170	98,446	9,041	356,090	103,148	7,222

Production of basic open-hearth steel and consumption and stocks of fluorspar (domestic and foreign) at basic open-hearth steel plants, 1941–45

	1941	1942	1943	1944	1945
Production of basic open-hearth steel ingots and castings……long tons	66,056,000	67,821,000	69,695,000	71,387,000	64,510,000
Consumption of fluorspar in basic open-hearth steel production……short tons	191,300	217,100	205,676	201,788	176,488
Consumption of fluorspar per ton of steel made……pounds	5.8	6.4	5.9	5.7	5.5
Stocks of fluorspar at basic open-hearth steel plants at end of year……short tons	84,200	60,400	57,200	53,100	63,900

Fluorspar was reported consumed in 38 States and the District of Columbia in 1945, but 3 States—Illinois, Ohio, and Pennsylvania—used 199,625 tons or 56 percent of the total consumption. Pennsylvania was again the chief consuming State; it ranked first in consumption of fluorspar in both steel and glass and second in hydrofluoric acid. Illinois maintained its rank as the largest consumer of fluorspar in hydrofluoric acid in 1945.

The next table shows, so far as possible without revealing the figures of individual companies, the consumption of fluorspar, by States, in 1944 and 1945.

Fluorspar (domestic and foreign) consumed in the United States, 1944–45, by States, in short tons

State	1944	1945
Alabama, Georgia	11,120	9,177
Arkansas, Florida, Louisiana, Mississippi, North Carolina	322	3,894

West Virginia	6,102	5,945
	410,170	356,090

PRICES

Prices fixed by the Office of Price Administration on July 1, 1943, remained in effect in 1945; they were $30 to $33 a short ton for metallurgical-grade fluorspar and $37 a ton for acid and ceramic grades.

STOCKS AT MINES OR SHIPPING POINTS

According to reports of producers, the quantity of fluorspar in stock at mines or shipping points at the close of 1945 totaled 72,473 tons or 16 percent more than in 1944. These stocks comprised 20,249 tons of finished fluorspar and 52,224 tons of crude fluorspar (calculated to be equivalent to 27,000 tons of finished fluorspar).

Stocks of fluorspar at mines or shipping points in the United States, December 31, 1944 and 1945, by States, in short tons

State	1944			1945

[1] This crude (run-of-mine) fluorspar must be beneficiated before it can be marketed.
[2] Revised figure.

TECHNOLOGIC DEVELOPMENTS

Interest in the heavy-media and flotation processes for treating fluorspar ores continued in 1945. With the heavy-media process, lower-grade ore can be mined and beneficiated than is economical with jigs, treatment costs are lowered, a better concentrate with lower tailing losses is obtained, and production is increased. The flotation process is now used successfully at many mines to concentrate the disseminated ores that could not be jigged and also to recover additional fluorspar from the slime overflow at gravity-concentrating plants.

Western Minerals Co. completed a small heavy-media plant to serve the Mitchem mine near Keller, Ferry County, Wash.; it began operating in February 1945.

To cut down the loss of ferrosilicon, the Rosiclare Lead & Fluorspar Mining Co., Rosiclare, Ill., made certain adjustments in its heavy-media plant, which began operating in March 1944.

In 1945 the Aluminum Ore Co., which has a flotation mill at Rosiclare to produce acid-grade fluorspar concentrates, had under construction a heavy-media unit. Concerning the heavy-media unit of the Aluminum Ore Co., the American Cyanamid Co. reports as follows:[6]

> * * * Operating experience has demonstrated that any great lowering of the head feed value makes it difficult to maintain fluorspar recoveries and the grade of concentrate. Consequently, when mining operations dictated the utilization of "low-grade" ore, it became necessary to make a revision in milling methods. The development of some suitable means to treat this "low-grade" ore economi-

[6] American Cyanamid Co., Heavy-Media Separation Processes: Ore Dressing Notes 14, December 1945, pp. 41–42.

cally would make possible the production of many thousands of tons of concentrates from material that is now considered waste.

Various types of concentration tests were made on this low-grade ore and it was found that treatment by a Heavy-Media Separation unit would produce a superior grade of mill feed. Accordingly, it was decided to install such a unit ahead of flotation.

This type of treatment will reject one-third to one-half of the minus 2-inch, plus 10-mesh material in the feed, with a loss of approximately 5 percent of the fluorspar values. This is possible because the ore is naturally "free milling"; liberation of most of the gangue minerals being accomplished by a minus half inch crush. Estimated treatment costs are low and it is felt that a part of these costs will be offset by lowered costs for grinding and flotation. These sections profit by the removal of the gangue in coarse sizes, as such material is the hardest to grind and in grinding forms slimes which are detrimental to flotation. * * *

The unit is designed to treat 25 tons of crude ore per hour and by rejecting one-third to one-half of the coarse material in the feed will supply an enriched product for flotation feed. Resulting advantages will be cleaner mining and increased ore reserves due to the ability to mine ore of lower grade than is now possible, increased flotation recoveries, increased flotation capacity and lowered flotation and grinding costs. These advantages should result in a longer property life and will assist in the conservation of a national resource which seems to be none too plentiful.

Flotation plants were completed in 1945 near Colorado Springs, Colo., by Kramer Mines, Inc., near Salida, Colo., by the Chaffee County Fluorspar Corp. (later acquired by United States Fluorspar, Inc.), and at Marion, Ky., by Minerals Flotation Corp. Davenport Mine, Inc., installed six flotation cells to treat sand spar at the Davenport mine near Salem, Ky. The Western Fluorite Co. added a flotation unit to its milling plant to treat ore from its Eagle Mountains mine near Van Horn, Tex. The Rosiclare Lead & Fluorspar Mining Co. added a battery of cells to its flotation mill at Rosiclare, Ill. Output of flotation concentrates from domestic ore totaled 121,670 short tons in 1945 compared with 156,672 tons in 1944. In addition, flotation mills in the United States recovered 17,374 and 4,855 tons, respectively, from milling Mexican ore in 1945 and 1944.

The Bureau of Mines continued its metallurgical studies on fluorspar. Further progress was made in perfecting the separation of fluorspar and barite, and an investigation of various binders for agglomerating fine fluorspar for metallurgical use was continued at the Rolla Laboratory.

According to Jardine,[7] a metallurgical concern in Salt Lake City is said to have developed an improved method for the treatment of complex fluorite ore to produce acid-grade concentrate. The treatment involves a new flotation technique in which barite and calcite are depressed and fluorite floated.

FLUORSPAR INDUSTRY IN 1945, BY STATES

Arizona.—Production in Arizona in 1945, totaling 1,100 short tons, came from mines and prospects in Greenlee, Maricopa, and Yuma Counties; that from Greenlee County was shipped to a flotation plant at Deming, N. Mex. The concentrates recovered from the fluorspar, rather than the milling ore, have been credited in the statistics to Arizona. The fluorspar from Maricopa County came from the Contact and Mammoth mines operated by the Big Spar Mining & Milling Co., the West End mine operated by Isaac Campbell, the

[7] Jardine, F. M., Ore Concentrating and Milling: Min. and Met., vol. 26, No. 458, February 1945, p. 64.

Union Hill and West End mines operated by Harry Hershkowitz, and the Contreras mine operated by Frank L. Metler and Raymond Contreras. The fluorspar from these mines, which are near Wickenburg, was shipped to steel plants. The Big Spar Mining & Milling Co. was installing a jig plant to treat ore from its mines. The fluorspar from Yuma County was a byproduct from the Sonora lead mine and was shipped to a steel plant and to an iron foundry. The Southwestern Mineral Co., which has a flotation plant near Duncan, produced a small quantity of off-grade concentrates which were sold to a flotation plant at Deming, N. Mex.

California.—No fluorspar was reported produced in California in 1945, nor did the plants of Industrial Minerals & Chemical Co. at West Berkeley and Robinson & Stephens at La Verne grind any fluorspar during the year.

Colorado.—Chiefly because of greatly reduced operations by the Western Fluorspar Corp.—largest producer in 1944—and the Fluorspar Processing Co., production of finished fluorspar declined to 52,200 tons in 1945 from 65,300 tons in 1944. In addition, some crude ore equivalent to 200 tons of finished fluorspar was mined but not milled in 1945. Thus, production (expressed in terms of finished fluorspar) totaled 52,400 tons in 1945 compared with 53,900 tons in 1944. Output came from Boulder, Chaffee, Jackson, Mineral, and Park Counties.

Shipments from Colorado were 52,437 tons in 1945 compared with 65,209 tons in 1944. The 1945 shipments comprised 26,838 tons of metallurgical-grade fluorspar and 25,599 tons of flotation concentrates.

During 1945 Harry M. Williamson & Son improved its flotation unit by adding a classifier, a filter, a conditioner, and a boiling circuit. At the Emmett and Argo mines each shaft was sunk an additional 100 feet. Production of finished fluorspar was 23 percent more than in 1944 and comprised almost equal quantities of fluxing gravel and acid-grade flotation concentrates. The company's entire production was under contract to the Office of Metals Reserve until December 12, and as a consequence the decline in demand after VJ-day had little effect on its 1945 operations. The ore treated in the mill came chiefly from the company-operated Emmett mine, but some was also contributed by its Argo and Blue Jay mines, all in Boulder County.

Production of flotation concentrates at the mill (near Jamestown) of General Chemical Co. was 5 percent less than in 1944. The output of the mill was shipped to the hydrofluoric acid plants of the company. The flotation-mill feed comprised ore from the company-operated Alice, Burlington, Chancellor, Invincible, and Yellow Girl mines in Boulder County and some purchased ore. This company also operates a flotation mill in New Mexico.

The fluorspar properties of the Colorado Fluorspar Corp. near Salida, Chaffee County, were sold on February 5 to Colorado Fluorspar Mines, Inc., which immediately started to increase the productive capacity of both mine and mill. A 5 by 5 ball mill, a duplex classifier, six flotation cells, a 3 by 30 rotary drier, and two banks of jigs were added to the mill. A three-compartment shaft was sunk, and a 75-foot head frame and a double-drum hoist were installed at the mine. Sinking the shaft an additional 100 feet was in progress at the end of the year. A new crushing plant was installed, and a

200-ton steel ore bin was erected. The combined production of both operators in 1945 was 56 percent greater than in 1944. The 1945 output comprised 46 percent fluxing gravel and 54 percent flotation concentrates.

The entire output of the American Fluorspar Corp. was obtained from its Dostal mine near Salida. Production of fluxing-gravel fluorspar was 32 percent greater than in 1944; but its output of milling ore, which was sold to local mills, was 94 percent less. The flotation mill of the Fluorspar Processing Co.—on property of the American Fluorspar Corp.—was only operated in January and 10 days in February 1945 as compared with 12 months in 1944, consequently production of fluorspar concentrates was 97 percent less.

The new flotation mill of the Chaffee County Fluorspar Corp. near Salida was brought into production in February 1945. After making a small output, the mill and mine were sold to United States Fluorspar, Inc., on September 1, since which time that company has been developing the mine and improving the flotation plant by the addition of cells, a classifier, and a ball mill to replace a rod mill. The company also has installed pelletizing equipment. Meanwhile, a small quantity of flotation concentrates was produced.

The heavy-media plant of Western Fluorspar Corp. near Northgate, Jackson County, was closed during the first 4 months of 1945 for equipment repairs, and on August 26 it was again closed because of reduced demand for fluorspar. Consequently, production of fluxing-gravel fluorspar in 1945 was 79 percent less than in 1944.

The Crystal prospect—a new discovery—also near Northgate, was being developed in 1945.

The new flotation mill of Kramer Mines, Inc., near Colorado Springs, El Paso County, began operating in February 1945 but discontinued production in September. The mill feed comprised ore from the company-operated mines, also near Colorado Springs.

The Wagon Wheel Gap mine, in Mineral County, of the Colorado Fuel & Iron Corp. was operated throughout 1945, but output was 10 percent less than in 1944.

A small quantity of fluorspar was produced in 1945 by Luke E. Smith at the Bear Cat mine near Jefferson, Park County.

The fluorspar deposits of Colorado have been described in some detail by Cox.[8]

During 1945 a fluorspar section of the Colorado Mining Association was formed in the interest of the industry in Colorado, New Mexico, and Utah.

Idaho.—A 60-ton flotation mill to serve the Chamac mine near Forney, Lemhi County, was reported completed in 1944 by A. E. Chambers. Except for a short test run in 1944, the mill has not operated.

Illinois.—Partly because of the Ohio River flood in March and partly because of reduced demand following VJ-day, production of fluorspar in Illinois declined in 1945; nevertheless, Illinois maintained its rank as the chief producing State. Production of finished fluorspar was 148,900 short tons in 1945; about 98 percent came

[8] Cox, D. C., General Features of Colorado Fluorspar Deposits: Proc. Colorado Sci. Soc., vol. 14, No. 6, 1945, pp. 263–285.

from Hardin County and 2 percent from Pope County. In addition, some crude ore equivalent to 2,500 tons of finished fluorspar was mined but not milled in 1945. Thus, production (expressed in terms of finished fluorspar) totaled 151,400 tons in 1945 compared with 177,000 tons in 1944. Much Kentucky fluorspar is milled in Illinois, and some Illinois fluorspar is milled in Kentucky; the finished fluorspar so recovered, as well as that shipped, is credited in the statistics to the State of origin. The Argo, Austin, Blue Diggings, Crystal, Deardorff, Douglas, Fairview, West Green, Hawkins, Hillside, Knox, Midway-North Boundary-Air Shaft, Minerva, Rose Creek, Rosiclare, Victory, and Wall properties supplied about 97 percent of the fluorspar produced in Illinois in 1945; the remainder came from many mines and prospects, including the W. L. Davis, Deep Shaft, East Green, Hill, Humm, Iron Hill, Lead Hill, Preen, Recovery Shaft, Red Tipple, Rock Candy Mountain, and Winn.

Shipments of fluorspar from Illinois (147,251 tons) were 16 percent less than in 1944 but constituted 45 percent of the total shipped. The 1945 shipments comprised 65,440 tons to steel plants, 55,688 tons to hydrofluoric acid plants, 19,171 tons to glass and enamel plants, 6,166 tons to iron foundries, nonferrous smelters, aluminum- and magnesium-reduction plants, and ferro-alloy, nickel, and welding-rod manufacturers, and 786 tons to Brazil, Canada, and Peru. Of the 1945 total, 30,327 tons were shipped by river or river-rail to consumers compared with 41,790 tons in 1944.

The Aluminum Ore Co., largest producer of fluorspar in the United States in 1944, dropped to fourth place in 1945, because of a 44-percent decline in output at its flotation mill. The mill feed comprised ore from the company-operated Argo, Blue Diggings, and Fairview mines. Development was carried on at various levels of these mines in 1945. A small tonnage of Mexican ore was also milled by the company; but the flotation concentrates so recovered, as well as shipped, are not included in the statistics for Illinois. The Fairview and Blue Diggings mines and the flotation mill have been described briefly by Avery.[9]

The Crystal Fluorspar Co. produced 29 percent less fluorspar at its Crystal mine in 1945 than in 1944. The company did 14,043 feet of churn and diamond drilling in 1945.

Production of gravel and flotation concentrates by Inland Steel Co. (successor to Hillside Fluor Spar Mines on June 1) was 30 and 20 percent, respectively, less than in 1944. The mill feed comprised ore from the Hillside and Wall mines at Rosiclare, Ill., and the Barnes, Guill, and Keystone mines near Marion, Ky., purchased ore chiefly from the Austin, Douglas, Knox, Lead Hill (Grischy), and Rose Hill mines, and tailings from previous milling operations. Production and shipments of finished fluorspar from the Barnes, Guill, and Keystone mines have been credited in the statistics to Kentucky. The company acquired the Barnes mine in Kentucky and the Rock Candy Mountain mine in Illinois in 1945.

The Victory mine of the Victory Fluorspar Mining Co. produced 17 percent less fluorspar than in 1944. The mine was closed August 9

[9] Avery, W. M., Aluminum Ore Company Answered S. O. S. for Vital Defense Material: Pit and Quarry vol. 38, No. 4, October 1945, pp. 72–75.

because of a strike. On August 13 the interests of the other partners in the Victory Fluorspar Mining Co. were purchased by Martin Schwerin.

The flotation mill of Mahoning Mining Co. produced 13 percent less fluorspar concentrates from domestic ore than in 1944. The mill feed comprised ore from the W. L. Davis, Deardorff, East Green, and West Green mines near Cave in Rock, Ill., the Klondike and Mineral Ridge mines near Smithland, Ky., and some purchased ore. Production of finished fluorspar comprised 80.3 percent acid-grade, 19.4 percent pelletized gravel, and 0.3 percent filter cake; the filter cake was sold to local producers for blending with fluxing gravel. Production and shipments of finished fluorspar from the Klondike and Mineral Ridge mines have been credited in the statistics to Kentucky. A comparatively small tonnage of Mexican fluorspar was also milled by the company in 1945; the flotation concentrates so recovered, as well as shipped, are not included in the statistics for Illinois.

The Rosiclare Lead & Fluorspar Mining Co. operated the Deep Shaft, Hawkins, Midway-North Boundary-Air Shaft, Recovery Shaft, and Rosiclare properties in 1945. The Rosiclare mine was flooded by the high water from the Ohio River in March and was out of production until May 20, when hoisting of ore was resumed; nevertheless, it was the chief producing mine of the company. The ore from the company mines is mill feed for its heavy-media-process plant and flotation mill. A substantial quantity of tailings from previous milling operations was treated in the heavy-media plant in 1945. Production of finished fluorspar of all grades was 9 percent less than in 1944, and shipments were 14 percent smaller.

The mine and flotation mill of Minerva Oil Co., both of which were brought into operation in March 1944, were operated throughout 1945, and output of flotation concentrates was double that of 1944. The company also milled a comparatively small tonnage of Mexican fluorspar; but the flotation concentrates so recovered, as well as shipped, are not included in the statistics for Illinois.

The Lead Hill and Stewart mines of the Fluorspar Products Co. were inactive most of 1945; in consequence, output declined sharply.

The Rose Creek and Douglas mines, operated by Yingling Mining Co., were worked at a greatly reduced rate in 1945. Its entire output was sold to local mills for treatment.

Kentucky.—Production of fluorspar in Kentucky has declined progressively since 1942. Output of finished fluorspar was 95,000 short tons in 1945. However, the production includes 600 tons of finished fluorspar recovered from milling some crude ore mined before 1945. Consequently, total mine production (expressed in terms of finished fluorspar) was 94,400 tons in 1945 compared with 107,900 tons in 1944. Shipments also declined; they amounted to 95,142 tons—a 16-percent decrease from 1944. The 1945 shipments comprised 81,563 tons to steel plants, 11,251 tons to glass, enamel, and hydrofluoric acid plants, 2,292 tons to iron foundries, nonferrous smelters, cement, ferro-alloy, and miscellaneous plants, and 36 tons to Canada. Of the 1945 shipments, 22,391 tons were shipped to consumers by river or river-rail compared with 27,746 tons in 1944.

717372—47——91

Output in Caldwell County was much less than in 1944, chiefly because the Eureka, Hollowell & Hobby, Hughett, and Senator mines, which furnished the bulk of the 1944 production, were nonproductive in 1945. Most of the small output in Caldwell County came from the Glass, Ray Hill, Tyree, and Williamson mines, and from tailings milled by Albert Melhman, who acquired and rehabilitated the Crook mill at Crider.

The major part of the 1945 output in Crittenden County came from a few mines—Bachelor, Big Four, Blue, Davenport, Keystone, Pigmy, and Tabb. Most of the remainder came from many smaller producing mines (including the Babb, Ball, Barnes, Cook, Eagle (Watson), Gilless, Henley, Hickory Cane, Hodge, Kelley, Krause, La Rue, Pogue, Reiter, Waddell, Watkins, and Yates) and from numerous prospects; some was reclaimed from waste dumps and old workings of abandoned mines.

The Eagle Fluor Spar Co. worked the Babb and Eagle (Watson) mines at a greatly reduced rate in 1945.

The United States Coal & Coke Co. was the largest producer of fluorspar in the United States in 1945; it produced 16 percent more finished fluorspar than in 1944, but shipments were only 2 percent greater. The output came chiefly from the company-operated Tabb mines, but some was from the Big Four mine owned by the company but operated by Perry & Loyd.

The Kentucky Fluor Spar Co. and affiliates shipped 25 percent more fluorspar than in 1944. The company operates a mill at Marion and, through its mining division (Roberts & Frazer), operated the C. R. Babb, Carr, Ellis, and Wright mines in Livingston County. About three-fourths of the company supply came from these mines and the remainder chiefly from the Gilless, Minerva, Nancy Hanks, and Watkins.

The Keystone mine of Inland Steel Co. was flooded by the high waters in March and made little production during the remainder of 1945. The company also produced some fluorspar at the Barnes and Guill mines; the Barnes mine in Crittenden County was acquired in 1945. Although the fluorspar from these mines is finished at the company mill at Rosiclare, Ill., production and shipments are credited in the statistics to Kentucky.

The Pigmy mine of the Pigmy Corp. (subsidiary of the Rosiclare Lead & Fluorspar Mining Co.) produced 16 percent less fluorspar than in 1944.

The Davenport mine and equipment of the National Fluorspar Co. were sold on January 16 to Davenport Mine, Inc. During the first 4 months of 1945 production was suspended or seriously hampered by water problems brought on by continual heavy rains, consequently output at this operation was 28 percent less than in 1944.

The Delhi Fluorspar Corp. produced less fluorspar at the Bachelor mine for the fourth successive year and made no output at the Eureka mine in Caldwell County in 1945. However, the company purchased both finished fluorspar and milling ore from many producers; its shipments were 16 percent less than in 1944.

Shipments of fluorspar by L. Conyer, operating the Yates mine and a mill, both near Marion, were 19 percent smaller than in 1944.

Conyer purchases both finished fluorspar and milling ore from many local producers, and most of his shipments came from these sources.

Crider Bros. Fluorspar Co. worked the Blue mine near Mexico and the Jameson mine near Lola, reclaimed fluorspar from the Blue dumps, and purchased some fluorspar from local producers. Its sales were 40 percent less than in 1944.

In Livingston County most of the output came from the C. R. Babb, Carr, Ellis, Guill, Jameson, Klondike, Lovelace, Mineral Ridge, Nancy Hanks, Old Silver, and Wright mines and from reworking the C. R. Babb, Klondike, and other tailings.

Output at the C. R. Babb, Carr, Ellis, and Wright mines of Roberts & Frazer was about the same as in 1944. E. W. Frazer reworked the tailings at the C. R. Babb and other mines and recovered a small quantity of fluorspar.

Production of gravel fluorspar at the Nancy Hanks mine, operated by W. V. Haynes, Jr. and Tinsley & Loyd, was 36 percent more than in 1944, but recovery of sand spar was 58 percent less.

Butler & Moodie continued to reclaim fluorspar from Klondike tailings, and Butler, Moodie & Craighead made a small output at the Old Silver mine before it was flooded in March.

The Mahoning Mining Co. continued development at its Klondike and Mineral Ridge mines near Smithland, in the course of which some ore was produced.

In the Central Kentucky district production and shipments of fluorspar declined to 1,040 and 1,097 tons, respectively (1,867 and 1,707 tons in 1944). Output from this district in 1945 came from the Faircloth mine in Woodford County near Wilmore and the "Lone Oak" mine near Harrodsburg and the Twin Chimney and Britton mines near Mundys Landing, all in Mercer County. The Britton, Faircloth, and Twin Chimney mines, as well as the Gobel Dean, in Mercer County near Talmage, were acquired in mid-1945 by the Gilbert & Hageman Co. A jig mill was completed at the Twin Chimney mine, and a shaft was being sunk at the Faircloth mine. The company production of fluorspar will be shipped by barge from Mundys Landing on the Kentucky River.

Production at the "Lone Oak" mine, operated by J. B. Towles, ceased in May, because of the low grade of the ore.

Nevada.—Shipments of fluorspar from Nevada (7,038 short tons) were 3 percent smaller than in 1944. Most of the 1945 total went to steel plants, but some was shipped to hydrofluoric acid and cement plants and to an iron foundry.

The chief producing mine in Nevada in 1945 was the Baxter in Mineral County, operated by V. S. Baxter; its production was 31 percent less than in 1944. The other producing mine was the Daisy in Nye County, operated by J. Irving Crowell, Jr., but its production was 70 percent more than in 1944. The Baxter mine has been described by Thurston.[10]

New Mexico.—Fluorspar production in New Mexico, which reached an all-time high in 1944 after an unbroken 8-year upward trend,

[10] Thurston, W. R., Preliminary Report on the Baxter Fluorspar Deposit near Broken Hills, Nev. Geol. Survey Strategic Minerals Investigations, Preliminary Rept. 3-196, 1946, 3 pp.

declined in 1945. Much of the loss was due to the fact that the flotation mill of Zuñi Milling Co. operated almost entirely on Mexican ore in 1945. Production of finished fluorspar totaled 14,400 short tons, a loss of 66 percent from 1944. In addition, some crude ore equivalent to 14,200 tons of finished fluorspar was mined but not milled in 1945. Thus, production (expressed in terms of finished fluorspar) totaled 28,600 tons in 1945 compared with 40,500 tons in 1944. The output came from Catron, Dona Ana, Grant, Luna, and Valencia Counties.

Shipments from New Mexico totaled 14,449 tons, a decline of 66 percent from the all-time high established in 1944.

The flotation mill of General Chemical Co. at Deming did not operate during the latter part of 1945; consequently, production of concentrates from domestic ore was 11 percent less than in 1944. The mill feed comprised ore from the company Spar Group and Sadler mines in Luna County and the Osmer mine in Grant County and purchased ore from local mines. In addition, the company milled some Mexican ore, but the concentrates so recovered and shipped are not included in the statistics for New Mexico. Virtually all the flotation concentrates produced were shipped to the hydrofluoric acid plants of the company.

The Zuñi Milling Co., which operates a flotation mill at Los Lunas, was the largest producer of fluorspar in New Mexico in 1945. However, the mill feed comprised ore chiefly from Mexico, and the concentrates so recovered and shipped are not included in the statistics for New Mexico. A small tonnage of domestic ore stocked at the mill was also treated in 1945. The company continued development at its mines near Grants in Valencia County, in the course of which some ore was mined; it also purchased milling ore from nearby producers. The flotation mill did not operate the last 4 months of 1945, and as a consequence production from both Mexican and domestic ore was 24 percent less in 1945 than in 1944.

The Grattan flotation mill at Deming, acquired on August 1, 1944, by Edgar J. Marston, who made substantial improvements in the plant, discontinued operating in April because of his inability to make a satisfactory ratio of concentration. The mill feed comprised ore from the Greenleaf and Sadler (Grattan) mines in Luna County and the Land Lease mine in Dona Ana County—all operated by Marston—and ore purchased from the Burro Chief mine in Grant County. The concentrates produced were shipped to hydrofluoric acid plants.

During October 1945 the Grattan mill was operated by I. S. James, who produced a small tonnage of flotation concentrates which were shipped to a hydrofluoric acid plant. The Sadler (Grattan) mine was operated from June to October and produced a small tonnage of metallurgical-grade fluorspar, which was shipped to steel plants.

The heavy-media-process plant at Gila, owned by the Office of Metals Reserve and operated for that agency by the International Minerals & Chemical Co., discontinued operating in January 1945; during the month it produced 255 tons of fluxing-gravel fluorspar, which was placed in the Government stock pile at Gila. However, the Office of Metals Reserve continued to purchase milling ore until June 30, when the depot was closed. The milling ore purchased in 1945 came from the Blue Bonny, Burro Chief, Clum, Demique, Foster, Great Eagle, and Lost Brother mines. The mill was put into operation on December 27, 1943; since that time it has produced 17,908 tons of fluxing-gravel fluorspar, all of which is in the Government stock pile at Gila. The mill has operated entirely on ore purchased locally; the total quantity purchased was 79,500 tons, of which 97 percent came from the Burro Chief, Clum, Great Eagle, and Huckleberry mines.

The flotation mill of Indian Metals Co. at Lordsburg was operated sporadically during 1945, and output was about half that of 1944. The mill feed was supplied by purchased ore from the Lost Brother, Money Maker No. 1, and Spar Hill mines in Grant County near Lordsburg.

At the Burro Chief mine near Tyrone, Grant County, operated by H. E. McCray, the 400-foot level was being opened, and a washing plant was completed. However, the washing plant did not solve the cleaning problem, and a jig plant was being installed. A substantial tonnage of milling ore and some fluxing-gravel fluorspar were produced and shipped in 1945.

The Mirabal mine near Grants, Valencia County, was operated by various producers in 1945; its output comprised fluxing-gravel fluorspar which was shipped to steel plants and milling ore which was sold to the Zuñi Milling Co. The nearby Keeney and Boyd mines also produced some milling ore which was sold to the Zuñi Milling Co.

The White Star, Oakland, and Universal fluorspar veins near Hot Springs, N. Mex., have been described by Rothrock.[11]

Texas.—Production and shipments (3,518 and 3,413 short tons, respectively) were each 28 percent less than the all-time high of 1944. Production was from the Eagle Mountains mine in Hudspeth County, near Van Horn, operated by the Western Fluorite Co. A bank of flotation cells was added to the mill in 1945.

The Gibbs mine in Burnet County near Burnet was being developed by W. J. McDaniel.

The flotation mill near El Paso, Tex., which was sold on October 19, 1944, to the Continental Milling Co. for milling ore from the Moll mine in Mexico, operated a few months in 1945, after which milling of ore was discontinued. The flotation concentrates recovered from milling Mexican ore, as well as shipped, are not included in the statistics for Texas.

Utah.—Production of finished fluorspar in Utah was 2,918 short tons in 1945 compared with 3,490 tons in 1944, an all-time high. Shipments declined to 2,973 tons (3,466 tons in 1944).

The chief producer in Utah was the Tintic Standard Mining Co., which operated its Cougar mine and concentrating mill in Beaver County near Milford until September 30, when operations were suspended on account of the termination of a sales contract with the

[11] Rothrock, H. E., Preliminary Report on the White Star, Oakland, and Universal Fluorspar Veins near Hot Springs, Sierra County, N. Mex.: Geol. Survey Strategic Minerals Investigations, Preliminary Rept. 3-190, 1945, 3 pp.

Office of Metals Reserve. Production of finished fluorspar by the company was 43 percent greater than in 1944. A tunnel was being driven at a lower level in the Cougar mine. The mine and mill have been described in Mining World.[12]

Fred Staats, operating the Staats mine in Beaver County near Lund, and George Spor & Sons, operating the "Spor" mine in Juab County near Delta, also contributed to the production in Utah, but the output of these operators was 31 and 72 percent less than in 1944. The Western Fluorite Co. and the Manassa Mining & Milling Co. made no production or shipments of fluorspar in 1945.

Washington.—At the Mitchem mine in Ferry County near Keller, where development was under way and a small heavy-media-process plant was under construction by the Western Minerals Co. in 1944, both units were brought into production in February 1945. The mine is still under development. Production of fluxing-gravel fluorspar was 169 short tons in 1945, most of which was shipped to steel plants.

FOREIGN TRADE

Imports.—Receipts of imported fluorspar into the United States established a new record of 100,725 short tons in 1945—a gain of 9 percent over 1944, the previous peak. Some of the imported fluorspar placed in bonded warehouses in 1944 was withdrawn during 1945.

Fluorspar imported for consumption in the United States was 103,133 tons—a gain of 18 percent over 1944. The imports in 1945 comprised 10,275 tons containing more than 97 percent calcium fluoride and 92,858 tons of lower grade. They were valued [13] at $2,156,458. The value assigned to the higher-grade foreign fluorspar averaged $24.80 a ton in 1945 and that to the lower grade $20.48. The cost to consumers in the United States also includes duty, loading charges, insurance, consular fee, and freight to consuming plants. The duty on fluorspar containing not more than 97 percent calcium fluoride is $5.625 a short ton and on fluorspar containing more than 97 percent calcium fluoride $3.75 a ton.

In 1945, as in 1944 and 1943, the bulk of the imported fluorspar was delivered to Government stock piles. However, 22,500 tons of imported fluorspar were milled in 1945 at flotation plants in the United States; and 16,486 tons of acid-grade, 433 tons of ceramic-grade, and 455 tons of metallurgical-grade fluorspar were recovered therefrom.

[12] Mining World, Mining Utah Fluorspar—Tintic Standard's New Cougar Operation: Vol. 7, No. 8, 1945, pp. 25-27.

[13] As defined in sec. 402 of the tariff act of 1930, "The value of imported merchandise * * * is the foreign value or the export value, whichever is higher—that is, the market value or the price at which the merchandise, at the time of exportation to the United States, is offered for sale in the principal markets of the country from which exported, including the cost of containers or coverings and all expenses (including any export tax) incident to placing the merchandise in condition ready for shipment to the United States."

[1] Bureau of Mines has determined that 1,691 tons, valued at $56,918, credited to Canada by the U. S. Department of Commerce, originated in Newfoundland.

The following table, compiled from data supplied the Bureau of Mines by importers and by domestic companies milling foreign fluorspar, shows the quantities of imported fluorspar delivered to consumers in the United States in 1944 and 1945, irrespective of year of importation into the United States; it differs from the preceding table, which shows the quantity and grade imported into the United States in 1944 and 1945. The quantities in the following table are based upon the actual outturn weights and include the finished fluorspar recovered from milling foreign ore rather than the ore milled.

Imported fluorspar delivered to consumers in the United States, 1944–45, by uses

Exports.—Producers of fluorspar reported exports of 1,420 short tons of fluorspar valued at $45,939 in 1945 compared with 1,980 tons valued at $65,909 in 1944. The exports by producers in 1945 comprised 620 tons of ceramic ground and flotation concentrates to Canada; 401 tons of ground and flotation concentrates to Peru; 388 tons of flotation concentrates to Belgium; and 11 tons of ceramic ground to Brazil.

Fluorspar reported by producers as exported from the United States, 1941–45

[5] January to September, inclusive.

Canada.—According to the Dominion Bureau of Mines, production of fluorspar in Canada was 6,279 metric tons [14] (all from Ontario) in 1945 compared with 6,281 tons in 1944. In Canada output falls short of consumption, and the greater part of the deficiency is met by importations from Mexico, Newfoundland, and the United States. Imports in 1944 were 33,657 metric tons.

Germany.—The following information concerning the fluorspar industry in Germany is taken from a recent report: [15]

Germany has been for many years one of the leading producers and exporters of fluorspar, second only to the United States. In recent years the industry has been highly integrated, with control in the hands of four or five strong companies. Until the outbreak of war exports were maintained at 30,000 to 40,000 tons a year, about ⅓ of which was shipped to the United States. German consumption rose with the rapid expansion of the steel and aluminum industries from a few thousand tons in 1932 to 120,000 tons in 1938 and 180,000 tons in 1942.

[14] 1 metric ton is equivalent to 1.10231 short tons.
[15] Office of Military Government for Germany (U. S.), Non-Metallic Mineral Resources of Germany: Economic Division, Industry Branch, Coal and Non-Metallic Mining Section, Dec. 1, 1945, pp. 5–7.

Workable deposits of fluorspar are found in Bavaria, Thuringia, Anhalt, Prussia, Saxony and Baden, but the most productive mines are in the Stulln-Nabburg-Woelsendorf area of Bavaria and in the vicinity of Rottleberode in the Harz mountains. Third in importance are the deposits in the Thuringian Forest where under wartime demand a number of small mines together produced more than 30,000 tons a year.

The principal Bavarian mines are in a granite belt extending from Schwarzenfeld, some 20 kilometers northeast to Nabburg. In this district the fluorspar occurs in nearly vertical veins along shear zones in the granite, associated with barite and quartz. The Woelsendorf mine was the leading Bavarian producer with output of about 2,000 tons a month. At this mine two veins are developed by a shaft to a depth of 200 meters and over a length of 1,000 meters. Mine production was about 250 tons of ore per day from which about 80 tons of hand sorted lump, jig and flotation concentrates were recovered. A byproduct of lump barite also was recovered on the sorting table. The hand sorted lump and the jig concentrates contain 85 to 90 percent CaF_2 and are suitable for metallurgical flux used in the production of basic steel in Siemens-Martin or electric furnaces. Two flotation products were made; one containing 95 percent CaF_2 for the glass and enamel industry; and one containing 98 percent CaF_2 (acid grade) for making hydrofluoric acid used in the manufacture of artificial cryolite (sodium aluminum fluoride) and other fluorine compounds.

The oldest fluorspar mining district is in the Harz mountains in the vicinity of Rottleberode and Siptenfelde. Here fluorspar was first mined in the sixteenth century for use as a flux in the smelting of copper ores mined and smelted near Mansfeld and Eisleben. The fluorspar occurs in veins, quite commonly associated with barite which constitutes an important co-product at many of the mines.

Before and during the war expansion of the steel industry and establishment of an aluminum industry in Germany greatly increased the demand for metallurgical and acid grade fluorspar which together probably account for 80 percent or more of total consumption. Under this stimulus the less productive fields in Thuringia, Saxony and Baden were exploited to the fullest extent and production rose to 176,000 tons in 1942.

In 1934 Germany produced 71,000 tons of fluorspar and exported 31,000 tons. In the intervening years before the war exports remained at about the same level (30,000 to 40,000 tons a year) but production rose rapidly in step with the industrial expansion that accompanied the re-armament program. Steel plants were the chief consumers, and the growing demand from this source was augmented by expanding use of fluorine compounds and hydrofluoric acid, particularly in the manufacture of artificial cryolite for aluminum production. The supply from Greenland, the only source of natural cryolite, was sure to be cut off in time of war; hence the establishment of facilities for the manufacture of artificial cryolite was an essential preparatory measure, since maintenance of aluminum production was likewise an absolute necessity.

The productive capacity of fluorspar mines is divided among the zones of occupation approximately as follows:

American Zone	50 percent
British Zone	None
Russian Zone	42 percent
French Zone	8 percent

Virtually no war damage was sustained by the Bavarian mines. The extent of damage, if any, in the other producing districts is not known. In general, small mines and plants remote from industrial areas were not strategic targets and any damage was incidental to fighting in the vicinity and likely to be of a nature easily repaired.

Production during the war probably approached 200,000 tons a year. It seems a fair assumption that present capacity is not less than 75 percent of that amount, or 150,000 tons annually. It is understood that reserves are not large but would be sufficient to maintain that rate of production for 10 to 20 years.

Presumably no more aluminum will be produced in Germany, and the level of steel production will be only a fraction of wartime output. Under these conditions domestic requirements would not exceed 50,000 to 60,000 tons annually, and production at full capacity would provide an exportable surplus of around 100,000 tons a year, which is doubtless more than could be disposed of. It appears feasible to produce any quantity for export that may be needed. Stocks are believed to be small and not available for export unless the mines are reopened and production resumed.

The names, locations, and approximate capacities of the principal fluorspar mines (in the United States zone) are listed below.

Mine	Location	Capacity, tons per year
Rheinfluss	Sulzbach a. D., Bavaria	4,000

[1] Not stated.

Mexico.—Formerly a small producer, Mexico has become an important one, as indicated by exports of 50,251 metric tons in 1945 and exports of 56,450 tons in 1944. The bulk of the exports went to the United States, but some went to Canada. Some ore from the Moll mine was milled at the flotation mill near El Paso, Tex., in 1945. The mill was operated by the Continental Milling Co., which discontinued milling operations there in the early part of 1945.

Newfoundland.—The St. Lawrence Corp. of Newfoundland, Ltd., which has a gravity-concentrating mill and a flotation mill for treating the ore from its mines, and Newfoundland Fluorspar, Ltd. (a subsidiary of the Aluminum Co. of Canada, Ltd.), which ships crushed fluorspar from its mine to Arvida, Quebec, where it has a flotation plant, were the only producers in Newfoundland in 1945. Operations of both producers were adversely affected by the end of hostilities, since which time Newfoundland Fluorspar, Ltd., has suspended production and the St. Lawrence Corp. of Newfoundland, Ltd., has curtailed operations. Chiefly for this reason, production declined to 49,841 metric tons in 1945 from 58,290 tons in 1944. The output of the St. Lawrence Corp. was shipped to the United States and Canada. The flotation concentrate produced from ore mined by Newfoundland Fluorspar, Ltd., is used by the Aluminum Co. of Canada, Ltd., at Arvida, but some ore was exported in 1945.

Spain.—Chiefly as a result of demand by Germany and the United States, production of fluorspar in Spain increased from an average of 7,509 metric tons annually during the 5 years 1936–40 to 55,595 tons in 1944. The defeat of Germany and discontinuance of preclusive buying by the United States resulted in a phenomenal decline in production to 6,458 tons in 1945. The following information on Spanish fluorspar mines is taken from a report by Bennett.[16]

The most important fluorspar mines in Spain are in Asturias near Gijon and Ribadesella. These mines are capable of producing metallurgical spar of 89–91 percent CaF_2, with 5 percent silica, in considerable quantity. There is also a modern flotation plant capable of producing about 50 tons per day of acid grade. All these mines are close to tidewater, that is, within 30 or 40 km. (19 to 25 mi.) of the ship loading point.

There is a mine in Cordoba, the Fuenteovejuna, capable of producing acid lump. It has a freight rate of 65 pesetas [17] a ton to shipping points at Huelva or Seville, however.

There are two mines in Catalonia, the Osor and the Papiol, of somewhat questionable value, but should be investigated in any general study of Spanish fluorspar. The Osor mine has a good flotation plant and may be able to produce acid grade. Altogether, there is little doubt that the Spanish mines can produce 50,000 to 60,000 tons per year, including possibly 10,000 tons of acid spar between lump and flotation concentrates.

Collada mine 15 km. (9 mi.) south of Gijon, Asturias. Reserves are between 50,000 and 100,000 tons. Ore is clean with only silica gangue. Ore can be shipped as mined, at 89–91 percent CaF_2 with maximum 7 percent SiO_2. There is a gravity washing plant capable of treating 3,000 tons per month. The maximum depth worked is 60 meters (197 feet). There is a 5 km. (3 mi.) aerial tramway to the railway at Langreo, whence ore is shipped 20 km. (12 mi.) to Gijon for loading on ship. This mine was producing 2,000 tons monthly in 1944. A flotation plant to serve this mine has been built at Pinzales, 10 km. (6 mi.) from Gijon, of about 50 tons daily capacity, with the idea of shipping acid spar. It has never been used.

Pilar, Pie de Potro mine, 16 km. (10 mi.) west of Ribadesella, Asturias. High grade product, with some barite. Was producing 300–400 tons a month in 1944. Superficially developed.

Caravia mine near the Pilar. Has had some production but is relatively undeveloped.

Papiol mine near Barcelona in Barcelona Province. An old lead mine which has been worked at times for fluorspar pockets. Not considered promising.

Felguerosa mine. Adjoins Collada, 15 km. (9 mi.) south of Gijon, Asturias Province. Reserves estimated at 40,000 tons. Was producing 250 tons per month in 1944. Ore is hand-sorted and hand-jigged to produce a product of 90 percent CaF_2.

Dosal mine near the Pilar mine, west of Ribadesella. Reserves estimated at 50,000 tons. Was shipping 1,000 tons monthly in 1944 of 92–93 percent CaF_2 and 9 percent silica. Open pit and shallow underground workings.

Fuenteovejuna mine, Cordoba Province, 75 km. (47 mi.) northwest of Cordoba. It is described as a 5-meter (16-foot) vein, but is probably a replacement deposit. Similar to the Asturias deposits. It produces acid grade lump, hand-sorted. The freight rate of 65 pesetas to seaport is a heavy burden but it operates profitably. No estimate of reserves. Open pit workings.

Berbes mine, near Ribadesella in Asturias. No estimate of reserves. Was producing 500 tons a month of metallurgical spar in 1944. Superficially developed.

Osor mine, 20 km. (12 mi.) west of Gerona in Gerona Province, northeast of Barcelona. Deposits are extensive and well-developed by Germans, who planned to export acid spar to Germany. Has a recently-completed flotation plant. Ore is complicated by inclusions of lead, zinc, and barite, which are removable by flotation and leaching, but the process is undoubtedly expensive. Also, the mine is 75 km. (47 mi.) from the nearest port, San Felix de Guixols, and 115 km. (71 mi.) from Barcelona.

[16] Bennett, Evan, minerals attaché, American Embassy, Madrid, July 6, 1945, 4 pp.
[17] At the rate of exchange in February 1946, a peseta was equivalent to 9.13 cents.

CRYOLITE

Imports of cryolite were 17,952 long tons valued at $1,349,678 in 1945 compared with 15,680 tons valued at $1,155,787 in 1944. Except for 2 tons and a few hundred pounds, respectively, from Canada in 1945 and 1944, the cryolite imported in both years came from Greenland.

Exports of cryolite were 1,697 long tons valued at $420,592 in 1945 compared with 950 tons valued at $226,087 in 1944.

Cryolite occurs in commercial quantity and is mined at only one place—Ivigtut, Greenland. Gibbs [18] has described the mine at Ivigtut, the grades of ore produced, methods of processing and purification, and various uses of cryolite.

Artificial cryolite was manufactured in the United States in 1945 by the Aluminum Ore Co. at East St. Louis, Ill. Production was 4 percent less than in 1944. Plants for the manufacture of artificial cryolite were completed in 1943 at Bauxite, Ark., and Cornwells Heights, Pa., but neither has been operated.

The chief use of cryolite is in the reduction of aluminum; comparatively small quantities are used in glass, enamels, abrasives, and insecticides.

[18] Gibbs, A. E. (technical director, Pennsylvania Salt Manufacturing Co.), Cryolite as a Chemical Raw Material: Chem. Ind., vol. 38, May 1936, pp. 471–476.

FELDSPAR

By Robert W. Metcalf and A. B. Holleman

SUMMARY OUTLINE

SUMMARY

Paced by the accelerated demand for glass and glass products, a continued high level of pottery sales, and the increasing market for enameled ware, the production of both crude and ground feldspar in 1945 broke all previous records by substantial margins. Tonnages of crude and ground feldspar in 1945 rose 10 and 8 percent, respectively, above those in the former peak year for each (1941), while the values of the crude and ground spar sold were 11 and 10 percent, respectively, higher than in 1944, the former record year in realization for both. Production of "aplite" decreased only slightly from the peak output in 1944. Imports of Canadian crude feldspar were the highest since 1930, and imports of unground nepheline syenite (also from Canada) reached record levels, 20 percent greater than in the former peak year 1943.

Salient statistics of the feldspar industry in the United States, 1943–45

	1943	1944	1945	Percent of change in 1945
Crude feldspar:				
Domestic sales:				
Long tons	308, 180	327, 408	373, 054	+13. 9
Value	$1, 646, 277	$1, 813, 937	$2, 021, 529	+11. 4

Value	$417	$203	----------	—100. 0
Average per short ton	$10. 17	$20. 30	----------	----------

The output of crude feldspar in practically all the chief producing States was larger in 1945 than in 1944. Production in North Carolina rose 21 percent in tonnage and 11 percent in value to a new record. The output of crude spar in Virginia also rose 21 percent. Colorado and Maine in 1945 had high proportionate gains over 1944. Sales of ground feldspar in North Carolina in 1945 topped production in other individual States for the first time since 1936, and the output of North Carolina and Tennessee combined increased in quantity and value by more than one-quarter compared with 1944. Production of ground feldspar at southern mills and in South Dakota showed large increases in 1945 compared with 1944 in contrast to the decreases (mostly moderate) in New England States and western producing areas other than South Dakota.

Although the over-all value of glass products decreased, probably, for the most part, on account of the curtailed output of plate glass in the latter part of the year, most of the other market indicators reflecting activity in the glass trades and other industries consuming sizable quantities of feldspar showed healthy increases. Production and shipments of glass containers, perhaps the largest single market for feldspar, were 6 and 11 percent, respectively, higher in 1945 than in 1944 and were accompanied by a 14-percent drop in inventories at the end of 1945 compared with the end of 1944. Manufacturers' sales of machine-made table, kitchen, and household glassware rose approximately 10 percent, and production and shipments of automatic tumblers increased in 1945 compared with 1944. The comparatively small yet significant jump in privately financed residential building in 1945 also is of interest to feldspar producers, as well as the 13-percent increase in the value of sales of porcelain enamel products. The first 4 months of 1946 have seen substantial gains in production, shipments, and value over the corresponding periods in 1945 in most market outlets for feldspar. Barring the effects of strikes and shortages of equipment and material, the general business recovery and specifically the expected large housing and commercial building programs should react directly and favorably upon the feldspar industry.

DOMESTIC PRODUCTION

Following the usual practice in the industry, crude feldspar is reported in long tons of 2,240 pounds and ground feldspar in short (net) tons of 2,000 pounds.

Crude feldspar.—Production of crude feldspar in 1945 continued at an accelerated pace and topped all previous records in both quantity and value. The total output rose to 373,054 long tons valued at $2,021,529, or 10 percent higher in tonnage than in 1941, the former high year, and 11 percent higher in value than the previous highest realization (in 1944). The 1945 output was 14 percent above that for 1944.

Output in practically all the important producing States in 1945 showed at least small increases. The fairly large gains in production over 1944 were not confined to one section of the country but affected both eastern and western mining areas impartially.

Crude feldspar sold or used by producers in the United States, 1941–45

[Value at mine or nearest shipping point]

Year	Long tons	Value		Year	Long tons	Value	
		Total	Average			Total	Average
1941	338,860	$1,519,456	$4.48	1944	327,408	$1,813,937	$5.54
1942	316,166	1,546,702	4.89	1945	373,054	2,021,529	5.42
1943	308,180	1,646,277	5.34				

Feldspar was mined in 13 States in 1945, the same States as in 1942, 1943, and 1944. North Carolina in 1945 again produced a record tonnage with a record realization—148,493 long tons valued at $863,740, or 21 percent higher in tonnage and 11 percent higher in value than in 1944, the previous peak year. The output in Virginia increased 21 percent. Connecticut had a small gain in 1945 over 1944. Production in Maine rose 37 percent, although output still was considerably under 1941 and most prior years. New Hampshire, whose figures may not be shown, increased its output in 1945 compared with 1944. Production in South Dakota, the second largest producer, increased 6 percent. Colorado showed the largest percentage increase of any State (66 percent). Output in Wyoming, which markets practically all its crude spar to mills in Colorado, declined by nearly one-quarter in 1945 compared with 1944. Decreases (mostly small) occurred in Arizona, California, New York, and Pennsylvania.

Crude feldspar sold or used by producers in the United States, 1943–45, by States

[2] Includes States indicated by "(1)."

Quotations on crude feldspar do not appear in the trade press. However, average realizations by States have been computed from the questionnaires returned to the Bureau of Mines each year from mineral producers. According to these producers, the average sales realization per long ton for crude spar in 1945 was \$5.42—2 percent less than in 1944—and, except for 1944, was the highest since 1934. Average realizations in most States were somewhat higher in 1945 than in 1944. Decreases in realization were noted in five States—Colorado, Connecticut, Maine, New York, and North Carolina. Averages per ton for certain States in 1944 and 1945 (1944 in parentheses) follow: North Carolina, \$5.82 (\$6.33); Virginia, \$6.14 (\$6.13); Connecticut, \$6.39 (\$6.62); Maine, \$5.68 (\$5.98); Colorado, \$4 (\$5.19); and South Dakota, \$4.60 (\$4.45).

Ground feldspar.—Sales of ground feldspar by merchant mills in 1945 totaled 381,728 short tons valued at \$4,246,961 and established records in both tonnage and value. Sales in 1945 were 11 percent higher in quantity than in 1944 and 8 percent higher than the former peak sales of ground spar in 1941. The value of sales in 1945 was 10 percent greater than in the previous high year (1944). In the New England States and in Western States other than South Dakota, production of ground feldspar was less in 1945 than in 1944. Output from southern mills showed large gains. North Carolina and Tennessee mills combined supplied 37 percent of the total sales of feldspar ground in the United States in 1945 compared with 32 percent in 1944, 30 percent in 1943, and 26 percent in 1942. Sales of feldspar of Canadian origin ground in merchant mills in the United States were only 2 percent of total merchant sales in 1945, as in 1943 and 1944, compared with 3 percent in 1942 and slightly higher percentages in preceding years, such as 6 percent in 1937 and 1936. In addition to the amounts just mentioned, relatively small tonnages of Canadian origin are ground by consumers, principally pottery and cleanser manufacturers, who import their spar direct and whose figures are not included in these compilations.

Ground feldspar sold by merchant mills [1] *in the United States, 1941–45*

[1] Excludes potters or others who grind for consumption in their own plants.

For the first time since 1936, North Carolina topped all States in the production of ground feldspar in 1945, followed by South Dakota, Tennessee, New Hampshire, and Colorado. Output in North Carolina and Tennessee combined rose in 1945 to 142,208 short tons valued at \$1,665,634, or 29 percent in tonnage and 26 percent in value greater than in 1944. New Jersey and Connecticut combined showed a 13-percent drop in tonnage, as did Maine, while output in Colorado decreased 9 percent and that in California 32 percent. Substantial gains in the production of ground spar, however, were reported for South Dakota and Virginia and a small increase for New York. In other States, for which figures cannot be given, small to moderate decreases were noted.

The average realization per short ton for ground feldspar in 1945 declined slightly to $11.13; except for 1944, however, this was the highest since 1938 ($11.50). In all States except Illinois, New York, and Virginia, the percentages of change from 1944 to 1945 varied from less than 1 to 6 percent. The average realization for New York increased slightly more than 6 percent, that for Virginia declined at a somewhat higher rate, and in Illinois remained unchanged. Realizations in Colorado, Maine, New Hampshire, South Dakota, and New Jersey-Connecticut were higher in 1945 than in 1944. Other States were less in 1945 than in 1944. Average values per short ton for individual States in 1945 ranged from $7.42 to $18.58. Average realizations for ground spar for selected States in 1945 follow: Colorado, $7.42; South Dakota, $7.98; North Carolina-Tennessee, $11.71; New Hampshire, $11.90; Maine, $16.07; and New Jersey-Connecticut, $18.58.

According to E&MJ Metal and Mineral Markets, quotations on ground feldspar in 1945 were the same as in the years immediately preceding. Potash and soda feldspars, in bulk, f. o. b. North Carolina or Maine, 200-mesh, white, were quoted at $17 and $19, respectively. Granular glass spar, f. o. b. North Carolina, 20-mesh, white, in bulk, was quoted at $12.50 per ton and semigranular glass spar at $11.75. Quotations on Virginia feldspar, as given by the same journal, were: No. 1, 230-mesh, $18; 200-mesh, $17; glassmakers' spar No. 18, $12.50; and No. 17, $11.75. Ground feldspar for enamelers' use ranged from $14 to $16 per ton, f. o. b., on either a Spruce Pine, N. C., or Keene, N. H., basis.

CONSUMPTION AND USES

Crude feldspar.—Most crude feldspar is sold to merchant mills, which may obtain their requirements from several mines or localities. The raw spar is stock-piled, sorted according to grade and source, blended, and ground to specified fineness, perhaps run through magnetic separators or put through a flotation machine, and sold to ultimate consumers. However, a few pottery and enamel manufacturers purchase part or all of their feldspar crude and grind it in their own mills. Certain makers of soap, cleansers, and sweeping compounds also mine or purchase crude feldspar, largely from New England, Virginia, and North Carolina, and after grinding or otherwise processing it utilize the abrasive properties of the spar in their products. Some Canadian crude spar also is purchased direct by consumers in this country. Manufacturers of artificial teeth annually consume a small tonnage of very carefully selected crude material, which must be free of all grit and is sold at a considerable premium over the No. 1 grade commercial feldspar.

Ground feldspar.—Sales of ground feldspar to ceramic industries in 1945 were 99 percent of total shipments compared with 98 percent in 1944. By far the bulk of the ground spar consumed is sold to glass and pottery manufacturers. Shipments to the glass industry in 1945 rose to 249,927 short tons, a record tonnage, 13 percent larger than the previous high in 1944. Sales to potteries also were at a high level and were 5 percent higher in 1945 than in 1944. Sales to glass plants rose to about 66 percent of total shipments in 1945 compared with 64 percent in 1944. Although there was an actual increase in tonnage of ground spar sold to potteries in 1945 compared with 1944, the percentage of pottery sales to total sales declined 2 percentage points. Sales to glass and pottery manufacturers in 1945 were 53 and 41 percent, respectively, of the total value, compared with 51 and 43 percent in 1944. Sales of enamel spar rose 63 percent in 1945 compared with 1944. Although still very much under prewar years, this increase heralds the recovery of that industry from its war-time lows. Sales of ground feldspar for use in soaps, cleansers, and abrasives decreased by about one-third in 1945 compared with 1944. The remainder of the ground feldspar sold by merchant mills in 1945 (much less than 1 percent of total shipments) was consumed in miscellaneous ceramic applications other than glass, pottery, or enamel and for various other uses, the nature of which was not specified.

[2] Includes Arkansas, Colorado, Connecticut, District of Columbia, Hawaii, Kentucky, Louisiana, Maryland (1941), Massachusetts (1941), Michigan, Minnesota, Mississippi, Missouri, Oklahoma (1941, 1943–45), Puerto Rico, Rhode Island, South Carolina, and Texas and other States (shipments to which cannot be segregated), also small shipments to Belgium, Canada, England, and Mexico.

TECHNOLOGIC DEVELOPMENTS

The exhaustion of the more readily available deposits of the better grades of feldspar and the shortage of labor for hand-picking high-grade feldspar suitable for glass and various ceramic products, with the accompanying rise in cost of mining, have encouraged the development and adaptation of flotation methods to the refining of this mineral. Alaskite, granite, syenite, and other similar abundant rocks can readily be used in place of relatively scarce smaller deposits of comparatively pure feldspar. Costly hand-picking would be curtailed, as the impurities would be removed mechanically in the flotation process. Large quarrying operations might replace, to a certain extent, at least, the present small-scale mining, resulting in lower extraction costs. One large flotation mill already is in production in North Carolina, a second plant is being built in North Carolina, and another company (in New Hampshire) has been seriously considering operation of a similar mill. In the process, small quantities of long-chain amines and hydrofluoric acid are employed as flotation agents [1] in the so-called Steffensen air flotation machine.[2]

Direct substitution of soda spar for potash spar on a pound-for-pound basis in semivitreous dinnerware resulted in no significant change in properties except perhaps lowered crazing resistance, according to Loomis and Blackburn.[3] Where crazing occurs, a slightly lower thermal expansion in the regular glaze was suggested as a corrective. In sanitary porcelain and similar vitreous whiteware bodies, equal amounts of soda spar did not produce as effective vitrification as with the straight potash-feldspar bodies in current use, and modification of the glaze to fit the soda-feldspar bodies probably would be required. To facilitate feeding without dust and to aid in

[3] Loomis, George A., and Blackburn, A. R., Use of Soda Feldspar in Whiteware Bodies: Am. Ceram. Soc. Jour. and Ceram. Abs., vol. 29, No. 2, Feb. 1, 1946, p. 48.

clean storage of glassmaking materials, a method of nodulating the conventional glass batch has been devised.[4] Utilization of feldspar as a screening aid in the washing of small sizes of coal in Great Britain was claimed to have resulted in a heavy reduction of ash content in the cleaned products.[5]

OTHER DEVELOPMENTS

Northern Feldspars, Inc., was operating its new mill near West Rumney, N. H., in 1945. The Interstate Feldspar Corp., was reported to have built a grinding mill during 1945 at Dillsboro, N. C. The Feldspar Milling Co., Burnsville, N. C., also is understood to be planning the erection of a milling plant near Bryson City, N. C. A detailed description of the Bedford, Va., plant of the Carolina Mineral Co., Inc., which produces glass spar, was given by Swanson.[6] The extraction of usable feldspar concentrates from southeast Missouri granite was studied by the Missouri Geological Survey.[7] It is understood that treatment of anorthosite in Wyoming to obtain alumina and a dicalcium silicate residue suitable for the production of low-alumina, high-silica cement has not yet proved feasible.[8]

Feldspar (and quartz) has been mined on a small scale since 1931 near Bangalore, Mysore, India, for use in a Government-owned porcelain factory. Difficulties of exploitation are set forth, and the discovery of other large feldspar resources is mentioned.[9] Mining of feldspar in the Transvaal in the Union of South Africa has supplied the scouring-powder industry with an abrasive material since 1943.[10] Feldspar from this area also has been used in a small way in glass manufacture and in ceramics. In addition to small-scale mining of feldspar in Egypt and in Palestine, potash-feldspar deposits are known in Iran.[11]

NEPHELINE SYENITE

Nepheline syenite is a quartz-free crystalline rock consisting principally of nephelite (an alumina-potash-soda silicate) and albite and microcline feldspars. Often associated are the iron-bearing minerals, black mica and magnetite, and accessory minerals such as zircon, corundum, and others. Its high alumina content (20 to 30 percent compared with 17 to 20 percent in most commercial feldspars) has made it especially desirable in the manufacture of glass. Continued research has broadened possible applications to other branches of ceramics, such as pottery, sanitary and electrical porcelain, floor and wall tile, glazes, and related uses. Its most active market, however, is the manufacture of glass and glass products.

Except for Russia, whose output is not known, Canada is said to be the only commercial producer of nepheline syenite. The American

Nepheline Corp., at its large plant in Rochester, N. Y., prepares glass and pottery grades and smaller quantities for enamel manufacture. Raw material was obtained from the quarries of American Nepheline, Ltd., at Blue Mountain, Methuen Township, Peterborough County, southeastern Ontario. After preliminary tests and semiplant investigations, the Rochester mill was changed over to flotation separation to eliminate the objectionable impurities, chiefly corundum. Port Coldwell Mines & Metals, Ltd., which also owns a nepheline property on the northern shore of Lake Superior at Port Coldwell, plans erection and operation of a mill at its more recently acquired deposits near Bancroft, Hastings County, eastern Ontario.

Undeveloped deposits of nepheline syenite are reported in the French River area, Georgian Bay district, Ontario; in the Montreal and Labelle-Annonciation areas, Quebec; and in the Ice River district, near Field, British Columbia. The Russian deposits on the Kola Peninsula in northern European Russia (U. S. S. R.) are worked on a large scale for the recovery of the phosphate (apatite), with nephelite as a byproduct. Russian experiments also contemplate the treatment of nepheline for the recovery of alumina.[12] In the United States, nepheline syenite in Arkansas recently has been investigated to determine the possibilities of this substance as a raw material for ceramics. The experiments are chiefly directed toward reduction below 1 percent of the approximately 6 percent iron content inherent in the rock as mined.[13]

The larger part of the Canadian output is shipped in crude form to the mill at Rochester, N. Y., ground, and marketed to consumers in the United States. Imports of crude nepheline syenite in 1945 rose to 51,785 short tons valued at $194,975 and were the highest yet recorded—20 percent in quantity and 30 percent in value larger than in 1943, the previous peak year. Receipts of ground nepheline syenite totaled 1,073 short tons valued at $11,461, the largest reported since 1941. All imports of crude and ground material have originated in Canada.

Nepheline syenite imported for consumption in the United States, 1941–45

Year	Crude		Ground		Year	Crude		Ground	
	Short tons	Value	Short tons	Value		Short tons	Value	Short tons	Value
1941	35,799	$112,101	1,359	$13,695	1944	39,043	$136,664		
1942	35,990	120,688	4	44	1945	51,785	194,975	1,073	$11,461
1943	43,105	150,225	737	7,680					

Quotations on crude nepheline syenite are not reported in the trade press; however, average values per short ton (estimated foreign market value) of imports for consumption in the United States in recent years were as follows: 1941, $3.13; 1942, $3.35; 1943, $3.49; 1944, $3.50; and 1945, $3.77. During both 1944 and 1945, ground nepheline syenite was quoted by Oil, Paint and Drug Reporter as follows (prices

are per short ton in bulk, f. o. b. Rochester, N. Y.): Glass-grade, 24-mesh, $12 per ton; pottery-grade, 200-mesh, $15.50 per ton. Packed in bags, prices are $2 higher.

APLITE

Shipments of ground "aplite" in 1945 showed a small decline in both tonnage and value compared with 1944. Virtually the entire production of aplite is consumed in the manufacture of glass, particularly glass containers, with quite small amounts used for enamel. Figures, however, may not be published, as to do so would reveal operations of individual firms. Calcining at temperatures ranging from 1,650° to 2,000° F. facilitates the reduction of the aplite to a grain size suitable for use in ceramic ware or for similar purposes.[14]

Two companies mine and process aplite: Dominion Minerals, Inc., Washington, D. C. (the first company to commence mining), and Carolina Mineral Co., Erwin, Tenn., an affiliate of the Consolidated Feldspar Corp., Trenton, N. J. Both firms operate mills near Piney River, Va.

IMPORTS [15]

Feldspar.—Imports for consumption of crude feldspar in the United States in 1945 amounted to 14,924 long tons, valued at $114,917—28 percent greater in tonnage than in 1944 and the highest in both quantity and value since 1930. The 1945 receipts, however, were only slightly more than half the average annual imports during the 5 or 6 years (1924–29) preceding 1930. No ground feldspar was imported in 1945. All the crude spar received came from Canada.

Feldspar imported for consumption in the United States, 1941–45

Year	Crude		Ground		Year	Crude		Ground	
	Long tons	Value	Short tons	Value		Long tons	Value	Short tons	Value
1941	11,253	$73,236			1944	11,686	$95,956	10	$203
1942	9,525	69,798			1945	14,924	114,917		
1943	10,758	83,073	41	$417					

Cornwall stone.—Imports for consumption of unmanufactured Cornwall stone in 1945 totaled 838 long tons valued at $11,317, or 81 percent in tonnage and 77 percent in value greater than in 1944. Receipts, however, were much less than in 1940 and 1941. Average value in 1945 declined to $13.50 per long ton. No ground Cornwall stone was imported in 1945. All imports have originated in the United Kingdom.

WORLD PRODUCTION

The United States produces by far the major portion of the world's reported output of feldspar. Sizable quantities have been mined in normal years in Canada, Finland, Norway, Sweden, Germany (Bavaria), Czechoslovakia, France, Italy, and China. In South America, Argentina and Brazil have reported production. Indicating the widespread occurrence of feldspar and the increasing tendency toward development of local nonmetallic mineral resources, production has been reported during the last 3 or 4 years from a number of other countries, including Spain, United Kingdom, Northern Ireland, Palestine, Madagascar, and Uruguay.

World production of feldspar, 1938–45, by countries, in metric tons [1]

ASBESTOS

By Oliver Bowles and Dorothy I. Marsh

SUMMARY OUTLINE

SUMMARY

Asbestos production in the United States in 1945 experienced a substantial gain over 1944. As in previous years, most of the domestic output consisted of the shorter grades of chrysotile mined in Vermont. Production in 1945 totaled 13,590 short tons compared with 7,558 tons in 1944, a gain of 80 percent. Domestic sales reached 12,226 short tons, a gain of 83 percent over 1944. The domestic producing industry furnished only 3 percent of total consumption in the United States during 1945.

Canada furnished a large part of the United States requirements of shingle stock, paper stock, and other of the nonspinning grades. Africa supplied a substantial part of longer grades that were of great importance in the military program and will continue in strong demand under peacetime conditions. Woven friction materials, particularly for automotive manufacture, and packings and gaskets employed in power-generating plants are among the important uses of the long fibers.

Amosite asbestos, used extensively in making 85-percent magnesia and other high-temperature molded insulation, is obtained only in South Africa. Blue asbestos (crocidolite), an important use of which is for making asbestos-cement pipe, is obtained chiefly in South Africa, although small quantities sometimes originate in Australia.

Tremolite asbestos, which is of value for filtering chemicals, was mined in Maryland for many years until the deposit was exhausted. Production has now shifted to California and Alaska.

There were no serious interruptions to imports of fiber either from Africa or Canada in 1945; accordingly, adequate supplies were available for military and essential industrial needs and to build up a stock pile as a reserve. With cessation of major military operations during the latter part of 1945, the situation was so favorable that all special canvasses conducted by the War Production Board were discontinued, and steps were taken to liquidate a large part of the

Government stock pile, which was no longer regarded as necessary. Early in 1946, 3,000 tons of C & G3 and 1,400 tons of C & G4 (Rhodesian grades of chrysotile) were sold to the French Raw Materials Mission; and 1,500 tons of C & G3 and 4,000 tons of C & G4 to the Belgian Purchasing Mission. The Government stock pile is, therefore, almost depleted. At the end of 1945 there was a world shortage of shingle and paper grades of asbestos. As the building program attains increasing volume, the shortage will probably become more acute.

Salient statistics for asbestos in 1944 and 1945 are summarized in the following table.

Salient statistics of the asbestos industry in the United States, 1944–45

	1944		1945

DOMESTIC INDUSTRY

REVIEW BY STATES

Alaska.—Tremolite asbestos was again produced in the Dahl Creek area, Kobuk River district. A small quantity of long slip-fiber chrysotile also was produced. The deposits of both varieties were worked by the Arctic Circle Exploration Co., Candle, Alaska.

Arizona.—The Arizona Chrysotile Asbestos Co. of Globe continued to be the largest producer in the State. Arthur Enders produced both spinning and short fibers at the Reynolds Falls mine about 50 miles from Globe, Gila County. The Globe Los Angeles Mining Co. (address 724 S. Spring St., Los Angeles 14, Calif.) recovered short fiber from the waste dumps of the Canadian mine in Gila County. Guy Phillips of Globe and John A. Bacon of Roosevelt also produced in Gila County. The entire production of Arizona was of the chrysotile variety. Sales were considerably greater than in 1944.

The mill of Pine Top Asbestos Mines, financed by the Defense Plant Corporation, has been acquired by the Globe Asbestos Co. and is said to have begun production in January 1946.

California.—The Powhatan Mining Co. (Woodlawn, Baltimore, Md.) produced tremolite asbestos near Castella and Hazel Creek (Sims), Shasta County—shipping point, Dunsmuir. Homer E. Fenn also reported sales of tremolite from a deposit near Hazel Creek. Kohler & Chase shipped short-fiber chrysotile from the mine near Monticello, Napa County, but did not produce. Sales in 1945 were considerably smaller than in 1944.

Georgia.—The only producer in Georgia in 1945 was the Powhatan Mining Co. from its amphibole asbestos property near Dillard, Rabun County.

North Carolina.—A deposit of amphibole asbestos in Macon County not far from Dillard, which is over the line in Georgia, was worked by the Powhatan Mining Co. of Woodlawn, Baltimore, Md.

Vermont.—The Vermont Asbestos Mines Division of the Ruberoid Co. (500 5th Ave., New York 18, N. Y.) is operating both the new quarry 1 mile from the mill, and the old quarry close to the mill site. Both mill and quarries were operated most of the time throughout the winter of 1945–46, as well as during the summer months, but production was limited by a serious shortage of labor. The long fiber obtained in the new quarry has not yet been adapted to spinning purposes but is being prepared as a high-grade shingle fiber. Most of the output is short-fiber chrysotile. Production was far below plant capacity but was, nevertheless, much greater than in 1944.

TRENDS IN CONSUMPTION

Domestic consumption of unmanufactured asbestos and the value of exports of asbestos products for a 10-year period are indicated in the accompanying table. The value of asbestos products manufac-

Raw asbestos consumed in and asbestos products exported from the United States, 1936–45

Year	Raw asbestos—apparent consumption (short tons)	Asbestos products—exports (value)	Year	Raw asbestos—apparent consumption (short tons)	Asbestos products—exports (value)
1936	250,922	$2,479,273	1941	438,741	$4,835,194
1937	316,263	3,047,078	1942	433,919	5,116,919
1938	187,150	2,533,916	1943	445,902	4,877,864
1939	255,547	3,354,920	1944 [1]	389,241	5,614,243
1940	262,199	3,473,248	1945	377,875	7,264,087

[1] Revised figures.

tured in the United States has not been compiled by the Bureau of the Census since 1939.

The building industry furnishes an extensive market for asbestos-cement, heat-insulating, and fireproofing products; accordingly, consumption trends of asbestos should correspond in general with trends in the construction industries. Power plants and industrial organizations also provide substantial markets for asbestos in the form of gaskets, packings, boiler lagging, pipe covering, and friction materials. The market requirements for such products may therefore be measured approximately by the volume of industrial production. These relationships are brought out in figure 1, in which asbestos consumption is plotted against total new construction and industrial production.

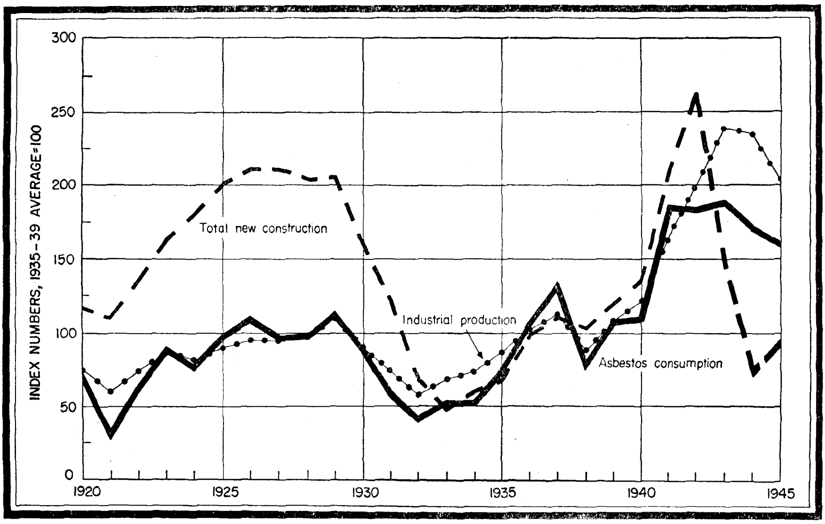

FIGURE 1.—Consumption of asbestos compared with total new construction and industrial production, 1920–45. Units are reduced to percentages of the 1935–39 average. Statistics on value of construction from Bureau of Foreign and Domestic Commerce and on industrial production from Federal Reserve Board.

CONSUMPTION ACCORDING TO USE

The Bureau of Mines has, for the first time, conducted a canvass of asbestos consumption by uses, but the returns are too incomplete and interpretation of the figures too complex to permit incorporation in this chapter. The figures will appear separately at a later time.

MARKET CONDITIONS

Although the Canadian mines were operating virtually at capacity and imports from Africa were uninterrupted, market demands threatened to exceed supply. Demands for spinning fibers eased somewhat during the early months of 1945 but became stronger toward its close. Decreased requirements because of canceled war orders were more than compensated by demands from liberated countries for crudes and spinning and shingle fibers. Moreover, there was an increasing demand for fibers of the latter category to supply the needs of new asbestos-cement industries recently established in several countries. A definite shortage of both spinning and shingle fibers had developed at the end of the year.

PRICES

Prices of asbestos as quoted in E&MJ Metal and Mineral Markets were unchanged throughout the year, as follows:

Per ton, f. o. b. Quebec mines, tax and bags included: Crude No. 1, \$650–\$750; crude No. 2 and sundry crudes, \$165–\$385; spinning fibers, \$124–\$233; magnesia and compressed sheet fibers, \$124–\$146.50; various grades shingle stock, \$62.50–\$85; various grades paper stock, \$44–\$49; cement stock, \$28.50–\$33; floats, \$19.50–\$21; shorts, \$14.50–\$26.50. Quotations in United States currency.

Per ton, f. o. b. Hyde Park, Vt.; Shingle fiber, \$62.50–\$65.50; paper-stock fiber, \$44–\$53; waste, \$33; shorts, \$14.50–\$28.50; floats, \$19.50.

NEW DEVELOPMENTS

Several new asbestos products have been perfected lately, among them an asbestos paper as thin as cigarette paper. Because of its excellent binding properties, its low moisture absorption, and its resistence to moderately high temperatures asbestos has a promising future for use in combination with plastics. Amosite asbestos has been suggested as a satisfactory substitute for kapok used in life jackets.

The new asbestos quarry and mill of the Compania Minas de Cemento de Tinaquillo, near Tinaquillo, Venezuela, began operation in 1945. A factory for making cement-asbestos products now under construction at Caracas will use the shorter fibers, and an export trade for the longer fibers will be sought.

FUTURE OUTLOOK

The largest tonnages of asbestos are used in the building trades. Asbestos-cement products in the form of flat and corrugated sheeting, wallboard, millboard, lumber, and roofing shingles are finding wider application at this time because of a lumber shortage. As the building program enlarges during 1946, the demands for such products will so increase that shortage of cement-stock fibers is forecast. Important accessories to the building trades are heat-insulation materials, such as pipe and boiler covering. Eighty-five percent magnesia pipe covering and block insulation, air-cell pipe covering made of asbestos paper, cements, and other insulating products will doubtless be in heavy demand to supply the needs of new industrial units, as well as many new public and private building projects.

A strong demand is in prospect also for the longer fibers applied to textile use. The revivified automobile industry will demand large quantities of woven brake linings and clutch facings, and many woven packings and gaskets will be needed to satisfy the requirements of industrial and power plants. There will, of course, be a tremendous decline in demand for cable coverings, other Navy uses, and friction materials for army mobile equipment and aircraft, but it is believed that industrial and construction needs will more than compensate for these losses.

The rehabilitation of asbestos products industries in foreign countries is an important factor in the raw materials situation. In most of the countries where such plants exist, there are no asbestos-producing industries. The supplies of raw materials must originate in the long-established centers of production, namely Canada, Africa, and Soviet Russia. This condition threatens to increase further the danger of a shortage of supply of certain grades. The U. S. S. R. is a large asbestos producer, but with growing industrialization it seems unlikely that large quantities of Russian fiber will be made available to world markets.

FOREIGN TRADE [1]

The following table shows imports of unmanufactured asbestos into the United States in 1944 and 1945. Total imports declined 2 percent in quantity and 12 percent in value. The larger proportional decline in value is due to a falling off in imports of crudes and high-grade mill fibers and an increase in imports of low-priced short fibers. Imports from Africa declined greatly. Imports from the U. S. S. R. were about the same in 1945 as in 1944, but the fiber received in 1945 was of higher grade.

Asbestos (unmanufactured) imported for consumption in the United States, 1944–45 by countries and classes

[6] January to June, inclusive.
[7] Preliminary.

CANADA

Production of asbestos in the Thetford Mines area of the Province of Quebec in 1945 was 11 percent greater than in 1944 and was only 2 percent less than in the peak year 1941. Production of crude fiber continues to decline. The extensive program of underground mining by the block-caving method undertaken by Canadian Johns-Manville is progressing satisfactorily, and production from stopes may begin within a year.

To the three United States asbestos-products manufacturers that have asbestos mines and mills in Quebec is to be added a fourth—Flintkote Mines, Ltd., a subsidiary of the Flintkote Co., 4111 R. C. A. Building, New York 20, N. Y. This firm has purchased an asbestos property a few miles north of Thetford Mines.

The figures for 1945 in the following table have been released by the Department of Mines of the Province of Quebec.

AFRICA

Southern Rhodesia.—No figures for Rhodesian asbestos production were published from 1940 to 1944, but export data, which are available for those years, are a fair measure of production because local consumption is quite small. As indicated in the following table, production data are now available for 1944 and 1945. Exports for 1944 were 46,755 short tons valued at £1,627,187.

Asbestos exported from or produced in Southern Rhodesia, 1940–45

Year	Short tons	Value	Year	Short tons	Value
1940	[1] 57,891	£1,419,566	1943	[1] 56,382	£1,827,387

Swaziland.—Chrysotile production in Swaziland is increasing greatly. As indicated in the preceding table of world production, output in 1944 was 28 percent greater than in 1942, the year of highest production up to 1944.

Union of South Africa.—Data for the first 9 months of 1945 show that both production and exports for the Union were considerably lower than in any year since 1941. Available data on exports and production, by Provinces, are given in the following table.

Asbestos produced in and exported from the Union of South Africa, 1940–45

Year	Production (short tons)				Exports	
	Transvaal	Cape Province	Natal	Total	Short tons	Value
1940	21,011	6,381	(1)	27,392	43,482	£934,417

[2] Partly estimated.
[3] Subject to revision.
[4] January to September, inclusive.

Four varieties of asbestos are marketed in the Union. Amosite, the principal variety, is produced only in the Transvaal. Crocidolite (blue asbestos) is mined in both the Transvaal and Cape Provinces. Because of depletion of the Amianthus mine chrysotile production in the Transvaal has declined greatly since 1937. The following table shows the tonnage of each variety produced, by Provinces, during recent years.

Asbestos produced in the Union of South Africa, 1940–45, by varieties and sources, in short tons [1]

Variety and source	1940	1941 [2]	1942	1943	1944	1945 [3]
Amosite (Transvaal)	17,767	19,211	24,924	23,189	22,848	13,067

[2] Partly estimated.
[3] January to September, inclusive.

OTHER COUNTRIES

Statistics of the Russian asbestos industry have not been available for several years. Egypt, French Morocco, Turkey, and Kenya Colony have recently become small producers. The Cyprus industry is active, but statistics of production or exports since 1943 are not now available.

BARITE, WITHERITE, AND BARIUM CHEMICALS

By Charles L. Harness and F. M. Barsigian [1]

SUMMARY OUTLINE

SUMMARY

New records were established in all important phases of the barite industry in 1945. Domestic production reached 692,330 short tons, 34 percent higher than the previous 1944 record. Consumption of domestic and imported barite was reported as 720,903 tons, 21 percent greater than during the prior high year, 1944. Arkansas and Missouri mills grinding for the Gulf well-drilling trade were mainly responsible for the unprecedented output of ground barite, the national total being 468,939 short tons as against 344,757 for 1944, the previous record year.

On the other hand, decreases were noted in shipments of barium chemicals and lithopone, largely owing to shortages of crude barite and labor in eastern plants.

New deposits were opened in California, Nevada, and Missouri, while capacity of existing plants was expanded in Arkansas and Missouri. The only regularly producing State which did not report an increase was Tennessee.

The distribution of consumption of barite in the United States in 1945 was reported as follows (1944 in parentheses): For well drilling, 407,871 short tons (277,792); for chemicals, 99,173 (100,921); for lithopone, 139,288 (134,597); for glass, 25,761 (24,153); for paint filler, 21,000 (23,000); for rubber filler, 10,000 (10,000); and for other purposes, including grinding losses, 17,810 (25,100); total, 720,903 (595,563).

The Bureau of Mines prepared a circular of general interest concerning barite.[2]

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

SALIENT STATISTICS

The term "Crude (primary) barite" in the following table applies to barite as first offered to the trade, whether lump, crushed, or ground. The figure thus includes ground barite from Malvern, Ark., and El Portal, Calif., and lump barite from washers, open pits, and underground workings. Where ground barite has been reported to the Bureau as original production, an estimate of the value of the crude equivalent of the ground was assigned to such tonnage.

Although the apparent new supply of barite—752,956 short tons—was some 32,000 tons greater than reported consumption in 1945, this indicated merely an attempt to accumulate normal stocks rather than an excess of production or imports. The excess of consumption over new supply during the war years was not balanced even so, for there remained an annual average deficit of 2,600 tons consumption over new supply for the 5-year period 1941–45.

Salient statistics of the barite, witherite, and barium-chemical industries in the United States, 1941–45

	1941	1942	1943	1944	1945

[1] F. o. b. mine shipping point.
[2] Declared value f. o. b. foreign market.
[3] Barite sold or used by producers plus imports.
[4] Although all barite is crushed before use in chemicals, barite used in chemicals is not included in the 1945 total. In 1944 and prior years small quantities of crushed barite used by chemical producers are included.
[5] Revised figures; see table "Barium chemicals produced and used or sold by producers in the United States, 1941–45."
[6] Exclusive of cadmium lithopone.

BARITE

CRUDE

PRODUCTION AND CONSUMPTION

For the second successive year, Arkansas produced more barite than any other State, leading Missouri by nearly 38,000 short tons in 1945. The development of a barite industry in Arkansas is quite recent when compared with the pre-Civil War origin of the Missouri industry. Barite was discovered accidentally in Arkansas in drilling a water well on the northern slope of Chamberlin Creek Valley, 15 miles east of Hot Spring, in 1900, but no commercial use was made of it at the time, owing to its impure state and the distance from usual markets. About 100 acres of this area are underlain with barite; and reserves, as yet incompletely mapped, are estimated conservatively at several million tons. The barite bed occurs as a replacement of Stanley shale of Mississippian age, and the width of the minable zone varies from 30 to 70 feet. Little exploratory work was done until about 1930, when interest in the use of barite in drilling oil wells in the Gulf area was becoming widespread. Commercial development still had to await a feasible means of purifying the barite, which contained about 70 percent barium sulfate, the remainder consisting mostly of quartz, shale, and iron oxide. Research by the Bureau of Mines in the 1930's proved that 98 percent pure barite could be obtained from the crude material with a 90-percent recovery using pine oil flotation. Much the same principle is used by the two producers in the area today, except that one floats the barite and the other depresses it.

Sustained production was begun in 1941 by the Magnet Cove Barium Corp., followed in 1942 by the Baroid Sales Division of the National Lead Co. The present workings of the two firms are on opposite converging wings of the same bedded synclinal deposit.

More barite has been taken from Missouri than from any other State, production having been continuous since the 1850's. Although none of the plants is as large as either of the flotation mills in Arkansas, the aggregate of 24 washers suffices to place Missouri just a little below Arkansas as second greatest producer in 1945. Nearly all the washer capacity in Missouri is centered in Washington County, and the average washer produces 1,000 tons a month. The two new washers of the Baroid Sales Division, National Lead Co., in Washington County have about double this capacity.

The new 30-foot double-log washer of the De Soto Mining Co. operated by J. Marshall Thompson in Washington County was described by Shaffer.[3] The new features in this washer, which may become general throughout the county, are detachable Nihard teeth tips on the logs and a revolving grizzly which hastens breaking up of the barite-bearing clay and prevents clogging.

Barite occurs in Missouri, Georgia, and Tennessee in residual clay from weathered dolomite. In Missouri there is very little overburden to be scraped off in order to reach the barite-bearing clay, but in Tennessee and Georgia sometimes 50 to 60 feet of overburden must be removed. Owing to increasing overburden, accompanied by growing mining costs, several producers shifted equipment from Georgia and Tennessee to Missouri in 1945, accounting in part for the increase in Missouri production and the slump in Tennessee

[3] Shaffer, L. S., Barite Mining: Excavating Eng., vol. 40, No. 4, April 1946, pp. 182–185, 219–220.

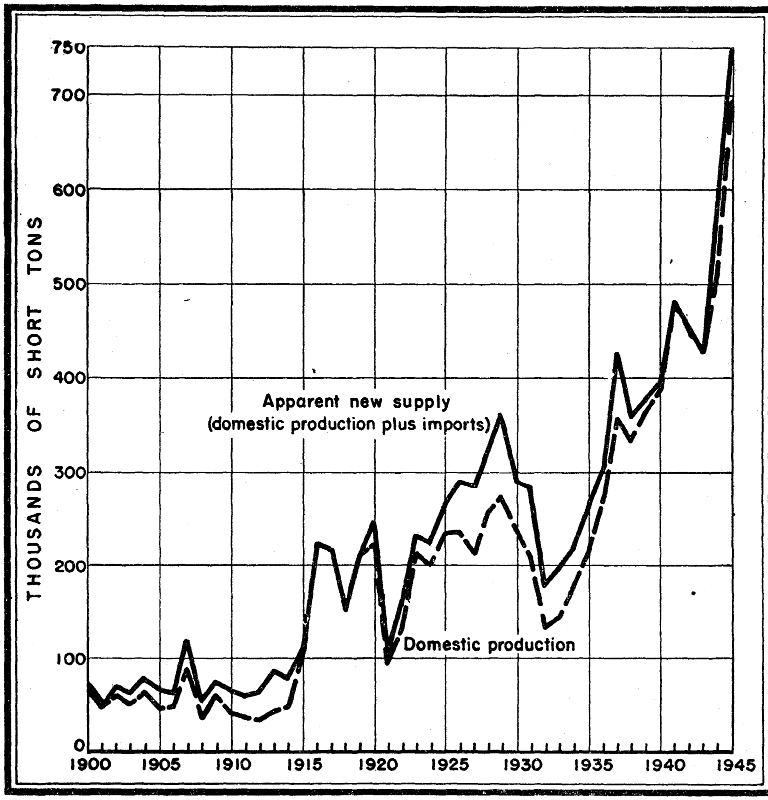

FIGURE 1.—Apparent new supply of barite in the United States, 1900–1945.

output. Among the new producers in Missouri in 1945 were Barytes Mining Co., Potosi, and Missouri Barite Co., Lynn Creek. A new crusher to prepare barite for use in glass was put in operation by Acme Barite Co., Mineral Point, Mo.

The abandonment proceedings initiated by the bondholders of the Yosemite Valley Railroad in 1944 were approved in 1945 by the Interstate Commerce Commission. This railroad carried ground barite for the National Lead Co. from its mill at El Portal, Calif., to Merced, Calif., where the line connected with the Southern Pacific Railway. During the latter part of the year the National Lead Co. instituted a trucking system by building a roadway over part of the former rail bed, crossing the Merced River by bridge a short distance from the mill and continuing to Merced via the All-Year Highway. Shipments, of course, ceased during the conversion of transportation but were resumed in early 1946.

Western producers were active in seeking new deposits. California-Nevada Barytes Mines Division of the Glidden Co. reopened a mine at Tonopah, Nev. Barium Products, Ltd., started production at a mine near Greenville, Plumas County, Calif. Baroid Sales Division of the National Lead Co. acquired the barite property of Industrial Minerals & Chemical Co. at Washington, Calif., and opened a new mine at Auburn, Placer County.

Crude (primary) barite sold or used by producers in the United States, 1944–45, by States

State	1944		1945

Crude barite (domestic and imported) used in the manufacture of ground barite and barium chemicals in the United States, 1941–45, in short tons

Year	In manufacture of—			Total	Year	In manufacture of—			Total
	Ground barite [1]	Lithopone	Barium chemicals			Ground barite [1]	Lithopone	Barium chemicals	
1941	243,846	153,982	93,005	490,833	1944	360,045	134,597	100,921	595,563
1942	200,443	144,821	104,160	449,424	1945	482,442	139,288	99,173	720,903
1943	225,154	129,493	99,097	453,744					

[1] Includes some crushed barite.

PRICES

Crude barite in Missouri was sold under a price ceiling established in July 1944 of $8.50 a short ton. Georgia and Tennessee producers have individual ceilings ranging up to $11.50 a long ton. Crude barite in California and Nevada is either used by the producer or sold by contract, and the prices are not available for publication in either case. New ceilings for chemical-grade barite announced under Maximum Price Regulation 327 in 1945 were: L–16, June 18, L. A. Wood Co., $11.50 per long ton, f. o. b. Sweetwater, Tenn. (an increase of $1.50 a ton); L–20, September 17, Barytes Mining Co., $11.50 per long ton, f. o. b. Cartersville, Ga.; and L–21, September 17, New Riverside Ochre Co., $11.50 per long ton, f. o. b. Cartersville, Ga.

WORLD PRODUCTION

World production of barite, 1938–45, by countries, in metric tons [1]

[Compiled by B. B. Waldbauer]

Country [1]	1938	1939	1940	1941	1942	1943	1944	1945

[1] In addition to the countries listed, barite is produced in China, Czechoslovakia, Japan, Mexico, Norway, and U. S. S. R., but data on production are not available.
[2] Data not available.
[3] Exports.
[4] Official figures which, it is reported, cover only output of mines included under the mining law.
[5] Estimate.
[6] January to September, inclusive.
[7] Includes witherite.

Germany.—The Office of Military Government for Germany has released data on German output of barite since 1938. Following the pattern of World War I, production dropped sharply owing to the disappearance of the usual export markets and leveled off to a constant figure reflecting domestic requirements. Figures are given in the accompanying world production table. Barite occurs in bedded deposits at Meggen in Westphalia and in veins in Hessen, Thuringia, Bavaria, Baden, and Silesia. The Meggen deposits are the most productive, yielding on the average from 60 to 75 percent of the total German output. The remainder comes from a large number of small mines. The Meggen properties normally employ about 750 workmen.

Between the two late wars Germany exported substantial quantities of barite to the United States, mostly from Meggen. It was shipped the short distance to the Rhine via canal, loaded on barges there, and towed to Rotterdam. Occasionally in the United States import statistics barite has been reported imported from Netherlands, but as there is no known production in that country it is assumed that the barite is of German origin.

Barite consumers in the Baltimore-to-New York coast area are naturally interested in resumption of purchases of Meggen barite, owing to scarcity of the commodity in the Eastern States, but considerable time is expected to elapse before shipments are received in quantity. After World War I, although transport facilities were virtually intact, no sizable lots were brought over until 1920.

Canada.—The decline in Tennessee production has resulted in profitable importation of barite from Nova Scotia. Canadian Industrial Minerals, a subsidiary of Springer Sturgeon Gold Mines, again increased its production in 1945 and appeared to have excellent prospects for 1946. At a meeting of shareholders it was revealed that the firm had a contract for 26,000 tons with an American consumer and that negotiations were under way with other American firms. Shipments were made to England, Belgium, and the West Indies in early 1946. The barite subsidiary started with a capital of $90,000, and the plant alone is now said to be worth over a million dollars.[4] The mine is said to have produced 106,000 short tons in 1944.[5]

Mexico.—A new source of barite was developed during the closing months of the war, and a few thousand tons were shipped to a lithopone maker in the midwest United States. The barite is mined near La Rosita, Coahuila.

GROUND (AND CRUSHED)

SALES

Oil-well drilling took 86 percent of the ground barite produced in 1945. This outlet has grown tremendously since the 1920's, when a few thousand tons annually were used in "problem" wells of abnormal pressures. The smaller uses of ground and crushed barite, including glass, paint, and rubber, showed little change from 1944.

[4] The Northern Miner, Barite Subsidiary Grows Steadily: Vol. 32, No. 6, May 2, 1946, p. 567 (15).
[5] Currie, D. L., The Mineral Industry of Nova Scotia: Canadian Min. Jour., vol. 67, No. 2, February 1946, p. 112.

Ground (and crushed) barite produced and sold by producers in the United States, 1943–45 [1]

Year	Plants	Production (short tons)	Sales	
			Short tons	Value
1943	18	215,464	208,252	$3,743,919
1944	19	344,377	344,757	5,455,835
1945	20	473,749	468,939	7,519,759

[1] Although all barite is crushed before use in chemicals, barite used in chemicals is not included in the 1945 total. In 1944 and prior years small quantities of crushed barite used by chemical producers are included.

Much of the ground barite reported for use in paint and rubber is bleached; it is also used as a white filler in wall paper, printing ink, and plastics. Unbleached, or "off-colored" ground barite, is used in linoleum, phonograph records, dark paints, and other products where color is immaterial.

Ground (and crushed) barite sold by producers, 1943–45, by consuming industries [1]

Industry	1943		1944		1945	
	Short tons	Percent of total	Short tons	Percent of total	Short tons	Percent of total
Well drilling	144,452	69	277,792	80	407,871	87
Paint	15,000	7	23,000	7	21,000	4
Glass	25,464	12	24,153	7	25,761	6
Rubber	8,000	4	10,000	3	10,000	2
Undistributed	15,336	8	9,812	3	4,307	1
	208,252	100	344,757	100	468,939	100

[1] Although all barite is crushed before use in chemicals, barite used in chemicals is not included in the 1945 total. In 1944 and prior years small quantities of crushed barite used by chemical producers are included.

In the foregoing table figures for consumption of ground barite in "Paint," "Rubber," and "Undistributed" have been estimated partly by the grinders and partly by the Bureau of Mines.

PRICES

The average price per short ton of ground and crushed barite in 1945 was $16.04, a slight increase over 1944. Several new ceiling prices on glass-grade barite were published by the Office of Price Administration under Maximum Price Regulation 327 in 1945, as follows: L–1, January 30, Wolf River Corp., $13 per short ton, f. o. b. Jamestown, Tenn.; L–6, March 15, L. A. Wood, $13.50 per short ton, f. o. b. Sweetwater, Tenn. (an increase of $1.00); L–13, May 10, Acme Barite Co., $16.50 per short ton, f. o. b. Mineral Point, Mo.; L–21, September 17, New Riverside Ochre Co., $13 per short ton, f. o. b. Cartersville, Ga. (an increase of $1.50); and L–39, May 8, 1946, J. R. Dellinger, $15.50 per short ton, f. o. b. Tiff, Mo. All the above prices are for bulk material; $2 per ton additional is permitted when packed in multi-ply paper bags.

According to the Oil, Paint, and Drug Reporter, ground bleached barite was quoted at $27.65 a short ton in bags, carlots, St. Louis, Mo., an increase of $2.30 over the 1944 price.

WITHERITE

The shipping shortage of 1944 eased sufficiently in 1945 to permit importation of a little witherite from Great Britain, the world's source. The Baroid Sales Division of the National Lead Co. mined a mixed witherite-barite near El Portal, Calif., and ground the material without separation for oil-well drilling muds. The production of this mixture is reported as barite.

Witherite, crude, unground, imported for consumption in the United States, 1941–45

[Value at point of shipment]

Year	Short tons	Value	Year	Short tons	Value
1941	4,790	$107,238	1944		
1942	3,066	60,824	1945	896	$26,736
1943	448	9,452			

According to the Oil, Paint, and Drug Reporter, witherite, 99 percent through 200-mesh, bags, carlots, works, was nominally quoted at $43 a short ton in 1945.

BARIUM CHEMICALS

PRODUCTION

Output of several of the barium chemicals declined further in 1945 from the peaks attained in 1943, notably the chloride, hydroxide, and nitrate. On the other hand, reconversion of brick kilns accounted for record production of barium carbonate for use as a brick descummer. Production of oxide, peroxide, and sulfate was also up. As all barium chemicals, with the possible exception of the nitrate, have well-recognized peacetime uses, business should be brisk as soon as the Nation recovers from the war.

Barium chemicals produced and used or sold by producers in the United States, 1941–45, in short tons

Chemical	Plants	Produced	Used by producers in other barium chemicals [1]	Sold by producers [2]	
				Short tons	Value

[1] Exclusive of cadmium lithopone.

CONSUMPTION

In its 1945 canvass of barium chemicals, the Bureau of Mines, at the request of some of the producers, for the first time asked for end uses of certain barium chemicals. Precise figures were not available in some cases, as not all of the respondents maintained records of end uses of their chemicals sold. The following table is therefore only an approximation, consisting partly of precise figures and partly of estimates. One chemical on the questionnaire, barium peroxide, is not shown because there were only two producers; and another item, barium hydroxide, is not shown because of the uncertainty of the percentages of its end use distribution (mostly lubricants). Each of the figures represents sales of at least three firms, in order to avoid disclosure of individual operations.

Estimated distribution of consumption of specified barium chemicals in the United States in 1945, in short tons

[Exclusive of consumption in making other barium chemicals]

Consuming industry	Precipitated barium carbonate	Barium chloride, basis 100% $BaCl_2$	Precipitated barium sulfate (blanc fixe)
Brick descumming	5,200		
Ceramics, glazes, enamels, and glass	3,400		(1)
Linoleum and oilcloth			[2] 700
Oil well drilling	4,000		
Paint and printing ink		1,700	[3] 22,100

POTASH

By Bertrand L. Johnson and Dorothy I. Marsh

SUMMARY OUTLINE

GENERAL CONDITIONS

More new records were made in 1945 in the potash industry of the United States, new highs being reached both in the production of marketable potassium salts and in sales. In 1945, 1,588,305 short tons of potassium salts containing 874,243 tons of equivalent potash were produced. (See fig. 1.) A slightly larger quantity (1,597,160 tons), also a record, was sold; this material contained 870,370 tons of equivalent potash, according to the producers. Stocks of potassium

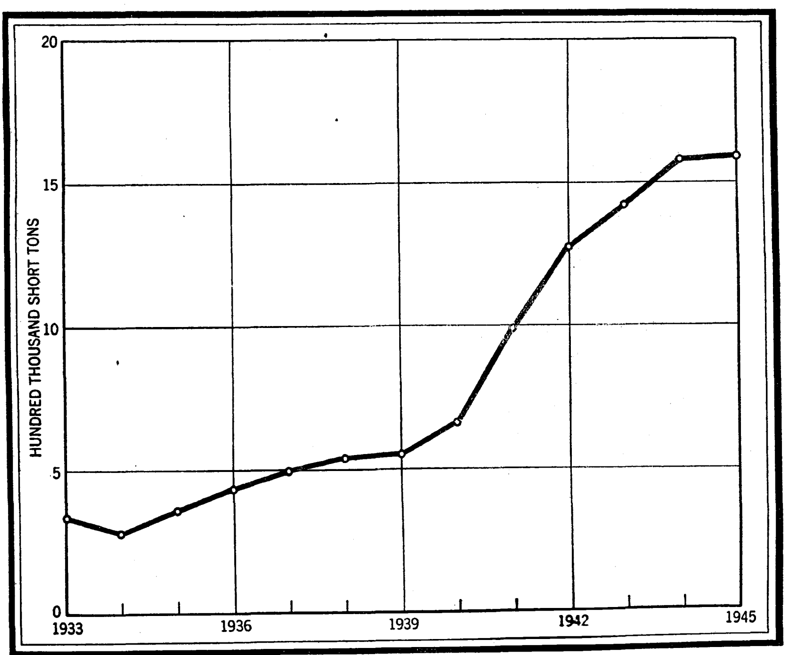

FIGURE 1.—Production of marketable potash salts in the United States, 1933–45.

salts in producers' hands at the end of 1945 were a little less than in 1944 but in terms of contained K_2O are reported to have been larger than in any recent year. Exports of fertilizer potash materials were less in 1945 than in 1944, but those for chemical uses were somewhat larger. Imports of potash materials for fertilizer purposes in 1945 were about half those in 1944, whereas those for chemical use were about double the imports for that use in 1944. Domestic consumption of potash again made a new high record—this time exceeding 800,000 short tons.

The economics of the domestic potash industry were discussed by Backman,[1] in a paper prepared for the American Potash Institute and published by that organization early in 1946, and by Turrentine,[2] in a paper in Better Crops with Plant Food, a journal published by the American Potash Institute.

[1] Estimate by Bureau of Mines.
[2] Quantity sold by producers, plus imports, minus exports.

Potash Allocation Order M–291 was amended April 3, 1944, and extended another 12 months. Effective March 22, 1945, however, all primary potash salts (muriate of potash, sulfate of potash, and sulfate of potash-magnesia) were removed from Allocation Order M–291 and placed in Schedule 98 under General Chemical Order M–300. This schedule was later revoked, effective September 30, 1945, and the above-mentioned potassium salts removed from allocation, but contract commitments for delivery made during the allocation period extended through March 31, 1946, delaying establishment of the order until after that date. Early in March, however, the Potash Producers Industry Advisory Committee recommended to the Civilian Produc-

[1] Backman, Jules, The Economics of the Potash Industry: Am. Potash Inst., Inc., Washington, D. C., 1946, 55 pp.

tion Administration that primary potash salts be put back under allocation until present excessive demands are reduced to more normal levels.

OUTLOOK

World demand for potash appears to exceed supply, and it is expected that domestic production will be forced to continue for some time at a high rate to meet an enlarged food-production program and foreign commitments. Present domestic potash mines can produce much more than normal peacetime requirements; this surplus must, if maintained, inevitably compete with the large European and Near East supplies when the needs of the famine-stricken portions of the world have been met. The eventual availability of large foreign supplies will limit American participation in foreign markets and certain of these foreign potash-producing nations may enter the domestic market, especially if it is considered advisable in a long-range perspective to restrict domestic production to conserve our known potash reserves.

Early in 1946 a comprehensive study by Turrentine of past consumption and future requirements of potash salts in American agriculture was released by the American Potash Institute.[3]

DOMESTIC RESERVES

The world potash industry is based primarily upon immense natural deposits of potassium chloride, principally in Germany and Russia. Any study of domestic reserves of this intensely competitive commodity, especially with the free importation of potash fertilizers into the United States, must consider that fact. The development of a domestic industry based upon the higher unit-cost sulfate salts in competition with German and Russian chlorides would be difficult.

The domestic deposits of potassium chloride, of present known commercial workability, from which potash can be recovered profitably at the current level of prices are limited to four isolated sylvite deposits near Carlsbad, N. Mex., and to the natural brines of Searles Lake, Calif., and Salduro Marsh, Utah. Reserves of potassium sulfates of proved economic importance are limited to a langbeinite bed in the Carlsbad region, N. Mex. Most of the proved economically important potash deposits in the United States are in New Mexico. Compared with these, the potash reserves in the workable brines of California and Utah are much less important.

A study of the potash reserves of the United States by Samuel H. Dolbear of Behre Dolbear & Co., consulting mining engineers and geologists, made for the American Potash Institute, the national organization of the domestic potash producers, was released by the latter organization early in 1946.[4] This report estimated the total known net recoverable reserves of potash in the brines and highly soluble salts in the United States at 73,000,000 short tons K_2O. It placed the economically recoverable reserves of New Mexico, in terms

of merchantable potash salts produced, at only 58,000,000 tons of K_2O in beds containing not less than 14 percent K_2O, in salts of high solubility, and not less than 4 feet in thickness. The actual lower limit of profitably workable beds in terms of grade and thickness is not stated, the lower limits used being those arbitrarily chosen in previous estimates. The above figure includes a considerable quantity of potash in mine pillars, which may or may not be recoverable in future operations. No evidence has been published indicating the existence in the New Mexico field of similar high-grade commercial deposits of either sylvite or langbeinite, and while they might exist and should be sought for, because of the peculiarly isolated spotty occurrence of the known commercial deposits in this field, other deposits would be very hard to locate if they existed. From the published data no estimates of additional reserves in these at present hypothetical deposits appear justifiable.

Potash reserves in the brines of Searles Lake, San Bernardino County, Calif., were originally estimated by Gale and Hicks[5] at 20 million tons of K_2O. The Dolbear report states that "further development has * * * * extended the amount stated in this estimate and potash in solution in the brines is still believed to be not less than 20 million tons after deducting past production," of which 14,000,000 tons is said to be definitely recoverable, assuming 70 percent extraction.

The above estimate may be somewhat high when the reserves in the lake are considered in the light of information given in a recent report of the Alien Property Custodian.[6] Substantially all of the crystalline salt body of Searles Lake is controlled by two companies, the American Potash & Chemical Corp., and the West End Chemical Co. Regarding the holdings of the American Potash & Chemical Corp. the prospectus states:

The Director of the Research and Development Department of the Company estimated that as of July 1, 1945, the recoverable brine reserves in the fee and leased lands contained 8,561,874 tons of equivalent muriate of potash, 60 percent K_2O. Such brine reserves have an average concentration of potassium chloride equivalent to the average concentration pumped into the plant over the past 6 years. On the basis of the Company's experience of an over-all efficiency of 60 percent recovery from the brine in the lake in the past 2 years' operations, he estimated that such brine reserves in the fee and leased lands are sufficient for at least 25 years at the present annual production rate of approximately 200,000 tons of equivalent muriate of potash, 60 percent K_2O. * * * *

In arriving at his estimate, the Director of the Research and Development Department of the Company proceeded on the assumption that the Company would continue to operate the leased and fee lands as a unit for the period stated. If, however, all of the brine requirements of the plant at the present annual rate of consumption were drawn from the fee lands alone, he estimates that the brine reserves contained in the fee lands having an average chemical concentration equal to the average of the grade drawn from the entire property over the past 6 years would be sufficient for at least 2 years' operations.

In making the foregoing estimates the Director of the Research and Development Department did not take into consideration the large quantity of lower-grade brine reserves in the fee lands and in the leased lands, nor did he consider the large tonnage of raw material present as solid salts in the deposits. The Research and Development Department of the Company has under investigation the lower-grade brine reserves and the solid salts. Such investigation has not

[5] Gale, H. S., and Hicks, W. B., Potash in 1917: Geol. Survey Mineral Resources of the United States, 1917, part II: 26, 1919, pp. 397–481.

[6] Alien Property Custodian, Prospectus, 478,194 Shares American Potash & Chemical Corp. Class B Stock: 120 Broadway, New York 5, N. Y., Mar. 11, 1946, 32 pp.

yet reached the point which will permit any conclusion to be drawn as to the extent of such reserves or salts or the possibility of utilization thereof on a commercial basis.

The company's estimate of recoverable brine reserves containing 8,561,874 tons of muriate of potash, 60 percent K_2O, reduces to 5,137,-124 tons of K_2O, of which only 60 percent can be extracted in the plant operations, or 3,082,275 tons of K_2O in merchantable potash salts.

No estimates of the potash reserves in the 2,780-acre lease of the West End Chemical Co. are available, but on a comparable basis they might amount to 2,780,000 tons of equivalent muriate of potash, 60 percent K_2O, possibly capable of yielding approximately 1 million tons of K_2O in merchantable potash salts. The total potash reserves in the brines of Searles Lake recoverable in merchantable potash salts would be about 4 million tons of K_2O.

Regarding the reserves in the Salduro Marsh, Utah, the Dolbear report states that:

The extent of these brines has been partly determined by drilling but there are no published estimates of reserves. Such figures as are available indicate a maximum amount of 1,700,000 tons of K_2O. Recoverable potash may amount to around 1,000,000 tons.

All potash resources in the United States other than those considered above have yet to be proved by actual commercial operations to be recoverable profitably at the current level of prices. These sources include the Grand County, Utah, sylvite deposits, polyhalite, greensands, shales, slates, wyomingite, cement-kiln and blast-furnice dusts, mine tailings, alunite, feldspar, distillery wastes, seawater, and kelp. These "strategic" or "potential" reserves are discussed in considerable detail in the Dolbear report and quantitative estimates given of the K_2O content obtainable from many of them.

PRODUCTION AND SALES

Since 1934 production and sales of domestic marketable potassium salts have increased annually. The increase in 1945 over 1944 was not as large, however, as that shown in the latter year over 1943, either in the salts produced or in the sales. Production of potassium salts in 1945 totaled 1,588,305 short tons, with an equivalent K_2O content of 874,243 tons. Sales were 1,597,160 tons, with an equivalent K_2O content of 870,370 tons. Sales of potassium salts exceeded production, and producers' stocks decreased, but the contained K_2O content of the sales was less than that of the output as reported by the producers, and the K_2O content of the stocks increased and was larger than in recent years. The value of the sales exceeded 30 million dollars. The average value per ton of the potassium salts sold in 1945 was $18.98.

Production of both grades of muriate of potash, as shown in the following table, was larger in 1945 than in 1944. Production of manure salts and of the sulfate of potash and sulfate of potash-magnesia was, however, much less.

Western States production still dominates the potash industry. California, New Mexico, and Utah furnished virtually all of the 1945 output, the larger part coming from the deeply buried Permian saline sedimentary deposits of the Carlsbad region of southeastern New

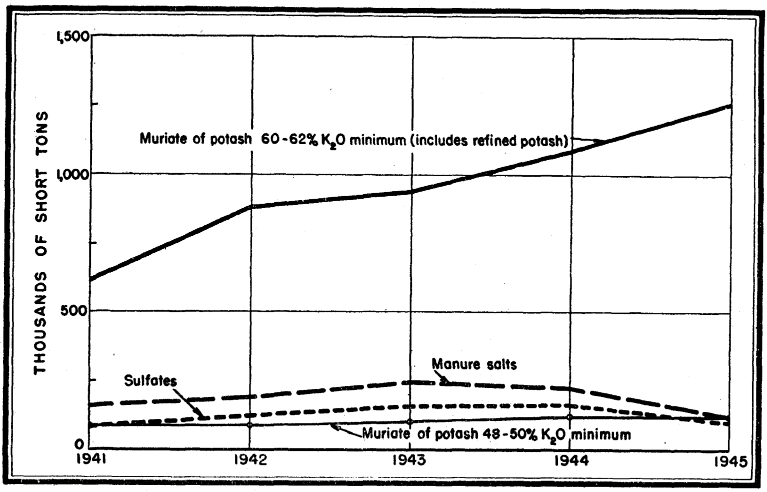

FIGURE 2.—Potassium salts produced in the United States, 1941–45, by grades, in short tons.

Potassium salts produced in the United States, 1943–45, by grades, in short tons

CONSUMPTION

Apparent consumption of potash salts in the United States and its possessions increased from 753,880 short tons of potash (K_2O) in 1944 to 808,809 tons in 1945, as determined by subtracting exports from the sum of the imports and producers' sales.

The following table, based largely upon deliveries of potash of domestic origin as reported by the American Potash Institute, indicates actual sales of 807,038 tons for domestic consumption in the United States in 1945, a considerable increase over the 752,319 tons in 1944.

Sales of potash in the United States for consumption and export, 1943–45, in short tons of K_2O

	1943	1944	1945
Deliveries of primary potash of domestic origin by major companies, as from reports of American Potash Institute—			
In United States and possessions:			
Agricultural	590,733	675,787	724,900
Chemical	84,367	82,198	85,169
For export	55,261	57,850	58,117
	730,361	815,835	868,186
Imports for consumption plus sales of minor domestic producers	17,777	5,364	6,435
	748,138	821,199	874,621
Total exports (estimate by Bureau of Mines)	70,007	68,880	67,583
Actual sales for consumption in the United States	678,131	752,319	807,038

Apparent domestic consumption of potassium salts, in terms of equivalent potash (K_2O), and its relationships to sales of domestic producers, as reported to the Bureau of Mines for a period of years, are shown in figure 3.

According to the American Potash Institute, 90 percent of the total deliveries of America's potash in 1945 was to the fertilizer industry and 10 percent for chemicals.

Deliveries of agricultural and chemical potash in 1945 are shown by States of destination in the accompanying tables. Georgia was the leading recipient of agricultural potash in 1945, taking, however, only a little over 9 percent of total deliveries for that purpose. New York took 67 percent of potash deliveries for chemical purposes; no other State took over 6 percent.

Deliveries in 1945 of agricultural potash salts of American origin, by states of destination, in short tons of K_2O

PRICES

Maximum Price Regulation 404—Potash, effective June 18, 1943, was in effect until July 5, 1944, when it was superseded by Revised Maximum Price Regulation 205 (Fertilizer Raw Materials) of June 30, 1944. Muriate of potash, manure salts, sulfate of potash, and sulfate of potash-magnesia were covered in the new regulations, as in the old. No changes were made in the base ceiling prices in the new regulation and none have since been made.

The following prices were reported by various producing companies for the 1945–46 fertilizer season; most of them are ceiling prices, but that for the muriate of potash, 50 percent K_2O grade, is below ceiling price.

Muriate of potash (62 to 63 percent; 62 percent K_2O minimum)	53½ cents per unit K_2O
Muriate of potash (60 percent K_2O minimum)	
Muriate of potash granular (50 percent K_2O minimum)	
Muriate of potash, granular (48 percent K_2O minimum)	
Manure salts (22 percent K_2O minimum)	20 cents per unit K_2O.
Sulfate of potash (90 to 95 percent K_2SO_4, basis 90 percent K_2SO_4)	\$36.25 per short ton.
Sulfate of potash-magnesia (basis 40 percent K_2SO_4, 18.50 percent MgO)	\$26.00 per short ton.

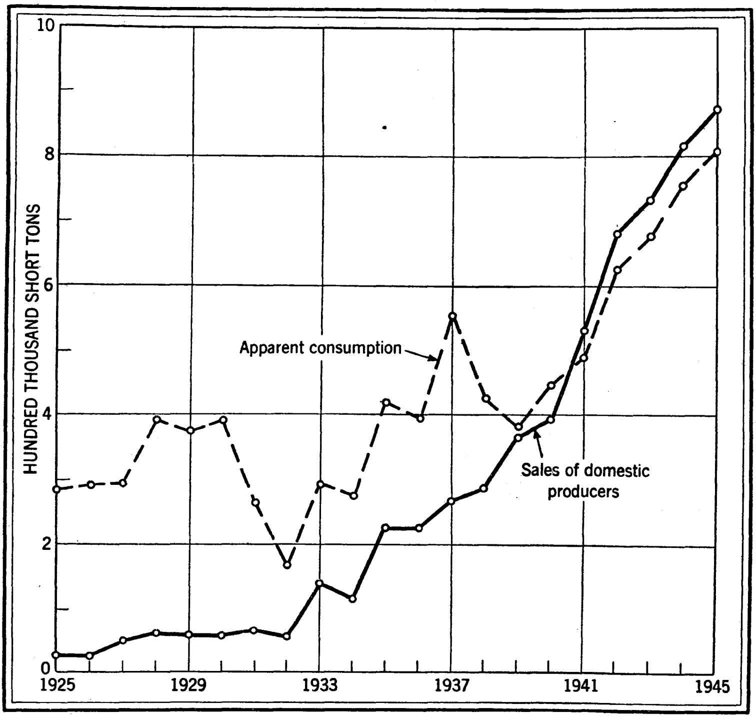

FIGURE 3.—Comparison of apparent domestic consumption of potash (K_2O) and sales by domestic producers of potash in the United States, 1925–45.

Retail prices of potash were covered during 1945 by Second Revised Maximum Price Regulation 135 as amended at diverse times up to and including amendment 4, effective November 26, 1945.

REVIEW BY STATES

General.—Four States—California, Maryland, New Mexico, and Utah—produced merchantable potash salts in 1945. The output of the individual States cannot be given (except for New Mexico, where three companies were operating) without disclosing individual company returns. New Mexico was by far the largest domestic producer, furnishing 85 percent of the total. California, although a much smaller producer than New Mexico, furnished much more than the combined output of the other two States.

A $CaCl_2$-KCl brine from the Gulf Oil Corp. Salina No. 1 well near Bay City, Mich., is reported [7] to be the most highly mineralized brine ever recorded. The total solids contained in the brine amounted to 642,798 milligrams per liter. The potassium (K) content was 21.362 milligrams per liter.

California.—The only potash producer in California, which is also the only one on the entire Pacific Coast, is the American Potash &

[7] Case, L. C., Exceptional Silurian Brine near Bay City, Mich.: Bull. Am. Assoc. Petrol. Geol., vol. 29, No. 5, May 1945, pp. 567–570.

Chemical Corp. (122 East Forty-second Street, New York, N. Y.). This company, recovering potash from the brine saturating the crystalline salt mess of Searles Lake in southeastern California, produces and markets potassium chloride and potassium sulfate. Several descriptions of the company and its operations have been published lately.[8]

The 478,194 shares (90.79 percent of those issued and outstanding) of the stock of the American Potash & Chemical Corp., which had been vested by the Alien Property Custodian by Vesting Order 249 executed at Washington, D. C., on October 20, 1942, as amended, under the authority of the Trading with the Enemy Act, as amended, and Executive Order 9095, as amended, was sold by the Custodian on March 27, 1946, to a group of investment bankers.

On February 12, 1946, the United States instituted an action against the American Potash & Chemical Corp. in the District Court of the United States for the Southern District of California, Central Division, to cancel the company's leases, claiming certain violations of the antitrust laws and misrepresentation to the United States Department of the Interior of the citizenship of the holders of its stock. On the same day the company filed its answer denying the charges and averring that the 90.79 percent of the capital stock of the company had been vested by the Alien Property Custodian, after which, according to the prospectus issued by the Custodian:

> The Court, without any evidence having been adduced and without any findings of fact or conclusions of law, entered a consent judgment which, among other things, imposes certain restrictions upon the issuance and transferability of certain shares of capital stock of the Company (which stock was on February 16, 1946, converted into the Class B. stock of the Company) * * * *. The judgment also enjoins the Company, during the term of the leases and any extension thereof, from disposing of any of its property, or transferring direct or indirect control of any of its property, to any person, corporation, or other business organization to whom issuance of stock is prohibited by the judgment, but excluded from such injunction sales of the Company's products and assets in the normal course of business. * * * * The judgment further provides for forfeiture of the leases upon proof of violation of any of the provisions of the judgment outlined above, or upon election or employment, as an officer or director of the Company, of any person to whom the issuance of stock of the Company is prohibited by the consent judgment. The judgment also directs the execution of an amendment to each of the leases in the form annexed to the judgment which incorporates therein substantially all of the provision of the consent judgment and provides for forfeiture upon proof of violation of any of the provision of the lease as so amended. Each of the leases was amended in accordance with the directions of the judgment.

Maryland.—Only one company in Maryland produced potash in 1945. This was the North American Cement Corp., of New York City, which recovered byproduct potash at its plant at Security, Washington County, near Hagerstown. The product, an impure sulfate of potash from the cement-kiln flue dust, was sold for agricultural use.

This was also the only operation of this kind reported in the United States in 1945.

New Mexico.—Mine production of potash salts in the Carlsbad re-

gion of New Mexico continued to increase in 1945, and again a new record was made. The three companies operating in this area mined 3,949,983 short tons of sylvinite and crude langbeinite combined—an increase of 200,733 tons over 1944 but a smaller increase than was made in 1944 over 1943. The K_2O content of the mine production in 1945 was 842,930 short tons. The average equivalent K_2O content of the mined salts increased but slightly, only from 21.33 percent in 1944 to 21.34 percent in 1945.

All three companies mined sylvite (potassium chloride) and one—the International Minerals & Chemical Corp.—also mined langbeinite (a potassium-magnesium sulfate). The greater part of the mine production was sylvite, most of which was processed to yield 60 percent or higher-grade K_2O muriate. The production of merchantable potash salts in New Mexico in 1945 was 1,354,187 short tons, with an equivalent K_2O content of 738,782 tons. Sales were 1,360,189 tons, with an equivalent K_2O content of 733,176 tons, valued at $25,456,731. Muriate of potash was produced by all three companies. Potassium sulfate and potassium-magnesium sulfate (sulfate of potash-magnesia) were produced from crude langbeinite by the International Minerals & Chemical Corp. in the refinery at its mine near Carlsbad. Potassium sulfate was also produced by the Potash Company of America.

Developments in 1945 in the New Mexico[9] potash mines were described by Barr.

Utah.—Commercial production of potash in Utah in 1945 was restricted to the potassium-bearing brines of Salduro Marsh and to the alunite deposits of the Marysvale district.

Bonneville, Ltd., continued to produce potassium chloride from these brines at its plant near Wendover, Tooele County, northwestern Utah. A description of the operations of this company was published during the year.[10]

Alunite-mining operations were carried on in the Marysvale district, Piute County, by Kalunite, Inc. (600 West 33d South, Salt Lake City, 8, Utah), at the White Horse mine at Marysvale. A small tonnage of alunite was mined in open-cut operation. Several thousand tons of crude alunite, largely from mine stocks, were shipped to its Salt Lake City alumina plant, where it was milled, with a considerable tonnage from the stocks at that place. The Salt Lake City plant was operated only on an experimental basis, most of the potash from the ore milled being used in building up to cyclic circulating load in the mill solutions. However, a few tons of potassium sulfate were produced, representing the excess potassium sulfate in the crude ore milled over and above the actual potash reagent requirements. None of the products were sold.

A brief report, with a geologic map of the Manning Creek alunite deposit, was published in 1945.[11] This deposit is about 7 miles east of Marysvale in an area of volcanic rocks. A total reserve of 800,000 tons was estimated for the two largest deposits.

No development work is known to have been done in 1945 in the Grand County potash field, eastern Utah.

FOREIGN TRADE [12]

Imports.—Imports of potash salts continued at recent low levels in 1945, the total of 17,212 short tons (6,022 tons K_2O) imported being even below that of 1944. The total value of the imports, however, increased greatly, to $3,310,475 from $2,048,351 in 1944, because nearly double the amount of argols was imported in 1945 as came in during 1944. The U. S. S. R. was the principal source of the imports.

Potash (K_2O) for fertilizer use constituted only 64.3 percent of the total imports in 1945, whereas in 1944 fertilizers had formed 77.2 percent of the total. Imports for chemical use in 1945 rose to 35.7 percent of the total compared with 22.8 percent in 1944.

The principal potassium salt imported for fertilizer use was potassium chloride, which came almost entirely from the U. S. S. R.; the balance of less than 1 ton came from Canada. Imports of potassium-bearing materials for consumption in the chemical industries consisted largely of potassium bitartrate as argols and cream of tartar from numerous countries, but principally from France, Algeria, Argentina, Portugal, and French Morocco.

Potash materials imported for consumption in the United States, 1944–45, by countries, in short tons

[1] Chiefly wood ashes from Canada. [2] Less than 1 ton.

A slight change has been made in the import tables in the content of K_2O assigned to "Other potash fertilizer material." Dr. A. R. Merz of the Tariff Commission suggested that, insomuch as the material now imported under this classification is chiefly wood ashes from Canada that 6 percent K_2O be used for that class instead of the 60 percent carried for many years, and the change was made.

Exports.—The total value of the domestic export trade in potash materials increased in 1945 to $6,635,785 from $6,281,727 in 1944, a decline being registered in the value of fertilizer potash materials exported, and a marked increase being shown in exports of chemical potash. The total quantity of fertilizer potash materials exported in 1945—104,687 short tons—was considerably less than in 1944, and the value fell below $3,000,000. The fertilizer exports went largely to Canada (82,302 tons), with smaller quantities to numerous other countries. Exports of chemical potash materials increased in 1945 to 18,966 tons, with a value of $3,648,795. The principal potash-fertilizer material exported was potassium chloride; the principal potash chemicals exported were, in order of size, the hydroxide (caustic potash), nitrate and mixtures, and carbonate and mixtures. Canada, United Kingdom, Brazil, and the U. S. S. R., in the order named, were the leading recipients of the potash chemicals exported in 1945.

1 Containing 20 percent or more potassium oxide (K_2O) equivalent (25 percent K_2O-content equivalent basis).
2 Containing less than 20 percent potassium oxide (K_2O)-equivalent basis.
3 Less than 1 ton.

WORLD PRODUCTION

Little statistical information is available regarding potash production in foreign countries in recent years, although operations have been in progress in various countries. Such official information as is available is included in the accompanying world production table. Soviet Russia, with its large reserves in the Solikamsk region, the former Polish potash fields, and its recently acquired predominant control of the former German potash production, has intensified its control of the potash industry of eastern Europe. The smaller remainder of the productive area of Germany is distributed among the British, American, and French zones of occupation.

Potash beds containing the potassium minerals sylvite and polyhalite were discovered during wartime oil-well drilling in North Yorkshire, England, at a reported depth of 4,000 feet. They are considered by the concessionaires to be too deep for profitable extraction. It has been suggested that these beds may be the continuation of the potash deposits of northwestern Germany.

A detailed description of the Lake Campion, Western Australia, alunitic clay deposit, the mining operations, and the method of treatment of the material for the recovery of potassium-sodium sulfate is given in an article by Fitzgerald [13] published early in 1945.

An article by Holloway [14] on Eritrea contains a geologic map of Eritrea and part of Ethiopia, covering the formerly productive potash area. A later report by the same author [15] describes the potash deposits.

The Spanish potash deposits were described in the June, 1945, issue of Minería y Metalurgia.[16]

The international position of the potash industry was discussed by Marcus Nadler [17] in a report released by the American Potash Institute early in 1946.

[1] In addition to countries listed Iran is reported to produce a small quantity of potash salts, but statistics of production are not available.
[2] Data not available.
[3] Equivalent K_2O content estimated at approximately 17 percent.
[4] Includes some natural kieserite.
[5] Salable.
[6] Unofficial estimate.
[7] Estimated production (Imperial Institute, London).
[8] Exports of potassium carbonate.
[9] Fiscal year ending March 31 of year stated.
[10] Extracted from waters of Dead Sea.
[11] Exports.
[12] Extracted from waters of Red Sea.

MICA

By G. Richards Gwinn and E. M. Tucker

SUMMARY OUTLINE

SUMMARY

Domestic production and consumption of all kinds of mica decreased in 1945. Domestic production supplied 13 percent of all receipts of the strategic grades of muscovite block and film for the first 6 months of 1945; however, the curtailment of the Colonial Mica Corporation's domestic mica-buying program, which began with the first of the year, and its complete cancellation due to the cessation of hostilities toward the end of the year eliminated almost entirely the production of domestic ruby block mica of the better grades by the end of 1945. The abridgment and final revocation of the Colonial Mica Corporation's domestic mica-buying program was based on recommendations of the War Production Board because of the favorable supply position and the decreased consumption of mica in the war program.

The major mica-producing countries of the world in 1945, as in the previous year, were India and Brazil. Production of phlogopite mica in Madagascar was reduced by the exorbitant prices fixed by the Madagascar Office of Economic Affairs, which were not acceptable to American and British buyers.

WPB Conservation Orders M-101 and M-101a, covering the allocation and control, respectively, of block mica and mica splittings, were revoked August 21, 1945. However, the Government buying program in Brazil and India continued until November 30, 1945, and African mica was under control of the British Government until December 31, 1945. The WPB continued allocation control over block and splitting mica to assure industry adequate supplies of mica until private purchase could be resumed.

A study of the color classification of muscovite mica used by the consuming industry was made by the National Bureau of Standards in 1945 at the request of the WPB and the Metals Reserve Company. The results of this study, which set up in fundamental terms a color standard for ruby mica that previously existed only in the memories of mica inspectors, have recently been released.[1]

A shortage of ground mica of roofing-grade quality, used in the preparation of asphalt landing mats for the armed services, developed in the first quarter of 1945; but, as it was primarily a shortage of the finished product and not the raw material, the supply was increased to adequate proportions in a few months. In the interest of a continuing domestic mica industry, it is hoped that private buyers will require at least three-quarter trim material. Otherwise the advancements in mining and processing of domestic mica gained during the war period will be lost, and the production of sheet mica will fall to a level lower than that of the years immediately preceding World War II.

The accompanying table of salient statistics summarizes domestic production and total supply of mica available in the United States during the past 5 years.

Salient statistics of the mica industry in the United States, 1941–45

	1941	1942	1943	1944	1945
Domestic mica sold or used by producers:					
Total uncut sheet and punch:					
Pounds	2,666,453	2,761,844	3,448,199	1,523,313	1,298,587
Value	$566,858	$725,030	$3,228,742	$3,262,711	$737,342
Average per pound	$0.21	$0.26	$0.94	$2.14	$0.57
Scrap:[1]					
Short tons	32,500	43,262	46,138	51,727	32,880
Value	$442,789	$671,165	$738,025	$1,089,072	$509,600
Average per ton	$13.62	$15.51	$16.00	$21.05	$15.50
Total sheet and scrap:[1]					
Short tons	33,833	44,643	47,862	52,489	33,529
Value	$1,009,647	$1,396,195	$3,966,767	$4,351,783	$1,246,942
Total ground:[1]					
Short tons	43,419	46,979	51,582	52,713	48,224
Value	$1,532,351	$1,653,358	$1,990,144	$1,914,709	$1,990,596
Consumption of splittings:					
Pounds	7,297,628	6,636,639	8,413,362	8,816,965	7,897,402
Value	$2,832,939	$2,835,421	$3,518,822	$4,657,730	$3,415,696
Imports for consumption:					
Total uncut sheet and punch:					
Pounds	2,016,852	3,244,857	5,501,745	5,032,983	4,284,720
Value	$1,119,584	$2,141,465	$6,313,900	$3,921,078	$4,125,016
Scrap:					
Short tons	1,251	2,179	2,048	2,412	3,567
Value	$12,791	$25,879	$27,102	$32,688	$41,410
Total sheet and scrap:					
Short tons	2,259	3,801	4,799	4,928	5,709
Value	$1,132,375	$2,167,344	$6,341,002	$3,953,766	$4,166,426
Manufactured:					
Short tons	6,041	7,493	8,960	2,314	3,695
Value	$3,282,656	$6,860,434	$8,513,064	$3,707,718	$2,172,333
Total imports:					
Short tons	8,300	11,294	13,759	7,242	9,405
Value	$4,415,031	$9,027,778	$14,854,066	$7,661,484	$6,338,759
Exports (all classes of mica):					
Short tons	1,163	1,001	693	619	981
Value	$280,810	$303,526	$653,889	$526,824	$377,473

[1] Includes mica recovered from kaolin and mica schists.

[1] Judd, D. B., Color Standard for Ruby Mica: Nat. Bureau of Standards Research Paper 1671, 1945, 12 pp.

DOMESTIC PRODUCTION

Sheet mica.—The quantity of sheet and punch mica produced in 1945 amounted to 1,298,587 pounds valued at $737,342 compared with 1,523,313 pounds valued at $3,262,711 in 1944. Punch mica supplied 90 percent of the 1945 total or 1,166,858 pounds valued at $166,116 compared with 55 percent of the 1944 production or 835,402 pounds valued at $147,635. In 1945 North Carolina was the largest producer of uncut mica larger than punch or circle, supplying 55 percent of the total, and New Hampshire was the largest producer of punch and circle, supplying 45 percent of the total.

The sharp reduction in output of sheet and punch mica in 1945 is attributed to the reduced consumption of mica by the armed forces. This brought about an increasingly favorable supply position, which in turn caused a gradual reduction and finally cancellation of the Colonial Mica Corporation's domestic mica-buying program. Private purchasers could not match the subsidized Government prices, and as only a few operators could meet the rigid specifications required by the Colonial Mica Corporation large numbers of the mines were closed.

Mica sold or used by producers in the United States, 1935–39 (average) and 1939–45

Year	Sheet mica						Scrap mica and mica recovered from kaolin and schists		Total	
	Uncut punch and circle mica		Uncut mica larger than punch and circle		Total uncut sheet mica [1]

[1] Includes small quantities of splittings in certain years.
[2] 1944: Alabama, Arizona, Colorado, Idaho, Maine, Massachusetts, Montana, Nevada, New Mexico, Pennsylvania, Virginia, and Wyoming; 1945: Alabama, Arizona, California, Colorado, Georgia, Maine, Massachusetts, Nevada, New Mexico, Pennsylvania, South Carolina, Virginia, and Wyoming.

The production of sheet and punch mica is not segregated into clear and stained material on Bureau of Mines annual reports. An index of the quantities of these classes mined may be obtained, however, from the statistics of purchases of clear and stained mica, as indicated on a quarterly basis in figure 1.

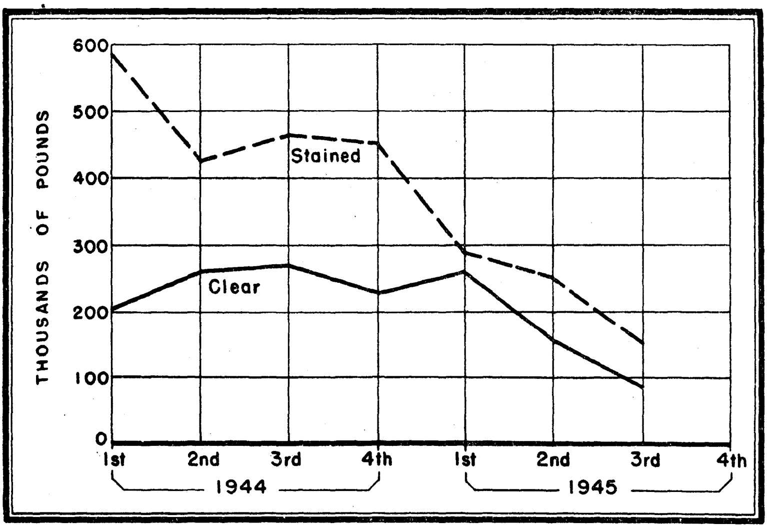

FIGURE 1.—Average monthly purchases of domestic sheet mica, clear and stained, for each quarter of 1944 and the first three quarters of 1945.

Scrap mica.—Production of scrap mica in 1945 amounted to 32,880 short tons valued at $509,600 compared with 51,727 tons valued at $1,089,072 in 1944. In addition to mine and factory scrap, these figures include 7,152 tons valued at $23,223 of mica reclaimed from the washing of kaolin and by milling mica schists. Although the product obtained in reclaiming operations is a ground mica, it represents an original recovery of mica. The production of scrap and reclaimed mica from 1940 through 1945 and the 1935–39 average are given in the following table.

Scrap and reclaimed mica sold or used by producers in the United States, 1935–39 (average) and 1940–45

Year	Scrap		Reclaimed		Total	
	Short tons	Value	Short tons	Value	Short tons	Value
1935–39 (average)	13,582	$168,688	8,404	$116,824	21,986	$285,512
1940	12,712	176,417	9,674	138,148	22,386	314,565
1941	16,917	257,303	15,583	185,486	32,500	442,789
1942	22,781	355,358	20,481	315,807	43,262	671,165
1943	22,025	423,174	24,113	314,851	46,138	738,025
1944	29,620	603,505	22,107	485,567	51,727	1,089,072
1945	25,728	486,377	7,152	23,223	32,880	509,600

Ground mica.—Total output of ground mica in 1945 reached 48,224 short tons, valued at $1,990,596, and represents a 9-percent decrease from the record high of 52,713 tons, valued at $1,914,709, in 1944.

The roofing industry consumes a major part of the dry ground-mica production, and the paint, rubber, wallpaper, and lubricant manufacturers utilize most of the wet-ground product. It is claimed that wet-ground mica used in paints to give flexibility to the film increases the life of the paint. It may be substituted in part or entirely for magnesium silicate and basic carbonate white lead and for a small part of the titanium dioxide. In wallpaper the glossy, water-ground flakes increase light reflection. The rubber industry utilizes ground mica chiefly as a dusting powder to prevent sticking.

The history of the scrap- and ground-mica industries over a series of years is indicated in figure 2.

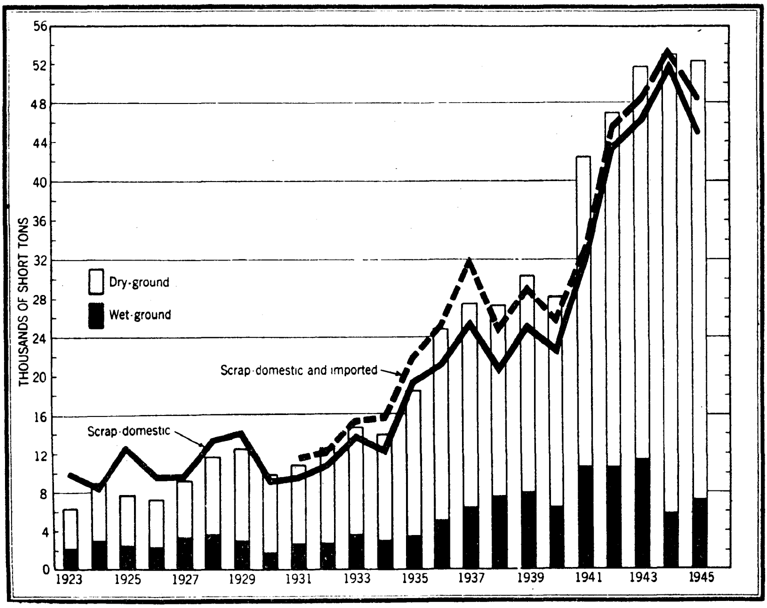

FIGURE 2.—Scrap and ground mica sold in the United States 1923–45.

Ground mica (including mica from kaolin and schists) sold by producers in the United States to various industries, 1944–45

Industry	1944			1945		
	Quantity		Value	Quantity		Value
	Short tons	Percent of total		Short tons	Percent of total	
Roofing	21,280	40	$495,431	24,825	51	$705,802
Wallpaper	1,325	3	123,180	1,911	4	139,719

1945	40,891	1,316,702	7,333	673,894	48,224	1,990,596

The total production of sheet, punch, and scrap mica in the United States from 1941 through 1945, by districts, is given in the following table. States in the districts are as follows: Northeastern—Connecticut, Maine, Massachusetts, New Hampshire, New York, and Vermont; Southeastern—Alabama, Georgia, Maryland, North Carolina, Pennsylvania, South Carolina, and Virginia; Black Hills—South

Sheet, punch, and scrap mica sold or used in the United States, 1941-45, by districts

Dakota; Northwestern—Idaho, Montana, Nevada, and Wyoming; Southwestern—Arizona, California, Colorado, New Mexico, and Texas. All the States in each district are not represented in each year's production but reported output in at least 1 year of the reporting period.

It is apparent from this table that the Southeastern district is the principal producer of sheet. Of the total output of punch mica, New England contributed 50 percent and the Southeastern district 45 percent in 1945.

The Southeastern district produces the bulk of the scrap mica recovered and therefore is the seat of most of the mica-grinding mills.

TOTAL CONSUMPTION OF BLOCK AND SHEET MICA

The sharp reduction in the consumption of block and sheet mica is attributed primarily to the reduction in requirements of the armed forces because of the substitution of glass and ceramic components for mica in radio condensers and spark plugs. Our total supply position thus became more favorable. However, some sizes of mica sheet remained in short supply throughout the year. It is true that larger sizes and better qualities may be substituted for smaller sizes and poorer qualities, but the potential relief is limited by the smaller quantities of the better qualities and sizes available. The margin of safety in supplies however was such that the United States Government and that of Great Britain withdrew from the markets in Argentina, Canada, Peru, and Mexico early in 1945 in order to return those markets to private buying. Private purchase in Brazil was made possible by the end of September 1945, and the importation of mica of all classes was released from the restriction of WPB General Import Order M–63 at approximately that same date.

Figure 3 summarizes graphically the situation with respect to imports and domestic production.

A summary of domestic production of sheet and punch mica and the apparent United States consumption of sheet, punch, and splittings from 1935 to 1945 is given in the following table.

Production of sheet and punch mica and apparent consumption of sheet and punch mica and mica splittings in the United States, 1935–45

Year	Production	Apparent consumption	Year	Production	Apparent consumption
	Pounds	Pounds		Pounds	Pounds
1935	936, 633	4, 123, 659	1941	2, 666, 453	10, 087, 576
1936	1, 319, 233	5, 721, 685	1942	2, 761, 844	10, 344, 973
1937	1, 694, 538	7, 160, 616	1943	3, 448, 199	12, 355, 896
1938	939, 507	3, 029, 447	1944	1, 523, 313	7, 791, 898
1939	813, 708	5, 147, 448	1945	1, 298, 587	6, 285, 867
1940	1, 625, 437	8, 093, 174			

The average yearly domestic production for the 1935–39 period was 1,140,724 pounds, and yearly consumption averaged 5,036,571 pounds or a self-sufficiency percentage of 23 from domestic production for the period. Comparable figures for 1941–45 are 2,339,679 pounds of domestically produced punch and sheet and 9,373,242 pounds consumed yearly, or a self-sufficiency of 25 percent. Figures for the latter period emphasize the large quantities of mica consumed during the war years, and our continued dependence on foreign sources for the major portion of our supplies.

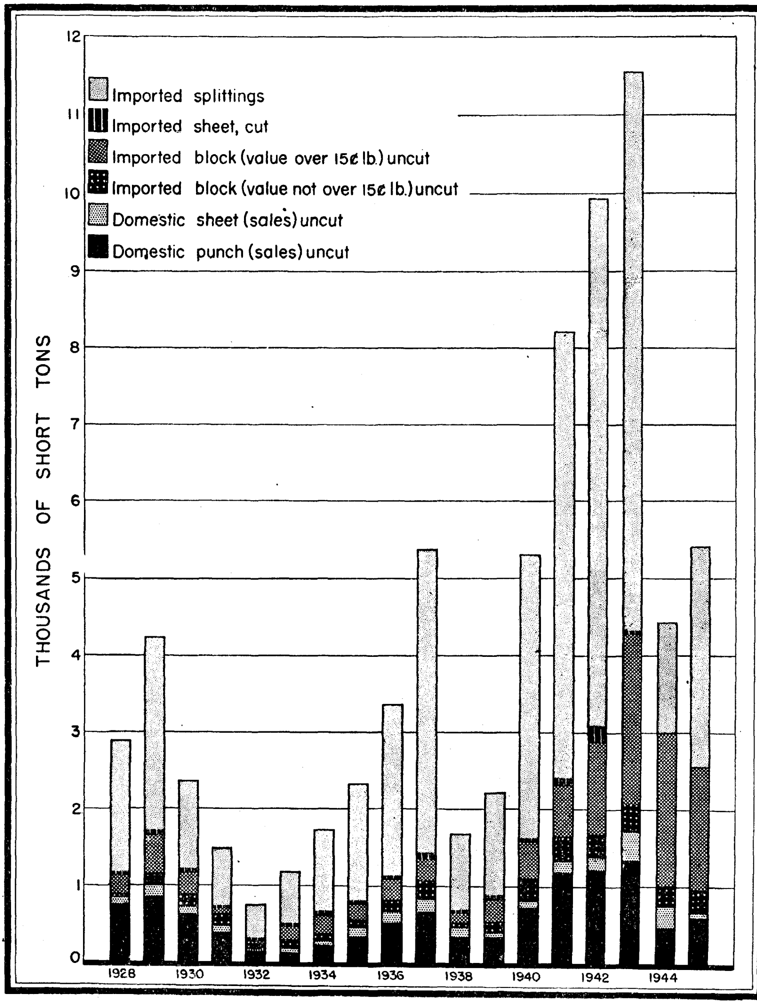

FIGURE 3—Block and sheet mica (cut) and splittings imported for consumption in the United States, and sales of domestic sheet and punch mica, 1928–45.

MICA SPLITTINGS

The consumption of mica splittings in the United States in 1945 reached 7,897,402 pounds valued at $3,415,696, a quantity 10 percent below the record high of 8,816,965 pounds valued at $4,657,730 in 1944.

Stocks of splittings decreased in 1945. Although industry stocks decreased only 23 percent from a January 1 figure of 3,994,977 pounds valued at $2,025,165 to a year-end total of 3,064,589 pounds valued at $1,391,617, Government stocks in the same period declined from 12,400,261 pounds to 4,710,426. Total stocks on hand at the end of 1945 were 7,775,015 pounds compared with 16,395,238 at the end of the last previous year.

Consumption and stocks of mica splittings in the United States, 1941–45, by sources, as reported by the consumers

Year	India		Canada		Madagascar		Total	
	Pounds	Value	Pounds	Value	Pounds	Value	Pounds	Value

1941	9,212,891	3,434,336	115,529	81,988	223,235	134,143	9,551,655	3,650,467
1942	8,202,240	3,367,788	257,591	178,082	321,529	201,274	8,781,360	3,747,144
1943	4,031,849	1,708,096	138,564	85,893	215,639	139,797	[1] 4,517,211	[1] 2,032,758
1944	3,578,885	1,749,011	141,427	95,850	184,970	121,307	[2] 3,994,977	[2] 2,025,165
1945	2,684,848	1,145,176	143,102	91,115	193,763	130,661	[3] 3,064,589	[3] 1,391,617

[1] Consumption includes 26,510 pounds of domestic splittings and 55,191 pounds of Mexican splittings, valued at $11,308 and $46,057, respectively; stocks include 2,200 pounds of domestic splittings and 128,959 pounds of Mexican splittings, valued at $1,009 and $97,963, respectively.

[2] Consumption includes 58,350 pounds of domestic and 76,729 pounds of Mexican splittings, valued at $23,862 and $55,282, respectively; stocks include 3,694 pounds of domestic and 86,001 pounds of Mexican, valued at $1,365 and $57,632, respectively.

[3] Consumption includes 94,716 pounds of domestic and 71,771 pounds of Mexican splittings, valued at $46,731 and $46,764, respectively; stocks include 7,000 pounds of domestic and 35,876 pounds of Mexican, valued at $3,430 and $21,235, respectively.

Muscovite splittings made up 88 percent of the combined stocks. Although this percentage is somewhat above normal, it is explained by the decline in purchases, either public or private, of Madagascar splittings in 1945. WPB Order M–101a which limited the use of No. 5 or larger bookform muscovite splittings was revoked on August 21, 1945; however, splittings remained under allocation control as part of the Government's program to relieve civilian deficiencies of raw materials until private contracts can be completed. Peak consumption of muscovite splittings was reached in the second quarter. Amber splittings reached a peak in the second quarter also. Grade 6 loose splittings—first, second, and third quality—in 1945 constituted 77 percent of the total consumption of muscovite splittings.

Consumption of splittings from July 1944 through December 1945 is summarized graphically upon a quarterly basis in figure 4.

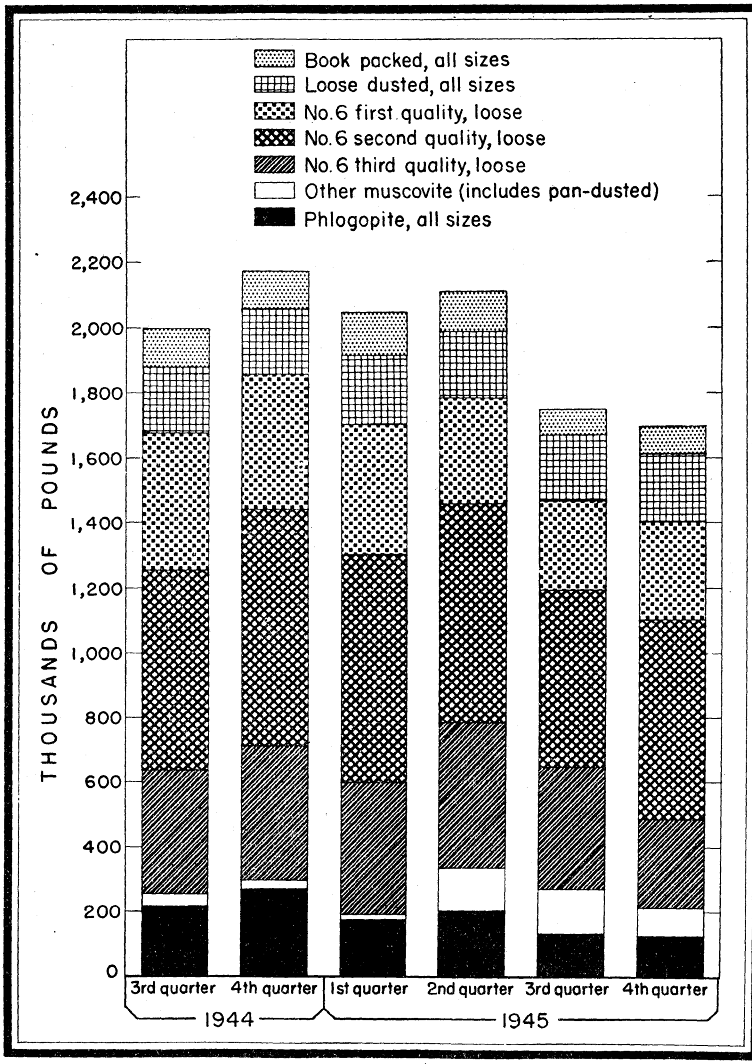

FIGURE 4.—Consumption of specified sizes and qualities of mica splittings in the United States, by quarters, July 1944 to December 1945.

BUILT-UP MICA

The consumption of built-up mica products in 1945 reached 7,194,909 pounds valued at $9,846,719, a decrease of 3 percent from the record high of 7,438,249 pounds valued at $10,143,873, reported in 1944. Part of the decrease may be attributed to the small quantity available of large-size, low-quality sheet, which is required for electrical appliances. During the war period specifications permitted the marketing of only the better grades; however the failure of industry to meet its quota of finished electrical appliances in 1945 cannot be attributed to the lack of mica but to a shortage of other components.

Built-up mica produced in the United States, 1944–45, by kinds of product[1]

Product	1944		1945	
	Pounds	Value	Pounds	Value
Molding plate	1,792,052	$1,816,920	2,015,993	$2,096,267
Segment plate	2,521,527	3,073,074	2,441,076	3,074,435

Flexible (cold)	817,255	1,004,719	775,342	955,126
All other (tape, etc)	1,942,642	3,876,477	1,571,900	3,003,988
	7,438,249	10,143,873	7,194,909	9,846,719

[1] Partly estimated.

PRICES

The wartime price schedule for sheet and punch mica, which was set up by the Colonial Mica Corporation in 1942, was abandoned on August 30, 1945. Specifications were changed at the first of the year, and although prices remained at $8 per pound for acceptable material the quantity of mica that could meet specifications was curtailed. At the end of the first quarter, the subsidized prices for domestic sheet mica were canceled.

During the second quarter, prices for domestic sheet were based on those paid by the United States Government for mica from foreign countries, plus import duty and an allowance of not less than 10 percent to cover charges incident to landing foreign purchases in the United States. This second-quarter schedule was later continued until the end of 1945. However, on August 30, 1945, the Colonial Mica Corporation announced termination of the domestic mica-purchasing program as of November 30, 1945. This date coincided with termination of all foreign purchasing agreements of the United States Government.

Prices for scrap mica in 1945 ranged from $17 per short ton f. o. b. mine in the Western States to $25 per ton in North Carolina and New England. Prices for ground mica, as quoted in the Oil, Paint and Drug Reporter, were as follows: Dry-ground, per ton f. o. b. mill—$30 to $45 in carlots and $35 to $48.50 in less than carlots, depending on the mesh size; wet-ground—freight allowed, $85 to $100 in carlots and $95 to $110 in less than carlots, depending on mesh size.

MICA SUBSTITUTES

Reports received near the end of 1945 gave a description of a mica substitute developed by the Germans. The trade name is Glushartgewebe. It consists of several layers of impregnated glass fiber bonded together by a homogeneous mixture of resinol alcohol and very finely divided kaolin. It is reported to be superior to mica.[2] A silicone rubber "silastic" developed recently at the Mellon Institute is also a satisfactory substitute for mica in certain applications.

[2] Chemical Age, German Insulating Material: Vol. 53, 1945, No. 1382, pp. 597–598.

The Germans also report the successful synthesis of mica. Blocks 3½ inches in diameter having the same cleavage as natural mica have been produced. Successful production is based on careful control in cooling the melt through the critical range of 1,270°–1,230° C. and the introduction of a magnetic field at right angles to the vertical axis of the crucible. The process has not been introduced to industry, however, as it is still in the laboratory stage.

FOREIGN TRADE[3]

Imports.—In 1945 imports of all kinds of mica totaled 9,405 short tons valued at $6,338,759 compared with 7,242 tons valued at $7,661,484 in 1944. Imports of all classes increased except untrimmed phlogopite (1 by 2 inches), unmanufactured "other" valued above 15 cents a pound, manufactured (cut or stamped) which declined greatly, and ground or pulverized mica. Further details on imports by kinds and sources of origin may be found in the following tables.

Mica imported for consumption in the United States in 1945,[1] by kinds and by countries

Country	Unmanufactured									
	Waste and scrap, valued not more than 5 cents per pound				Untrimmed phlogopite mica from which no rectangular piece exceeding in size 1 inch by 2 inches may be cut (duty, 10 percent)		Other

1944	5, 853	9, 225	399	5, 518			530, 909	15, 994

Exports.—Exports of unmanufactured mica in 1945 increased 34 percent in quantity over 1944 but decreased 33 percent in value. Canada, Mexico, Ecuador, and India were the chief foreign destinations. Exports of ground or pulverized mica increased greatly, but exports of other manufactured products declined. Details of exports appear in the following table.

Mica and manufactures of mica exported from the United States in 1945, by countries

[1] Changes for table in Minerals Yearbook, 1944, p. 1481, are as follows: Value of ground or pulverized mica exported to Canada should read $23,745; total value should read $32,990.

WORLD PRODUCTION

Complete data on world production are not available; however with the lifting of Government and international controls and close cooperation from various countries of the world the amount of information available increased markedly, as indicated in the following table, showing production by countries, from 1938 to 1945.

World production of mica, 1938–45, in metric tons [1]

[Compiled by B. B. Waldbauer]

Country [1]	1938	1939	1940	1941	1942	1943	1944	1945

[1] In addition to the countries listed mica is also produced in Colombia, U. S. S. R., and Uruguay, but data on production are not available.
[2] Exports.
[3] Data not available.
[4] Includes following quantities recovered from kaolin and schists—1938: 5,942 tons; 1939: 9,082 tons; 1940: 8,776 tons; 1941: 14,137 tons; 1942: 18,580 tons; 1943: 21,875 tons; 1944: 20,055 tons; 1945: 6,488 tons.
[5] Estimate.
[6] January to June, inclusive.
[7] January to September, inclusive.
[8] Less than 1 ton.

Australia.—The increasing industrial demand during the war years for mica led to a thorough investigation of mica deposits in Australia. The Western Australian Department of Mines, in a recently issued bulletin, gives the location of deposits, percentage of sheet and scrap recovered, and lists of consumers of mica.[4]

Brazil.—Production of mica in Brazil reached an all-time high by the first quarter of 1945. Prospects for a large postwar industry are also favorable. The exploitation and development of Brazilian deposits by United States technicians have improved greatly the quantity of acceptable sheet and punch recovered. It seems probable, therefore, that the Brazilian mica industry is in a more favorable condition with respect to United States markets than any other foreign country.

[4] Matheson, R. S., Mineral Resources of Western Australia: Western Australia Dept. of Mines, Bull. 2, 1944, 35 pp.

Canada.—Production of muscovite and phlogopite sheet mica decreased in 1945. The Purdy mine, largest muscovite producer, virtually ceased operations in April; and the Kingston Mica Mining Co. of Ontario, one of the largest phlogopite operators, ceased operations December 31, 1944. The decrease in phlogopite production was offset to some extent, however, by the reopening of the General Electric Co. Lacey mine. Scrap mica continued in good demand, and large quantities were recovered from mine dumps.

Ceylon.—The mica industry in Ceylon at the end of 1945 was in a precarious position. The purchase of mica by the Anglo-American Mica Mission ceased on November 30, 1945, and by the end of the year 75 percent of the mica mines were closed. The Government ban on exports of mica from Ceylon has been lifted. However, the scarcity of skilled labor, the difficulty in obtaining a license for the necessary freight facilities, and the lack of capital in the hands of mica miners curtailed activity.

India.—Although the quantity of mica necessary to meet wartime requirements was produced in 1945, output declined, and conditions in the industry were unfavorable because of a shortage of tools and machinery. The major part of India's production comes from the State of Bihar and is concentrated over an area of approximately 1,500 square miles. The remaining Indian production comes largely from the Nellore district of Madras and from Rajputana. A comprehensive report on the Nellore mica district has recently been released.[5] The central and provincial Governments of India have begun a program to improve mining in general and mica mining in particular. It has been suggested that a school be set up at Gundar to train miners and mine managers. It is reported also that the inquiry committee on wages of mica miners has brought out a favorable report, and wages of miners have been substantially raised.

New Zealand.—The production and processing of mica from deposits near the Paringa River in South Westland were reported in 1945. Because of the relatively inaccessible location of the deposits, which makes for high costs, it seems probable that the industry will not survive under peacetime economic conditions. The current operations are the first instance of mass production of mica in New Zealand.

Sweden.—It is reported that domestic requirements for mica in Sweden during the war period were met largely from a privately owned mine in northern Jamtland. New deposits have been opened on the eastern border of the Province of Jamtland which, when put into full production, will be able to supply the country's entire needs. Samples of mica from Sweden received in the United States during 1945 were not of strategic quality.

SALT

By Florence E. Harris and E. M. Tucker

SUMMARY OUTLINE

SUMMARY

Although total salt output in 1945 declined to 15,394,141 short tons, a drop of 2 percent from the peak of 1944, it was higher than in any other preceding year. The unit value in 1945 increased slightly from that in 1944. Evaporated salt output decreased 8 percent and salt brine declined 1 percent, but rock salt increased almost 2 percent.

The greatest decreases occurred in salt consumed in the manufacture of chlorine and soda ash. A shortage of chlorine for many industries was occasioned by lack of cylinders and tank cars. Demand persisted in excess of supply throughout 1945. Many industries were in line for salt compounds that were unobtainable. Calls for salt for meat packing and for livestock diminished perceptibly.

Most of the salt works ran at or near maximum capacity in 1945. However, two companies reported strikes, of 3 and 8 weeks' duration, respectively. Several plants that have not operated since the beginning of the war remained inactive, and at least two others joined the idle group in 1945 but sold from stock. Prices of salt were stable, but wages were reported to be higher in some sections than in 1944. Labor was so scarce in certain areas that some producers had to close their works. In other sections where labor was available, producers speeded operation by putting on additional shifts. In general, greater productivity per man was reported for the war years.

Continued shortage of supplies retarded filling orders, and many producers were behind in orders to the end of the year, the cessation of war giving no easement. Enough of a backlog of orders existed to absorb production no longer needed for war purposes. The military services continued to a certain extent to purchase salt for the armed forces, and the United States Department of Agriculture purchased table salt for its supply programs. In the latter part of 1945 the situation concerning materials for containers, both textile and paper, and difficulties in transportation were reported in certain areas as worse than during the war. Difficulty and delay in obtaining machinery and parts and making repairs, as in preceding war years, were experienced also in 1945.

Salient statistics of the salt industry in the United States, 1935–39 (average) and 1941–45

	1935–39 (average)	1941	1942	1943	1944	1945
Sold or used by producers:						
Manufactured (evaporated) short tons	2,507,374	3,330,106	3,517,832	3,993,899	3,942,621	3,630,729

Value	$521,652	$807,925	$892,160	$1,173,139	$1,620,226	$1,509,301
Apparent consumption [3] short tons	8,616,767	12,612,866	13,582,614	15,069,607	15,524,357	15,208,170

[1] Values are f. o. b. mine or refinery and do not include cost of cooperage or containers.
[2] Includes salt in bags, sacks, barrels, or other packages—1942: 122 tons, $1,200.
[3] Quantity sold or used by producers plus imports minus exports.

In the middle and eastern parts of the country no substantial additions were made to plant capacity during the war. On the Pacific coast, however, considerable additional areas were put into solar-salt

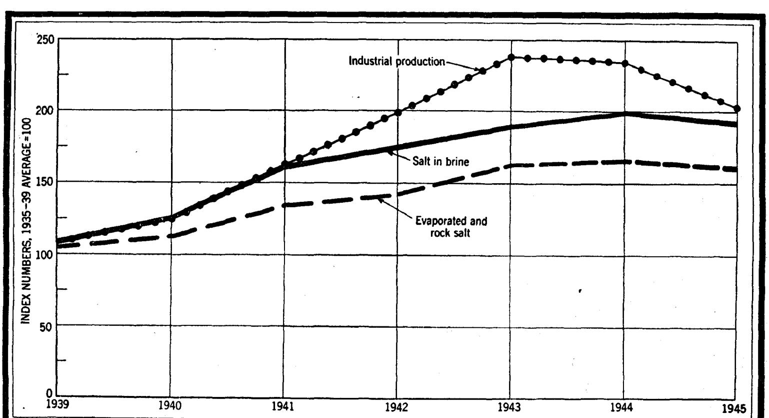

FIGURE 1.—Index of salt in brine and of evaporated and rock salt sold or used compared with industrial production, 1939-45. Index of industrial production from Federal Reserve Board.

production, resulting in an increase in output of more than 20 percent. At the same time, notable strides have been made mechanically in the handling of the product at a large operation in California, particularly as to harvesting. The equipment has been so perfected that hand harvesting has been eliminated, and all is accomplished mechanically. The end of the war had little effect on reduction of salt usage on the Pacific coast.

PRODUCTION

During 1945 salt was produced in 74 plants of 49 companies compared with 81 plants of 53 companies in 1944. Of the 1945 output 209,821 short tons of the evaporated and rock salt were iodized.

Production by States.—Thirteen States and Puerto Rico contributed to the total in 1945.

Salt sold or used by producers in the United States, 1943–45, by States

State	1943			1944			1945

[2] Included in "Other States."
[3] 1943: Nevada and Virginia; 1944–45: Nevada, Oklahoma, and Virginia.

Methods of manufacture.—No changes in the basic methods used to produce salt were noted in 1945. The output by the several methods employed is given in the accompanying table.

Salt sold or used by producers in the United States, 1944–45, by methods of manufacture

Method of manufacture	1944		1945	
	Short tons	Value	Short tons	Value
Evaporated:				
Bulk:				
Open pans or grainers	531,091	$5,452,389	944,612	$8,204,398
Vacuum pans	2,589,832	17,387,166	2,001,373	14,316,734
Solar	547,482	1,963,780	442,112	1,701,651
Pressed blocks	274,216	2,797,015	242,632	2,479,109
Rock:				
Bulk	3,369,175	11,500,601	3,410,929	12,115,237
Pressed blocks	79,063	724,456	94,811	849,154
Salt in brine (sold or used as such)	8,326,312	6,163,857	8,257,672	6,402,781
	15,717,171	45,989,264	15,394,141	46,069,064

Evaporated salt.—Continued shortage of containers made marketing difficult for evaporated salt, especially table salt. In 1945 the output of 3,630,729 short tons of evaporated salt was supplied by 52 plants in 12 States and Puerto Rico. It was produced either from the original brine of wells and ponds or from brine artificially produced from rock salt deposits. Of the 1945 output, 175,296 tons were iodized.

Evaporated salt sold or used by producers in the United States, 1944–45, by States

State	1944		1945	
	Short tons	Value	Short tons	Value
California	550,049	$2,806,964	581,730	$3,114,191

[1] Includes a quantity of salt contained in brine for chemical use reported as evaporated salt with value as evaporated salt.
[2] Included under "Other States."
[3] 1944–45: Nevada, New Mexico, Oklahoma, and Texas.

Rock salt.—Nineteen operations produced 3,505,740 short tons in eight States. This is an all-time high record for rock salt, representing an increase of more than 1 percent over 1944. Of the quantity, 34,525 tons were iodized.

Rock salt sold by producers in the United States, 1941–45

Year	Short tons	Value	Year	Short tons	Value
1941	2,619,087	$8,761,827	1944	3,448,238	$12,225,057
1942	2,802,287	9,623,461	1945	3,505,740	12,964,391
1943	3,259,138	11,180,884			

Pressed blocks.—Eighteen evaporated-salt plants and 8 rock-salt plants supplied the output of pressed blocks. The total included 32,594 short tons of evaporated and 24,478 tons of rock salt blocks that were iodized.

Pressed-salt blocks sold by original producers of the salt in the United States, 1941–45

Year	From evaporated salt		From rock salt		Total	
	Short tons	Value	Short tons	Value	Short tons	Value
1941	182,331	$1,505,040	56,701	$461,265	239,032	$1,966,305
1942	240,354	2,228,062	67,490	569,014	307,844	2,797,076
1943	269,064	2,598,873	77,912	668,027	346,976	3,266,900
1944	274,216	2,797,015	79,063	724,456	353,279	3,521,471
1945	242,632	2,479,109	94,811	849,154	337,443	3,328,263

Salt content of brine.—Thirteen plants in 7 States contributed to a total of 8,257,672 short tons of salt in brine in 1945, or almost 54 percent of total salt produced.

DISTRIBUTION

In the accompanying table, salt shipped to destinations within a State in which it is produced is added to that shipped from other States. As reshipments are disregarded the statistics represent only original shipments into States by producers.

Distribution (shipments) of evaporated and rock salt in the United States, 1944–45, by States of destination, in short tons

Destination	1944		1945	
	Evaporated	Rock	Evaporated	Rock

[2] Shipping weight; not strictly comparable to earlier years.

CHANGES IN THE INDUSTRY

California.—Leslie Salt Co., San Francisco, which operated a rock-salt deposit at Fallon, Nev., during the war, has reported the permanent shut-down of the operation. Imperial Salt Co. had no salt crop in 1945 but expects to produce in 1946. Long Beach Salt Co. reports all production at its Los Angeles County plant stopped November 30, 1945. The Monterey Bay Salt Works was destroyed by fire October 10, 1945. The company is rebuilding the plant.

Kansas.—On June 29, 1945, the entire refining plant and evaporated-salt packaging plant of the American Salt Corp., Lyons, was destroyed by fire. Since then most of the production of this company has been rock salt. A new plant is being built which probably will be completed by midsummer 1946.

Michigan.—The Marysville plant of the Morton Salt Co. was inactive part of 1945, owing to a fire that destroyed the packing and shipping department in 1944.

New Mexico.—Curtis Salt Co., Catron County, reports that its supply of salt is about exhausted.

Ohio.—Pomeroy Salt Corp., Minersville, did not produce in 1945 owing to war conditions but expects to resume operation early in 1946. The Colonial Salt Co., Akron, was bought by the General Foods Corp. on August 15, 1945, and operation was continued by the purchaser.

Oklahoma.—Ezra S. Blackmon Salt Co., Freedom, produced no salt in 1945. The operation was bought in 1944 and the plant was being dismantled and sold in 1945.

Puerto Rico.—Sobrinos de Gonzales & Co., operation was inactive in 1945 but the shut-down is temporary.

West Virginia.—The Ohio River Corp., Mason, did not produce in 1945.

RESOURCES

According to the Mississippi Geological Survey, the Mississippi Oil and Gas Engineering Committee report for January 1946 lists 27 salt domes recently discovered in 16 counties of the southern half of the State. In many places the salt is associated with anhydrite. The cap rock ranges in depth from 290 to 7,817 feet.

In 1945, a map [1] including text was published, furnishing new information on the extent and thickness of the salt beds of Salina age of Michigan and Ontario.

Other resources and plants were described during the year.[2] It is significant that wherever rock salt is developed by drilling, that locality becomes a potential site for a chemical industry—chlorine, electrolytic caustic soda, and other sodium chemicals.

USES

Previous Yearbook chapters on salt have elucidated the war uses of salt and salt compounds, many of which survived for civilian use. DDT, now being produced by more than 10 companies, is being used not only in homes and camps but is being sprayed from airplanes over fields and forests for insect control. Moreover, the material is incorporated in paints and wall washes and is used as a sheep dip.

The quantity of salt consumed in making synthetic rubber rose to 200,000 short tons in 1945 from 140,000 tons in 1944 and 66,000 tons in 1943. This is exclusive of that used in making chlorine therefor and in rubberlike materials.

Salt sold or used by producers in the United States, 1944–45, by classes and uses, in short tons

IMPORTS AND EXPORTS[3]

Both imports and exports of salt declined in 1945. Such transactions are relatively small compared with domestic trade. It is notable that fish salt imports were lacking again in 1945.

Salt imported for consumption in the United States, 1941–45, by classes

Year	In bags, sacks, barrels, or other packages (dutiable)[1]		Bulk			
			Dutiable		Free (used in curing fish)	
	Short tons	Value	Short tons	Value	Short tons	Value

[1] Less than 1 ton.

WORLD PRODUCTION

Total world production of salt in 1944 is estimated at more than 33,000,000 metric tons, of which the United States produced about 43 percent. Because salt is the basic raw material of the important alkali chemicals, the world distribution of supplies has significant implications. If the United States had not possessed a virtually inexhaustible salt supply as well as a great chemical industry during the last half decade our country would have been seriously handicapped during the war. Moreover, it was Germany's large salt resources and well-developed chemical industry that enabled it to obtain substantial foreign credits through export of large quantities of salt and sodium compounds derived therefrom.

Unlike the United States, in a majority of foreign countries the salt industry is a government monopoly and is rigidly controlled. During World War II, a number of countries had to ration salt, the supply was so short. Many gift packages sent abroad from the United States contained small supplies of salt.

Significant facts and figures for as many foreign salt-producing countries as are obtainable at present are given herein by main geographic divisions. The tons are metric unless otherwise stated.

NORTH AMERICA

Salt is produced in *Canada* by 9 companies; all is recovered from brine except in Nova Scotia, where it is mined from rock-salt deposits. A new process to beneficiate the mined salt has been tried out in a 25-ton per day pilot plant, operation difficulties have been overcome, and a first-class product is being obtained. Salt resources of the Amherst, N. S., area, proved by diamond-drilling to be extensive, are being developed by the Maritime Industries Ltd. (subsidiary of Standard Chemical Co. Ltd.), at Nappan, for the manufacture of evaporated salt and chemicals, also to provide salt heretofore imported suitable for curing fish. *Newfoundland*, in the spring of 1945, approved in principle a long-term investigation of salt potentialities in the Codroy area and made provision for the purchase of a diamond drill. Nothing was done on the salt survey in 1945, awaiting arrival of the equipment. It is felt that inasmuch as Newfoundland annually imports 50,000 tons of salt it would be advantageous to obtain it locally. The *West Indies* include several islands that produce solar salt from sea water. Except for *Cuba* and *Turks and Caicos Islands* the annual output does not reach 50,000 tons. Cuba has 20 salt works that supply 80 percent of domestic requirements, and the remainder is supplied by imports, chiefly from the United States.

SOUTH AMERICA

Large sources of salt having been found in accessible parts of *Brazil*, plants have been established for making alkali chemicals, and expansion of the industry is forecast. Several years ago a Salt Institute was created to equalize the rights of small producers competing with larger ones. *Chile* produces enough salt to satisfy domestic needs. The greatest single use of salt is in metallurgy, although the country has been endeavoring to develop a chemical industry. *Colombia's* salt output—derived from rock-salt mines, saline springs, and marine salinas—is devoted to local use; exports are negligible. Production in *Ecuador* is large enough to provide an exportable surplus. Both output and sale are under strict control of a Government agency known as "Estanco." About 57 percent of the salt produced in *Peru* is from sea water by solar evaporation, 23 percent from rock-salt deposits, and 20 percent from saline springs. In *Venezuela* the most important source of salt is the Peninsula of Araya, State of Sucre. The small island of Coche nearby at times has produced salt but Araya can supply more than the country's requirements. In mid-1942 new salt works were under construction.

EUROPE

Germany, from 1939 to 1944, had an average output of 3,633,000 tons of rock salt and 604,000 tons of refined salt. Formerly first among world exporters of salt, Germany exported only 734,000 tons in 1940. The industry in war years is well-described in two Bureau of Mines reports.[4] Many of Germany's salt mines were used during the war as storage places of valuables of gold and art treasures, which curtailed salt-production facilities; and by the war's end common salt was being produced from the Wintershall potash mine at Herringen, Hessen Province, where it had not been produced heretofore. The principal salt operations in the United States Zone total 10; in the British, 28; in the Russian, 23; and in the French Zone 6. Production of salt in *Italy* and colonies in the 1932–41 decade ranged from almost 1 million to 1½ million tons a year. Of this salt more than half was sea salt, most of the remainder was rock salt, and a relatively small tonnage was recovered from springs. Figures for the war years 1942–44 are not yet available; those for rock salt for the greater part of 1945 indicate a probable output of about 32,000 tons of that type. In 1940 aggregate salt exports placed the Italian Empire, including the African colonies, third on the list of world exporters, with the colonies exporting far more than Italy proper with its 156,000 tons. The *Netherlands* salt sources have been worked for many years and increasingly since 1930. By 1934 the annual output was 75,000 tons and since 1939 has averaged 200,000 tons. It is recovered entirely from wells in the eastern part of the country near the German border. The wells were undamaged by war. Availability of salt resulted in the establishment of a modern alkali industry which has grown in recent years. Improvements in salt refining are contemplated and up-to-date technology is being studied. *Rumania* is an important salt-producing country. Reliable, up-to-date figures are lacking; but in 1938, the Government monopoly's 9 mines (mostly mechanized) produced a total of 370,000 tons, of which 290,000 tons were edible and 80,000 industrial salt. Exports totaled 79,000 tons; 21,000 tons of block, ground, and industrial salt were shipped to Hungary, and 58,000 tons of block were shipped to Bulgaria and Yugoslavia. Salt is found in many places in *Spain* and normally about 20 Provinces contribute to the total production. In the first 3 years (pre-Civil War) of the decade 1933–42, salt output averaged 870,000 tons.

[4] Bureau of Mines, Mineral Trade Notes: Vol. 21, No. 2, August 1945, p. 38; vol. 22, No. 3, March 1946, p. 36.

During the Civil War, production was at the rate of about 365,000 tons. In the period 1940–42, the average was 625,000 tons. In 1943, 29 mines produced 266,226 tons of rock salt and 113 plants produced 500,392 tons of evaporated salt. The rock salt was produced chiefly in Santander Province. Alicante Province (8 plants) led in output of evaporated salt, followed by the Province of Cadiz (35 plants) 119,394 tons, and Murcia (4 plants) 76,214 tons. The remainder was supplied by 66 smaller plants in 10 other Provinces. For a time Spain was second in the list of world exporters of salt. The salt industry in *U. S. S. R.* was reported to be making a generally quick recovery. According to the press,[5] geologists resumed prospecting the Davidovsky salt deposits begun before the war. The salt mine at Artemovsk, Donets Basin, said to be the largest in U. S. S. R., has been dewatered. It is being mechanized and will have an output capacity of 1,500,000 tons a year.

ASIA

The *Ceylon* Government derives about $US900,000 annually from its salt monopoly. Exports of salt without Government license are prohibited; imports are negligible. Annual production (solar salt) normally averages about 500,000 cwt. (of 112 pounds) chiefly from Hambantota in the south and Puttalam in northwest Ceylon. Some salt also comes from the Jaffna and Trincomalee districts. In 1945 the retail price per hundredweight, including Government tax, remained at $1.39. That marketed direct to the consumer at the saltern was sold at $1.07, in carlots delivered to any rail point on the island, the consumer supplying the containers. Salt in containers supplied by the Salt Department was marketed through nine retail stores. During World War II, *China* was deprived of its vast coastal supplies of salt and had to depend upon the interior fields, the most important of which are in Szechwan [6] and the Northwest Provinces of Kansu, Tsinghai, and Ningsia. Free China's nationwide salt monopoly, as established in January 1942, functions under the Ministry of Finance and is administered by the Directorate General of Salt Administration in Chungking. It aims at increasing the nation's revenue and stabilizing the price of an important daily necessity. It operates on the basis of: Production by the people; purchase and transportation by the Government; and distribution and sale by Government-supervised commercial firms. The methods of production and the quality of the product are being improved. The Northwest District Salt Administration functions through the agency of 78 offices in the three Provinces mentioned. The salt lakes of the District are divided into two categories—Mongolian and earth-salt lakes; the first-named supplied 52 percent of the total in 1943. During the war, it was difficult for producers in Free China to obtain iron kettles and pans for making salt, and it was necessary to utilize bamboo extensively for such items as twine, rope, piping, containers, and other supplies. *India* for many years has produced more than 1½ million tons of salt annually and output in 1942 and 1943 was nearly two million, the greater part of which was solar salt. The increase during the war is

[5] Chemical and Engineering News, vol. 23, No. 15, Aug. 10, 1945, p. 1374.
[6] Chong, T. Y., Modernization of Salt Mining in Szechwan: Mining Jour. (London), vol. 225, No. 5735, July 21, 1945, pp. 466–467.

attributed to efforts to offset quantities formerly imported from Middle East countries and to the 100-percent increase in chemical production in the period.[7] *Japan* has small resources of salt on its home islands; sea water is the sole source. The country has depended upon supplies from Formosa (Taiwan), Manchuria, Kwantung (Leased Territory), China, and China's coastal areas, and, in the past, upon imports from Aden, African Colonies, Ceylon, and at times from Turkey. During the war it attempted to develop the industry at Singkwang, on the west coast of Borneo, to insure self-sufficiency of the island during occupancy. Japan utilized salt not only for its domestic production of heavy chemicals but also in chemical establishments in the territories of the Japanese Empire. As early as 1936 Japan had planned a program for developing its territorial salt fields and an augmented salt production to supply its rapidly expanding alkali industry. Late in 1939, the Japanese organized the North China Salt Co., a subsidiary of their monopolistic North China Development Co., primarily to expand Changlu production and promote salt exports to Japan. On November 24, 1945, General MacArthur granted the Japanese Government permission to import salt; the quantities to depend upon availability of shipping as well as Japan's ability to pay in commensurate exports. The important salt operations in *Korea* (*Chosen*) are the Ch'ongch'on, in North and South Heian Province, Chuan, Keiki Province, and Kwangnyang-man in South Heian.[8] Production of salt in *Turkey* has increased noticeably in the last few years. The total in 1945 consisted of 181,482 tons of sea salt, 40,463 tons of salt from wells, 33,358 tons of lake salt, and 16,193 tons of rock salt. At the end of 1945 it was planned to improve the salt fields at Camalti near Izmir, where a new plant for making salt compounds will be built.

AFRICA

Most of the salt produced in northern and upper eastern African coastal countries is from sea water, although several produce some rock salt also. Both sources normally supply large tonnages but during the war output was reduced considerably. The brine of the Mediterranean, the Red Sea, and other sea waters thereabout are reported to be more saline than the Atlantic Ocean because the rate of evaporation of the water is more rapid and few fresh-water streams empty into the more confined sea waters to dilute the brine. *Egypt*, the most important salt-producing country in this continent, obtains salt by solar evaporation at Alexandria and Port Said. A concessionaire operates at each place under Egyptian Government control. Normally the combined production of the two operations met all local needs (65,000 tons annually) and provided a large exportable surplus of about 280,000 tons.[9] In 1943 prices of salt for ballast ranged from 8 to 13 shillings ($US1.61 to $2.61) per ton compared with $1.21 in 1942. The prices of salt sold for commercial uses are calculated according to the markets where sold and therefore differ greatly. In Egypt salt usually sells for about $7.45 per ton in bulk. Egyptian Sudan annual output averaged 40,000 tons in 1941–43.

[1] In addition to the countries listed salt is produced in Albania, Bolivia, Formosa (Taiwan), Gold Coast, Japan, Leeward Islands, Madagascar, Philippine Islands, Southern Rhodesia, U. S. S. R., and Victoria (Australia), but figures of production are not available.
[2] Data not available.
[3] Estimate.
[4] Exports.
[5] Estimated production of only remaining mine, which is in Solnohrad near Presov, Slovakia; portion located in Sub-Carpathia, Ukraine, is now ceded to U. S. S. R.
[6] January to June, inclusive (Croatia only).
[7] Unoccupied China.
[8] January to September, inclusive.
[9] Incomplete data.

MAGNESIUM COMPOUNDS AND MISCELLANEOUS SALINES

By CHARLES L. HARNESS AND F. M. BARSIGIAN[1]

SUMMARY OUTLINE

SUMMARY

The down-trend in basic refractory requirements continued in 1945, but most of the decrease in mine output of magnesite was caused by suspension of operation of the greatest individual producer in the history of the industry, Basic Magnesium, Inc., Gabbs, Nev. The plant was shut down in late 1944. Output of most of the natural salines, such as sodium sulfate and carbonate, magnesium sulfate, and calcium chloride, showed increases. Iodine was produced in somewhat greater volume than in 1944. The borates industry, with the aid of recently built capacity, showed the best year since 1937.

Part I.—MAGNESIUM COMPOUNDS

MAGNESITE

Mine production of crude magnesite in 1945 was 336,458 short tons, the lowest since 1940, but still high compared with prewar figures—the 3 year average of 1937–39, for example, having been 166,000 short tons. The main reason for the decline was the closing in 1944 of the giant Basic Magnesium, Inc., flotation plant at Gabbs, Nev. The sharp drop in production of caustic-calcined magnesia from a peak of 191,792 short tons in 1943 to 43,270 tons in 1945 was similarly caused by the Basic Magnesium, Inc., shut-down. The dwindling war requirements for steel in 1945 eased the demand for refractory magnesias, accounting for the 8-percent drop in this category.

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce.

Salient statistics of the magnesite industry in the United States, 1941–45

	1941	1942	1943	1944	1945
Crude:					
Mined: [1]					
Short tons	374,799	497,368	754,832	561,450	336,458
Value	$2,655,547	$3,874,334	$6,071,596	$4,407,461	$2,324,957
Sold by producers:					
Short tons	4,536	6,835	4,090	(2)	(2)
Value	$54,045	$57,350	$47,788	(2)	(2)
Average per ton [3]	$11.91	$8.39	$11.68	(2)	(2)
Imports for consumption:					
Short tons				1,039	
Value				$34,588	
Caustic-calcined magnesia:					
Sold or used by producers: [4]					
Short tons	30,225	41,889	191,792	139,243	43,270
Value	$1,052,077	$2,028,126	$11,497,505	$6,481,963	$2,503,544
Average per ton [3]	$34.81	$48.42	$59.95	$46.55	$57.86
Imports for consumption:					
Short tons	864	578	290	559	445
Value	$23,972	$19,105	$13,122	$15,286	$12,134
Refractory magnesia:					
Sold or used by producers: [5]					
Short tons	201,481	273,661	301,382	278,490	254,994
Value	$5,052,879	$7,823,963	$9,341,183	$8,426,049	$7,414,218
Average per ton [3]	$25.08	$28.59	$30.99	$30.26	$29.08
Imports for consumption:					
Short tons	36,791	7,728	9,233	6,176	5,506
Value	$824,068	$280,342	$310,497	$260,062	$234,519

[1] Partly estimated; most of the crude is processed by the mining companies, and very little enters open market.
[2] Bureau of Mines not at liberty to publish figures.
[3] Average receipts f. o. b. mine shipping point.
[4] 1941: Includes caustic-calcined magnesite and caustic-calcined magnesia from sea-water bitterns; 1942–45: Includes caustic-calcined magnesite and reactive magnesia from sea-water bitterns, well brines, and raw sea water and from precipitated magnesium carbonate obtained from dolomite.
[5] 1941: Includes dead-burned magnesite and refractory magnesia from brucite, dolomite, and sea-water bitterns; 1942–43 and 1945: Includes dead-burned magnesite and refractory magnesia from brucite, dolomite, sea-water bitterns, well brines, and raw sea water; 1944: Includes dead-burned magnesite and refractory magnesia from brucite, dolomite, sea-water bitterns, and raw sea water.

Magnesia sold or used by producers in the United States, 1943–1944, by kinds and sources

[Quantities and values reported apply to finished products, not raw materials]

Finished product	From magnesite		From brucite, dolomite, and sea-water bitterns		From well brines and raw sea water	
	Short tons	Value	Short tons	Value	Short tons	Value
1943						
Caustic-calcined	137,300	$7,941,587	8,649	$547,888	45,843	$3,008,030

In 1945, further inroads were made on the conventional magnesite-slag open-hearth bottom by rammed bottoms and plastic chrome sub-hearths, and it appears that the trend may be accentuated even more in the future. A canvass of basic steel plants in 1945 by the Open Hearths Committee, Irons and Steel Division, American Institute of Mining and Metallurgical Engineers,[2] showed that 386 of the 610

[2] Debenham, W. S., Analysis of Questionnaire on Open-Hearth Bottom Construction and Materials: Proc., Open-Hearth Conference, Am. Inst. Min. and Met. Eng., vol. 28, 1945, pp. 85–110.

furnaces canvassed were using the conventional magnesite-slag bottom; only 72, however, stated a preference for this type of bottom over other bottoms. Plastic chrome ore subhearths with magnesite surfaces were used in 82 furnaces; the respondents reported that this number would be increased to 135 in future rebuilding. The greatest increase, however, may be anticipated in rammed construction. At the time of the questionnaire, 126 of the 610 bottoms were rammed, 61 being unsurfaced, 38 surfaced with magnesia, and 27 with dolomite-magnesia surfacing materials. The replies showed that 355 furnaces would be converted to rammed bottoms, 96 using no surfacer, 132 using magnesia on an 80-percent magnesia bottom, 108 using magnesia on a 70-percent magnesia bottom, and 19 using magnesia-dolomite on a 70-percent magnesia bottom.

Magnesia sold or used by producers in the United States, 1944–45, by kinds and sources

[1] Less than 1 ton.

Although the conventional magnesite-slag hearth appears to be on the decline in a hearth of customary construction, experiments with the all-basic furnace indicate that a burned-in magnesite hearth is necessary in the higher temperatures possible with a basic roof. Also, it has been shown that the advantages of the high magnesia content of magnesite grain may be retained without the disadvantage of having to burn it in for 14 to 16 days, if the magnesite grain is crushed fine and 10 percent slag is added. Dense layers 4 inches thick may be sintered in 30 hours, it is claimed.[3]

A disadvantage of rammed mixes is their low bulk specific gravity compared to that of sintered magnesite. Cores taken from the flat of a rammed bottom showed bulk specific gravities ranging from 2.24 to 2.62, compared with 3.12 for cores of sintered grain magnesite. Snow has pointed out that the usual method of wetting the ramming mix is partly responsible for the low density. As the mix is received in the plant, it contains enough fines to fill pore space between grains. The mix must be wetted to render it workable, and this is done in a concrete mixer. The fines aggregate as balls and contribute nothing to filling pore space.[4] A nonrotary mixing method may be indicated.

Sosman summarized the advantages and disadvantages of all-basic open hearth. Advantages are (1) increased speed of melting, (2) longer life of furnace, (3) less silica in slag, and (4) easier cleanout of slag pockets. Disadvantages were stated to be higher initial cost and greater weight.[5]

The United States Tariff Commission prepared a valuable economic study on magnesite.[6]

PRICES

Except for the withdrawal of mined periclase from the market in 1944, the prices of magnesias listed by Westvaco Chlorine Products Corp. were the same in 1945 as in 1944, as follows (carlots f. o. b. Calif.): Caustic-calcined magnesite, bulk—$52.75, powdered—$58.75; calcined (sea-water) magnesia, bulk—$54, powdered—$60; sea-water periclase, bulk, 85 percent—$36, 90 percent—$36.50. Dead-burned grain magnesite, as sold by Northwest Magnesite Co., remained at $22 a short ton f. o. b. Chewelah, Wash. There has been little fluctuation in this quotation since 1928.

On August 4, the Office of Price Administration issued ceiling prices for magnesia ramming mixes, as follows:

Brand	Producers	Price per net ton in sacks
H-W Magnamix	Harbison-Walker Refractories Co	$54.00
Magnehearth	General Refractories Co	54.00
Ramix	Basic Refractories, Inc	56.00
Basimix	do	66.50
Basiplast	do	66.50
Standard cold patch	Standard Lime & Stone Co	56.00

In general, the prices are f. o. b. plant. Details are given in the Federal Register, August 7, 1945, p. 9716.

REVIEW BY STATES

California.—Johns-Manville Corp., 22 East Fortieth Street, New York 16, N. Y., recovered purified magnesium carbonate from magnesite at Redwood City for use in 85-percent magnesia insulation. Marine Magnesium Products Corp., South San Francisco, continued its output of specialty magnesias, using as raw materials lime, dolomite, and the waters of San Francisco Bay. Permanente Metals Corp. operated its magnesia-from-seawater plant at Moss Landing during the early part of the year for use in its own magnesium metal-reduction plant at Manteca and also for making refractory magnesia for shipment. Plant Rubber & Asbestos Works, 537 Brannan Street, San Francisco, Calif., made 85 percent magnesia at its Emeryville and Redwood City plants. Westvaco Chlorine Products Corp., Newark, Calif., stopped production temporarily at its Western mine at Livermore owing to increasing mining costs. Magnesite from the mine formerly was calcined to a dense periclase, but now the firm has discovered a method of obtaining a comparable periclase from its well-known sea-water magnesia. The producer also reports that a new improved magnesia is on the market for use in oxychloride cements consisting of about two-thirds caustic-calcined magnesite (from Gabbs, Nev.) and one-third caustic-calcined sea-water magnesia.

Georgia.—International Minerals & Chemical Corp., 20 North Wacker Drive, Chicago 6, Ill., produced epsom salt from serpentine and sulfuric acid at its Augusta plant.

Illinois.—Johns-Manville Corp., 22 East Fortieth Street, New York 16, N. Y., produced precipitated magnesium carbonate by the Pattinson process for use in 85 percent magnesia insulation at its Waukegan plant.

Michigan.—The Dow Chemical Co., Midland, Mich., continued its production of magnesium chloride and sulfate from well brines and dolomite. The Defense Plant Corporation at Ludington, formerly operated by Dow Magnesium Corp. for the recovery of magnesium chloride, was closed during the year. Michigan Chemical Corp., St. Louis, Mich., recovered magnesia from dolomite and well brines. Morton Salt Co., 310 South Michigan Avenue, Chicago 4, Ill., produced precipitated magnesium carbonate from lime and well brines at its Manistee plant.

Nevada.—Basic Refractories, Inc., mined brucite at Gabbs for shipment to Narlo, Ohio, for calcining and manufacture into basic open-hearth dressings and ramming mixes. Sierra Magnesite Co., Newark, Calif., an association joining the interests of Westvaco Chlorine Products Corp. and Henry Kaiser and associates, continued to mine magnesite at Gabbs, all for "caustic-calcined" uses.

New Jersey.—Johns-Manville Corp., 22 East Fortieth Street, New York 16, N. Y., produced precipitated magnesium carbonate by the Pattinson process for use in 85 percent magnesia insulation at its Manville plant. Northwest Magnesite Co., 1800 Farmers Bank Building, Pittsburgh 2, Pa., recovered refractory magnesia from raw sea water at its Cape May plant.

Ohio.—Diamond Alkali Co., Oliver Building, 535 Smithfield Street, Pittsburgh 22, Pa., processed magnesium chloride from dolomite and waste calcium chloride liquors at its Fairport, Ohio, plant for sale to the nearby Defense Plant Corporation magnesium reduction plant.

Pennsylvania.—Three firms used the Pattinson process in making magnesium carbonate for 85 percent magnesia insulation and other purposes in the Philadelphia area, namely the Philip Carey Manufacturing Co., 1935 Easton Boulevard, Lockland 15, Cincinnati, Ohio, plant at Plymouth Meeting, Pa.; Ehret Magnesia Manufacturing Co., Valley Forge Pa.; and Keasbey & Mattison Co., Butler Avenue and Maple Street, Ambler, Pa. General Magnesite & Magnesia Corp., 2960 East Venango Street, Philadelphia 34, Pa., made magnesium oxide from purchased magnesium carbonate.

Texas.—Arizona Chemical Co., 30 Rockefeller Plaza, New York 20, N. Y., recovered anhydrous magnesium sulfate from well brines at O'Donnell. The plant has since been dismantled, and there will be no further operation, it was stated. Dow Magnesium Corp., Freeport, Tex., and Defense Plant Corporation, Freeport, Tex. (operated by Dow Magnesium Corp.), recovered magnesium chloride from sea water for use in making magnesium metal. Gardner and Cates, Llano, Tex., made caustic-calcined magnesite with two kilns for fertilizer use.

Washington.—Northwest Magnesite Co., 1800 Farmers Bank Building, Pittsburgh, Pa., was the sole producer of refractory magnesite in 1945, mining and calcining at Chewelah. Wicken [7] reviewed the current process of separating crushed quartz, talc, and dolomite from magnesite by means of ferrosilicon heavy media.

West Virginia.—The Standard Lime & Stone Co. continued its recovery of refractory magnesia by leaching dolomite at its Millville plant, where magnesium carbonate also is produced by the Pattinson process for 85 percent magnesia insulation.

FOREIGN COUNTRIES

Information of foreign developments in magnesite has been meager since the outbreak of the war. The latest Minerals Yearbook table showing world production by countries appeared in the volume reviewing 1939. During the 5-year period 1934–38, the U. S. S. R. produced annually about 534,000 short tons, Austria 403,000 tons, Manchuria, 233,000 tons, United States 157,000 tons, Greece 134,000 tons, and Czechoslovakia 83,000 tons.

Owing largely to the efforts of the mineral attachés of the Bureau of Mines and the consular offices of the State Department, production data and other information for some of the smaller producing countries have been received recently, as follows:

Brazil.—Magnesita S. A. stated that it would produce high-quality magnesite refractory brick and metallic magnesium from its deposits in Baía.[8]

Germany.—Prussian magnesite production, 1938–42, has been reported as: 1938, 23,860 metric tons; 1939, 24,065 tons; 1940, 23,576 tons; 1941, 28,716 tons; and 1942, 25,407 tons.[9]

[7] Wicken, O. H., Urgent Demand for Vital Magnesite Met by Using Sink and Float System: Pit and Quarry, vol. 37, No. 10, April 1945, pp. 83–88.

[9] Bureau of Mines Mineral Trade Notes, vol. 21, No. 2, August 20, 1945, p. 35.

India.—Several known occurrences of magnesite in the Salem and Trichinopoly districts were examined by the Geological Survey of India, and reserves were estimated at about 82,650,000 long tons. The average MgO content was reported as 31.5 percent.[10]

Italy.—Production during the period 1936–43 was reported as follows, in metric tons: 1936, 3,155; 1937, 5,392; 1938, 6,157; 1939, 14,977; 1940, 5,055; 1941, 4,587; 1942, 13,686; and 1943 (first 6 months), 2,876.[11]

Spain.—Production of dead-burned magnesite totaled 6,693 metric tons in 1945, compared with 7,276 tons in 1944.

Sweden.—An important deposit of magnesite discovered some 10 years ago in the Arctic region of Sweden (Sarek National Park) is now being worked as an emergency measure because of lack of imported material. The mineral is transported by sleds, planes, river boats, and by rail to refractory plants.

Turkey.—During 1944, 797 metric tons of magnesite were produced from four deposits in the Province of Eskisehir, compared with 137 tons in 1943.[12]

DOLOMITE

The tapering off of war demands upon the steel industry in the last half of 1945 was reflected in an 8-percent decrease in dead-burned dolomite sold or used by producers in 1945. Imports remained negligible.

Dead-burned dolomite sold in and imported into the United States, 1941–45

Year	Sales		Imports [1]		Year	Sales		Imports [1]	
	Short tons	Value	Short tons	Value		Short tons	Value	Short tons	Value
1941	1,069,887	$9,111,172	64	$654	1944	1,290,790	$11,441,612	40	$691
1942	1,229,357	10,817,634	449	11,260	1945	1,187,334	10,613,711	73	33
1943	1,276,725	11,243,017	739	22,563					

[1] Reported as "Dead-burned basic refractory material."

Interest in the recovery of magnesia from dolomite continued in 1945. References are listed in the footnote.[13]

The old problem of preventing dead-burned dolomite from absorbing water vapor and carbon dioxide received attention. Syz[14] suggested that dolomite be calcined with fluorspar (1.5 to 3 percent) at 900° to 1,000° C.

Additional information on dolomite will be found in the chapter on Stone of this volume.

OTHER MAGNESIUM COMPOUNDS

Curtailment in magnesium-metal manufacture accounted for the severe drop in production of magnesium chloride. As peacetime uses of magnesium sulfate as a rayon coagulant, in stock feeds, and as a fertilizer are substantial, production in 1945 increased. The Bureau of Mines in 1945 attempted a breakdown of U.S.P. and technical magnesias according to "lightness." It was found that there were not enough producers to show total production of each grade; therefore, only "extra-light" with four producers was shown separately. (See accompanying table.)

Specified magnesium compounds produced, sold, and used by producers in the United States, 1944–45

Product	Plants	Produced (short tons)	Sold [1]		Used (short tons)
			Short tons	Value	
1944					
Specified magnesias and magnesium hydroxide:

[1] Magnesium silicofluoride or fluosilicate included under "Magnesium salts and compounds, n. s. p. f."
[2] 50 pounds.
[3] 20 pounds.

Magnesium hydroxide, medicinal grade, according to the Oil, Paint and Drug Reporter, was quoted at 29 to 30 cents a pound in 1945 (same as in 1944); magnesium carbonate, technical, bags, carlots, northern Atlantic Coast States, 7¼ cents a pound; U.S.P. grade, 8 cents (1944: technical 6¼, U. S. P. 8). Magnesium chloride, flake, barrels, carlots, works, was quoted at $32 a ton, the same as in 1944. Magnesium sulfate, fertilizer grade, 65 percent, bags, carlots, delivered at eastern consuming points, was quoted at $59.50 a ton; industrial grade, 80 percent, 5 to 5¾ cents a pound.

Part II.—MISCELLANEOUS SALINES

CALCIUM CHLORIDE

The main use of calcium chloride is in stabilizing rural roads; it is generally bladed into the road during the spring while the roadbed is moist and pliant. In the spring of 1945, despite the great shortage in road-repair labor, substantial quantities of calcium chloride were consumed, as in years past.

Calcium chloride is also used in concrete mixes to obtain early high strength, and in freeze-proofing coal and ores in freight cars. Recent experimental uses in fog-dispersing [15] and in preservation of tobacco seed [16] have been discussed in the press.

Calcium chloride and calcium-magnesium chloride from natural brines sold by producers in the United States, 1941–45

[In terms of 75 percent (Ca, Mg) Cl_2]

Year	Short tons	Value	Year	Short tons	Value
1941	165,932	$1,333,370	1944	200,964	$1,621,227
1942	224,527	1,733,169	1945	218,320	1,818,219
1943	199,796	1,549,565			

Calcium chloride imported for consumption and exported from the United States, 1941–45

Year	Imports		Exports	
	Short tons	Value	Short tons	Value
1941	7	$795	20,777	$511,366
1942	1,443	18,926	8,336	223,184
1943	8,000	102,080	12,725	434,933
1944	2,761	35,125	8,534	233,641
1945	4,040	51,409	6,871	188,141

There were 10 producers of calcium chloride in 1945 and 12 in 1944. The following firms reported production of calcium chloride (and calcium-magnesium chloride) from natural brines in 1945: California Rock Salt Co., 2436 Hunter Street, Los Angeles 21, Calif., plant at Amboy, Calif.; J. Q. Dickinson & Co., Malden, W. Va.; Dow Chemical Co., Midland, Mich.; Hill Brothers Chemical Co., 2159 Bay Street,

[15] Calcium Chloride Association News, vol. 11, No. 6, December 1945, pp. 1, 11; also vol. 12, No. 2, April 1946, p. 4.

[16] Calcium Chloride Association News, vol. 12, No. 1, February 1946, p. 9.

Los Angeles 21, Calif., plant at Amboy, Calif.; Liverpool Salt Co., Hartford, W. Va.; Michigan Chemical Corp., St. Louis, Mich.; National Chloride Co., Amboy, Calif.; Rademaker Chemical Corp., Eastlake, Mich.; and Westvaco Chlorine Products Corp., 405 Lexington Avenue, New York 17, N. Y., plants at Chula Vista, Calif., and South Charleston, W. Va.

BROMINE

Sales of bromine compounds by primary producers amounted to 79,709,857 pounds of contained bromine in 1945, a drop of 22 percent from the historical record of 102,112,462 pounds produced in 1944. With the exception of a few percent used in photographic emulsions and laboratory reagents, almost all bromine produced in the United States is added to ethylene to produce ethylene dibromide, an almost indispensable assister for the gasoline antiknock, tetraethyl lead.

Bromine and bromine in compounds sold or used by producers in the United States, 1941–45

Year	Pounds	Value	Year	Pounds	Value
1941	68, 317, 019	$11, 506, 213	1944	102, 112, 462	$19, 712, 819

	1944			1945		
	Pounds	Value	Bromine content (pounds)	Pounds	Value	Bromine content (pounds)
Elemental bromine	3, 742, 307	$766, 059	3, 742, 307	2, 157, 820	$379, 336	2, 157, 820
Sodium bromide	1, 452, 901	273, 839	1, 133, 263	1, 203, 398	242, 758	938, 650
Potassium bromide	2, 687, 604	586, 948	1, 800, 695	3, 152, 080	626, 255	2, 111, 894
Ammonium bromide	438, 953	111, 910	359, 941	482, 749	108, 930	395, 854
Other, including ethylene dibromide	112, 281, 833	17, 974, 063	95, 076, 256	87, 484, 382	13, 438, 950	74, 105, 639
	120, 603, 598	19, 712, 819	102, 112, 462	94, 480, 429	14, 796, 229	79, 709, 857

According to Oil, Paint and Drug Reporter, potassium and sodium bromides, U. S. P., granular, 500-pound barrels, works, were quoted at $0.25 a pound in 1945. Bottled elemental bromine in cases, carlots, works, was quoted at $0.21 a pound. The same prices prevailed in 1944.

Ethyl-Dow Chemical Co., the largest producer, recovered bromine from sea water at its Wilmington, N. C., and Freeport, Tex., plants. Dow Chemical Co., Midland, Mich., second-largest producer, recovered bromine from Michigan well brines as a byproduct of magnesium and calcium chlorides. American Potash & Chemical Corp., Trona, Calif., recovered bromine from Searles Lake, and Westvaco

Chlorine Products Corp., Newark and Chula Vista, Calif., from sea-water bitterns. The following won bromine from well brines: Great Lakes Chemical Corp., Filer City, Mich.; Michigan Chemical Corp., St. Louis, Mich.; Morton Salt Co., Manistee, Mich.; Rademaker Chemical Corp., Eastlake, Mich.; and Westvaco Chlorine Products Corp., South Charleston, W. Va.

IODINE

Imports of iodine (all from Chile) dropped sharply in 1945 owing to the wartime accumulation of large stocks by the Chile Nitrate Sales Corp. (sales agent for producers of iodine from caliche in Chile). Although the bulk of domestic consumption is supplied by imports, a fair share of the market is enjoyed by two California firms that recover iodine from oil-well brines, namely, Dow Chemical Co., Midland, Mich., plant at Seal Beach, Calif., and Deepwater Chemical Co., Ltd., Victoria Avenue, Compton, Calif. The latest year for which figures on domestic production may be shown is 1937, when 299,286 pounds valued at $242,422 were produced. Output in recent years has been considerably higher.

The time-honored use of iodine is as a disinfectant, and despite the trend in medical thinking toward asepsis rather than antisepsis, there will probably be a place for the iodine bottle in the home medicine chest for years to come. Iodine is also used (as iodides) in photographic emulsions, in organic syntheses, and in foodstuffs to prevent goiter.

Crude iodine imported for consumption in the United States, 1941–45

Year	Pounds	Value	Year	Pounds	Value
1941	1,010,039	$1,121,513	1944	1,204,303	$1,321,274
1942	951,243	1,051,432	1945	220,526	232,070
1943	2,744,930	3,041,609			

The price of crude iodine has been frozen by the Office of Price Administration at $1.28¼ per pound in 150-pound kegs since 1942. Resublimed iodine in 5-pound bottles sold at $2 to $2.10 a pound during 1945.

SODIUM SULFATES AND CARBONATES

Sales of natural sodium sulfates and carbonates increased in 1945 over 1944, carbonate sales establishing a new record. Natural sodium sulfate is used principally in the West and South in the manufacture of kraft paper, glass, in stock feeds, and as a flux in metallurgy. Natural sodium carbonate is consumed principally on the Pacific coast, where it is used in glass manufacture and in alkali cleansers.

Natural sodium sulfates and sodium carbonates sold or used by producers in the United States, 1941–45

Year	Sodium sulfates [1]		Sodium carbonates [2]	
	Short tons	Value	Short tons	Value
1941	154,327	$1,443,137	146,677	$1,822,986
1942	169,870	1,669,983	150,619	2,145,289
1943	160,622	1,553,549	165,993	2,544,086
1944	168,923	1,577,982	184,826	2,869,243
1945	178,196	1,525,159	194,045	3,034,118

[1] Tonnage figures for sulfates include Glauber's salt converted to 100 percent Na_2SO_4 basis. In earlier chapters of this series the figures given for sulfates include those for Glauber's salt not so converted and were as follows—1941: 157,524 tons; 1942: 175,033 tons; and 1943: 165,908 tons. Figures for 1941–42 include some burkeite.

[2] 1941: Soda ash, bicarbonate, and trona; 1942–45: Soda ash and trona.

The following firms reported production of natural sodium sulfates: American Potash & Chemical Corp., 122 East Forty-second Street, New York City, plant at Trona, Calif.; Arizona Chemical Co., 30 Rockefeller Plaza, New York City, plants at O'Donnell and Brownfield, Tex.; Iowa Soda Products Co., Council Bluffs, Iowa, plant at Rawlins, Wyo.; Ozark Chemical Co., Post Office Box 449, Tulsa, Okla., plant at Monahans, Tex.; and Wm. E. Pratt, Post Office Box 738, Casper, Wyo.

The following firms reported production of natural sodium carbonates: American Potash & Chemical Corp., Trona, Calif.; Natural Soda Products Co., 405 Montgomery Street, San Francisco 4, Calif., plant at Keeler; Pittsburgh Plate Glass Co., Columbia Chemical Division, Bartlett, Calif.; and West End Chemical Co., 608 Latham Square Building, Oakland 12, Calif., plant at Westend.

Production of sodium sulfate in the United States, 1941–45, in short tons [1]

Year	Glauber's salt and salt cake (crude)[2]	Anhydrous (refined) 100 percent Na_2SO_4	Total
1941	721,796	54,248	776,044
1942	793,409	57,735	851,144
1943	805,257	64,219	869,476
1944	799,596	75,482	875,078
1945	755,397	83,201	838,598

[1] Source: U. S. Bureau of the Census.

[2] Includes natural sodium sulfate as shown in previous table.

Domestic salt cake was quoted at $15 a short ton, bulk, works; anhydrous sodium sulfate at $1.70 per hundredweight, works; and Glauber's salt at $1.05 to $1.45 per hundredweight in 1945, according to Oil, Paint and Drug Reporter. These prices are presumably for byproduct sodium sulfate, both crude and refined, as natural sodium sulfate, although pure enough (98 percent plus) to be classed as anhydrous grade, generally sells for somewhat lower prices. Soda ash, calcined sodium carbonate, light, bags, carlots, works, was quoted at $1.05 to $1.18 a hundredweight.

Production data for sodium carbonate produced by the ammonia-soda process for the last 5 years, according to the Bureau of the Census, are: 1941, 3,606,826 short tons; 1942, 3,788,583; 1943, 4,407,618; 1944, 4,538,398; and 1945, 4,375,017 tons.

Estimated consumption of sodium carbonate in the United States, 1941–45, by industries, in short tons [1]

Industry	1941	1942	1943	1944	1945
Glass	990,000	1,100,000	1,200,000	1,290,000	1,320,000
Soap	170,000	165,000	150,000	162,000	140,000
Caustic and bicarbonate	1,033,000	960,000	1,010,000	1,033,000	1,076,000
Other chemicals	800,000	840,000	950,000	1,025,000	960,000
Cleansers and modified sodas	70,000	80,000	85,000	90,000	90,000
Pulp and paper	155,000	145,000	155,000	160,000	165,000

1944	31,305	446,935					31,305	446,935
1945	20,293	289,940					20,293	289,940

Sodium metal.—Sodium metal is produced by two firms, E. I. du Pont de Nemours & Co., Inc., at Niagara Falls, and Ethyl Gasoline Corp., at Baton Rouge, La. It is used principally in the manufacture of tetraethyl lead, the gasoline antiknock, but large quantities are consumed in making sodium peroxide, sodium cyanide, pharmaceuticals, rubber accelerators, and in descaling steel. From November 15, 1943, until the end of the war, sodium was allocated under M–300–16 to obtain adequate quantities for making tetraethyl lead.

The price of sodium metal in 1945 remained at 15 cents a pound in blocks, carlots, works, the same as in 1944.

BORATES

Reconversion of the refrigerator, washing machine, and ceramic industries brought about the greatest production of boron minerals since 1937. Production, which had been mounting steadily since the wartime low of 226,723 short tons in 1942, reached 325,935 tons in 1945, or, in terms of B_2O_3 content, 104,600 short tons in 1945, as against 77,600 tons in 1942.

Besides being an essential ingredient of the enamel on sheet steel articles, boron minerals are also used in glass (the main wartime use), water treatment, soaps, medicines, ferrous alloys, flame-resisting paints, and fertilizers. The United States is the world's main source of boron minerals, in normal times exporting one-third to one-half of production.

Salient statistics of the boron-mineral industry in the United States, 1941–45

	1941	1942	1943	1944	1945

[1] 1941: Borax, kernite, boric acid, and colemanite; 1942–45: Borax, anhydrous sodium tetraborate, kernite, boric acid, and colemanite.
[2] Also 525 pounds of crude valued at $7 in 1943.
[3] Quantity sold or used by producers plus imports minus exports.

In 1945 the following firms reported production of boron minerals: American Potash & Chemical Corp., 122 East Forty-second Street, New York City, plant at Trona, Calif., on Searles Lake; Pacific Coast Borax Co., 510 West Sixth Street, Los Angeles 14, Calif., mine at Boron; United States Borax Co., 510 West Sixth Street, Los Angeles 14, Calif., mine near Shoshone; West End Chemical Co., 608 Latham Square Building, Oakland, Calif., plant at Westend, on Searles Lake.

On July 27, 1945, the Pacific Coast Borax Co. brought motions to dismiss the antitrust suits filed against it and the American Potash & Chemical Corp. involving an alleged conspiracy to monopolize the boron industry. The court denied the motion,[17] and on August 16, 1945, the defendants entered into a consent decree, paying fines and waiving claims to certain properties.[18]

The new boric acid plant of Pacific Coast Borax Co., begun in 1944 and completed in the latter part of 1945, contributed materially to the supply of boric acid.

An interesting flow sheet of the borax and allied processes of American Potash & Chemical Corp. at Trona, Calif., appeared.[19]

The methods of mining crude rasorite utilized by Pacific Coast Borax Co. were reviewed.[20]

The price of technical borax, 99½ percent, granular, bulk, carlots, freight allowed, remained at $41.50 a short ton throughout 1945; this price has prevailed for several years.

GEM STONES

By Sydney H. Ball

SUMMARY OUTLINE

JEWELRY INDUSTRY IN 1945

Jewelry sales (taxable) reached a peak in 1945 (tax, $198,944,988); in consequence, retail jewelry-store sales—considering nontaxable sales together with taxable sales by department stores and others—amounted to about $1,200,000,000, an all-time peak and a gain of some 12 percent over 1944. Sales in the first quarter of the year were distinctly below those of 1944; from April to July they exceeded those of 1944 by 20 percent. The surrender of Japan in August decreased but did not stop increased sales in August and September, and in the last quarter of the year sales forged ahead. Montana, Texas, and Utah showed particularly large gains. Christmas time sales reached unusual proportions. Admittedly, certain stocks were in short supply, but the populace had money and bought what was available. All holiday records were exceeded. Jewel sales, generally including diamonds, in five figures were not unusual. Americans were not the only heavy buyers; Brazilians and South Africans were equally extravagant. Retail jewelers' stocks in America decreased somewhat during the year.

Sales by wholesale jewelry houses were up slightly from those of 1944, and in dollar value their inventories increased slightly in 1945. The wholesale trade centers in New York City.

Jewelry prosperity in 1945 was built upon the people's large wartime savings; demobilized GI's returning home with their savings; a high national income; a flood of marriages (only slightly below the 1943 peak); and the dearth of other durable goods to attract money from the industry. It should, however, be emphasized that in the past decade wealth has shifted from the "400" to the medium- and lower-income brackets. The carriage trade is almost extinct, and hereafter the retailers will sell fewer expensive items and more medium- and low-priced goods.

The numerous women gainfully employed during the past 6 years have, on the average, spent more money on clothing and luxuries than the housewives. In department stores particularly, sales of medium- to high-priced costume jewelry have expanded the business of the jewelry departments.

Some jewelers anticipate a recession in sales; in consequence, the Jewelry Industry Publicity Board has had a study made of conditions in the industry, in the hope of maintaining activity in the future.

FASHIONS IN JEWELS

More jewelry was worn in 1945 than ever before. Platinum is again available for mounting, and we may expect to see palladium relegated to the side lines, except in earrings and certain clips, where its lightness is a distinct advantage. Stones mounted in invisible settings are particularly attractive. Two-toned gold retains its popularity.

In view of the shortage of skilled goldsmiths, the work of the designers merits praise. On the whole, designs were lighter and more artistic than in recent years. The three most popular motifs—flowers (sometimes in sprays or bouquets); sunburst, star, and snowflake designs; and leaves—were attractive.

Necklaces, particularly the flexible type fitting snugly to the neck, were fashionable. Clips were worn not only on dresses but attached to the necklace and on the hat. Earrings were in vogue due to the up-swept hair mode. Bracelets, singly or in groups, are as popular as ever. Rings were characterized by high pavé-domes, set with small stones rather than single gems. More and more they are being worn over gloves. Lanyards and barrettes, bandeaus, and stars for the hair are gaining in popularity.

Old jewelry is still sold but was a less-important element in the trade than in 1944.

Ensemble jewelry, three or four pieces set with the same gem, finds ready sale, as does jewelry that may be divided into two or more pieces as need arises. The double wedding-ring ceremony is now standard.

Marquise and other unusual diamond cuts are gaining in favor. Small diamonds for mountings are still in short supply, hence tiny cabochon rubies and sapphires in part supplant them. Diamond, ruby, and sapphire, including the lighter-color Ceylonese stones, led in popularity, followed by the yellow-brown gems (topaz and citrine), pearl, amethyst, turquoise, and aquamarine. Aquamarine held its own; amethyst and turquoise gained; but citrine and topaz, to a considerable extent, lost their appeal. The emerald had pride of place among the sophisticated.

The ever-insistent demand for diamonds caused colorless gems to be most popular, followed by red and blue gems; yellow, purple, and green gems were in lesser demand, in the order named.

DOMESTIC PRODUCTION

Mining for gold and mining for gem stones have been affected by war more adversely than any other branches of the industry. Production value of gem stones in 1945 dropped to about $40,000, the lowest in a decade. The decline is attributed to shortages of labor, mining supplies, tires, and gasoline. The gem hobbyists and the amateur and semiprofessional lapidaries could not replenish their stocks of rough; and most of their best customers, the touring automobilists, stayed at home. Further, the supply of most strategic minerals became adequate early in the year, and pegmatite mining waned. It should be stated, however, that pegmatite mining during the war furnished disappointingly few gem stones. Late in the year, gasoline and other supplies became available; and this, with the return of men from the war, will doubtless encourage greater production in 1946.

Oregon and Washington lapidaries were active in 1945. There are at least 50 shops, and the value of the 1945 output is variously estimated at $100,000 to $500,000.

For the first time the value of jade produced certainly exceeded that of sapphire and probably that of turquoise. In 1945 Wyoming produced a number of tons of light-green nephrite and almost as much black jade. The publicity the press has given Wyoming jade (all produced from float) has attracted a number of outside prospectors to the State. The largest boulders yet found were located during 1945.

There are three professional and half a dozen amateur cutters at Lander, and the Lander region remains the chief producer. Black nephrite, which takes a fine polish, is being obtained from the Red Desert. Discovery of jade in the Laramie Range is reported. The white "jade" said to have been found near Kemmerer is, according to reliable information, chalcedony. The so-called jade as found is sold at $1 to over $5 a pound. When peace is restored, China, may well become a good market for Wyoming jade. (Personal communications from Fred Abernathy, H. C. Dake, O. W. Plaga, Bert A. Rhoads, and Horace D. Thomas.)

Alaska jade appeared on the market in 1945. The locality, on the north side of Kobuk River, has been well-known to the local Eskimos and Indians since the Thule stage of Eskimo culture (A. D. 600 to 1600).[1] Late in 1945 the Arctic Exploration Co. of Fairbanks located mining claims in the district and flew a considerable shipment of jade to Fairbanks. Some of the material is stated to be of gem quality, but most is fit only for objets d'art. The Chinese have purchased some of it. It is reported that three or four men were collecting boulders from the bed of Kobuk River last summer. The better Alaskan material compares favorably with the better New Zealand nephrite. It is suitable for tourist jewelry and objets d'art.

Turquoise is occasionally found at the Castle Dome copper mine in Arizona. It is "high-graded" by the miners and sold in Miami or Globe. Some of it is of fine quality. A company official states—

> As in the past, turquoise of an undetermined amount was recovered during routine mining operations. As a whole, the quality of the material recovered at greater depth has improved, both in hardness and in color, the latter occurring in the lighter shades of blue.

Turquoise mining was relatively active in Nevada, particularly in the Tonopah and Battle Mountain districts. Most of the material is shipped to New Mexico, although some is cut locally, there being five cutting shops at Battle Mountain (personal communication, Jay A. Carpenter). Alfred L. Ransome states that the lessors, Lee Hand

[1] Ball, Sydney, H., The Mining of Gems and Ornamental Stones by American Indians: Bureau Am. Ethnol., Anthropol. Paper 13, 1941, p. 37.

and Paul Bare, of the Pedro claim on the Copper Basin property of the Copper Canyon Mining Co., Battle Mountain, produced 3,601 pounds of cobbed turquoise in 1945. The Elko County mines appear to have made no shipments in 1945.

In Colorado the King mine, now renamed the Lickspittle, was operated in 1945 by Charles King of Manassa, Colo. Twelve men were employed. The Hall mine, near Villagrove, Saguache County, will soon be operated again. There are rumors of a new turquoise deposit in the Cripple Creek district. New Mexico produced no turquoise, although Indians sorted some material from the dumps. Stuart A. Northrop states that the Indian jewelers are using chrysocolla, malachite, and chalcedony, largely from Arizona, as substitutes for turquoise. Reports indicate intermittent work on the turquoise deposit near Van Horn, Tex.

The agate deposits on the Priday property in Jefferson County, Oreg., a large producer by hand methods, are to be operated mechanically in the future (personal communication from Dr. H. C. Dake). The moss agate deposits of Yellowstone River in Montana, long productive, are said to have produced less than usual in 1945. The easily accessible material is exhausted. Philip S. Hoyt produced some chalcedony in New Mexico and Arizona, which, after staining, is set in costume jewelry. Considerable rose quartz was produced in South Dakota, but most of it (which was poor quality) was sold to decorate rock gardens. Some fine rose quartz was found at the Bon Ami workings at Plumbago Mountain, Newry, Maine, according to Stanley I. Perham.

Utah produced less variscite in 1945 than in the recent past. Junius J. Hayes reports that the Clay Canyon deposit (Utah County) produced about 1,000 pounds; that the Amatrice Hill deposit near Grantsville (Tooele County), although not regularly worked, produced about 200 pounds; and that the Lucin deposit (Box Elder County) probably was not worked.

No sapphires were produced during the year in Montana; as Dr. Francis A. Thomson explains, they have lost their commercial market to the synthetic stones. A little ruby and sapphire were reported to have been produced in Franklin and Clay Counties, N. C. Charles E. Hunter reports that Linten B. Greene procured a fine sapphire at the Corundum Hill mine, Macon County. It is a deep-blue tabular crystal ½ inch thick and 1 inch across. He intends to keep it in his collection as a rough crystal.

Dr. A. M. Butler reports that a considerable amount of "marekanite" (black obsidian nodules in Arizona perlite beds) is being cut cabochon and set in "Indian" silver jewelry. The Superior district south of Queen Creek is the most important locality.

Eldred D. Wilson (Arizona Bureau of Mines Bull. 152, Tucson, Ariz., October 1944) estimates the production value of precious stones in Arizona from 1900 to 1921 at $300,000, an average of $13,636 a year. In recent years production has been much less. Wilson lists the precious stones found in the State, apparently in order of production, as follows: Turquoise, silicified wood, oxidized-copper minerals (azurite, malachite, and chrysocolla), garnet, peridot, Mexican onyx, opal, tourmaline, and obsidian; and, of less importance, rock crystal,

717372—47——98

amethyst, chrysoprase, agate, dumortierite, and catlinite. Small pyrope garnets and peridot are collected by Navajo Indians, the former from Garnet Ridge and Buell Park in Apache County and the latter from the same localities and from west of San Carlos, Gila County. At the latter locality, peridots of over 233-carat weight have been found.

Deep blue dumortierite resembling lapis lazuli occurs as boulders in gravel along the Colorado River 30 miles north of Yuma.

Mrs. E. M. Roe states that only one Sioux Indian mined catlinite at Pipestone, Minn., in 1945 but that a number of returned Indian servicemen expect to dig catlinite and fabricate it.

When the test atom bomb was dropped in New Mexico, the sand near the crater, according to the press, was fused to a grayish green glass. It was dubbed "atomsite," and souvenirs are said to have been made from it.

The States and Territory leading in gem production in 1945 were Wyoming, Oregon, Alaska, Nevada, Utah, and Arizona.

Other gem stones produced in small amounts in 1945 include agate (Idaho, Wyoming, and Luna and Sierra Counties, N. Mex.); amazonite (Amelia, Va.); amethyst (North Carolina and Mineral Valley, Millard County, Utah); aquamarine (Mitchell, Yancey, Avery, Macon, and Ashe Counties, N. C.); asteriated rose quartz (Newry, Maine); chalcedony (Nevada); citrine (North Carolina); emerald (Mitchell and Yancey Counties, N. C.); garnet and golden beryl (Mitchell County, N. C.); jasper (Idaho and near Hot Springs, N. Mex.); moonstone (New Mexico and Mitchell County, N. C.); moss agate (Wyoming); opal (Idaho and Virgin Valley, Nev.); opalized wood (Nevada and New Mexico); rock crystal (Hot Springs district, Ark.); sapphire (Idaho); green smithsonite (Magdalena, N. Mex.), and smoky quartz (North Rumford, Maine).

Heizer and Treganza have written an interesting article on the California Indian Mines and Quarries (see Bibliography). They list 142 sites worked by the Indians for various stones. Turquoise, quartz crystal, chrysocolla, chrysoprase, tourmaline, and malachite were among the gem materials used. They found that the San Bernardino County turquoise mines were worked by the Pueblos of New Mexico and Arizona, who made periodic trips to the mines.

CANADIAN GEM STONES

Canada apparently produced no precious stones in 1945, but a number of amateur lapidaries, particularly near Toronto, cut such Canadian rough as they could get. G. G. Waite,[2] an amateur lapidary, lists a large number of Canadian precious stones suitable for cutting; few, if any, of them are of commercial importance. Some of the Thunder Bay amethyst, however, is of fine color.

ACCESSIONS TO MUSEUMS

The National Museum, Washington, D. C., has added several fine gems to its collection, notably an unusually large and fine green chrysoberyl (120.45 carats) from Ceylon and a zincite (5.12 carats)

[2] Waite, G. G., Contributions to Canadian Mineralogy: University of Toronto, No. 49, 1944, pp. 75-78.

from Franklin, N. J. During the year the American Museum of Natural History acquired a 16-carat cut zincite and a 19-carat oval-cut brazilianite. The latter gem is of pleasing lemon-yellow color and quite brilliant, although it is so soft that it is suitable only for mounting as a pendant. The University of South Carolina recently acquired the Colburn mineral collection of Southern Appalachian gem stones, comprising notably representative specimens of hiddenite, rhodolite, and emerald.

During the year, the well-known star sapphire, The Star of Artaban (300 carats), was presented to the National Museum in Washington.

NOMENCLATURE

The Precious Stone Dealers Association of New York on October 11, 1945, adopted preferred names for gem stones.[3] The use of a geographic designation ("Burma sapphire," for instance) for precious stones similar to the normal type produced by the country named, even if the stone may come from another country thousands of miles away, is highly recommended. It is poor practice, however, to name any member of the quartz family "topaz"; the proper name for yellow or brownish rock crystal is "citrine" or less acceptably "topaz quartz." Even the latter term is incorrect and undesirable. The association attempts in its nomenclature to draw a sharp line between natural and treated stones. The nomenclature committee consisted of H. N. Paskow (chairman), Leo Nathan, and Thomas H. Benedict.

EDUCATION IN GEM STONES

GI's are now permitted, as an educational benefit for service rendered, to enroll in the courses of the Gemological Institute of America. Gem courses in American institutions of learning apparently have a record number of students. The Australian Gemological Association has been formed to advance the knowledge of gem stones in that continent.

The Gem Trade Laboratories, Inc. (36 W. 47th St., New York City), sponsored by the colored-stone and pearl merchants of the city, now identifies stones and will make tests of them on a commercial basis. Dr. A. E. Alexander is in charge.

A new film, The Magic Stone, publicizes the diamond.

IMPORTS

The value of imports of precious and semiprecious real and imitation stones, exclusive of industrial diamonds, as listed by the United States Department of Commerce, totaled $114,435,231, 48 percent more than in 1944. The great gains were in polished diamonds and in cut stones of other types, both natural and synthetic. The figures for imports follow.

GOVERNMENT REGULATIONS

The end of the war has not diminished greatly the number of Government regulations affecting trade in precious stones.

In the United States, the OPA relinquished price control on "synthetic and semiprecious stones for jewelry purposes" on October 15, 1945. On December 27, the United States Government liberalized the export of jewelry, including that containing diamonds, but has refused to reduce the excise tax (20 percent) on jewelry sales, an element that encourages a black market in the jewelry trade. Canada early in the year removed price controls on jewelry.

As a postwar measure, during the year Australia permitted the import and export of jewelry. On October 21, 1945, Mexico removed the export duty on silver jewelry, even if set with stones of local origin; and Argentina, as of May 4, unified at 5 percent its sales tax on jewelry. In the fall Mexico imposed a 3-percent sales tax on jewelry. As of October 1945, South Africa still required export permits for gold and diamond jewelry. Late in the year the Italian Government removed the ban on trade in precious metals and gems.

To protect its mines and its cutters of precious stones, Brazil (January 22, 1945) required import licenses for all precious stones, diamonds, and quartz crystals; after May 25, 1945, upon presentation of import licenses, 1 unit of cut synthetic gems could be imported, provided at the same time 10 units of rough synthetic gems were imported.

In Uruguay the sales tax (February 23, 1945) on jewelry became 13 percent. On March 31, 1945, France increased the luxury tax on jewelry sales from 10 to 25 percent, and late in the year Bolivia increased the luxury tax to a point that threatens the disappearance of jewelry from the retailers' shelves in that country.

As to taxes, the Quebec jewelers find themselves in what would be a ludicrous position, were it not serious. Their sales are subject to a 25-percent Federal tax, a 6-percent Provincial tax, and a 2-percent municipal tax.

DIAMOND

Nineteen forty-five was a highly prosperous year in the diamond industry. The sales of the Diamond Trading Co., the principal seller of rough stones, reached £24,500,000—an all-time peak; presumably, the sales of cut goods also attained a record. Indeed, the United States imports of cut were appreciably above those of the lush 1920's. Again consumption greatly exceeded production, and the drain on stocks was heavy. Stocks in certain categories of both rough and cut are depleted, and in no grade are they large. In consequence, both the gem and industrial diamond trades must look more and more to current production for their diamonds. Additional mines are being equipped, but no great increase in production can be expected for 3 or 4 years.

World production was almost 14,000,000 carats, a fifth greater than that of 1944. Of the total, 83 percent by weight were industrials and 17 percent gem grades.

The price of gem rough again advanced, although there has been no increase in the wholesale price of industrials in 7 or 8 years. Uncut gem diamonds are now quoted at more than twice the prewar price. Cut has never been so high. Since 1939, melee has at least tripled in price, and larger cut has more than doubled in price. The price of large stones (10 carats or more) is a matter of negotiation between buyer and seller. Fine cut, in the United States at least, was in short supply much of the year.

Industrials, once a drug on the market, now represent about 20 percent, in dollar value, of the world's rough sales. Yearly the distinction between gem grades and industrials is defined more sharply.

With the war's end, investment in diamonds has not ceased. The people of much of the world have more confidence in diamonds than in their own countries' currency.

Share dealings.—The shares of diamond-mining companies, virtually all of which are listed on the London Stock Exchange, gained about 17 percent in 1945 as contrasted with the slight loss suffered in 1944. Strangely enough, quotations were affected only slightly by the surrender of Germany and Japan, but much more so by sales of rough, dividend declarations, and publication of annual reports. Of the eight principal mining companies, all paid dividends in 1945, although the yield at year-end prices varied greatly.

Imports.—Imports of gem diamonds into the United States increased from $26,186,948 in 1942 to $107,308,028 in 1945, or almost 310 percent.

The following table shows comparative figures of imports during 1944 and 1945. The figures for rough are almost identical; those for cut show an increase, respectively, of 123 percent by weight and 119 percent by value. The grade of the imports was somewhat poorer in 1945 than in 1944.

Diamonds imported into the United States, 1944–45, by countries

[1] Less than 1 carat.
[2] Effective Jan. 1, 1945, includes Gambia and Sierra Leone.

Cutting.—Due largely to revival of part of the Belgian cutting industry, the number of artisans employed jumped from 14,000 at the end of 1944 to 25,000 at the end of 1945. The amount of rough gem material has not been increased proportionately; and, because of shortages of rough, there will presumably be considerable unemployment in the trade in 1946. The best cutting of large stones today is done in the United States and the finest small cut in the United

States, Palestine, and Belgium. The Belgian industry has made a remarkable come-back and at the year end had 10,000 operatives. The other principal cutting centers are New York City, Palestine, Brazil, and Holland.

World production.—Owing to the war, accurate diamond-production statistics are not available, but the estimates in the following table are believed to be fairly reliable. World production (gems and industrials) in 1945 is estimated to have been 14,257,000 carats (3.129 short tons), worth about $64,750,000. The quantity was about 22 percent greater and the value 35 percent greater than in 1944. Of the total, cuttables made up about 18 percent of the total, a smaller proportion than last year because of the large production of crushing bort by BCK, a Belgian Congo producer. By weight, some 5,125 pounds were industrials and 1,130 pounds gem stones.

The Belgian Congo was the leading producer by weight (72.9 percent), although it represented but 13 percent of the value. On the other hand, the British Empire, accounting for only 19.2 percent of the weight, represented 71 percent of the value.

Compared with 1944, the Belgian Congo increased its production, by weight, 38 percent. Tanganyika Territory continued its gain in output; in consequence, DeBeers sent engineers to look over the field. DeBeers operated its Dutoitspan and Bulfontein pipe mines and is beginning to reopen Premier and New Jagersfontein, although it will be several years before these are producing. The South African alluvial production increased. The Venezuelan production continued to decrease, and that of Brazil probably was less than in 1944.

The following table shows as accurately as available statistics permit world production for the past 5 years.

[2] Includes Venezuela (12,769 carats), Borneo, India, New South Wales, and U. S. S. R.

Industrial diamonds.—With the end of World War II, it was expected that imports (roughly, consumption) would fall markedly. Many war contracts were canceled after VJ-day but imports, as to weight, held up surprisingly, although the drastic decline in value indicates that crushing bort formed an ever-increasing percentage of American imports. Consumption again largely exceeded production, and stocks were heavily drawn on and are perhaps dangerously low; certainly, they are largely depleted as to some sizes and grades. Manufacturers of diamond-set tools have, through inertia, demanded of the trade a type of diamonds that may be in short supply. Provided they show ingenuity in using diamonds physically more or less similar, they will find a fair stock at their disposal. American industrial diamond merchants probably have a relatively large stock.

Thanks to the large production of BCK, the 1945 output of industrials was an all-time record, but much of it was crushing bort, and no great increase in the production of bort can be expected for 2 or 3 years.

After VJ-day, the United States Government removed many of its controls over industrial diamonds, although import and inventory controls are still in effect. The British Government removed all controls in the Empire in December.

Diamond drilling was exceedingly active in 1945 due to the mining boom in Canada and the increasing use of diamond bits in stope drilling. Diamond consumption in drilling increased greatly. Diamond-impregnated wheels—the bond being a plastic, a ceramic product, or a powdered metal—are having wide peacetime use. Standardization of diamond powders has been accepted by the industry. War-born uses for diamond tools and dies insure a satisfactory peacetime demand.

Figure 1, originally prepared by Herbert Backman several years ago, shows the tremendous increase in use and the sharp decline in price per carat in American imports in the last 27 years.

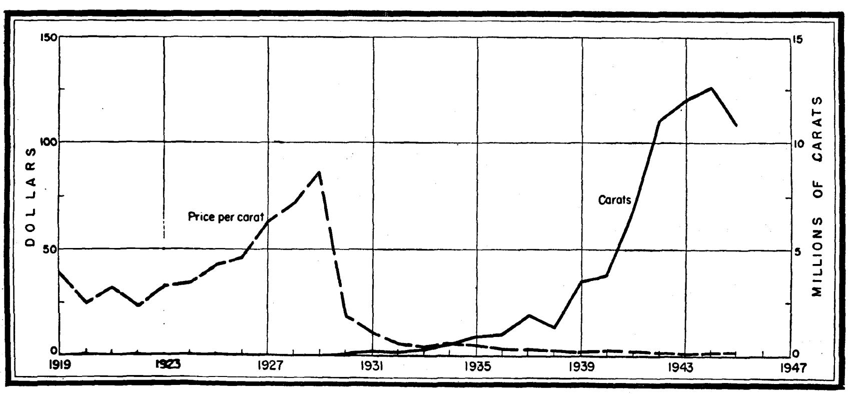

FIGURE 1.—United States imports and average price per carat of industrial diamonds, 1919–45.

Imports of industrial diamonds into the United States during the past 5 years were as follows:

Industrial diamonds (glaziers', engravers', and miners') imported for consumption in the United States, 1941–45

Year	Carats	Value		Year	Carats	Value	
		Total	Average			Total	Average
1941	6,882,248	$14,908,809	$2.17	1944	12,614,507	$22,861,401	$1.81

1943	12,084,133	21,890,568	1.81				

RUBY, SAPPHIRE, AND EMERALD

Of the world's purchases of precious stones, at least 95 percent are diamonds. Because of this and because the types of the deposits of the ruby, sapphire, and emerald do not lend themselves to large-scale operations, successful gem mining by large companies is confined to the diamond. It is true that Burma Ruby Mines, Ltd., for over 3 decades worked the Burmese ruby mines and that several entrepreneurs have leased and worked the Colombian emerald mines, but such enterprises were failures. Fine rubies come from Burma; gem sapphires from Thailand, Indochina, Kashmir, and Ceylon; and emeralds from Colombia and the Urals in Russia. In the first half of 1945, the United States imported from Russia 1,682 carats of cut emeralds valued at some $31,000, or roughly $18.50 a carat. The price suggests that the quality was poor. Today some of these deposits are shut down; Indochina and Kashmir are practically exhausted, or at least it is so reported; the Colombian emerald deposits are dormant; and during World War II the Ceylonese gem miners were recruited to mine graphite. Furthermore, the colonial laws made the marketing of gems complicated, if not almost impossible. Shipments from Ceylon to America are inferior to prewar shipments. The Ceylonese have more money than formerly to buy fine gems, and they have lost their European markets for inferior gems. The native miners of Burma, Thailand and Indochina in 1945 continued to mine a few gems, although they could scarcely have sold many to the Japanese. Happily, the Burma ruby mines were reoccupied by the United Nations on March 20, 1945, and Thailand and Indochina later.

In consequence of the above circumstances, very few newly mined colored gems are coming on the market, and today we look to jewelers' stocks and old jewelry for our supply. Some fine emeralds are being obtained from once-wealthy nationals of Spain and England, and rubies and sapphires from the out-moded jewelry of England and the Continent. The demand is insistent, but the supply is inadequate. Although prices today are very high, they are likely to follow the law of supply and demand and go higher.

Fine rubies, sapphires, and emeralds of size are hard to find in New York today and are by no means modestly priced. The New York market must also compete with the Far Eastern market, where colored stones are highly regarded, not alone for their beauty, but also as the safest of investments. Compared with the diamond the noble gems, particularly the emerald, have a more restricted group of admirers, although these may well be the more intelligent and intellectual of the populace. The diamond, therefore, has a higher rank as an investment.

At present, demand and supply are badly out of balance and will be in the immediate future, unless demand becomes less insistent.

Our soldiers in the East continue to buy gems, and as amateurs they are commonly duped with synthetic or inferior gems. At times, however, they may pick up lucky bargains. Their purchases have forced up prices appreciably.

It has been noted that colored glass used to direct traffic on American airfields in Burma disappeared; it is a possible source of some of the "gems" the boys are buying. The members of the American Gem Society have offered to test free for veterans the stones they have purchased.

The Muzo and Coscuez emerald mines in Colombia have been shut down since 1938. The Colombian Government desires to turn the ownership of these mines from a liability into an asset. The emeralds in the Bank of the Republic owned by the Government, valued by Modero and Dixon at pesos 1,200,459.26, were said to have been sold early in 1946 to an American jewelry firm for some $685,000 United States currency.

LESSER GEMS

In America the opal has been used more in fine jewelry in the past year than for several generations; and our armed forces, when stationed in Australia, bought many fine gems. The stone's beauty deservedly warrants its revived popularity. During the war few Australian opals were produced, and the Mexican production has been small, hence the price trend of all grades is upward.

A new gem stone of considerable beauty, brazilianite, was discovered during the year. Zincite of an attractive deep-red color, from Franklin, N. J., has recently been cut into gems. Reference has been made to both of these gems in the section on Accessions to Museums and in the bibliography.

The aquamarine remains one of the most popular gem stones, so popular, in fact, that blue topaz, which if fine in quality is a superior stone, is appearing on the market as a substitute. Price has moved up markedly, apparently to an unwarranted extent. Brazil is the premier producer, particularly Minas Gerais and to a lesser extent Ceará. Minas Gerais includes the production of aquamarine with tourmaline. In 1936 over 7,235,000 carats of the two gems were produced; since then production has fallen and in 1943 was only 1,469,000 carats. Exports of aquamarine to the United States, however, have increased considerably—in 1943 158,695 carats valued at about $232,000 ($1.46 per carat) and in 1944, 364,285 carats valued at $578,506 ($1.58 per carat). Brazil also produces a much smaller amount of kunzite, a few emeralds, a little topaz, fine garnets, and much rock crystal and citrine.[4] Brazil stains a certain amount of chalcedony to black onyx, some of the product being exported.

[4] See also Pough, Frederick H., Jewelers' Circular-Keystone, February 1945, pp. 143–144, 158–163.

The Madagascar gem-mining industry, which was negligible during the war, may revive, as certain French firms wish to import rough gem stones.

The gem production of Ceylon during the war was small, labor being diverted to more important industries.

South African jewelry manufacturers are attempting to interest the public in the Dominion's rather mediocre gem stones, the diamond of course, being the exception.

It is reported that production at the Nishapur (Iran) turquoise mine has been very small during the past few years (personal communication from Lester S. Thompson). Lithuania is again beginning to produce and fabricate amber. Meerschaum was one of the principal exports of Turkey before the war; to a certain extent the industry is reviving (1944 production, 9,520 kilograms).

Asteriated quartz colored blue is being offered on the market as a substitute for the star sapphire.

NITROGEN COMPOUNDS

By Bertrand L. Johnson[1]

SUMMARY OUTLINE

GENERAL CONDITIONS

War, with its insistent call for nitrogen for munitions and the concomitant increased nitrogen requirements of an intensified agriculture and industry, demands immense supplies of this element. World War II, the greatest of all wars, created correspondingly large needs for nitrogen, far in excess of the capacity of domestic plants at the start of the war. Erection of many new synthetic nitrogen plants boosted the productive capacity, and domestic output of nitrogen reached new peaks. Rising from only 450,000 tons in 1939, it exceeded 1,250,000 tons annually in the final years of the war.[2] During the war agricultural and industrial consumption of nitrogen doubled, and military consumption rose from 59,000 short tons in 1941 to nearly 600,000 tons a year at the close.

The conclusion of major hostilities in 1945 was followed by collapse of the military demand for nitrogen for munitions, closing of several Government-owned synthetic nitrogen plants, and diversion of the

product from other plants to agricultural instead of military uses. The shift from war to peacetime conditions in the nitrogen industry is still in progress, hampered by industrial uncertainties and complicated by the sudden increased demand from famine-threatened countries for nitrogenous fertilizers.

OUTLOOK

The reconversion period following World War II finds the United States with a tremendous domestic nitrogen productive capacity of 1,500,000 to 1,700,000 short tons of nitrogen annually, which, combined with annual net imports of 200,000 to 300,000 tons, could make available supplies of 1,700,000 to 2,000,000 tons of nitrogen a year. This capacity is more than double prewar domestic consumption and greatly exceeds present needs, which the most favorable estimates place at less than 1,200,000 tons. The domestic plant capacity is enough to make the United States more than self-sufficient in nitrogen, except where cyanamide from Canada and natural nitrates from Chile are specifically demanded. As the combination of existing privately owned plants and imports does not appear to be able to meet domestic demands, except under depression conditions, some supplies from the Government-owned fixed-nitrogen plants are deemed necessary. Many of these Government-owned plants have been declared surplus, and their ultimate disposal is uncertain.

The total consumption of nitrogen in the immediate future is expected to be considerably less than that reached during the war. Munition requirements are expected to be relatively small. Industrial consumption, at a peak of over 300,000 tons in 1943–44, decreased slightly in 1944–45 and may decline much further under unfavorable industrial conditions. The demand for fertilizer nitrogen will probably continue at a high level, at least for a year or two, because of the world-wide food shortage.

The prospective nitrogen situation is discussed in considerable detail in a recent report of the Surplus Property Administration.[3]

INORGANIC NITROGEN COMPOUNDS

NATURAL NITRATES

Domestic nitrate deposits.—None of the deposits of soluble nitrate minerals scattered throughout the United States have yet proved of sufficient size or grade to serve as a basis for a domestic nitrate industry. Consequently, little attention has been paid to them in recent years, and none of the deposits is known to have been under investigation or development in 1945. Many have been described. The published reports are cited in the Nitrogen Compounds chapter, Minerals Yearbook, 1942, page 1522.

Chilean nitrate.—Large quantities of natural sodium nitrate continue to be imported from Chile. Imports in 1945 were much larger than in 1944. No sodium-potassium nitrate was imported in 1945, however, although several thousand tons a year usually enter the United States from Chile. These imports in recent calendar years are shown in the accompanying tables. Imports in 1946 are expected to be much smaller than in 1945 because increased quantities have been diverted to European markets and the supply available for the United States has decreased in consequence. Even with an expected increase of domestically produced synthetic sodium nitrate, it is reported that the total amount of foreign and domestic supplies of sodium nitrate available for agriculture in the crop year 1945–46 probably will not exceed 75 percent of the tonnage delivered to agriculture in the season of 1944–45 in the States east of the Rocky Mountains.

During the war, in order to maintain the movement of sodium nitrate from Chile and to sell the product below the ceiling of the Office of Price Administration, a wartime subsidy ranging upward

[3] Surplus Property Administration, Chemical Plants and Facilities: Washington, D. C., 1945, 80 pp. Progress in Disposal of Synthetic Ammonia and Alcohol Plants: Suppl. 3, 1945, 8 pp.

to about $7 a ton was paid; the United States Government thereby absorbed some of the increased production and shipping costs. This practice, however, is reported to have been discontinued in July 1945.

During the first 9 months of 1945 imported sodium nitrate was allocated under Schedule 80 (Nitrogen Compounds) of WPB General Allocation Order M–300 which governed the distribution of nitrogen compounds. With easing of wartime restrictions on business, this order was revoked, as of September 30, 1945; and imported sodium nitrate, with the other "nitrogen compounds", was removed from allocation. Allocation had been necessary because of the insufficiency of the supply of sodium nitrate for full agricultural requirements. Its use in the United States east of the Rocky Mountains was restricted to direct application to the soil as side and top dressings. Little was allotted to mixed fertilizers.

Prices of imported sodium nitrate at the wholesale level throughout 1945 were covered by Revised Maximum Price Regulation 205 of June 30, 1944, and amendment 4 to that regulation, effective November 16, 1944. The maximum delivered price at any destination was set at $30 per ton in bulk, $33 in 100-pound bags, or $32.40 in 167- or 200-pound bags, plus the lowest carlot freight rate per ton on the material to the destination from the nitrate port that has the lowest carlot freight rate.

The maximum delivered price at any destination for nitrate of soda-potash (minimum nitrogen content, 14 percent) was fixed at $38 per ton in bulk, $41 in 100-pound bags, or $40.40 in 167- or 200-pound bags, plus the lowest carlot rail freight as defined above.

Amendment 4 permits an increase of 50 cents per ton for imported nitrate of soda loaded on trucks at warehouses in New York, N. Y., Camden, N. J., and Baltimore, Md.

Retail prices of agricultural sodium nitrate were covered by Second Revised Maximum Price Regulation 135 and amendments up to No. 4 (effective November 26, 1945).

Early in 1946 the Federal Trade Commission announced that a monopoly complaint against the Chilean Nitrate Sales Corp. and the Barrett Co., both of New York, charging them with conspiring to monopolize the sale of raw nitrate of soda, had been "dismissed without prejudice."

On April 3, 1945, the State Department announced[4] that, as a result of discussions between the United States and Chilean delegations at the recent Inter-American Conference on Problems of War and Peace at Mexico City, regarding the operation and disposal of synthetic nitrogen plants owned by the Government of the United States—

> The Secretary of State informed the Minister of Foreign Affairs of Chile that it was not the intention of the Government of the United States that the production by the Government of synthetic nitrogen in plants owned by it and constructed for war purposes, should be continued beyond the period necessitated by the conditions or consequences of the war, except as might be necessary in order to maintain the plants in efficient operating condition for national security from the point of view not only of physical condition but also for the purpose of continuing scientific research and technological progress. The Chilean Minister of Foreign Affairs was also informed that should it be necessary for the Government of the United States to modify this position, there would be consultation with the Government of Chile before action was taken.

[4] U. S. Department of State, Press Release 293: Apr. 5, 1945, 1 p. (mim.).

The Secretary of State also informed the Foreign Minister of the intention of the Government of the United States to consult with the Government of Chile with respect to such Government plants for the production of synthetic nitrogen, constructed for war purposes, as might not be dismantled, or converted to uses other than the production of synthetic nitrogen or maintained for national security, if the terms or conditions of cession, sale or lease of such plants to private interests might create serious problems affecting the production or exportation of Chilean nitrates. Such consultation would be for the purpose of reaching such accord with respect to those problems as would, while protecting the interests of the United States Government, give due consideration to the effects upon Chile, particularly from the point of view of the competitive situation created by the terms or conditions of cession, sale, or lease of those plants.

SYNTHETIC NITROGEN COMPOUNDS

General.—The general situation in the synthetic nitrogen industry in the United States in recent years has been covered in the Nitrogen Compounds chapters in Minerals Yearbooks, 1942, 1943, and 1944. This chapter presents the major developments in 1945.

Ammonia and certain other nitrogen compounds were assembled December 26, 1944, under WPB General Allocation Order M–300, Schedules 79 (Synthetic Ammonia) and 80 (Nitrogen Compounds) as appendix B materials. The nitrogen compounds listed under Schedule 80 were ammonium sulfate, sodium nitrate, ammonium nitrate (fertilizer grade), calcium cyanamide, ammonium phosphate (fertilizer grade), ammonium nitrate mixtures, mixed nitrogen solutions, B liquors, urea mixtures of 42 percent nitrogen (including Uramon but not including food-grade urea). On February 7, 1945, Schedule 80 was amended to substitute aqua ammonia (A, B, and C liquors) for B liquor. These schedules governed distribution of the commodities above specified for the first 9 months of 1945 but were then revoked, and the commodities referred to in them were removed from allocation as of September 30, 1945.

Ammonia and its compounds.—Early in 1945, 19 synthetic ammonia plants are said to have been in operation in the United States. These included 10 Government-owned plants—the 8 ordnance plants, and those of the Tennessee Valley Authority and the Defense Plant Corporation—and 9 private companies. Various data regarding the Government-owned plants are provided in the accompanying table. Many other details and the general situation surrounding their disposal are given in a report of the Surplus Property Administration.[5] The greater part of the production of domestic private plants came from 2, owned, respectively, by E. I. du Pont de Nemours & Co. and the Allied Chemical & Dye Corp. These 2 plants have about 90 percent of the total domestic private synthetic ammonia production capacity.

Following cessation of hostilities in 1945 several ordnance plants (Ohio River, Dixie, Buckeye, Jayhawk, Ozark, Cactus, and Morgantown) and the Defense Plant Corporation operation at Lake Charles, La., were declared surplus and were advertised for purchase or lease in September 1945 by the Reconstruction Finance Corporation. Since then the Ozark, Jayhawk, and Buckeye plants are reported to have been leased to commercial operators. Morgantown ordnance and Missouri ordnance are now being held by the Army for military

[2] Actual peak performance in some months has been higher than annual rates for several of the plants, indicating a possible ultimate capacity of 891,200 tons per year.
[3] With only 1 synthesis unit on ammonia.

stand-by. Pending Army need the Missouri plant, near Louisiana, Mo. (less than 100 miles above St. Louis on the Mississippi River), has been taken over by the Bureau of Mines, United States Department of the Interior, for conversion to an experimental synthetic liquid-fuel demonstration operation for the production of synthetic gasoline and oil from coal and lignite, to supplement and conserve the Nation's petroleum reserves. The plans of the Bureau of Mines call for two distinct units, one using the direct hydrogenation method of producing synthetic fuels, and the other employing the indirect gas-synthesis process. All changes are to be so made that the plant may be reconverted to the production of ammonia should another emergency occur.

Part of Nitrate Plant No. 1 of the Tennessee Valley Authority at Muscle Shoals, Ala., has been leased for 10 years to the Reynolds Metal Co., of New York.

The ultimate disposal of the other Government-owned plants is still uncertain.

Production of domestic byproduct-coke ammonia liquor (NH_3 content) was 27,607 short tons compared with 31,665 tons in 1944. Sales were 25,720 tons in 1945 compared with 30,004 tons in 1944.

Ammonium sulfate is one of the principal sources of nitrogen used in mixed fertilizers, and virtually all that is produced goes into fertilizers. Almost the entire production in the United States comes from byproduct-coke ovens, that chemical being the preferred form in which ammonia generated from the distillation of coal is recovered. A small quantity is of synthetic origin. Lower production, greater sales, and decreased stocks characterized the ammonium sulfate industry in 1945. The output of byproduct ammonium sulfate decreased from 818,244 short tons in 1944 to 764,293 tons in 1945, a decline of 53,951 tons, whereas sales increased from 776,962 tons in 1944 to 801,062 tons in 1945. Stocks were cut more than one-half, decreasing from 69,031 tons at the end of 1944 to 32,175 tons at the close of 1945.

Maximum prices of ammonium sulfate at the wholesale level are still fixed by Revised Maximum Price Regulation 205 of June 30, 1944, and later amendments of the Office of Price Administration.

Ammonium nitrate results from neutralization of nitric acid with ammonia. Domestic production before World War II was only a few thousand tons a year, and a large proportion of the domestic consumption was imported. During the war, however, production and consumption in the United States increased greatly, and because of continued shortage from domestic sources large quantities were imported from Canada. Munition requirements had preference, but large quantities were diverted to agricultural use to supplement the inadequate supplies of other inorganic nitrogen materials. Ammonium nitrate is a present and possibly permanent competitor of sodium nitrate and ammonium sulfate, which formerly dominated the business of top-dressing and side-dressing crops.

Domestic production comes from both Government-owned and private plants. Four of the Government's fixed-nitrogen plants have facilities for producing ammonium nitrate solutions; their combined capacity is rated at 55,000 tons of 100-percent ammonium nitrate per month. These plants are the Buckeye Ordnance Works, South Point, Ohio; the Ozark Ordnance Works, El Dorado, Ark.; the Jayhawk Ordnance Works, Baxter Springs, Kans.; and the Tennessee Valley Authority, Muscle Shoals, Ala. The ammonium nitrate solution from the ordnance plants is shipped to plants with graining facilities for conversion into fertilizers in solid form. Thirteen of the Government-owned ammunition-loading plants contain facilities for graining ammonium nitrate. Late in 1945 five of these plants were producing solid ammonium nitrate crystals for sale to the Commodity Credit Corporation for resale as fertilizer. These plants were the Wolf Creek, Milan, Tenn.; Louisiana, Minden, Ala.; Kansas, Parsons, Kans.; Lone Star, Texarkana, Tex.; and Cornhusker, Grand Island Nebr. In these five plants, near the end of 1945, ammonium nitrate was being grained at the rate of 100,000 tons of nitrogen a year. The other ammunition-loading plants had operated their grainers for short periods at one time or another but at the end of the year had been shut down for a considerable period. The Tennessee Valley Authority operated its own fertilizer-producing facilities at Muscle Shoals, Ala. Late in 1945 ammonium nitrate solution facilities were being installed at the Defense Plant Corporation plant at Lake Charles, La., operated by the Mathieson Alkali Co. The Hercules Powder Co., Hercules, Calif., and the Allied Chemical & Dye Corp. are also reported to have been manufacturing ammonium nitrate.

According to the annual report of the Tennessee Valley Authority for the fiscal year ended June 30, 1945, the Authority produced ammonium nitrate both for military and agricultural interests during the year. Production for the armed forces ranged from relatively small amounts at some times to total plant capacity at others. Besides meeting military demands (15,400 tons of ammonium nitrate crystal), during the fiscal year TVA produced 111,400 tons of ammonium nitrate, treated by a TVA process to prevent caking, for fertilizer use. This 15-percent reduction from the previous year resulted from the demand of the War Department for munitions-grade ammonium nitrate crystal and ammonia. At the close of the fiscal year, however, all military production of ammonium nitrate had been ordered halted, and full-scale fertilizer production had been resumed. Considerable research was done during the year to replace the present ammonium nitrate graining process, which was recognized as potentially hazardous, relatively expensive, and not best-suited to producing fertilizer materials. Two processes investigated appeared definitely superior to the method now in use at the plant.

On February 1, 1944, distribution of the ammonium nitrate being produced in Government-owned plants for use in the manufacture of fertilizers was placed in the hands of the Commodity Credit Corporation, which in turn designated Associated Cooperatives, Inc., as its agent in the distribution of the material. In 1945 the Commodity Credit Corporation continued to purchase the solid ammonium nitrate crystals produced in Government-owned ammonium nitrate graining plants for resale as fertilizer material for domestic consumption and for export. The imported Canadian product is reported to be distributed in the United States by a private domestic company.

Several articles on the production, properties, and uses of ammonium nitrate have appeared in the past several months.[6]

Synthetic sodium nitrate.—The synthetic sodium nitrate consumed in the United States has, in the past, come from both domestic and foreign sources. From 1928 to 1945 the domestic production has come from a single unit—the Hopewell, Va., plant of the Allied Chemical & Dye Corp. In addition to the synthetic sodium nitrate from this source, small amounts were also imported from Germany and Canada in the period before World War II. The total annual prewar consumption of sodium nitrate (both natural and synthetic) is reported to have been approximately 1 million tons, of which 15 percent was consumed by industry (all synthetic) and the remaining 85 percent by agriculture (both natural and synthetic).[7] This would indicate that domestic consumption of synthetic sodium nitrate at that time exceeded 150,000 tons a year.

During the recent war little foreign synthetic sodium nitrate entered the United States, and the supply came almost entirely from the Hopewell plant. Little information is available regarding the current production or utilization of domestically produced synthetic sodium nitrate, but it is reported in the trade journals that production in 1945 is expected to be somewhat larger than in 1944.

Synthetic sodium nitrate has been under allocation, as was the natural product, under Schedule 80 (Nitrogen Compounds) of WPB General Allocation Order M-300 and was under the same restrictions as to use. Early in September 1945, this order was revoked, and synthetic sodium nitrate was removed from allocation as of September 30, 1945.

Prices of synthetic sodium nitrate remain under revised OPA Maximum Price Regulation 205. Quotations throughout 1945 were \$27 per ton for crude in bulk and \$30.05 per ton in 100-pound bags, carlots, works. Prices for refined granulated synthetic sodium nitrate in 10-ton lots were \$3.60 per 100 pounds, and in smaller lots, \$3.75 to \$4 per hundred pounds.

Second Revised Maximum Price Regulation 135 (including amendments 1–4), covered retail prices of agricultural sodium nitrate during 1945.

About mid-1945 it was announced by the WPB that Holston (Kingsport, Tenn.) byproduct sodium nitrate would be available during the latter part of the year for use in mixed fertilizers.

ORGANIC MATERIALS

Restrictions in the use of chemical nitrogen early in World War II so increased the demand for organic nitrogen-bearing materials that, to secure equitable distribution, it became necessary to institute Government control of sales. On May 7, 1943, the War Food Administration issued Food Production Order 12, effective May 1, 1943, banning purchase of these materials by fertilizer manufacturers without prior approval of the director of food production. A month later a revised Food Production Order 12, effective June 1, 1943, to July 1, 1944, limited the amount of the materials that could be used as fertilizer. The broad general War Food Order 12 was revoked on July 1, 1944, and replaced by a more limited War Food Order 105, covering only edible oilseed meals or cake. Restrictions are retained on these because of the heavy requirements for them for livestock feed, which remains the dominant factor in the situation. The order also contained provisions governing the distribution, for fertilizer use, of edible-type oil-seed meals of inedible quality. This order was revised and amended in Amendment 1, on June 30, 1945, the effective period to be July 1, 1945, to June 30, 1946. Individual purchasers were restricted to the same proportion of the total quantity of edible oilseed meal made available for fertilizer purposes as the proportion such person used for fertilizer purposes of the total quantity used by all applicants for such purposes during the period July 1, 1941, to June 30, 1942.

Calcium cyanamide ($CaCN_2$) is of importance to the domestic nitrogen industry as a competing source of nitrogen. It is not produced in the United States, but considerable quantities are imported each year from Canada, where it is produced at Niagara Falls, Ontario, by the North American Cyanamid, Ltd., wholly owned subsidiary of the American Cyanamid Co., in a plant leased from the parent company. It is marketed under the trade name Cyanamid for both agricultural and industrial uses. Imports in 1945 were 141,057 short tons. Cyanamide was under allocation with other nitrogen compounds during most of 1945 under Schedule 80 (Nitrogen Compounds) of WPB General Allocation Order M–300. This schedule, however, was revoked and cyanamide removed from allocation as of September 30, 1945.

MINOR NONMETALS

By G. W. Josephson and G. Richards Gwinn[1]

SUMMARY OUTLINE

GRAPHITE

Production and sales of domestic natural graphite began to decline in 1944, and this trend continued through 1945. There are too few domestic producers to allow publication of separate statistics on the amorphous and crystalline types, but the accompanying table shows combined figures for the past 5 years. Producers' stocks totaled 427 short tons at the end of the year.

Production and shipments of natural graphite in the United States, 1941–45

Year	Production (short tons)	Shipments		Year	Production (short tons)	Shipments	
		Short tons	Value			Short tons	Value

1942	7,120	7,253	401,690	1945	4,888	5,334	289,207
1943	9,939	9,597	903,102				

A substantial quantity of artificial graphite is manufactured in the United States by the Acheson Graphite Division of the National Carbon Co., Inc., the International Graphite & Electrode Corp., the Great Lakes Carbon Corp., and the Stackpole Carbon Co. Petroleum coke is used as the raw material. The coke is formed into electrode shapes, and an elaborate heat-treatment process gradually converts them into graphite electrodes. These graphite electrodes do not compete with natural graphite, but a considerable tonnage of artificial graphite powder is produced by intent or as a byproduct, and this material has wide use in industry in direct competition with natural graphite. Owing to the small number of producers, the Bureau of Mines is not at liberty to publish this figure.

Production of natural graphite in the United States has flourished only in times of war, when importation of high-grade foreign graphite has been greatly curtailed or cut off. The numerous failures in

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

peacetime have been caused principally by inability to meet foreign competition in the market for large tough flakes used in crucibles. Estimates of domestic reserves based simply on flake size are misleading, because resistance to mechanical break-down in the mixing process is a major factor in crucible making. A review of the specifications of graphite for crucible use,[2] and a summary of developments in the Alabama graphite industry during the war[3] have been released recently.

As procurement became less difficult, the War Production Board removed restrictions on all types of graphite. Ceylon amorphous, either in lump or ground form, having more than 95 percent graphitic carbon, was retained on the list of "strategic" materials until September, but on April 1, 1945, public purchase of all other types was discontinued, and procurement was left to private contract. On September 18, 1945, Order M-61, covering graphite, was revoked.

Graphite (natural and artificial) imported for consumption in the United States, 1941–45

The WPB has reported that in 1944 a total of 4,430 short tons of Madagascar flake was consumed as follows: 81 percent in crucibles, 3 in retorts, 10 in lubricants, and 6 in other uses. In 1943 it was reported that 578 short tons of crucible-grade Ceylon lump and chip graphite were used—37 percent went into crucibles; 16 into retorts; 44 into stoppers, sleeves, and nozzles; 1 into foundry facings; and 2 into other uses. Of the 950 tons of Ceylon (97–98 percent C) large lump consumed in 1944, 69 percent was used in carbon brushes, 19 in pencils, 2 in lubricants, 3 in bearings, 1 in batteries, and 6 in other uses.

[3] Pallister, H. D., and Smith, R. W., Alabama Flake Graphite in World War II: Am. Inst. Min. and Met. Eng., Tech. Pub. 1908, 1945, 11 pp.

In 1945 exports of graphite products were reported to be 1,308 short tons, valued at $134,414.

Trade-journal quotations of prices for graphite, f. o. b. New York, were: Ceylon lump, 10–12 cents per pound; carbon lump, 9–10 cents; chip, 7–8 cents; dust, 4–5 cents; Madagascar flake, 9–10 cents. Prices nominal. No. 1 flake was 9–16 cents per pound; No. 2, 7 cents upward; fine-ground, 55 to 70 percent carbon, 3 cents upward; amorphous, 3 cents upward. Prices nominal. Crude amorphous graphite was $14 to $30 per ton according to grade.

World production figures for graphite covering the period 1915–39 were published in Minerals Yearbook 1940 (p. 1414), and the accompanying table shows available statistics for 1937–45.

World production of natural graphite, 1937–45, by countries, in metric tons [1]

GREENSAND

Production of greensand by three companies in New Jersey in 1945 reached 4,738 short tons, and shipments totaled 4,986 tons valued at $477,919. Three companies in 1944 produced 7,896 tons and shipped 4,908 tons valued at $505,651. All shipments during recent years were of refined material used in water-softening compounds and water-purification agents.

Statistics for greensand sold or used are presented in the following table.

Greensand marl sold or used by producers in the United States, 1941–45

Year	Short tons	Value	Year	Short tons	Value
1941	11,120	$619,664	1944	4,908	$505,651
1942	10,110	448,440	1945	4,986	477,919
1943	10,056	522,124			

KYANITE, ANDALUSITE, AND DUMORTIERITE

Domestic production and imports of kyanite increased in 1945. Most of the imported material came from India, but a minor tonnage came from British East Africa. Receipts from Australia, believed to be sillimanite, totaled 341 short tons valued at $3,867. Approximately 179 tons, valued at $10,276, of material that entered from Canada was described as "crude sillimanite (synthetic)."

A summary of trade statistics for recent years is given in the following table.

Domestic shipments, imports, new supply, and stocks of kyanite in the United States, 1941–45

Year	New supply						Stocks of Indian kyanite [1]	
	Domestic shipments		Imports		Total new supply			
	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value

1 Industry and Government stocks as of December 31, as reported by Miscellaneous Minerals Division, War Production Board, Reconstruction Finance Corporation, and consumers.
2 Figures not available.
3 Bureau of Mines not at liberty to publish figures.

After the end of hostilities demand for kyanite continued high, and growing transportation and food problems in India indicated a possible shortage for 1946.

At the end of the year stocks of crude Indian kyanite totaled approximately 8,000 tons, of which 3,058 were in the Government stockpile and the rest were held by private companies.

The cost of Indian kyanite delivered to stock piles in this country in 1945 was about $38 per short ton. Prices of domestic kyanite established by the Office of Price Administration ranged from $24 per short ton for raw kyanite, 35-mesh, in carlots, to $42.50 for 325-mesh material, less than carlots, in 100-pound bags; and for calcined kyanite from $31.50 per short ton, 35-mesh, in carlots, to $47.50 for 325-mesh material, less than carlots, f. o. b. Cullen or Pamplin, Va.

In 1945 production of kyanite was reported by the Kyanite Mining Corp., near Farmville, Va., and by the Vitrefrax Corp., near Ogilby, Calif. The Vitrefrax Corp. converts all of its output to mullite products, but the Kyanite Mining Corp. sells kyanite on the open market.

Champion Sillimanite, Inc., produced andalusite in Mono County, Calif., and dumortierite in Pershing County, Nev. This company is the only producer of these minerals in the United States. They are not sold on the open market but are used by the parent company, Champion Spark Plug Co., for manufacturing spark-plug cores.

Owing to the relatively high quality of Indian kyanite, the United States depends on it to supply a large portion of domestic needs, but the search for an adequate domestic supply continues. The kyanite that occurs as small crystals in schists in Virginia, North Carolina, and Georgia has given trouble when used in brick and block but is satisfactory for plastics and refractory mortars and, when the iron content is reduced, for glass. South Carolina topaz serves as a good bond and improves the quality. Georgia massive kyanite is good material, but further exploration will be required to prove the existence of commercial reserves. A large tonnage of true sillimanite has been indicated in Georgia, South Carolina, and North Carolina, and a few deposits may be rich enough for commercial development. A flotation process developed at the Southern Experiment Station of the Bureau of Mines beneficiates the material satisfactorily. The refractory qualities of the sillimanite concentrate are now being tested.[4]

During the war Germany, being cut off from Indian kyanite, developed a synthetic sillimanite that is said to have given good service. It was made from clay, aluminum hydrate, fused alumina, and feldspar. They were mixed, burned to mullite, and crushed for refractory use. The product was said to cost over three times as much as Indian kyanite.

LITHIUM MINERALS

During the war the utilization of lithium products reached record levels. New plants and mines were opened to furnish large quantities of lithium compounds, such as lithium hydride—a source of hydrogen for inflating radio antenna balloons included in Navy rescue equip-

[4] Information furnished by Hewitt Wilson, Bureau of Mines, Norris, Tenn.

ment; but when Government contracts were canceled, other markets of comparable size were not available. As the cut-back came at the end of 1944, the effect was felt throughout 1945, and mine shipments of lithium minerals—spodumene, amblygonite, lepidolite, and dilithium sodium phosphate—declined 82 percent from the record of 13,319 tons set in 1944.

The spodumene mine operated by the Solvay Process Co. at Kings Mountain, N. C., was idle after February, and the Black Hills Tin Co., Tinton, S. Dak., was inactive throughout 1945, but several other companies reported sales of spodumene, amblygonite, and lepidolite in South Dakota, and one mined lepidolite in Colorado.

Although production of all other lithium raw materials declined in 1945, the output of dilithium sodium phosphate increased. This compound is recovered as a flotation concentrate by the American Potash & Chemical Corp. at Searles Lake, Calif.[5]

Tonnage and value of lithium ores and compounds shipped in recent years and approximations of total Li_2O content are shown in the accompanying table.

The eventual loss of Government orders was foreseen by the industry, and considerable effort went into market analysis and laboratory research to find new and larger peacetime markets. Although their comparatively high cost is a handicap, lithium compounds show promise in many fields. They are of value in glass, welding fluxes, special lubricants, air conditioning, storage batteries, fluorescent light tubes, and as an alloying element; the organic compounds of lithium are also being investigated.

The industry is now in a difficult reconversion period in which it is attempting to expand its markets sufficiently to utilize the available production capacity.

Lithium sold from $12.50 to $20.00 per pound in 1945, but producers believe that prices as low as $5 per pound may be reached if volume consumption is attained in the future. Trade journal prices of lithium ores were as follows: Spodumene, $5 to $6 per 20 pounds of contained Li_2O on 6-percent grade, carlots, North Carolina; amblygonite, 8 to 9 percent Li_2O, $40 to $50 per short ton, f. o. b. mine; and lepidolite, lump, $24 to $25 per ton for ordinary grades, f. o. b. mine. The price of dilithium sodium phosphate has been reported at about $232 per ton.

Shipments of lithium ores and compounds from mines in the United States, 1935–39 (average) and 1940–45

Year	Ore (short tons)	Value	Li_2O (short tons)	Year	Ore (short tons)	Value	Li_2O (short tons)
1935-39 (average)	1,327	$48,280	88	1943	8,155	$314,660	463
1940	2,011	80,679	113	1944	13,319	552,977	848
1941	3,832	115,718	209	1945	2,446	285,520	274
1942	5,405	243,516	299

MINERAL EARTH PIGMENTS

[Prepared by Charles L. Harness]

Total iron oxide and earth-pigment sales by domestic processors increased over 1944 sales, despite sharp drops in military end uses in the last half of 1945. Direct sales from processors to the Army are said to have been negligible since 1944; and direct sales to the Navy paint plants, although substantial in early 1945, declined to a very small volume later in the year. The loss of military orders was more than compensated by revival in demands from peacetime industries, mostly paints, linoleum, and mortar colors. The unusually large sales of red oxides presaged a general painting of farm buildings and box cars. The only iron oxide pigments that were in easy supply at the end of 1945 were the yellows, both natural and synthetic, owing to the lowered requirements for olive drab paints.

Mineral Pigments Corp., Muirkirk, Md., announced that it was erecting a plant for the production of pure red oxides from metal. The oxides are said to have an extremely fine particle size and an almost complete absence of soluble salts.[6]

Natural mineral pigments and manufactured iron oxide pigments sold by processors in the United States, 1944–45, by kinds

Pigment	1944		1945	
	Short tons	Value	Short tons	Value
Mineral blacks	3,388	$94,192	2,960	$61,388

[1] Less than 1 ton.

Receipts of Spanish red oxide were reported to be regular but small, owing to transport difficulties in the interior of Spain. Most domestic processors have been offering replacements for Spanish oxide for several years. French ochers were still off the market, and Italian siennas were said to be available only in small quantities and at high prices. Small amounts of pure oxides from Great Britain were imported in 1945, but at high prices. Turkey umbers from Cyprus livened the foreign pigment situation late in 1945, when supplies became available in quantity. Persian Gulf oxide has been off the market almost completely since 1940, but importers hope that shipments will be resumed in 1946.

Prices of finished earth pigments, which are quoted in cents per pound, were generally unchanged during 1945, according to the Oil, Paint and Drug Reporter. Precipitated magnetic blacks, in barrels, carlots, works, were quoted at 8½; metallic browns were 2½; synthetic (pure) browns, 12; siennas, American type, 3¾ to 5; burnt siennas, Italian type, 8¾ to 10¾; raw siennas, American type, 4 to 10; raw siennas, Italian type, 8 to 10; umbers, Turkey type, 4¾ to 5⅞, depending on point of purchase; synthetic (pure) red iron oxides, 9 to 9¾; Venetian reds, 2.2 to 4, depending on iron oxide content; natural (metallic) red oxide, 2; natural yellow oxides, high iron, 4½ to 6¼; synthetic (pure) iron oxide yellows, 6.85; and domestic ochers, French type, 8.45.

MINERAL WOOL

Production statistics of the mineral-wool industry were compiled for 1942 to 1944 by the Bureau of Mines, and these figures were published in the Minor Nonmetals chapters of Minerals Yearbooks for 1943 and 1944. No canvass of the industry was made by the Bureau of Mines for 1945 as this function was transferred to the Bureau of the Census. As no canvass covering 1945 has been made by the Bureau of the Census, no statistics for that year are available.

In 1945 mineral-wool production was at a very high level. Even during the war, when construction was limited, mineral-wool output increased owing to heavy demand for military and industrial use and for insulating existing buildings. When hostilities came to an end and new home construction began to increase, demand intensified.

In 1944 there were 38 companies operating 51 plants in 19 States. There were probably more in 1945, as trade journals reported many new plants under construction and old plants being expanded.

Although competition is not currently as strong a force as in a buyers' market, attention is being given to refinement in equipment that will give more efficient operation. Reports of new plants mention installation of waste-heat boilers and preheaters for blast air, which will reduce heat losses.

During the war, mineral and glass wools were used in many new products. Panels, of various thicknesses, of resin-bonded wool were used for heat and sound insulation in military equipment. Some were faced with asbestos or glass cloth for fireproofing and appearance. Addition of glass fiber to asbestos roving relieved an asbestos shortage during one period. Mineral wool served as a packing for shipping corrosive acids. Superfine glass fibers that have exceptional insulating capacity and light weight were used in some aircraft. For some structural uses, plastics strengthened by glass fibers can compete successfully with metals.

For the peacetime market the mineral-wool industry offers a well-tested line of general and specialized products that are certain to be widely used, and current research is expanding the market.

As there is a wide diversity in test procedures used in the mineral-wool industry, the Bureau of Standards compiled and presented to the industry for approval, a Recommended Commercial Standard for Industrial Mineral Wool, All Types—Testing and Reporting—TS-4030. By establishing a uniform system of testing and reporting, much of the confusion resulting from diversity of test procedures should be eliminated.

MONAZITE

Monazite has been produced from small deposits in the Southeastern States, but now the commercial supplies of the United States are imported. At present the principal sources are beach deposits along the coasts of Brazil and India. The mineral occurs in black sand with zircon, rutile, ilmenite, and other minerals, from which it is separated by gravity, electrostatic, and electromagnetic methods. Imports totaled 4,980 short tons in 1943, but in 1945 only about one-tenth of that amount was reported by the United States Department of Commerce. India is usually the main supplier; but, as is shown in the accompanying table, most of the import tonnage came from Brazil in 1945.

Monazite sand and other thorium ore,[1] imported for consumption in the United States, 1941–45, by countries

Country	1941		1942		1943		1944		1945	
	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value
Brazil	734	$25,240	1,346	$62,555	1,911	$88,548			437	$15,342
India and Dependencies	2,714	82,068	3,052	112,928	3,033	128,379	384	$13,782	112	4,239
United Kingdom					36	3,553				
	3,448	107,308	4,398	175,483	4,980	220,480	384	13,782	549	19,581

[1] Quantities are gross weight; monazite content not reported.

Monazite is a complex mineral, principally a phosphate of cerium, lanthanum, and other rare earths but also containing thorium, silica, and mesothorium. Although only a few years ago monazite was said to be moribund, it now is sufficiently essential to be classified as a strategic mineral. By complex chemical processes the mineral is converted into a number of valuable products. Rare-earth fluorides and oxides are used in electrodes; misch metal in pyrophoric alloys; and rare-earth oxides, thorium and rare-earth hydrates and fluorides, and ammonium nitrates in optical glass. Rare-earth acetates are utilized to mildewproof textiles, and the oxide is used in polishing glass, as it is faster than rouge. Gas mantles are treated with thorium nitrate. More uses of these products can be listed than space will allow. Essential as are the established uses of monazite, they may be dwarfed in future by possible utilization in the rapidly developing field of atomic fission.

As such a large portion of the output of the products of monazite is furnished by a single company, the Bureau of Mines is not at liberty to publish production and use statistics.

Interest in monazite is developing in Australia. Deposits are known to occur in the beach sands of northern New South Wales and southern Queensland.[7]

OLIVINE

Shipments of olivine in North Carolina in 1945 were somewhat higher than in 1944, but the Bureau cannot publish the figures without revealing the output of individual firms. As in the previous year, the entire production was consumed in refractories. Shipments of olivine by domestic producers during recent years are shown in the following table.

[7] Chemical Engineering and Mining Review, Glass Polishing with Rare Earth Oxides: Vol. 38, No. 448, Jan. 10, 1946, pp. 125–128.

Olivine sold or used by producers in the United States, 1941–45

Year	Short tons	Value	Year	Short tons	Value
1941	4,828	$24,401	1944	3,270	$35,207
1942	5,739	45,201	1945	(1)	(1)
1943	5,415	48,633			

[1] Data not available for publication.

United States Patent 2,372,571, relating to the production of metallic magnesium by direct reduction of magnesium silicates, was granted to Dr. F. J. Hansgirg on March 27, 1945. Two other patents, 2,384,008 and 2,384,010, devoted respectively to converting unstable hydrous magnesium silicates of the serpentine group (hydrated olivine rocks) into basic products, and a method of producing magnesium sulfate from magnesium oxide-bearing materials by the use of sulfurous acid, were granted on September 4, 1945, to H. R. Brandenburg. It is reported that a refractory-grade olivine deposit on Cypress Island in the San Juan Archipelago, Wash., has been outlined.[8]

PERLITE

In the last few years interest in the use of expanded perlite has been increasing. Perlite rock is one of the glassy members of the rhyolites, varying in texture from porphyritic to glassy. This rock contains some water, and when heated close to the melting point it expands into a lightweight, cellular form. The heating curve must be carefully controlled to produce a sufficiently strong and uniform product. The weight of aggregate usually ranges from 12 to 16 pounds per cubic foot.

Although expanded perlite is not yet firmly established commercially, it is being used as a lightweight aggregate, as loose filler for insulation, and as chicken litter; fines have been used in a cleanser. The current building boom should assist perlite in gaining its share of the market in competition with expanded slag, clay, vermiculite, and other lightweight materials. At least nine companies are actively experimenting, and several hundred tons have been produced commercially in Arizona, California, and Nevada. The following patents describe some of the processes developed recently: 2,207,911; 2,209,163; 2,209,170; 2,247,120; 2,306,462.

RADIO-GRADE QUARTZ

A period of great expansion in the use of quartz crystal came to an end with the surrender of Japan. Although output of oscillators had tapered off somewhat during the first half of the year, the volume was large until military demand collapsed in August. Many companies went out of business or turned their attention to other products. A total of 113 companies were in production in 1944, but by the end of June 1945 the number had declined to 96. Although considerable cutting equipment went out of production after the war, there remains a large capacity available to supply the coming peacetime needs. It

[8] Brick and Clay Record, Washington Olivine Deposits to be Developed Commercially: Vol. 107, 1945, No. 4, p. 60.

has been estimated that postwar production of oscillators will come from about 20 companies.

Much of the remaining stock of crystal was turned over to the contracting Government agencies, who in turn assigned it to the War Assets Administration as surplus material. Stocks of crude quartz held by the Metals Reserve Company were also declared surplus and were acquired by WAA. The bulk of the radio-grade material is being transferred to the stock pile of the Army and Navy Munitions Board.

Quartz crystal has been recognized by Congress as one of the strategic minerals that must be stock-piled for national defense. Small deposits are known to exist in the United States, but they are so limited that our commercial supply comes almost entirely from foreign sources.

At present Brazil enjoys a virtual monopoly. Up to now, quartz crystal has been mined and classified in Brazil and has been shipped crude to the consuming countries, where it is cut into oscillators, resonators, and optical shapes. The war stimulated this trade tremendously. Electricity is the lifeblood of mechanized warfare. Communication, detection, and control devices are more essential than ever before. As quartz-crystal oscillators and resonators assure accurate frequency control for electrical circuits, they were used by the millions to equip the Allied armies. The need was so great that when the submarine warfare was at its height crystals were flown from Brazil to the United States in planes. The United States Government assisted Brazil to expand output by furnishing necessary equipment, technical advice, and funds.

An accompanying table shows the number of piezoelectric devices produced during the war years.

Imports of uncut quartz crystal, consumption of radio-grade quartz, and production of finished crystals in the United States, 1940–45

Year	Imports of uncut quartz crystal [1]		Consumption of radio-grade quartz [2] (pounds)	Production of finished crystals [3] [4] (number)
	Pounds	Value		
1940	126, 521	$264, 436	31, 000	(5)
1941	2, 237, 608	3, 830, 344	59, 000	(5)
1942	2, 612, 106	8, 987, 108	682, 000	6, 888, 000
1943	3, 356, 000	11, 409, 803	1, 588, 000	22, 575, 000

[3] 1942–44, WPB.
[4] Includes oscillators, resonators, and other piezoelectric devices.
[5] Data not available.

Germany had acquired a small stock of crystals before the war, but when cut off from Brazil it tried to develop synthetic crystals as substitutes. A few showed limited promise, but they were still in the laboratory stage when the war ended.

Although no postwar market is in sight comparable in size with the demand during the war, the quantity of quartz crystal that will be used in radio and other electrical circuits promises to be much larger than before the war. The outlook is so favorable that Brazil has recently shown interest in developing a cutting industry and would then offer for sale partly or fully processed products as well as crude quartz.

As shown in the accompanying table, both imports and consumption of quartz crystal (Brazilian pebble) were lower in 1945 than in 1944—imports 42 percent and consumption 44 percent. Except for 1 pound reported from Chile, all imports came from Brazil in 1945.

In the early days of the war, the number of oscillator plates obtained per pound of usable quartz was relatively low—9.5 in 1942; but with improvement in cutting efficiency, recovery of imperfect plates, and use of smaller sizes, the number increased until, in 1945, approximately 18 plates were produced per pound.

The search for domestic sources of high-grade quartz crystal ended in practical failure. A few thousand pounds (3,934 in 1944) are known to have been produced, but these quantities were negligible in comparison with requirements. Although small quantities probably were found, there is no record of any domestic production in 1945.

Government purchase prices paid in 1945 (ranging from $1.56 to $36.95 per pound, according to quality) were given in detail in the Minor Nonmetals chapter of Minerals Yearbook, 1943. Some Government buying of crystal continued throughout 1945, as contracts with Brazilian producers provided for a gradual closing of the program.

An accompanying table shows the selling prices of the various grades and sizes of quartz crystal in the United States in 1945.

Metals Reserve Company selling prices for quartz crystal, faced material [1]

[Price per pound, f. o. b. Bureau of Standards, Washington, D. C.]

Size (grams)	Grade 1			Grade 2			Grade 3
	30–45 percent usability	45–60 percent usability	60–100 percent usability	30–45 percent usability	45–60 percent usability	60–100 percent usability	60–100 percent usability
200–300	4.95	7.45	9.90	4.15	6.20	8.25	2.45
300–500	6.60	9.90	13.20	5.50	8.25	11.00	3.30
500–700	8.25	12.40	16.50	6.90	10.30	13.75	4.10
700–1,000	9.90	14.85	19.80	8.25	12.40	16.50	4.95
1,000–2,000	12.40	18.55	24.75	10.30	15.45	20.65	6.20
2,000–3,000	14.85	22.30	29.70	12.40	18.55	24.75	7.45
3,000–4,000	16.50	24.75	33.00	13.75	20.65	27.50	8.25
4,000–5,000	18.15	27.25	36.30	15.15	22.80	30.25	9.10
5,000–7,000	19.80	29.70	39.60	16.50	24.75	33.60	9.90
7,000–10,000	21.45	32.20	42.90	17.90	26.80	35.75	10.75
Over 10,000	23.10	34.65	46.20	19.25	30.00	38.50	11.50

[1] 20 percent discount allowed for unfaced material (irregulars) in sizes of 200–500 grams. 10 percent discount allowed for unfaced material (irregulars) in sizes larger than 500 grams. Optical quartz 50 percent higher than 60–100 percent usability prices of Grade 1. Less than 200-gram faced material (80 percent or better eye clean)-$2.25 per pound.

WPB Order M–146, covering conservation of quartz crystals, was revoked August 20, 1945.

A paper describing some of the Brazilian deposits was published early in 1946.[9]

[9] Knouse, Frederick L., Deposits of Quartz Crystal in Espirito Santo and Eastern Minas Gerais, Brazil: Am. Inst. Min. and Met. Eng., Min. Technol., vol. 10, No. 2, March 1946, pp. 1–9.

STRONTIUM MINERALS

[By Charles L. Harness]

The celestite (strontium sulfate) industry waned further in 1945, four producers reporting shipments of 2,784 short tons valued at $27,840, compared with 3,005 tons valued at $48,165 in 1944.

During the war, domestic celestite was valuable as a substitute for barite in weighting rotary oil-well drilling muds and to some extent in the manufacture of strontium chemicals. As war demands eased, barite became more plentiful in the drilling areas, and also requirements for strontium chemicals in tracer bullets and flares were reduced drastically. Celestite producers have been forced to seek additional outlets, generally local, such as use in purifying caustic soda solutions and in making small quantities of strontium chemicals for peacetime application.

Imports of celestite for consumption in the United States, by countries, 1943–45, in short tons

Country	1943		1944		1945	
	Short tons	Value	Short tons	Value	Short tons	Value
United Kingdom	1,367	$21,347	1	$652		
Mexico	11,060	148,233	3,170	38,191	3,016	$38,365
Spain	4,454	80,000	2,622	47,576	675	12,251
	16,881	249,580	5,793	86,419	3,691	50,616

Exports of strontium chemicals from the United States, 1944–45, in short tons

	1944		1945	
	Short tons	Value	Short tons	Value
Strontium nitrate	223	$36,698	284	$52,129
Strontium oxalate	2	1,198	19	15,058
Other	13	7,823	16	24,254
	238	45,719	319	91,441

The following producers reported shipments in 1945: W. C. Buehler & W. N. Rowe, 1555 Sunset Ave., Pasadena 3, Calif.; The Pan-Chemical Co., 205 First National Bank Building, Pomona, Calif.; Milwhite Co., Inc., Cotton Exchange Building, Houston, Tex.; and Bennett-Clark Co., Inc., Nacogdoches, Tex.

A flow sheet covering the preparation of strontium chemicals from celestite was reviewed.[10]

[10] Chemical and Metallurgical Engineering, Strontium Chemicals: Vol. 53, No. 1, January 1946, pp. 152–155.

TOPAZ

Shipments of topaz in 1945 from the Brewer mine, near Kershaw, S. C., by the United Feldspar & Minerals Corp. of Spruce Pine and the Carolina Mining & Exploration Corp. of Naples, N. C., decreased from the 1944 total. Two products were marketed—crude topaz in lump form and crushed and screened material. Topaz was used in 1945 by the refractory industries and for thinning slag in open-hearth furnaces.

VERMICULITE

Sales of vermiculite in 1945 reached a new high of 64,808 short tons, 12 percent above the previous record set in 1942. The increase is attributed primarily to the sharp rise in home and industrial building which followed relaxation of Government restrictions on construction. The wider use of exfoliated vermiculite that developed during the war was another factor in the increased output.

Vermiculite is used as a heat and sound insulator in loose form in walls and ceilings and in bonded form in concrete and plaster. It is durable and fireproof, and its light weight puts less load on building frames than do some other materials. Other uses are as an oil absorbent for machine-shop floors, a paint extender, a refractory, and a soil conditioner.

Production in 1945 was reported from five States—Colorado, Montana, North Carolina, South Carolina, and Wyoming. As in previous years, the bulk of the output came from Montana. In Colorado, Erl-ite Mineral Insulation operated in Fremont County and the AleXite Engineering Co., in Gunnison County. The Universal Zonolite Insulation Co. produced in Lincoln County, Mont. Minerals, Inc., which has been producing vermiculite in Macon County, N. C., was reorganized as Vercalite Industries, Inc., and increased its plant capacity. Bee Tree Vermiculite Mines operated in Greenville County, S. C. In Wyoming, Lewis and Martin Smith produced in Converse County, the Mikolite Mining & Development Co. in Carbon County, and the AleXite Engineering Co. in Carbon County. The tonnages and values of screened and cleaned vermiculite shipped in recent years are shown in the accompanying table.

Screened and cleaned vermiculite brings $8 to $12 per short ton at the mine. After it has been exfoliated in the consuming area, it sells for $56 to $100 per ton packaged in 25-pound bags. Loss of weight in exfoliating is estimated at about 10 percent. Assuming an average price of $75 per ton, the total value of exfoliated vermiculite sold in 1945 would be approximately $4,375,000.

Interest in vermiculite is increasing in other countries as well as in the United States. Trade journals described deposits and uses of the mineral in South Africa, and a review including information on location, geology, and production from Australian deposits was published in 1945.[11]

[11] Chemical Engineering and Mining Review, Occurrence of Vermiculite in Western Australia: Vol. 37, No. 436, Jan. 10, 1945, p. 119.

Screened and cleaned vermiculite sold or used by producers in the United States, 1935–39 (average) and 1940–45

Year	Short tons	Value	Year	Short tons	Value
1935–39 (average)	18,486	$180,297	1943	46,645	$471,595
1940	22,299	137,698	1944	54,116	541,744
1941	23,438	125,444	1945	64,808	648,077
1942	57,848	319,931			

WOLLASTONITE

Production and sales of wollastonite in 1945 from the Burnham property near Willsboro, N. Y., exceeded considerably the total of 1944. The property was operated under lease by the Titanium Alloy Manufacturing Co. until November 1, 1945, when it was returned to the estate of J. B. Burnham.

PART IV. MINE SAFETY

EMPLOYMENT AND INJURIES IN THE MINERAL INDUSTRIES

By Forrest T. Moyer

SUMMARY OUTLINE

SUMMARY

Employment in the mineral industries continued to decline in 1945, and the average number of men working daily fell to 639,800. Although the 1945 average number of men was 6 percent below 1944, there was a reversal shortly after midyear of the downtrend in the labor force that had started in 1942. The abrupt termination of war contracts, the closing of munitions, armament, ship-building and other war-fostered industries and the release of men from the armed forces shortly after the end of the Pacific war resulted in an easement of the critical labor shortage which had plagued nearly all mineral industries since 1942. The termination of war contracts also resulted in a decline in demand for some mineral raw materials, as the manufacturing industry of the country entered the period of reconversion to peacetime operations. Reconversion in general proceeded more rapidly and easily than expected until it was retarded by a wave of strikes which further reduced demand for raw materials toward the close of the year. In many mineral industries the monthly pattern of employment through 1945 probably resembled that shown by a monthly series of the average number of men at work daily in bituminous-coal mines. In this series employment declined 3 percent from January to the low monthly total (in months of no strikes) for the year in August and turned upward in September to regain all of the earlier loss by November. The average number of men at work daily in December was slightly lower than in November owing probably to absenteeism before and during the holidays. In those mineral industries in which demand had been restricted by war controls, notably construction materials, the average number of men working daily in 1945 was higher than in 1944, indicating a rapid gain in employment in the closing months of the year. Injury experience of the mineral industries improved over this trying period, and the frequency of all injuries (fatal plus nonfatal) was reduced in 1945 to 55.69 per million man-hours from a frequency of 56.61 in 1944.

Man-hours worked in the mineral industries during 1945 continued the decline that began in 1944. Owing principally to a decreased demand for some mineral raw materials and to two widespread work stoppages in the bituminous-coal industry and one in the anthracite industry, the 1945 total of approximately 1⅓ billion man-hours of productive time was 10 percent below 1944. The time worked in 1945 was lower than in 1944 in each mineral industry group except in nonmetal mines and quarries, for which slight gains were noted. As in man-hours data, the total reported man-days of work for all extractive industries during 1945 fell 10 percent below 1944. Man-days of productive work declined in 1945 in all mineral-industry groups, except in nonmetal mines and quarries, where slightly higher activity was reported.

Salient statistics of employment and injury experience in the mineral industries in the United States, 1942–45, by mineral-industry groups

	1942	1943	1944	1945 [1]
Average number of men working daily: [2]				
Coal mines	530,861	486,516	[3] 457,500	437,000

Total	61.24	[5] 56.60	55.59	54.76

[1] Preliminary figures based upon an average of 75 percent coverage.
[2] The average number of men at work each day the mines were active. Because absenteeism is taken into consideration, this number is lower than the number of men available for work as measured by a count of names on the payroll.
[3] Preliminary figures based upon 75 percent coverage of the industry.
[4] Revised by transfer of figures for fluorspar in Kentucky and Illinois from "Metal mines" to "Nonmetal mines."
[5] Revised figures.
[6] An average in which the operating time of each mine is weighted by the average number of workers in the mine.

As a result of the declining demand for some minerals and the coal strikes, all mineral operations in the country were active an average of only 273 days in 1945, or 13 less than in 1944. The average length of work shift was only slightly changed—from 7.92 hours in 1944 to 7.94 hours in 1945—owing to longer shifts worked in coal, nonmetal, and quarry operations, which more than compensated for shorter shifts worked in metal mines, coke plants, and metallurgical plants. However, employees had a shorter workyear of 2,169 hours in 1945 compared with 2,264 in 1944 because of the fewer days worked in 1945.

The safety of mineral operations continued to improve in 1945, and the over-all attainment, as measured by frequency of injuries per million man-hours of exposure to hazards, was better than in any year since the start in 1931 of complete injury statistics on the mineral industries. The total of 1,285 fatalities to men at work in the mineral industries was lower than in any year since 1933; and for the first time since the series started in 1931, fatalities happened at a rate less than 1 for each million man-hours. The estimated rate in 1945 was 0.93 per million man-hours or slightly lower than the corresponding rate of 1.02 in 1944 and well below the high rate for the period since 1930 of 1.52 in 1932. The estimate for 1945 of 76,005 nonfatal injuries that disabled employees for longer than the day on which the accident occurred was appreciably below the 85,675 nonfatals recorded for 1944 and lower than in any year since 1939. These injuries in 1945 occurred at a rate of 54.76 per million man-hours of work, the lowest rate in the statistical series starting in 1931. However, the improvement in the nonfatal-injury rate in 1945 over 1944 was slight, owing to the greater length of time of exposure in 1944.

The fatality experience was improved in 1945 in all mineral-industry groups except at coke plants. The betterment was most marked at quarries, where the number of fatalities was reduced from 73 in 1944 to 48 in 1945, with a resulting decline in fatality frequency to 0.37 per million man-hours in 1945. At metallurgical plants the number of fatalities was only half that of 1944; but, as man-hours of exposure declined sharply, the fatality rate at these plants in 1945 was reduced

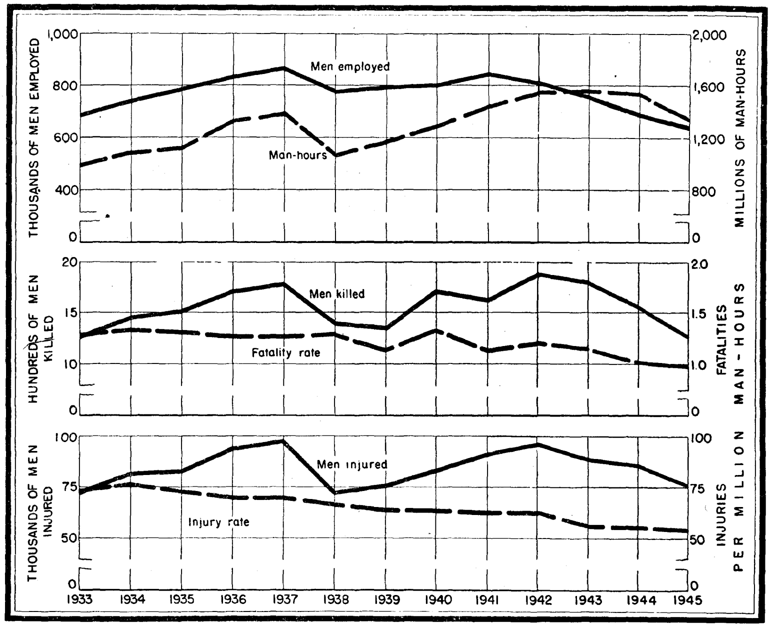

FIGURE 1.—Trends of employment and fatal and nonfatal injuries in the mineral industries of the United States, 1933–45.

to only 0.16 from 0.25 in 1944. Fatalities at coal mines were reduced 215 from 1944 to a total of 1,079, at a rate of 1.19 per million man-hours of working time or a lower frequency than in any other year in a statistical series starting in 1911. The greater number of fatalities at coke plants in 1945, together with the reduced time of exposure, resulted in a 36-percent increase over 1944 in the fatality rate.

The number of nonfatal injuries in 1945 was reduced from 1944 in all mineral-industry groups, and there was an accompanying decline in the frequencies of occurrence for each group except metallurgical plants. However, as man-hours of exposure were well below 1944 in coal mines, metal mines, and coke plants, the decline in frequencies for these groups were not as marked as the reductions in number of injuries. Although there were 6,550 fewer nonfatals in coal mines, the rate of occurrence was only slightly lower in 1945 than in 1944. At metallurgical plants the number of nonfatal injuries declined 853 to a 1945 total of 3,305, which occurred at a rate of 27.76 per million man-hours compared with the 1944 rate of 27.30.

COAL MINES

Injury experience in coal mines was more satisfactory in 1945, and both fatal and nonfatal frequency rates were lower than in 1944. Employment fell to an average of 437,000 men working daily who were exposed to hazards for 905,000,000 man-hours or 10 percent below 1944. These men worked an average of 262 days for an average workyear of 2,071 hours compared with 2,188 in 1944.

BITUMINOUS COAL

Employment.—Manpower was scarce at bituminous-coal mines during the first half of 1945, owing principally to the drafting of men into the armed forces and to the persistent reduction by accidents and retirement of the unexpandable total supply of men available for work in the mines. Results of a monthly canvass of bituminous-coal operations with approximately 75 percent coverage of total production showed an irregular month-to-month downtrend (in months of no strikes) in the average number of men working daily from 369,000 in January to 357,000 in August. From this low point of the year, the average number of men at work increased each month to 369,000 in November, or the same as in January. The average in December fell to 365,000, owing probably to greater than usual absenteeism over the holidays. For 1945, the average number of men working each day the mines were active, totaled 363,000 or 4 percent below 1944.

The estimated output of 576,000,000 short tons of bituminous coal in 1945 was 7 percent lower than in 1944. It was attained despite the reduced labor force and widespread work stoppages in April and October 1945 by operating the mines an average of 261 days, on which the men spent 762,000,000 man-hours of productive work or 9 percent below 1944. The 94,750,000 man-days of work in 1945 declined 10 percent below 1944. The average employee worked 8.04 hours per day compared with 8.00 hours in 1944. The hours of work per year by the average employee totaled 2,099 in 1945, or 109 hours less than in 1944.

The foregoing data on hours and those in the tables relate only to productive work and exclude "travel time" of underground employees and "lunch time" of all employees. The 1943 wage contract of the bituminous-coal industry, which became effective in nearly all parts of the country in November 1943, made portal-to-portal time (except for 15 minutes lunch time) the pay basis for underground workers. In the 1945 wage agreement, which became effective in April 1945, the pay basis for underground men was made total portal-to-portal time by eliminating lunch time through staggering it so as not to interfere with production. With additional data reported by the companies, it has been estimated that complete portal-to-portal time (work time plus actual travel time plus lunch time, whether or not paid for, of underground men and work time of surface men) at bituminous-coal mines in 1945 was 841,000,000 man-hours compared to 927,000,000 in 1944. These portal-to-portal man-hours, which represent the total time of exposure-to-hazard of all employees, yield an average length of shift of 8.88 hours in 1945 and 8.84 hours in 1944.

Injuries.—There was real improvement in the fatality experience in bituminous-coal mines in 1945. It is estimated that the number of men killed in mine accidents in 1945 totaled 936, or 184 fewer than in 1944. These fatalities occurred at a rate of 1.23 per million man-hours of productive work in 1945, an 8-percent reduction from the 1944 rate of 1.33. Although the estimated number of nonfatal injuries was reduced by 5,150 to a total of 47,750 in 1945, the frequency of occurrence of 62.66 per million hours of productive work was only slightly more favorable than in 1944.

In the past, company reports to the Bureau of Mines have included all accidents to underground men, whether or not the accident happened while the man was traveling in or out of the mine or while eating lunch. Combination of this count of injuries with man-hours of productive work resulted in artificially high frequency rates of injuries, as the man-hours of work excluded travel and lunch times and thus did not represent the total time of exposure to hazard. With the portal-to-portal man-hour figures for 1944 and 1945 given in the preceding section on employment, it is possible for the first time to compute true injury-frequency rates for bituminous-coal mines. Fatality rates on a portal-to-portal basis were 1.21 per million man-hours in 1944 and 1.11 in 1945. The rate of occurrence of nonfatal injuries on the same basis was 57.07 per million man-hours in 1944 and 56.78 in 1945. It is notable that the portal-to-portal fatality rates for 1944 and 1945 are, respectively, 9.0 and 9.8 percent and nonfatality rates 9.5 and 9.4 percent below the corresponding work-time rates for the same years.

The 5 major disasters in 1945 killed 68 men, of whom 63 lost their lives in 4 mine explosions and 5 in a roof fall. The explosion disasters occurred as follows: January 17 in an Oklahoma mine, killing 9; March 14 in a Utah mine, killing 7; May 9 in a Utah mine, killing 23; and December 26 in a Kentucky mine, killing 24. The fall-of-roof disaster was on March 12 in a Pennsylvania mine and killed 5 men.

Employment and injury experience at coal mines in the United States, 1941–45 [1]

	Men working daily	Average active mine-days	Man-hours worked	Number of injuries		Injury rates per million man-hours	
				Fatal	Nonfatal	Fatal	Nonfatal
Bituminous-coal mines: [2]							
1941	457,744	214	691,049,388	1,072	46,637	1.55	67.49

1944	457,500	279	1,001,000,000	1,294	65,900	1.29	65.83
1945	437,000	262	905,000,000	1,079	59,350	1.19	65.58

[1] Data for 1944 and 1945 are preliminary.
[2] Includes lignite.

In 1944 there were 4 major disasters, in which 94 men lost their lives—22 in mine explosions and 72 in mine fires.

Of the 936 fatalities at bituminous-coal mines in 1945, approximately 91 percent were in underground workings, 6 percent in surface work at underground mines, and 3 percent at strip mines. Distribution of the causes of the fatalities was 49 percent from falls of roof and face, 22 percent involving haulage, 8 percent from gas or dust explosions, 4 percent machinery, 2 percent electrical, and the remainder from other causes. Detailed information on the causes of nonfatal injuries is not available; but experience in recent years indicates that the principal causes, in order of frequency of occurrence, are haulage, falls of roof or face, handling materials, machinery, and hand tools.

ANTHRACITE

Employment.—The average number of men working daily at anthracite mines in Pennsylvania declined 5 percent from 1944 to a total of 74,000 during 1945. Although the shortage of labor was less acute at the end of the year, the general scarcity of men that prevailed through most of the year in anthracite as well as in bituminous-coal mining was the principal factor limiting production. Anthracite operations were worked an average (weighted) of 267 days; and, with the available labor force, an aggregate production of 54,400,000 short tons was attained from underground mines, strippings, culm banks, and dredges. This tonnage excludes "bootleg" coal purchased and prepared by recognized producers and was 14 percent below the 1944 output, which was produced with an average of 77,500 men working 292 days. Man-days of work were 13 percent lower than in 1944, but man-hours declined in the slightly smaller proportion of 12 percent owing to the increase in the average length of shift from 7.16 in 1944 to 7.24 in 1945. The average employee at anthracite operations worked 1,932 hours in 1945 compared with 2,090 in 1944.

Injuries.—The total number of fatalities in 1945 is estimated at 143, or 31 fewer than in 1944. The 1945 fatalities occurred at a rate of 1.00 per million man-hours—an improvement over the 1.07 frequency in 1944. Although the number of nonfatal injuries was reduced 1,400 from 1944 to a total of 11,600 in 1945, the frequency of occurrence of 81.12 per million man-hours was less favorable than the corresponding rate in 1944. Of the fatal injuries in 1945, about 91 percent occurred in underground workings, 8 percent in surface works at underground mines (including breakers), and 1 percent at strip mines. The principal causes of fatalities were falls of roof and face, haulage, and explosives.

"*Bootleg holes.*"—"Bootleg holes" are considerably less safe than are operations of "recognized" producers. According to the Anthracite Committee,[1] there were 16 fatalities in "bootleg holes" in 1945. As the estimated total output from these operations was 1,026,000 tons, the fatalities occurred at a rate of 1 for every 64,125 tons mined. In comparison, 380,420 tons were produced per fatality in "recognized" operations during 1945. Although there was a slight improve-

[1] Anthracite Committee, Eighth Survey of Bootleg Holes: Commonwealth of Pennsylvania Dept. of Commerce, Mar. 30, 1946, 8 pp.

ment over 1944, the 1945 fatality experience in "bootleg holes" indicates marked deterioration [2] in safety since 1941, when 103,279 tons were mined per fatality.

METAL MINES

The over-all safety record in metal mines was more favorable in 1945 than in 1944, owing to varying degrees of improvement in each of the industry groups, except the fatality experience at iron mines and the nonfatality experience at gold and silver lode mines and miscellaneous metal mines. The average number of men working daily declined 12 percent from 1944 to 62,200 in 1945 who were exposed to hazard for 143,020,000 man-hours. These men worked an average of 288 days (1 less than in 1944) for an average workyear of 2,299 hours, which was only 16 hours shorter than in 1944.

IRON

All iron-mining operations in the United States are included in this group for the first time, and the 1943 and 1944 statistics have been revised to be comparable. The new classification, in addition to iron-ore mines, includes those operations producing manganiferous and titaniferous iron ores, which formerly had been included in the miscellaneous metal group.

Employment.—Employment at iron mines declined 8 percent from 1944 to 23,700 men working daily in 1945. The reduced force in 1945 worked 288 days in 1945 for a total of 54,710,000 man-hours, which was 7 percent below 1944. The average employee worked an 8-hour shift and had 2,308 hours of work during the year compared to 2,265 hours in 1944.

Injuries.—The 38 fatalities in 1945 (1 less than in 1944) occurred at a frequency of 0.69 per million man-hours, or slightly higher than in 1944. The nonfatal-injury record was slightly more favorable, and the 1,305 injuries in 1945 occurred at a rate of 23.85 per million man-hours compared to 1,412 injuries and a rate of 24.11 in 1944.

COPPER

Employment.—The end of the war had marked effects upon employment at copper-mining operations, and a sharp decline in activity of underground operations was offset only in part by moderately increased activity at open-cuts. The total average number of men working daily declined 20 percent, and man-hours of work fell 23 percent from 1944. As indicated by man-hour data, activity at underground mines in 1945 was about one-third below 1944, whereas at open-cuts it was nearly one-tenth above 1944. The change was due in part to the closing or reduction in operations of some of the higher-cost mines when premium payments on certain operations were reduced by the Federal Government on September 1 and also to the continued scarcity of labor at some of the large underground mining centers. The average employee in copper-mining operations worked a shift of 8.01 hours on the 302 days the mines were active and had a total workyear of 2,416 hours during 1945 compared to 2,523 hours in 1944.

[2] Bureau of Mines, Coal-Mine Fatalities: CMF 175, January 1946, pp. 9–10.

Employment and injury experience at metal mines in the United States, 1943–45, by industry groups [1]

	Men working daily	Average active mine-days	Man-hours worked	Number of injuries		Injury rates per million man-hours	
				Fatal	Nonfatal	Fatal	Nonfatal
Iron mines: [2]							
1943 [3]	30,058	290	70,018,866	48	1,742	0.69	24.88

Miscellaneous: [6]							
1943 [3]	8,797	282	19,916,349	19	1,361	.95	68.34
1944 [3]	5,156	259	10,816,716	7	708	.65	65.45
1945	4,100	268	8,960,000	5	610	.56	68.08

[1] Data for 1945 are preliminary.
[2] Includes manganiferous and titaniferous iron ore mines.
[3] Revised figures.
[4] Figures include all lead-zinc mines in the United States for the first time.
[5] Includes only gold-silver lode mines.
[6] Includes antimony, bauxite, chromite, cobalt, manganese, mercury, molybdenum, pyrite, titanium, tungsten, and vanadium-uranium mines.

Injuries.—Over-all injury experience at copper mines improved considerably in 1945, and the fatality and nonfatality rates declined, respectively, to 0.71 and 42.90 per million man-hours. The number of fatal injuries fell from 38 in 1944 to 26 in 1945, and nonfatal injuries declined approximately 1,000 to a 1945 total of 1,565. The sharp changes in activity at underground and open-cut operations, described in the preceding paragraph, undoubtedly were important factors in the much more favorable accident record in 1945.

LEAD-ZINC

All lead-zinc mining operations in the United States are included in this classification for the first time. Formerly, the only statistics available were limited to lead-zinc mines in the Mississippi Valley States, and data on the lead-zinc mines in other States were included in the gold-silver group. To obtain the present grouping, reports on all mines in the gold-silver group were reclassified according to the producers' reports of the principal metal of each mine. Statistics for 1943 and 1944 have been revised to be comparable with the 1945 figures.

Employment.—Employment at all lead-zinc mines in the United States continued to decline and in 1945 fell 10 percent to a total of 14,900 men. Man-hours of work decreased 11 percent from 1944, owing to the scarcity of labor. The average employee worked a shift of 7.82 hours on each of the 294 active mine-days and accumulated a total of 2,302 hours of work during 1945. In 1944 the average shift was 7.96 hours, for 293 active mine-days and a total of 2,337 hours in the average workyear.

Injuries.—The accident record at lead-zinc mines was improved appreciably in 1945, and the frequency of fatalities and nonfatalities declined, respectively, to 0.96 and 94.46 per million man-hours. Owing to the smaller man-hours of exposure in 1945, the decline from 1944 in the number of injuries was in greater proportion than the declines in frequency rates. In 1945 there were estimated to be 33 fatal and 3,240 nonfatal injuries.

GOLD AND SILVER LODE

This classification includes only those mines for which the producers reported gold or silver as the principal metal. Lead-zinc mines outside the Mississippi Valley States, which formerly had been included, have been reclassified in the lead-zinc group. Data for 1943 and 1944 have been revised for comparability.

Employment.—Operations at gold and silver lode mines continued at a low rate in 1945, although the war measure of the Federal Government that closed gold mines in 1942 was revoked, effective July 1, 1945. It is apparent that many gold producers could not recruit labor after July 1, owing to the scarcity of help and other reasons. The average number of men working daily fell to 2,300 or 17 percent below 1944. As the mines operated 283 days in 1945 compared to 249 in 1944, the total man-hours of work declined only 4 percent from 1944. The average length of shift was 8.14 hours, and the average workyear per employee was 2,300 hours in 1945 compared to 1,987 in 1944.

Injuries.—The frequency of fatalities fell to 0.38 per million man-hours in 1945, or less than half the 1944 rate. Only two fatalities occurred in 1945 or three less than in 1944. Although the number of nonfatal injuries was virtually unchanged from 1944, the 1945 frequency of occurrence was less favorable owing to the smaller number of man-hours.

GOLD PLACER

Employment.—Following removal of the ban on operations on July 1, activity at gold placers was expanded appreciably. Both the average number of men at work and total man-hours of work in 1945 were nearly two-thirds greater than in 1944.

Injuries.—The number of nonfatal injuries increased from 48 in 1944 to 70 in 1945; but as man-hours of exposure were sharply higher, the frequency of occurrences of these nonfatals declined to 21.34 in 1945. No fatal injuries were reported at gold placers in 1944 or 1945.

MISCELLANEOUS METAL

Mines producing antimony, bauxite, chromite, cobalt, manganese, mercury, molybdenum, pyrite, titanium, tungsten, and vanadium-uranium are included in this group. Data on manganiferous and titaniferous iron ores have been reclassified in the iron-ore group, and the 1943 and 1944 statistics have been revised for comparability.

Employment.—Employment at the mines in this group continued to fall rapidly, and the 1945 total of 4,100 men was 20 percent below

1944. The decline in man-hours of work was in nearly similar proportions. The average man worked an 8.17-hour shift on the 268 days the mines were active and accumulated a total of 2,185 hours of work during the year compared to 2,098 hours in 1944.

Injuries.—The 5 fatalities in 1945 occurred at a rate of 0.56 per million man-hours—an improvement over the 1944 frequency. Although there were 98 fewer nonfatal injuries in 1945, the rate of occurrence was 68.08 per million man-hours, a less satisfactory record than in 1944.

NONMETAL MINES

Barite, feldspar, fluorspar, gypsum, magnesite, mica, phosphate rock, rock salt, sulfur, and miscellaneous nonmetallic-mineral operations are included in this group.

Employment.—Mines in this classification were one of the relatively few segments of the mineral industry in which employment increased in 1945. The average number of men working increased to 12,200, and these men worked 3 percent more man-hours than in 1944. The

Employment and injury experience at nonmetal mines and quarries in the United States, 1943–45, by industry groups [1]

[1] Data for 1945 are preliminary.
[2] Includes barite, feldspar, fluorspar, gypsum, magnesite, mica, phosphate rock, rock salt, sulfur, and miscellaneous nonmetallic-mineral mines.
[3] Revised figures.
[4] Includes burning or calcining and other mill operations.

mines were active 268 days, for an average daily shift of 8.16 hours. The number of hours worked per employee during the year was 2,185, or 103 hours less than in 1944.

Injuries.—Injury experience at these operations in 1945 was more favorable, and the number and frequency of both fatal and nonfatal injuries declined from 1944. The 1945 fatality frequency was 0.60 per million man-hours, and the nonfatal rate was 42.39.

QUARRIES

All quarry materials are closely related to construction, and as the end of the war signified early relaxing of the war controls on construction, most of these mineral industries became more active in the latter half of the year. The average number of men working daily increased slightly to a 1945 total of 59,400 men. Man-hours of work also were greater in 1945. An average employee in the quarrying industries in 1945 worked an 8.28-hour shift for 264 days and had a workyear total of 2,189 hours compared to 2,211 hours in 1944. Over-all injury experience was more favorable in 1945, and the number and frequency rate of both fatal and nonfatal injuries were lower than in 1944.

CEMENT

Employment.—The average number of men at work daily in cement quarries and mills advanced to 21,200 in 1945, and these men worked an average of 279 days for 48,260,000 man-hours or 5 percent more than in 1944. The average length of shift was 8.15 hours, and each employee worked an average of 2,276 man-hours during 1945.

Injuries.—Despite the slightly greater activity at cement mills and quarries in 1945, the number of both fatal and nonfatal injuries was reduced from 1944. This resulted in more satisfactory frequency rates in 1945 of 0.21 per million man-hours for fatalities and 12.33 for nonfatalities. There were 10 fatalities and 595 nonfatal injuries in 1945.

LIMESTONE

Employment.—Employment at limestone operations gained slightly over 1944 to reach a total of 18,400 men in 1945. However, man-hours of work declined 4 percent, owing to the reduced number of active days in 1945. The average man worked a shift of 8.41 hours for 234 days and accumulated a total workyear of 1,969 hours.

Injuries.—The safety record at limestone operations was improved over 1944, and the frequency rate of fatal injuries declined to 0.52 and of nonfatal injuries to 39.06 per million man-hours of exposure in 1945. The 19 fatal and 1,415 nonfatal injuries in 1945 were lower in each instance than in 1944.

LIME

Employment.—Reports indicate that 8,200 men were working daily in lime plants and quarries in 1945, a small reduction in labor force from 1944. These men worked an aggregate of 20,730,000 man-hours or 7 percent less than in 1944. The average length of shift was 8.13 hours on the 311 days active, and the average number of hours per man in 1945 was 2,528.

Injuries.—The estimated totals of 9 fatalities and 990 nonfatalities in 1945 occurred at frequencies of 0.43 and 47.76 per million man-hours of work. The rate of fatal injuries was improved in 1945, but for nonfatal injuries the rate was less favorable than in 1944.

MARBLE

Employment.—The down trend in employment at marble quarries which started in 1940 was reversed in 1945, when the average number of men advanced to 1,800. Man-hours of employment were slightly higher than in 1944. The average employee worked an 8.51-hour shift for 250 days and accumulated a total workyear of 2,128 hours in 1945.

Injuries.—The slightly greater activity in marble operations was accompanied by a much less satisfactory safety record than in 1944, and the number and frequency of both fatal and nonfatal injuries were higher in 1945. The 2 fatalities and 180 nonfatalities occurred at respective rates of 0.52 and 47.00 per million man-hours.

GRANITE

Employment.—The number of men working daily at granite quarries was still virtually unchanged, but as these men worked 261 days in 1945 (13 more than in 1944), man-hours of employment gained 6 percent over 1944. The average workyear per employee was 2,202 hours (109 hours longer than in 1944), and the average length of shift was 8.44 hours in 1945.

Injuries.—The reduced number of fatalities in 1945—five—occurred at a frequency of 0.53 per million man-hours, an improved rate over 1944. However, the number of nonfatal injuries increased to 445 and was at the less favorable rate of 46.99 per million man-hours in 1945.

TRAPROCK

Employment.—Available reports indicate that employment at traprock quarries advanced to a total of 2,100 men who worked 4,080,000 man-hours in 1945. The average man worked an 8.50-hour shift on 229 days and had an average workyear of 1,943 hours, which was only slightly lower than in 1944.

Injuries.—The industry was free of fatal accidents in 1945, and the nonfatal injury rate was reduced appreciably to 47.79 per million man-hours. There were 195 nonfatal injuries in 1945 compared with 228 in 1944.

SLATE

Employment.—The number of men working at slate quarries increased to 1,200 in 1945; and, as the quarries were active 263 days, the man-hours of employment showed a corresponding gain over 1944. The average employee worked an 8.86-hour shift and had a workyear of 2,333 hours—104 hours longer than in 1944.

Injuries.—Injury experience improved markedly in 1945. No fatalities were reported, and the reduced number of nonfatal injuries occurred at a rate of 44.64 per million man-hours compared with the corresponding rate of 61.17 in 1944.

717372—47——101

SANDSTONE

Employment.—Employment at sandstone operations in 1945 was changed only slightly from 1944. However, as the 2,200 men worked 252 days in 1945 or 9 days less than in 1944, man-hours of work declined more sharply. The average length of shift was 8.32 hours and the average hours per man per year were 2,095.

Injuries.—The 3 fatalities in 1945 represented a frequency of 0.65 per million man-hours, a less favorable rate than in 1944. However, nonfatal injuries were reduced to 265 and occurred at the improved rate of 57.48 per million man-hours.

COKE PLANTS

The end of the war, the reconversion period, and the year-end strikes in the steel and certain steel-consuming industries combined to relieve some of the pressure on the coke industry in 1945. Fatality experience was less favorable than in 1944, but the nonfatal-injury experience improved.

Employment and injury experience at coke plants in the United States, 1943–45 [1]

	Men working daily	Average active plant-days	Man-hours worked	Number of injuries		Injury rates per million man-hours	
				Fatal	Nonfatal	Fatal	Nonfatal
Byproduct ovens:							
1943	21,632	363	62,652,039	15	611	0.24	9.75
1944	21,586	363	62,848,032	12	752	.19	11.97
1945	20,500	362	59,180,000	18	630	.30	10.65

1943	4,133	265	8,026,872	2	375	.25	46.72
1944	3,180	267	6,742,049	3	236	.44	35.00
1945	2,600	230	4,900,000	1	185	.20	37.76

[1] Data for 1945 are preliminary.

BYPRODUCT COKE

Employment.—Available reports indicate that 20,500 men—approximately 1,000 less than in 1944—worked 59,180,000 man-hours which was 6 percent below the 1944 figure. The plants were active 362 days and the average employee worked a 7.98-hour shift on these days to accumulate a workyear of 2,887 hours, which was only 25 hours shorter than in 1944.

Injuries.—The fatality record was less satisfactory than in 1944, and the 18 fatal injuries in 1945 occurred at a frequency of 0.30 per million man-hours. Nonfatal injuries were reduced to 630, and these occurred at a rate of 10.65 per million man-hours, an improvement over the 1944 rate of 11.97.

BEEHIVE COKE

Employment.—Employment at beehive plants fell 18 percent to a total of 2,600 men in 1945. As the plants were active only 230 days—37 days less than in 1944—man-hours of work declined 27 percent. The average man worked a daily shift of 8.18 hours and had a total workyear of 1,885 hours or 235 hours below 1944.

Injuries.—The 1 fatal injury in 1945 represented a rate of 0.20 per million man-hours, an improvement over 1944. Nonfatal injuries totaled 185 and had a less satisfactory frequency of 37.76 per million man-hours in 1945.

METALLURGICAL PLANTS

The average number of men working daily at metallurgical plants fell sharply from 1944 to a 1945 total of 45,900, who worked 22 percent fewer man-hours than in 1944. The plants were active 336 days, and the average man worked a shift of 7.73 hours.

ORE-DRESSING PLANTS AND AUXILIARY WORKS

Plants or mills in this group are those in which ores of all metals are processed by the various methods of treatment.

Employment.—Total employment at these plants in 1945 was 15,300, an appreciable reduction from 1944, owing to the scarcity of labor, the smaller tonnages of metallic ores treated, and the closing of some Government-owned ore-dressing mills after the end of the war. Man-hours of work in 1945 declined 19 percent from 1944 owing to decreases for each group of mills.

Employment and injury experience at mills and auxiliary works in the United States 1943–45, by metals

[1] Includes crushers, grinders, washers, ore concentration, sintering, cyaniding, leaching, and all other metallic ore-dressing plants.
[2] Includes maintenance and repair shops, yards, general construction, and other associated works.
[3] Revised figures.
[4] Corrected figure.
[5] Includes antimony, bauxite, mercury, manganese, tungsten, chromite, vanadium, molybdenum, and other metals. Manganiferous iron ore and one titaniferous iron-ore mine have been transferred to iron.

Injuries.—The combined fatal- and non-fatal-injury rate at mills and associated works was less satisfactory than in 1944. Injuries at mills occurred at a frequency of 34.37 per million man-hours in 1945 compared to 29.54 in 1944 whereas the injury record at auxiliary works was at the improved rate of 22.02 per million man-hours compared with 24.03 in 1944. Iron mills and auxiliary works had the best safety record in 1945 and lead-zinc plants had the least satisfactory record of the group.

SMELTERS, REFINERIES, REDUCTION PLANTS, AND AUXILIARY WORKS

Plants in this group are engaged in the primary extraction of nonferrous metals from ores and concentrates and include, among others, smelters, refineries, and reduction, roasting, electrolytic, and retort plants. Iron and steel plants are excluded.

Employment and injury experience at primary smelters, refineries, reduction plants, and auxiliary works in the United States, 1943–45, by metals

1945 (estimate)	3,100	3,300	6,400	7,260	8,180	15,440	59.50	25.18	41.32
Total:									
1943 [4]	29,510	15,936	45,446	81,569	44,036	125,605	30.72	19.67	26.85
1944	26,059	13,894	39,953	70,082	37,202	107,284	31.63	19.95	27.58
1945 (estimate)	19,000	11,600	30,600	51,150	31,270	82,420	31.63	19.48	27.02

[1] Includes smelters, refineries, and reduction, roasting, electrolytic, retort, and all other plants producing nonferrous metals.
[2] Includes maintenance and repair shops, yards, general construction, and other associated works.
[3] Includes mercury, antimony, tin, and magnesium plants.
[4] Revised figures.

Employment.—Employment and man-hours of work at these plants and their associated works declined, owing to the closing of Government-owned plants before and after the end of the war and to the general shortage of labor. The total number of men and the man-hours of work both declined 23 percent from 1944. Of the 30,600 men working in 1945, approximately two-thirds were employed in the smelters or refineries and the remainder in the auxiliary works.

Injuries.—Injury experience (fatal plus nonfatal) in these plants was slightly more favorable than in 1944, owing to an improved rate of occurrence in auxiliary works. The frequency of injuries in smelters was unchanged from 1944 at 31.63 per million man-hours. In the group classed according to the metal produced, the injury record was more favorable in 1945 in the copper and zinc plants and less favorable in the lead and miscellaneous metal plants. Injuries occurred less frequently in lead plants and most frequently in the miscellaneous metal plants in 1945.

PART V. FOREIGN MINERALS

FOREIGN MINERALS REVIEW

SUMMARY OUTLINE

GENERAL SUMMARY

By J. S. McGrath

By the close of 1945 evidence was ample that reconversion of the world economy from a wartime to a satisfactory peacetime basis could be brought about only through political decisions on certain fundamental issues that were discussed by the Council of Foreign Ministers at London in September and at Moscow in December. Issues requiring primary consideration by all nations, and particularly by the powers represented on the council, were (1) recognition of the menacing consequences of the atomic bomb on the relationships of all States, (2) cooperation of the nations for the solution of world economic problems as provided in the Charter of the United Nations, (3) unification of control for the whole of Germany and the former Japanese Empire, (4) exaction of reparations from the former Axis powers and agreement as to the form and volume of the reparations, and (5) determination of the future industrial capacity of Germany, Japan, and Italy. Although discussions on these basic issues continued throughout the year, no decisions were reached.

Minerals, either directly or indirectly, are involved in each of the five aforementioned basic issues, principally because the political, economic, and social welfare of the industrial nations depends to a marked degree on their mineral supplies; this was quite clearly demonstrated by the adverse effects of postwar shortages of coal and fertilizers on the population of every country in Europe and on those of China and Japan. These effects, in addition to others of similar character, have made evident the urgent need for international cooperation through an agency such as the United Nations organization if the hazardous results of mineral deficiencies are to be avoided and the adoption of restrictive trade policies and objectionable private international commodity agreements is to be forestalled.

Of primary importance in connection with the necessity for a functioning international organization is the subject of atomic energy. This energy of the future—and probably of the not very distant future—poses a new problem for the world, one which, for the present at least, is basically mineral in character. Within a relatively short time, reserves of mineral fissionable materials will in all probability be the most important factor in a nation's development of atomic power for peacetime industrial uses. Industrial atomic power, when it comes, however, will compete with power derived from two other minerals, coal and petroleum, and this competition among the several power-producing minerals is certain to influence materially the economic status of many countries and their populations.

The near future of many of the nations of the world, as indicated above, today probably depends more on mineral assets than at any time in the past. The following sections of this chapter have been prepared with that fact in mind; the data they contain indicate clearly the interdependence of the nations for minerals and the critical need for an international body to effect their equitable distribution.[1]

[1] A few discrepancies exist between the foreign statistics in some of the commodity chapters and the statistics presented in this chapter inasmuch as the latter are based in part on new and revised information received from abroad, subsequent to the preparation of the commodity chapters.

BRITISH DOMINIONS OF NORTH AMERICA

By Frank L. Fisher

CANADA

Canada's mineral production was valued at $479,587,911 in 1945 compared to $485,819,114 in 1944.[2] Fuels and metals decreased in value for the year, while nonmetallics and structural materials showed increases. Gold production dropped 10 million dollars in value from the previous year, for a total of $102,000,000. Copper and nickel decreased in value and quantity, while a decreased production of zinc had a higher value than 1944. Lead production increased in quantity and value over the previous year, and iron-ore production was doubled. Coal production dropped about 300,000 tons from 1944, and oil production was down 1.5 million barrels. Natural gas increased about 6,000,000 thousand cubic feet. In the nonmetallic minerals group, gains over 1944 were noted for asbestos, barite, feldspar, graphite, gypsum, magnesitic dolomite, and nepheline syenite; but salt, quartz. sodium sulfate, and sulfur showed a decrease. In the structural materials group, gains over 1944 were reported for production of clay products, cement, and sand and gravel; but limestone and stone decreased.

Ontario continued to be the major mineral-producing province, with an annual value of production in 1945 of $199,807,489, or 41.66 percent of the Dominion total. Quebec was next, with 18.51 percent of the production value, and British Columbia and Alberta had 13.28 and 10.72 percent, respectively. The only marked increase in value of mineral production over 1944 was reported for British Columbia with a gain of 1.40 percent.

Copper.—Production of refined copper in 1945 decreased for the fourth consecutive year, and amounted to 227,486 tons valued at $59,499,670. The 1945 mine production was 238,142 tons. Ontario remained the largest producer, with 118,174 tons, and Quebec had 53,819 tons as the second ranking Dominion producer. An extensive exploration program was conducted during the year by the Quemont Mining Corp., Ltd., on a copper-gold-silver deposit, adjoining the property of Noranda Mines, Ltd., in the Rouyn area of Quebec.

Gold.—Gold production in 1945 dropped 261,344 ounces for a total of 2,661,567 ounces for the year. Ontario produced 1,590,339 ounces, followed by Quebec with 664,226 ounces for the year and British Columbia with 188,380 ounces. The gold-mining industry showed an improved outlook after years of war, and general expansion began with the lifting of restrictions. Increased activity in exploratory work was noted, especially in Quebec, Ontario, Manitoba, and the Northwest Territories.

Iron ore.—Production of iron ore in 1945 totaled 1,134,808 tons, a sharp increase from the 553,252 tons produced in 1944. Iron-ore shipments were made in 1945 from the New Helen mine of Algoma

[2] All references to dollars are in terms of Canadian dollars. The official buying rate for drafts on New York throughout 1945 was 1 Canadian dollar equaled 0.90909 American dollar. Canadian statistics are reported in short tons, unless otherwise indicated.

Ore Properties, Ltd., in the Michipicoten area of Ontario, and the Steep Rock mines near Atikokan, Ontario. Exploratory work continued during the year in the Michipicoten area of Ontario and on the reportedly large iron-ore deposits in the Sawyer Lake region along the Quebec-Labrador boundary. The four Canadian steel companies produced a normal 1,777,958 tons of pig iron and 2,881,323 tons of finished steel during 1945.

Lead.—The increased demand for lead resulted in a production in 1945 of 172,728 tons, which was 20,437 tons over 1944.

Nickel.—Nickel production in 1945 was 121,978 tons, a decrease from the 137,299 tons produced in 1944. Virtually the entire production continued to come from the plants of the International Nickel Co. of Canada, Ltd., and the Falconbridge Nickel Mines, Ltd., both near Sudbury, Ontario. The Falconbridge Co. resumed matte shipments in 1945 to its refinery at Kristiansand, Norway.

Platinum group.—Production of platinum from copper-nickel ore was 162,000 ounces in 1945, a slight increase over 1944. Production of the other platinum-group metals was 155,600 ounces for 1945.

Silver.—Silver production continued a 6-year decline, with a total of 12,866,597 fine ounces in 1945. The decrease was 760,512 fine ounces less than the 1944 production and a drop of 10,967,155 fine ounces from the 1940 production. British Columbia continued to be the principal producing Province.

Zinc.—The mine production of zinc in 1945 continued to decrease, with a total for the year of 254,819 tons—a drop of over 20,000 tons from 1944. British Columbia continued to be the major Provincial producer.

Other metals.—The production of cobalt, bismuth, cadmium, and selenium showed a marked increase during 1945, while production of arsenic, chrome, magnesium, antimony, molybdenite, and ilmenite decreased sharply. Mercury, manganese, and tungsten were not produced in the Dominion on a commerical basis during 1945. Tin production from tailings of the Sullivan mine was 425 tons for the year.

Other nonmetallic minerals.—*Asbestos* production in 1945 was 460,051 tons compared to 419,265 tons for 1944. The bulk of the production was exported in the unmanufactured state to the United States. The 1945 production was valued at $21,405,391. Production of *barite* continued to increase sharply, amounting to 140,198 tons in 1945. The bulk of the production came from the plant of the Canadian Industrial Minerals, Ltd., at Walton, Hants County, Nova Scotia, and from Parson, near Golden, British Columbia. Production of *sulfur* as a byproduct of smelters and refineries increased slightly during the year, for a total production of 245,859 tons. *Salt* production from all sources decreased several thousand tons for a 1945 total of 678,004 tons.

Sodium sulfate production dropped sharply during the year to 86,643 tons. *Talc and soapstone* production decreased slightly in 1945. *Quartz* production continued to decline with a production for 1945 of 1,458,847 tons. *Nepheline syenite* production continued to increase, with a 1945 total of 60,133 tons coming solely from Lakefield, in Peterborough County, Ontario. *Mica* production continued at an accelerated rate during the year, with a production of 7,369,964 pounds of all grades. Production from the exceptionally rich deposits in the Eau Claire area, Ontario, decreased considerably during 1945. Production of *magnesitic dolomite and brucite* showed a slight increase in 1945, with the bulk of the production quarried and processed at Kilmar and Harrington East, Argenteuil County, Quebec, and Wakefield, Quebec. The 1945 sales of *gypsum* were 822,380 tons compared to 596,164 tons for 1944, but the industry was still far short of the prewar normal. The 1945 production of *graphite* from the Black Donald mine, Renfrew County, Ontario, the only producer, was 1,840 tons. Minor production in 1945 was reported for *feldspar*, *fluorspar*, *corundum*, *ocher*, *phosphate rock*, *quartz rock*, and *sodium carbonate*.

Fuels.—*Coal* production dropped to 16,457,000 tons, reflecting a steady decline since 1942. The 1944 production was 17,026,499 tons. Alberta continued to be the largest producer, with 7,829,468 tons, followed by Nova Scotia and British Columbia, with 5,232,667 tons and 1,711,182 tons, respectively. *Natural-gas* production increased from 45,067,158 thousand cubic feet in 1944 to 50,794,000 thousand cubic feet in 1945. The Turner Valley field in Alberta continued to have primary importance. *Crude petroleum* production dropped in 1945 to 8,550,000 barrels, from 10,099,404 barrels in 1944. Ninety percent of the Canadian production comes from the Turner Valley field in Alberta, which had an output of 8,039,000 barrels in 1945. The discontinuance of operations on the Canol project at Norman Wells in 1945 accounted for much of the drop in Canadian production. The project operated from May 1942 to March 1945 and produced 1,858,447 barrels from a recoverable reserve, estimated in 1945, of 36,250,000 barrels. A new field, the Lloydminster of Saskatchewan, began producing in the spring of 1945.

Clay products and other structural materials.—The value of *clay products* increased sharply from 6,997,425 Canadian dollars in 1944 to 8,385,185 Canadian dollars in 1945. *Cement* production also increased to 1,330,116 tons in 1945 compared to 1,141,594 tons for the previous year. Production of *lime* decreased slightly during the year to 831,982 tons. *Sand and gravel* production increased slightly to 29,021,249 tons, and *stone* decreased to 5,884,718 tons.

NEWFOUNDLAND

The mineral industries of Newfoundland had another year of continued prosperity in 1945.[3] Production increases were noted for iron ore and copper, lead, and zinc concentrates.

Iron-ore production from the Wabana mines was approximately 1,000,000 tons in 1945. No new iron ore deposits were reported, but continued exploration on known deposits in Labrador indicated that they were larger than first anticipated and would rank among the world's largest iron-ore deposits. The Buchans mine increased production in 1945 to 1,200 tons of ore per day compared to 1,000 tons in 1944. The 1945 production was 24,251 tons (3,365 tons copper content) of copper concentrate, 32,352 tons (22,608 tons lead content) of lead concentrate, and 75,096 tons (49,350 tons zinc content) of zinc concentrate.

[3] Sanderhoff, L. O. (American vice consul), Newfoundland's Economy—1945 (Mining and Geological Survey section by Consul R. J. Cavanaugh): State Department Dispatch 15, St. Johns, Newfoundland, Mar. 13, 1946, 37 pages.

MIDDLE AMERICA[4]

By Sumner M. Anderson

BRITISH WEST INDIES

Mineral production in the British West Indies is confined to asphalt and petroleum in important quantities and to limestone and lime, salt, and phosphate rock.

Bahamas.—In addition to sufficient limestone plus conch shells to produce approximately 1,700 metric tons of lime, about 500 tons were quarried for use in domestic construction. Total limestone quarried and calcined in 1945 was virtually the same as in 1944. West India Chemicals, Ltd., extracted 38,825 metric tons of salt from sea water, compared with 60,960 tons in 1944.

Although no petroleum production has yet been established in the Bahamas, concessions totaling 47,309 square miles of land and offshore waters have been granted by the government to one local, three American, and three British oil companies, and exploration on a large scale was begun in 1945. Location for the first test was staked in November by Bahamas Oil Co., Ltd. (Superior Oil Co. of California), at the approximate center of the northern end of Andros Island. Exploration elsewhere includes seismograph operations in the Bimini Islands and a gravity survey on Grand Bahama Island.

Barbados.—Small local industry on Barbados regularly produces limestone and lime, sandstone, sand, and earth for domestic consumption in quantities that are not reported. Salt has not been produced since 1941. A variety of asphalt known as manjak is mined for export to the United States; output amounted to 33 metric tons in 1944, but only 9 tons in 1945. Production of crude petroleum by the British Union Oil Co. dropped steadily from 3,737 barrels in 1939 to 652 barrels in 1944; in 1945, continued bailing from shallow wells yielded 1,738 barrels, all of which was refined locally, as usual, to supplement essential imports. Natural gas valued at £2,025 was sold from the same field in 1945.

Bermuda.—No record is kept of the limestone and lime produced annually, for local use only, on the island of Bermuda.

Jamaica.—Limestone is quarried in many places on the island of Jamaica for various domestic purposes, including the calcining of lime; but no tonnage record is available, and none of the stone is exported. During 1945 a British firm was granted a franchise to manufacture cement near Port Henderson, but local opposition to the terms has held up the project.

Both the Reynolds Metals Co. and Jamaica Bauxites Ltd. (Aluminum Co. of Canada, Ltd.) acquired options to extensive bauxite deposits, following examination started in 1942. Some additional prospecting was done, but commercial development has been postponed; pending adoption of a proposed mining code for Jamaica.

Turks and Caicos Islands (Jamaica Dependencies).—This island group has only one important industry; it is the largest producer and

[4] Unless otherwise indicated, statistics for all Middle America countries are in metric tons.

exporter of salt in the British West Indies. The drop in production from 33,779 metric tons in 1944 to 21,229 tons in 1945 was brought about by the hurricane of September 1945, which wrecked the salinas and destroyed extensive Government-owned stocks. Rehabilitation of the industry was initiated by the Government in November.

Cayman Islands (*Jamaica Dependencies*).—Phosphate-rock production, revived on a very small scale during 1942–44, dwindled to insignificance in 1945.

Trinidad.—Limestone production amounted to 617,350 metric tons in 1945 compared with 599,581 tons in 1941, with the intervening years not reported. Production of natural asphalt from the famous Trinidad lake, unreported during the war years 1942–44, dropped from 81,753 metric tons in 1941 to 29,462 tons in 1945. Security regulations surrounding the oil industry during the war have been lifted, revealing the following production figures for crude petroleum, in barrels: 1941—20,505,980; 1942—22,069,178; 1943—21,385,240; 1944—22,138,502; 1945—21,092,608. Of the 16 Trinidad fields, Forest Reserve and Francique on the Fyzabad structure supply nearly half the island's output at present and have yielded well over half of the cumulative total of 317,966,315 barrels through 1945. New developments during the year included a submarine concession granted to the Trinidad Petroleum Development Co., Ltd., to explore an area off the south coast.

Trinidad Leaseholds, Ltd., owns 60.0 of the 74.3 miles of pipe lines that distribute crude petroleum from fields to refineries and has joint interest with Siparia Trinidad Oilfields, Ltd., and Trinidad Central Oilfields, Ltd. in the remainder. Refinery capacity exceeds crude production, and virtually all of the crude is refined on the island. Exports of refinery products amounted to 17,208,745 barrels in 1945 (16,461,494 barrels in 1944).

CUBA

In 1945 the United States Geological Survey completed large-scale investigations of Cuban minerals and mining methods which had been started in 1940 and which had contributed materially to the development of mineral resources—particularly manganese ore and chromite—during the war years. With the end of the war, however, the United States Commercial Company discontinued its strategic minerals purchase program, and Cuban production of chromite, manganese ore, and barite declined abruptly. Production of copper, which responded to the discovery of new reserves, and of nickel oxide, which did not start until December 1943, increased substantially.

METALS

Chromite.—Production of refractory-grade chromite in the Camaguey and Punta Gorda areas was held at a high level during the first three quarters of the year but dropped enough in the fourth quarter to bring the year's total down to 161,612 metric tons, compared with 173,220 tons in 1944. Four producers, Cía. Cubana de Minas y Minarales, S. A., Juragua Iron Co., Minera Moa, S. A., and Primativo Portal, supplied the total output. Metallurgical-grade chromite was mined on a reduced scale all year, and the combined output of Mayarí

Mining Co., S. A., Miranda-Gasset, and Landa y Asencio amounted to only 11,014 metric tons, a 42 percent drop from the 1944 figure of 18,911 tons.

Copper.—Minas de Matahambre, S. A., the only copper company now active in Cuba, started development of its newly found reserves and boosted total production of copper-in-concentrates from 6,584 metric tons in 1944 to 9,067 tons in 1945. Further improvement is expected in 1946.

Iron.—The mining of iron ore in Cuba, which dropped from 192,851 metric tons in 1941 to 28,370 tons in 1944, ceased before the close of the latter year. The mines are owned by the Juragua Iron Co.; extensive reserves remain undeveloped, but the company has been unable to maintain the uniform ore composition demanded by steel makers.

Manganese.—Manganese-nodule production declined from 135,638 metric tons in 1944 to 132,317 tons in 1945. Production of ore other than that used for sintering dropped from 122,226 tons in 1944 to 65,676 tons in 1945. Resultant total output of ore carrying 45 percent manganese or better was 257,864 metric tons in 1944, 197,993 tons in 1945. Ores suitable for sintering are disappearing rapidly, and a further decrease in total output is expected in 1946. Most of the 50 or more mines operating in the first quarter of 1945 were closed down indefinitely during the latter half of the year, leaving an estimated 3,500 workers without employment.

Nickel.—The Nicaro Nickel Co. attained full operating capacity of its United States Government-sponsored nickel oxide plant in Oriente Province by the end of 1945. A total of 14,152 metric tons of oxide containing 10,940 tons of nickel was produced, as against 6,260 metric tons of oxide containing 4,679 tons of nickel in 1944. (Nickel-content figures include unreported quantities of cobalt.) Recovery of oxide from ore was improved during the year, and is hoped to be improved further as experimental work is continued. Profitable operation of the plant on a competitive basis is yet to be demonstrated.

Tungsten.—The Pan American Tungsten Corp. reopened its Lela mine (closed in 1943) on the Isle of Pines in 1945 but suspended operations before the end of the year after having extracted 9 metric tons of 60-percent WO_3 concentrates.

Precious metals.—Production of gold and silver has never been important in Cuba and was not reported in 1945. United States imports from Cuba, however, amounted to 423 troy ounces of gold and 107,195 ounces of silver, mostly contained in copper concentrates from the Matahambre mine. Renewal of gold mining early in 1946 on the Isle of Pines has been reported.

NONMETALLIC MINERALS

Barite.—To complete a contract made in 1944 with the United States Commercial Company, 2,094 metric tons of barite was quarried in 1945 at Amelia (west of Pinar del Rio) and processed at the grinding plant of Mineral Products Corp. at Regla, Habana. Output of the same company amounted to 4,787 metric tons in 1944.

Cement.—La Cía. Cubana de Cemento Portland operates the only cement plant in Cuba on Mariel Bay, about 30 miles west of Habana. Production, which has been mounting steadily since 1940, attained a new peak of 180,166 metric tons (1,059,800 barrels) in 1945, as against 173,750 tons (1,022,060 barrels) in 1944 and was supplemented by imports of 81,354 metric tons (477,000 barrels), compared with 57,818 tons (339,000 barrels) in 1944; but demand, based on a continued construction boom that began about 1937, still exceeded the supply. Indicated consumption amounted to 261,520 metric tons (1,536,800 barrels) in 1945 and 231,568 tons (1,361,060 barrels) in 1944.

Diamonds.—Although diamonds are not mined in Cuba, a cutting industry established by European refugees during the war grew to 28 factories employing 1,500 workers at the end of 1944. On May 1, 1945, controls over the local diamond industry, which had been confined to imports to and exports from the United States, were relinquished through the American Embassy at Habana. As a result the industry broadened; rough diamonds have been received from England and cut stones exported to Mexico, and by the close of the year the number of factories had expanded to 52, employing 3,500 workers, although production was retarded by labor difficulties during the first quarter. Moreover, the quality of workmanship is said to have improved during the year, but full competition from the prewar production centers has not yet been felt, and the future of the Cuban branch of the industry is, therefore, still uncertain. Total imports of rough stones, amounting to 201,983 carats valued at $2,543,000 in 1944, have not been reported for 1945. Total exports of cut and polished diamonds since the industry started have been as follows:

Cuban exports of diamonds, 1942–45

Year	Carats	Value, f. o. b. Habana	Value per carat
1942	2, 590. 44	$297, 668. 54	$114. 91
1943	22, 190. 21	3, 292, 011. 45	148. 35
1944	67, 959. 80	10, 164, 630. 19	149. 57
1945	59, 894. 00	9, 950, 728. 00	166. 14

Other nonmetallic minerals.—Reported 1945 production of other industrial minerals in metric tons, compared parenthetically with 1944, included calcined gypsum, 2,974 (4,061); magnesite, none (86); and marine salt, 63,504 (15,422). Production of lime, stone, sand, gravel, clay, and pigment earths was not reported quantitatively.

HYDROCARBONS

Asphalt.—The reported estimate of 9,070 metric tons of asphalt produced in 1945 is believed to apply only to gilsonite, sold chiefly in export. Another type of asphaltite averaging up to 20 percent ash is mined and used locally for fuel, although production may have diminished since the lifting of war restrictions on fuel imports. Overall production of asphalt in 1944 amounted to 40,000 metric tons.

Petroleum.—Production of naphtha (natural gasoline) in the Motembo field dropped from 94,171 barrels in 1944 to an estimated

55,900 barrels in 1945, continuing the steady decline from the peak year 1941, while that of natural-gas oil in the Jarahueca field increased to an estimated 87,600 barrels in 1945, compared with 14,831 barrels in 1944 and 3,825 barrels in 1943, the first year of production. The two fields yielded a combined production estimated at 143,500 barrels of liquid fuel, for a net increase over the 109,002 barrels in 1944. The Bucuranao field has yielded no crude petroleum since 1943 and is said to be exhausted. Results of test drilling by Standard Oil Co. of Cuba and the Estrella Co. (Shell and others) in 1945 reportedly were more promising than during the previous year but were unproductive.

The natural-gas oil from the Jarahueca field was treated by the three small refineries of the Union Oil Co. at Bucuranao, Destiladora de Jarahueca, and Petrolera de Jarahueca at Jarahueca, yielding gas oil, gasoline, kerosine, fuel oil, and residue.

DOMINICAN REPUBLIC

Gold.—Exports of gold continued the steady decline from 1941 and reached a new low of 486 troy ounces in 1945. Beginning in 1946, exports can no longer be regarded as an index of production, as most of the output is to be added to a Government reserve as a guarantee for Dominican currency, when and if such currency is issued, and few future exports are contemplated. A Government contract, granted November 15, 1944, and revised December 3, 1945, has given to an American geologist an exclusive gold-mining concession covering five provinces for a period of 3 years, and introduction of dredging methods are being considered.

Bauxite.—Culminating 2 years of field work, the Alcoa Exploration Co. announced the discovery of 6,000,000 tons of low-grade bauxite in central Barahona and on April 2, 1945, obtained a mining concession from the Government. The Reynolds Metals Co. has withdrawn from similar exploration, at least temporarily, to concentrate its field work on bauxite deposits in Jamaica.

Cement.—Construction of the Dominican Republic's first cement plant near Ciudad Trujillo, started in 1944 by the Foundation Co. of New York, progressed during the year and is expected to be completed and the plant in operation during the last half of 1946.

Gypsum.—In 1945, 3,258 metric tons of gypsum were produced by Salinera Dominicana from mines 25 miles north of Barahona, compared with 2,146 tons in 1944. Total output is exported to Puerto Rico for use in the Ponce and San Juan cement plants. Future production may be expected to increase to meet domestic requirements exclusively when the cement plant near Ciudad Trujillo goes into operation.

Lime.—About 25,000 metric tons of lime are produced annually in Dominican Republic in a primitive beehive system of ovens. A large part of the production and about 85 percent of the consumption are accounted for by the sugar industry; 15 percent is used in construction.

Salt.—Estimated salt production in 1945 amounted to 2,650 metric tons derived from the evaporation of sea water and 12,450 tons dug from the Barahona mines, making a total of about 15,100 tons, or

3,800 tons more than the amount estimated for 1944. The profitable salt concession has been held, up to date, by Salinera Dominicana, C. por A. (President Trujillo, owner), but will be taken over in 1946 by the Banco Agricola, which is controlled by the Banco de Reservas de la Republica Dominicana (President Trujillo, majority stock holder). Both sea salt and rock salt are included in the terms of the concession. Exports of salt are negligible.

Petroleum.—Exploratory work by Seaboard Dominicana, a subsidiary of Standard Oil Co. of New Jersey, was closed down during 1945 for lack of heavy drilling equipment, which has since been received. Drilling on the shores of Lake Enriquillo was expected to start in February 1946.

FRENCH WEST INDIES

There is no known mineral industry in the French West Indies.

HAITI

Gold.—Purchase of placer gold by the Banque National de la Republique d'Haiti amounted to 161 troy ounces in 1944; the amount recovered but unreported or smuggled out of the country is unknown. Production in 1945 has been officially estimated at "500 to 1,000 ounces," but the estimate is believed to be high, as only 73 ounces were imported into the United States from Haiti during the year.

Bauxite.—The Reynolds Mining Co. continued examination and development of its bauxite deposits in the Ste. Croix area and shipped about 300 tons of bauxite to the United States for experimental purposes. The Reynolds contract with the Haitian Government calls for active exploitation of its concession after August 4, 1946, and plans are being made to start active operations on or before that date.

Salt.—Recovery of crude salt from sea water, for domestic use only, continued in 1945 at approximately the average annual rate of 8,000 tons.

Building material.—Small local industry in Haiti regularly produces lime, common brick, and some building and construction stone, but in amounts that are not reported.

Petroleum.—The Atlantic Refining Co. completed two test wells, 47 and 50 miles north-northeast of Port-au-Prince in the Jurinat area, with negative results. Exploration work was continued in the Cul-de-Sac Valley.

NETHERLANDS WEST INDIES

Phosphate.—Natural phosphate of lime amounting to 8,770 metric tons was mined at Newport and exported from the island of Curaçao in 1945, compared with 7,813 tons in 1944. Mining ceased, however, in the latter half of the year and is not expected to be resumed, unless a market such as existed in prewar years reopens in Denmark and Sweden.

Salt.—Shipments of marine salt dropped from 5,150 metric tons in 1944 to 3,109 tons in 1945, of which 2,635 tons were exported from the island of Bonaire, 330 tons from St. Martin, and 144 tons from St. Eustace.

Petroleum.—The quantities of Venezuelan and Colombian crude petroleum treated in the great refineries of Aruba and Curaçao during the war years have recently been revealed as follows, in thousands of barrels: 1939—142,850; 1940—116,780; 1941—148,332; 1942—110,315; 1943—145,776; 1944—190,040; 1945—not yet reported. An important byproduct contribution to the steel requirements of the United Nations during these years was the collection of vanadium-carrying residues from boiler plants, refinery furnaces, and ships that burn Venezuelan fuel oil.

MEXICO

Four of the principal ores and metals of Mexico—pig iron, lead, copper, and cadmium flue dust—reversed the production trends of 1944 and registered increased output in 1945. Twelve other items in this grouping decreased in proportions ranging from 1.9 to 60.1 percent relative to 1944. Except for mica, nonmetallic minerals and fuels fared much better; production of petroleum, coal, and strontium minerals rose, and that of graphite and crude sulfur appears to be the highest on record. The general recession in metallic mining, except for the metals cited, reflects the relaxation of demand in the United States following the close of the war, and Mexico is now looking to reopening of some of the Latin American and European markets that have been closed for the past 6 years. The industry is also feeling the influence of Government policy, as reflected in the present laws regulating taxation and conditions of labor,[5] and difficulties that have arisen in transportation.

The following table presents a comparison of production reported for the past 2 years.

Summary of mineral production of Mexico, 1944–45 [1]

[Metric tons, except as otherwise indicated]

Mineral	1944	1945	Difference (percent)
METALLIC ORES AND METALS			
Antimony (contained metal)	10,930	8,754	−19.9
Arsenic oxide (white arsenic)	15,306	15,013	−1.9
Bismuth kilograms	165,379	161,368	−2.4
Cadmium, in flue dust do	682,295	1,052,766	+54.3
Copper	41,300	61,680	+49.3
Gold troy ounces	508,882	499,301	−1.9
Iron ore	186,961	175,165	−6.3
Iron, pig	134,632	208,148	+54.6
Lead (content of ore mined)	185,281	205,315	+10.8
Manganese ore, Mn content	29,070	18,542	−36.2
Mercury flasks (76 pounds net)	23,064	16,443	−28.7
Molybdenum ore, MoS_2 content	1,195	781	−34.6
Silver troy ounces	65,460,073	61,097,727	−6.7
Tin	322	177	−45.0
Tungsten ore, 60 percent WO_3 equivalent	336	134	−60.1
Zinc (content of ore mined)	218,965	209,940	−4.1
NONMETALLIC MINERALS			
Graphite	12,977	23,634	+82.1
Strontium minerals (U. S. imports)	2,308	2,736	+18.5
Sulfur, crude	30,512	42,691	+39.9
HYDROCARBONS			
Coal	904,198	914,614	+1.2
Petroleum, crude barrels	38,203,105	43,547,360	+14.0

[1] Other minerals and products known to be produced but in quantities that have not been reported include cement, chalk, clay, fluorite, gypsum, lime, limestone, building and ornamental stone, salt, sodium carbonate, talc, and petroleum refinery products.

[5] Perez Durate, Constantino, Mexican Mining Must Have Tax Relief: Eng. and Min. Jour., vol. 146, No. 12, December 1945, pp. 96–99. Just, Evan, Mexico Is Strangling Its Mining Industry: Eng. and Min. Jour., vol. 147, No. 6, June 1946, pp. 76–80.

METALS

Cadmium.—On a mine basis, Mexico is probably the world's largest producer of cadmium, most of which is shipped to the United States contained in zinc concentrates and not added to the reported production of cadmium content of flue dust collected in Mexican zinc smelting. The indicated 54.3 percent rise in output of cadmium in the latter form, from 1944 to 1945, does not appear to be compatible with the 0.5 percent decrease in the production of slab zinc.

Copper.—The marked increase in copper production was made possible by successful operation of the new low-grade project of the Cananea Consolidated Copper Co. at Cananea, Sonora. Cananea is the most important producer in Mexico, and its new project, financed during the war by the Metals Reserve Company, has more than offset retarded operations in other units of the industry in 1945. The French enterprise Compagnie du Boleo sustained its Santa Rosalia mine during the past 2 years on subsidies granted by the Metals Reserve Company and the Mexican Government, and early in 1946 turned over its operation to a cooperative organization of the miners, retaining operative control of its smelter. Total 1945 production included 53,287 tons of furnace products and 8,393 tons contained in untreated ores and concentrates.

Copper exports amounted to 59,910 metric tons in 1945 (41,295 tons in 1944).

Iron and steel.—Cía. Fundidora de Fierro y Acero de Monterrey, S. A., operated the only two blast furnaces in Mexico producing pig iron and ferro-alloys until July 1944, when Altos Hornos de Mexico, S. A., started a third furnace of 350-ton capacity at Monclova, Coahuila. Consequently pig-iron output rose 54.6 percent in 1945 compared with 1944—an increase that has not been reconciled with the reported 6.3-percent decrease in the production of iron ore. Steel production likewise rose from roughly 198,000 tons in 1944 to 235,000 tons in 1945, an increase of 18.7 percent to the highest output on record.

Lead.—Sustained demand and decreasing supplies of lead in the United States stimulated Mexican production to a 10.8-percent increase in 1945 over 1944. The total comprised 201,078 metric tons of lead in refined and impure bars and oxides, plus 4,237 tons contained in untreated concentrates. Activity in the lead industry is expected to continue at a high level throughout 1946.

Precious metals.—On September 21, 1945, the United States increased the purchase price of foreign silver from 44.750 to 71.111 cents per troy ounce; but increased taxes and labor costs shortly thereafter canceled the benefits to the Mexican industry, and production continued the decline that started in 1943. Gold, largely a byproduct of silver and base-metal mining, also declined, though to a lesser extent.

Other metals.—Production of antimony, arsenic, bismuth, manganese, mercury, molybdenum, tin, tungsten, and zinc decreased in line with general conditions as indicated in the introductory paragraph. Official figures on tin are believed to be incomplete throughout the

717372—47——102

years, as illegal local sales have long been common practice. Actual production has been estimated at roughly 1,000 tons annually during the late war years.

NONMETALLIC MINERALS

Fluorspar.—While exports of fluorspar decreased from 56,450 metric tons in 1944 to 50,251 tons in 1945, the figures are not necessarily indicative of the trend in production, as the fluorite needs of the Mexican steel industry are also supplied, for the most part, by mines in the State of Guerrero.

Graphite.—United States requirements for Mexican amorphous graphite were well-sustained in 1945, with a resulting 82-percent gain in production, largely from southern Sonora.

Mica.—Mica mining by Cía. Mercantil de Oaxaca, the only producer in Mexico, was discontinued in June 1945 following production that had dwindled to only 15 to 20 tons during the 6-month period. Exports amounting to 409 tons in 1945 compared with 111 tons in 1944 are thought to have been made up largely of Canadian mica imported under bond for reexport after splitting and trimming in the shops of the Oaxaca Co.

Strontium.—United States imports of strontium minerals indicate that Mexican production was well-maintained throughout the year at a level higher than in 1944 but well below that in 1942–43.

Sulfur.—Sulfur requirements of the Mexican chemical industry are partly supplied by imports totaling 4,000 to 6,000 tons annually. Sulfur ore found in 18 States and produced chiefly in the area of Cerritos, San Louis Potosi, is of very poor grade, containing only 15 to 20 percent pure sulfur, and is in part exported; countries of destination for the past 4 years were the United States, Nicaragua, Guatemala, and Argentina. Official production figures are incomplete insofar as they fail to include small amounts of sulfur extracted for local use. Two new companies, one a Government entity, are considering development of deposits in the Tehuantepec area.

Other nonmetallic minerals.—In 1939, 5 companies operated 7 cement plants in Mexico; 10 firms employing 1,425 people are said to have entered the field since April 1941. Production amounted to 588,476 metric tons in 1942 and 578,253 tons in 1943 but has not been reported since. No reports have been received covering production of chalk, clay, gypsum, lime and limestone, construction and ornamental stone, salt, sodium carbonate, or talc.

HYDROCARBONS

Coal.—Production of coal, chiefly from the Sabinas field in the State of Coahuila, exceeded that of 1944 but continued far short of the peak of 1,444,498 metric tons attained in 1925. Ordinarily output is adequate for domestic requirements.

Petroleum.—Although a substantial increase in crude petroleum production made 1945 Mexico's best year since 1940, it was insufficient to mark a definite change of the general even trend that has fluctuated between 35 and 47 million barrels annually since the end of 1928. (Mexico's peak year was 1921, with 193.4 million barrels.)

Of the 1945 total, 88 percent came from the Tampico area and 12 percent from the Isthmus of Tehuantepec. The Poza Rica field alone supplied 19,148,452 barrels, or 44 percent of the total. Wells in northeastern Mexico (States of Tamaulipas and Coahuila) yield natural gas and some distillate in unreported quantities. Petróleos Mexicanos employed 28 exploration parties in 1945 (17 geological, 6 seismic, 4 gravity, and 1 electrical) and plans to increase the total to 36 in 1946, supplemented with 30 exploratory and 45 development wells per year. Known reserves have been calculated at 870 million barrels, of which more than 500 million belong to the Poza Rica field.

The Government (Petróleos Mexicanos) operates 11 refining plants having a total throughput capacity of 149,000 barrels daily. By 1947, 28,000-barrel capacity is expected to be added to the Atzcapotzalco plant near Mexico City and a new 30,000-barrel plant completed at Salamanca, State of Guanajuato. The Salamanca plant is being built partly from old equipment from the Mata Redonda and Bella Vista plants, which are being dismantled, deducting 16,000 barrels from the present national capacity and leaving a total expected capacity of 191,000 barrels per day by 1947. Actual production of petroleum refinery products has not been reported.

BRITISH HONDURAS

The only known mineral industry in British Honduras is the operation of Government-owned limestone quarries. Limestone production during the past 5 years has been approximately as follows, in metric tons: 1941–40,600; 1942–36,700; 1943–34,300; 1944–43,800; 1945–29,000.

COSTA RICA

The United States (exclusive buyer) imported 3,054 troy ounces of gold and 1,380 troy ounces of silver contained in concentrates and base bullion from Costa Rica in 1945, compared with 3,606 ounces of gold and 3,506 ounces of silver in like form in 1944. These figures, though possibly including small quantities of precious metal scrap, are believed to be closely indicative of Costa Rican total production and exports, which in 1945 reached the lowest point in many years. In the early part of 1945 Panammas, Inc. (controlled by Ventures, Ltd., of Toronto and New York), began exploring the Albangares mining properties under an option granted the previous year and extending to July 1946. Later in 1945 the New York and Honduras Rosario Mining Co. began a similar operation at Aguacate where, at the Union de Aguacate mine, a small cyanide plant was erected. Other groups have plans for both dredging and digging in the sands and gravels of the Osa Peninsula near the Panama border. The future of precious metal mining will be determined largely by the success or failure of these various ventures.

Several million tons of magnetic iron ore, in a deposit at "Old Harbor" on the Atlantic coast south of Limon, has been reported by American engineers. No action has been taken toward development of these deposits, nor toward reopening manganese deposits on the Nicoya Peninsula.[6]

[6] See Roberts, R. J., Manganese Deposits in Costa Rica: Geol. Survey Bull. 935-H, 1944 pp. 387-414.

An estimated 2,500 metric tons of lime and 50 tons of kieselguhr were produced during 1945 for domestic use. Evaporation of sea water on the Pacific coast yielded 6,033 metric tons of salt.

An American firm sent representatives to Costa Rica to investigate the possibilities of conducting an intensive survey of potential oil fields.

GUATEMALA

METALS

Chromite.—Production of chromite in the Department of Jalapa amounted to 442 metric tons containing 211 tons of Cr_2O_3 in 1945, compared with 97 tons containing 43 tons of Cr_2O_3 in 1944. As usual, all shipments went to the United States.

Gold.—Panning of alluvial gravels by individuals has virtually ceased, judging by United States imports of gold from Guatemala, which dropped from 126 troy ounces in 1944 to 66 ounces in 1945. The only dredging operation in the country was abandoned several years ago. Production in 1941 was 2,560 ounces.

Iron.—About 150 tons of iron ore a month are mined from a deposit near Zacapa for use in the Guatemala City cement plant. Late in 1945 an American mining company is reported to have started negotiations with the Guatemalan Government for an iron-mining concession.

Lead.—Lead ore is mined at a small, fairly uniform rate from workings in the vicinity of Huehuetenango. Recovery of metal in small local furnaces, for domestic use only, amounted to 115 metric tons in 1945 and 136 tons in 1944.

NONMETALLIC MINERALS

Cement.—La Fabrica National de Cemento de los Señores Novella y Cía. continued to operate the country's only cement plant near Guatemala City throughout 1945, but production figures have not been reported. The product of the plant is consumed totally within Guatemala.

Mica.—The sporadic mining of mica in the Departments of Quiché and Baja Verapaz was revived in 1941 by wartime demand in the United States, but the peak output (exports) attained in 1943 amounted to only 5,356 kilograms, dropping to 468 kilograms in 1944. Production in 1945, as gaged by United States imports, was 1,156 kilograms (2,549 pounds) valued at $1,146.

Quartz crystal.—The United States imported a total of 1,091 kilograms of quartz crystal from Guatemala during the 3-year period 1942–44 and none in 1945; experimental production apparently has proved unprofitable and has ceased.

Other nonmetallic minerals.—Production of salt, amounting to 12,618 metric tons in 1943 and 12,645 tons in 1944, was unreported in 1945. Also unreported was the usually small production of mineral pigments and sulfur.

Petroleum.—Inasmuch as Guatemalan law limits petroleum exploration to companies in which at least 51 percent of the stock is owned by citizens of Guatemala, no concessions have been explored, and none are now held despite the presence of oil seeps and the recognition of other factors favorable to production possibilities in the northeastern part of the country. Proposed revision of the petroleum law, designed to be more attractive to outside capital, is expected to be offered to the Congress of Guatemala before the end of 1946.

HONDURAS

The general economy of Honduras was at a high level throughout 1945. Although mineral production showed no improvement over the preceding year, mineral interest has been active in exploration and development that may well lead to increased production during the years to come. All major active mining operations and most of the claims and exploration work in Honduras are under the ownership, control, and management of United States interests.

Precious metals.—The New York and Honduras Rosario Mining Co. continued to be the only major producer of precious metals in the country, supplying from its San Juancito mine, Department of Francisco Morazan,[7] all of the 3,042,604 ounces of silver and most of the 20,060 ounces of gold exported to the United States during the year. Rosario's shipments were in the form of doré bullion. Placer gold, amounting to less than a thousand ounces, was bought from individuals by a Tegucigalpa firm and exported as bullion. In February the Rosario company obtained controlling interest in the silver-gold mines of Yuscaran in the Department of El Paraiso. Thorough exploratory examination has been started at this property and at the previously acquired El Mochito silver-lead and Caliche silver mines on the west side of Lake Yojoa, Department of Santa Barbara, and El Transito gold property (held jointly with the American Smelting & Refining Co.) near the Bay of Fonseca, Department of El Valle.

Compañía Minera Agua Fría, S. A., which has been inactive since May 1943, started exploratory work during the third quarter of 1945 preparatory to resuming production at its gold-silver mine near Danli, Department of Francisco Morazan. At the close of the year the entire 1942–43 output of this mine, containing 299,682 ounces of gold, 234 ounces of silver, and relatively insignificant amounts of arsenic, copper, antimony, and lead, was still in storage awaiting shipment to the United States.

New York interests have taken over the San Andres gold-silver property southwest of Santa Rosa de Copan and hope to start operating in 1946. Pan American Mining & Development Co. of Salt Lake City, Utah, acquired a 2,000-hectare concession in the Department of Olancho and started construction of an airfield and 60-mile road in preparation for the development of gold placers from its headquarters camp at Viajao. Other private American interests obtained control of gold-placer claims covering 2,000 hectares in the Territory of Mosquitia and planned to test the ground during the closing months of the year.

Antimony.—The production of antimony in Honduras ceased in 1945, because of unfavorable contract conditions, with the shipment of 28 metric tons of 61-percent hand-sorted ore from El Quetzal mine, Department of Copan, in February.

[7] Formerly Department of Tegucigalpa.

Mercury.—Development of a cinnabar deposit at Los Izotes, Department of Francisco Morazan, was started in 1941 and culminated during the second quarter of 1945 in the production of 23 flasks of mercury that were purchased and exported by Casa Uhler of Tegucigalpa. Operations have been discontinued and are not expected to be resumed.

Iron and manganese.—An American mining company applied in December 1945 for the right to examine and possibly develop iron (and manganese) deposits in (1) a 2,000-hectare concession at Agalteca, Department of Francisco Morazan; (2) a 1,000-hectare concession in the Department of Yoro and Atlántida; and (3) a 1,000-hectare concession in the Department of Comayagua. The Agalteca deposit is a hematite-magnetite iron ore, believed to be high-grade but of limited tonnage.

Salt.—Production of salt by the evaporation of sea water was estimated at 900 metric tons in 1945—the lowest in the past 5 years. Total output is consumed within the country.

Petroleum.—The Government has granted several concessions for petroleum exploration, and other applications are pending; most of these are in the Department of Olancho and the Territory of Mosquitia. The presence of petroleum in commercial quantity has yet to be proved.

NICARAGUA

Gold and silver.—The production of precious metals, as measured by exports, all of which are destined to the United States, amounted to 207,427 troy ounces of gold and 234,379 troy ounces of silver in 1945, showing a slight decline from the 223,910 ounces of gold and 248,529 ounces of silver shipped in 1944. This trend was of some concern to producers, whose hopes of increased postwar production had made inadequate allowance for the time element between the eased supply situation and arrival of new equipment at the mines. Corrective action was under way by February 1946, however, as owners undertook to operate the mines at full capacity 24 hours a day.

As usual in recent years, five major and four minor companies supplied the total gold-silver production of the country. The companies, in the order of value of output, were La Luz Mines, Ltd., Neptune Gold Mining Co., Empresa Minera de Nicaragua, Cía. Minera de La India, Cía. Minera de Jabalí, Cía. Minas Matagalpa, Esmeralda, San Juan Mines Co., and Cía. Minera San Gregorio.

Other metals.—The largest positive reserve of copper ore in Central America has been blocked out at the Rosita mine in the Department of Bluefield, but is not being exploited. Negligible quantities of copper, lead, and zinc are shipped with the gold-silver concentrates.

Salt.—Recovery of salt for domestic use by the evaporation of sea water continued on the west coast at the yearly rate of about 6,000 metric tons. A few hundred tons of salt are imported every year to supplement this supply.

Cement.—Production of cement by Nicaragua's single cement plant at San Rafael del Sur is estimated at 16,000 metric tons in 1945, based on actual production of 3,962 tons in the first 3 months. Production was 10,034 tons in 1944, 10,627 tons in 1943, and 620 tons in 1942, the first year of operation.

Petroleum.—The American International Petroleum & Refining Co., controlled jointly by the Gulf Oil Co. and the Atlantic Refining Co., engaged in a geologic and seismographic search for possible oil structures during 1945 and drilled one deep hole that yielded nothing beyond stratigraphic information.

PANAMA

Until the end of 1942, Panama produced salt and diminishing quantities of gold. The year 1943 saw no mineral production of any kind; 10,000 metric tons of salt were recovered by the evaporation of sea water in 1944 and 2,437 metric tons in 1945, while gold mining remained dormant. Salt production is controlled by the Banco Agro-Pecuario e Industrial, and that of the past 2 years represents the maximum output permitted.

EL SALVADOR

Precious metals.—Metal mining, as measured by United States imports from El Salvador, the only datum now available, was confined to the output of 9,823 troy ounces of gold and 212,864 troy ounces of silver in 1945, compared with 23,204 ounces of gold and 305,922 ounces of silver in 1944.

Nonmetallic minerals.—There is no record of the quarrying of ornamental stone since 1941, when 1,509 metric tons were shipped to the United States. Salt is regularly recovered from sea water in unreported quantity, and about 400 tons are shipped annually to neighboring countries.

SOUTH AMERICA [8]

BY SUMNER M. ANDERSON

ARGENTINA

Under a prolonged policy of military secrecy, Argentina has withheld production figures for the last 2 to 3 years on such mineral items as antimony, chromite, copper, iron and steel, asbestos, barite, construction materials and ornamental stone, clay, diatomite, feldspar, fluorspar, garnet, mineral water, mineral pigments, salt, sulfur, sulfates, talc, volcanic materials, zeolites, asphalites, and coal, while reports on gold, silver, lead, zinc, and tin have been incomplete. Of the materials in this list, however, only gold and silver, lead and zinc, construction materials (including cement, lime, stone, and sand), and salt are produced in important quantities.

Break-down of rail transportation and termination of United States purchasing agreements seriously depressed the mining industry in 1945. Refined-lead production of 21,159 metric tons, of which 6,019 tons were derived from imported Bolivian concentrates, was the lowest in 3 years. Zinc content of zinc concentrates, estimated at 14,300 tons, was approximately 30 percent less than the 1944 output

[8] Unless otherwise indicated, all statistics for South American countries are in metric tons.

and the lowest in at least 7 years. Electrolytic zinc probably changed little from the estimated 1,500 tons in 1944. Amounts of gold and silver mined are unreported; silver refined amounted to 909,352 troy ounces in 1945 compared with 1,723,280 ounces in 1943, consistent with the drop in output of lead and zinc concentrates from which most of the silver is derived. An estimated 550 tons of tin mined in 1945 were approximately 225 tons less than in the previous year and represented only half the 1941 output. Approximate production of tungsten concentrates (60 percent WO_3 equivalent) in 1945, the lowest since 1934, was only 500 metric tons compared with 2,488 tons in the peak year 1944 and 2,420 tons in 1943. Output of beryllium ore (11 percent BeO), which reached 2,186 metric tons in 1941, declined rapidly to about 300 tons in 1944 and only 40 tons in 1945, during which year exportation was prohibited by the Argentine Government. Slightly more than 2 metric tons of tantalite containing approximately 44 percent Ta_2O_5 were mined in 1945 (8 tons in 1944). Output of sheet mica amounted to about 170 metric tons in 1945 compared to 187 tons in 1944 and 525 tons in the peak year 1942.

Following the lead of other Latin American countries, Argentina issued a decree on September 26, 1945, prohibiting the export of uranium minerals, production of which has never been reported.

The outstanding event of the year to the mining industry was Decree 31,559, Department of Industry and Commerce, December 12, 1945, authorizing Yacimientos Petróliferos Fiscales (State Oil Fields) to explore and exploit chromite, tungsten, molybdenum, nickel, cobalt, vanadium, bauxite, kaolin, bentonite, clay, fluorite, barite, "and all other deposits which are to be found within the holdings of YPF." This decree is another long step toward nationalization of the mineral industries and away from the mining code sanctioned by Congress December 8, 1886, which specifically opposed operation of mines by the State.

Reserves of 6,300,000 tons of good-quality coal at the Rio Turbio mine and 2,000,000 tons at Cancha Carrera, Santa Cruz, have been mapped by the Yacimientos Petróliferos Fiscales, adding somewhat to a totally inadequate national supply. Control of both coal and natural-gas exploitation, however, has recently been transferred from YPF to the Dirección National de la Energía. How the control of natural gas will function independently from that of petroleum remains to be seen.

Argentina is second only to Venezuela in South American production of petroleum but requires imports of crude in quantities greater than have been obtainable during the war emergency to meet domestic needs. In 1945 approximately 1,800,000 tons of foodstuffs (mostly grain) were burned to relieve the fuel shortage. Production of crude petroleum attained its peak in 1943, with 27,714,000 barrels. Production in 1945 (with 1944 equivalents in parentheses) amounted to 22,880,910 (24,230,198) barrels, of which 15,439,169 (16,205,925) barrels came from YPF and 7,421,741 (8,024,273) barrels from five private companies. The four producing districts, in order of importance, were Comodoro Rivadavia, Mendoza, Plaza Huincul, and Salta. The refineries of the country processed 23,131,632 (23,634,386) barrels of crude produced domestically and 980,598 (976,686) barrels of imported crude, making a total of 24,112,230 (24,611,072) barrels.

From this intake, 23,107,684 (23,723,182) barrels of refinery products were derived, including, in order of volume, fuel oil, gasoline, Diesel oil, kerosine, agricol (tractor oil), coke, lubricants, asphalt, gas oil, supergas, aviation gasoline, grease, paraffin, and denaturalizers.

Argentina has no pipe lines, aside from field gathering systems. Transportation is handled primarily by river and ocean tankers, of which YPF has an 80,000-ton fleet, and railway tank cars.

In addition to crude petroleum, Argentina produces about 110,000 barrels of natural gasoline and 675 million cubic meters of natural gas annually, but exact output in 1945 has not yet been reported. Wet gas is drawn from all four of the petroleum districts, dry gas from the Comodoro Rivadavia and Plaza Huincul districts only.

BOLIVIA

Minerals comprise well over 90 percent of the total value of Bolivian exports, and exports of metallic minerals (except bismuth and gold), asbestos, fluorspar, mica, and sulfur are regarded as closely indicative of production. On this basis, the total value of mineral production in 1945 was practically the same as in 1944, but some change was seen in proportional distribution. Tin, which supplied 73 percent of the total value in 1944, amounted to 82 percent in 1945; tungsten dropped from 14 to 4.5 percent; silver rose relatively to slightly more than tungsten in value. Quantitative changes are presented in the following table.

Summary of mineral production of Bolivia, 1944–45

[Metric tons, except as otherwise indicated]

Mineral	1944	1945	Difference (percent)
METALS IN CONCENTRATES (EXPORTS)			
Antimony	7,448	5,535	−25.7
Copper	6,170	6,097	−1.2
Lead	9,047	9,508	+5.1
Mercury ... flasks	2	3	+50.0
Silver ... troy ounces	6,797,631	6,683,561	−1.7
Tin	39,341	43,168	+9.7
Tungsten ore, 60 percent WO_3 equivalent	7,935	3,851	−51.5
Zinc	16,319	20,976	+28.5
NONMETALLIC MINERALS (EXPORTS)			
Asbestos	13	61	
Fluorspar		19	
Mica ... kilograms	1,928		−100.0
Sulfur	6,146	617	−89.7
HYDROCARBONS (PRODUCTION)			
Petroleum, crude ... barrels	314,467	[1] 406,114	[1] +29.1

[1] Estimated.

METALS

Antimony.—Bolivia's lowest level of antimony production since 1937 was reached in the second half of 1944 following termination of the purchase contract with the United States Commercial Company at the close of the preceding year and the accumulation of stocks in the United States. In 1945 the demand improved; and output in Bolivia, stimulated also by reduced taxation, climbed fairly steadily throughout the year but at a rate insufficient to raise the total to that of 1944. Only one operating mine in the country is mechanized;

the industry is conducted principally in small and medium mines, without benefit of mechanical equipment. Improvement in 1946 is anticipated because of the price guarantee offered by Banco Minero until December 31, 1946.

Bismuth.—Exports of bismuth in concentrates ordinarily reflect production but are not believed to have done so in the past 2 years. When the purchase agreement with the United States Commercial Company was terminated at the close of 1943, shipments virtually ceased, although concentrates separated as a byproduct of tin mining continued to accumulate within the country. On May 1, 1946, the Banco Minero raised the price on bismuth concentrates, and stocks and current mill output again found a market. Exports of contained metal amounted to 12,419 kilograms in 1943, 605 in 1944, and 15,337 in 1945; the 1945 quantity undoubtedy represented concentrates treated during both 1944 and 1945.

Copper.—The American Smelting and Refining Co. (Cía. American Smelting Bolivina Consolidada) at Corocoro and Mauricio Hochschild, S. A. M. I. (Cía. Minera Huanchaca de Bolivia) have maintained copper production at an even though relatively unimportant rate for the past 6 years. Tonnage output was retarded slightly in 1945 by the shortage of labor.

Gold and silver.—For the past several years recorded exports of gold have been less than production, though to an extent that probably will never be known. The byproduct of other mining is regularly exported in the ores and concentrates of base metals, but a large part of that recovered from placers has escaped the country by smuggling to Argentina and Peru because of (1) the willingness of individuals in those countries to pay more than the world price and (2) the offerings of Banco Central and Banco Minero to purchase at less than world price. By March 1945 purchases of the Banco Minero had dropped to nothing, and the Government attacked the "flight-of-gold" problem by authorizing the two banks to purchase gold at world prices in foreign exchange, which may be utilized to import luxury goods, effective May 23. Purchases during the remainder of the year increased greatly. Negotiation for a new contract for exploitation of the Tipuasi-Rio Kaka were started, to replace the old contract abrogated in 1944. If successfully concluded, this should increase production further in 1946. Official exports amounted to 4,561 troy ounces in 1944 and 28,901 ounces in 1945.

Bolivia is surpassed only by Mexico and Peru in Latin American production of silver. Exports, which showed a negligible decrease in 1945, consist of silver contained in the ores and concentrates of base metals—principally tin.

Lead.—Production of lead, which threatened to decline further in 1945, was maintained and slightly improved by an advanced price schedule established May 1 by the Banco Minero and a reduction in freight rates obtained in April on the Villazón-Atocha Railway in southern Bolivia. Cía. Huanchaca de Bolivia continued to be the country's leading producer; and, as usual, about 60 percent of the total output went to Argentina for smelting. The Government is discussing construction of a lead smelter in southern Bolivia to further stimulate the industry, and the outlook for 1946 is good.

Tin.—Production of tin in 1945 fluctuated with price, with the bulk of the year's over-all increase showing between March 3 and October 1, when the contract agreement between the United States Commercial Company and independent producers called for payment of U. S. $0.63½ per pound of contained tin. Price was $0.60 under the old contract and $0.62 during the last quarter of 1945. Individual mines that showed the greatest increase were the Colquiri and San José-Machacamarca mines of Cía. Minera de Oruro and the Chorolque mine of Cía. Aramayo de Mines en Bolivia, all exploiting rich viens discovered in late 1944 and early 1945; the Santa Fé mine of Empresa Minera de Santa Fé; the Chojlla Tanapaca mine of International Mining Corp. (W. R. Grace); and the Huanuni mine of the Bolivian Tin & Tungsten Corp., which suspended operation in the last quarter to install a new flotation plant. Other operations that were suspended during the year—all small—include Patino's Colquechaca mine on January 15, and the Japo mine of Bolivian Tin & Tungsten Corp. and the Vino mine of Cía. Minera de Oruro on April 1. The Bolivian International Mining Corp., which suspended in 1944, reopened dredging operations June 18. To permit continuation of operation by small miners, the Government on May 21 suspended collection of the principal export tax on tin, but in June the Banco Minero stopped purchase from the Department of Potosi of ore containing less than 18 percent tin and raised the limit to 20 percent on the first of August. This limitation had little effect other than on the small producers, but it raised the average grade of ore sold to the United States Commercial Company from 37.28 percent in the second quarter to 39.03 percent in the third quarter of the year. United States purchases are smelted at Texas City; output of mines belonging to the Patino interests continued to be sold by contract to England.

The new sink-and-float plant at Patino's Llallagua mine at Catavi showed promise of successful operation in 1946, but the Tainton-process plant of Cía. Minera Unificada del Cerro de Potosi (Mauricio Hochschild) continues to be a failure.

Contract prices with Bolivian independent producers call for payment of $0.60½ per pound for tin delivered in the first quarter of 1946 and $0.58½ per pound in the second quarter. Production outlook for the year is uncertain and will be strongly influenced by prices prevailing during the second half of the period.

Tungsten.—Although tungsten-ore production attained its wartime peak in 1944, a downward trend followed price reductions in July and November, and the year closed with termination of the purchase contract with the United States Commercial Company. On January 30, 1945, one of the major producers—the Bolsa Negra mine of Mauricio Hochschild—was forced to follow the example of many smaller producers by suspending operations. Improvement of demand and price during the second and third quarters collapsed in the fourth, and the industry failed to respond to a major reduction in export taxes; 1945 closed with a total output of tungsten ore less than half that of the preceding year and the expectation of further decline in 1946.

Zinc.—Zinc mining recovered from its 1944 decline to within 98 tons of peak production in 1943. The turn came in the second quarter, with the opening of important markets in Great Britain, Belgium, France, and Spain, supplementing that in the United States. Ore from the Cía. Huanchaca de Bolivia, the country's most important zinc producer, contains silver, and production received additional upward impetus following the United States price increase for foreign silver on September 21. Output of zinc in 1946 is expected to exceed that of 1945.

NONMETALLIC MINERALS

Asbestos.—Asbestos mining, never important in Bolivia, has supplied exports decreasing from 211 tons in 1941 to 22 tons in 1943 and 13 in 1944. Mining was resumed east of Cochabamba in 1945, and 61 tons were shipped; the fiber is unsatisfactory for spinning but good for cement shingles. Requirements of the Argentine market appear to justify a prediction of increased production in 1946.

Fluorspar.—Investigations of deposits, made during the early part of 1945, led to Bolivia's first production and export of fluorspar, amounting to 19 tons. Continued exploitation of the mineral will be determined by price.

Other nonmetallic minerals.—Exploitation of a mica-columbite deposit near Santa Cruz failed to materialize, and mica exports dropped to nothing. Shipments of sulfur to neighboring countries dwindled from a few thousand to a few hundred tons. Production of cement, stone, clay, and salt for domestic use has not been reported.

HYDROCARBONS

Petroleum.—Development of Bolivia's oil industry was curtailed during the war by scarcity of materials. Though relatively unimportant quantitatively, production in 1945 showed a substantial percentage increase over 1944, and an aggressive drilling campaign is planned as soon as machinery and equipment become available in adequate amount. Of the estimated 406,114 barrels of crude petroleum produced in 1945, about 174,485 barrels came from the Bermejo field, 129,448 barrels from the Camiri field, and 102,181 barrels from the Sanandita field. A refining plant of 400 barrels daily capacity is operated at Sanandita and an 800-barrel plant at Camiri.

Since 1937 the Bolivian oil industry has been operated as a State monopoly through Yaciementos Petrólifera Fiscales Bolivina. Plans for expansion include working agreements with the Governments of Argentina and Brazil for joint exploration and development, wholly within Bolivia.

BRAZIL

At the time of review, 1945 figures on production had not been received from Brazil, and export statistics were incomplete. The overall minerals outlook at the end of the year was somewhat confused as a consequence of the deflationary trend resulting from termination in mid-1944 of several of the United States Government buying programs which had stimulated the Brazilian industry during most of the war period, although activity of the United States Commercial Company continued well into 1945 in some lines—notably mica and quartz crystal.

METALS

Aluminum.—The first aluminum metal to be made south of the Rio Grande was poured on March 29, 1945, at the new plant of Electro-Quimica do Brazil at Saramenha, near Ouro Preto, Minas Gerais. The plant is expected to attain an annual capacity of 2,500 metric tons of ingots, though by midyear only half the electric pots had been installed and the amount of current available was sufficient to permit production of only about 1,500 tons annually. Bauxite for the plant is obtained from the Ouro Preto deposit. Total Brazilian production of bauxite in 1945 is not known; exports (to Argentina) were 7,061 metric tons, compared with 2,979 tons in 1944.

Beryl, tantalite, and columbite.—These ores are ordinarily mined together from deposits that were not worked in 1945. The Departmento Nacional da Produção Mineral will not authorize export of beryl and tantalite at prices less than specified by Decree 224 of May 15, 1944, and reaffirmed by Decree 377 of June 1, 1945, which are about 80 percent higher than those last paid by the United States Commercial Company. Despite these decrees, 510 metric tons of beryl and 30 tons of tantalite were exported to the United States in 1945 from stocks, compared with 1,185 tons of beryl and 201 tons of tantalite in 1944. Columbite has not been shipped since 1942. Stocks at the end of 1945 amounted to 15 tons of tantalite and an estimated 500–750 tons of beryl; stocks of columbite are not known.

Chromite.—Chromite production, as measured by exports, which reached a peak of 7,813 metric tons in 1943, dropped to 4,721 tons in 1944 and 1,490 tons in 1945. Most if not all of the 1945 shipments were made by Chromium Mineração, S. A., from its property near Píuhy, Minas Gerais. Port stocks at the end of the year may have been sizable, as Chromita do Brazil, S. A., reported during the third quarter that it had been producing and shipping about 300 tons of chromite per month to São Paulo.

Gold.—Hoarding and smuggling of gold to an estimated extent of about a million grams (32,000 ounces) a year were practiced in 1943 and 1944, and on June 19, 1945, the Finance Ministry announced that producers would no longer be required to sell their gold to the Banco do Brazil, though the bank continues controls over gold exports and imports. Bank purchases from both underground and alluvial mines were much less in June and subsequent months than previously, but production is not believed to have declined substantially from the estimated 178,300 ounces of 1944.

Iron and steel.—Brazilian exports of iron ore increased 46 percent from 205,797 metric tons in 1944 to 299,994 tons in 1945. The principal export market is in Great Britain. In addition, an estimated 475,000 tons of iron ore was produced to supply the 25 charcoal blast furnaces in Brazil.

Progress on construction of the new iron and steel plant of National Steel (Companhia Siderúrgica National) at Volta Redonda is indicated by the following table.

Volta Redonda steel project—percent completion, end of year

Unit	1944	1945
Sewers and drains	100	100
Coke ovens and coke byproducts plant	98	100
Blast furnace	97	100
Water-supply system	95	100
Gas storage tanks and distribution system	65	100
Shops	95	99
Grading	88	98
Steam electric generating plant	80	98
Open-hearth furnaces	58	93
Plant railway	59	75
Electric power distribution system	55	74
Rolling mills	20	40

On February 20, 1946, the coke ovens were lighted for initial warming up, and production of pig iron is expected before the end of the year.[9]

Lead.—Companhia Plumbum, S. A., recovered lead carbonate and sulfide ore from the Panelas, or Brejauvas, mine near Ribeira, São Paulo—the only lead mine known to be active in 1945. In September the company produced its first lead bullion in a plant completed near the start of the year and equipped to refine lead and recover precious metals. Production of 7 tons of lead a day is anticipated, but the plant is handicapped by lack of adequate fuel; initial operations utilized charcoal.

Manganese.—While exports of manganese ore jumped from 146,983 metric tons in 1944 to 244,649 tons in 1945, production is estimated to have dropped from 203,751 to roughly 196,000 tons in the same period.

Titanium.—Exports of titanium ores in 1945, with comparable figures for 1944 in parentheses, were as follows, in metric tons: ilmenite, 5,000 (3,250); rutile, 160 (1,564); total, 5,160 (4,814). All but 53 tons of rutile (20 tons in 1944) went to the United States.

Tungsten.—Exports of tungsten ore (60 percent WO_3 equivalent) increased from 2,221 metric tons in 1944 to 2,242 tons in 1945. Of the 1945 total, it is estimated that about 1,925 tons represents scheelite from northeastern Brazil and 114 tons wolframite from the Inhandjara mine in São Paulo. The grade of the shipped concentrates is believed to range from 65 to 70 percent WO_3.

Zirconium.—Zirconium ore (caldasite) exports dropped from 2,152 to 758 metric tons in the 1944–45 period. The ore was mined in São Paulo and southwestern Minas Gerais; all but 35 tons in 1944 and 49 tons in 1945 went to the United States.

NONMETALLIC MINERALS

Amblygonite.—This ore of lithium is a byproduct of beryl-tantalite mining in Brazil. Exports dropped from 600 metric tons in 1944 to nothing in 1945, when the beryl-tantalite mines were shut down.

[9] According to the Brazilian press, blowing-in of the 1,000-ton blastf urnace a Volta Redonda took place on June 9, 1946.

Barite.—Companhia Pigmentos Minerais Industrial e Comercial, S. A., proceeded with development of the ore body, installation of a mining and milling plant (completed January 22), and construction of an ore-loading dock on Camanũ Island, Bahia. A flotation mill was bought in Cuba for transfer to the property. All mining will be open-cut; enough development work has been done to assure 1,000,000 metric tons of barite, ranging from 88 to 98 percent $BaSO_4$. Production started early in the year, and the first shipment was made in April.

Cement.—The unusual building activity of the last 5 years has given tremendous impetus to cement consumption in Brazil. A reduction from the 1944 output of 809,908 metric tons is implied in the 15.7-percent reduction in electric power sales to the cement industry in 1945, although official sources have estimated an increase to approximately 815,000 tons. Imports have been reported as 101,755 metric tons in 1944 and 254,757 tons in 1945. Exports never greatly exceed 1,000 tons. Seven plants were in operation in 1945, and an extension of total capacity is planned for 1946.

Diamonds.—Diamond exports in 1945, compared parenthetically with 1944, were as follows, in carats: Gemstones, cut and rough, 91,910 (192,185); carbonados 3,910 (10,795); total 95,820 (202,980), of which 94 (97) percent went to the United States. A comparable decrease in production is believed to have taken place. Prices, high in the first quarter, were nearly equalized with those of the London syndicate in the second, when demand for rough stones by the local cutting industry exceeded supply, and stones—mainly small and melee—were imported from the United States and the Union of South Africa.

Mica.—Mica exports of 985 metric tons in 1945, compared with 941 tons in 1944, were the highest since 1940. With the tightening of grade specifications, many small operators were forced to shut down in the early part of the year with unsalable stocks on hand, and production declined until May, when the United States Commercial Company initiated a program of granting loans to exporters based on their purchases and stocks in the interior. Output improved greatly and was well-maintained until November 30, when all mica-purchasing agreements with the United States Commercial Company were terminated. The year closed with mica exporters establishing private marketing contacts.

Monazite.—Substantial recovery was seen in the export of 1,031 metric tons of monazite in 1945, compared with 3 tons in 1944 and 1,550 tons in 1943. Brazilian monazite is said to contain better than 6 percent thorium.

Quartz crystal.—Purchases of quartz crystal declined rapidly following the military collapse of Germany and were reflected in exports of only 609 metric tons for the total year 1945 (the lowest since 1938), compared with 1,122 tons in 1944. Based on statistics for the first 9 months of 1945, 77 percent of purchases were by private buyers in the United States, 15 percent by the United States Commercial Company (which terminated its purchase agreement on December 31), and 8 percent by Great Britain. The days of flush production in Brazil are past; several important deposits have been exhausted, and no new major discoveries have been made since 1941, and quality has declined steadily since 1943. Well-known areas that have been either abandoned or seriously reduced in productivity include the Pacú district among others in Minas Gerais, the Cristalina and Pium districts in Goiaz, and the Xique-Xique and Mimosa districts in Bahia.

Semiprecious stones.—End-of-the-war demand for jewelry was reflected in the spectacular increase in exports of semiprecious gemstones from 483,601 grams in 1944 to 1,895,041 grams in 1945. The more important stones usually included in this group are citrine, amethyst, aquamarine, garnet, topaz, gem agate, tourmaline, and turquoise.

HYDROCARBONS

Coal.—Efforts to improve the output of the southern Brazilian coal mines appear to have been successful relative to 1944 clean-coal production of 1,433,158 metric tons but to have fallen considerably short of expectations. Production in the first 6 months of 1945 was recorded at 1,043,994 tons as against 863,900 tons during the comparable period in 1944. Demand was and will continue to be strong, and opinion is to the effect that requirements of the Volta Redonda iron and steel plant, from the viewpoint of quality as well as quantity, will have to be heavily supplemented by imported coal for at least the next few years.

Petroleum.—Brazil's 7-year-old petroleum industry maintained production at 79,326 barrels in 1945, compared to an estimated 80,000 barrels in 1944. Distribution of 1945 production, in barrels, showed 36,663 from the Candeias field, 29,221 from the Itaparica field, 6,728 from the Lobato field, and 6,714 from the Aratu field. During the year 12 wells were completed, of which 2 were dry, 9 produced oil, and 1 struck gas. Production and utilization of natural gas have not been reported. The entire oil and gas industry is controlled by the Government-owned Conselho Nacional do Petroleo and is thus far confined to the State of Bahia.

BRITISH GUIANA

Bauxite.—Exports of bauxite from British Guiana continued to decline in 1945, amounting to 750,398 metric tons, compared with 891,103 tons in 1944 and 1,931,910 tons in the peak year 1943. (Actual production, in metric tons, over the same period was: 1945—678,482; 1944—928,178; 1943—1,919,060.) Most of the output was from the Demerara Bauxite Co., Ltd. (Aluminum Co. of Canada), but a small portion came from the Berbice Co., Ltd. (American Cyanamid & Chemical Corp.), which, inactive since 1943, resumed production late in 1945. The principal outlet for bauxite from British Guiana shifted in 1940 from the United States to Canada. In 1945 the United States took only 3,371 of the total tons exported. Decreased total exports are expected in 1946 and 1947.

Gold.—The trend of gold production that started down in 1939 turned upward in mid-1945 to bring the total year's output to 22,533 troy ounces, compared with 18,986 in 1944, 19,470 in 1943, and 29,267 in 1942. The increase is the result of discovery of new lode deposits and completion of a new cyanide plant by Cuyuni Goldfields, Ltd., and the discovery of new placer deposits by British Guiana Consolidated Goldfields, Ltd. In consequence of proposed further expansion by both companies—the only two gold-mining companies now operating in the Colony—and entrance into the industry of two new organizations—the Rupununi Gold Mining Co. and the Wairiri Gold Mines—production in the next several years is expected to exceed the 1938 output of 38,482 ounces. That portion of production furnished by individual prospectors probably will not change substantially.

Since 1940, increasing amounts of gold have been sold within the Colony, where a ready market has been afforded by the small jewelry-manufacturing industry, largely operated by East Indians. Exports, chiefly to the United States, amounted to 9,711 ounces in 1945; 7,571 in 1944; 11,611 in 1943; 18,572 in 1942.

Diamonds.—Depletion of readily available deposits, lack of proper internal transportation, high cost of food in the interior, lack of organization of the industry, and loss of miners to other industries are held responsible for the continued decline in the production of diamonds, which has dropped from more than 214,000 carats in the peak year 1923 to only 15,442 carats in 1945. Exports of diamonds, however, rose to 17,251 carats valued at $513,677 (the highest value since 1933) in 1945 from 13,911 carats valued at $327,310 in 1944. In order to encourage the Colony's small cutting and polishing industry, established in early 1944, the export duty on cut diamonds and cut and polished diamonds was abolished.

Granite.—Output of quarried granite amounted to 25,688 metric tons in 1945, slightly more than in the years 1941 and 1942. Production was only 7,833 tons in 1943 and none in 1944.

CHILE

Production figures for Chile in 1945 are totally incomplete and have been only partly estimated at the time of review, although trends are reasonably clear. Mining in general declined from the high level of 1944 but continued to be the mainstay of the Chilean economy, supplying 80 percent of the value of total exports; on the whole, the industry enjoyed one of the best years on record.

METALS

Copper.—Refining of copper was down some 7.6 percent from the previous year, subsiding from an estimated 500,573 metric tons in 1944 to 462,588 tons in 1945. The decrease was the normal result of the close of the war, but was not as abrupt as anticipated. The United States Commercial Company reduced its purchases from the large American producers (Chile Exploration, Andes Copper, and Braden Copper) and on September 30 canceled its contract with small producers, most of whom suspended operations shortly thereafter. The custom smelter at Naltagua ceased operations during the first quarter after more than 37 years of continuous service, and Chile's only other custom smelter at Chagres was shut down on November 19. The two smelters together produced 11,118 tons of copper in 1945, and their elimination makes it increasingly difficult

717372—47——103

for the few remaining Chilean operators of small mines to dispose of their ores and concentrates, which cannot be sold profitably to United States smelters because of high freight rates and production costs.

The reopening of European markets is not regarded as adequate to arrest a continued decline of production in 1946.

The industry suffered one of the most tragic disasters in mining history on June 19, when 354 persons were killed in an underground fire in El Tiente mine of the Braden Copper Co. Two persons subsequently died, and 100 recovered from injuries received.

Gold and silver.—Preliminary estimates indicate a 28-percent drop in the output of gold, from 243,883 troy ounces in 1944 to 180,462 ounces in 1945. The sharpest cut-back appears to have been in gold contained in ores, concentrates, and copper bars, which were directly tied in with United States Commercial Company contract. Silver, mostly a byproduct of other metal mining, is believed to have declined below the million mark in 1945. The estimate of output in 1944 was 1,094,894 troy ounces.

Iron.—With wartime curtailment of shipping, production of iron ore dropped from a roughly normal 1,600,000 tons annually to less than half a million in 1942 and 1943. Output was stepped up to 674,529 metric tons in 1944 and was further revived at the end of the war, bringing the total in 1945, when shipments to the United States were resumed, to 944,863 tons. Chilean pig-iron production, amounting to only about 6,000 tons annually, indicates the probability of large accumulated stocks of iron ore at El Tofo mines.

Manganese.—Although manganese mines in the Provinces of Coquimbo, Atacama, Antofagasta, and O'Higgins were shut down in mid-1944, interest is reviving. During the war, and prior to the shut-down, 234,000 tons of ore were stock-piled; and during the first 11 months of 1945, 86,064 tons were exported, mostly to the United States, compared with 4,038 tons in the equivalent period of 1944. Although it is true that a large part of the wartime production was made possible by premium prices, a number of the properties are capable of substantial output for normal markets if properly managed.

Mercury.—Mercury production by Chile's only mine at Punitaqui, Coquimbo, is believed to have stayed at roughly the 1,000-flask level to which it dropped in 1944. Small shipments were made to the United States and Argentina.

Molybdenum.—Separation of molybdenum concentrates from copper ores was pushed to about 1,800 tons in 1944 and held at virtually the same rate for 1945. About half the 1945 output was in port stocks at the end of the year; shipments were to the United States and Great Britain.

NONMETALLIC MINERALS

Nitrates and associated salts.—The production of natural nitrate, which declined steadily from 1,437,451 metric tons in 1940 to 973,615 tons in 1944, has been greatly stimulated in Chile since the end of the European phase of the war and a survey of Germany's reduced synthetic nitrate industry, resulting in recovery to an output of 1,366,877 tons in 1945. During the first half of the year ships for transport to consuming centers were obtained with great difficulty; but the situation eased considerably in the latter half, and accelerated activity was noted in the nitrate ports of Chile, particularly Tocopilla. Still of first importance to the Chilean industry is the disposal to be made of the war-born synthetic nitrate industry of the United States, and Chilean producers have endeavored to put every possible ton of production capacity into operation to recapture and hold a place on the future market. The two plants using the Guggenheim process—Maria Elena and Pedro de Valdivia—were producing at capacity for the first time in history. These two plants, together with the new Victoria plants of Cía. Tarapacá y Antofagasta, account for about two-thirds of Chile's nitrate production; plants employing the Shanks process, of which 19 were in operation at the end of the year, account for the other third. This third embraces the uneconomical part of the industry, employing hand methods at higher costs of operation. The number of nitrate "oficinas" in operation at the end of the year was 22, compared with 14 at the end of 1944.

Recovery of iodine and such minerals associated with nitrates as sodium, calcium, and magnesium sulfates, borax, potassium chloride, and sodium carbonate has not been reported for 1945, though sodium sulfate is known to have responded to an active market.

Other nonmetallic minerals.—No record of output of the various minor nonmetallic minerals is as yet available for 1945. Cement was in short supply throughout the year, and both of the country's two plants were shut down by strikes during part of the last quarter. Sulfur exports, all to Argentina, nearly doubled those of 1944; but production was down, and the plant of one company, Cía. Andes, was destroyed by fire October 4. Possibility of substantial increase in production is seen in the proposed development of a large and rich sulfur deposit in the high Cordillera east of Copiapó. Activity in the production of limestone, gypsum, clay, salt, phosphate rock, mineral pigments, kieselguhr, feldspar, quartz, and talc ranged from unspectacular to dormant, and in some lines cut-backs or shut-downs are anticipated with return to normal channels of international trade.

HYDROCARBONS

Coal.—Coal production dropped about 10 percent from that of 1944 to an estimated 1,836,000 metric tons (net weight) in 1945. Production and consumption were nearly in balance for the first half of the year, but at the end of the year a critical shortage was facing Chile, primarily as a result of labor difficulties in the principal coal-mining districts. The largest mine in Magallanes Province was closed early in the year, terminating shipments of coal from that district to Argentina. The immediate coal problem facing Chile is the development of new mines on its proved lands.

Petroleum.—The outstanding mineral development during 1945 was the discovery of oil at Springhill, 6 miles from the north end of the Straits of Magellan on the island of Tierra del Fuego, on December 29. The premium-quality paraffin-base oil has an estimated free flow of 200 barrels daily and represents the world's farthest-south production. The well was completed at 7,460 feet, and the producing Tertiary beds lie between 7,419 and 7,438 feet. A second test penetrated the same beds near midyear 1946, with negative results, but successful development of a field is anticipated.

From 1930–37, seven tests were drilled in the vicinity of the Straits, of which 1 produced 30 barrels of oil. The 1945 discovery resulted from seismic exploration by an American geophysical company that has been mapping the area since 1941 under the supervision and control of the semifiscal Fomento Corp., which plans further exploration and, if successful, installation of storage facilities and a pipe line to the nearest deep-water port, and construction of a refinery. The potential value of a native petroleum industry to Chile cannot be overestimated.

The discovery has revived speculation regarding the possibilities of petroleum development in Antarctica.

COLOMBIA

METALS

Precious metals.—Production of gold and silver declined appreciably in 1945, while that of platinum, stimulated by strategic need in the United States until the close of hostilities, registered a slight gain. Output in 1945, with comparable figures for 1944 in parentheses, was as follows, in troy ounces: gold, 506,695 (553,530); silver, 168,699 (197,323); and platinum, 34,758 (34,304). Total platinum exported, amounting to 35,129 ounces, went to the United States.

Iron and steel.—Starting in 1942, a small iron furnace at Capitanes has been producing about 1,500 metric tons of iron annually for sale to domestic foundries.

Progress of the steel plant of Empressa Siderúrgica, S.A., at Medellín, which started operating on a commercial scale in 1944, has not been reported for 1945. A new project sponsored by the Instituto de Fomento Industrial plans construction of a plant to utilize the iron-ore deposit at Paz del Rio for the annual production of more than 100,000 tons of such iron and steel products as rails, structural shapes, reinforcing rods, wire, and cast-iron pipe. Adequate capital for the project is believed to be obtainable from Latin America and Europe; United States capital has been unresponsive.

Lead.—Exploration for new lead deposits was terminated without success in March 1945. A small pilot plant at Mochancuta has produced 10 metric tons of metallic lead in 1942, 4 tons in 1943, nothing in 1944, and 20 tons in 1945.

NONMETALLIC MINERALS

Barite.—About 2,600 tons of barite have been mined in each of the past 2 years, mostly from open-cuts at Los Santos in Santander, but supplemented by several small mines in southern Tolima. Extensive reserves of barite, as yet unexploited, were discovered only a few years ago at Chiriguaná, Magdalena. The mineral is sold chiefly for use in oil-well drilling; very minor amounts are used in the local manufacture of paint and other commodities.

Clay.—Clay is undoubtedly produced in larger tonnage than any other industrial mineral in Colombia, but its exploitation is scattered among so many small manufacturers of tile, brick, and other ceramic products that production figures are not obtainable.

Cement.—Notwithstanding shortages of machinery replacements, spare parts, paper bags, and trucking equipment, the six plants of five companies pushed Colombia's cement production to a new record, continuing an upward trend that has been broken but once (1942) since 1935. Production in 1945 amounted to 300,981 metric tons, compared with 281,626 tons in 1944. Plans for the construction of two additional cement plants, announced in 1944, have not yet materialized.

Emeralds.—The Muzo emerald mines ceased operations in 1938—the Chivor mines about 1940—pending sale of a large stock of stones that had accumulated in the Bank of the Republic, which has a Government monopoly on the sale of uncut emeralds for export. The largest recent single transaction was the sale to a United States firm of stones valued at $685,000 during the first week of 1946.

Gypsum.—Estimates of gypsum production, used mostly for the manufacture of cement, indicate a rise from roughly 13,200 metric tons in 1944 to 17,200 tons in 1945.

Salt.—In 1944 Colombian total production of salt was unreported, but that recovered from the evaporation of sea water amounted to 31,671 metric tons. In 1945 only 14,445 tons were so derived, plus 90,627 tons in brines and rock salt, making a total salt output of 105,072 tons for the year.

Other industrial minerals.—In an attempt to contribute as much as possible to the strategic mineral need of the United Nations during 1942–44, efforts were made to find and exploit deposits of mica, optical calcite, and quartz crystal. These efforts resulted in negligible production, however, and were abandoned before 1945 as commercially unprofitable.

HYDROCARBONS

Coal.—Coal production, which rose steadily from 1941 to the end of 1944, had not yet been reported for 1945 but may be expected to have retained a position close to or exceeding the half-million-ton mark reached in the preceding year. Exports amounted to only 137 metric tons in 1944 and 177 tons during the first 7 months of 1945.

Petroleum.—Crude petroleum attained its highest output since 1941 with 22,824,941 barrels in 1945; 19,542,689 barrels were exported and 4,883,631 barrels refined within the country. Comparable figures for 1944 are 22,647,476 barrels produced, 18,561,431 barrels exported, 3,854,742 barrels refined.

With completion of a pipe line connecting Casabe with the line of Andian International Corp. that leads from the De Mares concession to Cartegena, the Casabe concession of Cía. de Petróleo Shell de Colombia went into full field production for export on June 6, 1945. Most of the total production, as in past years, came from the De Mares concession of the Tropical Oil Co. and the Barco concession of the Colombia Petroleum Co. Developments during the year include opening of the new Galan field in the De Mares concession and completion of seven producing wells in Shell's Dificil field in the lower Magdalena Valley. Less promising areas were opened by Socony-Vacuum at Cantagallo, Bolivar, and by Socony and Tropical in northwestern Colombia.

Refinery products were the output of the Tropical Oil Co.'s large and complete plant near Barranca-Bermeja and Colombia Petroleum Co.'s small topping plant in the Petrólea field.

ECUADOR

Gold and silver.—Operation of the gold-silver mine of the South American Development Co. at Portovelo was below normal during most of 1945 because of the break-down in January of one of the two hydroelectric plants, following flooding of the mine at the close of 1944. High operating costs have forced high-grading of the mine to meet expenses; and by the end of 1945 only low-grade ore remained, and the life of the mine was reported to be shortening rapidly. The possibility of continuing exploration work will probably be determined by the results of operation in 1946.

The Macuchi silver-gold-copper mine of the Cotopaxi Exploration Co. also operated on a reduced scale in 1945, and failure to find a new ore body forced the company to notify the Government in May 1946 that exploitation of ore would cease, probably before the end of the year.

Combined production of the above two companies amounted to an estimated 66,975 troy ounces of gold and 255,965 ounces of silver in 1945, compared with 84,234 ounces of gold and 376,565 ounces of silver in 1944.

Copper and lead.—Ecuadoran copper and lead production amounted to 3,649 and 159 metric tons, respectively, in 1945, as against 3,009 and 485 metric tons, respectively, in 1944. Nearly all of the copper is in the form of blister bars from the Macuchi smelter; the lead is contained in concentrates derived from the ores of both the Macuchi and Portovelo mines. Consequently production of copper and lead is expected to follow the downward trend of gold and silver in 1946.

Cement.—The Estero Salado plant of La Cemento National, C. A., near Guayaquil—built in 1922 and the only cement plant in Ecuador—has been operating on an upward trend since 1938 or before and has doubled its output between 1942 and 1945. The new record production of 40,617 metric tons in 1945 was a 15.7-percent advance over the previous 1944 peak of 34,691 tons. However, production continues to lag behind demand, largely because of domestic activity in highway construction, and had to be supplemented by imports from Great Britain and the United States in 1945. Ecuadoran cement exports to Peru and Colombia in the spring of 1945 have been explained by internal transportation difficulties that resulted in a temporary accumulation in excess of the company's storage capacity. The general cement shortage and the monopolistic position of the company have combined to create exorbitant prices that are said to have reached as high as 90 sucres ($6.75) per sack. Relief is seen in an announced plan to construct a new plant of 200 tons daily capacity at Riobamba, to supply the needs of the Sierra region and to utilize hydroelectric power, fuel (lignite), and raw materials that can be developed locally.

Minor industrial minerals and hydrocarbons.—Marine salt production was maintained at an adequate level, although it declined 23.2 percent from 35,958 metric tons in 1944 to about 27,600 tons in 1945. The reported 1945 production of other minerals, compared in parentheses with 1944, was as follows, in metric tons: China clay, 40 (38); geyerite, 65 (89); iron oxide, 4 (111); ocher, 6 (not reported); crude sulfur, 103 (13); natural asphalt, 3 (9); and coal, 41 (76). Quantitative production of gypsum, lime, and stone has not been reported. New mining claims filed during the year included six for china clay, seven for gypsum, and one for ocher.

Petroleum.—Crude petroleum production, as usual, was confined to the peninsula of Santa Elena and was distributed among fields as follows during the past 2 years:

Ecuador—production of crude petroleum, 1944–45

[Barrels of 42 gallons]

Field:	*1944*	*1945*
Ancon-Santa Elena	2, 151, 392	1, 966, 358
Carolina-Santa Paula	36, 249	56, 292
Concepcion	90, 839	103, 286
El Cautivo	41, 586	434, 886
El Tigre	520, 195	
El Tambo	751	832
Petropolis	125, 957	102, 072
Total	2, 966, 969	2, 663, 726

Anglo-Ecuadorian Oilfields, Ltd., accounted for all of the output from the Ancon and part from El Tigre fields; the remainder, in descending order of importance, was supplied by Ecuador Oilfields, Ltd., Concepcion Ecuador Oilfields, Ltd., International Ecuadorian Petroleum Co., Carolina Oil Co., and Petropolis Oil Co.

Shell Oil Co. completed at 5,187 feet the first test well in its 25,000,000-acre concession in eastern Ecuador. It was unproductive, but three other tests are planned for 1946. This represents the first drilling in Ecuador to explore for oil in the great llanos region east of the Andes.

In addition to crude petroleum, 38,408 barrels of natural gasoline in 1944 and 41,768 barrels in 1945 were produced in the Santa Elena district. Output of refinery products (exclusive of losses) by the three plants of Anglo-Ecuadorian at La Liberdad, Ecuador Oilfields at Cuativo, and Carolina Oil Co. at Carolina amounted to 961,215 barrels in 1944 and about 913,000 barrels in 1945.

FRENCH GUIANA

Gold.—Placer mining of gold in French Guiana has declined steadily since the beginning of World War II, due to degeneration of general conditions rather than any serious depletion of resources. United States imports of gold from French Guiana amounted to only 7,761 troy ounces in 1945 (13,224 ounces in 1944). (Exports from French Guiana in 1939 totaled 37,606 ounces). Gold mining is the only mineral industry in the colony.

PARAGUAY

Paraguay has no established mining or mineral industry. The Union Oil Co. of California, under contract with the Paraguayan Government, engaged in seismographic and gravimetric surveys of prospective oil lands throughout the year and expects to start test drilling in the Chaco of northern Paraguay in 1946.

PERU

PRODUCTION

In general, Peruvian mineral production in 1945 declined appreciably from that of 1944. Exceptions for which increases were recorded included gold, silver, mercury, and vanadium among the metals, manufactured building materials (cement, lime, calcined gypsum) and salt among the nonmetallic minerals, and coal and natural gasoline. Comparative production in the last 2 years is presented in the following table.

Summary of mineral production of Peru, 1944–45

[Metric tons, except as otherwise noted]

Mineral	1944	1945	Change (percent)
METALLIC ORES AND METALS			
Antimony	1,058	[1] 781	−25.6
Arsenic oxide (white arsenic)	6,899	6,397	−7.3
Bismuth kilograms	416,159	309,000	−25.7
Cadmium do	2,174	1,250	−42.5
Copper	32,396	[1] 28,839	−11.0
Gold troy ounces	175,180	[1] 180,402	+3.0
Lead	52,501	[1] 51,935	−1.1
Mercury flasks (76 pounds net)	152	[1] 209	+37.5
Molybdenum	62	[1] 30	−51.6
Silver troy ounces	15,832,440	[1] 16,081,833	+1.6
Tin, in dross		125	
Tungsten concentrates, 60 percent WO_3	635	[1] 317	−49.9
Vanadium	518	620	+19.7
Zinc	56,263	[1] 38,400	−31.7
NONMETALLIC MINERALS			
Aluminum sulfate	80	[1] 150	+87.5
Barite	2,352	3,000	+27.6
Clay	7,924	[1] 9,000	+13.6
Cement	248,537	[1] 255,000	+2.6
Gypsum, calcined	25,190	[1] 27,000	+7.2
Lime	82,997	[1] 100,000	+20.5
Magnesium sulfate	663	[1] 650	−2.0
Manganese sulfate	89	25	−71.9
Mica	113	[1] 20	−82.3
Mineral water gallons	1,701,266	1,717,170	+.9
Quartz and marble	3,878	6,500	+67.6
Quartzite and other rock	(2)	[1] 3,000	(2)
Salt	53,818	[1] 60,000	+11.5
Silica	(2)	[1] 8,000	(2)
Sulfur	611	[1] 650	+6.4
HYDROCARBONS			
Coal:			
Anthracite	14,545	[1] 28,000	+92.5
Bituminous	158,814	[1] 160,000	+.7
Total	173,359	[1] 188,000	+8.5
Natural gasoline barrels (42 gallons)	1,033,768	1,075,137	+4.0
Petroleum, crude do	14,385,926	13,748,228	−4.4

[1] Estimate, subject to revision.
[2] Not reported.

METALLIC ORES AND METALS

Antimony.—Some antimony mines have maintained operations throughout 1945 and are expected to continue, notwithstanding comparatively low prices. Decline in production dates from 1943, during which peak year the United States Commercial Company discontinued its antimony purchase contract. Of the total 1945 output, 269 tons was the metallic product of the Cerro de Pasco plant at Oroya.

Byproduct metals.—The 1945 decrease in output of white arsenic, bismuth, and cadmium was normal to the decrease in the smelting of copper, lead, and zinc ores, of which they are byproducts, at Oroya. During the year the Cerro de Pasco Copper Corp. started construction of a new plant at Oroya for the manufacture of calcium arsenate, for domestic sale as an insecticide to Peruvian cotton growers. The 125 tons of tin reported by the Oroya smelter (and derived from Cerro de Pasco ores) probably represented a 2-year accumulation of dross, as no production was recorded in 1944. Byproduct recovery of electrolytic tellurium and indium, started at Oroya in 1943, has not been reported for 1944–45. Oroya is also equipped to manufacture calcium carbide, sulfuric acid, and refractory and building brick.

Copper.—Peruvian production of copper in 1945 was the lowest since 1933. The trend has been downward since 1940, but the 11 percent drop from the previous year in 1945 was greater than expected, particularly in view of the fact that total United States purchases of foreign copper in 1945 were larger than in 1944. Of the 28,833 metric tons of copper in ore mined in Peru in 1945, 25,306 tons were extracted at Oroya in the form of blister bars, 206 tons in electrolytic bars, and 127 tons in matte. Construction of a copper refinery was started at Oroya by the Cerro de Pasco Copper Corp.

Gold.—The notable feature of the over-all 1945 increase in gold production is that it included a 10.7 percent increase over 1944 in gold contained in copper bars, while output of copper bars decreased 4.4 percent, indicating a rise in the average gold : copper ratio of copper ores mined. Production in other categories (content of gold-silver bars, ores and concentrates exported, and output of placers) remained about the same as in 1944, roughly 126,000 troy ounces. Official figures do not include unknown amounts of gold sold by Indian placer miners to small merchants who never report this production to the Government, thereby evading tax payments. Total gold production is expected to increase further as soon as additional mining equipment is obtainable from the United States.

Iron and steel.—The Santa Corporation (Corporación Peruana del Santa, a corporate agency of the Peruvian Government) completed the construction of extensive port works at Chimbote Bay in May 1945. A large hydroelectric power plant in Cañon del Pato and rehabilitation of the 80-kilometer Chimbote-Ancos railway were also completed during the year. Future projects of the corporation include establishment at Chimbote of an iron and steel plant planned to utilize coal exploited at Ancos and 16,000 tons of iron ore per month from deposits near the coast at Marcona, 650 miles south.

Lead.—Lead production was only slightly under that of the preceding record year 1944 and was higher than in any other year in Peruvian history. Of the total, 40,001 tons were refined in bars at the Oroya plant and 11,934 tons shipped in concentrates. Sales were principally to the United States Commercial Company. Projects of the Santa Corporation include plans to construct a small lead smelter at Chimbote to treat concentrates from plants not in Central Peru.

Mercury.—Although output of mercury increased 37.5 percent over 1944, the 209 flasks produced in 1945 were not enough to be significant. The Chonta plant (Huánuco) was the only one known to have been operated during the year; construction of a 250-ton reduction plant at the Santa Barbara mine, Huancavelica, continued. The Santa Barbara plant, when finished, is expected to make possible the exploitation of a large reserve of low-grade ore.

Molybdenum.—Peru Molibdeno, S. A., the only important producer of molybdenum in Peru, closed its concentrator in October 1944 and later resumed operations for about 3 months, until minable ore was exhausted and its contract with the United States Commercial Company was canceled. In August 1945 the company was liquidated and all mining, concentrating, and other equipment sold. The only other producer, the Salazar mine, is operated on a very small scale.

Radioactive minerals.—Development of the atomic bomb has stimulated an active search for radioactive minerals in Peru by prospectors, mining companies, and Federal agencies. On September 18, 1945, the Ministerio de Fomento announced that all rare and radioactive mineral deposits in the Provinces of Costillas, Condesuyos, and Caravelí, Department of Arequipa (some of which have been known for several years), have been declared reserved for the State.

Silver.—The moderate rise in silver production was brought about by increased output of silver in shipping concentrates and in silver and gold-silver bars, which more than balanced the decrease in silver-carrying copper bars and resulted in the largest silver production since 1940. In 1944–45 Peru surpassed Canada and became the world's third largest producer of silver, exceeded only by Mexico and the United States. However, this advance in relative position was brought about by Canada's excessive decline rather than by spectacular gains in Peru. The United States increase in the purchase price of foreign silver from $0.4475 to $0.71111 per ounce, announced September 20, 1945, by the Office of Price Administration, was good news to producers throughout the world, and its stimulating effect on the dozen or more gold-silver mines in Peru should be more evident in 1946. Domestic sales to Peruvian silversmiths have greatly increased since the beginning of the war, reaching 1,092,289 ounces in 1943 and 1,576,351 ounces in 1944 (1945 figures not available), with a parallel rise in domestic and export sale of hand-worked silverware. The Cerro de Pasco Copper Corp. at Oroya is the only producer of refined silver bars.

Tungsten.—The sharp decrease in production of tungsten concentrates, most of which came from the mines of Fermin Malaga Santolalla i Hijos, was a normal reflection of a similar decrease in demand in the United States, which dates from VJ-day. Presumably the concentrates were the product of beneficiation at the Peruvian Government's tungsten concentrator near Callao.

Vanadium.—The new $4,000,000 plant at Junasha, built with Defense Plant Corporation funds and operated by the Vanadium Corp. of America, using low-grade ores from Minaragra, was completed near the beginning of 1945 but did not attain full mechanical operation until June. A number of mechanical defects in the plant have been corrected, but considerably more improvement will have to be made before production of V_2O_5 comes close to preconstruction expectations. Meanwhile, the old plant continues treatment of higher-grade ores at the monthly rate of about 2,500 tons. Combined vanadium output of the two plants in 1945 resulted in an increase of only 102 tons over that of the old plant alone in 1944.

Zinc.—While the decline in lead production from 1944 to 1945 was less than 600 tons, that of zinc, according to preliminary figures, was about 17,800 tons. Production in 1944 was a surprising record, however; and the relatively reduced output in 1945, estimated at 38,400 tons, appears to be nevertheless the second highest in the history of Peruvian zinc mining. The Santa Corp. proposes to establish a zinc concentrator and electrolytic refinery of 75 or 100 tons daily refined zinc capacity at Chimbote, to cut exports of zinc in the form of concentrates. Revival of similar plans by the Cerro de Pasco Copper Corp., postponed by the recent war, have not been announced.

NONMETALLIC MINERALS

Barite.—Barite first appeared on Peru's list of industrial minerals in 1944, with production of 2,352 tons; an increase to 3,000 tons in 1945 was estimated. Sales are confined to local consumers.

Calcined materials.—Continued activity in the construction of highways and buildings raised cement production an estimated 6,500 tons in 1945. Output of Cía. Peruana de Cemento Portland, the sole producer, was insufficient to meet domestic demands and had to be supplemented by imports. Consumption of cement (not reported for 1945) has risen steadily in Peru from 160,000 tons in 1939 to 246,000 tons in 1944. Calcined gypsum (plaster) and lime production are governed by the same demand factors as cement and rose accordingly.

Mica.—Of the three companies that started mining mica in southern Peru in 1943, only the Cía. Peruana de Mica continued operations into 1945. Trimmed and scrap mica were sold to private buyers in the United States after February 28, when the contract with the United States Commercial Company expired.

HYDROCARBONS

Coal.—The bulk of the 1945 gain in coal production was in anthracite and represents the beginning of what is expected to become a much greater expansion in the development of the Ancos deposits that lie inland from Chimbote and are connected with that port by an 80-kilometer narrow-gage railroad. Cía. Carbonera Pallasca and Cía. Carbonera Ancos have recently completed the construction of coal-cleaning plants at their respective properties. The total present capacity of the coal cleaning and sizing facilities of the district is roughly 250 tons daily, and the potential capacity of the mines is much greater. The district is expected to supply fuel for the iron, steel, chemical, and general manufacturing industries envisioned for the Chimbote area and to increase the sale of Peruvian coal for export.

Petroleum.—Production of crude petroleum in 1945 receded by nearly 638,000 barrels to about the level of 1942. Distribution of production was as follows: International Petroleum Co. (La Brea-Pariñas fields), 11,278,387 barrels; Cía. Petrólera Lobitos (Restin-El Alto fields), 2,263,506 barrels; Peruvian Government (Zorritos and Los Orangos fields), 141,065 barrels; and Cía. Petróleo Ganso Azul

(Agua Caliente field), 65,270 barrels. In addition, natural gasoline was produced as follows: International Petroleum Co., 957,991 barrels; and Cía. Petrólera Lobitos, 117,146 barrels. The International Petroleum Co. produced 13,103,268 barrels of refinery products at Talara, the Peruvian Government 305,524 barrels at Villar, and Cía. Petróleo Ganso Azul 65,303 barrels at its field topping plant, making a total of 13,474,095 barrels of refinery products, of which 212,737 barrels represented residue fuel oil, still gas, and losses. Of these total outputs, 272,488 barrels of crude oil and 8,941,179 barrels of refinery products were exported. Peruvian consumption of refinery products amounted to 4,880,239 barrels.

SURINAM (NETHERLANDS GUIANA)

The liberation of Holland and prospects of an early resumption of trade brightened the economic outlook of Surinam considerably in 1945. Noticeable gains have been made, and conditions during 1946 should improve steadily.

Bauxite.—Exports of bauxite amounted to 683,990 metric tons in 1945—far below the 1943 peak, but 58,186 tons ahead of 1944. Surinamsche Bauxite Maatschappij (Alcoa) shipped 87 percent of the total from its plants at Paranam and Moengo; the remaining 13 percent was sold to Alcoa by N. V. Billiton Maatshappij of Smalkalden. Of the total shipped, 225,049 metric tons went to the stock pile at Trinidad and 458,941 tons went to the United States, including 4,877 tons to manufacturers of refractories. The total also included 16,786 metric tons of high-grade chemical bauxite. Billiton canceled its plans to suspend operations at the close of 1945.

Gold.—Placer gold production in 1945, although amounting to only 5,895 troy ounces, showed a slight improvement over both 1944 (5,723 ounces) and 1943 (5,795 ounces). Output is from two organized companies, Sara Creek Mining Co. and White Water Mines, Ltd., and numerous independent operators.

Granite.—The Department of Public Works operates a granite quarry at Fedra as a source of material for construction and repair of streets in Paramarito, 45 miles to the north. Tonnage crushed has not been reported for 1944 or 1945.

URUGUAY

Since 1942, when gold mining dwindled to insignificance, the mineral industry of Uruguay has been confined to the production of nonmetallic mineral raw materials, chiefly for use in construction. Sand and gravel output amounted to 2,586,039 metric tons (2,333,918 sand, 252,121 gravel) in 1945, compared to 2,777,128 tons (2,569,578 sand, 207,550 gravel) in 1944. Rarely important in foreign trade, more than half of that produced in Uruguay is regularly exported to Argentina, but this trade may be restricted by Argentina in 1946 to permit development of its own deposits. Ground quartz for special use in glass making was also produced to the extent of 1,357 metric tons in 1945 and 1,457 tons in 1944, of which 843 tons in 1945 and 904 tons in 1944 were exported.

Of the 390,432 tons and 303,989 tons of limestone quarried in 1945 and 1944, enough was calcined to produce 185,290 tons and 165,990 tons of cement, in the same years, respectively, by the two cement plants at Montevideo and Nueva Carrera. Cement exports amounted to 8,504 metric tons in 1945 (25,199 tons in 1944). Gypsum required for cement production is imported normally from Argentina, although at present and apparently for political reasons exports of gypsum and salt from Argentina to Uruguay are prohibited, and Uruguay's source of gypsum in 1946 probably will be American-occupied Germany. Salt requirements are expected to be filled by imports from Spain.

Uruguayan production of stone for building and construction purposes, aside from limestone in excess of that used for cement and small quantities of curb, flag, and paving stone, was as follows in 1945, with equivalent figures for 1944 in parentheses: Rough stone, 8,874 (28,638) tons; marble, 33,360 (16,440) tons; ballast, not reported (111,471 tons). Exports, chiefly to Argentina and Brazil, were rough stone, 1,259 (4,063) tons and marble, 1,183 (583) tons.

Output of refractory clay dropped from 2,144 metric tons in 1944 to 1,592 tons in 1945. About one-third of the output was exported in each year. Production of common clay, amounting to 19,300 tons in 1944, was not reported in 1945. Production of talc, used by the paper industry and by manufacturers of soap and talcum powder, declined from 2,257 tons in 1944 to 1,823 tons in 1945 and exports from 1,861 to 1,503 tons. Feldspar and mica output, amounting to 264 and 3 tons, respectively, in 1944, was not reported in 1945.

VENEZUELA

METALS

Gold.—Venezuelan production of gold has been reported as 77,716 troy ounces in 1944 and 76,839 ounces in 1945. Believed to average 760 fine, as reported in 1941–43, output thus appears to have amounted to only 59,064 ounces in 1944 and 58,397 ounces in 1945 when reduced to fine gold. In March, New Goldfields of Venezuela, Ltd., took over operation of the properties of Cía. Francesa de la Mocupia in addition to its own, and the combined mines, near Guasipati in the State of Bolivar, supplied 78 percent of the total output. The remaining 22 percent came from the Vuela Caras mine in the same district and from placer workings, mainly in the Caroni region. New Goldfields of Venezuela, Ltd., continued to show an operating loss despite the removal of wartime restrictions against procurement of equipment and supplies and faces a depressing future unless costs can be greatly reduced.

Iron.—Throughout the year Iron Mines Co. of Venezuela (Bethlehem Steel) continued preparations to develop its iron-ore reserves at El Pao, 30 miles south of San Felix, but has not as yet started mining. A small island off the coast of Trinidad has been selected for the site of the loading station. Work continued also on construction of a fleet of 4 ore ships, the first of which (the *Venore*) was launched January 22.

Nickel.—The International Nickel Co. continued examination of a garnierite deposit at Lorno de Hierro, near San Pedras, but a report of results has not been received.

Uranium.—Interest in exploration for deposits of radioactive minerals has been stimulated in Venezuela, as elsewhere, by the wartime developments in the controlled use of atomic energy. Discovery of pitchblende and a sample tentatively identified as calciocarnotite have been reported from the State of Merida—one from the Cerro Santa Lucia northwest of Timotes and the other from about 1 kilometer northeast of the city of Merida. On October 13, 1945, the Ministro de Fomento issued Decree 339 declaring that no exploration for or exploitation of radioactive minerals can be undertaken without special permission of the Venezuelan Government.

Vanadium.—During 1945 the United States imported 133,795 pounds (61 metric tons) of flue dust containing 46,952 pounds (21 metric tons) of V_2O_5 from Curaçao. This represents material derived from crude petroleum of Venezuelan origin, though only a portion of the total available from that source.

NONMETALLIC MINERALS

Asbestos.—Cía. Anónima Minas de Amiante de Tinaquillo started operation, late in the year, of its asbestos mill west of Tinaquillo, State of Cojedes, but did not achieve a full production rate. Tonnage produced has not been reported but is believed to be small.

Cement.—At the end of 1944 Cía. Cemento Portland National operated the only two cement plants in Venezuela, at Caracas and Valencia, having a combined annual capacity of 120,000 metric tons. During 1945 two new plants began operations, one (ownership not reported) at Merida, with an annual capacity of 15,000 tons, and the other built by Cía. Venezolana de Cemento at Barquisimeto, with an annual capacity of 40,000 tons. Cement production increased from 119,670 metric tons in 1944 to a new record high of 124,447 tons in 1945 and is expected to continue upward for the next few years. Cía. Venezolana de Cemento plans to complete a 90,000-ton plant at Maracaibo in 1946 and another of equal size at Pertigalete in 1942. E. P. Haliburton, an American industrialist, proposes to erect a 125,000-ton plant at Chichiriviche, to be completed by mid-1946. If all of these plans materialize, the Venezuelan annual cement capacity will be 480,000 tons by early 1947, as against a growing annual demand that had reached about 300,000 tons by the end of 1944. Limestone, gypsum, and clay are obtainable locally, as is oil for fuel, and Venezuela may well attain self-sufficiency in cement within the next few years.

Diamonds.—The production of diamonds dropped 42 percent, from 22,037 carats in 1944 to 12,769 carats in 1945, the smallest output since 1939. Production by districts was as follows:

Diamond production, State of Bolivar, Venezuela (carats)

Producing areas:	*1944*	*1945*
Lower Caroni-Paragua Basin	5, 128. 15	2, 414. 28
Upper Caroni Basin (Gran Sabana)	16, 691. 62	10, 228. 00
Cuyuni and Mazaruni Basins	217. 30	126. 60
Total Venezuela	22, 037. 07	12, 768. 88

The 42-percent drop reflects the closing of the gap between supply and demand for industrial stones during the last year of the war.

Other nonmetallic minerals.—Recovery of salt from sea water, estimated at 25,000 tons in 1944, amounted to 44,166 metric tons in 1945, the highest since 1940. Principal production is on the Araya Peninsula, State of Sucre, and is for domestic use only. La Industria Nueva Esparta, C. A., mined 5,600 metric tons of crude magnesite on Margarita Island in 1945, compared with only 700 tons in 1944 and 589 tons in 1943. The company uses this raw material for the manufacture of calcined products in its plant in Caracas. Quantitative production of limestone, lime, gypsum, clay, sand, and gravel has not been reported.

HYDROCARBONS

Coal.—Mine output of coal, never significant in Venezuela, dropped from 12,473 metric tons in 1944 to 7,022 in 1945, of which 4,957 tons was from the Government mine at Naricual and 2,065 tons from the Corcobado mine of Hulleras de Guárico near Altagracia.

Petroleum.—The close of the war in midyear failed to curb Venezuelan production of crude petroleum, which rose from the previous peak of 257,045,668 barrels in 1944 to a new record of 323,414,505 barrels in 1945, for a remarkable increase of 25.8 percent. Sustained demands for war during the first half of the year, continued absence of the Netherlands East Indies and Central Europe from world markets, and curtailment of production in the Near East were factors to which the increase was largely attributed. As in 1944, 95 percent of the total output was supplied by the three largest producers: Creole Petroleum Corp. (Standard Oil of New Jersey), Mene Grande Oil Co. (Gulf Oil Corp.), and the Shell Oil Co. (through its subsidiaries Caribbean Petroleum Co., Venezuelan Oil Concessions Ltd., and Colon Development Co., Ltd.); the remainder came from Consolidated Petroleum Co. (Sinclair Oil Co.), Socony-Vacuum Oil Co., Texas Petroleum Co., British Controlled Oilfields Ltd., Orinoco Oil Co. (Pure Oil Co.), Venezuelan Atlantic Refining Co., and S. A. Petrólera Las Mercedes. Production is divided between the larger Western district, which includes the Lake Maracaibo basin, and the Eastern district in the States of Monagas and Anzoategui and the Territory of Delta Amacuro. Discovery by the Texas Petroleum Co. and affiliates of fields at Los Mercedes in Guarico indicate the possibility of a third Central district, and an extended exploration program is scheduled there as well as in the other two. Under the Petroleum Law of March 13, 1943, the holders of exploration concessions have a period of 3 years in which to select not more than 50 percent of their exploration acreage, the remainder to revert to the Government as national reserve; in most instances less than 2 years remain, and all companies are working against time. Companies engaged in exploration, in addition to the producers listed above, include the Philips Petroleum Co. (first producing well completed in May 1946) and the Richmond Exploration Co. (Standard Oil Co. of California). Venezuela is the world's second largest producer of crude petroleum, and the present high level of output is expected to be well-maintained throughout 1946.

Refinery throughput amounted to 32,645,515 barrels in 1945, distributed among the following six companies through their eight refineries: Creole Petroleum Corp. at La Salina and Caripito, Caribbean Petroleum Co. at San Lorenzo, Mene Grande Oil Co. at Cabinas and

Oficina, Colon Development Co., Ltd., at El Cubo, Socony-Vacuum Oil Co. at Guario, and British Controlled Oilfields, Ltd., at El Mene de Mauroa. Plans for new refineries in accordance with the Government program agreed upon in 1943 include: Creole Petroleum Co., a 40,000-barrel plant, probably on the Paraguana Peninsula; Shell Oil Co., a 40,000-barrel plant now under construction at Punta Cardon, Paraguana Peninsula; Consolidated Petroleum Co., a 40,000-barrel plant at Puerto La Cruz; and Mene Grande Oil Co., a 20,000-barrel plant at Puerto La Cruz.

A new decree, applying to 1946 only, imposes an excess-profit tax of 20 percent on all individuals and corporations whose profits exceed $560,000; 15 percent on $400,001–$560,000; 10 percent on $280,001–$400,000; and 6 percent on $225,001–$280,000. Most of the oil producers in Venezuela will be in the 20-percent bracket.

AFRICA [10]

By Frank L. Fisher

The African mineral-producing countries responded satisfactorily to the shift from war to peace conditions. Gold production in 1945 took an upward trend toward the close of the year for the first time since a gradual decline started in 1941, although total annual production in 1945 was slightly less than in 1944. Diamond production reached a new high, and base-metal production remained consistently good through the year. A sharp decrease in the intensity in the search and exploitation of strategic materials was noted.

The Union of South Africa, Belgian Congo, Northern and Southern Rhodesia, British West Africa (Nigeria, Gold Coast, and Sierra Leone), and French North Africa (Algeria, Morocco, and Tunisia) continued as the countries of major importance in dollar value of minerals produced during 1945. The mineral industries of Angola, Bechuanaland, British East Africa (Kenya, Uganda, Tanganyika), Egypt, French Equatorial Africa, Madagascar, Mozambique, and South-West Africa were of secondary importance in 1945. The remainder of Africa, comprising countries with over half of the land area, has no significant mineral production, except for primitive mining of gold and salt, and includes Anglo Egyptian Sudan, British Somaliland, Cabinda, Eritrea, Ethiopia, French Somaliland, French West Africa, Gambia, Italian East Africa, Liberia, Libya, Rio de Oro, Rio Muni, and Spanish Guinea.

UNION OF SOUTH AFRICA

The Union of South Africa suffered very little by World War II, and gold production in the Union for 1945 amounted to 12,213,545 fine ounces, a decrease of 63,683 fine ounces from the 1944 yield.[11] The Transvaal Chamber of Mines reported a decrease for its member mines in average recovery a ton from 0.202 fine ounce in 1944 to 0.199 fine ounce in 1945. Working costs continued to rise to $4.73 a ton of

[10] Unless otherwise indicated, statistics for all countries in Africa are in metric tons.
[11] Abstracted from information supplied by William O. Vanderburg, American minerals attaché, Pretoria, South Africa.

ore as compared to $3.96 a ton of ore for 1939. Gold-mine dividends decreased to 52 million dollars for 1945.

A report was issued during the year on deep-level mining, and the reserves locked up in deep-level mining on the Central Witwatersrand were estimated at nearly 800 million dollars. The present methods of wet mining with modifications and with refrigeration are believed adaptable between 8,500 and 10,000 feet, but below that depth it is necessary to resort to dry methods of mining.

Coal output of the Union of South Africa in 1945 was 25,465,584 tons, with exports amounting to 4,511,896 tons—almost a 100-percent increase over 1938. The Union also had an increased output of blister copper, corundum, fluorspar, vermiculite, and iron ore in 1945 compared with the previous year and a decreased output of manganese ore, chrome ore, tungsten concentrates, antimony, and mercury.

BELGIAN CONGO

Gold production declined further, as transition back to this type of mining was not realized fully enough in 1945 to check the downward trend. The 381,206 fine ounces produced in 1945 was 174,198 less than the 1940 production. The production of industrial diamonds and gem stones, primarily from the Beceka field, was a peak 9,927,340 carats of industrials and 459,000 of gem stones. This compares to 7,144,552 carats of industrials and 388,814 of gem stones produced in 1944. Copper production continued at a normal rate, with 160,200 tons reported for 1945, which brings the total production since operations began in 1925 to nearly 3 million tons. A sharp increase in cobalt production to 7,250 tons of white alloy was reported for 1945. Tin production also reached a new high in 1945, with 24,099 tons of cassiterite produced, having a metal content of 17,351 tons of contained tin.

NORTHERN AND SOUTHERN RHODESIA

Northern Rhodesia maintained its position as the principal base metal producer on the African continent in 1945.[12] Copper production continued the decline from that of the peak year 1940, when 262,394 long tons of metal were produced. Production of cobalt alloy, a by-product of the copper operation, showed an over-all increase during the war, as did lead, zinc, and vanadium from the Broken Hill district.

Production of gold in Southern Rhodesia in 1945 declined 24,488 fine ounces from the previous year to 568,241 fine ounces, continuing the steady decline since 1940. Southern Rhodesia produced 56,348 short tons of asbestos, a slight decrease under the preceding year, and 205,382 short tons of chrome ore, which was a sharp reduction from the 305,398 short tons produced in 1944. Minor production of mica, tin, tungsten, and silver were also reported. Coal production decreased slightly to 1,839,583 short tons from 1,992,678 short tons in 1944, the bulk of the production coming from the Wankie deposits.

BRITISH WEST AFRICA

Gold Coast.—Diamond production dropped to 812,451 carats in 1945 after a record of 1,165,858 carats in 1944. Gold production dropped 59,080 fine ounces from 1944 to a total of 475,407 fine ounces

[12] Abstracted from information supplied by William O. Vanderburg, American minerals attaché, Pretoria, South Africa.

717372—47——104

for 1945. Manganese exports were over 500,000 tons for the year, of which about 60 percent was metallurgical grade; and bauxite production was normal, with 148,539 tons.

Nigeria.—Tin ore production in Nigeria was approximately the same as in the previous year, when over 17,000 tons of 73.5 percent tin were produced. Production of columbite continued at peak rate throughout the year, and coal production also kept the 1944 rate of over 600,000 tons.

Sierra Leone.—Diamonds and ferro-alloy minerals continued to be the principal minerals produced in 1945 from Sierra Leone. Actual production statistics have not been released, but it is estimated that diamond production will exceed 500,000 carats, while production of iron ore was limited to shipping and storage space available.

FRENCH NORTH AFRICA

Algeria.—The continued drought and the lack of assistance from France stalemated the mineral industry of Algeria in 1945. Iron and phosphate production in 1945 was up to the limit of the technical capacity of the two industries under prevailing conditions. Phosphate production for the year exceeded 300,000 tons.

French Morocco.—The total production of dried raw phosphates was approximately 1,635,000 tons, an increase over the 1,444,902 tons produced in 1944. Coal production increased 33,000 tons over the preceding year for a total of 180,000 tons for 1945. The manganese mines produced 42,000 tons compared with 27,550 tons in 1944. Production of lead ore totaled 15,500 tons, compared to 13,500 tons for the previous year, and petroleum production continued to decline sharply, with a 1945 production of less than 3,500 tons. Small, relatively unimportant quantities of cobalt, zinc, copper, graphite, and asbestos were also extracted during 1945.

Tunisia.—The mineral industry of Tunisia progressed slowly during 1945 in approaching the prewar average production levels of 1,800,000 tons of phosphate rock, 800,000 tons of iron ore, and 30,000 tons of lead ore. Production had reached 50 percent of the average production of phosphate and 15 percent of the iron ore as the year ended.

OTHER COUNTRIES

Angola.—Mineral production in Angola was confined primarily to diamonds, gold, and asphalt. Statistics for 1945 are unavailable but are not expected to vary from the 1944 production statistics.

Bechuanaland.—Mineral production in Bechuanaland in 1945 was 11,299 fine ounces of gold and 1,236 fine ounces of silver, which was approximately the same as the previous year.

British East Africa (Kenya, Tanganyika, and Uganda).—The highlight for British East Africa (Kenya, Tanganyika, and Uganda) production in 1945 was the continued increase in output of Tanganyika diamonds and Kenya soda. The output of soda ash in Kenya from Lake Magadi paralleled the value of the yearly production of gold in 1945, with an increase of 9,250 tons over 1944 for a record production for 1945 of 72,163 tons of soda. Production of diamonds in Tanganyika continued to increase in 1945, with an exported total of 115,660 carats. Gold production increased to 90,633 fine ounces compared to the 1940 peak of 143,694 fine ounces. Sharp declines were reported in production in Uganda for several strategic minerals.

Egypt.—Mineral production in Egypt continued to progress favorably during 1945, with increased emphasis on structural materials. Petroleum production increased to 1,349,473 tons for 1945, and important productions of cement, gypsum, phosphate rock, and iron oxide were reported.

French Cameroun.—Mineral production in the French Cameroun declined in 1945, with a production of 165 tons of tin concentrate, 17,880 fine ounces of gold, and 1,040 tons of rutile.

French Equatorial Africa.—Gold production in French Equatorial Africa was normal in 1945, with a production of 83,669 fine ounces. Diamonds showed a sharp increase to 82,849 carats, an increase over 1944 of 24,849 carats. An insignificant production of lead and zinc was also reported for the year.

Madagascar.—Mining operations in Madagascar for mica, corundum, and graphite declined considerably during 1945. Gold production increased for the year. Madagascar also reported a production of quartz crystals, beryl, and semiprecious stones.

Mozambique.—There were no particularly noteworthy developments in Mozambique during 1945. The 1945 mineral statistics are not available at this writing, but they are not expected to deviate from the 1944 figures.

South-West Africa.—Production of diamonds in South-West Africa continued at an annual rate of over 150,000 carats in 1945. Production of vanadium ore increased from 3,423 long tons in 1944 to 3,930 long tons in 1945 while tin increased from 74 long tons to 267 long tons for the same years.

Spanish Morocco.—Spanish Morocco iron-ore exports in 1945 from the Melilla deposit were 717,856 tons compared to the prewar normal of 1 million tons and a production of 780,408 tons of 61 to 65 percent ore for 1944. Spanish Morocco also reports exports of 125 tons of 70-percent lead ore, 325 tons of antimony concentrate, and 250 tons of graphite during 1945.

EUROPE [13]

By Frank L. Fisher

The European mineral industry in 1945 made slight progress against extreme handicaps. The bomb damage through actual warfare was slight, possibly less than 10 percent. The most serious direct effect of the war on the mineral industry is the extreme overexploitation by the Nazis, in which any future operation of the deposit was disregarded. The second problem in 1945 was the general deterioration of equipment and the dire shortages of mine supports. The third major problem that hindered rejuvenation of the European mineral industry was the labor shortage and the failure of the nations to evolve any immediate plan to successfully employ captive labor. Two reasons why the men were not overanxious to work in the mines were the hazardous condition and the economic chaos of inflation.

The fourth major problem was the complete break-down of transportation and the necessity of permitting transportation on a priority basis when restoration was effected. The fifth major problem was

[13] Unless otherwise indicated, statistics for all countries in Europe are in metric tons.

the necessity of providing food and fuel to the peoples of Europe to enable them to be physically able for industrial work.

BELGIUM

Belgian industrial economy centers around the availability of coal. War conditions had cut the production to considerably less than 2,000,000 tons a month as compared to a monthly prewar average of 2,500,000 tons. The recovery trend became noticeable in September 1945, and in December of that year a production of 1,732,370 tons was obtained during the 24-day work month.

Belgium had 47 blast furnaces in operation in 1937 and an average monthly prewar production of 264,300 tons of pig iron, 252,600 tons of crude steel, and 193,100 tons of finished steel. The iron and steel industry had recovered to the extent that, in December 1945, 22 blast furnaces operated to obtain a production of 129,800 tons of pig iron, 132,100 tons of crude steel, and 100,800 tons of finished steel. In addition, Luxembourg had 10 blast furnaces in operation, with a December 1945 production of 72,000 tons of pig iron and 56,000 tons of crude steel.

The nonferrous metals industries recovered at a much slower rate in 1945 than the ferrous industry, largely owing to small allocations of coal and the difficulty in obtaining supplies of foreign ores. Resumption of normal shipments of copper matte from the Belgian Congo, zinc ores from Mexico, Australia, and Sweden, and lead ores from Yugoslavia, South America, and Sweden are not expected to begin until 1946. The nonferrous metal industry was producing at a monthly rate, in November 1945, of 180 tons of crude copper, 2,400 tons of crude zinc, and 670 tons of crude lead. The Antwerp diamond-cutting industry appeared to be staging a satisfactory recovery.

FINLAND

The Finnish mineral statistics for 1945 are not available at this time. The Outokumpu Copper Co. announced plans during the year to increase the annual capacity of its plant from the present 600,000 tons of ore. A new copper deposit was discovered during the year at Luikonlahti, Kaavi, and a talc deposit of significance was discovered at Leppalahti in Liperi. The loss of the nickel-copper deposit at Petsamo to U. S. S. R. was a severe blow to the Finnish mineral industry.

FRANCE

The general economic condition of the mineral industry in France registered slow improvement in 1945 until October when a decline set in which continued throughout the remainder of the year.[14] One of the primary effects of the German occupation was a complete scavenging of French metal and mineral stocks and an intensive exploitation of deposits. It was not possible to replenish stocks, and stocks on hand during the year have been extremely low.

Lead and zinc.—Lead production (lead content of ores and concentrate) in 1945 was 7,527 tons compared to 3,528 tons of ore in 1944 and 4,220 tons of ore in 1938. Imports of lead ore began in October and amounted to 18,309 tons for the year, about half the 1938 imports.

[14] Abstracted from Ducoté, Charles H., Review of Economic Conditions in France—1945: Rept. 208, Paris, Feb. 18, 1946, 145 pages.

Smelter production of metallic lead in 1945 was 4,832 tons of pig compared to 42,183 tons for 1938. Zinc-ore production (zinc content of ores and concentrate) was 6,599 tons compared to 2,387 tons for 1944. Production of metallic zinc was 8,064 tons in 1945, reflecting a steady decline in the war years from a production of 54,713 tons in 1938.

Bauxite and aluminum.—The firmly established French bauxite industry reached a peak in 1943, with over 900,000 tons. Production of both bauxite and aluminum was steady in 1945, and these industries were two of the few to approach their prewar output at the end of the year. Bauxite production climbed to about 30,000 tons a month by the end of the year, and monthly production of aluminum averaged 3,500 tons. Over 80 percent of the bauxite continued to come from deposits near Brigoles, Department of Var. The aluminum plants suffered only slight damage from the war.

Potash.—The recovery in the important potash mines was rapid, and in December production had reached 186,630 tons with a 1945 total of 852,732 tons. The mines were operated during the war by the German "Pruessag" and in 1942 attained a production record of 129.4 percent of the 1938 production. Some of the mines escaped with slight war damage, several required 2 to 5 months for repairs, and the Ensishein and Anna mines will require 2 years before the seriously damaged plants can operate again.

Iron and steel.—Iron-ore production in France during 1945 totaled 7,824,136 tons. By comparison, the 1938 production was approximately 33 million tons. About 96 percent of the iron ore came from the Lorraine Basin. France was fifth among the world steel producers before the war and had approximately 200 furnaces, with a capacity of 12 million tons a year, which enabled France to export 20 to 30 percent of the production. The 1945 steel production capacity was about the prewar normal because it suffered practically no war damage but production was down to nearly 10 percent of the normal.

Coal.—The availability of coal held the keynote to the industrial rehabilitation of France in 1945. Strenuous efforts resulted in increasing production which in December reached 3,542,000 tons, approximately the 1938 monthly average. Output per man-shift underground, however, was only 74 percent of the 1938 average, a decrease attributable to the relatively large infiltration of German prisoners-of-war. The total increase in underground workers for 1945 was 61,000, of which 35,000 were prisoners. Coal consumption was only 57 percent of the 1938 normal because of restrictions and general curtailment regulations.

Petroleum.—France imported over 96 percent of the country's petroleum requirements before the war. The French petroleum industry suffered considerable war damage from sabotage and bombings. Approximately 30 percent of the refining capacity and about 60 percent of the storage capacity were completely destroyed. The petroleum-transportation facilities were destroyed to an estimated over-all 50 percent. The production of refined petroleum products in 1946 may reach 50 percent of the prewar normal, but complete recovery for the industry is expected to evolve through a proposed 10-year restoration plan.

Other metals.—The four copper refineries produced 9,607 tons of refined copper in 1945 from ores, matte, blister, and scrap. Several small antimony deposits were worked during 1945 resulting in a production of 2,011 tons of ore used primarily in the manufacture of oxide and 421 tons of metal were obtained from domestic and North African ores. Pyrite production was normal during the year, with a total of 146,615 tons.

GERMANY

The summary of the German mineral industry in 1945 is integrated with a nation engaging in and defeated at modern war. The industry was subjected to years of dilated imports and abnormal foreign trade, overexpanded and heavily subsidized domestic production, and finally marked depletion of resources and exhaustion of the physical structure of the mineral industry itself. A study of the state of the German mineral resources in 1945 indicates that any economic revival will be slow, regardless of the form of government, the policies, or the reparations levied upon Germany. The foundation of German industrial might has been the importation of essential materials, the encompassing chemical industry, and heavy, uneconomic, Government subsidy. The division of Germany into zones of occupation, governed by four separate Allied Nations, resulted in the elimination of any or all of the pillars of German industrial might to the extent that the foundation is now so weakened that the mineral economic structure cannot be rebuilt firmly, if it is possible for it to exist at all.

During the first 45 years of the 20th century, Germany spent 10 years engaged in active warfare, 15 years in extensive military preparation, and 14 years in complete economic disruption resulting from the pan-Germanic militarism. This has taken a tremendous toll of German mineral resources.

Germany actually had legitimate resources of lead and zinc; ample resources of iron ore; a substantial supply of copper; excellent resources of fluorspar, barite, gypsum, pyrite, graphite, and sodium, potassium, and magnesium salts; sufficient bituminous and brown coal; and the minor metallics, china clay, talc, diatomite, fuller's earth, and borax, in quantity.

At the start of World War II, Germany lacked the ferro-alloy minerals—manganese, chrome, tungsten, and molybdenum; had a major deficiency in mercury, tin, nickel, cobalt, gold, silver, and platinum; only one small, unimportant bauxite deposit; insignificant sources of natural abrasives; literally no industrial diamonds, mica, asbestos, or phosphates; and inadequate petroleum resources.

Systematic looting of the conquered countries temporarily prolonged the dwindling supplies, but by 1943 the stocks of tungsten, molybdenum, and manganese were exhausted. In 1945, at the close of World War II, reserves of domestic mineral resources were found to be noticeably depleted; surface equipment was sorely in need of repair, and many plants were badly damaged or destroyed.

The lifeblood of the German industrial machine was the foreign trade in metals and minerals, upon which Germany depended to exist as an industrial empire. The machinery for this industrial empire was the large, highly integrated industrial enterprises. The cessation of foreign trade and the partition of Germany by the zones of occupation in 1945 completely paralyzed the mineral industry.

GREECE

Famine and other ravages of war and the 3½ years of German occupation completely demoralized the mineral industry of Greece in 1945. The Germans had actively exploited the chrome, nickel, and bauxite deposits and left a trail of destruction, pillage, and looting. The general domestic political unrest also became a factor in the Greek industrial decadence throughout the year. Mineral statistics for the year have not been made available.

HUNGARY

Only meager information of the Hungarian mineral industry was available for 1945. The important bauxite industry depends on an export market, and no stable market was available to absorb the production during the year. The German overexploitation during the years of occupation resulted in a 1942 peak production of 1,038,000 tons of bauxite. The petroleum industry produced 655,657 tons of crude oil in 1945, a decrease of 19 percent from 1944. Coal production was 4,000,000 tons during the year, approximately half of the production for Hungary in 1938.

ITALY

An appalling situation of distorted economics, dating back to the years of the self-sufficiency doctrines of Fascism, continued to grip the mineral industry of Italy in 1945.[15] Italy is far from rich in mineral wealth. Excluding quarry products, it is self-sufficient only in sulfur, mercury, iron pyrites, zinc, and bauxite. Italy is extremely deficient in solid and liquid fuels. The Fascist policy artificially expanded the mineral industry, employing 136,000 persons to attain maximum production, regardless of economy, by artificial prices, control of stocks, and Government ownership of mining enterprises. Postwar reconversion will also be seriously handicapped by the loss to Italy, by ceding to Yugoslavia, of the main Italian bauxite fields and the largest subbituminous coal field in Italy.

The output of minerals produced in 1945 was 35 percent of their 1938 volume. The only mineral to exceed the 1938 production was sulfur ore—ground, which is a 30-percent sulfur rock now used as an insecticide. Mercury, tin concentrate, and crude sulfur were the only minerals exported in 1945. Coal production from Sardinia was 558,723 tons of semibituminous. The Sardinian coal mines increased production during the year from 33,400 to 65,000 tons a month. The output of rock asphalt for road construction made noticeable progress, with an output of 138,472 tons in 1945.

Sulfur production from Sicily attained 30 percent of the total for 1939, with a production of 53,690 tons. The pyrite industry reached 20 percent of the prewar production level at the end of 1945, with a monthly rate of 15,000 tons. The bauxite and iron-ore mines were relatively inactive during the year, with a production of 2,584 tons and 49,256 tons, respectively. Mercury mines produced at the rate of about 100 tons of metal a month. The Sardinian lead smelter began operations in December 1945, and conditions in the lead and zinc industry were expected to improve. Italy also reported small produc-

[15] Abstracted from information received from C. A. Botsford, American mineral attaché, Rome, Italy.

tion for the year of tin concentrate, nickel concentrate, antimony ore, copper ore, manganese ore, asbestos, graphite, talc, and salt.

THE NETHERLANDS

The Netherlands is not in an area of extreme mineral wealth. The Limburg coal deposit in the far south of the country reported a production in December of 24,000 tons per day, which is more than 50 percent of the 1938 average of over 44,000 tons per day. The iron and steel industry was reported to be operating at the end of the year at approximately 60 percent of the 1940 production. The tin- and zinc-smelting industries were relatively inactive during 1945 because of a lack of foreign imports. The diamond-cutting industry showed steady improvement.

NORWAY

The loss of the German market, which consumed over 70 percent of Norwegian mineral exports, considerably depressed the industry in 1945. During the latter half of the year, not 1 ton of iron ore was exported. The Norwegian iron and pyrite ores are complex, and the German metallurgical plants were the only plants equipped to treat these ores. The associated copper and zinc industries are also in a depressed state.

Norway has no domestic bauxite, and the companies controlled by French, English, and Canadian interests did not operate because of the insufficient price differential between alumina and aluminum. The Norsk Aluminium Co. A/S was able to operate most of the year and attained an annual rate of 7,000 tons of its 8,000-ton capacity because this company could treat a year's supply of bauxite which the Nazis left. The Germans made extensive plans to increase the capacity of the Norwegian aluminum industry from a prewar 35,800 tons to 176,000 tons, with the addition of eight plants to the present six. The war ended with little or no construction of the plants begun, and it is questionable whether these plants ever will be completed, with the exception of the alumina plant at Sandesjøen and the aluminum plant at Aardel.

POLAND

Reports indicate that the Polish mineral industry made remarkable progress in returning to normal in 1945. Coal, iron and steel, lead and zinc, petroleum, and salt were all reported approaching prewar levels. It must be pointed out, however, that the boundaries of Poland shifted considerably in 1945 and that any comparison must be placed on that basis.

Coal production had a monthly rate of 3,000,000 tons at the end of 1945. Coke and briquet production also increased during the year. The 1945 output was 21,004,477 tons of coal, 934,365 tons of coke, and 59,599 tons of briquets.

In the last 11 months of 1945 the Polish lead-zinc industry mined 236,857 tons of zinc ore and smelted 36,385 tons of metallic zinc. This compares to a 1940 production of about 120,000 tons of metallic zinc. During the same period in 1945, 6,861 tons of lead and 49 tons of cadmium metal were produced. Production of pig iron in 1945 was 211,278 tons, while the steel ingots output totaled 486,566 tons. Production of iron ore was slow in approaching prewar volume. Polish salt production reached 15,000 tons a month during 1945.

PORTUGAL

Generally increased activity was noted in the Portuguese mineral industry for 1945, with sharp decreases in the production of tin and tungsten ore.[16] Coal production increased to 582,089 tons compared to 553,609 tons in 1944. Anthracite constituted 436,117 tons of the 1945 production. Domestic production was 54.4 percent of the 1945 coal consumption, with imports, chiefly from United Kingdom, totaling 1,070,750 tons. An increase in available shipping space explained an advance in pyrite production in 1945 to 170,967 tons, compared to 131,890 tons in 1944. Metal content of copper produced in 1945 amounted to 219 tons, mainly as cement copper, from the leaching and precipitating operations of the São Domingos mine. Sulfur production from sublimation at the same mine increased to 13,243 tons in 1945 compared to 10,948 tons for 1944.

Tin production was 591 tons, metal content, for 1945 compared to 1772, tons the previous year. Portugal also reported small productions of gold, manganese, chrome ore, lead, tungsten, titanium, and kaolin and increased production of tripoli and cement.

RUMANIA

The petroleum industry of Rumania again resumed an important role in 1945 after the destructive operations directed against it in World War II. Production from the four principal fields was 4,640,000 tons in 1945 compared to a 1939 production of 6,240,000 tons. The Prahova district continued to supply the bulk of the petroleum, with 3,103,000 tons for 1945. The Astra Romana continued to be the major producing company for the year, with an output of 1,572,043 tons. Drilling operations in 1945 were 50 percent of normal. Coal production for the year was estimated at 1,750,000 tons, the Petrosani Co. continuing to be the most important producer. Information on the rest of the Rumanian mineral industry is lacking.

SPAIN

The Spanish mining industry suffered from a power and water shortage in 1945 due to a serious drought during the year.[17] The lead, copper, and sulfur industries were particularly affected. The tungsten, amblygonite, mica, and strontium mines were again inactive.

Coal production was highest on record, with 11,953,755 tons. The Puertollano shale-oil distillation plant continued operation throughout the year. Iron-ore production continued strong owing to heavy British demand. Pyrite production for 1945 was 406,700 tons compared to 512,249 tons for 1944; but copper production decreased to 5,042 tons compared to 10,891 tons of copper content for 1944, and the associated sulfur industry decreased from 29,576 tons in 1944 to 19,300 tons for 1945.

A sharp decline was noted for the lead industry, which produced concentrates with a metal content of 26,175 tons in 1945 compared to 34,776 tons for the previous year. Zinc production was 17,262 tons of metal content, a slight decrease from 1945. Mercury production was 40,089 flasks in 1945, a decrease from the 68,938 flasks produced in 1944. Mercury stocks on hand continued large. The extreme

[16] Information abstracted from reports by Evan Bennett, American minerals attaché, Madrid, Spain.
[17] Bennett, Evan (minerals attaché), Mining Industry, Spain, 1945: State Department Dispatch 444, Madrid, February 1946, 20 pages.

shortage of tin resulted in production of an estimated 600 tons of metal during the year. Tungsten was produced only as a byproduct of the tin mining during the year and amounted to 215 tons.

Potash and phosphate production continued at a normal rate during 1945, with an increased demand for potash toward the close of the year. Potash production was an estimated 115,000 tons of contained potassium salts. Spain also reported a minor production during 1945 of manganese, molybdenum, nickel-chrome ore, antimony, bismuth, gold, fluorspar, graphite, bauxite, mica, magnesite, ferrosilicon, titanium, and ocher.

U. S. S. R.

Accurate information on the status of the U. S. S. R. mineral industry in 1945 was extremely meager. The Russians have released planned production goals for 1950, based on percentage increases over the production or the production goals for 1945 and 1940, but to revert back and assume the 1945 production from these figures results in an extremely problematic sum. The heavy metallurgical industry, sheltered in the Urals, escaped the ravages of the war which the Ukraine suffered and was at peak production during 1945.

The U. S. S. R. is known to have adequate quantities of platinum, phosphate, potash, manganese, chrome, asbestos, iron ore, coal, and pyrite to readily supply its domestic consumption in 1945 and allow an exportable surplus. Nickel production made rapid gains during the war years, and the 1945 production is estimated to approach 15,000 tons of metallic nickel. Production of tin also increased but was far below expectations. Molybdenum production made a slow gain but was far below requirements. Tungsten production was still insignificant. The production of aluminum in 1945 increased less than it did in other aluminum-producing countries for the same year. Magnesium production was insignificant. Copper, lead, and zinc production were not believed to have met expectations in 1945, in the light of the accelerated plans in construction for these nonferrous metals in the 1950 program. The petroleum industry continued at a high rate of development, and enough supplies were obtainable from neighboring countries, particularly Rumania, to supply the demand.

UNITED KINGDOM

The impact of peace after 6 years of war and the transition period to normal vitally affected the mineral industry of the United Kingdom in 1945. The nonferrous metal industry relies mainly on imported ore, and restoration of this trade was not established to any prewar degree during 1945. The lead and zinc industry produced 3,588 long tons of 79.87-percent lead concentrate and 6,360 long tons of 56-percent zinc concentrate in 1945. Tin production in 1945 was 993 long tons, and tungsten production amounted to 71 tons of tungsten metal content in the same year. In the nonmetallics, gypsum, barite, and fluorspar production in 1945 was 1,326,596 long tons, 93,215 long tons, and 43,582 long tons, respectively.

Coal.—The outstanding developments in the British coal-mining industry during 1945 were the further reduction in output, prohibition of practically all exports to conserve available stocks for domestic use, and proposed nationalization of the industry. Strip mining, a war innovation, contributed about 8,000,000 long tons in 1945, about 600,000 long tons less than the 1944 output. Underground mining totaled about 174 million long tons, or about 10 million long tons less than in the previous year. Metallurgical coke production was 13,985 long tons in 1945, and briquet production totaled 922,224 long tons.

Iron and steel.—The iron and steel industry was extremely active during 1945, with a production, slightly under 1944, of 11,808,000 long tons, or 5 percent above the 1935–38 average. Domestic iron-ore production in 1945 was 14,124,347 long tons, averaging 29.03 percent iron. Plans for reequipping, modernizing, and expanding the industry have been formulated by the British Iron and Steel Institute for a 5-year period, which will result in an expected increase in the productive capacity to 18 million long tons annually.

YUGOSLAVIA

At the close of 1945 there was no indication that any real progress had been made toward the general revival of mineral industrial production in Yugoslavia. Metal production was 20 percent, coal production 40 percent, and the production of other minerals 35 percent of the 1939 output. Production statistics were not available for 1945.

OTHER COUNTRIES

Albania.—Information on Albanian mineral production for 1945 is not available at this time.

Bulgaria.—This country was still under an armistice regime, and information on mineral statistics was not procurable.

Czechoslovakia.—Only meager information regarding mineral statistics from 1938 to 1945 has been released. All mines have been nationalized since the end of the war, and during the Nazi protectorate it was believed that statistics were deliberately inaccurate and falsified.

Denmark.—This agrarian country expects to produce 7 million tons of peat in 1945 contrasted to a production of 5,640,000 tons in 1944.

Iceland.—The only mining activity in Iceland in 1945 was the surface digging of peat for domestic consumption.. The Icelandic Government's mineralogist estimated the 1945 production at 11,000 tons compared to 11,973 tons for 1944.

Ireland.—The lack of coal trade with England during the war years resulted in an intensified Irish peat industry, which has a 10-year postwar development program.

Northern Ireland.—The mineral industry of Northern Ireland is insignificant, and there was no change in 1945.

Switzerland.—Insufficient coal continued to be the principal handicap to Swiss economy and industry. The 1945 production was 311,282 tons of coal and 497,429 tons of peat.

THE MIDDLE EAST [18]

By Frank L. Fisher

A revival of interest in the exploitation of Middle East mineral wealth was noted in 1945, with the greatest attention centering on the petroleum resources. The Middle East is primarily an agricultural region experiencing little maladjustment in the economic structure by World War II.

[18] Unless otherwise indicated, statistics for all countries in the Middle East are in metric tons.

IRAN

A production of 107,828 tons of coal (semibituminous) and small amounts of copper, iron ore, antimony, arsenic, sulfur, and nickel ore were reported for the Iranian year March 21, 1944, to March 20, 1945.

IRAQ

Iraq had no significant change in the general economic pattern during 1945. The country's large potential petroleum resources continued to share the spotlight. The Iraqi Government made public its intention of erecting and operating its own refinery at Baiji. Plans were also made in 1945 for two new 16-inch pipe lines. Oil production by Iraqi Petroleum Co. in 1945 was 4,313,400 tons compared to a production of 3,882,600 tons for 1944. Permission was granted the Anglo-Iraqi Co. to prospect for copper during the year. The only mineral reported exploited during the year besides petroleum was coal: a minor quantity was produced.

TURKEY

The Turkish mineral industry was normal during 1945.[19] The production of coal and iron ore increased with coal production totaling 3,716,000 tons (unwashed) compared to 3,560,000 tons (unwashed) for 1944. The iron-ore deposit at Dirvik produced 125,000 tons for the State-owned steel plant at Karabuk. The 1945 chrome production for the year came from the State-owned Guleman mine which produced an estimated 70,000 tons. The private chrome mines were idle during 1945. The 1944 production from all sources was 184,573 tons. Copper production in 1945 was 9,800 tons of blister of which 9,544 tons came from the Ergani mine. Sulfur production remained normal, with an estimated total of 3,000 tons of 65-percent concentrate and 778 tons of refined sulfur. The 1945 production of salt from all sources was 271,496 tons. The meerschaum pits near Eskisehir were reopened during the year. Production of coke and lignite was normal. The emery mines were inactive during the year, as were the antimony mines near Turhal. Production of manganese, mercury, and magnesite was insignificant.

The Turkish Mining and Prospecting Institute was extremely active and examined 1,300 mineral deposits. A hematite deposit was discovered at Sogutlu, near Adapazari, a few miles east of Istanbul, with reserves estimated at several million tons. Bauxite deposits were discovered in the area of Antalya and Iskenderun.

OTHER COUNTRIES

Cyprus.—This island was greatly affected by war conditions, and revival to normal operations was necessarily slow during 1945. Cyprus exported 3,797 tons of asbestos, 1,070 tons of chrome iron ore concentrates averaging 48 percent Cr_2O_3, and 101,676 tons of cupreous iron pyrites averaging 48 percent sulfur and 1 to 2 percent copper in 1945.

Palestine.—A partial exodus of the diamond-cutting industry back to Antwerp was the most significant factor in the Palestine mineral

[19] Lawson, Edward R. (counselor of embassy for economic affairs), Turkey. Annual Economic Review—1945 (Minerals compiled by J. R. Short, Jr.), State Department Dispatch 131, Ankara, Turkey, Mar. 1, 1946, 98 pages.

industry in 1945. Extraction of minerals from the Dead Sea continued at a normal rate, the Government sharing the 5-percent royalty with Trans-Jordan. Production of potash, the major mineral extracted, was 93,625 tons containing 80 percent KCl.

Saudi Arabia.—The Saudi Arabian Mining Syndicate resumed gold operations in March 1945.

Syria.—Mineral production in Syria, including Lebanon, Latskia, and Djebel Druse in 1945, was 190,000 tons of cement, 12,000 tons of salt, 13,000 tons of asphalt, 300 tons of ocher, and small amounts of sulfur, manganese, lignite, and bitumen.

Trans-Jordan.—This agricultural country produced 4,867 tons of raw phosphate in 1945, a slight decrease from the previous year. Trans-Jordan also reported minor production of kaolin, manganese, silica sand, and ocher, which are used in domestic brick and pottery manufacture.

THE FAR EAST AND PACIFIC AREAS

By Nelson Dickerman

Termination of hostilities in 1945 resulted in complete collapse of the temporary but far-flung economic structure set up by the military expansion of Japan. The former peacetime channels of industry and commerce are not yet reestablished.

India, Australia, Ceylon, New Caledonia, and New Zealand face conversion from war to peacetime activities. The Philippines, Netherlands East Indies, Burma, Malaya, Siam, French Indochina, and parts of China must recover from the effects of invasion before an effective and permanent economy can be inaugurated. Mineral resources developed under the domination of Japan will be revised to fit the industrial needs of the individual countries.

Production figures for the year are far from complete, but fragmentary evidence is sufficient to indicate trends and to show the state of an economy almost paralyzed by the effects of the war.

AUSTRALIA

Australia found that the transition to peace was not easy. Many factories had been built to produce the goods formerly imported, but the cancellation of contracts for war minerals also forced curtailment in many mines. Minerals and metals declined from their 1944 production, especially coal, on which the iron and steel industry largely depends. Production was estimated at 1 million long tons less black coal than the 13,721,468 tons in 1944.

Iron and steel.—The Broken Hill Proprietary Co., which owns the large steel works at Newcastle, is developing the Cockatoo Island, Yampi Sound (Western Australia), iron-ore deposits and planning to build four ore vessels of 12,500 tons to bring the ore to Wyalla, Newcastle, and Port Kembla, South Australia. They are also investigating the iron-ore deposits on New Caledonia, estimated to be 30 million tons, which could be blended with the Australian ore. They are also putting in a new 10-inch rod and bar mill at Port Kembla and a new battery of byproduct-coke ovens at the same place. The manufacture of alloy steels will be continued. Zirconium is being substituted for vanadium in many steels.

Petroleum.—The Lithgow Shale Oil Works at Marrangaroo, New South Wales, which was opened 5 years ago as a war measure, has been closed. During the war it produced 2 million gallons of crude from which 1 million gallons of gasoline were refined. Bitumen & Oil Refineries, Ltd., an American-Australian company, is planning oil refineries in New South Wales and Victoria to use crude supplied by the California-Texas Oil Co.

Nonferrous metals.—The large output of copper from the Mount Isa mine in Queensland has been stopped. A new mill to treat 30,000 tons of 4-percent copper ore a month and a copper smelter with a capacity of 1,500 tons of blister copper a month are to be added to the present works. The mine and the old mill have been turned back to treating the lead-zinc ore they were designed for. Magnesium metal is now being produced in quantity by the Broken Hill Pty. Tin production continues at about 2,500 tons a year. Gold production was about the same as in 1944, but plans are being made to open up many mines closed down by the war and lack of labor. In New Guinea the Bulolo Dredging Co. is planning to restart operations. Crews are restoring the dams and dredges. The greatest difficulty is lack of transport and shipping.

Extensive asbestos deposits have been opened up in the Hammersley Range of Western Australia.

BURMA

Political friction has interfered with economic rehabilitation since the Japanese capitulation. It is reported that the Bawdwin lead-zinc-copper-nickel-silver mine will not be back in production for 3 years because of damage to the mine plant, railroad track, and bridges.

The oil fields are being restored but the refineries must be rebuilt completely.

No reports have been received on the tin dredges in the south or the Mawchi tin-tungsten property.

CEYLON

Crystalline graphite, the principal strategic mineral of Ceylon, is produced for export only. Output decreased in 1945. Gem stones were in great demand, and prices were high for stones, including sapphires, alexandrites, cat's eyes, beryls, aquamarines, topaz, tourmalines, spinels, garnets, zircons, and moonstones. Salt production exceeded local demand and was exported.

CHINA

China Proper.—Not many factual data on the mineral output for 1945 are available. The large mines of the Kailan Mining Administration in northern Hopeh Province were producing 11,000 long tons of coal a day in March 1946 as against 9,000 tons in December 1945. The Chunghsing coal mines and Mentoukou anthracite mines in Hopeh were down to 1,700 and 800 long tons daily in early 1946. Production could be stepped up to 6,000 tons a day at each, if new power plants were installed.

All coal mines in other parts of China are producing below prewar figures, causing much interruption to transport, both railroad and steamer. The northern Kwangtung Province coal mines are in bad shape due to war damage and looting. The Fookwok Mining Co. mines are idle, as is the former Kan-ah-tung mine.

Many of the tin, tungsten, antimony, and mercury mines are closed owing to the political instability and to the fluctuations in Chinese currency.

Formosa.—Production activity under the Chinese Government is unknown. Japan had developed the island with many agricultural and industrial plants, leading to surpluses for export of sugar, salt, camphor, coal, copper, gold, and sulfur.

Manchuria.—Production figures for 1945 are lacking. The Russians withdrew occupational forces by April 30, 1946. Removal by the Russians of critical pieces of machinery, power generators, and railroad equipment crippled the mineral industry. Production at the large Fushun coal mine was reduced from 30,000 tons a day to 1,000 tons, all of which was badly needed by the railroads. The steel, chemical, and paper industries are closed.

Years will be required to restore equipment and technical supervision needed to reestablish the industrial position of Manchuria which amounts to more than 70 percent of the entire Chinese production capacity.

FRENCH INDOCHINA

Chinese, British, and French troops occupying the country after the Japanese surrender met native resistance, but comparative peace has been reestablished. The coal washing and loading equipment near Haiphong was badly damaged during the war and will require extensive and time-consuming repair. The four tin mines will require 6 months to a year of repair before production is resumed. The tin smelter at Haiphong is reported to be intact, but only 550 metric tons of tin and 570 tons of 40- to 70-percent concentrate were found after the Japanese evacuation. The mining of apatite rock was reported to have been expanded by the Japanese to a production rate of 150,000 to 200,000 metric tons a year. No report of the zinc mines has been received.

An agreement between the French and the Chinese giving the Chinese shipping rights on the Haiphong-Kunming railroad and duty-free export from Haiphong has been of no help, because much of the roadbed, rails, and bridges was destroyed or removed and replacements have not been made.

INDIA

Conversion from production of war materials to peacetime operation is delayed by political instability.

The coal situation is improved by the importation of more machinery and by raising the working standards of the miners. The iron and steel industry is in much better shape because of expansions and improvements made during the war.

Intensive search was made for strategic minerals during the war, but India is still deficient in oil, copper, lead, zinc, sulfur, and tin. Exportable surpluses of mica, manganese, and chrome will be in demand for other countries. Aluminum and magnesium industries await future development.

War contracts for beryl were terminated on January 1, 1946, and shipments of thorium sands to the United States were discontinued by the Dewan of Travancore in April 1946.

A strong movement has been started in India to require that raw minerals, including monazite and other sands, shall be processed at home before being shipped abroad.

JAPAN

Japan was reduced essentially to the four home islands. Not only the territorial gains of the war, but also Formosa, the Ryukyu Islands, Korea, Manchuria, the Kurile Islands, the southern half of Sakhalin Island, and the Marshall, Caroline, and Marianas Island groups are lost to Japan. Consequently, Japanese industry must be curtailed as well as modified to meet drastically reduced raw material supplies and to reduce war-making potentialities.

Coal.—Monthly production of coal mines in the Japanese home islands, which averaged 5,500,000 metric tons in 1942, dropped to 600,000 tons in October 1945 but was back to 1,400,000 tons in March 1946.

Iron and steel.—Capacities and incomplete production figures for iron and steel are given:

	1944 annual capacity (metric tons)	*December 1945 production (metric tons)*
Pig iron	6, 588, 000	9, 036
Electric furnace steel	3, 335, 000	(1)
Open-hearth steel	10, 633, 000	8, 770
Rolled steel	8, 702, 000	(1)

1 Data not available.

Petroleum.—Petroleum production was not affected seriously by the war. About 3,700 barrels of oil were produced from 4,526 wells in October 1945, which amounts to approximately 15 percent of requirements. A survey is in progress to determine possible increases.

Nonferrous metals.—Refined-copper production was over 120,000 metric tons for 1943, but only an estimated 400 metric tons were produced in January 1946. Lead mine production was 22,706 metric tons in 1943, and the forecast for 1946 was 8,680 tons. Zinc mine production was 93,307 metric tons in 1943 and 32,770 tons forecast for 1946. Aluminum production amounted to only 59 tons in December 1945 compared with 109,525 tons produced in 1944. Cement production dropped from the 4,250,000 metric tons per annum rate of 1940 to less than a million tons in 1945. Antimony refined in January 1946 was 13 metric tons and nickel refined 36 metric tons. A manganese production of 400,000 metric tons in 1944 averaged only 31 percent in grade.

KOREA (CHOSEN)

The political future of Korea has not been established in terms of economic unity. Occupational division, with the Russians north of the 38° parallel and Americans to the south, has divided the area and interfered with the possible development of self-sufficiency.

The north is predominantly industrial, with most of the developed hydroelectric power, coal, and gold mines. The south, predominantly agricultural, has deposits of asbestos, molybdenum, graphite, nickel, lead, and zinc. Coal is relatively inaccessible, and since none is coming from the Russian mines in the north it is being supplied by an allotment of 70,000 tons a month from Japan.

The railroads need rolling stock and repairs, which will come largely from Japan.

MALAYA

The condition of the tin dredges and hydraulic and washing plants in Malaya was much better than had been expected. Machinery on tin dredges was much run down, due to improper lubrication and lack of replacement of parts. Some of the motors, tools, and supplies had been taken away and will have to be replaced. Repair shops, tin cleaning plants, offices, and houses had not been maintained. Older dredges had been damaged by neglect. The loss of power plants in some cases was serious. However, operation was partly resumed, and engineers have placed orders for machinery and supplies. The Chinese dulong washers and pit mines were put in operation and for the first quarter of 1946 produced 802 long tons of tin-metal content, about equally divided between the two methods. By March 1, 1946, 91 mines, including 4 dredges, were operating.

The return to normal production will be hindered by the long time required for delivery of needed machinery, supplies, and spare parts. The scarcity of coal, petroleum and its products, food, and clothing is slowing many operations; but every month probably will see increased output of tin, and by the beginning of 1947 stocks of tin should be much larger.

Luckily, the large public power plants were not damaged. The output of coal will have to be stepped up to supply the railroads. The iron and bauxite mines worked by the Japanese will not be opened immediately.

NETHERLANDS EAST INDIES

Like Malaya, the tin mines in Bangka, Billiton, and Singkep Islands were found in early 1946 in much better condition than had been expected. The dredges were much the worse for wear and neglect, but some were soon back in operation. One underground mine at Bangka was badly damaged and may never be reopened. Some 5,000 tons of tin metal and some concentrates were found at Bangka, which the Japanese could not remove. The smelters can be put in operation without undue delay. The Billiton Co. announced on June 28, 1946, from The Hague that 6 large bucket dredges, 2 large suction dredges, and 11 small suction dredges were operating at Billiton. At Bangka 9 tin mines are operating, but no large dredges. Two large dredges are expected to start up there in August 1946.

No report on the nickel mines on Celebes has been received or on the condition of the bauxite mines on Bintan and Kojan Islands near Singapore. These are the best bauxite deposits so far known in the Far East. The petroleum fields in Borneo are being restored and by early 1946 were shipping oil abroad. The condition of the oil fields and refineries on Sumatra is not known here, but as soon as political conditions permit they will be rapidly restored to production. The same is true of the coal mines on Sumatra.

717372—47——105

NEW CALEDONIA

Exports of nickel matte to the United States terminated on June 30, 1945, when the contract expired, and the matte now is being shipped to France; 5,098 metric tons of 76- to 79-percent nickel matte were shipped in 1945. Chrome ore amounting to 50,952 metric tons was shipped to the United States and to France in 1945.

NEW ZEALAND

Coal production increased to an estimated 2,825,000 long tons from 2,805,970 long tons in 1944 but was still short of demand. Gold production in 1945 is estimated at 125,000 fine ounces compared with 142,287 fine ounces in 1944. The drop is due to lack of labor and essential supplies. Manganese and mercury production was discontinued after the termination of hostilities, but some scheelite was still being mined by private operators.

PHILIPPINE ISLANDS

The Philippine Islands attained independence on July 4, 1946. The new government is faced with the enormous task of restoring commercial and industrial activity. Most of the mines and factories were badly damaged or looted, and both machinery and supplies must be imported.

The American Government has furnished large quantities of former military construction and transportation equipment and will assist financially in the restoration and rehabilitation program. Free trade with the United States for 8 years will be a helpful factor.

Many of the large mining and industrial companies in which Americans were interested have retained engineers to advise on reconstruction, and new companies are being organized for development purposes.

SIAM

Tin dredges and mines in Siam suffered no war damage but are badly run down through lack of maintenance and repair. No reports of resumed operations have been received.

U. S. S. R.—SIBERIA

Information is meager on resource developments of the Provinces bordering on the Sea of Okhotsk and the Sea of Japan. The Russians have built steel and manufacturing plants at Komsomolsky and Kharbarovsk, as well as oil refineries to handle crude oil from Sakhalin Island. The Soviet press has reported that oil production in the northern part of Sakhalin Island is being expanded, and total production is expected to be at the rate of 4 to 5 million barrels a year. Coal production on the island and in the Maritime Provinces is greater than before the war, and further expansion is planned. New mineral deposits are reported, but data on quality and reserves are lacking.
