The libraries provide public access to a wide range of material, including online exhibits, digitized collections, archival finding aids, our catalog, online articles, and a growing range of materials in many media.

When possible, we provide rights information in catalog records, finding aids, and other metadata that accompanies collections or items. However, it is always the user's obligation to evaluate copyright and rights issues in light of their own use.

MINERALS YEARBOOK

U.S.
DEPARTMENT
OF THE
INTERIOR

BUREAU
OF
MINES

UNITED STATES DEPARTMENT OF THE INTERIOR • Bruce Babbitt, Secretary

BUREAU OF MINES

As the Nation's principal conservation agency, the Department of the Interior has responsibility for most of our nationally owned public lands and natural resources. This includes fostering the wisest use of our land and water resources, protecting our fish and wildlife, preserving the environmental and cultural values of our national parks and historical places, and providing for the enjoyment of life through outdoor recreation. The Department assesses our energy and mineral resources and works to assure that their development is in the best interests of all our people. The Department also has a major responsibility for American Indian reservation communities and for people who live in Island Territories under U.S. administration.

Foreword

This edition of the Minerals Yearbook discusses the performance of the worldwide minerals industry during 1991 and provides background information to assist in interpreting that performance. Content of the individual Yearbook volumes follows:

Volume I, Metals and Minerals, contains chapters on virtually all metallic and industrial mineral commodities important to the U.S. economy. Chapters on advanced materials and nonrenewable organic materials also were added to the Minerals Yearbook series beginning with the 1989 and 1990 volumes, respectively. A new chapter on nonferrous metals recycling has been initiated in this 1991 volume. In addition, a chapter on survey methods used in data collection with a statistical summary of nonfuel minerals and a chapter on trends in mining and quarrying in the metals and industrial mineral industries are included.

Volume II, Area Reports: Domestic, contains chapters on the minerals industry of each of the 50 States, Puerto Rico, Northern Marianas, Island Possessions, and Trust Territory. This volume also has a chapter on survey methods used in data collection, including a statistical summary of domestic nonfuel minerals.

Volume III, Area Reports: International, contains the latest available mineral data on more than 150 foreign countries and discusses the importance of minerals to the economies of these nations. Beginning with the 1989 review, Volume III is presented as six reports: Mineral Industries of the Middle East, Mineral Industries of Africa, Mineral Industries of Asia and the Pacific, Mineral Industries of Latin America and Canada, Mineral Industries of Europe and Central Eurasia, and Minerals in the World Economy. This year's reports incorporate location maps, industry structure tables, and an outlook section previously incorporated in our Mineral Perspectives Series quinquennial regional books, which are being discontinued.

The U.S. Bureau of Mines continually strives to improve the value of its publications to users. Therefore, constructive comments and suggestions by readers of the Yearbook will be welcomed.

Acknowledgments

Volume I, Metals and Minerals, of the Minerals Yearbook presents data on about 90 material commodities that were obtained as a result of the information gathering activities of the U.S. Bureau of Mines.

The collection, compilation, and analysis of domestic minerals industries data were performed by the staffs of the Division of Mineral Commodities and the Division of Statistics and Information Services. Statistical data were compiled from information supplied by mineral producers and consumers in response to canvasses, and their voluntary response is gratefully appreciated. Information obtained from individual firms by means of the U.S. Bureau of Mines canvasses has been grouped to provide statistical aggregates. Data on individual firms are presented only if available from published or other nonproprietary sources or when permission of the respondent has been granted.

The chapter "Survey Methods and Statistical Summary of Nonfuel Minerals" discusses in somewhat greater detail procedures for canvassing the minerals industry and the processing and evaluation of these data.

Other information appearing in the volume was obtained from the trade and technical press, industry contacts, and additional sources; this cooperation is gratefully acknowledged.

Statistics on world production were compiled in the Division of Statistics and Information Services and Division of International Minerals from numerous sources, including reports from the U.S. Department of State. U.S. foreign trade data were obtained from reports of the Bureau of the Census, U.S. Department of Commerce. Data on production costs for several commodities were supplied by the U.S. Bureau of Mines, Minerals Availability System.

The U.S. Bureau of Mines has been assisted in collecting mine production data and other supporting information by numerous cooperating State agencies. These organizations are listed in the acknowledgments of Volume II.

Donald G. Rogich
Chief, Division of Mineral Commodities

SURVEY METHODS AND STATISTICAL SUMMARY OF NONFUEL MINERALS

By Jacqueline A. McClaskey and Stephen D. Smith

Ms. McClaskey, an operations research analyst with 6 years of Government experience, has been with the U.S. Bureau of Mines Branch of Statistics and Methods Development since 1990.

Mr. Smith, industry data analyst in the Section of Industry Data Analysis and Coordination, was assisted in the preparation of the Statistical Summary by Imogene P. Bynum, Chief, Section of Metals Data; Rosa McGee, Chief, Section of Industrial Minerals Data; William L. Zajac, Chief, Section of International Data; and Jim F. Lemons, Jr., Chief, Branch of Materials.

SURVEY METHODS

The U.S. Bureau of Mines Information and Analysis Directorate collects worldwide data on virtually every commercially important nonfuel mineral commodity. These data form the base for tracking and assessing the health of the minerals sector of the U.S. economy.

The Bureau's data collection activity was instituted by the 47th Congress in an appropriations act of August 7, 1882 (22 Stat. 329), which placed the collection of mineral statistics on an annual basis. The most recent authority for the U.S. Bureau of Mines survey activity is the National Materials and Minerals Policy, Research and Development Act of 1980 (Public Law 96-479, 96th Congress). This act strengthens protection for proprietary data provided to the U.S. Department of the Interior by persons or firms engaged in any phase of mineral or mineral-material production or consumption.

Data Collection Surveys

The Bureau begins the collection of domestic nonfuel minerals and materials statistics by appraising the information requirements of Government and private organizations of the United States. Requirements that can be met by collecting data from minerals establishments are posed as questions on U.S. Bureau of Mines surveys. Figure 1 shows a typical survey form.

Specific questions about the production, consumption, shipments, etc., of mineral commodities are structured in the survey forms to provide meaningful aggregated data. Thus, the entire mineral economic cycle from production through consumption is covered by 167 monthly, quarterly, semiannual, annual, and biennial surveys.

After the survey form has been designed, a list of the appropriate establishments to be canvassed is developed. Many sources are used to determine which companies, mines, plants, and other operations should be included on the survey mailing list. Bureau of Mines State Mineral Officers, State geologists, Federal organizations (e.g., Mine Safety and Health Administration), trade associations, industry representatives, and trade publications and directories are some of the sources that are used to develop and update survey listings. With few exceptions, a complete canvass of the list of establishments is employed rather than a sample survey. The iron and steel scrap industry is one of the exceptions where a sample survey is conducted.

The Paperwork Reduction Act requires that any Government agency wishing to collect information from 10 or more people first obtain approval from the Office of Management and Budget (OMB). OMB approves the need to collect the data and protects industry from unwarranted Government paperwork. (See *figure 1.*)

Survey Processing

The Bureau surveys approximately 25,500 establishments. Each year the Bureau mails about 50,000 forms that gather information for 167 different surveys. Each completed survey form returned to the Bureau undergoes extensive scrutiny to ensure the highest possible accuracy of the mineral data. The statistical staff monitors all surveys to ensure that errors are not created by reporting in physical units different from the units requested on the form. Relationships between related measures, such as produced crude ore and marketable crude ore, are analyzed for consistency. Engineering relationships, such as recovery factors from ores and concentrates, are also employed. The totals for each form are verified, and currently reported data are checked against prior reports to detect possible errors or omissions.

For the majority of the surveys, which are automated, the forms are reviewed to ensure that data are complete and correct before entering into the computer. The computer is programmed to conduct a series of automated checks to verify mathematical consistency and to identify discrepancies between the data reported and logically acceptable responses.

The U.S. Bureau of Mines is modernizing and automating all of its survey processing and data dissemination functions. Automated commodity data system functions include computerized preparation of statistical tables; the use of

desktop publishing to integrate text and tables; and the implementation of a microcomputer bulletin board, known as MINES-DATA, for electronic dissemination of minerals data.

Survey Responses.—To enable the reader to better understand the basis on which the statistics are calculated, each commodity annual report includes a section entitled "Domestic Data Coverage." This section briefly describes the data sources, the number of establishments surveyed, the response percentage, and the method of estimating the production or consumption for nonrespondents.

To produce reliable aggregated data, the Bureau employs efficient procedures for handling instances of nonresponse. Failure to return the initial survey form results in a second mailing of the form. If the second form is not returned, telephone calls are made to the nonrespondents. The followup calls provide the necessary data to complete the survey forms and/or verify questionable data entries. Periodic visits to important minerals establishments are also made by Bureau commodity specialists or State Mineral Officers to gather missing data and to explain the importance of the establishment's reporting. By describing the use of the published statistics and showing the impact of nonresponse, the Bureau strives to encourage respondents to give a complete and accurate reply.

The OMB "Guidelines for Reducing Reporting Burden" stipulates that the minimum acceptable response rate shall be 75% of the panel surveyed. In addition, the Bureau strives for a minimum reporting level of 75% of the quantity produced or consumed (depending on the survey) for certain key statistics. Response rates are periodically reviewed. For those surveys not meeting the minimum reporting level, procedures are developed and implemented to improve response rates.

Estimation for Nonresponse.—When efforts to obtain a response to a survey fail, it becomes necessary to employ

estimation or imputation techniques to account for missing data. These techniques are most effective when the response rate is relatively high. Some of the estimation methods depend on knowledge of prior establishment reporting, while other techniques rely on external information to estimate the missing data. When survey forms are received after the current publication has been completed, the forms are edited, necessary imputations are made for missing data, and the survey data base is updated. The revised data are reported in later publications.

Protection of Proprietary Data.—The U.S. Bureau of Mines relies on the cooperation of the U.S. minerals industry to provide the mineral data that are presented in this and other Bureau publications. Without a strong response to survey requests, the Bureau would not be able to present reliable statistics. The Bureau in turn respects the proprietary nature of the data received from the individual companies and establishments. To ensure that proprietary rights will not be violated, the Bureau analyzes each of the aggregated statistics to determine if the data reported by an individual establishment can be deduced from the aggregated statistics. If, for example, there are only two significant producers of a commodity in a given State, the Bureau will not publish the State total because either producer could readily estimate the production of the other. It is this obligation to protect proprietary information that results in the "Withheld" or "W" entries in the published tables. However, if a company gives permission in writing, the Bureau will publish the data as long as the data from other producers are protected from disclosure.

International Data

International data are collected by country specialists in the U.S. Bureau of Mines Division of International Minerals with assistance from the Section of International Data. The data are gathered from various sources, including published reports of foreign Government mineral

and statistical agencies, international organizations, the U.S. Department of State, the United Nations, the Organization of Petroleum Exporting Countries, and personal contact by specialists traveling abroad. Each February an annual "Minerals Questionnaire" is sent through the Department of State to more than 130 U.S. Embassies asking them to provide estimates of mineral production for the host country for the preceding year. Missing data are estimated by Bureau country specialists based on historical trends and specialists' knowledge of current production capabilities in each country.

Publications

The U.S. Bureau of Mines disseminates current and historical minerals information through a broad range of printed publications.

The Minerals Yearbook summarizes annually, on a calendar-year basis, the significant economic and technical developments in the mineral industries. Three separate volumes are issued each year: Volume I, Metals and Minerals; Volume II, Area Reports, Domestic; and Volume III, Area Reports, International. Chapters in these volumes are issued separately as annual reports before the bound volumes are available. (Volume III country reports appear in bound volume only.)

Volume I of the Minerals Yearbook presents, by mineral commodity, salient statistics on production, trade, consumption, reserves, and other measures of economic activity.

Volume II of the Minerals Yearbook reviews the U.S. minerals industry by State and island possessions.

Volume III of the Minerals Yearbook presents the latest available mineral statistics for more than 170 countries with a summary review of the role of minerals in the world economy.

Mineral Industry Surveys contain timely statistical and economic data on minerals. The surveys are designed to keep Government agencies and the public, particularly the mineral industry

and the business community, informed of trends in the production, distribution, inventories, and consumption of minerals. Frequency of issue depends on the demand for current data. Mineral Industry Surveys are released monthly, quarterly, semiannually, or annually.

Mineral Commodity Summaries, an up-to-date summary of about 90 nonfuel mineral commodities, is the earliest Government publication to furnish estimates covering the previous year's nonfuel mineral industry data. It contains information on the domestic industry structure, Government programs, tariffs, 5-year salient statistics, and a summary of international mining news.

State Mineral Summaries provide estimated data and summaries of mineral activities at the State level for the previous year. These summaries have been prepared in cooperation with State geological surveys or related agencies.

Minerals Today, published bimonthly, provides readers with the latest information about developments, trends, and issues concerning the mining, processing, and use of minerals and materials.

Metal Industry Indicators, published monthly, contains indexes that measure the current and future performance of four U.S. minerals industries. For each of the four industries, a composite coincident index and a composite leading index have been developed based on procedures and data similar to those used to construct the U.S. Department of Commerce's coincident and leading cyclical indicators for the national economy.

Information Circulars are primarily concerned with Bureau economic reviews and interpretative analyses. The series also includes surveys of mining and operating activities, guides to marketing of mineral commodities, and compilations of historical information and statistical and economic data on minerals.

To purchase Volumes I, II, and III of the Minerals Yearbook and Minerals Today, contact the Superintendent of Documents, U.S. Government Printing Office, Washington, DC 20402. For free copies of individual annual reports of the

Minerals Yearbook, the Mineral Industry Surveys, the Mineral Commodity Summaries, the State Mineral Summaries, and Information Circulars, contact Publications Distribution, U.S. Bureau of Mines, Cochran Mill Road, P.O. Box 18070, Pittsburgh, PA 15236. To receive a copy of the Metal Industry Indicators, contact the Branch of Statistics and Methods Development, U.S. Bureau of Mines, MS 9701, 810 7th Street, NW, Washington, DC 20241.

Electronic Data Dissemination

In addition to the Bureau's printed publications, current Mineral Industry Surveys for several commodities and selected annual reports from the Minerals Yearbook are now available through the Bureau's MINES-DATA computer bulletin board. Using this system, the public may obtain information up to 4 weeks before published copies of the reports would arrive in the mail. The MINES-DATA system may be accessed by calling (202) 501-0373 using a modem set to 1200 or 2400 baud, 8 data bits, no parity, and 1 stop bit. Further information on how to use the MINES-DATA system may be obtained from the system operator by calling (202) 501-0406.

STATISTICAL SUMMARY

This annual report summarizes data on crude nonfuel mineral production for the United States, its island possessions, and the Commonwealth of Puerto Rico. Also included are tables that show the principal nonfuel mineral commodities exported from and imported into the United States and that compare world and U.S. mineral production. The detailed data from which these tables were derived are contained in the individual annual reports of Volume I and in the State reports of Volume II of this edition of the Minerals Yearbook.

Although crude mineral production may be measured at any of several stages of extraction and processing, the stage of measurement used in this annual report is what is termed "mine output." It usually

refers to minerals or ores in the form in which they are first extracted from the ground, but customarily includes the output from auxiliary processing at or near the mines.

Because of inadequacies in the statistics available, some series deviate from the foregoing definition. For copper, gold, lead, silver, tin, and zinc, the quantities are recorded on a mine basis (as the recoverable content of ore sold or treated). However, the values assigned to these quantities are based on the average selling price of refined metal, not the mine value. Mercury is measured as recovered metal and valued at the average New York price for the metal.

The weight or volume units shown are those customarily used in the particular industries producing the commodities. Values shown are in current dollars, with no adjustments made to compensate for changes in the purchasing power of the dollar.

Dimension	short tons	1,206,995	208,311	*1,186,216	*209,691	1,133,992	195,259
Sulfur (Frasch)	thousand metric tons	3,780	378,712	3,676	335,189	3,119	271,598
Talc and pyrophyllite	metric tons	1,253,128	W	W	W	W	W
Tripoli	do.	105,229	2,537	94,389	3,188	88,642	3,271
Vermiculite	short tons	293,320	32,550	229,584	19,075	185,103	13,410
Combined value of apatite, brucite, calcium chloride (natural), emery, graphite (natural, 1989), helium (crude), kyanite, lithium minerals, magnesite, magnesium compounds, marl (greensand), olivine, pyrites, staurolite, wollastonite, and values indicated by symbol W							
		XX	*483,673	XX	473,453	XX	506,275
Total industrial minerals³		XX	20,357,000	XX	*20,895,000	XX	19,539,000
Grand total⁴		XX	*32,220,000	XX	*33,337,000	XX	30,489,000

*Estimated. †Revised. NA Not available. W Withheld to avoid disclosing company proprietary data; value included with "Combined value" data. XX Not applicable.

¹Production as measured by mine shipments, sales, or marketable production (including consumption by producers).

²Recoverable content of ores, etc.

³Content of ore and concentrate.

⁴Data series revised to exclude nonnickel ore.

⁵Revised due to the separation of palladium metal from platinum metal.

⁶Data may not add to totals shown because of rounding.

⁷Grindstones, pulpstones, and sharpening stones; excludes mill liners and grinding pebbles.

⁸Excludes abrasive stone and bituminous limestone and sandstone; all included elsewhere in table.

TABLE 2
TOTAL U.S. NONRENEWABLE ORGANIC MATERIALS PRODUCTION, BY QUANTITY AND VALUE¹

(Million metric tons, unless otherwise specified)

Category	1989		1990		1991 [*]	
	Quantity	Value (millions)	Quantity	Value (millions)	Quantity	Value (millions)
Asphalt and road oil	25.52	\$2,817	25.02	\$3,480	25.69	\$2,944
Lubricants, waxes, and miscellaneous products	12.78	1,499	12.51	1,863	12.10	1,506
Petrochemical industries	55.66	6,331	57.75	7,759	65.09	7,455
Petroleum coke and coal	11.47	900	13.05	1,291	13.07	1,058
Total²	105.43	11,548	108.33	14,394	115.95	12,964

^{*}Estimated.

¹Quantities valued at the fossil fuel prices given in the Department of Energy, Energy Information Administration, Annual Energy Review 1991, June 1992, p. 69.

²Data may not add to totals shown because of independent rounding.

NOTE.—Nonrenewable organic materials represent all nonfuel uses in physical structure applications. The petrochemical industries category includes feedstocks for the production of plastics, synthetic rubber, synthetic fibers, pesticides, coatings, solvents, fertilizers, and other petrochemicals.

TABLE 3¹
NONFUEL MINERALS PRODUCED IN THE UNITED STATES AND PRINCIPAL PRODUCING STATES IN 1991

Mineral	Principal producing States, in order of quantity	Other producing States
Abrasives ²	AR, WY, OH	
Antimony ³	ID	
Aplite	VA	
Asbestos	CA and VT	
Barite	NV, GA, MO, MT	IL.
Bauxite	AL and GA	
Beryllium concentrate	UT	
Boron minerals	CA	
Bromine ^o	AR	
Brucite	NV	
Calcium chloride (natural)	MI and CA	
Cement:		
Masonry	IN, MI, PA, SC	All other States except AK, CT, DE, LA, MA, MN, MS, NV, NH, NJ, NC, ND, OR, RI, VT, WI, WY.
Portland	CA, TX, PA, MI	All other States except CT, DE, LA, MA, MN, NH, NJ, NC, ND, RI, VT, WI.
Clays	GA, WY, CA, TN	All other States except AK, DE, HI, RI, VT, WI.
Copper ³	AZ, NM, UT, MT	CA, CO, ID, MI, MO, NV, OR, TN.
Diatomite	CA, NV, WA, OR	
Emery	OR	
Feldspar	NC, CA, OK, GA	CT, ID, SD.
Fluorspar	IL	
Garnet (abrasive)	IN and NY	
Gold ³	NV, CA, UT, MT	AK, AZ, CO, ID, NM, SC, SD, WA.
Graphite (natural)	(⁴)	
Gypsum (crude)	MI, OK, IA, NV	AR, AZ, CA, CO, IN, KS, LA, NM, NY, SD, TX, UT, VA, WA, WY.
Helium (crude and Grade-A)	KS, WY, TX, CO	NM.
Iodine	OK	
Iron ore (includes byproduct)	MN, MI, UT, MO	AZ, CA, MT, NM, SD, TX.
Iron oxide pigments (crude)	MO, GA, MI, VA	AZ.
Kyanite	VA	
Lead ³	MO, AK, ID, CO	AZ, MT, NM, NV, NY, TN, WA.
Lime	MO, PA, OH, KY	All other States except AK, CT, DE, FL, GA, HI, KS, ME, MD, MS, NH, NJ, NM, NY, NC, RI, SC, VT.
Lithium minerals	NC and NV	
Magnesite	NV	
Magnesium compounds	MI, CA, FL, UT	DE and TX.
Magnesium metal	TX, WA, UT	
Manganiferous ore	SC	
Marl (greensand)	NJ	
Mercury	NV and CA	
Mica (scrap)	NC, NM, GA, SC	CA, CT, PA, SD.
Molybdenum	CA, AZ, UT, MT	CA, ID, NM, NV.
Nickel ore	OR	
Olivine	WA and NC	
Palladium metal	MT	
Peat	MI, FL, MN, IL	CO, IA, IN, MA, ME, MT, NC, NJ, NY, OH, PA, SC, WA, WI, WV.

See footnotes at end of table.

TABLE 3¹—Continued

NONFUEL MINERALS PRODUCED IN THE UNITED STATES AND PRINCIPAL PRODUCING STATES IN 1991

Mineral	Principal producing States, in order of quantity	Other producing States
Perlite	NM, AZ, CA, ID	CO and NV.
Phosphate rock	FL, NC, ID, UT	MT.
Platinum metal	MT	
Potash	NM, UT, CA, MI	
Pumice	CA, OR, AZ, NM	ID and KS.
Pyrites (ore and concentrate)	AZ	
Rare-earth metal concentrates	CA and FL	
Salt	NY, LA, OH, MI	AL, AZ, CA, KS, NM, NV, OK, TX, UT, WV.
Sand and gravel:		
Construction	CA, OH, WA, TX	All other States.
Industrial	IL, CA, TX, NJ	All other States except AK, CT, DE, HI, IA, ME, NH, NM, ND, OR, SD, UT, VT, WY.
Silver ³	NV, ID, AK, MT	AZ, CA, CO, MI, MO, NM, NY, SC, SD, TN, UT, WA.
Sodium compounds:		
Soda ash	WY and CA	
Sodium sulfate (natural)	CA, TX, UT	
Staurolite	FL	
Stone:		
Crushed	PA, IL, VA, FL	All other States except DE.
Dimension	VT, IN, SD, GA	All other States except AK, DE, FL, HI, KY, LA, MS, NE, NV, NJ, ND, OR, RI, UT, WV, WY.
Sulfur (Frasch)	TX and LA	
Talc and pyrophyllite	MT, NY, TX, VT	AL, CA, NC, OR, VA.
Tin	AK	
Titanium concentrates	FL, NJ, CA	
Tripoli	IL, AR, OK, PA	
Tungsten ³	CA	
Vanadium ³	ID	
Vermiculite (crude)	SC, VA, MT	
Wollastonite	NY	
Zinc ³	AK, TN, NY, MO	CO, ID, IL, MT, NM, NV, OR, WA.
Zircon concentrates	FL and NJ	

¹Estimated.²This table had been table 2 in previous issues of the Minerals Yearbook.³Grindstones, pulpstones, and sharpening stones; excludes mill liners and grinding pebbles.⁴Content of ores, etc.⁵No production reported.

TABLE 4¹
**VALUE OF NONFUEL MINERAL PRODUCTION IN THE UNITED STATES AND
 PRINCIPAL NONFUEL MINERALS PRODUCED IN 1991**

State	Value (thousands)	Rank	Percent of U.S. total	Principal minerals, in order of value
Alabama	\$539,915	20	1.77	Cement (portland), stone (crushed and broken), lime, sand and gravel (construction).
Alaska	494,064	21	1.62	Zinc, lead, sand and gravel (construction), gold.
Arizona	2,829,123	1	9.28	Copper, sand and gravel (construction), molybdenum, cement (portland).
Arkansas	360,984	26	1.18	Bromine, stone (crushed and broken), sand and gravel (construction), cement (portland).
California	2,532,043	2	8.30	Cement (portland), sand and gravel (construction), boron minerals, gold.
Colorado	338,405	31	1.11	Sand and gravel (construction), molybdenum, cement (portland), stone (crushed and broken).
Connecticut	90,833	43	.30	Stone (crushed and broken), sand and gravel (construction, industrial), feldspar.
Delaware ²	5,101	50	.02	Sand and gravel (construction) and gemstones.
Florida	1,396,164	5	4.58	Phosphate rock, stone (crushed and broken), cement (portland), sand and gravel (construction).
Georgia	1,298,621	6	4.26	Clays, stone (crushed and broken), cement (portland), stone (dimension).
Hawaii ²	141,112	39	.46	Stone (crushed and broken), cement (portland), sand and gravel (construction), cement (masonry).
Idaho	297,048	33	.97	Phosphate rock, silver, gold, sand and gravel (construction).
Illinois	673,291	16	2.21	Stone (crushed and broken), cement (portland), sand and gravel (construction, industrial).
Indiana	403,295	24	1.32	Stone (crushed and broken), cement (portland), sand and gravel (construction), stone (dimension).
Iowa	344,032	29	1.13	Stone (crushed and broken), cement (portland), sand and gravel (construction), gypsum (crude).
Kansas	365,679	25	1.20	Helium (crude and Grade-A), salt, stone (crushed and broken), cement (portland).
Kentucky	343,124	30	1.13	Stone (crushed and broken), lime, cement (portland), sand and gravel (construction).
Louisiana	351,802	27	1.15	Salt, sulfur (Frasch), sand and gravel (construction), stone (crushed and broken).
Maine	41,304	46	.14	Cement (portland), sand and gravel (construction), stone (crushed and broken), cement (masonry).
Maryland	348,212	28	1.14	Stone (crushed and broken), cement (portland), sand and gravel (construction), cement (masonry).
Massachusetts	111,597	41	.37	Stone (crushed and broken), sand and gravel (construction), stone (dimension), lime.
Michigan	1,503,268	4	4.93	Iron ore (usable), cement (portland), magnesium compounds, sand and gravel (construction).
Minnesota	1,288,885	7	4.23	Iron ore (usable), sand and gravel (construction), stone (crushed and broken), sand and gravel (industrial).
Mississippi	101,859	42	.33	Clays, sand and gravel (construction), cement (portland), stone (crushed and broken).
Missouri	880,352	12	2.89	Lead, cement (portland), stone (crushed and broken), lime.
Montana	590,297	17	1.94	Gold, copper, cement (portland), silver.
Nebraska	89,392	44	.29	Cement (portland), sand and gravel (construction), stone (crushed and broken), lime.
Nevada	2,392,901	3	7.85	Gold, silver, sand and gravel (construction), diatomite.
New Hampshire ²	30,392	47	.10	Sand and gravel (construction), stone (crushed and broken, dimension), and gemstones.
New Jersey	204,988	37	.67	Stone (crushed and broken), sand and gravel (construction, industrial), zircon concentrates.
New Mexico	985,563	10	3.23	Copper, potash, sand and gravel (construction), molybdenum.

See footnotes at end of table.

TABLE 4¹—Continued
**VALUE OF NONFUEL MINERAL PRODUCTION IN THE UNITED STATES AND
 PRINCIPAL NONFUEL MINERALS PRODUCED IN 1991**

State	Value (thousands)	Rank	Percent of U.S. total	Principal minerals, in order of value
New York	\$698,659	14	2.29	Stone (crushed and broken), salt, cement (portland), sand and gravel (construction).
North Carolina	552,898	18	1.81	Stone (crushed and broken), phosphate rock, lithium minerals, sand and gravel (construction).
North Dakota ²	17,366	48	.06	Sand and gravel (construction), lime, gemstones.
Ohio	683,585	15	2.24	Stone (crushed and broken), sand and gravel (construction), salt, lime.
Oklahoma	275,525	35	.90	Stone (crushed and broken), cement (portland), iodine (crude), sand and gravel (construction).
Oregon	197,928	38	.65	Stone (crushed and broken), sand and gravel (construction), cement (portland), lime.
Pennsylvania	844,001	13	2.77	Stone (crushed and broken), cement (portland), lime, sand and gravel (construction).
Rhode Island ²	13,263	49	.04	Stone (crushed and broken), sand and gravel (construction), gemstones.
South Carolina	338,145	32	1.11	Cement (portland), stone (crushed and broken), gold, clays.
South Dakota	289,922	34	.95	Gold, cement (portland), sand and gravel (construction), stone (crushed and broken).
Tennessee	547,787	19	1.80	Stone (crushed and broken), zinc, cement (portland), clays.
Texas	1,264,661	8	4.15	Cement (portland), stone (crushed and broken), magnesium metal, sulfur (Frasch).
Utah	1,149,067	9	3.78	Copper, gold, magnesium metal, cement (portland).
Vermont	59,820	45	.20	Stone (dimension, crushed and broken), sand and gravel (construction), talc and pyrophyllite.
Virginia	428,045	23	1.40	Stone (crushed and broken), lime, cement (portland), sand and gravel (construction).
Washington	482,659	22	1.58	Sand and gravel (construction), gold, magnesium metal, stone (crushed and broken).
West Virginia	116,931	40	.38	Stone (crushed and broken), cement (portland), sand and gravel (industrial, construction).
Wisconsin	213,849	36	.70	Stone (crushed and broken), sand and gravel (construction), lime, sand and gravel (industrial).
Wyoming	929,176	11	3.05	Soda ash, clays, helium (Grade-A), cement (portland).

Mercury metal	metric tons	311	2,440	786	3,144
Molybdenum (molybdenum content):					
Ferromolybdenum	do.	300	2,372	375	3,058
Ore and concentrates	do.	41,380	169,888	33,424	113,709
Oxides and hydroxides	do.	787	5,095	1,571	9,678
Molybdates (all)	do.	680	3,963	740	3,965
Powder	do.	292	4,565	230	4,907
Unwrought	do.	180	2,453	88	1,204
Wire	do.	338	12,863	360	12,053
Wrought	do.	190	7,595	110	5,570
Nickel (nickel content):					
Unwrought					
Primary [anodes (electroplating), briquets, cathodes, chemicals (catalysts and salts), ferrouckel, flakes, oxide sinter, pellets, powder, and shot]	do.	8,873	77,047	9,104	91,359
Secondary (stainless steel and scrap)	do.	37,057	338,770	36,902	334,764
Wrought (bars, foil, pipes, profiles, rods, sheets, strips, tubes, and wire)	do.	465	5,937	354	5,756
Platinum-group metals (iridium, osmium, palladium, platinum, rhodium, ruthenium, and waste and scrap)	kilograms	55,044	415,605	39,624	461,588
Rare-earth metals (rare-earth oxide content):					
Cerium compounds	do.	1,729,771	9,983	1,368,535	8,195
Compounds (inorganic and organic)	do.	2,085,214	18,010	1,793,092	20,954
Ferrocium and pyrophoric alloys	do.	2,033,217	8,685	2,099,616	9,343

See footnotes at end of table.

Mineral	1990 ^a		1991		
	Quantity	Value (thousands)	Quantity	Value (thousands)	
METALS—Continued					
Rare-earth metals (rare-earth oxide content)—Continued:					
Metals (includes scandium and yttrium)	kilograms	201,122	\$1,249	59,035	\$2,683
Ores and concentrates	metric tons	NA	NA	459	NA
Selenium (metal, waste and scrap, selenium content)	kilograms	194,608	1,283	210,495	1,939
Silicon:					
Ferrosilicon	metric tons	50,079	43,993	50,393	43,008
Metal	do.	8,980	92,229	8,246	112,323
Silver:					
Bullion (refined)	kilograms	735,993	119,892	787,474	115,224
Doré and precipitates	do.	13,184	2,353	53,128	8,486
Ores and concentrates	do.	21,861	3,994	299	49
Waste and scrap	do.	1,077,421	159,194	840,229	124,015
Tantalum:					
Ores and concentrates (includes synthetic)	thousand kilograms	14	138	11	248
Unwrought (alloys, metal, powders, and waste and scrap)	waste and scrap do.	183	29,200	208	27,646
Wrought	do.	60	20,068	77	26,580
Thorium:					
Compounds	kilograms	220	68	2,649	154
Tin:					
Ingots and pigs	metric tons	658	3,344	970	5,455
Tin scrap and other tin-bearing material, except tinplate scrap, (includes bars, rods, profiles, wire, powders, flakes, tubes, and pipes)	do.	106,389	55,921	121,359	88,327
Tinplate and terneplate	do.	145,396	78,687	150,187	89,677
Titanium:					
Metal:					
Scrap	do.	5,487	22,443	4,568	10,706
Sponge	do.	331	2,073	418	2,604
Other unwrought (billet, blooms and sheet bars, ingots, etc.)	do.	5,472	69,235	3,845	47,833
Wrought (bars, rods, etc.)	do.	4,526	148,290	3,300	113,060
Ores and concentrates	do.	18,765	7,398	26,912	10,167
Pigments (dioxides and oxides)	do.	202,288	434,560	189,679	349,516
Tungsten (tungsten content):					
Ammonium paratungstate	do.	356	2,456	770	4,114
Carbide powder	do.	1,074	21,946	839	18,880
Metal and alloy powder	do.	988	18,587	689	13,947
Miscellaneous tungsten-bearing materials [ferrotungsten and ferrosilicon tungsten, unwrought, wire (metal and alloy), wrought, other compounds (other tungstates), and other metal]	do.	795	36,683	822	40,037
Ore and concentrate	do.	139	765	21	165
Vanadium:					
Aluminum-vanadium master alloy	kilograms	381,595	7,468	170,392	4,344
Compounds [pentoxide (includes catalysts), and other (excludes vanadates), vanadium content]	do.	2,437,934	16,166	1,810,150	10,957
Ferrovandium	do.	334,272	5,480	178,027	2,454

See footnotes at end of table.

Wire (gross weight) do.	3	249	2	211
Wrought (gross weight) do.	61	4,217	53	3,275
Other (inorganic compounds, orange, waste and scrap, and other, gross weight) do.	1,133	5,268	1,186	6,237
Nickel (nickel content):				
Unwrought				
Primary [briquets, cathodes, chemicals (catalysts and salts), ferronickel, flakes, oxide sinter, pellets, powder, and shot] do.	131,116	1,177,634	132,445	1,123,536
Secondary (stainless steel scrap and waste and scrap) do.	142,749	1,255,682	138,657	1,182,174
Wrought (bars, foil, pipes, profiles, rods, sheets, strips, tubes, and wire) do.	1,035	15,495	1,131	16,880
Platinum-group metals (iridium, osmium, palladium, platinum, rhodium, ruthenium, ores, and waste and scrap) kilograms	125,354	1,905,830	125,661	1,742,866
Rare-earth metals (rare-earth oxide content):				
Cerium compounds (includes chlorides, hydroxides, nitrates, oxides, oxilate, and sulfates) do.	359,230	2,040	544,962	4,913
Compounds (includes hydroxides, nitrates, oxides, and others, except chlorides) do.	4,989,646	37,325	3,693,163	34,079
Chloride mixtures (except cerium chloride) do.	1,362,951	12,813	3,377,242	8,890
Ferrocerium and other pyrophoric alloys do.	93,130	1,495	92,997	1,424,071
Monazite metric tons	440	686	—	—
Oxide mixtures (except cerium oxides) kilograms	150,728	8,018	892,277	13,138
Rare-earth metals (whether intermixed or alloyed) do.	198,840	3,050	225,820	3,329
Rhenium:				
Ammonium perrhenate do.	3,002	2,127	3,513	2,815
Metal do.	5,888	6,864	10,847	13,316

^a See footnotes at end of table.

MINING AND QUARRYING TRENDS IN THE METALS AND INDUSTRIAL MINERALS INDUSTRIES

By Brian T. Brady, Gregory J. Chekan, and Charles V. Jude

Dr. Brady is a physicist who has been with the U.S. Bureau of Mines, Denver Research Center, for over 25 years. Mr. Chekan is a geologist who has been with the U.S. Bureau of Mines, Pittsburgh Research Center, for 4 years. Mr. Jude is a mining engineer at the Denver Research Center who has extensive industrial and research experience in block caving mining operations. Domestic survey data were prepared by Stephen D. Smith, mineral data assistant.

MINING HIGHLIGHTS

Summary

The year 1991 recorded unprecedented change throughout the world; war in the Middle East, economic recession in key industrial nations, upheaval in Eastern Europe, and the disintegration of the former U.S.S.R. These issues and growing environmental concerns will affect the entire world mining industry.

Environmental issues continue to have an ever greater effect on industrial minerals. In the United States, major issues involving the Clean Air Act, Clean Water Act, and the recent Stormwater Rule by the U.S. Environmental Protection Agency (EPA) affect many types of mineral operations. Significant developments include an important decision in 1991 by a Federal Appellate Court to overturn EPA's asbestos ban on certain products, partly on environmental grounds, and proposed legislation that would overhaul or abandon the 1872 Mining Act. On a global scale, prominent issues include environmental concerns over mining in the Antarctic and Arctic regions and a cutback in plans to clean up the Kola Peninsula in the Commonwealth of Independent States (C.I.S.).

In the United States, the EPA Stormwater Rule will have a pronounced effect on industrial mineral operations. EPA claims that stormwater runoff is the leading source of water pollution in the country. Under the new rule, mine operators will be required to outline pollution prevention measures (spill prevention and containment) before a mining permit is granted. The rule is expected to apply to a wide variety of more than 12,000 operations, including crushed rock operations. In some cases, group-permit applications will be allowed.

In October 1991, a Federal Appellate Court in New Orleans overturned a 1989 EPA ruling prohibiting the use of asbestos in many products such as brake linings and construction-related products such as coatings, shingles, and cement-bounded pipe. The EPA ruling was intended to gradually phase out the use of products containing asbestos by 1997. Although the court did not dispute the possible health hazards, it said EPA "presented insufficient evidence to justify the asbestos ban." Although the court decision was welcome news to the remaining producers of asbestos and its products in the United States and Canada, the proposed ban is likely to resurface in the court system in the near future.

Considerable press has been given to proposed legislation aimed at overhauling or discarding the Mining Law of 1872.

Antimining and environmental forces support such changes, but opponents fear these changes would cripple the mining industry. A chief point of contention is the proposed 8% gross Federal royalty on production. Many observers have noted that this royalty level could force many mines to close because it would exceed their profits. Other significant points of disagreement include expensive reclamation regulations that would require a performance bond for reclamation before mining, conditions on the right to mine, and patents.

Another first last year was the announcement by the Robertson Group public limited company that it had acquired sales rights from the Soviet Ministry of Geology for limited quantities of previously unavailable maps showing locations of Soviet diamonds, gas, gold, industrial minerals, metallic minerals, and oil.¹

FMC Corp. announced plans to develop brine deposits in northern Argentina that could make FMC a major producer of lithium carbonate, which is used in producing batteries, ceramics, glass, and rubber. The projected output of 7,000 to 15,000 metric tons per year compares with current annual world production of about 30,000 tons.²

The discovery of a new, very white marble deposit has been made north of Atlanta, GA. Reserves are estimated at

40 million tons. The marble is sufficiently pure to be used in paper.

The graphite industry continues to expand in Canada. Although some deposits are not high grade, the fact that many contain the flake type of graphite makes them easy to produce. Despite low grade and high labor costs, the low beneficiation costs and high demand for flake graphite results in a good profit and is expected to continue.

In Brazil, despite declining domestic consumption and export value of aluminum, State-controlled Companhia Vale do Rio Doce announced plans to significantly increase production of bauxite and aluminum over several years, with projected aluminum sales of about \$750 million annually and doubling by 1995.

The dimension stone industry has been growing steadily during the past decade. Among market economy countries, Italy, Spain, and the United States are the leading producers, with Italy producing more than 20% of the total. Most people are aware of world-famous Italian marbles, but few realize that granites are a major component of Italy's dimension stone production. Spain has a rapidly growing granite industry, particularly the "Spanish Pink" granite that makes up one-half of that country's total granite production.

China has become a major dimension stone producer, particularly in granite. Estimates show that granite block production is about one-third greater than that for Italy and three times greater than U.S. production. China also has a marble stone industry, although it is much smaller.

Many important developments occurred in the diamond industry in 1991, and China again made news with the discovery of a 60.5-carat stone in Liaoning Province (northeast China). Eastern China contains many kimberlites, and some are known to contain diamonds. A smaller number of diamond placer deposits are also known. Although data are sketchy, China could become a major diamond producer.

Another important diamond discovery occurred when results from core samples

of kimberlites in Saskatchewan indicated that Canadian Province may eventually have its first diamond mine. Many diamonds have been found in the samples (up to 0.6 carat) and some are gem quality.

Early in 1991, Poseidon's Bow River diamond operation in Western Australia announced it had exceeded its 1990 goal by almost 40% and had produced more than 720,000 carats. About 20% of the stones in this world-class deposit are gem quality, including pink stones. The company also announced that the alluvial gravels containing these diamonds occupy a larger area than originally realized.

De Beers and Botswanan interests renewed their 5-year agreement by which all diamonds mined by the De Beers-Botswanan Company, Debswana, will be marketed through the Central Selling Organization. Despite record production, the lower quality mix of stones in 1990 means a sharply lower gross national product for Botswana in 1991. Diamonds are a major component of the Botswanan economy.

In other diamond developments, De Beers-owned Tanex Ltd. signed an agreement with the Government of Tanzania to prospect for diamonds over a sizable area in the northern part of that country. Previous diamondiferous kimberlites in Tanzania have proven uneconomical.

De Beers has not fared as well in Zimbabwe with regard to its River Branch diamond claims. The Government insists that its Minerals Marketing Corp. act as agents and take a percentage of the production for domestic use. De Beers, although leaving the door open for future negotiations, may forfeit its claims after 2 years of disagreement. Other companies are showing an interest in exploring this area.

An Indonesian Diamond Corp. is developing an alluvial mining operation at Danau Seran that, at full production, should produce from 30,000 to 54,000 carats per year with a high proportion of gems. The company also expects to extract gold and platinum from the gravel.

Finally, Angola rejoined the Central Selling Organization. That country had been the only major diamond producer outside the organization since 1985.

The fertilizer industry in 1991 had a very slow year. Although production declined in some countries and planned expansions in the former U.S.S.R. were placed on hold, there are plenty of potash reserves. Demand for this commodity is not expected to surge in the near term. One expansion that concerns the Association of South-East Asian Nations countries is an agreement to set up a company to mine potash in Thailand with an expected production of 1 million tons per year by 1995.

Mining of phosphate rock has ended at Rhône-Poulenc's Mine at Mount Pleasant, TN. The company said the high cost for electricity to operate the thermal phosphoric acid process is uncompetitive compared to wet processing. The plant will continue to process its inventory of mined phosphate rock and expects to close in 1993.

Some sulfur prices have risen, in part because of the removal of some production by the Persian Gulf War. This loss portends tight supplies and higher prices until more projects come on-line and Middle Eastern production returns to normal.

The mineral sands industry is changing, particularly with respect to rutile and ilmenite, which serve as sources for titania. When heavy metals were banned, especially lead, titania became extremely important. Its high index of refraction (high reflectivity), relative stability, and nontoxic nature made it an ideal component for many applications such as ceramic glazes, enamels, paints, pigments, and plastics. Demand for titania and zirconia, with its special refractory applications, is the major reason for growth in mineral sands operations.

Despite a recession-related drop in sales in 1990, plants using the newer chloride process on mineral sands, developed by Du Pont De Numours, are expanding capacity. This process uses 50% less energy and generates 80% less waste than the older sulfate process,

which is still used widely in Europe. By the end of 1991, capacity at chloride plants will have increased by 233,000 metric tons per year.

Hazcare Pty. Ltd., a subsidiary of Pioneer Resources, has signed a preliminary agreement with Sierra Leone to mine and process deposits containing rutile, ilmenite, and lesser amounts of zircon. Richard Bay Minerals' plans to mine beach sands off the South African coast for rutile and ilmenite have run into problems with environmentalists because this coastal area is considered by some to be an internationally important wetlands area.

Uranium inventories remained high last year, similar to those of 1990, and prices stayed low. Industry analysts expect little increase in demand in the near term. Market conditions have reduced output at many mines and closed several mines. Marginal producers cannot compete in such an environment.

Yugoslavia closed its only uranium mine in 1990, and its last shipment of uranium cake was sent to the United States for processing in 1991. Czechoslovakia is expected to close several mines over the next few years, partly due to exhaustion of reserves.

Now that contracts to supply the U.S.S.R. have expired, plants in Czechoslovakia and eastern Germany must find new markets for their production. Once Canada's uranium-rich Cigar Lake project—said to be on schedule—begins production, it should be able to supply most needs in the Western Hemisphere.

Environmentalists are in a dilemma. Most have long opposed nuclear power, but they also face a growing awareness that fossil-fuel power generation has produced global environmental problems. Ironically, nuclear power may eventually regain stature with its opponents if acceptable safety features and waste disposal methods can be built into nuclear plants.

Izhorskiy Works in St. Petersburg (Leningrad), C.I.S., is apparently planning to market a new generation of small nuclear power stations that are small enough to be transported by motor

vehicle, motor boat, or helicopter. The units are claimed to be totally automatic and accident-proof, with a 25-year lifetime. These units will be marketed as ideal sources of electricity for villages, particularly in remote or coastal areas.³

Production Overview

Total processed nonfuel mineral materials in the United States during 1991 were valued at approximately \$297 billion. Raw nonfuel minerals production in 1991 was estimated at \$30.8 billion, a 5.8% decline from that in 1990. The metals component of production value has fluctuated much more than the industrial minerals component, reflecting the greater volatility of metal prices.

Employment in metal mining rose slightly in 1991, but this gain was more than offset by a decline in employment in industrial mineral mining, resulting in an overall decline of 3.0% to 164,000 workers in 1991. Prices of several major metals declined during 1991, reflecting weakness in the economy and causing some metal mines to shut down or reduce operation.

Industrial Minerals

The slowdown of the U.S. economy influenced the construction industry by affecting the demand for construction aggregates. The demand in 1991 for crushed stone was estimated to be about 1.1 billion short tons (st), and the demand for construction sand and gravel was expected to be about 820 million st. This is about a 10% decrease in demand for both commodities. The U.S. demand for cement declined 12% to 78.7 million st. This was the fourth consecutive year of decline following the peak reached in 1987. In addition, passage of the highway bill in 1991 should spur production in the portland cement industry in early spring when weather warms and construction crews start repairing the highway system.

Agricultural Minerals

Nitrogen represents the largest fertilizer market, with annual demand of about 80 million nutrient tons compared with 38 million tons for phosphates and about 28 million tons for potash. Rising nitrogen imports into the United States have displaced about 15% of U.S. capacity over the past decade. But over the past 18 months, the nitrogen business has been good to those who persevered. Phosphate rock production in 1991 was approximately the same as that of 1990. The world's potash producers stayed in overcapacity, but several producers operated at partial capacity to maintain prices.

While the breakup of the C.I.S. aided some of the agricultural minerals industry, sulfur demand there dropped sharply. This disrupted international trading patterns for sulfur and caused an all-out trade war during 1991. The result was a 40% drop in sulfur prices in just 12 months to the lowest mark since 1979. A complete recovery depends on the ability to predict what course the new C.I.S. will take. Eastern Europe and the former U.S.S.R. will continue to create interesting challenges for all types of minerals industries.

Metals

Throughout 1991, the United States remained totally dependent on foreign sources of bauxite for the production of primary aluminum metal. Despite a decline in primary aluminum ingot prices, domestic production continued to increase. World demand for aluminum metal leveled off in 1991, while primary aluminum ingot reserves rose dramatically during the year. This increase in reserves and the decline in aluminum ingot prices caused many companies throughout the world to begin to reevaluate the status of their higher cost aluminum reduction facilities.

Copper.—For the first time since 1975, the United States will be a net exporter of copper for 1991. Disruptions to the world copper mine production continued,

including strikes, mine accidents, and at yearend, civil unrest in Zaire. Even so, the supply of copper concentrates from mines in the United States and Chile was expected to surpass available smelter capacity for some time. Environmental concerns continued to delay any new mine or smelter copper project in the United States and Canada. U.S. exports of concentrates, refined copper, and semifabricates continued to be high; U.S. net imports of brass mill semifabricates decreased for the seventh consecutive year.

Gold.—Although price prospects were poorer than in past years, the domestic gold mining industry completed its 12th successive year of growth, and for the 2d consecutive year, the United States was the 2d largest gold producer in the world, after the Republic of South Africa. However, of the 112 operations that produced gold in 1990 or started production in 1991, 32 are no longer being mined. Eighteen of these are continuing to produce limited amounts of gold from residual leaching operations. The other 14 have been shut down and are no longer producing gold. Domestic exploration leveled off, and many companies redirected their search for gold elsewhere, often to Latin America. Environmental pollution abatement continued to be of concern to domestic producers. The demand for gold in jewelry, dentistry, and industrial sectors remains strong despite the general weakness in the domestic economy.

Iron and Steel.—The iron and steel industry suffered from weak markets, partly the result of uncertainty created by the Persian Gulf War, which began in August 1990. Nevertheless, a large amount of steel was produced in the last quarter of 1990 in expectation of an imminent upturn in the economy. This resulted in an overhang of stocks at the beginning of 1991 and a drastic fall in production. Capacity utilization dropped to about 65% in February and stayed below 75% for the remainder of the year. As a result, steel production dropped by

12% compared with that of 1990, while shipments of steel dropped by only 7% because of the industry's reserves. Shipments to the main markets (i.e., service centers, automobile producers, and construction) were 12% to 18% off their previous level.

Lead.—The United States continued to be a significant net exporter of lead concentrates for the second straight year as the two new Alaskan mines neared capacity production. This occurred in spite of the shutdown of two Missouri lead mines and several Western precious-metal and zinc-lead producers owing to lower prices. Domestic consumption of lead declined significantly in 1991 by about 75,000 metric tons. Secondary production remained strong, a result of strict battery disposal and/or mandatory recycling laws in 37 States. At yearend, legislative action was pending in six other States.

Platinum and Palladium.—U.S. production of platinum and palladium in 1991 was held at the same level as that in 1990. Lower prices for platinum made it necessary for the Nation's only mine and smelter, Stillwater Complex, near Nye, MT, to reduce the work force by 113. The price of platinum declined sharply as a result of a series of announcements that some companies had developed less expensive substitutes for platinum-group metals (PGM) used in auto catalysts. Two Japanese automobile companies announced new palladium-only auto catalysts; a South African firm announced a manganese-base auto catalyst; and a researcher in the Netherlands claimed development of an auto catalyst based on copper and chromium.

Silver.—U.S. silver production declined for the first time in 6 years. Domestic production was adversely affected by the closure or curtailment of operation at a number of mines, especially in the Coeur d'Alene area in Idaho. Mining activity was reduced in response to continued buildup of silver reserves and to the declining price of

silver, which fell to its lowest level in nearly two decades. Over the past few years, U.S. silver production has continued to increase despite declining prices and less from active silver mines. This increase is in response to increased byproduct silver production from gold leaching operations. In 1991, however, the recovery of byproduct silver was apparently unable to compensate for the lower production from primary silver mines.

Tantalum.—There has been no significant tantalum-mining industry since 1959, with the exception of small, unreported quantities of tantalum-bearing concentrates produced in 1989-91. Most of the world's resources of tantalum occur outside the United States, largely in Australia, Canada, Egypt, Malaysia, Nigeria, Thailand, and Zaire. In September 1991, the Defense Logistics Agency (DLA) accepted a sale offer from one of eight bidding firms to purchase 200,000 pounds (lb) of the product tantalum pentoxide for inventory in the Nation Defense Stockpile (NDS). Major uses of tantalum, as a metal powder, are in the production of electronic components, mainly in aircraft, capacitors used in computers, communication systems, missiles, ships, and weapon systems.

Zinc.—U.S. zinc mine production was at its highest level since 1965 even though six zinc-producing mines in the Western States closed during the year. Despite higher mine production, the United States continued to import most of its refined zinc because of a severe lack of smelting capacity. About one-half of the zinc concentrates produced was exported.

The General Accounting Office (GAO), the investigative arm of Congress, has determined that the gold mining industry and the Government have taken major steps to mitigate the potential threat that the use of cyanide may pose to wildlife and surface and ground waters. The report found that most cyanide-related wildlife deaths are preventable and

that most facilities have adopted improved techniques to prevent such deaths. The report GAO-RCED-91-145 is available from the GAO Document Service in Gaithersburg, MD.

Armco Steel has applied for a patent for a process it has developed over the past several years to dezinc bundles of galvanized sheet steel scrap. The process is almost the reverse of electrogalvanizing. Bales of galvanized sheet are immersed in a hot, caustic solution that has an electric current passing through it. The zinc coating is separated from the steel, which allows the steel to be recycled. With a number of automobiles containing zinc-coated steels now going to the scrap heap, steelmakers will have a way to recycle the metal from the cars. The process is 2 years away from commercial application.⁴

Lead scrap was the hottest item in the scrap exporter's arsenal in 1991, with export volumes rising by more than one-fifth over what was already a record-setting performance in 1990. U.S. traders sent abroad a total of 94,471 tons of lead scrap in 1991, up from 78,876 tons the year before. Scrap trade sources have said the growing importance of poorer countries as buyers in the international battery scrap market is a reflection of the difficulty some U.S. operators have had in ensuring that they can comply with increasingly strict environmental regulations.⁵

First National Minerals Education Conference

U.S. Bureau of Mines personnel participated in the first National Minerals Conference, held in Reno, NV, in February 1992. The event, sponsored by the Nevada Mining Association and the Nevada Department of Minerals, sought to bring together various organizations throughout the country interested in furthering student awareness of the importance of minerals and how they are recovered. Attendees included Mining Association education committees, professional societies, Government agencies, teachers and teacher organizations, educational productmakers,

and members of the mining industry. The 2-day conference included topics on the importance of minerals education, how minerals presentations can be extended to more classrooms, and panel discussions of various programs of the organizations.

Incentive Bonus Systems

Mining companies continue to use incentive bonus plans as part of their wage systems in 1991. As an example, Magma Copper Co. and its union workers agreed to an unusual 15-year contract in July. The agreement is very unique because it contains a binding arbitration provision that prevents the possibility of a strike for almost 8 years. The long-term labor contract was ratified 8 months before the current agreement expires. The new agreement provides an initial hourly increase of 35 cents and several automatic and conditional raises thereafter.

The innovative agreement is considered a key to prolonging operations in a copper mine operations at San Manuel, AZ, where underground mining of the San Manuel ore body has been scheduled to cease in 1997. The agreement allows for continued development and mining of the deeper, offset Kalamazoo ore body and results in preserving approximately 1,500 jobs.

Mexico Adopts New Mining Regulations

Mexico has adopted new national mining regulations to promote the growth of the Mexican mining industry by encouraging exploration and production and by promoting domestic and foreign investment. Among the significant changes introduced by the regulations are the mechanisms to increase foreign participation. The mechanism establishes trusts in both exploration and development of concessionable minerals. The exploration trust allows for 100% foreign ownership during a period of 30 years, with a renewal option. Through a similar trust, foreign control of mines is permitted for 12 years. After 12 years,

the foreign entity must sell at least 51% interest to Mexican citizens.

Another important step was taken to reduce government monopoly control of certain minerals. Under the new regulations, sulfur, phosphate rock, and potassium may be produced by private concerns through limited partnership with the government.

Other steps taken to promote growth and to increase participation in the mining industry include streamlining government processing of applications for approval of mineral concessions and the revision of criteria by which land is set aside within the national mineral reserves industry.

LEGISLATION AND GOVERNMENT ACTIONS

Summary

The mining industry is still waiting for definitive mine waste regulation. Resource Conservation and Recovery Act (RCRA) reauthorization has been a subject of intense debate, and novel EPA initiatives for consensus building such as Strawman and the Policy Dialogue Committee have not resolved the concerns of all interested parties. Pending RCRA reauthorization, the States have become more active in such areas as ground water protection. One particular State has proposed such stringent mining waste regulations that all future gold mining in that State could be foreclosed. The resultant uncertainty has made planning more risky, adding to new project costs. Proposed revisions to the Mining Law of 1872 have similarly been exhaustively debated without a consensus being reached. Independent studies show that there is a potential for significant reduction of exploration should the self-initiation features of the Mining Law of 1872 be repealed. The new provisions of the clean air legislation passed in 1990 seem to target the business sections rather than mining. The air toxics provisions of title III have caused considerable concern in the mining industry since many of the compounds listed as hazardous pollutants are found in mining environments.

EPA Activities—Mining Wastes

As part of its responsibilities to regulate noncoal wastes under RCRA, the EPA drafted two staff "Strawman" approaches toward the development of a minerals industry waste management regulatory program. The more recent approach, Strawman II, was released May 21, 1990. The EPA did not endorse either approach, but rather viewed them as working drafts to solicit comments from the public and other interested parties to assist in developing a mining waste management regulatory program. Unfortunately, both approaches failed to address a number of important issues that both the Departments of the Interior and Agriculture took exception to and formally addressed. Among the points EPA failed to take into account were the mandated responsibilities of the Federal land management agencies, (i.e., the Bureau of Land Management (BLM) and the U.S. Forest Service). Also, the regulatory program envisioned in Strawman II requires statutory authority beyond that currently available to the EPA in RCRA, such as the regulation of certain materials not now considered solid wastes. In general, these materials are in-process materials, such as ores being leached in heaps or dumps, or ores and subgrade ores in stockpiles.

Following the Strawman process, EPA established a Policy Dialogue Committee (PDC), which serves as a forum for continuing to refine and develop issues related to managing mining wastes. Although the PDC was to terminate by March 31, 1992, the charter has been extended and EPA will continue the committee's work beyond that date.

Reauthorization of RCRA

Activities leading to the reauthorization of RCRA are continuing to move forward. Reauthorization is necessary to avoid State-by-State changes that would create confusion at the Federal level, including the banning of shipments of interstate waste. Senator Max Baucus (D-MT), Chairman of the Senate Environment and Public Works

Environmental Protection Subcommittee, introduced a comprehensive Federal RCRA reauthorization bill, S. 976. This bill addresses the waste problem on several fronts: (1) reduces toxics in the waste stream and (2) stresses waste reduction and pollution prevention. A national goal of 50% recycling would be set for the year 2000. To ensure safe disposal, S. 976 establishes minimum Federal standards and permits for solid waste facilities.

Certain provisions of the Senate bill would affect the minerals industry. Although solid wastes generated from the extraction, beneficiation, and processing of ores and minerals are excluded from the permit guideline, standards for industrial waste management, the facility permit, and notification requirements remain. These provisions could result in significant costs for the minerals industry. Other sections of S. 976 relate to the regulation of recycled and secondary materials. These sections contain provisions that are expansive enough to subject several mine and mineral-processing activities, such as heap and dump piles, to RCRA regulation and result in additional costs. In addition, the bill includes a pollution-prevention section requiring detailed reporting on toxic generation, waste reduction, a reduction plan, goals, etc. While this provision does not specifically cover mines, it is applicable to mineral processing facilities.

In the House of Representatives, action has focused on reauthorization legislation by the Transportation and Hazardous Materials Subcommittee Chairman. The initial legislation (H.R. 3865) covered only municipal solid waste. On March 17, 1992, a substitute bill was released that includes new provisions for mining wastes. These provisions would require EPA to assist the States in program development and establishing mining waste programs.

Mineral Processing Waste

On May 20, 1991, EPA issued its final regulatory decision for the 20 special wastes from mineral processing activities.

These wastes were excluded from RCRA hazardous wastes regulations under subtitle C of the Bevill amendment. The final rule determined that subtitle C is inappropriate for all 20 wastes, because they exhibit negligible hazardous characteristics and pose low risks. The rule places 18 of the 20 wastes under the Agency's evolving subtitle D mining waste program. For the other two—phosphogypsum and phosphoric acid process wastewater—the rule concludes that neither subtitle C nor D regulation is warranted, and instead uses authorities under the Comprehensive Environmental Response Compensation and Liability Act (CERCLA) and the authority under the Toxic Substances Control Act (TSCA) to address the future generation and management of the wastes. EPA proposes to use existing RCRA and Superfund authorities to address any site-specific ground water contamination problems that are believed to pose substantial health and environmental risks. All other mineral processing wastes now are subject to regulation as hazardous wastes under subtitle C.

Revision of the Mining Law of 1872

Efforts continued in 1991 to amend the General Mining Law of 1872. Bills S. 433 and H.R. 918 were reintroduced in February 1991 and H.R. 2614 in June 1991. These bills provide for comprehensive changes to the current laws. Key arguments against the current law include (1) inadequate control of environmental damage, (2) patenting of surface ownership for \$2.50 or \$5.00 per acre, (3) lack of financial return to the government (royalties), and (4) nonmining abuses of claims. In April 1991, S. 785 was introduced to establish a commission to study existing laws and procedures relating to mining and to make recommendations for their modification.

Washington hearings on all four bills were held in June 1991. House field hearings were held in Denver, CO, Reno, NV, Santa Fe, NM, and Fairbanks, AK, during April and May 1991, and a Senate

field hearing was held during December 1991 in Salt Lake City, UT.

The Mining Law of 1872 established a policy of "self-initiation," whereby a prospector may file an unpatented mining claim if he makes a discovery. The filing of a claim establishes a property right to the minerals, subject to annual assessment and work requirements. The claimant can purchase (patent) the surface rights to a valuable mineral deposit after spending at least \$500 in development and paying the appropriate filing fees. Substantial investments may be incurred by a claimant to prove the value of a mineral deposit prior to being issued a patent.

Bills S. 433 and H.R. 918 are similar in some respects. Jurisdiction over minerals on Forest Service lands is moved to the Secretary of Agriculture. The concepts of "discovery" and "extralateral rights" are eliminated. A claimant is only given exclusive right of possession for mineral activities if a plan of operations, consistent with land-use plans, and financial guarantees for reclamation are submitted. Both bills require reclamation to premining site use. Mill site claims are eliminated. Patents are also eliminated, except where a patent application was filed before a certain date. Current claims or mill sites must be converted to the new system within 3 years. Both bills provide for user fees to recover administrative costs and establish a Hardrock Abandoned Mine Reclamation Fund, financed by fees or royalties, to address past mining damage. Virtually any citizen or noncitizen is given "standing" to sue the Secretary over noncompliance.

Significant differences exist between bills S. 433 and H.R. 918. Senate bill S. 433 provides for claims of up to 80 acres, establishes an incremental annual holding fee that is suspended on payment of royalties, imposes a 5% royalty on production, provides for surface use fees for mill sites, allows only 20 years to bring a mine into production, and requires biannual inspections by the land managing agency. House bill H.R. 918 limits claims to 40 acres, establishes annual rental fees (but no royalties) and incremental diligence expenditures or "in

lieu" payments, and requires quarterly inspections. Bill H.R. 2614 is similar to bill S. 433 in structure, but imposes an 8% royalty and bans foreign ownership of U.S. mines.

In striking a House provision to impose a fiscal year 1992 moratorium on patent issuance from the final fiscal year 1992 Interior Appropriations bill, H.R. 2686, it was agreed that the issues of fair market value of mining patents, a reversionary clause, and the holding fees would be taken up by the appropriate authorizing committee during fiscal year 1992.

On January 28, 1992, the American Mining Congress released an economic impact study of the Bumpers and Rahall reform bills prepared under contract by offices of Davis, Graham & Stubbs and Coopers & Lybrand, Denver, CO. The study concludes that annual fees and costs imposed on the mining industry would increase by more than \$120 million under S. 433 and by almost \$125 million under H.R. 918. The study asserts that as many as 30,000 jobs could be lost and reform could cost the Federal Government as much as \$230 million annually in lost revenue and increased spending. The study identifies annual holding/diligence expenditures as more than \$28 million under S. 433 and approximately \$100 million under H.R. 918 (fees minus credits). The latter amount approximates the Administration's projection for annual revenues to be generated by the \$100 holding fee.

The Bureau of Land Management Director testified in June 1991 "that the Administration opposes S. 433, H.R. 918, and any sweeping change of the discovery-location-patent system that has served us well." The Administration is said to be "committed to the retention of the four principles of the current Mining Law: (1) self-initiation of mineral rights, (2) free access across Federal lands, (3) security of tenure to mineral deposits, and (4) diligence that is self-policing." No statement has been made on bill H.R. 2614 by the Administration.

The mining industry concurred with the administration position and charged that complaints against the current mining

law were overstated and that the Bumpers and Rahall bills would have a devastating impact on domestic hard-rock mineral production. Industry concern focuses on loss of private tenure and project financing on significant holding costs and on new administrative expenses.

Clean Air Act Amendments (CAAA) 1990

The mining and minerals processing sectors will experience about an 11% compound annual growth rate for its direct capital expenditures for air pollution equipment over the next 3 years. Operating costs associated with this investment will increase, and those sectors that are sensitive to electrical energy costs will experience additional operating expense as the utilities pass through their added costs of compliance with acid rain provisions of the CAAA.

The air toxics provisions of the CAAA will impact mining and mineral processing in varied ways:

- (1) Existing coke oven batteries will have until January 1, 1998, to comply with emission standards by December 1992.
- (2) Heavy metals are prominent on the list of 189 hazardous substances to be regulated as air toxics. The mining companies have spent a good part of 1991 developing emissions characterization (a requirement for participation in the EPA's early reduction program).
- (3) Air toxics emitters will have to seek operating permits for the first time under the CAAA. The requirement to include public participation is in the legislation, but the degree of public participation and the magnitude of operational change that triggers public participation is still uncertain in the regulation.
- (4) The air toxics provisions also include a requirement to use risk assessment methods to assess human health risk after the best methods

have been replaced to meet standards. Risk assessment, as currently practiced, generally yields conservative risk estimates, which translate into greater costs.

The CAAA also mandated the EPA to study off-road diesel engine emissions, and the report has been issued. Mining interests are concerned that much of their equipment might be characterized as construction equipment (a troublesome category in the report) and thereby become initially subject to costly regulation.

Global warming from carbon dioxide (CO₂) and reconsideration of a short-term sulfur dioxide (SO₂) standard are two additional air pollution issues that have a potential for adding costs to mining and mineral processing.⁶

Lead-Acid Battery Recycling

Lead-acid battery recycling has increased in recent years. In 1989, the recycling rate was estimated to be 95%.⁷ Several factors have had a positive influence on the recycling rate: (1) battery recycling laws have been enacted by 33 States in the past several years, (2) the development of a multipath system to collect and recycle lead-acid batteries, (3) scrapped battery buyback programs at some stores have encouraged consumers to turn in their old batteries, (4) a growing public awareness of the potential environmental impacts that could result from batteries that are not recycled, and (5) an increase in the price of lead scrap.

Federal legislation related to the recycling of lead-acid batteries was introduced in the 101st Congress but was not acted upon. The "Lead Battery Recycling Incentives Act" bill, H.R. 870, and a comparable bill, S. 398, were introduced into the 102d Congress. These basically identical bills would require manufacturers and importers of lead-acid batteries to use a minimum amount of recycled lead in the batteries they produce. Domestic battery producers and importers who do not use recycled lead could be required to purchase credits from others who recycle batteries. Bill

S. 392, introduced in 1991, sets maximum lead content on certain products and prohibits the disposal of lead-acid batteries in landfills and incinerators. Legislation was also introduced (H.R. 2922) that would tax primary lead production at \$0.75/lb and secondary production at \$0.37/lb to pay for a \$1 billion trust fund for a lead abatement project.

In 1991, the EPA initiated a regulatory negotiation for a battery recycling rule. The regulatory negotiation was established under the Federal Advisory Committee Act (FACA). The committee negotiated issues to regulate the recycling of lead-acid batteries under section 6 of the TSCA. After 10 months, the regulatory negotiation came to an abrupt end when EPA officials announced that the costs associated with a Federal rule would outweigh any benefits it might promote.

The Doe Run Co. is completing the engineering phase of its \$38 million lead-acid battery recycling center in Boss, MO, and is gearing for a September 1992 opening. The facility is projected to produce as much as 60,000 tons of refined lead each year from 120,000 tons of used automobile materials. The facility will use a process that produces about one-third the volume of hazardous waste normally associated with battery recycling operations.⁸

Basel Convention

In March 1990, the United States signed the Basel Convention, an international agreement that deals with the international transboundary movement of hazardous waste. The Basel Convention is intended to put an end to the shipment of hazardous wastes for disposal in other nations, particularly Third World or developing nations. However, the convention agreement could affect the way metal waste and scrap, as well as other recyclable materials, are imported or exported as all of these materials are considered to be hazardous wastes in some countries, particularly within the European Community. Materials that are likely to be affected include, but are not

limited to, materials recovered from municipal waste, metal waste and scrap, precious-metal wastes and residues, and scrap batteries.

Under the Basel Convention, requirements will include advance notification of shipments of hazardous wastes through the Governments of the exporting and importing nations. Both the exporting and importing nations are obliged to ensure that the handling and disposal of the waste is environmentally sound. Trade in hazardous waste between a nation that is a party to the convention and one that is not will be prohibited, unless the nations enter into a separate agreement that is at least as protective of the environment as is the Basel Convention.

The Basel Treaty was submitted to the Senate on May 20, 1991. Legislation was introduced to provide the authority to implement the terms of the treaty in the United States. The Senate has not ratified the agreement, but it appears likely that the necessary signatures from 20 other countries will occur in early 1992.

Trade Issues

Canada, Mexico, and the United States began the negotiation of the North American Free Trade Agreement (NAFTA) in June 1991. In the NAFTA, the United States is seeking enhanced market access for goods and services, clarification of the rules governing trade and investment, enhanced intellectual property protection, and an effective mechanism for the settlement of trade and investment disputes. Mexico currently prohibits majority foreign ownership of mines, while the United States maintains no similar restrictions against foreign mineral investment. As of early spring 1992, the negotiations had advanced substantially, but no completion date for the talks had been established.

General Agreement of Tariffs and Trade (GATT) talks resumed in September 1991 in Geneva. In the middle of the Uruguay Round of tariff negotiations, countries, including Australia, Canada, and the United States,

are ready to adopt zero-for-zero tariffs for all nonferrous metals. Other countries are maintaining protective stances for certain metal industries. For example, France opposes any lessening of its 10% tariff on semifabricated aluminum products, while Japan continues to resist dropping tariffs on copper. Negotiators say that all nonferrous metals are being considered for zero-for-zero treatment. Although talks are still in the exploratory stage, it appears that it will not be possible to eliminate all such tariffs. The successful completion of these negotiations depends on resolution of the complex agricultural issues, on which only limited progress was reported during the year.⁹

Public Land Use

A U.S. Bureau of Mines report about potential mineral impacts of California desert land use bills is available. The report, Economic Analysis of the Minerals Potential of the East Mojave National Scenic Area (EMNSA), CA (OFR 55-92 and 56-92), covers both known mineral resources and the undiscovered metals potential of the 1.5-million-acre EMNSA. The report shows how the economic potential of these minerals would be affected under two proposals. One proposal, passed by the House in November 1991 as H.R. 2929, would change the land use management of many areas of the desert and would convert EMNSA into a national monument, similar to a park. Mining, except already developed sites, would be precluded from the area by this proposal. As an alternative, the Administration has proposed wilderness designation for several areas inside and outside EMNSA. Bill S. 21 was reintroduced at the start of the second session of the 102d Congress. The Administration's alternative bill, S. 2393, was also submitted and follows the recommendations of the BLM.

National Defense Stockpile

During 1991 the Department of Defense reviewed its stockpile needs. It asked Congress to hold off on authorizing

purchases that included 4.42 million lbs of tantalum, 15.8 million lbs of columbium, and \$1.7 billion in disposals until the Agency finishes a review of potential world threats and changes now taking place in Eastern Europe, the Middle East, and the new C.I.S. The Department may plan the stockpile according to a 1-year war scenario rather than a 3-year war. A fall report Defense to Congress on NDS requirements recommended the stockpile contain metals and materials worth a total of about \$5.6 billion rather than the \$7.3 billion it currently holds.¹⁰

EXPLORATION

International Overview

As 1991 began, world attention was focused on the Near East and the crisis caused by Iraq's invasion of Kuwait in 1990. The possibilities of a protracted war and of a major curtailment in global crude oil supplies, and consequent impact on world industrial activity, loomed large in the minds of many. The brevity and effectiveness of "Desert Storm" in restoring control of Kuwait to its lawful Government served to confine the impact of the episode on global mineral industry performance chiefly to Iraq's destruction of Kuwait's oil facilities and embargoes on Iraqi trade in oil and sulfur. There were also negative effects on mineral industry activities in other Near Eastern countries, especially resulting from transportation difficulties, as with Jordanian phosphates and potash.

The trade sanctions and the war disrupted trade between Turkey and its neighbors, particularly affecting Turkish steel exports and oil imports from Iraq. Balance of trade losses in 1990 and early 1991 may be offset by gains that may result from the war. Turkish steel, cement, other mineral materials, and labor forces may find ready markets in the rebuilding in Kuwait and Iraq.

Another possible benefit of the conflict is the chance for moderation of the Arab-Israeli conflict that has deterred investment in the area for decades. As the year ended, the U.S.-backed regional

peace talks offered hope for resolution of this issue.

Probably the single most notable trend in global mineral industry operations in 1991 was an overall move toward privatization. Shifts continued toward market economy operations in Central and Eastern European countries, and similar changes were developing within the C.I.S. More significantly, however, several countries with recent track records of nationalizing mineral operations reversed their directions. This trend was evidenced in the market economies of Western European, Latin American, African, and Asian countries.

For the countries of Eastern Europe that began this trend, the 1990 euphoria over economic and political freedom was tempered in 1991 by the realization that rationalization of inefficient industries would prove a painful process and that a sudden leap to total market economy doctrines was unrealistic. In most of these countries, 1991 output cutbacks reflected rationalization, but at a slower rate than had been expected. Using steel industry output as a measure, Czechoslovakian output in the first 5 months was only 2.2% below that of the last 5 months of 1990; Poland logged an 8% reduction in the same months, and Hungary registered a 10.6% drop. Although precisely comparable data were not available for Bulgaria and Romania, declines of about 20% to 30% could be realized.

A major pitfall to privatization in these countries is the inefficient nature of present operations that deters private investment. The physical plants are generally outmoded, environmentally unsound, and inefficient. Also, the nature and level of the work force must be considered. To reduce work forces to reasonable levels for economic operations would mean layoffs that would be unacceptable to the central Governments. The commitment to change remains in place, but the rate of change probably will be slower than originally intended. A newsworthy symptom of the difficulties experienced was the massive protests of conditions by Romanian coal industry personnel, who virtually laid siege to

Government offices in Bucharest that were quelled only by the use of force.

The year 1991 has been a painful one for the C.I.S. The separation of the Baltic Republics had only very modest direct impact on mineral industry operations, but it seemed to set the pattern for the demise of the U.S.S.R. as it has existed for 70 years and for the emergence of the remaining Republics as largely independent entities. This had a major effect on mineral industry operations. Central control of ventures was declining without emergence of any mechanism to replace it, and the coup attempt in August 1991 intensified the process of change toward control by the individual Republics.

Under the economic treaty prepared by the central Government late in the year and signed by a number of the constituent Republics, these Republics were to have sovereignty over their natural resources and have responsibility for their management. Even with these significant shifts, not all Republics signed the treaty.

Under these conditions, Soviet output of many mineral commodities fell. Steel output in the first 5 months of 1991 was 6.3% below the output for the last 5 months of 1990; cement output was down by 3% when compared to the same periods; and coal production, essential for almost all other industrial activity, was 10% below that of late 1990.

Within Western Europe, most activity was in the Federal Republic of Germany, where economic, environmental, and social pressures from unification were reflected in diminished mineral industry output in the Eastern states. The European Community moved toward a somewhat higher level of crude mineral supply self-sufficiency with expansion of output at the Neves-Corvo copper-tin operation in Portugal and the addition of the East German states. Steps toward further privatization of mineral industry operations were seen in France, Norway, the United Kingdom, and others.

In the Western Hemisphere, the overall Canadian economy was in a recession, and this, coupled with the economic situation in the United States, impacted upon Canada's mineral industry. A

strong U.S. economy is vital for Canada's mineral industry, for in normal times, about 75% of Canadian mineral exports is destined for the United States. The separatist movement in Quebec Province and environmental concerns exacerbated economic problems for the country's mineral industry.

In Latin America, a number of countries showed general economic rebounds to pre-1990 levels, with indications of stronger performances by Argentina, Chile, Colombia, Mexico, and Venezuela, among the larger countries. A significant contribution to these gains, however, was from the petroleum industries of the countries, and an overall upturn in nonfuel mineral operations was not so evident. Chile's copper industry made significant progress as the Escondida Mine was inaugurated. Through midyear, Peru seemed to be edging upward again in output of its major nonferrous metals after a disastrous 1990. In Mexico, of the major nonferrous metals, only zinc output was running ahead of 1990 levels at midyear. A Brazilian official predicted that 1991 output in that country's mineral sector would decrease except for output of iron ore.

Latin America as a whole was moving measurably back toward private enterprise, with official policies established in Argentina, Brazil, Chile, Costa Rica, Honduras, Mexico, Nicaragua, Peru, Uruguay, and Venezuela. Sale of Government equity in Mexico's La Caridad and Cananea copper operations in 1988 and 1990, respectively, was followed with similar actions in the steel industry and manganese and coal mining. Argentina and Brazil planned to sell government-owned steel mills, and Nicaragua announced its intention to sell three nationalized gold mines. The general economy of Nicaragua registered a gain for the first time in 8 years, after the governmental change.

A trend toward free trade agreements among Western Hemisphere countries seemed to be developing and could have implications for the mineral industry. Mexico was seeking a linkage with the

United States and Canada by early 1992. Similar linkages were sought by other groups of countries, including Argentina, Brazil, Paraguay, and Uruguay (The Southern Cone Common Market), Bolivia, Colombia, Ecuador, Peru, and Venezuela (an Andean Free Trade Zone), and 13 English-speaking Caribbean nations.

On the African continent, political changes in the Republic of South Africa led to removal of most international economic sanctions, brightening the prospects for mineral industry development. The country is a mineral-rich area most noted for its production of chromite, diamond, gold, manganese, platinum, and uranium. The agreement of the vast majority of South African political parties to the September National Peace Accord provided much hope for progress toward internal stability, but this accord will not be a panacea for all problems. The Republic's shift from apartheid will permit improved relations with other African states, thereby providing the opportunity for financial and technical assistance to the minerals sectors of these countries.

Elsewhere in Africa, political changes occurred that could bode well for mineral industry development. In Nigeria, the military government announced plans to install a civilian government in 1992. Already, reform programs to replace the state-run economy with a market economy have been implemented. In Zimbabwe, the lifting of the state of emergency in place for 25 years and implementation of a trade liberalization program aimed at export-oriented economic sectors were expected to improve the country's image as an investment site. In Ghana, the Government continued privatization efforts, finding buyers for a formerly Government-owned gold mine and a diamond mine.

Even in Liberia, where civil war closed the nation's two iron mines in 1990, there appeared to be prospects for a return to stability. One iron mine reopened in 1991, but there was no target reopening date for the other, and no

evidence of renewed exploration for gold and diamonds.

In Angola, finalization of peace accords in May 1991 terminated that country's multiyear civil war. This, and promise of multiparty elections in 1992, brightened the outlook for foreign investment, not only in Angola's mineral resources, but also in rail links through that country from its port to major mineral producers, Zaire and Zambia.

On the negative side, Zaire, a major copper and diamond producer and premier source of cobalt, suffered riots in its copper-producing area in 1991 that led to the flight of the expatriate technical staff. This, along with a major copper-cobalt mine cave-in, shortages of fuel and spare parts for mining equipment, and a host of managerial and political problems, led to a downturn in output of copper and cobalt and to a negative climate for investment. By early November, the cobalt shortfall increased prices to more than \$30 per pound.

In Asia, the continued growth of Japan's economy was reflected in record levels of steel and cement output and increasing consumption levels for most major nonferrous metals, at least through midyear. Output and usage of other mineral commodities presumably advanced as well.

China continued efforts to improve its nonferrous metals supply position, long a weak point. The steel industry was striving for greater production of high-quality steel while continuing expansion of total production. The legacy of Tiananmen Square, however, continued as an obstacle to increasing international involvement. The question of Chinese barriers to U.S. exports to China was raised in the United States as another reason for restricting imports from China due to the growing trade balance between the two nations. Another issue was the marketing of Chinese commodities, such as tungsten, at less than fair value.

The steel industries of the Republic of Korea and Taiwan continued to grow, marking their progress toward developed nation status, and these areas, as well as others such as Indonesia and Thailand,

continued expansion and diversification in overall mineral industry activities. The Philippines continued to experience economic difficulties that were reflected in mineral industry performance. Burma, with its authoritarian regime and civil strife, remained unlikely to receive significant foreign investment capital in mineral ventures.

Among the countries in the Pacific, Australia continued in its role as a major world supplier of bauxite, copper, diamond, iron ore, lead, and zinc, to cite but a few major commodities. Other notable Pacific mineral producers were Papua New Guinea, with copper, gold, and silver, and New Caledonia, with its lateritic nickel deposits.

Domestic Overview

The Society of Economic Geologists (SEG) conducts an annual Mineral Exploration Statistics Survey with financial support from the U.S. Bureau of Mines and the U.S. Geological Survey. The SEG survey gauges the levels of current international hard-rock mineral exploration by Canadian and U.S. companies. Based on 1990 survey responses from 29 United States and 26 Canadian companies operating in the United States, results show that the average corporate exploration budget increased over 1989 levels with the bulk of the funds still going to base metals and precious-metals targets. However, a contraction of the industry resulted in overall exploration expenditures remaining flat in 1990 with only a 1% increase over 1989 to \$164 million. Reported uranium budgets were at one-half of their prior year levels while industrial mineral programs were on the rise.

Base metals and precious-metals exploration in the United States during 1990 appeared to be growing, but only among those companies still maintaining exploration programs. The total number of companies involved in U.S. exploration continued to dwindle. Epithermal gold deposits were the primary focus of this exploration, although certain copper and zinc deposit

types were also sought. While most known U.S. porphyry copper deposits were owned by the large copper producers, companies were revisiting skarn targets because of the successful discoveries of large gold resources in Nevada and Washington. Positive results received at "porphyry-gold" targets in the Northwest and Alaska also attracted many companies. Although exploration for industrial minerals and uranium was at subordinate levels, a recent surge in acquisition of known U.S. uranium reserves is under way.

A shift in exploration spending appeared to have occurred between 1989 and 1990. Significant increases in the cost of administrative activities (5.6% of total budget) were measured, while field activities, such as geologic and geochemistry studies, prospecting, and drilling declined, by 2% to 4%. An increase in geophysical activities was also noted, which may reflect a returning interest in base metal targets as well as an increase in gold exploration. Overall, the numbers implied that, for companies with fixed exploration budgets, administrative costs increased at the expense of fieldwork.

A change in the composition of exploration staffs was also reported over the 1989-90 period. A sharp drop in the use of summer students was offset by a rise in the use of professional consultants. Also, a net increase in exploration staffs, mainly in the administrative and support category, was reported. This, along with higher reported administrative costs, may reflect the need to meet increasing environmental and regulatory compliance requirements.

Research by Balfour Holdings, used by the SEG to supplement survey results, indicates that more than 130 Canadian and 50 United States mineral firms, representing essentially all of the senior- and middle-tier metal producers, were operating in or establishing offices in Latin America. This rush to Latin America may reflect the following:

- (1) A perception that most of the large mineral deposits in the contiguous United States and Canada have been

developed and the acquisition market is saturated;

- (2) Improved foreign investment climate in many Latin America countries;
- (3) Increased environmental costs and permitting delays in bringing a new mine on-stream in the United States;
- (4) A perception that proposed reform of the General Mining Law of 1872 will substantially increase the holding cost and investment risk per exploration acre; and
- (5) Additional taxes and fees imposed or being considered at the State level.

If metal prices continue to stay relatively low, these factors could fuel a substantial deterioration in the number of companies willing to or financially able to develop the Nation's mineral resources.

DEVELOPMENT

Code of Federal Regulations— Implications for Mine Development

Leasing of Osage Reservation Lands for Mining for Minerals Other Than Oil and Gas.—The Bureau of Indian Affairs (BIA) is proposing to revise the regulations in 25 CFR 214 governing management of non-oil and gas minerals on Osage Reservation Lands in Oklahoma. The proposed revision eliminates specific royalties for minerals not found within the Osage Minerals estate and gives authority to the Osage Tribal Council, with the approval of the Superintendent of the Osage Agency, to set applicable royalty rates. This revision also replaces outmoded methods of exchange with modern methods and correctly designates those officials responsible for the management of non-oil and gas minerals within the Osage Mineral estate. The proposed revisions are intended to enhance the management ability of the Department over the production of these minerals and to

eliminate various inaccuracies in the current regulations.¹¹

Lead and Zinc Mining Operations, Quapaw Agency.—BIA proposes to amend 25 CFR 215 to update the operations and procedures for leasing, discovering, testing, and processing lead and zinc minerals on lands under the jurisdiction of the Bureau's Miami Agency in Ottawa County, OK. Current regulations governing such leases were developed more than 30 years ago and no longer reflect current practices or standards in the mining industry. The proposed revisions will assist affected Indians with the efficient development of their lead and zinc deposits without waste, avoidable loss, or damage to their natural resources, the environment, or other resources. The Bureau also proposes to retitle 25 CFR 215 as "Lead and Zinc Mining Operations and Leases, Miami Agency."¹²

Leasing of Certain Lands on the Wind River Indian Reservation, Wyoming, for Oil and Gas Mining.—The regulations of 24 CFR 227 are being revised to reflect organizational changes in the BIA and BLM. The principal changes update the reference to the BLM official assigned various responsibilities by the regulations.¹³

Geological and Geophysical Exploration of the Outer Continental Shelf.—The rule is revised to reflect the current requirements and practices and to conform with new or changed laws and regulations. It expands the requirements for filing notice to include all geological and geophysical research not conducted pursuant to a permit. It clarifies that those regulations are applicable only to oil, gas, and sulfur, as all other mineral resources on the Outer Continental Shelf are covered by 30 CFR Part 280. This rule will provide other pertinent information, such as current filing location addresses.¹⁴

Abandoned Mine Land Reclamation Fund Reauthorization.—Pursuant to the

recently enacted Abandoned Mine Reclamation Act of 1990, the regulations found in 30 CFR Subchapter R require revision and amendment to reflect and implement the new provisions contained in the statute. The subject provisions address the eligibility of both coal and noncoal reclamation projects and also relate to the collection and allocation of abandoned mine land fees to eligible reclamation projects, including the Rural Abandoned Mine Program and the Small Operator Assistance Program.¹⁵

Mining Claims Under the General Mining Laws.—This rule will require submission of financial guarantees for reclamation for all mining operations greater than casual use, create additional financial instruments for the purpose, and require operators with a record of noncompliance to file plans of operations.¹⁶

Mining in Military Withdrawals.—This proposed rule establishes guidelines for mining in certain military installations under the Mining Law of 1872, as amended, and unimpeded use of the lands for military purposes. The Military Lands Withdrawal Act of 1986 specifically provided for certain military lands previously withdrawn from mining to be considered for opening to the operation of the Mining Law of 1872, as amended, with certain special restrictions. Mining Lands identified as suitable for mining through the BLM's planning system are proposed to be opened on the effective date of an opening order that will be published in the Federal Register.¹⁷

Mining Claims Under the General Mining Law—Nature and Classes of Mining Claims Assessment Work.—This rulemaking will amend the existing regulations to include the criteria for the standard of discovery as applied to oil shale placer mining claims and provide clarification of what constitutes substantial compliance with assessment work requirements under the mining law.¹⁸

UNDERGROUND MINING

Coal Extraction Equipment

Continuous Mining.—A new addition to the Voest Alpine line is the Alpine Miner AM 85,¹⁹ a further development of the AM 75. Among its particular features is an increase of 30% in the sumping-in force when using the telescopic forward feed system, compared with conventional sumping through crawler advance. The telescopic forward feed system also minimizes ribs in the floor and roof.

The forward feed system allows the movement of the entire machine body, including loading table and chain conveyor relative to the track frames and the rear stabilizer. This feature enables the unit to sump smoothly and steadily even when poor floor conditions are encountered. The cutter motor is built into a carrier rather than being self supporting. The cutter transmission with the cutter head is directly flanged onto the motor carrier. This allows exchange of the cutting motor without the need to remove the cutter transmission and cutter heads.²⁰

Ingersoll-Rand, in conjunction with sister company Simmons-Rand, recently delivered a new LN-800 3TT continuous miner to Cape Breton Development Corp. for the Lingan Phalen Mine in Nova Scotia. The order followed the successful performance of a fleet of 15 LN-800 miners in the Selby coalfield, United Kingdom.

The LN-800 series was developed to meet the exacting requirements of British Coal and, according to Ingersoll-Rand, is now the best selling series of continuous miners in the British coalfields. The flexible mining capability ranges from seams as low as 4.5 feet (ft) to high seams as high as 12 ft. The full modular design of the LN-800 3TT is based on a four-piece chassis and two-piece conveyor/boom, facilitating easier movement underground.²¹

Joy Technologies and its global manufacturing companies in Australia, Republic of South Africa, and the United

Kingdom have introduced the 12CM20 Mk2 continuous miner fitted with four hydraulic roof bolters immediately behind an east-west conveyor. The machine has all-gear traction drive and has been designed to give low ground-bearing pressure, which improves maneuverability and lowers cycle times. Three such machines are now operating in Australia and Republic of South Africa.²²

Longwall Shearers.—British Coal has won a Queen's Award for Technological Achievement for its shearer Extraction Drum. The Extraction Drum has been under development for 10 years and became standard equipment on coal faces throughout Britain in 1987. It is the first device to successfully control both dust and ignitions at the coal face.

Underground measurements have shown reductions in respirable dust on the coal face of 80% compared with drums fitted with standard water sprays. Instances of face ignitions are down more than 50%, and pneumoconiosis, which affected 10% of the miners as recently as 1970, has been reduced to the lowest level in the history of coal mining, 0.7%.²³

The 6LS is Joy's most powerful shearer with an installed power of 1,120 kilowatts (kW) and the ability to mine seam thicknesses up to 14.8 ft. Six of these multimotor electric haulage units have been sold with good operational results. The combined tonnages of the first two machines exceeded 3.35 million tons in less than 9 months.

One of SAGEM's latest installations is a Panda single-drum shearer for the Warndt Mine in Germany. It is designed to cut an 18.4-ft-thick seam along a 985-ft longwall face at gradients exceeding 50%, which SAGEM claims is a world first. It cuts the seam, drum fully engaged, when moving from the bottom to the top of the face, and the same in reverse.

The mounting height is 7.6 ft above the floor, and the unit is equipped with an 8.2-ft cutting drum. The main motor power is 500 kW, continuous rating. The haulage pull is 40 tons, and the haulage speed is up to 35 feet per minute (ft/min).

The first of three recent longwall installations of interest supplied by Eickhoff is an EDW-230-2L-2W with Eicotrack, Eickhoff's chainless haulage system, at the Prosper-Haniel Mine in Germany. This machine is powered by two water-cooled 230-kW motors that are mounted directly on the ranging arms. This results in a short machine length in comparison with conventional shearers of the same rating.²⁴

In the United States, Westmoreland Coal's EDW-300-LN shearer loader, a new development for thin seams, is extremely short, but with its motor rating of 335 kW, is particularly powerful. The full power of 300 kW can be transmitted to the leading drum. This double-ended ranging drum shearer is equipped with electric haulage units and travels alongside the conveyor. A bridge to which the machine body is mounted straddles the face conveyor. If the Eicotrack system is positioned on the face side, the shearer is guided by a tube, and if it is on the gob side the Eicotrack rack bars serve as a guide.

The popularity of Anderson Longwall's Electra series continues to grow. This range of multimotor shearers is capable of working in seam sections from 40 to 235 inches (in) and can be supplied with power outputs from 375 to 1,200 kW. This year saw further Electra installations in Australia, France, Poland, United Kingdom, and the United States.

Machines for France and the United States both broke new ground. In the United States, the new Thin Seam Electra can mine down to 39 in. The shearer has various features unique to the thin-seam version, which allows for higher powers, greater reliability, easier maintenance, and safer operation. The Electra 2000 in France features installed power of 1,200 kW and operates at 5.5 kilovolts (kV). Each ranging arm motor is rated at 450 kW.²⁵

Longwall Supports.—In the United States, Gullick Dobson recently supplied equipment for a 15.6-ft-high longwall. The two-leg, 604-ton supports have a closed height for transportation of 6 ft and a hydraulic range of 7 to 16 ft. The

installation will be controlled using Gullick's Electroflex Machine Initiation System. Gullick claims that Electroflex, which incorporates motorized valves in place of the more traditional solenoid type, is becoming widely accepted as the most successful system to incorporate Shearer Machine Initiation.

The Bilsthorpe Mine is British Coal's first full-face longwall with heavy-duty two-leg supports. The electronically controlled immediate forward support chocks, with a yield of 510 tons, are being installed on the mine's first retreat face. The supports, manufactured by Mecco International, will be operated with the main hydraulic supply at 4,000 pounds per square inch (psi).

The largest two-leg supports in the world, with an 880-ton capacity, are being installed by Gullick Dobson at Australia's largest underground mine, the Gordonstone Mine.²⁶

Hard-Rock Equipment

Drilling.—A test program was conducted in a hard-rock mine in Sudbury, Ontario, to investigate dry drilling in underground bulk mining as potentially faster and more economical than wet drilling. The results indicate that penetration rates can be increased by approximately 24% by drilling with mine air as compared with wet drilling under the same circumstances. Bit life is reported to be substantially increased when drilling dry. An economic analysis for typical hard-rock drilling indicated that drilling productivity and cost savings can be increased by about 23% when dry drilling is used.

Dry drilling is usually shunned underground because of unacceptable levels of dust. The researchers wanted to know whether or not dry drilling provides enough increases in productivity and savings in drill costs to warrant the development or adaptation of dust control technology for use underground.²⁷

Corwall, United Kingdom-based CompAir Holman, has introduced a new generation crawler drill rig, the Unitrak. The Unitrak is capable of both vertical and horizontal drilling in confined spaces.

A versatile machine, its launch follows the success of the original M-Trak, CompAir Holman's successful crawler-mounted compact drill rig.

The Unitrak can drill vertical holes of up to 11.8-in diameter to a depth of 50 ft, and with a suitable compressor, can utilize up to 7.9 in DTH hammers. Like the M-Trak, the new drill rig is suited to methane extraction, site investigations, test boring, and other tasks. By hydraulically tilting the drill mast incorporating rotation and feed motors through a 90° angle, the Unitrak can carry out horizontal drilling, including rock bolting and grouting for tunnel wall cliff reinforcement.²⁸

Atlas Copco has introduced a new series of Boltec, fully mechanized rock bolting rigs, that are claimed to increase productivity in rock bolting by an average of 20%. These rigs can be used to install all types of rock bolts commonly used in mining. The main development is a compact single-feed drilling-bolting unit. A simple switch-over arrangement permits the operator to change from drilling to bolting without moving the feed from the hole position. The advantage is obvious: the bolt never misses the hole. It also gives the operator full visibility of the operation. The concept requires less space, is easier and faster to maneuver, and allows greater precision and accessibility. The improvement in stability of units having two heavy steel feeds is the direct result of the reduced swinging mass.

Uneven rock surfaces often prevent the rock bolts from being installed to their full length when using a mechanized bolting rig. The new Boltec unit permits all holes to be drilled to the full depth and proper installation of rock bolts in the most uneven conditions. The swing-away drill-steel support opens automatically to permit the rock drill and the bolt, respectively, to pass, utilizing the full length of the feed. The bolt magazine is mounted low and out of the way to avoid interference with uneven rock surfaces.²⁹

Water-Jet-Assisted Cutting.—The U.S. Department of Energy (DOE) has a cooperative agreement with Alpine

Equipment Co. to evaluate the water-jet-assisted mechanical cutting of oil shale. A concurrent goal of this project has been to determine the effectiveness of polycrystalline diamond composite (PCD) bits in cutting oil shale and the possible synergy of these bits and water-jet-assisted cutting.

PCD is about 300 times as wear resistant as carbide, making it an ideal cutting tool. The PCD cutter consists of a thin layer—0.01 to 0.04 in—of polycrystalline diamond integrally sintered at ultrahigh pressure and temperature to a cemented tungsten carbide substrate. Tests have shown convincingly that the potential for this technology is considerable. Experience with rotary PCD drill bits in the Unical oil shale mine in Colorado has shown that these cost about 10 times more than conventional carbide bits, but have a life expectancy of about 80 times longer. In this way, the combination of water-jet-assist and PCD bits may represent the first major advance in hard-rock cutting technology since the introduction of tungsten carbide tools 40 years ago.³⁰

Haulage.—A new underground truck designed primarily for transporting rock but able to carry out other essential tasks has been introduced by John Clark, Inc., (JCI) Denver, CO. The main feature of its design is the use of multiple containers or modules that can be interchanged, thus resulting in lower operating and capital costs than with conventional LHD or truck haulage. The JCI C1504, the 15-ton container truck, is a low profile, center articulated rear dump that allows one container to be loaded while another is being trammed to the dump.³¹

After almost 2 years of development, Getman Corp. has introduced the model RDG-1504C underground road builder for hard-rock mines. The machine is designed to eliminate the high maintenance cost of modified, lighter class vehicles currently in use. The unit is also meant to provide long life and high performance at a competitive price.

Graders offer advantages over other types of machinery used for servicing roadways that have been rolled or

compacted. After treatment with a grader, the road surface is left cleaner and harder. Remaining material is smooth and solid, not compacted and crushed and able to be loosened by continuous traffic. As a result of grader treatment, savings on vehicular wear from shock loading will be realized. In addition, vehicle life will be longer and downtime will be less.³²

DOE's Nuclear Waste Repository

Some scientists and environmental groups are pressing the DOE to abandon plans for a nuclear waste repository at Nevada's Yucca Mountain and to start searching for a site with more stable ground conditions. Critics of the Yucca Mountain site believe geological conditions surrounding the proposed repository are too unpredictable. They do not believe the repository can remain leak-free for the expected 10,000 years.

DOE is expected to spend \$4 billion studying the geological conditions of Yucca Mountain and another \$15 billion developing the repository over the next 20 years. The repository will house high-level radioactive waste from the Nation's military operations and industrial plants. DOE and the U.S. Geological Survey (USGS), which is leading the Yucca Mountain study, acknowledge that more study on Yucca Mountain's ground conditions is needed before it can be declared a suitable site. Results from drilling deep test holes to find water pockets above the known water table have been favorable.³³

Raise Boring at Craig Mine

The third of four 4,000-ft-long vent raises is in the final reaming stage at Falconbridge Ltd.'s new Craig Mine in the Sudbury district, Ontario. The raise is being bored by Redpath Raise-Boring Ltd. using one of the most powerful raise drills in existence, a 400-horsepower (hp) Robbins 97RL-DC belonging to Falconbridge.

Final diameter of all of the vent raises is 10 to 12 ft. The first two raises, one intake and one exhaust, were completed

in 1989 and 1990. The present one, an exhaust raise, will be finished in 1991. A fourth 12-ft-diameter exhaust raise will be drilled in 1993, which, combined with the service shaft (air intake), will complete the Craig Mine's ventilation system. Each of these vent raises really consists of two separate raises, making eight in all. Together, they will total more than 16,000 ft in length and are some of the largest and longest raises ever to be bored in Canada.³⁴

Rock Stress Measurement

Mining engineers recognize that the design of the safest and most cost-effective excavations underground depends on the accurate measurement of the magnitude and direction of rock stress fields.

There are two main methods of measuring rock stress, overcoring and hydrofracture. Commonwealth Scientific and Industrial Research Organization's (CSIRO) Division of Geomechanics has investigated and applied hydraulic fracturing techniques over the past 15 years and is considered to be a world leader in rock stress measurement. The Minifrac system has evolved from this research as a portable kit for rock stress measurements from small diameter boreholes of up to 98 ft long and has now been fully developed and tested at a number of underground engineering sites in Australia.

The system has generated considerable interest from Australia and overseas during its development; the first customer outside Australia was British Coal at Bretby. British Coal researchers are testing its suitability for quick, exploratory stress estimations before more accurate methods are used, such as overcoring, which is the normal technique.³⁵

Solid-Woven Conveyor Belts

The solid-woven conveyor belting concept was developed for underground coal mining. In many countries, it has replaced the traditional multi-ply and steel-cord constructions. It is now

making inroads into the aboveground market, in short- and long-haul installations where tear and impact resistance are particularly appreciated.

Steel-cord belts were traditionally used on long-haul installations and have shown their worth in hundreds of cases. However, they do have shortcomings. The steel cords can corrode and will do so more rapidly depending on the corrosiveness of the product they are carrying or the environment in which they are used.

Solid-woven construction consists of a fully interconnected structure with a high density of ultrastrong monofilament synthetic yarns both in the warp and the weft directions. The outer layers contain spun, synthetic yarns for additional impact protection and the whole is fully impregnated with polyvinyl chloride (PVC) to form a composite with exceptional tear resistance in the longitudinal and the transverse directions. The measured test according to tear strength of solid-woven belts is as much as 300% higher than correspondingly rated multi-ply belts and many times greater still than woven steel or breaker reinforced steel cord constructions.³⁶

SURFACE MINING

In 1991, gold continued its trend as the most sought after commodity. Several new metal mines came on-line, and some notable milestones were achieved by both domestic and foreign producers.

South Carolina's fourth gold mine began operation in early 1991. The new open pit, heap-leaching operation, known as the Barite Hill Mine, is near McCormick, SC, about 30 miles north of Augusta, GA. Company officials expect the Barite Hill to yield about 20,500 troy ounces per year (tr oz/yr) of gold and 61,500 tr oz/yr of silver. Barite Hill was developed by Gwalia (U.S.A.) Ltd., a subsidiary of Gwalia International Ltd. of Perth, Western Australia, and is centered around several long-abandoned gold mines, including the old Dorn Mine, which produced gold between the 1850's and 1930's.

New Zealand's second lode gold mine, the Macraes Mine, recently commenced production. The new open pit operation, wholly owned by Macraes Mining Co. Ltd., is in the Otago region about 37 miles north of Dunedin on New Zealand's South Island. Gold production during the first year of operation is expected to exceed 55,000 tr oz/yr and amount to almost 90,000 tr oz/yr thereafter. Ore reserves at the Macraes are reportedly sufficient to sustain operations for at least 10 years.³⁷

North America's largest gold mine, The Gold Quarry Mine, has produced a record 1 million troy ounces (tr oz) of gold in the year to December 22, 1991. The mine, which is owned and operated by Newmont Gold Co., produced 939,800 tr oz of gold in 1990 and is expected to produce almost 1 million tr oz of gold in 1992. The mine was commissioned in 1985 and produced 106,500 tr oz of gold that year. At the end of 1990, the mine contained 8.9 million tr oz of proven and probable reserves.³⁸

Channar is the first new iron ore mine in Australia in 15 years and the first overseas mining project in which China has taken a direct equity interest. Channar is a joint venture between a wholly owned subsidiary of Hamersley Holdings Ltd. (60%) and the China Metallurgical Import and Export Corp. (40%). The mine will supply approximately 220 million st of high-grade iron ore to China for a period of 20 years—3.3 million short tons per year (st/yr) in the first year of operation, rising to 11 million st/yr by 1997. Iron ore is mined from five major ore bodies approximately 12.4 miles east of Hamersley Iron's Paraburdoo Mine. Operations started in 1990, and the first year's production was on schedule with 6.6 million st being moved to provide 3.4 million st of crusher product. Production of crusher product in 1991 should rise to 6.1 million st.³⁹

A major vanadium mine is to be brought on-line by Precious Metals Australia (PMA). The Windimurra project will be Australia's first vanadium mine and is expected to be producing

4,070 st/yr vanadium pentoxide by the end of 1992. Windimurra is in the Murchison District of Western Australia, about 37 miles from the Youanmi Gold Mine, which the directors of PMA brought into production a few years ago. The vanadium potential of the district has been known for many years. PMA controls 244 square miles (mi²) of the deposit, which is approximately 230 ft wide and outcrops as a low ridge about 16 m in length. Proven reserves are 16.5 million st of vanadiferous titanomagnetite, but the probable resource could be as much as 110 million st. Vanadium is present in solid solution in the magnetite.⁴⁰

Arco Coal's Black Thunder Mine, near Wright, WY, celebrated the shipment of its first 250 million st of coal. Black Thunder is the Nation's largest producing coal mine. Mine employees celebrated the milestone as a train loaded with low-sulfur coal left for Kansas City Power and Light Co.'s electricity generating station. Black Thunder achieved this milestone in just 14 years of operation.⁴¹

Trends for Crawler Tractors

The new crawler tractors of the 1990's have advanced hand-in-hand with technology. Today's mining tractors are almost twice the size of tractors that were manufactured 20 years ago. While horsepower and weight have now seemingly leveled off, more emphasis is being placed in specialized areas.

The most significant advances in crawler technology have been with undercarriages. There really have not been any major design modifications, but rather a fine-tuning of what is already present. Quality improvements, such as seal and metallurgy, extend the wear life of today's undercarriages. The ultimate goal of any manufacturer is to produce a maintenance-free undercarriage.

Also high in importance are tracks and grousers. There have been several significant changes to grouser and track design in the past 5 years. More alloys have been incorporated into grousers to increase life, while maintaining a balance between materials that are too soft or too

brittle. Constant minor improvements to track seals usually go unnoticed, but such changes add to track life.

The higher operating weight and horsepower of today's machines allow one machine to perform the work previously accomplished with two. Horsepower and weight, however, are not the answer to larger demands. Instead, the machine needs to be balanced to take full advantage of high horsepower and weight.

Fine-tuning has found its way into rippers as well. Although there have been no significant changes in ripper mechanics, current model rippers travel through materials at a much faster rate. The larger dozers can rip unblasted limestone, which was unheard of in the past. An assortment of accessories, such as specialized ripper tips, assist the operator. Impact rippers, a ripper that uses an internal percussive force, allows modern dozers to rip what was once thought to be unrippable. Also, closer attention has been placed on operator visibility. Adding to safety, an improved line-of-sight ensures operator confidence.

Manufacturers expect electronics to be the driving force of continued improvements. Onboard diagnostics will warn of out-of-tolerance conditions and will show what is causing the conditions. Operator errors can be discussed openly to avoid repetition. The diagnostics will also record and track preventive maintenance. Possible breakdowns can be charted and either avoided or planned for. Recorded data, such as maintenance history and fuel consumption, provide good information for maintenance and operator management.⁴²

Dragline Bucket Design

High technology has also entered the world of bucket design. Major dragline and bucket manufacturers have engineering teams devoted strictly to bucket design. With the advent of computer-aided design (CAD) and finite-element analysis (FEA), several innovations have been made in the design process.

Bucket research over the past several years has resulted in many new innovations. Most of the major changes revolve around the center of gravity. The geometry of buckets has been changed to make more use of the pulling force of the dragline rather than the bucket weight to achieve maximum tooth penetration. This change allowed the removal of weight while maintaining the key elements of structural integrity and wear protection. This weight savings directly translated into additional bucket capacity.

Through the use of new technological advances, dragline and bucket manufacturers have created durable buckets by dropping some of the weight after careful design analysis. The most common technique for increasing bucket size is to widen the lip. Such a move reduces the cutting force per inch of lip width, which is detrimental to performance. The bucket simply will not dig effectively in hard material, which further adds to drag-fill time.⁴³

New Equipment

Caterpillar introduced the world's largest mechanical drive truck in 1991. The Caterpillar 793 truck offers miners a new 217-ton hauling unit for large mine haulage capacity with mechanical drive efficiency. The 793 is designed to be shovel loaded in three to four passes for high productivity and lower cost per ton. The 793 uses a Cat 3516 turbocharged and aftercooled 16 cylinder diesel engine. An electronically controlled, six-speed powershift transmission gives a 33.3-miles-per-hour (mph) maximum travel speed. The dual-slope body with V-bottom helps center the load, reduces spillage, and maintains a low center of gravity. Weight distribution of the truck is 46.3% on the front axle and 53.7% on the rear axle. The loaded weight is 33.7% on the front axle and 66.3% on the rear axle. Overall length is 42.25 ft; width, 22.4 ft; and height, 21.1 ft. Gross vehicle weight is 355 tons.⁴⁴

After an investment of millions of dollars in more than 12 years of research and development, Komatsu has

introduced its D575A-2 dozer, the world's largest. Komatsu used a design approach that allows the D575A-2 to generate needed drawbar pull without a proportional increase in machine weight. The V-12 Komatsu engine and the vehicle's weight of 132 tons produce an impressive drawbar pull of 200 tons. A huge 70-cubic-yard (yd³) U-dozer blade or a 58.9-yd³ semi-U dozer blade accommodates a large quantity of material per cycle for increased productivity. This giant blade, a high-output engine, and Komatsu's Resilient Equalized Undercarriage (REU) allow the D575A-2 to push at least 50% more material per hour than the Komatsu D475A-2, the company's next largest dozer. The entire dozer blade is made of high tensile strength steel for increased durability. An optional dual-tilt blade system concentrates blade force where maximum penetration is needed.⁴⁵

After 8 years of design and testwork, Voest Alpine has developed the VASM, a surface miner intended for continuous extraction of materials in block operations. The cutting system of the VASM is quite different from other European-built surface miners, such as the Krupp and Wirtgen machines. It comprises a series of tooled cutter drums, which both rotate and oscillate, and a boom that positions the drums. It has four drums fitted with 48 rock picks. To adapt the cutting action to a wide range of rock types and to yield required products sizes, the rotational speed, frequency of oscillation, depth of cut, and rate of lowering can be controlled as appropriate. The VASM is crawler mounted and can operate at gradients of up to 20%, with crossfall of up to 5%. The machine is equipped with an onboard loading/conveying system that can deliver cut material to either trucks or conveyors. The cabin is positioned so that the operator has an excellent view of the working face. Full-function remote control and data transfer are also possible. Equipment is available that allows the operator to control the payload delivered at design level and to measure actual production in tons.⁴⁶

The Cat model 994 is the biggest machine Caterpillar has ever made. The Cat model 994 is also the largest mechanical-drive, front-end loader being manufactured today.⁴⁷ It approaches 60 ft in length, stands more than 21 ft in height with the bucket on the ground, and can load a Cat 789 truck (180 st) in six passes. In breakout force, it rivals the smaller hydraulic excavators (210,000 lb). The 994 wheel loader has a 70,000-lb bucket payload (about 35 st), which can be carried in bucket volumes from 18 to 26 yd³. A 40-yd³ bucket is available for coal, and a 16-yd³ spaded-edge bucket with teeth is available for denser materials, such as iron ore. The 994 was formally introduced at Cyprus Sierrita's surface copper mine south of Tucson, AZ, in late 1990.⁴⁸

O&K and Ziemens has introduced a state-of-the-art bucket wheel excavator (BWE). Bagger 292 is a BWE weighing approximately 13,500 tons, 738 ft in overall length, with a central tower structure 315 ft high. The main advantages offered by the 292 are more precise controls, a better working environment for the operator, and a better working protection of the machine's environment. Excavating accuracy is improved by three new systems. Laser guidance is used to ensure that the BWE stays on exactly the right plane. Gamma radiation sensors are used to track the coal/sandstone boundary so that no waste is mined. And the third system—already used on O&K hydraulic excavators—allows the details of a first, operator-controlled cut to be memorized for subsequent automatic replication. Also upgraded are the systems for condition monitoring of major mechanical and electrical functions, so that the operator gets early warning of any impending problems. In regard to the impact of the BWE on its surrounding when working, the main improvement has been the addition of water sprays for dust suppression.⁴⁹

Atlas Copco's Construction and Mining division launched a new tophammer drilling system that the company feels could bring about a revolution in blasthole drilling. Known as COPROD,

it is claimed that the system opens the way for more powerful rock drills to be used with retained, perfect hole straightness and an improved drill-string life expectancy. The result of more than 10 years of research and development, the COPROD concept is nevertheless simple. It utilizes threadless hydraulic rock drills. The new version is equipped with an anvil that transmits percussion and a tube chuck that transmits rotation. Maximum impact power output is 40 kW, with a corresponding frequency of 3,000 blows per minute. Atlas Copco claims that features of the system include a penetration rate twice that of DTH drilling, accuracy in drilling equal to tube or DTH drilling, superior drill string service life, and drills that are lighter in relation to the hole dimensions.⁵⁰

Diamond Bit Technology

Those involved in the diamond drilling industry for the past 15 to 20 years have doubtless marvelled at the advances that have occurred recently, as far as diamond bits are concerned. The past 10 years have seen bit life increase from performance measured in tens of feet up to hundreds of feet.

The technical advances made in synthetic or engineered diamonds, powder metallurgy, furnace equipment, etc., have all contributed to the progress of impregnated diamond bit technology. The manufacturing process involved in achieving the levels of performance now commonplace is becoming increasingly sophisticated, requiring substantial investment in new equipment. The powder metals utilized in current technology could certainly be described as "exotic" and require very advanced methods of handling, treatment, storage, and processing to take advantage of the benefits accruing from their use.

One notable advance has been the introduction of PCD products to the coal mining and oilfield industries. PCD compacts consist of synthetic diamond layers integrally sintered to tungsten carbide backing to form a hard abrasion-resistant cutting disk. These products drill with a shearing rather than a

crushing or grinding action. The 100% exposure of these cutters results in higher penetration rates than have been possible with conventional surface set products or the more recent impregnated bits. PCD drill bits have rapidly replaced the more conventional drill bits used in cable bolting, cross-measure drilling, methane drainage, and surface open-hole drilling.⁵¹

Blasting Primers

Spherical primers, a new shape in primers, are able to uniformly initiate a bulk explosive in a blasthole in all directions. The new spherical-shaped primer was developed after many years of research by ICI Australia Explosives Group in Deer Park, Victoria, Australia. It is expected to be particularly effective in surface coal mines where blasters need considerable forward movement, as in cast blasting when the bulk explosives must react as quickly and fully as possible, and in highwall conditions where it is necessary that the toe must move out effectively.

The spherical primers are also aimed at applications using large-diameter (9- to 18-in) holes, 100 to 150 ft deep, in which special blasting agents such as heavy Anfo, pumped explosives, and microspheres for extra sensitivity are employed.

Conical boosters, another variation on the shape of cylindrical cast boosters and primers, have proven to be highly effective in protecting the coal seam from damage during blasting. Developed and tested by Trojan Corp. during the past 4 years, the shape of the novel unit is actually frusto-conical—a part of a cone blending with a cylinder.⁵²

REMOTE MINING

Borehole Detection Systems

The German mining company Preussag AG Metall has developed an ore detection probe, the Preussag Slimhole Analyzer (PSA), for more accurate stopping. The PSA system has successfully been applied for 4 years at Preussag's lead and zinc mines near Bad Grund. The system is

designed for ordinary 1.58-in-diameter blastholes. Ore analyses from holes up to 70 ft long are displayed immediately at the drilling site. The PSA uses X-ray fluorescence. It measures moderate to high lead and zinc grades but can be modified for other ores. The PSA is specifically designed for rapid analysis. The procedure is almost fully automatic; the only manual operations are the positioning of the probe at the hole collar and pushing the start button on the control panel. This control panel also permits the interruption of the measuring procedure at any time, changing of program parameters, and checking the apparatus.

Because the measuring principle of the PSA is independent of the element being measured and the detection system is constructed modularly, adaptation of the system to other types of ore should be possible. This promises an extended field of application for the PSA system. Any deposit with exacting requirements for close-range reconnaissance is a prime candidate where the ability to define cutoff grades is of interest. A selective extraction of rich ore (such as the copper zones in massive sulfide deposits) combined with the avoidance of nonpay mineralization is possible with this system.⁵³

The Swedish company Abem AD has developed a system to investigate rock formations and obtain a direct and easily read picture of the rock around tunnels and boreholes. Rock absorbs radio waves, but there is a frequency range between 10 and 100 MHz that can be used to send out a pulse from a borehole and measure reflections in the surrounding rock. Abem makes use of this phenomenon in its Ramac system. The system was developed as a part of a large project of Svensk Karnbranslehantering AB (SKB) in Stripa, in the Vastmanland province. The project is a collaboration between the nuclear fuel authorities in Canada, Finland, Great Britain, Japan, Sweden, Switzerland, and the United States. To build safe storage locations for nuclear fuel, the designer needs a very clear picture of the rock

formation surrounding the proposed building site.

The equipment has even more applications. It can be used anywhere there is a borehole, as long as the rock does not absorb radar waves. The system provides excellent results in limestone, gneiss, and granite. It can also be used in places where limestone has become weak from disintegration and small cracks. A possible application is in connection with boring tunnels. Another is in mining to "look" in front of the work area and see where dangerous weak spots are located.⁵⁴

A new, gyro-based, all-attitude downhole surveying system, called the Smart⁵⁵ System, is being offered by Humphrey, Inc., and is applicable to vertical, horizontal, or a combination of vertical-horizontal holes. It is effectively a steering tool that includes supporting computer software and provides real-time viewing of all outputs both as raw voltages and computer angular displacements. The computerized system orchestrates the borehole surveying sequence, automatically initiating tie-on survey/realignment procedures as required to continually survey any deviation in the direction of the borehole. It is a three-part system that consists of a surface control unit, a gyroscope attitude-sensing borehole probe, and survey-coordinating computer software. Using gyroscopic attitude sensing, performance is unaffected by low level erratic magnetic fields and can be used in steel pipe.⁵⁶

Electromagnetic Imaging

Using electromagnetic (EM) fields and imaging techniques similar to those used in medicine, engineers at Sandia National Laboratories have devised new methods to aid in the difficult task of detecting unmapped mine entries. The electromagnetic technique has improved detection accuracy, which often is hampered by the presence of mineral deposits and by the variety of subterranean rock and sediment. By using lower frequency EM signals than have been used in other detection

methods, Sandia researchers have been able to reduce the incidence of false signals, which can be triggered by mineral deposits and other naturally occurring materials. Low frequencies—in this case, between 128 hertz and 9,216 hertz—are more effective because they can travel longer between distances underground.⁵⁷

Continuous Miner Automation

As technology advances, full automation of underground mining moves closer and closer toward reality. The U.S. Bureau of Mines, in an effort to develop technology for computer-assisted mining systems, is working on laser-guided navigation. The current research focus is the guidance of a continuous miner during room-and-pillar mining.

The system used Lasernet laser-scanning sensors that report the angular coordinates of retroreflective targets. The lasers, on a stationary reference structure, horizontally scan a beam of laser light across laser targets mounted at fixed locations on the continuous miner. A microcomputer system processes the laser data, determines position and heading, handles requests for data, and controls tram maneuvers.⁵⁸

Santa Cruz In Situ Leaching Project

The successful injection and recovery of saline and bromine solutions at the Santa Cruz In Situ Copper Mining Research Project outside Casa Grande, AZ, have lead the joint venturers and the U.S. Bureau of Mines to begin preparing for the permitting process for a pilot scale well-field and surface plant.

The copper mining research project is designed to determine the feasibility of mining a deeply buried copper deposit in situ, or in place, by injecting a dilute solution of sulfuric acid to dissolve the contained oxide copper minerals. The copper-laden solution then would be pumped to the surface where the copper would be recovered in a solvent extraction/electrowinning plant. The copper deposit is too deep and too low grade to be developed economically by

conventional underground or open pit mining methods.

The results of the field tests have been in the range predicted. There was no short circuiting of injected fluid, and indications are that a large volume of rock was contacted by the solution. Based on this projection, an adequate recovery of copper can be achieved.

The U.S. Bureau of Mines, which is studying the effects of drill core ore zone rocks on neutralization of dilute sulfuric acid, is generating the data to complete an environmental assessment as its portion of the project. Pending receipt of the necessary approvals, the pilot plant is expected to begin operation in 1993.⁵⁹

Coal Interface Detection Methods

The U.S. Bureau of Mines is developing the technology to create computer-assisted mining machines that will be capable of automatically tracking the boundaries of a coal seam and extracting only the desired material. If successful, this research should yield significant increases in mining productivity, worker safety, and quality of coal extract.

Several promising coal interface detection (CID) concepts currently being investigated by the Bureau include natural gamma radiation (NGR), machine vibration, and passive infrared (PIR).

The use of NGR sensors requires the strata adjacent to coal have higher levels of radiation than the coal seam to accurately measure the thickness of remaining coal. Commercially available NGR sensors have been used successfully as an autosteering technique on longwall miners and continuous miners in England since 1980.

The Bureau has obtained geological and mining data from more than 300 mines in the United States. Geological samples of the coal seam, roof, and floor have been collected from selected major seams and have been analyzed. NGR measurements made on these samples indicate that shaley materials typically have higher levels of NGR than coal. Results also indicate that in about 90% of the mines, the immediate roof and floor

strata consist of such shaley materials. This suggests that NGR sensors could be used in most coal seams in the United States.

Vibration sensing and analysis could be used as a possible CID method, provided that a definite contrast in mechanical strength exists between the coal and surrounding rock. The Bureau is investigating several vibrational CID approaches, including machine vibration, in-seam seismic, and acoustic methods.

A new CID concept that uses the PIR technique to measure temperature changes associated with the cutting of coal and adjacent strata is being investigated by the Bureau. Like the vibration method, a definite contrast in mechanical strength must exist between coal and rock for the PIR technique to work properly.

Advantages associated with this method are that the PIR responds instantaneously at the coal-rock interface and is minimally affected by dust or water sprays. Based on initial tests, results indicate that PIR can be applied successfully in mines having a hard immediate roof. It is expected that the end result of this research will lead to the development of a rugged, low-cost PIR-based CID sensing tool that can be routinely used by mine operators.⁶⁰

BENEFICIATION

Flotation

The installation of large-size column flotation cells is now being regularly considered by designers and operators of flotation circuits. The level of reliability of these larger units has reached a point where the equipment can be selected with confidence. Large-diameter column cells (more than 8 ft) have gained acceptance in mineral processing. The successful commissioning of 26.3- by 13.2-ft-square units at Minera Escondida's new copper concentrator in Chile, as well as 12-ft-diameter units at Ok Tedi Mining Ltd., in Papua, New Guinea, have demonstrated that large units can be successfully designed and operated. The larger units have been found to have a number of cost advantages over smaller units that merit

their consideration. The main advantage of large cells is their low capital costs per unit output and lower installation costs. Looking to the future, it will be interesting to see over the coming years what the upper limit for cell size will ultimately become.⁶¹

The performance of column flotation cells depends greatly on the froth phase. Yet, despite the importance of the froth phase, relatively few studies have been conducted that examined the impact of froth behavior on the performance of column flotation cells. This lack of information is surprising, considering that the froth phase is primarily responsible for the improved performance of columns over conventional flotation cells.

Laboratory flotation tests are being conducted by Virginia Polytechnic Institute to investigate the importance of the froth phase in column flotation cells. Experiments were designed to determine the ash and solids profiles within the froth column as a function of washwater. During high washwater rates, the data indicate most of the upgrading occurs at the froth-pulp interface. At lower washwater rates, additional upgrading occurs throughout the froth column in response to increased froth drainage. A simple volume balance around the froth zone of a column has been used to derive a relationship between column performance and froth behavior.⁶²

The Jameson cell is a new radical flotation device. The Jameson cell has only 25% of the height and mass specification of a column cell assigned the same plant duty. A throughput of 40 tons per hour per square foot of Jameson cell area is achievable. A total cell residence time of 2 minutes compares to the 45 minutes required by mechanical flotation cells. The cell is currently operational or under installation throughout Australia on coal, copper, lead, nickel, and zinc applications. Pilot testing is ongoing throughout the American, European, and African continents.⁶³

A fast air-injected hydrocyclone shallow tank (FAST) flotation system is being researched by the U.S. Bureau of Mines in Tuscaloosa, AL. Conventional flotation kinetics is a compromise

between two conflicting requirements—the need for an agitated zone for rapid bubble-particle collision and a quiescent zone for bubble-pulp separation. The Bureau has designed a flotation system in which bubble-particle collision and bubble separation are carried out in two unit operations. A bubble slurry and an ore slurry are mixed at a high rate in a modified air-injected hydrocyclone for rapid bubble-particle collision. The mixture is then fed into a unit specially designed for rapid separation of the bubbles from the pulp. The FAST system recovered copper ore much more quickly and as effectively during testing as a conventional flotation system.⁶⁴

The U.S. Bureau of Mines, under its Minerals and Materials Science Program, is investigating the feasibility of partitioning complex, difficult-to-process minerals into simple phases using sulfidation reactions. Such partitioning could improve the selective extraction of mineral constituents of value. Complex sulfide minerals such as chalcopyrite (CuFeS_2) and pentlandite [$(\text{Fe,Ni})_9\text{S}_8$] have been partitioned into the simple copper and iron sulfides (CuS plus FeS_2) and iron and nickel sulfides (FeS_2 plus NiS_2), respectively. Consequently, it may be possible to concentrate the simple, metal-rich phases by comminution and physical separation techniques, thus minimizing the troublesome emission of S-bearing gases presently associated with conventional roasting-smelting operations. The research revealed that the Cu contained in CuFeS_2 would convert to CuS in a matter of minutes as a result of processing the CuFeS_2 concentrate at 400°C in the presence of sulfur. More recently, experimentation has shown that similar processing of an ilmenite (FeTiO_3) concentrate results in partitioning of the Fe from the mineral complex to FeS , leaving an independent titanium oxide (TiO_2) phase. By applying conventional physical separation methods such as magnetic and/or flotation to these newly formed, independent phases, it may be possible to attain an upgraded TiO_2 product without total dissolution of the ilmenite, thus minimizing the environmental impact associated with

conventional processing. The research also indicated that simultaneous grinding during sulfidation could greatly increase the rate of reaction by continuously exposing new surfaces to the reacting species. The basic data developed by this research offer potential for innovative process modification to more efficiently separate high- and low-value constituents earlier in mineral processing operations.

A new flotation probe offers for the first time, reliable monitoring of froth and/or pulp levels in flotation cells. The Froth-Man probe was developed by the Atomic Energy Corp. of South Africa and is presently under test at Palabora Mining Co. Accurate measurement of both air/froth and froth/pulp interfaces leads to improved automatic control of flotation banks. The Froth-Man probe immediately determines whether or not froth or pulp is overflowing the lip and whether pulp level or frother addition needs adjusting.⁶⁵

The U.S. Bureau of Mines is investigating the potential of using color measurements as a potential technique for on-line monitoring of flotation froth properties in industrial circuits. Color measurements were made for pure minerals, mineral mixtures, and flotation froths loaded with different mixtures. An industrially available system consisting of a fiber-optic-based illuminator and detector was used to measure color. The device was able to detect differences in composition of mineral particle beds and mineralized froths. The color signal changed linearly as the ratios of chalcopyrite-to-pyrite and chalcopyrite-to-molybdenite mixtures were varied. Color measurements were also made on-line on a commercial copper-molybdenite rougher and cleaner circuits, and the measurements were found to be proportional to the copper-to-molybdenite ratio. Froth color monitors, when technology is developed to the commercial state, are nonnuclear and may provide instantaneous on-line information about froth composition. Color sensors have the potential to be multiplexed via fiber-optic cables such that one instrument may be able to monitor a number of flotation cells.

The U.S. Bureau of Mines has investigated a new method for increasing the selectivity in flotation by creating and regulating reagent concentration gradients within flotation columns at steady-state operation. Gradients were generated and traced in a water-only system with the use of fluorescent dyes under a variety of operating parameters. From this investigation, it was found that gradients could be generated in the froth cleaning zone and that they could be changed through manipulation of both physical and chemical operating parameters. The application of reagent gradient control to mineral systems could improve both flotation grade and recovery in commercial flotation operations without the use of additional flotation circuitry.

Coal Processing Methods and Equipment

A novel cleaning process for ultrafine coal has been developed at Virginia Tech that is capable of producing superclean products. This process, selective hydrophobic coagulation (SHC), uses pH modifier, the only chemical requirement for the process. Compared to other selective aggregation processes using hydrocarbons and flocculants, this process relies on the hydrophobicity of the coal surfaces to induce the selective coagulation of coal particulates in aqueous solution. The associated mineral matter is dispersed by simple pH control. As a result, the process is more economical and environmentally acceptable than other processes for treating micronized coal.⁶⁶

Pittsburgh Energy Technology Center (PETC) and the Electric Power Research Institute (EPRI) are experimenting with an advance fine-coal cleaning technique, spherical agglomeration. Bechtel National Inc. has demonstrated this process using Arcanum Corp. technology by constructing a 1/3-ton-per-hour unit at an EPRI test facility.

Although spherical agglomeration has been used commercially on fines, it has not become widely accepted in the coal industry due to the high cost of the petroleum bonding liquid and the odor

imparted to coal by the oil. The Arcanum/Bechtel process eliminates these impediments through the use of heptane, a recoverable hydrocarbon, to initiate the agglomeration process. Although it is inflammable, heptane has been demonstrated to be safe. The tests showed that spherical agglomeration can reduce pyritic sulfur from 70% to 90% and ash from 77% to 94%. Relatively dry (20% moisture), easily handled 3/8-in pellets can be produced from a pulverized coal slurry.⁶⁷

The use of dry magnetic separation has the potential to efficiently separate ash and pyritic sulfur from coal. Although the idea is about 20 years old, magnetic separation has not been applied to the commercial cleaning of coal for two principal reasons. First, there has been a lack of technical information on the magnetic makeup of American coals. Second, it has not been economically feasible to scale up conventional electromagnetic technology for applications in the coal processing industry. Recent developments in the areas of coal characterization and high field magnet design have made favorable changes in both of these crucial areas. A continuously operating, laboratory-scale magnetic separator has been developed by EXPORTech Co. Inc. Called the Para-Trap, the results obtained from operation indicate the laboratory separator can be scaled to commercial application. Dry magnetic separation has been proven effective in separating pyrites, ash, and sulfur-bearing minerals in sizes generally greater than 44 microns (μ) in a laboratory setting. Successful separations were carried out in all size ranges down to 325 mesh.⁶⁸

Mineral Processing Methods and Equipment

Technological advances continue in the application of superconducting magnetic separators in the treatment of minerals. A general trend in 1991 is the unceasing increase in the attainable magnetic field in various designs of magnetic separators with magnetic circuits based on permanent magnets, electromagnetic

conventional winding, as well as superconducting coils. Two manufacturers have developed separators that use this technology.

Master Magnets Ltd., Birmingham, AL, introduced its Series 1000 roll magnetic separators that can develop magnetic intensities exceeding 2 tons. Rolls 34.9 in long (feed width), with increased roll diameters, can reportedly treat higher tonnages of mineral. The separators are offered in one-, two-, four-, and six-roll versions. The multiroll separators enable retreatment of products on the lower rolls. Throughputs of up to 14 tons per hour of silica sand are reported. The roll speed is controlled by infinitely variable speed motor.

A separator developed by Cryogenic Consultants Ltd. London, is suitable for small producers and for production of special and high-quality materials. The Cryofilter High Gradient Magnetic Separator is designed for kaolin purification. Its throughput is up to 15 tons per hour, and the attainable induction of the magnetic field is up to 5 tons.⁶⁹

Outokumpu of Finland has for some years recognized the importance of efficient grinding control in mineral processing and the benefits in this area resulting from continuous particle size measurement. Elimination of overgrinding and undergrinding gives substantial cost benefits. Outokumpu has recently introduced its PSI-200 particle-size indicator that employs a simple yet innovative direct measurement technique that has been tested successfully on a variety of base metal, iron ore, and industrial mineral applications. Typical accuracies of 1% to 2% are achieved, reliability is reportedly excellent, and operating costs low. The screen-size range measurable is 28 to 500 mesh.⁷⁰

A recent development in the field of concentrate dewatering, the Outomec capillary-action filter, provides relatively low moisture contents at low operating costs. Capillary-action technology was originally developed in Finland for the papermaking industry. It soon became clear during the development process, however, that it was more suitable for

liquid-solid filtration in the mineral processing industry. The key to Outomec's capillary-action technology is a series of disks made out of a patented microporous sintered-alumina material, the inertness of which makes the disks suitable for the filtration of most water-based slurries. Each disk is constructed from a number of sectoral plates consisting of a permeable core to collect filtrate during dewatering.⁷¹

The EMDEE Microflot test is the only method that can determine the floatability spectrum of an ore by a simple direct experiment. Only a few inches of drill core provide enough material for 50 to 100 tests to determine the floatability of an ore. The method is fast, novel, accurate, and requires very small samples, 0.1 to 20 grams per test. The EMDEE package includes the Microflot agitator, a control unit, carrier for the centrifuge tube, and a software package.⁷²

On-Line Monitoring

One of the more recent developments changing the face of coal preparation has been the advent of on-line monitoring systems. These systems use gamma ray radiation to measure the various constituents of coal. On-line analyzers rapidly determine the ash content of coal both upstream and downstream from preparation plants, whether the coal is moving on conveyor belts or in a slurry. Some units provide elemental analysis of the other constituents, including moisture and sulfur. Such data are further analyzed to provide key information such as calorific values, pounds of SO₂ per million British thermal unit (Btu), total ash, and even ash fusion.

From such parameters, computer software uses the feedback of data to control plant processes, sorting and blending. Such controls and measurements are designed to reduce variations in the quality of coal, thereby minimizing penalties for out-of-spec coal and maximizing acceptable coal shipments.⁷³

A speedy and accurate on-line performance monitoring system, conceived by researchers at the

University of Kentucky's Institute of Mining and Minerals Research in Lexington, KY, can fine-tune gravity-based coal preparation operations to achieve the best quality product. The system, which uses fabricated tracer particles and metal detectors, is said to be a more scientific approach than the typical plant control methods that range from intuitive in-plant spot judgments to methods involving such devices as density gauges, floats, and on-the-spot float-sink tests.

The tracer system relies on magnetism during the washing process to trace and record the distribution of tagged synthetic particles of known size and specific gravity between the product and refuse output streams of coal or mineral.⁷⁴

Many mineral quality and processing specifications can be visually determined. The U.S. Bureau of Mines has developed an on-line computer vision-based system that is capable of the determining size distribution of flowing materials and is also capable of measuring particle shapes, brightness, and contrast. The system is nonobtrusive and is capable of measuring and controlling process parameters through a standard RS-485 serial port.

This computer vision system has been installed on the discharge belt of an agglomeration drum as part of a cooperative research project with the LTV Steel Co. and the Minnesota Department of Natural Resources. A visually based moisture content model has been developed using ball size and brightness as the independent parameters. Data have indicated the potential for controlling ball moisture content to within 0.1%. Accurate control of moisture content along with consistent ball size will result in better quality pellets with reduced operating costs.

Other applications include size and shape measurements of mine-run material and measurement during comminution processes. This system measured blast-size distribution with good correlation. It has also been used to measure the size distribution of feed to an autogenous mill.

Peroxide-Assisted Gold Leaching

The latest step in the chemical optimization of cyanidation is the use of hydrogen peroxide as a liquid oxidant. The peroxide-assisted leach (PAL) system allows the use of this strong oxidant in cyanidation while avoiding a reaction between H_2O_2 and cyanide. The availability of H_2O_2 in cyanidation significantly accelerates the extraction kinetics compared to standard technology that uses compressed air or oxygen as an oxidant. The optimized extraction kinetics leads to increased gold recoveries and reduced leach times. Furthermore, the use of a strong oxidant in cyanidation minimizes cyanide consumption by reducing the leach time, prevents cyanide losses by volatilization of HCN, and passivates cyanide-consuming sulfide minerals.

The main field of PAL application is the processing of sulfide ores, which are strongly oxygen and cyanide consuming. In contrast to standard aeration technology, the PAL process works very efficiently and economically on this ore type. The PAL process was first introduced to the mining industry about 3 years ago, and seven mines are currently using this technology. As oxide ore bodies are mined out and more sulfide gold ores must be mined, it is likely that PAL will become increasingly used in cyanidation.⁷⁵

Solvent Extraction and Electrowinning

Solvent extraction and electrowinning (SX-EW) in the worldwide copper industry continues to grow. Approximately 11% of the world copper supply is now produced by SX-EW methods, and new SX-EW plants commissioned in the past 3 years contribute 39% of all SX-EW production. As environmental laws become more stringent worldwide, particularly in the area of smelter emissions from conventional processing facilities, the trend toward primary copper production from SX-EW facilities is expected to definitely continue.

A few of the advantages of SX-EW technology over conventional mill smelter-refinery processing are the following:

- Low-cost copper cathode production (30 to 60 cents/lb).
- Environmental acceptability.
- Reduced capital costs compared with conventional facilities.
- The final product is high-quality, readily marketable cathode copper.⁷⁶

Warner Process

A new route from ore or concentrates to zinc metal could revolutionize the zinc industry. The net mine value of concentrates shipped to a distant smelter is typically 50% of the gross zinc value. The Warner Process should provide substantially higher returns by enabling zinc metal to be produced at the mine.

Other important advantages are that the process tolerates a higher percentage of gangue than permitted in zinc concentrates for shipment, and iron sulfide, because it is a heat source, is not a limitation. This means upstream flotation circuits can be operated for maximum recovery with little penalty on concentrate grade. Overall recovery from ore should therefore be higher.

The Warner Process has been under development by the University of Birmingham for the past 10 years, supported by the Mineral Industry Research Organization and the European Community, and is now ready to be taken through the final stages of engineering development.⁷⁷

HEALTH AND SAFETY

Safety Statistics

The number of coal mining deaths and injuries and the rates of fatalities and injuries per total hours worked in the United States dropped during the first 9 months of 1991 as compared to the same period of 1990, according to the Mine Safety and Health Administration (MSHA).

The rate of fatal injuries in coal mining was 0.04 injuries per 200,000 employee work-hours during the first 9 months of 1991, compared with 0.05 for the same period in 1990. Through September 1991, 45 miners were killed on the job, compared with 53 during the same period of 1990 and 55 for the first 9 months of 1989. Sixty-six coal miners died during all of 1990.

The rate of nonfatal coal mining injuries involving lost work time during the first 9 months of 1991 was 7.80 injuries per 200,000 employee-hours. This showed a decrease as compared with 7.82 in the same period of 1990 and 7.88 in the first 9 months of 1989. For the full year 1990, the nonfatal lost work time rate was 7.88. The rate for all types of injuries in coal mining was 10.02 per 200,000 work-hours in the first three quarters of 1991, compared with 10.08 for the same period in 1990.

The rate of fatal injuries in metal and nonmetal (noncoal) mining in the first half of 1991 was 0.02 per 200,000 employee-hours worked, compared with 0.03 for the same period of 1990, 0.03 for 1990 overall, and 0.02 for the same period on 1989. Twenty-two metal and nonmetal miners died in accidents through June 1991 compared with 29 for the same period in 1990, 56 for all of 1990, and 25 for the first half of 1989.

The rate of nonfatal lost-time injuries at metal and nonmetal mines was 3.98 for the first half of 1991, compared with 4.18 for the same period of 1990, 4.10 for all of last year, and 4.40 for the first half of 1989. The rate for all types of metal and nonmetal mining injuries for the first half of this year was 6.60 compared with 6.93 for the same period of 1990, 6.83 for all of last year, and 7.76 for the first half of 1989.⁷⁸

MSHA Regulations

MSHA plans to formulate new regulations to cover the hazards of work in confined spaces on mining property. Since 1980, about 78 fatal mining accidents have been related in some way to the hazards of work in confined spaces. While existing safety and health

standards cover some confined-space hazards, there is a need for a comprehensive regulation specifically targeting these types of dangers. MSHA has asked for input on the applicability of the concepts proposed by OSHA to the mining industry.⁷⁹

MSHA has revised Federal regulations for the handling of explosives and blasting in underground coal mines. The new rule changes the criteria for workers to be "qualified" to use explosives. The regulations deal with the hazard of stray electrical current, triggering detonators, and multiple-face blasts. Under the new rule, a miner must have had 1 year of experience with explosives before being designated as qualified—the experience could be gained in either mining or construction work.⁸⁰

MSHA announced civil fines totaling almost \$1 million against 14 mining companies and contractors in 9 States and Puerto Rico for negligent violations of safety and health regulations that led to deaths of 16 miners in fatal accidents. The civil penalties for 82 violations in 13 accidents that occurred between November 1990 and March 1991 included 8 \$50,000 fines—the highest dollar amount ever assessed by MSHA per violation. Another 26 violations were assessed penalties of \$10,000 to \$35,000. On November 5, 1990, Congress increased MSHA's maximum civil penalty amount per violation from \$10,000 to \$50,000. This group of penalties is the first to exceed the previous \$10,000 limit. Fines assessed in all of the accidents totaled \$976,020.⁸¹

Dust Control

One promising concept to reduce dust exposure to longwall miners is to maintain two splits of air along the entire length of the face. A curtain can create an intake split in the miners' walkway and a return (dusty) split over the face conveyor. The concept was earlier evaluated by the U.S. Bureau of Mines in trials using brattice. The brattice proved almost 100% effective in keeping the coal dust away from the miners, but severe visibility problems for the shearer

operators plagued its applicability underground. The Bureau has now come up with a way to maintain the air splits while eliminating the visibility handicap. The solution uses see-through polyester-mesh hung under roof shields where the lights are held.

Laboratory testing of the technique was conducted at the Bureau's Lake Lynn facility. A 500-ft test section of an entry was split with a mesh curtain containing 1/16-in and 1/8-in mesh openings at air velocities ranging between 200 to 800 ft/min. The 1/16-in mesh averaged better than a 60% clean split of air for the entire face over the whole air velocity range, while the 1/8-in mesh averaged almost a 50% clean split of air. Several vendors supply flame-retardant polyester material that meets MSHA standards.⁸²

Most of the dust from a longwall mining system is generated by the cutting action of the shearer drums. Numerous drum designs have been proposed to reduce dust generation, and one of the most promising is the so-called ventilating drum developed by the U.S. Bureau of Mines, working with Foster-Miller, Inc. The drum has 9 to 12 dust-capture tubes built into the shell of the shearer drum and arranged concentrically around the drum's center hub. High-pressure water is released from a spray ring manifold on the face side of the drum. The sprays act as a fan blowing toward the gob by entraining air and moving it from the face to the gob. The sprays also act as scrubbers, removing 90% to 95% of the respirable dust from the air drawn through the tubes. Because the tubes are open-ended and have no moving parts, it was thought that they would not be readily blocked by large debris. When tried under production conditions, however, the tubes did tend to block. Although this was not deemed an insurmountable problem, the Bureau came up with an alternative concept. Researchers took a conventional drum containing 26 low-pressure bit sprays on the shearer's bit blocks, angled the sprays 30° toward the face, installed new spray nozzles, and boosted the water spray pressure to about 1,000 psi. This resulted in an equivalent dust reduction

obtainable with the ventilating drum but without any of the associated maintenance problems.⁸³

Controlling quartz concentrations requires a different approach for respirable dust control. For instance, the wetting characteristics of quartz can be modified so that the capture efficiency is increased. The foam spray system is one such technique. Advantages of foam over conventional water sprays include the fact that a foam bubble has a larger surface area, which ensures better dust particulate capture. Also, foaming agents have better wettability characteristics than water.

A study was conducted in an operating mine to evaluate the effect of a compressed-air, foam-spray system mounted on a continuous miner. A foaming block containing two flat fan sprays was designed by the U.S. Bureau of Mines. It was welded to the back of the pan and directed so that the spray covered the pan and the gathering arms. Results of the study show that foam under-boom sprays appear to have a significant effect on quartz levels. Reduction in airborne intake dust concentrations was observed in 8 out of 11 cut comparisons. In the miner operator cab, however, the foam did not appear to reduce dust levels.⁸⁴

A shearer cutting drum that extracts up to 80% of respirable airborne dust in coal-cutting operations on longwall faces is felt to have substantial worldwide sales potential in areas where the longwall system of mining is used. More than 100 of the drums are currently in use in United Kingdom mines, helping to eliminate the health problems associated with airborne dust and also reducing the hazard of methane at the point of coal cutting. British Coal (BC), which developed the device, plans eventually to install this cutting device on all machines with which it is compatible.

The extraction drum was designed and developed over an extended period by BC's research and technical staff based on Bretby near Burton-on-Trent, England. The average life of a drum in regular use is 12 months, and it is estimated that there is a worldwide market for up to

1,000 drums per year. Development and field trials of the dust extraction unit have spanned a number of years. The unit uses high-pressure watersprays that direct air through a system of dust capture tubes fitted within the central hub of a standard cutting drum. Clean air is introduced to the cutting zone, diluting any methane gas that may be present and preventing the risk of frictional ignitions. Previous attempts to disperse methane at the face concentrated on improved ventilation, but this had the side effect of increasing dust dispersion. It is this dual hazard control aspect of the drum that makes it so significant to the coal mining industry.

A Mini-Scrubber Float Dust Filtration System to control float and respirable dust in underground mining, surface mining, and processing applications has been introduced by the Mining and Safety Supply Div. of the National Mine Service (NMS).

Engineered in a compact 2,000-ft³/min scrubber/fan package, the miniscrubber has cleaning efficiencies of 95% for respirable dust and 99% for float dust, reports NMS. According to the manufacturer, 1 gallon of water per minute at 60 psi is required to operate the system, compared with 5 to 10 gallons per minute or more with venturi and water-powered dust collectors. Dust-laden air drawn into the stainless steel unit mixes with water to form a slurry that is removed from the air by a demister. The slurry collects in a sump and drains onto the conveyor belt or is piped away to a drain.⁸⁶

Underground Fire Alarm

Recent research by the U.S. Bureau of Mines has demonstrated that encoded ultra-low-frequency (ULF) electromagnetic signaling can be used for an underground mine fire alarm. The system combines the transmission and reception of ULF EM fields through mine rock to send a fire-warning signal to underground miners. A magnetic field, generated about the transmitting loop antenna, transmits the signal. The field emanates from the transmitting antenna in a spherical manner.

What makes the system unique is the mobility of the receiving unit, which utilizes a ferric core antenna (5.9 in long) for signal reception. It has exceptional flux-gathering capabilities and can capture even the weakest electromagnetic signals. Also, the receiver is battery powered. It can be powered off of a cap-lamp battery or off of a vehicle, making the system completely portable and easy to carry. The prototype of the system has been tested at several mines. The signal transmission distance achieved during these tests was greater than 5,400 ft through overburden.⁸⁷

Lightning Warning System

Lightning has always been regarded as a serious threat to surface mine blasting operations. Recently, several detection techniques have been developed that permit a mine to more accurately determine when lightning is nearby.

Amax is applying a relatively inexpensive lightning tracking system, which is being linked to all of the company's midwestern surface mines. The tracking system is not only expected to help a mine prevent casualties from an unexpected lightning strike, but also to avoid having its blasting operations suspended unnecessarily. The system employs a satellite dish on a roof near a computer system. The different Amax mines are computer-linked. It was not until recently that access to a cost-effective and accurate timing source was made possible by technological breakthroughs and microprocessor design. The system selected by Amax is a time-of-arrival (TOA) system called lightning position and tracking system (LPATS).⁸⁸

Emergency Mine Vehicle

Several new technologies and some new inventions were introduced at the Ninth International Conference on Coal Research (ICCR), which was held recently in Washington, DC. Among the new inventions was the Numbat, presented by CSIRO, Div. of Geomechanics, located in Queensland, Australia.

Numbat, an emergency mine safety vehicle, is a single-hulled eight-wheeled, remotely controlled survey vehicle. The vehicle provides detailed information on underground conditions to the surface following a mine emergency such as a fire or explosion. It would operate in support of rescue, decreasing the chance of exposure to any unknown, and possibly dangerous, situations. The Numbat is one of only two postemergency coal mining survey vehicles known to be under development worldwide. The other is being produced by the Coal Mining Research Center-Japan, but details are unreported.⁸⁹

Rescue Through Drill Hole

Twenty-six coal miners trapped by a roof fall were rescued in Swaziland through a hole drilled from surface. It was the first of its kind in southern Africa, and one of very few in the world. Moreover, it is believed to be the largest number of men ever rescued through a drilled hole.

The Emaswati Coal Mine near Mpaka in the eastern Lowveld currently produces about 180,000 tons per year. About 350 workers are employed at the shallow (215-ft-deep) underground coal mine. At 10:00 a.m. on the morning of June 8, a 660-ft-long roof fall trapped a 26-employee crew inside the mine. An area 600 by 330 by 215 ft deep had collapsed to the surface. Drilling started at 3:15 a.m. and finally holed through at 11:45 a.m., a rate of about 30 feet per hour. Twenty-eight hours after being trapped, the workers were rescued. The drill has been used only once and, according to the South African Chamber of Mines, there were no problems. The equipment proved itself in the emergency.⁸⁹

W Withheld to avoid disclosing company proprietary data; included with "Other" or "Undistributed."

¹Excludes materials from wells, ponds, or pumping operations.

²All data are rounded to three significant digits. Data may not add to totals shown because of independent rounding.

³Includes material from exploration and development activities.

⁴Less than 1/2 unit.

⁵Includes bauxite, beryllium, magnesium metal, manganese, molybdenum, platinum-group metals, rare-earth concentrates, tungsten, and metal items indicated by symbol W.

⁶Excludes volcanic cinder and scoria.

⁷Includes apatite, asbestos, fluorspar, greensand marl, kyanite, lithium minerals, magnesite, magnesium-brines, olivine, wollastonite, and industrial mineral items indicated by symbol W.

⁸Includes North Dakota, Rhode Island, and State items indicated by symbol W.

Wisconsin	244	6	29	127	81	1	—
Wyoming	160	3	43	91	19	4	—
Undistributed ⁵	2,560	48	381	1,168	883	66	14
Total, States	7,065	167	1,074	3,206	2,365	222	31

¹Excludes wells, ponds, or pumping operations.

²Includes beryllium, magnesium metal, manganese, mercury, molybdenum, platinum-group metals, and tungsten.

³Excludes volcanic cinder and scoria.

⁴Includes apatite, asbestos, boron minerals, fluorspar, greensand marl, kyanite, magnesite, olivine, and wollastonite.

⁵Includes Alabama, Alaska, Arizona, Delaware, Hawaii, Illinois, Indiana, Iowa, Kansas, Kentucky, Maine, Massachusetts, Michigan, Montana, New Hampshire, North Dakota, Ohio, Oregon, South Dakota, Tennessee, Virginia, and undistributed data.

*Estimated. ¹Revised.

¹Distribution of industrial explosives and blasting agents by consuming industry in 1990 and 1991 estimated from indexes of industrial production and economics reported by the U.S. Department of Energy, Federal Reserve Board, Department of Transportation, and Bureau of the Census.

²Data may not add to totals shown because of independent rounding.

ABRASIVE MATERIALS

By Gordon T. Austin

Mr. Austin, a physical scientist with more than 30 years' industry and Government experience, has been the commodity specialist for abrasive materials since 1986. The staff of the Branch of Data Collection and Coordination prepared the domestic data tables.

The combined value of production of natural abrasives, which include tripoli, special silica stone, garnet, staurolite, and emery, increased about 4% in 1990. The decrease in the value of tripoli production was the result of a decrease in total production. Emery decreased owing to a decrease in the volume of the material produced. Special silica stone experienced a decrease in unit value and in the quantity produced. Garnet showed an 8% increase in quantity and an 8% increase in unit value. Staurolite increased about 38% in the quantity produced, and the value of production increased about 36%.

The fused aluminum oxide industry showed a 12% decline in the quantity produced and a 13% decline in the value of production. The silicon carbide industry saw a 47% decrease in the quantity produced and a 23% decrease in the value of production. Combined, the industries decreased 17% in quantity and value compared with those of 1990.

The quantity of metallic abrasives sold and shipped declined 3% in quantity and 7% in value compared with those of 1990. This was after 2 stable years that had followed 4 consecutive years of increases in both quantity and value. The industry includes the primary producers of steel, chilled and annealed iron, cut wire shot and grit, and shot and grit reclaimed by primary producers. Shipments in 1991 were about 11% below the industry's high of 239,619 metric tons¹ in 1979.

The United States continued as the world's largest single manufacturer, exporter, importer, and consumer of synthetic industrial diamond. The estimated apparent U.S. consumption of industrial diamond stones was 5.0 million

carats, a decrease of 46% compared with that of 1990, but was still significantly greater than the 48-year low in 1987. (See table 1.)

DOMESTIC DATA COVERAGE

Domestic production data for abrasive materials were from seven separate, voluntary U.S. Bureau of Mines surveys. Of the 61 operations producing natural and manufactured abrasives canvassed, all responded, representing 100% of the total production shown in tables 1, 5, 6, 9, 15, 16, and 21.

FOREIGN TRADE

The total value of abrasive materials, exports plus reexports, was \$320 million, about an 8% increase compared with the 1990 value.

The total value of abrasive materials imported was \$450.9 million, a decrease of 12% compared with the 1990 value. The average total value for the past 10 years was \$381.4 million per year, with the high in 1990 of \$512.8 million and the low of \$245.0 million in 1982. Abrasive material imports had, until the 1989 decrease, increased at a compounded rate of slightly less than 13% per year for 6 years. The 1990 increase put the level of imports back on trend, but the 1991 decrease set them back below the 1988 level. The level of imports was 84% greater at the end of the period than at the beginning.

The United States has shown a trade deficit in abrasive materials for every year of the past 10 years. In 1991, the deficit decreased 40% compared with 1990's record high \$217.4 million, which

was a 43% increase from that of 1989. (See tables 2, 3, and 4.)

TRIPOLI

The category of tripoli, as broadly defined, is composed of extremely fine-grained crystalline quartz in various stages of aggregation. The particle sizes usually range from 1 to 10 micrometers, but particles as small as 0.1 to 0.2 micrometers are common. Commercial tripoli contains 98% to 99% silica and minor amounts of alumina (as clay) and iron oxide. Tripoli may be white or some shade of yellow, brown, or red depending on the percentage of iron oxide. The U.S. Bureau of Mines includes not only tripoli, but other fine-grained, porous silica materials that have similar properties and end uses such as rottenstone and novaculite. It does not include fine-grained or porous silica materials included in other Mineral Annual Report chapters, such as pumice.

Production

In 1991, the quantity of crude tripoli produced decreased 6% and the value of production increased slightly compared with those of 1990. The average production for the past 10 years was 102,356 tons per year, with a high of 112,928 tons in 1984 and a low of 88,642 tons in 1991. In the United States, four firms produced tripoli. Malvern Minerals Co., Garland County, AR, produced crude and finished material. Malvern also produces a black material from novaculite. American Tripoli Co. produced crude material in Ottawa County, OK, and finished material in

Newton County, MO. Unimin Specialty Minerals Inc.'s Alco and Tamms plants, in Alexander County, IL, produced crude and finished material. Keystone Filler and Manufacturing Co. in Northumberland County, PA, processed rottenstone, a decomposed fine-grained siliceous shale, produced by B. J. Ulrich & Sons, also in Northumberland County, PA. (See table 5.)

Consumption and Uses

Processed tripoli, sold or used, decreased 9% in quantity and 6% in value compared with those of 1990.

Tripoli is processed in mills that are jasper lined using flint or jasper pebbled in closed circuits with banks of mechanical classifiers. Materials from the mechanical classifiers are fed to micronizing mills, in which it is ground and sized at the same time. Material that is 100% minus 10 micrometers and 96% minus 5 micrometers is the smallest particle size material sold. Even this very fine particle material is not the result of fragmentation of individual crystals; instead, clusters of quartz crystals, many less than 1 micrometer in size, that are joined at their points are broken apart. The ultrafine-grained tripoli is a collection of clusters and individual quartz crystals.

Tripoli has had unique uses as an abrasive because of its hardness and its grains lack distinct edges and corners. It is a mild abrasive, making it suitable for use in toothpaste and tooth polishing compounds, industrial soaps, and metal and jewelry polishing compounds. The automobile industry uses it in buffing and polishing compounds in lacquer finishing.

The end-use pattern for tripoli has changed significantly in the past 20 years. In 1970, about 70% of the processed tripoli was used as an abrasive. Today, 70% is used as a filler and extender in paint, plastic, rubber, caulking compounds, and enamel.

The largest use of tripoli is as a filler and extender in paints. These uses are estimated to account for as much as 85% of the tripoli used as filler and extender. Its use in exterior latex paints is as a low-

micrometer-grade micronized product. In these paints, tripoli aids in tint retention, durability, leveling, and flowability. In enamels, it permits higher loading with no appreciable increase in vehicle demand and improves sheen. Because of its controlled grain or particle size, paints containing tripoli disperse easier and result in a uniform film. Additionally, because of its abrasive qualities, the paints are more resistive to wear and more resistive to chemicals than those in which water-ground whittings and other reactive fillers are used.

Plastics, rubbers, and resins each use about 5% of total annual tripoli filler and extender production. It is used extensively in plastics for electrical uses because of its dielectric properties and its effects on flexural and compressive strengths. Its chemical resistance, weatherability, and resistance to salt spray also are important to its use in plastics. Its physical properties allow high loading in most compounds, but its abrasiveness results in high wear in extruding nozzles and molds. The same properties that makes tripoli useful as a filler and extender in plastics makes it valuable to the rubber and resin industries.

Tripoli is essentially 100% crystalline silica, so its use can cause silicosis and falls under the jurisdiction of the Occupational Safety and Health Administration's (OSHA) Hazard Communication Standard. The International Agency for Research on Cancer (IARC) and other independent studies have determined that crystalline silica is a probable carcinogen for humans. As a result, OSHA is required to regulate materials containing more than 0.1% crystalline silica. To date, it does not appear that these regulations have adversely affected the use of tripoli, but all tripoli must be labeled in compliance with OSHA regulations.

In the filler and extender uses listed, ground calcium carbonate, ground silica sand, pyrogenic and precipitated silica, calcined kaolin, and talc can be substituted.

The use of tripoli as an abrasive decreased about 12% in 1991 to a 10-year low of 21,239 tons; 1991 was the seventh

consecutive year of decline. During the 7-year period, consumption declined about 43%. The average annual consumption of abrasive tripoli for the past 10 years was 29,805 tons, with a high of 37,024 tons in 1984 and a low of 21,239 tons in 1991. The 1991 consumption was the lowest since 1949, when only 20,972 tons was sold or used.

After 5 consecutive years of growth, from 1982 to 1987, the amount of tripoli used as filler declined for the fourth consecutive year. The 7% decline in 1991 followed a 10% decrease in 1990, an 8% decrease in 1989, and an additional 4% decrease in 1988. The average consumption of filler-grade tripoli for the past 10 years was 61,022 tons per year, with a high of 71,160 tons in 1987 and a low of 50,180 tons in 1982. U.S. Bureau of Mines data show that tripoli use in the United States as a filler is about 71% of the total abrasive, 29%.

Prices

The average reported value of abrasive tripoli, sold or used, in the United States was \$142.12 per ton. The average annual value reported for abrasive tripoli for the past 10 years was \$110.60 per ton, with the high value in 1991 of \$142.12 and the low in 1982 of \$76.27. The value of abrasive tripoli has increased over the past 10 years at an annual compounded rate of 10% per year. The increase has been continuous; the annual rate of increase from 1985 to 1990 was significantly lower than the annual rate of increase from 1982 through 1984.

The average reported value of filler tripoli, sold or used, in the United States was \$197.78 per ton. The average annual value for the past 10 years was \$136.33 per ton, with a high of \$197.78 per ton in 1991 and a low of \$90.81 per ton in 1982. The value increased at an annual compounded rate of about 9% for the past 10 years.

SPECIAL SILICA STONE PRODUCTS

Special silica stone products include hones, whetstones, oilstones, stone files, grindstones, grinding pebbles, tube-mill liners, deburring media, and certain specialty products. These do not include product made from artificially bonded abrasive grains. Manufacture of these products was from novaculite, quartzite, or other quarried microcrystalline quartz rock.

Production

Plants manufactured oilstones, hones, whetstones, and files in Arkansas and Indiana and cuticle stones and coaster stones in Indiana. Additional production includes grindstones in Ohio, deburring media in Arkansas and Wisconsin, and grinding pebbles and mill liners in Minnesota. Production of the crude materials was in the same State as the products manufactured.

The process for estimating production of crude material changed in 1981 and again in 1987. Because of two changes in estimating production, 10-year averages and other production trends would be of no practical use.

The production of oilstones, hones, whetstones, files, and grindstones decreased about 40% in quantity to a 10-year low of 272 tons and 43% in value to \$3.6 million. The average annual production of the products for the past 10 years was 489 tons, with a high of 647 tons in 1982 and a low of 272 tons in 1991. The average value of annual production for the past 10 years was \$5.4 million, with a high of \$7.4 million in 1987 and a low of \$3.6 million in 1991. In the past 10 years, two distinct and different trends in the value of production appeared. One was from 1980 through 1984, when the average value of production was \$4.1 million per year. The other was 1985 through 1990, when the value of production was 68% greater at an average value of \$6.9 million per year. During 1985-90, the average annual quantity of production was less than the

10-year average and the average annual value of production was 19% greater than the 10-year average. The change in average annual value was the result of a significant increase in the value per ton of manufactured products, starting in 1985. The significant decreases in 1991 can be attributed to one of the major producers in the industry entering into bankruptcy. (See tables 6 and 7.)

The industry manufactured four main grades of Arkansas whetstone. They ranged in grade from the high-quality Black Hard Arkansas Stone down to the Washita Stone. The Black Hard has a porosity of 0.07% and a waxy luster, while Washita Stone has a porosity of 16% and resembles unglazed porcelain. The four main types are shown in table 8. (See table 8.)

Arkansas accounted for essentially 100% of the value and total quantity of special silica stone products reported as sold or used by U.S. producers.

Consumption and Uses

The domestic consumption of special silica stone products is a combination of residential, industrial, leisure, and craft uses. The major residential uses were the sharpening of knives and other cutlery such as scissors, shears, and lawn and garden tools. Major industrial uses were the sharpening and honing of cutting surfaces, polishing of metal surfaces, and the deburring of metal and plastic castings. The manufacture, repair, and modification of guns also make use of stone files. The recreational uses were the sharpening of sports knives, arrowheads, spear points, fish hooks, and other recreational items. Craft applications included uses in sharpening tools for wood carving, gun engraving, jewelrymaking, and other engraving work.

Prices

The value of crude novaculite suitable for cutting into finished products varied from \$19 per ton to \$1,266 per ton. The low value was for Washita grade and the high for Black Hard Arkansas grade. The manufacture of deburring media or

special-purpose crushed stone is from material not suited for making oilstones, hones, or whetstones. The value of these materials ranged from \$11 per ton to \$440 per ton. The average value in 1991 of oilstones, hones, whetstones, and grindstones, sold or used by U.S. producers, was \$13,251 per ton. The average annual value of the same items for the past 10 years was \$11,556 per ton, with a high of \$14,741 per ton in 1989 and a low of \$6,411 per ton in 1984. In the past 10 years, the unit value of special silica stone products followed three distinct negative trends. The first trend, a gradual decrease, occurred during the period 1980-84. The value per ton averaged \$7,227, with a high of \$8,284 and a low of \$6,411 in 1984. A second trend began in 1985 when the value per ton more than doubled from \$6,411 to \$13,361. The average annual value per ton for the period 1985-88 was \$13,006, with a high of \$14,113 in 1986 and a low of \$12,229 in 1988. The third trend began in 1989, with a value of \$14,741 followed by 2 years of declining average values. One possible explanation for the series of step-ramp trends is the introduction of new high-value products by a single manufacturer. The product then encounters significant price competition from other producers in subsequent years. New products can be duplicated by competitors quickly, because the special silica stone products industry is not high technology. This very quickly results in short-term price pressures. The reason for the significant decrease in 1991 is not apparent, but may be attributed to the quality of the data.

Foreign Trade

The value of exported special silica stone products was \$7.4 million, a decrease of 29% compared with that of 1990. The average annual value of exports for the past 10 years was \$4.0 million, with a 10-year high of \$10.4 million in 1990 and a low of \$2.0 million in 1987. The annual value of exports during the past 10 years did not appear to have established a trend. Instead, the value drifted between \$2.0 million and

\$2.6 million, with as many increases as decreases until the significant increase in 1989 and 1990, followed by the 1991 decrease.

The value of imported products was \$1.8 million, a decrease of 22% compared with that of 1990, but essentially the same compared with those of 1985, 1986, and 1989. The average annual value of imports for the past 10 years was \$1.5 million, with a high of \$2.3 million in 1990 and a low of \$0.9 million in 1982. The trend for products imported to the United States was generally upward with some occasional decreases. The United States continues to be a net exporter of special silica stone products. A portion of the finished products imported was from crude novaculite produced within the United States and exported for processing.

In 1991, the trade surplus in special silica stone products was \$5.6 million, a decrease of about 31%. During the past 10 years, the United States has enjoyed an average trade surplus of \$2.5 million per year, with a high of \$8.1 million in 1990 and a low of \$0.4 million in 1985. The trend for the past 10 years has been one of declining surpluses until the 1989 and 1990 increases. The average annual surplus for 4 years before the increases had been only \$0.6 million or about 24% of the 10-year average.

GARNET

Technical-grade industrial garnet from the United States is a solid solution of almandite and pyrope that, when under pressure, breaks into sharp chisel-edged plates. Industry uses this garnet as an abrasive powder and to manufacture coated abrasives. Low-quality industrial garnet found uses primarily as airblasting or hydroblasting media and as filtration media.

Background

Definitions, Grades, and Specifications.—Garnet is a general name for a family of complex silicate minerals having similar physical properties and crystal form. The general formula for

garnet is $A_3B_2(SiO_4)_3$, where A can be calcium, magnesium, ferrous iron, or manganese and B can be aluminum, ferric iron, or chromium, or rarely titanium. The most common garnet species are $Mg_3Al_2Si_3O_{12}$ (pyrope) and $Fe_3Al_2Si_3O_{12}$ (almandite). Almandite and almandite-pyrope solid solution garnets are the best abrasive garnets, but andradite, grossularite, and pyrope also are used. Garnet displays the greatest variety of color of any industrial mineral, having been found in all colors except blue. For example, grossularite can be colorless, white, gray, yellow, yellowish green, various shades of green, brown, pink, reddish, or black. Andradite garnet can be yellow-green, green, greenish brown, orange-yellow, brown, grayish black, or black. Pyrope is commonly purplish red, pinkish red, orange-red, crimson, or dark red; and almandite is deep red, brownish red, brownish black, or violet-red. Spessartite garnet can be red, reddish orange, orange, yellow-brown, reddish brown, or blackish brown.

The Mohs hardness of garnet varies from 6.5 to 9.0. Grossularite and uvarovite have a hardness of 6.5 to 7.5; andradite is 6.5 to 7.0; and pyrope, almandite, and spessartite are 7.0 to 7.5 in hardness. There are reports of almandite having a hardness of between 8.0 and 9.0.

As with hardness, the specific gravity of garnet varies considerably. The specific gravity may be as low as 3.2 grams/cubic meter or as high as 4.3 grams/cubic meter depending on chemical composition.

Consumers purchase garnet that has been crushed, ground, and graded to different particle sizes for different end uses. Descriptions of testing methods for materials to be used in the manufacturing of coated abrasives are contained in American National Standards Institute (ANSI) Specifications B74.18-1977, "Specifications for Grading of Certain Abrasive Grains on Coated Abrasive Products."² Other specifications are contained in ANSI Specification B74.12-1976, "Specification for Size of Abrasive Grains—Grinding Wheel, Polishing, and General Industrial Uses."³

If the garnet is to be used as a sandblasting medium at a U.S. Navy shipyard or a private shipyard working on U.S. Navy vessels, then it must meet MIL-A-22262(SH) specifications that qualify it for product list QPL-22262. These specifications set forth limits on the content of total metals, soluble metals, and radiation; specify the acceptable level of chemical conductivity; and require that the material be certified by the California Air Resources Board (ARB).

ARB requires all loose-grain abrasives used in the State to be certified at the ARB testing facility. The testing is conducted according to "Methods of Test of Abrasive Media Evaluation," Test Method No. Ca 371-A, and as required under ARB's title 17, subchapter 6, entitled, "Abrasive Blasting." Copies of these documents are available from the Compliance Div. of the California Air Resources Board, Sacramento, CA. In addition, air pollution control agencies in Louisiana, Minnesota, and Utah have adopted the ARB tests and require that only ARB-certified abrasives be used on State projects requiring sandblasting. The ARB's testing procedures and standards are focused on the environmental impact of sandblasting abrasives, not on their qualities or cutting performance and/or efficiency.

The Steel Structures Painting Council, a technical organization in Pittsburgh that has a committee on abrasives, is currently drafting abrasive specification SSPC-XAB1X, "Mineral and Slag Abrasives," which will address garnet specifically. The specification defines the requirements for selecting and evaluating mineral and slag abrasives used in blast cleaning steel and other surfaces for painting and other purposes.

The American Water Works Association (AWWA) has established specification B100-89, "Standards for Filtering Materials," but this specification does not cover high-density media such as garnet and ilmenite. The AWWA plans to include garnet and ilmenite in the updated specification B100-94. In general, specifications for filtration involve garnet's particle shape, specific gravity, effective grain size, coefficient of grain

size uniformity, content of acid-soluble impurities, and content of radioactive and heavy metals.

The sale of garnet for sandblasting, water filtration, and abrasive cutting is by screen size. In U.S. sandblasting, the most widely used domestically produced garnet is $-1.0+0.3$ millimeters, followed by $-0.59+0.21$ millimeters. The most popular grade of imported garnet in the U.S. market is the $-0.59+0.25$ -millimeters grade from Australia. In U.S. multimedia water filtration systems, two grades of garnet are used, a coarse grade that is $-4.75+1.41$ millimeters, and a fine grade that is either $-0.84+0.3$ or $-0.71+0.25$ millimeters. Abrasive cutting applications' most popular grade of garnet is $-0.25+0.177$ millimeters, which may account for as much as 90% of the garnet used.

There is no definitive method for testing the quality of garnet or any other loose-grain abrasive except by actual application. There are tests and examinations that can indicate a garnet product's probable abrasive performance in use. The fracture, sharpness, shape, and structure of the garnet and the presence of inclusions all can be studied with a microscope. The hardness and friability of the garnet can be evaluated by placing a sample between two glass microscope slides and rubbing them together. The relative scratch hardness of the grains and their degree of breakdown (attrition) can be measured in this manner. Additionally, ANSI standard B74.8-1965, "American Standard Test for Ball Mill Test for Friability of Abrasive Grain," can be used to determine the friability of garnet grains.

The U.S. National Institute for Standards and Technology developed an apparatus for evaluating the abrasive quality of corundum. This tester can be adapted for use with any loose-grain abrasive. Testing of loose-grain abrasives also can be performed with various production-scale and laboratory machines where the removal of glass from flat plates is evaluated. Data from such tests can be correlated with the anticipated performance of any abrasive grain relative to the other material to be

abraded. In these tests, abrasive performance is determined by the amount of stock removed, as found either by weighing or by dimensional measurements.

In judging the abrasive quality of garnet, stock removal is not the only important factor. Surface finish is just as important. If an abrasive is too hard or contains too-coarse grains for use on a certain material it can cause deep scratches in the surface, which cannot be removed in subsequent finishing operations. Additionally, if an abrasive does not have the proper grain shape or does not break down in such a manner as to sharpen itself, it will tend to burn or gouge the material being abraded, thus defeating the purpose of its use.

ARB's testing facility tests loose-grain abrasives for certification for use in the State. The test is focused on the environmental impact of sandblasting abrasives, not on their abrasive quality.

Other firms or laboratories that test the quality of loose abrasive grains include three firms involved in the abrasive cutting industry, Flow International Corp., Ingersoll Rand Corp., and Jet-Edge, Inc., that have laboratories for testing and evaluating garnet for use in their systems. Most of the evaluations in these laboratories involve the comparative testing of various abrasive grits, including measurements of particle size distribution and mechanical properties. KTA-Tator Inc. of Los Angeles, CA, is a major consulting-engineering-testing firm whose laboratory tests and evaluates the quality of garnet and other abrasives. Much of its work is oriented to the Steel Structures Painting Council (SSPC) specifications. The SSPC also can carry out comparative testing of garnet and other loose-grain abrasives to determine whether they meet military specifications, how clean the material is, how well the material cleans, the amount of degradation during use, and other quality factors. SSPC is part of Carnegie-Mellon Research Institute and must be careful not to conduct research that favors one abrasives supplier over another supplier who may be a member of the Council.

Industry Structure.—Currently, four firms produce garnet from four plants in two States. Each domestic producer has distinctive products. The Barton Mines Corp., Warren County, NY, garnet is a mixture of almandite and pyrope and is at the top of the garnet hardness range. It occurs as large crystals and exhibits incipient lamellar parting planes that break under pressure into sharp chisel-edged plates. It retains this chisel-edged shape even when crushed to a very fine size. Its garnet is used in coated abrasives, glass grinding and polishing, and metal lapping. The NYCO Div. of Processed Minerals Inc., Essex County, NY, and International Garnet Abrasive Inc., Clinton County, NY, garnet is a mixture of andradite and grossularite, and the crude garnet concentrate may contain diopside-hedenbergite ($\text{Ca}[\text{MgFe}]\text{Si}_2\text{O}_6$). The NYCO recovered garnet as a byproduct from its wollastonite operation. It sold both crude garnet concentrate for additional refining and refined garnet for use as blasting and filtration media. International Garnet Abrasives produced refined garnet from NYCO's crude garnet concentrate for use as blasting and filtration media. Emerald Creek Garnet Milling Co. was purchased by Hawkeye Development Co., an Idaho corporation, in November 1991. Under the new name of Emerald Creek Garnet Co., it continued mining and milling operations in Benewah County, ID. Blasting and filtration media were the primary uses of the garnet.

Abrasive garnet production in the United States began in 1878 at the Gore Mountain site of Barton Mines, near North Creek, Warren County, NY. During the first year, production was less than 100 tons. It was used in coated abrasives, both paper and cloth.⁴ Barton Mines Corp. mined and processed the abrasive-grade garnet on Gore Mountain until the company moved the mining operation and processing plant in 1982 to the adjoining Ruby Mountain. Barton Mines has been a family-owned operation since its formation. Reported past domestic garnet production was from California, Connecticut, Florida, Maine,

New Hampshire, North Carolina, and Pennsylvania.⁵

Nine manufacturers at 10 plants produced garnet coated abrasive papers and cloths. The plants are in New York and Virginia, two in each, and Massachusetts, Michigan, Minnesota, Mississippi, Ohio, and Pennsylvania, one in each.

Geology-Resources.—Garnet is found as an accessory mineral in a wide variety of rocks. Most commonly it is found in gneisses and schists, but it also is found in contact metamorphic rocks, crystalline limestones, pegmatites, volcanic rocks, eclogites, and serpentinites. Additionally, garnet is found in the gangue of veins formed at high temperatures. Because garnet is resistant to chemical and mechanical weathering, it is common in the sands of current or ancestral beaches, streams, and other types of alluvial deposits. Commercially attractive industrial garnet occurrences are not common. Many garnets that occur in deposits of economic size degrade during processing because of internal stresses. These stresses developed in the garnet crystal during formation and cooling. Stress relieving is not economical; therefore, these deposits have no commercial value as a high-grade abrasive material source.

Garnets are usually small in size. Grossularite crystals range up to about 15 centimeters in diameter. Almandite approximates the same range in size except at Gore Mountain and North Mountain, NY, where crystals range up to 60 centimeters in diameter. Spessartite crystals from Brazil can weigh as much as several kilograms. Most garnet crystals are less than 2.54 centimeters in size.

The majority of world garnet production is from alluvial deposits in the United States, Australia, China, and India. Possibly the world's highest quality garnet is mined, however, from almandite-bearing rock of uncertain origin in the Adirondack Mountains of New York.

New York and Maine have the only known high-quality garnet reserves in the United States. The Wing Hill garnet

deposit, near Rangeley in western Maine, is one of the largest and highest grade garnet deposits in the world. The host rock is a homogeneous garnet granofels that consists of 50% to 70% almandite garnet. It is medium grained and consists essentially of garnet and andesine plagioclase along with biotite and minor quartz. The garnet is present as discrete, well-formed crystals from less than 1 millimeter to about 10 millimeters in diameter but averaging 1.5 to 2 millimeters. The granofels is an east-west trending, tabular body more than 1,000 meters in length and as much as 700 meters thick. The garnet ranges in Mohs hardness from 7 to 8 and in density from 3.6 to 4.3 grams/cubic meter. When crushed, the garnet breaks into blocky grains, a shape that persists down to the finest fragment. The garnet is amenable to gravity and magnetic concentration when the ore is crushed to -3.36 millimeters. The estimate of reserves in the igneous rock deposit near Rangeley, ME, is more than 1.8 million tons of garnet.

Deposits of industrial garnet are found at two locations in New York. In the Gore Mountain area, technical-grade garnet is mined as the primary product, and near the town of Willsboro, commercial-grade garnet is recovered as a byproduct of wollastonite mining.

The deposit near Gore Mountain is an almandite-bearing diorite of uncertain, igneous or metamorphic origin. The ore body is approximately 2 kilometers long and 15 to 90 meters wide. The ore grade varies from less than 5% to about 20% garnet and averages slightly less than 10%. Hornblende and plagioclase feldspar make up 40% to 80% of the host rock, while hypersthene, magnetite, biotite, apatite, and pyrite are present in minor amounts. A rough estimate suggests that more than 600,000 tons of high-quality garnet can be recovered from Barton Mines Corp's deposit on Ruby Mountain in New York. The garnet is present as imperfectly developed crystals surrounded by a rim of coarsely crystalline hornblende. The crystals range from about 1 millimeter to almost 1 meter in diameter but average about 100

millimeters in diameter. The garnet has a pronounced laminated structure, which enables it to naturally break into thin plates from about 2 to 6 millimeters in thickness. Garnet fragments maintain this platy particle shape even as they are crushed smaller and smaller.

Garnet is recovered as a byproduct from a wollastonite deposit on the western side of Lake Champlain near Willsboro. The deposit is in a belt of wollastonite-bearing rocks that is about 10 kilometers long and 0.4 kilometer wide. The largest zone of wollastonite rock within the belt is from about 9 meters to more than 20 meters thick but averages about 13 meters thick. The wollastonite is interbanded with almandite garnet and iron-rich diopside. The garnet and diopside together comprise 10% to 20% of the ore. Both the garnet and diopside are feebly magnetic and are easily separated from the wollastonite by magnetic separators.

Alluvial deposits of almandite garnet were discovered in the early 1880's near Fernwood in Benewah County, but commercial mining did not start until the early 1940's. The deposits are on Emerald, Carpenter, and Meadow Creeks about 6.4 kilometers from a mica-garnet schist formation. The source schist is estimated to be about 1,200 meters thick. The garnet-bearing gravels are from about 1 meter to about 1.2 meters thick and contain 8% to 15% garnet. Garnets from these gravels range up to 40 millimeters in diameter, although about 95% of the garnet is smaller than 7 millimeters in diameter. The quantity of garnet-bearing gravels reported at Emerald Creek and Carpenter Creek in Idaho is large. A minimum of 450,000 tons of garnet is available in the Emerald Creek Garnet Co. deposits.

There can be little doubt that tremendous reserves of garnet similar to the lower priced materials can be located as needed.⁶ Also, the production of byproduct garnet from many current mining operations is possible if demand improved.

Reserves are significant in Australia, China, India, and the U.S.S.R., but accurate data are not available. Huge

inferred and undiscovered resources are likely to exist throughout the world.⁷

Technology.—Exploration.—Successful exploration for garnet deposits begins with selection of target areas based on the presence of known favorable host rocks. Geologic studies and maps, topographic maps, and aerial photographs are used to identify favorable metamorphic, igneous, alluvial, or eolian geological formations.

The second step is field examination of the selected targets. This may include geologic mapping and limited sampling, but in many cases reconnaissance studies are sufficient. The next step, if warranted, is to sample the deposit in detail, the purpose being to measure the physical parameters of the deposit, specifically its grade and size.

The method of sampling used depends upon the type of deposit. Hard-rock deposits, igneous or metamorphic, are sampled differently than alluvial or eolian deposits.

Hard-rock deposits can be either diamond core drilled or trenched. Trenches should be oriented perpendicular to the strike of the formation and can be dug by hand, with a bulldozer, or with a backhoe.

Placer deposits can be sampled by drilling, trenching, or by excavating pits or shafts. The physical nature of the deposit, its thickness, hardness, grain size, and whether it is above or below the water table influence the method of sampling chosen. For shallow deposits, hand augers or power augers can be used to drill sample holes. In deposits that are too hard to hand auger because of the presence of clay, iron oxide cement, or mild calcium carbonate cement, two-man motor-driven augers or vehicle-mounted augers (such as post hole diggers or telephone pole hole diggers) work well. However, augering does not always provide uncontaminated samples and is not effective below the water table.

Truck-mounted water-jet drills and rotary hammer drills are used to test thick deposits and deposits that are too hard to drill with other methods. A water-jet drill uses flush-jointed drill pipe with

perforations near the bit to direct jets of water forward and downward from the bit. A hammer advances the drill bit and casing at the same time. Water from the jets flushes out the hole and returns cuttings to the surface in the annulus between the drill pipe and casing. Also, truck-mounted rotary drills equipped with double-pipe drill string and downhole hydraulic hammers can be used. Compressed air is forced down the inner pipe and returns samples to the surface in the annulus between the inner pipe and outer casing. Bits are selected depending on the type of material to be drilled.

Trenching can be carried out using either a bulldozer or a backhoe, depending on the size and depth of the deposit. In unconsolidated sediments it is difficult to maintain the stability of the walls of trenches, and samples can be contaminated by material sloughing from above. Bulk samples can be collected from 1-cubic-meter pits or shafts. However, here again, wall stability can be a problem unless some form of shoring is used.

Evaluation of Deposits.—The evaluation of garnet deposits to determine their suitability for commercial production can be divided into five major factors: (1) size and grade of the reserves; (2) mining conditions; (3) quality of the garnet; (4) location of the deposit relative to markets and infrastructure; and (5) milling costs. The relative importance of each of these factors will vary from one deposit to another, but the final determination of economic viability will depend upon all of them.

1. Size and grade of reserves—An economic garnet deposit has reserves that are large enough and high enough in grade to provide full project capital recovery, meet all operating costs, and furnish a reasonable profit over the depreciable life of the project, which is normally at least 10 to 20 years. Generally, a deposit should contain a minimum of 2 million tons of ore. The cutoff grade used in calculating reserves will depend on the economics of the

specific deposit, but cutoff grades for most deposits average about 20% garnet.

2. Mining conditions—Mining conditions greatly affect the economics of a deposit and can even control whether the deposit can be developed. Early field examinations should identify any conditions, such as nearby houses, historical sites, national monuments, archeological or paleontological sites, wildlife refuges, municipal watersheds, etc., that could preclude mining the deposit. Local, county, and State zoning regulations, environmental regulations, and other constraints should be checked to establish their effects on mining the deposit.

Hard-rock garnet deposits are mined in benched open pits using conventional drill-and-blast methods. Some placer deposits are mined with dredges. The configuration and structure of the deposit should be such that there are no blocks of waste rock within the ore body and that the garnet is, ideally, uniformly distributed throughout the ore. All physical and chemical features of the ore and overburden will influence whether the deposit is amenable to open pit mining and will impact the total mining cost per ton.

3. Quality of the garnet—The garnet in a deposit must be tested to evaluate its performance and marketability as an abrasive. It should be recognized in this regard that most garnet used in abrasive applications is either the almandite or almandite-pyrope type. The garnet should be present in the deposit as discrete crystals that are at least 6 to 13 millimeters in size and that are liberated when the ore is crushed to -2 millimeters. The crystals should be free of any inclusions, such as quartz, mica, hornblende, and feldspar, and also should be free of alteration. The garnet should be relatively uniform in hardness and density throughout the deposit. It should not be badly weathered or highly friable. If an incipient parting is present in the garnet crystals, the effect this parting has on the quality of the final product and the distribution of such crystals within the deposit should be determined.

4. Location relative to markets and infrastructure.—The location of a garnet deposit must be evaluated relative to its proximity to the markets for garnet abrasives and filter media. If the deposit itself is not near major market areas, then it must be near adequate and inexpensive means of transportation, especially by rail or water. Deposits should be reasonably accessible from existing roads.

5. Milling costs—The type of milling required and the cost of processing the ore must be analyzed carefully. Ideal ore is that from which the garnet can be liberated with minimum crushing and can be recovered using gravity/density-based methods of mechanical concentration and where size classification of the concentrate yields a complete range of product sizes. In some cases portions of the concentrate will be ground to achieve proper particle size distribution.

Mining.—At the Barton Mine in New York, the Ruby Mountain ore body covers approximately 41,000 square meters, which is nearly the entire mountain. The ore is mined by open pit methods with benches 9 meters high. The ore is drilled and blasted, a drop ball provides secondary breakage, and power shovels load ore into trucks for haulage to mill, about 0.4 kilometer away.

At Emerald Creek and Carpenter Creek, Benewah County, ID, backhoes are used to strip 1 to 2 meters of overburden to expose the garnetiferous gravel. Mining is then carried out with draglines, and ore is trucked to a mill for processing.

Wollastonite mining at Willsboro, NY, yields a byproduct concentrate containing garnet, diopside-hedenbergite, and minor amounts of wollastonite. After drilling, blasting, and loading, the ore is transported 22 kilometers to the plant for separation of the wollastonite from the garnet-diopside.

Beneficiation.—The primary factors controlling the behavior of garnet ore during processing are the identity and characteristics of the minerals present, the percentage of each mineral present, and the size of the garnet grains. The major minerals associated with garnet in most

deposits are feldspar, mica, hornblende, pyroxene, and quartz. Magnetite, pyrite, ilmenite, limonite, pyrrhotite, and occasionally chalcopyrite, rutile, zoisite, chlorite, and corundum may be present in much smaller amounts. Sodium feldspar is the most common feldspar, biotite is the most common mica, and hypersthene and diopside are the most common varieties of pyroxene present. The most important physical property controlling the behavior of the major and minor minerals during concentration of the garnet is their specific gravity.

At Barton Mines Corp.'s plant in New York, garnet is liberated, concentrated, and further processed by combinations of crushing and grinding, screening, tabling, flotation, magnetic separation, water sedimentation, drying, heat treating, and air separation. Occasionally a single process will accomplish both sizing and the removal of gangue minerals, but this usually requires several processes. Particle size control can be difficult but is important in order for the concentration processes to work effectively.

The process used by Barton Mines to recover garnet has evolved over time. It began in 1924 with construction of the first "modern" plant where separation was accomplished using jigs. In 1941, heavy-media separation was added to the system, and in 1945, flotation was added. The current state-of-the-art mill is a combination of heavy-media and flotation circuits. Ore crushed to -7 millimeters is screened to 3.36 to 2.38 millimeters with the coarse fraction going to a heavy-media circuit using a density of 3.02 grams/cubic meter for primary separation and a density of 3.20 to 3.40 grams/cubic meters for secondary separation. The fine fraction from the screen goes to a flotation circuit where it is first ground to -0.3 millimeters in ball mills and then fed to float cells. The concentrate from the heavy-media circuit is roll crushed, combined with the float concentrate, and then dried and heat-treated in a rotary kiln.

At Emerald Creek Garnet Co.'s operation in Idaho, the ore is first processed through trommels to remove the gravel and is then concentrated in jigs

and on shaking tables. The garnet concentrate is dried, crushed, and screened. The maximum grain size of finished products is 46 millimeters.

At NYCO Minerals' mill in New York, beneficiation of the wollastonite-garnet ore requires two stages. The first stage involves drying, crushing, screening, and recrushing the feed to -1.19 millimeters. In the second stage, the -1.19 millimeter ore passes over a series of screens to attain -1.19+0.84, -0.84+0.42, -0.42+0.25 and -0.25 millimeter splits. A battery of magnetic separators then removes the garnet from each of these fractions. Four sizes of final product are bagged for shipment.

Today practically all grade-grain abrasive garnet is heat treated as a processing function, but not to improve its inherent abrasiveness. Impurities picked up during processing stick to the garnet particle surfaces. These impurities destroy the cleanliness and capillarity needed in later processing to give adhesion for bonding. In the early 1960's, scientific investigations determined that heat treating only cleaned the particle surfaces and that too high a temperature could destroy the abrasive quality of garnet. In the mid-1960's, the coated abrasive industry accepted uniform color standards. These standards ensured the cleanliness of the grain surface and a color most closely approaching the natural red color of abrasive garnet. The heat treatment needed to do this is the RT treatment.⁸

Annual Review

Production.—In 1991, the four U.S. firms produced 50,860 tons of crude garnet concentrate worth \$7.5 million, an 8% increase in quantity and salient statistics compared to those of 1990. The average annual production for the past 10 years was 36,262 tons, with a high of 50,860 in 1991 and a low of 24,769 in 1982. During the past 10 years, production increased about 105%, or at an annual compounded rate of about 8.5% per year. The production trend for the past 10 years has been one of

continued long-term growth with two downward adjustments. (See table 9.)

Consumption and Uses.—In 1991, the quantity of garnet sold or used by producers was 48,048 tons, an increase of 5%, and the value increased about 11% to \$13.0 million. The average annual quantity of garnet sold or used for the past 10 years was 34,488 tons, with a record high of 48,048 tons in 1991 and a low of 24,186 tons in 1982. The trend for the past 10 years was one of steady annual growth, except for 4% decreases in 1984. The growth rate averaged about 8% compounded annually.

The major industrial use for high-quality, high-value garnet since before 1880 has been as loose-grain abrasive for applications such as optical lens grinding and plate-glass grinding. In recent years, its applications included the high-quality, scratch-free lapping of semiconductor materials and other metals. The finishing of wood, leather, hard rubber, felt, and plastics often requires the use of garnet-coated abrasive papers and cloths.

The aluminum aircraft and shipbuilding industries in California and the Pacific Northwest use lower quality, lower cost alluvial garnet, primarily from Idaho, for sandblasting. Similar uses in the Eastern United States are for the cleaning and conditioning of aluminum and other soft metals and for cleaning of metal by structural steel fabrication shops. Mixed-media water filtration, using a mixture of sand, anthracite, and garnet, has displaced older filtration methods because it is more reliable and gives a better quality of water. Garnet also is used in hydrojet cutting—it is entrained in a high-pressure stream of water to cut many different materials. Demand for these uses has greatly increased. The manufacturers of nonskid floor paint also use alluvial and other low-cost garnets.

Garnet has obtained an intermediate place in the coated-abrasive field between low-cost quartz sand and more costly synthetic abrasives (silicon carbide and fused alumina). Garnet is reportedly more efficient based on unit production costs than quartz sand. It also produces a more

desirable finish on items made of wood, leather, hard rubber, felt, and plastic.

Garnet, especially the lower grades, cannot compete with synthetic abrasives for most metalworking applications requiring substantial metal removal because of its friable nature and lower hardness.

Prices.—The average value per ton of crude garnet concentrates was \$148, a 17% decrease compared with the 1990 average. The average value for the past 10 years was \$111 per ton, with a high of \$178 in 1990 and a low of \$88 per ton in 1986. During the past 10 years, the trend for the value of crude concentrates was one of general increase with decreases in some years. The 1991 value was 157% of the 1982 value.

In 1991, the average value per ton of garnet sold or used was \$271, an increase of 6% from that of 1990. The average value for the past 10 years was \$237 per ton, with a high of \$271 in 1991 and a low of \$216 per ton in 1987. The price trend of garnet sold or used during the past 10 years has been one of stable prices with very minor changes, except the 23% increase from 1987 to 1988.

Foreign Trade.—Garnet exports, as reported to the U.S. Bureau of Mines, by producers were about 10,000 tons, essentially the same as those for 1990. Export data on garnet were not available from the Bureau of the Census (Department of Commerce). Producers have reported exports to the U.S. Bureau of Mines for the past 5 years. According to reports by producers, exports increased significantly during the past 10 years.

Mineral brokers and other garnet importers reported to the U.S. Bureau of Mines about 5,000 tons of imported garnet, unchanged from those of 1989 and 1990. Import data for garnet also were not available from the Bureau of the Census. U.S. Bureau of Mines data, which are available for only 5 years, showed garnet imports as stable for the past 3 years. The United States was a net exporter of garnet in 1991; exports exceeded imports by 100%.

World Review.—The United States was the dominant world producer and consumer of garnet, accounting for approximately 45% of the estimated world output and almost 40% of estimated world consumption. Target Mines Ltd. (a subsidiary of Barton Mines) continued to produce at near capacity from its Australian garnet sand operation. The Chinese mines continued to increase production of garnet for the domestic and world market. Two mineral sand mining operations in India continued to produce garnet as a byproduct of mineral sands production. Turkey and the U.S.S.R. primarily produce for local markets. (See table 10.)

Outlook

The U.S. production and consumption of industrial garnet during the next 5 years will be a function of the installed capacity. Currently, the industry is operating at or near capacity. If capacity can be added, production and consumption will increase to approximately 60,000 tons per year by 1996. If garnet were not available, other abrasives could be used in its place, but in many cases with some sacrifices in work volume, quality of work, or cost.

Substitution of other natural and synthetic material is present to some extent for all major end uses of garnet. Fused alumina and staurolite compete with garnet as a sandblasting material in the transportation equipment industries. Ilmenite and plastics compete as filtration media. Diamond, corundum, and fused alumina compete for lens grinding and for many lapping operations. Finally, sand, silicon carbide, and fused alumina compete for grinding and finishing of plastics, wood furniture, and other products.

EMERY

Emery is a gray to black rock containing various minerals, including corundum, magnetite, hematite, or hercynite, and trace minerals such as mullite, titania, silica, and magnesia. Its hardness ranges between 7 and 9 on the

Mohs' scale and its specific gravity ranges from 3.2 to 4.5, depending upon its composition. It is used as an abrasive aggregate for nonskid, wear-resistant floors, pavements, and stair treads; as tumbling or deburring media; and in the manufacture of coated abrasives.

Production

A single firm, Oregon Emery, Albany, OR, produced emery in 1991 using open pit mining methods. The U.S. production of emery decreased about 81% in quantity and value compared with those of 1990. Production from the historical emery producer near Peekskill in Westchester County, NY, stopped in 1988. The emery mine was sold to a firm that converted the mine into a crushed stone quarry.

Consumption

The Bureau estimated that the United States consumed approximately 10,000 tons of emery in 1991. Imports from Greece and Turkey accounted for most of the material consumed. Four firms processed and distributed emery for domestic consumption: Washington Mills Abrasives Co., Emery-Crete Inc., Oregon Emery, and General Abrasives Co.

Foreign Trade

The United States did not export emery in 1990, nor has it done so in the past 10 years. During the past 10 years, the United States may have reexported a small amount of emery. The Bureau of the Census reports emery imports, exports, and reexports in mineral group categories; thus, exact data on emery are not available.

World Review

Turkey was the world's largest producer of emery. Its production is handled by Etibank in Ankara, by Ranar Minerals Industries Corp. in Istanbul, and by Lutfullah E. Kitapci Minerals Co., Ltd. in Izmir. Total production in 1991 was about 25,500 tons. Prices of Ranar

emery ranged from \$34 to \$48 per ton for crude and from \$220 to \$460 per ton for micronized grades.

The second largest producer was Greece. In Greece, government-owned deposits on the Island of Naxos are worked by villagers. It is estimated that 1991 production was about 10,000 tons.

STAUROLITE

Staurolite is a naturally occurring, complex, hydrated aluminosilicate of iron having a variable composition. The mineral most commonly occurs as opaque, reddish-brown to black crystals. It has a specific gravity ranging from 3.74 to 3.83 and Mohs' hardness of between 7 and 8.

Production

Georgia, North Carolina, and Virginia produced mineral specimen staurolite crystals. The crystals were in the cruciform twinned form commonly called "fairy crosses." E.I. du Pont de Nemours & Co. Inc. produced industrial-grade staurolite in Florida. Publishing production data would disclose company proprietary data; but, production of industrial staurolite increased 38% in quantity and 36% in value compared with those of 1990.

Industrial staurolite was a byproduct of heavy-mineral concentrates recovered from a beach sand deposit in Clay County, north-central Florida. Electrical and magnetic separators remove staurolite from the concentrates after scrubbing, washing with caustic, rinsing, and drying. The resulting material was about 77% clean, rounded, and uniformly sized grains of staurolite, with minor amounts of tourmaline, ilmenite and other titanium minerals, kyanite, zircon, and quartz. A nominal composition of this staurolite sand is 45% aluminum oxide (minimum), 18% ferric oxide (maximum), 5% silica (maximum), and 3% zirconium dioxide (maximum).

Consumption

During 1991, shipments of staurolite increased 30% in tonnage and 29% in value compared with those of 1990. Staurolite, marketed under the trade name Biasill, was used as molding material in nonferrous foundries because of its low thermal expansion, high thermal conductivity, and high melting point. Its low softening temperature often restricts its use to nonferrous casting. The major use of staurolite was as an abrasive for impact finishing of metals and sandblasting of buildings. The blasting media trade names were Starblast (80 mesh) and Siasill (90 mesh). A coarse grade (55 mesh) also was used as an abrasive. Some portland cement formulations consumed a minor amount. As regulations limiting the amounts of free silica in airblasting media became more stringent, the demand for staurolite increased.

Foreign Trade

Neither the Bureau of the Census nor the staurolite industry reported any exports or imports of staurolite. Given the limited market and the low price per ton, no international market for staurolite should develop in the near term.

World Review

India continued to produce small amounts of staurolite for local consumption. Other countries sometimes produce small amounts of staurolite as a byproduct of mineral sands or gemstone production.

INDUSTRIAL DIAMOND

Industrial diamond is natural diamond that does not meet the standards of gem diamond because of its color, size, or other imperfection. Also, it may be a synthetic diamond that is tailor-made for industrial applications.

Background

Definitions, Grades, and Specifications.—Natural industrial diamond is diamond that, because of color, structure, size, or shape, is unsuitable for use as gemstones. Major categories are industrial stones (die stones, tool stones, and drilling stones), crushing bort, and grit and powder. The distinction between stone and grit is not well defined; generally, the dividing line is a range of sizes. Stones usually are particles larger than 16 to 20 mesh, grit from 16 to 20 mesh to 325 to 400 mesh, and powder as particles smaller than 325 to 400 mesh. These categories are subdivided further into more than 100 groups.⁹

Bort is natural diamond that occurs in finely crystalline aggregates and usually is crushed into finer material. Originally, the term was the name for all crystalline diamonds not usable as gems. Later it designated those diamonds not usable as gems, tool stones, die stones, or drill stones. Currently, the term refers to low-grade industrial diamond suitable only for use in a fragmented form.

Most synthesized diamond marketed to date is 20 to 30 mesh and smaller. Recently, producers began to manufacture synthetic stones of 2 carats or larger. Marketing of these stones to date is of engineered pieces of the stones, not the entire stone. Polycrystalline synthetic diamond compacts and shapes can replace some larger stones. There are several types of synthetic diamond. They range from very friable material with a highly irregular shape to blocky, regular shapes with excellent crystal structure. The manufacture of industrial diamond stones is not commercially viable.

The metric carat, 0.2 gram, is the unit of measure for industrial diamond. One pound contains 2,268 carats, and 1 kilogram contains 5,000 carats. The carat is equal to 100 points. Diamond grit and powder sizes are identified by U.S. standard screen classifications, by ANSI Specification B74.16-1971,¹⁰ ANSI Specification B74-20-1981,¹¹ and by a proposed standard developed by the Industrial Diamond Association¹² for

subsieve micron-sized diamond or cubic boron nitride powders. The terms "sand," "grit," and "powder" also describe decreasing orders of fine diamond.

Machine-shop waste containing diamond is sludge if obtained from wet grinding and is called swarf if obtained from dry grinding.

Industry Structure.—The original discoveries of diamond in India, Borneo, and Brazil, and later in South Africa, were due to chance finds by local inhabitants. Certain desirable characteristics in diamond were noted first in India and led to active search by open pit workings and to concentration by hand methods.

Probably the first industrial use of diamond was as diamond powder for polishing gem diamonds and other precious stones. The art of diamond cutting and polishing was known in India, probably well before A.D. 1400.

Glasscutting was an early application of diamond in industry. It was the most important use of industrial diamond until the 1860's.

England issued a patent in 1819 for drawing wire through a diamond die. Diamond wiredrawing dies gave close dimensional accuracy to wire, even after long periods of use.

The use of diamond for metalcutting began in the 1860's, but the high price of diamond tools was a drawback to their acceptance. As the economic advantages of using diamond tools became known, demand increased rapidly.

The use of the first diamond drill was in 1864. The discovery of diamond in South Africa in 1867 provided ample supply for the new and growing demand for diamond drill bits.

With the introduction of cemented tungsten carbide cutting tools during World War I, industrial diamond use increased. The cause of the increase was that diamond was the most effective agent in grinding tungsten carbide. Requirements for industrial diamond expanded tremendously because of World War II, when demand increased for grinding wheels, die stones, tool stones, drill bits, dresser stones, and polishing

dust. The apparent supply of industrial diamond decreased rapidly following World War II.

In 1955, General Electric Co. announced the development of a process for the manufacture of diamond at its Schenectady, NY, laboratories. Commercial production started in 1957 at its plant in Detroit, MI. In 1969, production moved to Worthington, OH. In 1959, De Beers Consolidated Mines Ltd. announced the manufacture of industrial diamond at its laboratory in Johannesburg, Republic of South Africa. Since these two announcements, the production of synthetic diamond by General Electric, De Beers, and others continued to increase. Today it exceeds the production of natural diamond worldwide about five times.

Geology.—The major source of in-place diamond is kimberlite, an altered, darkgreen basic rock of igneous origin. Throughout the world there are approximately 1,000 occurrences of kimberlite, but most do not contain diamonds or do not contain diamonds in economic quantities. The term "diamond pipe" refers to an occurrence of kimberlite large enough and sufficiently diamondiferous to be mined. The size and shape of these pipes depend on the manner in which molten kimberlite passed through the country rock. They may be columnar, tabular, or irregular in shape. Where mining is deep enough, the diamond pipe always decreases in area and assume a dikelike habit. The diamond may contain inclusions of many minerals, and many of these minerals have inclusions of diamond. These accessory minerals include olivine, garnet, diopside, ilmenite, magnetite, rutile, and phlogopite. Every mine has some diamond that is typical of it, but most diamond is indistinguishable from that of other mines.

Currently, approximately 40% of diamond is from alluvial deposits. These may be alluvial placers, recent or elevated marine beach placers, or glacial deposits. Often the distance of transport has been great. In many areas, the diamond-bearing, alluvial placers were

deposited in former drainage systems unrelated to any present system.¹³

Technology.—Mining.—Currently, the United States has no commercial deposits of diamond. In other countries, mining methods range from very crude hand mining and panning to block caving of kimberlite pipes. Large-scale surface mining operations in Australia, Zaire, Angola, Namibia, and Sierra Leone¹⁴ use modern equipment, such as continuous bucket wheel excavators, power shovels, draglines, scraper-loaders, and motor trucks, to remove overburden and to mine and transport the diamond ore.

Processing.—The type of ore, size of operation, and other factors decide the types of processing equipment used. Crushing, where necessary, is done mostly with gyratory and roll crushers to avoid impact to diamond stones. Additional grinding is done with attrition and ball mills to further separate the gangue from diamond stones. Clayey ore may require the use of log washers. Diamond washing pans, jigs, heavy-medium separators, or hydrocyclones collect the primary or intermediate concentrates. Depending on the types, shapes, and sizes of diamond present, various final treatments are used. They include the use of grease tables and grease belts, electromagnetic separators, electrostatic separators, optical sorters, X-ray sorters, and other devices. In all processing plants, hand sorting is the final recovery process.¹⁵

Reclaiming industrial diamond stones from drill bits and grit from the wastes generated in grinding, sawing, and other operations is common. This is because of the high unit value of diamonds. Reclamation processes include physical methods such as distillation to remove coolants and lubricants, followed by electrostatic, magnetic, or flotation separation. Reclamation also uses chemical methods, including combustion, acid treatment, and fusion with alkalis.¹⁶ The treatment used depends primarily on the contaminants present.

Commercial production of synthetic diamond grit is by two basic methods.

Currently, the primary method used involves the application of ultrahigh pressure and high temperature to carbon-metal catalyst mixtures by powerful hydraulic presses. This method uses pyrophyllite and other materials for the reaction vessel. Pyrophyllite for this purpose is from the Republic of South Africa, where the local name for it is wonderstone. The major user of the method now uses synthetic reaction-vessel materials, alleviating the dependency on foreign sources for pyrophyllite. The material used for these replacement reaction vessels is proprietary. The other method employs explosive shock to the carbon-metal catalyst mixtures.

Industrial diamond particles of good quality up to 20 mesh and perhaps larger are produced. The shape and other characteristics can be controlled by proper manipulation of the variables, pressure, temperature, time, and catalyst type. Only micrometer-size particles are presently available from the explosive process. Other methods of diamond synthesis exist, but none are in commercial use in the United States. Other countries produce diamond grit; all of these apparently use the ultrahigh-pressure, high-temperature method involving hydraulic presses.

Polycrystalline synthetic diamond compacts are a laminated structure of synthetic diamond powder bonded to a cemented carbide substrate. Their production is by a proprietary high-pressure, high-temperature process that gives the product excellent uniform physical properties.¹⁷

The polycrystalline synthetic diamond shape is a dense, nonporous, fully intergrown product that is thermally stable to 1,200° C. Production uses a proprietary high-pressure, high-temperature process using a special binder phase that is retained as an integral part of the product and results in high resistance to shock loading.¹⁸

Annual Review

Government Programs.—The National Defense Stockpile (NDS) for industrial diamonds, as of December 31, 1991, had a goal of zero carats and an inventory of 14.0 million carats for crushing bort. The goal for industrial stones was 7.7 million carats, and the inventory was 7.78 million carats. There was 5 million carats of sales of crushed and crushing bort diamonds from the stockpile during 1991. There is currently legislative authority for disposal of 19,617 carats of bort and 2,400,000 carats of industrial stones, but there were no disposals of stones during the year. The inventory of small diamond dies was 25,473 pieces compared with a goal of 60,000 pieces; but, no purchase authorization was issued.

Production.—The United States was the largest producer of synthetic industrial diamond. This has made the United States independent of foreign sources for crushing bort or similar diamond except for grit sizes larger than about 20 mesh. Having no production of natural diamond, it was dependent on other countries for its natural diamond supply.

Three domestic firms produced synthetic industrial diamond in the United States: Du Pont Industrial Diamond Div., Gibbstown, NJ; General Electric Co., GE Superabrasives, Worthington, OH; and Megadiamond Industries Inc., a subsidiary of Smith International Inc., Provo, UT. A fourth company, U.S. Synthetics Corp., Orem, UT, manufactured polycrystalline diamond from purchased synthetic diamond grit. U.S. Synthetics had the capability to manufacture synthetic industrial diamond grit, but chose not to for economic reasons. Publishing production data would disclose company proprietary data. Domestic production did increase significantly. The United States continued to be the largest single producer of synthetic industrial diamond, a role it has enjoyed since 1957. During the past 10 years, production increased at an average rate of 9% compounded annually.

U.S. secondary production of industrial diamond was from six firms. They were Amplex Corp., Bloomfield, CT; Diamondsharp Corp., Keene, NH; Industrial Diamond Laboratory Inc., Bronx, NY; Industrial Diamond Powders Co., Pittsburgh, PA; International Diamond Services Inc., Houston, TX; and National Research Co., Fraser, MI. The firms reclaimed a total of about 3.8 million carats from used drill bits, diamond tools, and wet and dry diamond-containing waste, a decrease of 41% compared with that of 1990.

Consumption and Uses.—The United States continued to be the largest single consumer of industrial diamond. The U.S. Bureau of Mines estimate of apparent consumption of industrial diamond was approximately 86 million carats, an increase of about 19% compared with 1987 consumption. Average annual consumption for the past 10 years was about 64.1 million carats. During this period, two different trends for consumption occurred. The average annual consumption for 1979-83 was about 37.5 million carats, whereas that for 1984-88 was 97% greater or about 73.9 million carats. The second trend was the result of the strong movement to industrial diamond in the U.S. manufacturing sectors. This was because of the economic advantages in removing material and finishing surfaces using industrial diamond and diamond tools and wheels. Additionally, the continued economic growth of the U.S. industrial sector affected demand.

Diamond is far harder than any other natural or artificial abrasive material; so it was essential for some uses and much more efficient than other abrasives for many others. The principal uses of industrial diamond stones are in drilling bits and reaming shells, single- or multiple-point diamond tools, diamond saws, diamond wheels, abrasive, and diamond wire-drawing dies. Miscellaneous uses include: engraving points, glass cutters, bearings, surgical instruments, and special tools. Changes in technology and conventional wisdom have resulted in an increased use of synthetic

industrial diamonds and polycrystalline diamond shapes (PDS) and compacts (PDC) for many of the uses listed above. There has been an increased use of PDS, PDC, and matrix set synthetic diamond grit in drilling bits and reaming shells in the past 3 years. Diamond saws, diamond wheels, and diamond abrasive grit and powder are almost exclusively made from synthetic diamond. PDS and PDC are used in the manufacture of single- and multiple-point tools, and PCD is used in a majority of the diamond wire-drawing dies.

Mineral, oil, and gas exploration were the primary uses of drilling bits and shells. Foundation testing for dams, buildings, and other construction also used diamond bits and shells, as did masonry drilling in buildings for conduits and access and testing of concrete in various structures and other similar applications. The primary uses of diamond tools were for dressing and trueing grinding wheels and for cutting, machining, boring, and finishing. Beveling glass automobile windows also was a use. Cutting dimension stone, ceramics, and concrete in highway reconditioning were the major uses of diamond saws. The forming of refractory shapes for furnace linings also uses diamond saws. Diamond wire dies were essential for high-speed drawing of fine wire, especially from hard, high-strength metals and alloys.

Diamond grit, powders, and fragmented bort go into diamond grinding wheels, saws, impregnated bits and tools, and loose abrasives compounds for lapping and polishing.

Three major types of grinding wheels were made—resinoid, metal, and vitrified bonds—in many shapes and sizes designed for specific applications. The sizes range up to 1 meter in diameter for very large industrial wheels. Sharpening and shaping of carbide machine tool tips, grinding of dies, edging of plate glass, and optical grinding were among the primary applications of diamond grinding wheels. The cutting of concrete, stone, ceramics, and composite materials were uses of saws made with diamond grit. Very fine saws sliced wafers from brittle

metals and crystals for use in electronic and electric devices.

Finishing optical surfaces, jewel bearings, gemstones, wire-drawing dies, cutting tools, and metallographic specimens were the primary uses of polishing and lapping powder and compounds. Hundreds of other important items made from metals, ceramics, plastics, and glass also were finished with diamond compounds.

Prices.—The U.S. Bureau of Mines does not collect price data on industrial diamonds. The Bureau did track the average import value of various classifications of industrial diamonds. The average value of U.S. imports of natural grit and powder, synthetic grit and powder, and industrial stones was \$0.63 per carat, \$0.74 per carat, and \$6.94, respectively. The average annual value of imported natural grit and powder for the past 10 years was \$1.64 per carat. The high value was \$2.85 in 1980, and the low was \$0.82 in 1988. The average value of natural grit and powder, in current dollars, declined every year since 1980. The 1980 average value was 425% greater than that of 1988.

The average annual value of imported synthetic grit and powder for the past 10 years was \$1.30 per carat. The high value was \$1.86 per carat in 1981, and the low was \$1.08 in 1988. The average value of imported synthetic grit and powder decreased every year since 1981. The 1988 value declined 72% compared with that of 1981, while the decline from 1987 to 1988 was only about 26%. During the past 10 years, a major change occurred in the relationship of the average value of natural grit and powder to the average value of synthetic grit and powder. In 1979, natural grit and powder average value was 49% greater than the average value for the synthetics. In 1988, the average value for the synthetics was 32% greater than that for natural material. Natural grit and powder declined in value at a much greater rate than did synthetic grit and powder. This made the synthetic material more valuable.

The average annual value of imported industrial diamond stones for the past 10 years was \$9.19 per carat, with a high value of \$13.93 in 1981 and a low of \$7.24 in 1986. The trend for the value of industrial stones was mixed for the past 10 years. There was a small, 7%, decrease in the average value. The period started with 3 years of increasing values, followed by 3 years of decreasing values. Values the final 4 years were alternating decreases and increases. The 1988 average value was 5% less than the 1987 value, 44% less than the 1981 high, and 12% less than the 1979 value.

Foreign Trade

The United States was the largest exporter of industrial diamond grit and powder in the world. The United States exported and reexported a record 78.8 million carats of natural and synthetic grit and powder. The material was worth a record \$119.3 million. Additionally, the U.S. exported and reexported approximately 2.9 million carats of industrial stones valued at \$21.7 million.

Six countries received approximately 76% of the total U.S. exports of synthetic grit and powder. The countries and the percentage of exports they received were as follows: Japan, 27%; Federal Republic of Germany, 21%; Ireland, 8%; Italy, 7%, Belgium, 7%; and Republic of Korea, 6%. Six countries received about 74% of the total U.S. exports of industrial stones. The countries and the percentage of exports they received were as follows: Belgium, 24%; Ireland, 21%; Canada, 10%; Japan, 9%; France, 8%; and Federal Republic of Germany 6%.

The average annual exports plus reexports of natural and synthetic grit and powder for the past 10 years was 46.0 million carats, with an average value of \$85.9 million. The highest level of exports plus reexports during the past 10 years was 78.8 million carats valued at \$119.3 million in 1991. The lowest was 30.6 million carats valued at \$66.9 million in 1982. The trend of exports plus reexports for the past 10 years was one of continued growth. There was an increase of 158% during the period or an

annual average compounded growth rate of more than 10%.

The average annual exports plus reexports of industrial stones for the past 10 years were 3.0 million carats per year, and the average value was \$31.9 million. The high was 3.6 million carats in 1986, and the low was 1.7 million carats in 1990. There was not a distinct trend for the past 10 years.

The average annual imports of natural diamond grit and powder was 8.0 million carats per year for the past 10 years. The high was 13.0 million in 1988, and the low was 3.3 million in 1982. Imports as measured in carats were about 13% less than those in 1990 and 219% greater than those in 1982. The trend for the quantity of natural grit and powder imported during the past 10 years was one of significant increases. Yet, during this period, the quantity of natural grit and powder decreased from 23% to 20% of total grit and powder imports. During 1991, four countries supplied 78% of U.S. imports of natural grit and powder: Ireland, 34%; Belgium, 20%; the United Kingdom, 14%; and Zaire, 11%. Only Zaire was a producer of natural diamonds.

The average annual imports of synthetic diamond grit and powder was 31.7 million carats per year for the past 10 years. The high was 73.2 million carats in 1990, and the low was 11.0 million carats in 1982. Imports in 1991 were about 19% less than those in 1990 and 440% greater than those in 1982. The trend of synthetic grit and powder imports during the past 10 years was one of continued strong growth until the slight decline in 1989. The average annual compounded growth rate for the 10 years was about 17%; but, the average annual compounded rate of growth from the low in 1982 through 1989 was about 21%. The level of imports in 1988 through 1991 indicated that the growth trend has begun to increase at even a greater rate. Three countries furnished 81% of the synthetic diamond grit and powder imported into the United States in 1991: Ireland, 61%; U.S.S.R., 13%; and Federal Republic of Germany, 7%.

The 10-year average for imports of industrial diamond stones was 7.1 million carats per year, with a high of 11.0 million in 1990 and a low of 3.9 million in 1987. Imports of industrial diamonds lacked a distinct trend during the period; the quantity imported in 1991 was about 63% greater than the quantity imported in 1982. The 1991 imports were about 31% less than 1990 imports, but 1990 imports were highest in the past 10 years. Four countries accounted for about 87% of the diamond stones imported into the United States during 1988: Zaire, 34%; United Kingdom, 22%; Ireland, 20%; and Ghana, 10%.

The United States was a net exporter of diamond grit and powder and a net importer of industrial diamond stones. The United States was a net exporter of industrial diamond based on the total quantity and total gross value. The excess trade balance in industrial diamonds was about 4.2 million carats and \$32.6 million. (See tables 11 and 12.)

World Review

Botswana and the Republic of South Africa were the largest producers of good-quality industrial diamond stones. Australia and Zaire were the world's largest producers of natural industrial diamond and were the primary sources of natural crushing bort as well as substantial producers of industrial stones. Estimates suggest that the U.S.S.R. was the third largest producer of natural industrial diamond, but reliable data were lacking.¹⁹ The next largest, in order of volume, were Botswana and the Republic of South Africa. Other smaller but significant producers were Angola, Brazil, China, Ghana, and Venezuela.²⁰ Total world output of natural industrial diamond in 1991 was approximately 51.8 million carats, a slight increase over that of 1990. (See table 13.)

Angola.—The Government of Angola diamond company, Endiama, entered into a prospecting agreement with a Portuguese-Zairian consortium. The consortium is Sociedade Portuguesa de Envestimentos and SAICAN; both firms

are privately held. It is reported that the Zairian firm may have links with President Mobutu Sese Seko of Zaire. The prospecting rights are along the Cuango River near the Angola-Zaire border, the same area included in the April diamond sales agreement between Angola and De Beers Centenary.

Australia.—Stirling Resources NL has entered into a joint venture with Sabminco NL on Stirling's Boab Creek exploration licence in West Kimberleys of Western Australia. Stirling has identified what is interpreted to be a potential kimberlite pipe and buried alluvial channel. The license is adjacent to Sabminco's Diamond Mountain project area where Sabminco has recovered gem-quality diamonds from drill holes in a buried alluvial channel.

Canada.—Uranerz Exploration, operator of its joint venture with Cameco, announced the recovery of additional diamonds from drill samples from the Fort a la Corne property. The latest stones recovered averaged 0.04 carats, with the largest 0.6 carats. Some of the stones recovered were of gem quality.

Uranerz's exploration program has identified 70 potential kimberlite pipes in a corridor that is 50 kilometers by 20 kilometers from Price Albert to Nipawin in Saskatchewan. The first 15 sites tested proved to be kimberlites and, to date, a total of 160 diamonds have been recovered from drill cores. Uranerz is playing down the exploration results, but experts are speculating on the possibility of a diamond mine in Saskatchewan by the end of the decade. Normally, geologists search for indicator minerals, minerals that form under the same conditions as diamonds, but at the Fort a la Corne property they found the actual diamonds in the drill samples.

Dia Met Minerals Ltd. announced the results of the analysis of one drill hole on the Dia Met and BHP-Utah Mines Point Lake prospect, an 800-square-kilometer joint venture in the North West Territories. Analysis of a 59-kilogram sample of core taken from between 140 and 180 meters yielded 81 diamonds each

less than 2 millimeters in diameter. The drill hole was located in a kimberlite pipe that is estimated to have a surface area of between 40 and 80 acres and to have a depth of 1 kilometer. The Point Lake prospect is about 480 kilometers north of Yellowknife, the capital of North West Territories. The announcement has set off a rush to stake claim around the Point Lake prospect.

Ghana.—The Government of Ghana, Lazare Kaplan of the United States, and Inco Ltd. of Canada have entered into an agreement to mine and market Ghanaian diamonds. This is the first privatization of the diamond industry under the current Government. The agreement was 2 years in the making.

The agreement calls for a two-phased mining plan. First, which will take 7 to 11 years to complete, the mine will be brought to a production level of about 0.5 million carats per year. The second phase will be to bring the mine to a production level of about 1 million carats per year. Currently, the mine production is between 0.1 and 0.2 million carats per year.

Murtob Mining Co. Ltd. of Akwatia purchased a diamond concentrating plant from Somerville Engineering Associates of England. The plant is trommel and jig-grease tables style.

India.—Ashton Mining, an Australian company, negotiated an agreement with the Indian National Mineral Development Corp. to assist in the modernization of the Panna Mine. The mine produced about 20,000 carats of diamonds in 1991, and the modernization intended to increase production by increasing the amount of ore processed.

Indonesia.—Indonesian Diamond Corp. was delayed in the construction of its diamond plant in South-East Kalimantan; the plant was ready for production in December 1991. The pilot plant, capable of running about 30 cubic meters per hour, processed material from the mine until the commercial plant was completed. The delay and cost overruns resulted in the plant costing about \$1.1 million more than the original estimate of

\$2 million. The first diamonds from the commercial operation, 2,200 carats, were sold for an average price of \$191 per carat. It is planned to operate both plants in the coming year to process about 54,000 cubic meters of ore per month and recover about 5,400 carats of diamonds each month.

Japan.—Sumitomo Coal Mining Co. established a new subsidiary, Izumi Diamond, which will be the first Japanese firm to produce synthetic polycrystalline diamonds from graphite for nonabrasive applications. The planned output of the new firm is 1 million carats per year. Japan's Kobe Steel Ltd. announced that its research center in Britain has developed diamond crystals and films for electronic applications.²¹

Namibia.—Consolidated Diamond Mines (CDM) began production at the open pit Elizabeth Bay mine in June. It is planned that the mine will produce about 4 million tons of ore per year that will result in the recovery of about 250,000 carats of diamonds. The production from the Elizabeth Bay mine will increase CDM's annual production to about 1 million carats per year. During the expected 10-year life of the mine, the mine should produce about 2.5 million carats of diamonds.

Monarch Minerals and Mining Inc., a U.S. firm, announced production began at its new diamond mine in southeastern Namibia in July. The mine is on Monarch's 50-square-kilometer mining concession at the mouth of the Fish River.

U.S.S.R.—Reports on Radio Moscow indicate the discovery of a major diamond field in Buryatskaya on the Soviet side of the Mongolian border. It is reported that more than 10 diamond-bearing sites in the eastern part of the Sayany Mountains were found. The discovery comes after 50 years of small-scale prospecting in the region, during which small quantities of diamonds were found.

The world's biggest new source of diamonds in this century may be the five kimberlite diamond pipes near the village

of Pomorie at Lamonsov in the North Russian oblast of Archangelsk. Development plans for the pipes are for two shafts to a depth of about 1,000 meters, one on each side of the pipe. The cost to develop the five pipes, including the infrastructure and power station, is estimated to be \$4 billion. Funds of the project will have to come from foreign sources or joint ventures.

Zimbabwe.—Auridium Consolidated NL of Australia has acquired the exploration license for the Ranch River diamond project that was forfeited by De Beers early in 1991. Kimberlitic Searches Ltd., a De Beers subsidiary, evaluated the project in the early 1980's and found the diamond project was uneconomical at that time. Auridium and its partner, Cornerstone Investments Ltd., believe that, given the current diamond market, the project may be economical during the 1990's. Evaluations will be undertaken to determine if the deposit is economical at this time.

Delta Gold NL of Australia has applied for exploration rights in eight diamond-bearing areas totaling about 4,600 square kilometers. The company already has completed a great deal of fieldwork in the selected areas. (See table 14.)

Current Research.—General Electric announced the production of a new synthetic diamond made almost totally of carbon-13, the heavier and more rare of the two isotopes of carbon. The diamond is more dense and harder than natural diamond or regular synthetic diamond and has greater crystalline perfection. The new diamond's hardness makes it ideal for abrasive and cutting applications and other high-technology uses.

Outlook

Diamond grit and powder should experience substantial increases in domestic demand for every end use during the next 5 years. The increases for synthetic grit and powder are expected to be greater than for natural. The constant-dollar prices of these materials, especially

the synthetic diamond products, should continue to decrease or at least remain constant. This is because planned production increases will make them more cost-effective. The contract construction industry is an area in which the greatest increases will occur. This is because large quantities of saw-grade diamond will be required for highway and bridge repair and replacement. Large increases also are expected in the dimension stone industry as a cutting and polishing media. The stone, clay, and glass industries will increase their uses in cutting, shaping, and polishing media. Additionally, polycrystalline synthetic diamond compacts and shapes will continue to displace natural diamond stone and tungsten carbide drill bits in the mineral services sector. The probable average annual growth rate in U.S. production is about 6%, based on estimates by the U.S. producers. U.S. production of synthetic material is sufficient to supply U.S. diamond grit and powder demand. The United States will continue to be a major exporter.

The major domestic end use for industrial stones in the next 5 years will continue to be in the oil, gas, and mineral industries. These stones are natural and cannot yet be manufactured commercially. Polycrystalline synthetic diamond compacts and shapes have had a major negative impact on the natural industrial diamond stone markets. This will limit the growth of U.S. demand for stone during the next 5 years. U.S. consumption should average between 6 and 7 million carats per year for the next 5 years. Approximately 50% of the potential natural stone applications will be replaced by the synthetic compacts and shapes by the year 2000.

MANUFACTURED ABRASIVES

Manufactured abrasives include fused aluminum oxide, silicon carbide, alumina-zirconia oxide, and metallic shot and grit. Production data for fused aluminum oxide, silicon carbide, and alumina-zirconia oxide were for the United States and Canada. Data for metallic shot and grit were for the United States only.

The fused aluminum oxide, silicon carbide, and metallic abrasives industries continued to undergo consolidation and reorganization during the year. (See tables 15 and 16.)

Fused Aluminum Oxide

Government Programs.—The NDS, as of December 31, 1991, contained 227,152 tons of crude fused aluminum oxide and 46,169 tons of abrasive-grain fused aluminum oxide. The NDS goal for abrasive-grain fused aluminum oxide is 340,000 tons. There is no NDS goal for crude fused aluminum oxide; it is held as an offset against the abrasive-grain goal.

Production.—At yearend, four firms were producing fused aluminum oxide at seven plants in the United States and Canada. General Abrasives, a division of Abrasive Industries Inc. of Clearwater, FL, was purchased by Austrian-owned Treibacher of America. The new name will be General Abrasives Treibacher Inc. (GAT), a wholly owned subsidiary of Treibacher of America, which is a holding company owned by Treibacher Chemische Werke of Austria. GAT operates a plant at Niagara Falls, NY, that manufactures regular and high-purity fused aluminum oxide and a plant at Niagara Falls, Ontario, Canada, that makes regular-grade fused aluminum oxide and silicon carbide. Production of regular-grade fused aluminum oxide in 1991 was 138,440 tons, a decrease of about 16% from that of 1990. The average annual production for the past 10 years was 139,092 tons. The high was 172,157 tons in 1988, and the low was 105,893 tons in 1982. The production trend for the past 10 years was one of sharp decline, 27% in 3 years, followed by up and down years until 1991's production drop to essentially the same as that of 1985. The 1991 production was 24% greater than that of 1982.

Production of high-purity fused aluminum oxide increased 15% to 24,516 tons. The average annual production for the past 10 years was 20,214 tons. The high was 32,634 tons in 1988, and the

low was 13,468 tons in 1982. The production trend for the past 10 years began with production swinging between about 14,000 and 28,000 tons until the major increase of 82% in 1988, followed by 2 years of decline and then the increase in 1991. The period ended with production 182% that of 1982. Total 1991 production of 162,956 tons was 12% less than that of 1990, 37% higher than the low of 119,361 tons in 1982. (See table 17.)

Consumption and Uses.—Fused aluminum oxide has a number of different end uses in the form of graded grain. The total value of sales of fused aluminum oxide-graded grain for all uses decreased 12% compared to that of 1991, and was only 69% of the 10-year high recorded in 1988. Total value of sales by individual end use was all down with the exception of antislip abrasives. Sales for use in bonded abrasives were down 6%; coated abrasives, 17%; refractories, 5%; tumbling media, 22%; blasting abrasives, 19%; polishing cake and buffing compounds, 38%; polishing abrasives, 18%; and all other uses, 27%; and antislip abrasives were up 15%.

Prices.—The Bureau did not collect data on the prices of various grades of fused aluminum oxide. It did collect data on the value of fused aluminum oxide production. The average value of regular-grade fused aluminum oxide, as reported by producers, was approximately \$381 per ton. The average annual value for the past 10 years was \$364 per ton, with a high of \$394 in 1990 and a low of \$324 in 1988. In 1991, the average value of high-purity fused aluminum was \$619, up slightly from that of 1990, still less than the 1989 10-year high at \$635 per ton. The average annual value of the past 10 years was \$560 per ton, with a low of \$476 per ton in 1988. The average value of all grades of fused aluminum oxide in 1991 was \$417 per ton, essentially unchanged from the 10-year high in 1989. The average annual value for the past 10 years was \$387 per ton, with a high of \$420 in 1989 and a low of \$348

in 1988. The trend for fused aluminum oxide values for the past 10 years was a general upward trend from 1981 to 1983, then a general downward trend from 1983 to 1988. The 1989-91 average values increased about 21% compared with that of 1988 and decreased about 2% with that of 1982. Mineral price quotations in various December issues of trade magazines listed prices for regular-grade fused aluminum oxide of \$832 to \$925 per ton, while high-purity was quoted at \$1,110 to \$1,221 per ton.

Foreign Trade.—The quantity of exports plus reexports of fused aluminum oxide decreased 21% to 10,763 tons; the value of exports plus reexports increased 43% to \$25.3 million. The average value of 1 ton of fused aluminum oxide, exported or reexported, increased 82% to \$2,351. During the past 10 years, exports plus reexports have averaged 13,970 tons per year, with an average annual value of \$19.2 million and an average value per ton of \$1,480. The largest quantity of material exported in a single year in the past 10 years was 26,638 tons in 1982, and the smallest amount was 9,915 tons in 1986. During the past 10 years, no trend developed in the export and reexport of fused aluminum oxide. Quantities increased and decreased randomly, and the period ended in 1991 with exports about 60% below those of 1982.

Imports increased about 37% in 1991 to 140,176 tons, and the value of imports increased about 19% from \$66.7 million in 1990 to \$79.4 million in 1991. Average annual imports for the past 10 years were 124,850 tons, with a high of 158,770 tons in 1984 and a low of 98,000 tons in 1989. The trend of fused aluminum oxide imports for the past 10 years was one of general decline throughout 1986, then stabilizing for 3 years at about 81% of the 1981 level. This was followed by a significant 32% decline in 1989 and the 4% and 37% increases in 1990 and 1991, respectively.

World Review.—Union Corp., a Korean company, opened a plant to manufacture

high-purity fused aluminum oxide in Korea. The plant has an annual capacity of about 12,000 tons.

Silicon Carbide

Government Programs.—The NDS, as of December 31, 1991, contained 37,305 tons of silicon carbide; the goal was 26,364 tons. During 1991, the Defense National Stockpile Center of the Defense Logistics Agency disposed of 6,329 tons of silicon carbide. Existing legislation authorizes disposal of 11,158 tons in the future.

Production.—During 1991, four firms produced silicon carbide at six plants in the United States and Canada. At yearend, three firms were operating only four plants, one having closed during the third quarter of the year and another at the end of the third quarter. Production of abrasive-grade material decreased 22% to 42,380 tons from the 10-year high of 54,339 tons in 1990. Average annual production for the past 10 years of abrasive silicon carbide was 45,513 tons, with a low of 36,193 tons in 1983. Production of metallurgical-grade silicon carbide decreased about 27% to 36,562 tons, a 10-year low. Average annual production of metallurgical-grade silicon carbide for the past 10 years was 53,163 tons, with a high of 64,998 tons in 1988 and a low of 36,562 tons in 1991. Total production of silicon carbide decreased 25% in 1991 to 78,943 tons, compared with a 10-year average annual production of 107,151 tons. The high was 123,917 tons in 1984, and the low was 78,943 tons in 1991. The 10-year production trend for all grades of silicon carbide was one of 2 years of stability and then slow growth and recovery through 1989 to 143% of the 1982 production level, followed by the 1990 and 1991 declines. The level of production in 1991 was the lowest since 1955.

Consumption and Uses.—Silicon carbide has a number of different end uses in the form of graded grain. The total value of sales of silicon carbide

graded grain for all uses decreased about 16% in 1991 and was only 68% of the 10-year high recorded in 1988. The total value of sales by individual end use was a mixture of increases and decreases. Sales for use in bonded abrasives were up 4%, coated abrasives were up 9%, refractories increased slightly, tumbling media increased 43%, blasting abrasive decreased 28%, wiresawing abrasives were down 15%, polishing cake and buffing compounds were up 39%, antislip abrasives were up slightly, polishing abrasives were up 11%, metallurgical was down 35%, and all other uses were up 36%.

Prices.—The Bureau did not collect price data on the various grades of silicon carbide. Data were available on the value of production of the various grades. The average value per ton of abrasive-grade silicon carbide, as reported by producers, was \$517, metallurgical-grade averaged \$481, and the average value of all grades was \$500. The average value per ton of abrasive-grade material for the past 10 years was \$506, with a high of \$626 in 1982 and a low of \$436 in 1985. Metallurgical-grade silicon carbide averaged \$438, with a high of \$466 in 1983 and a low of \$391 in 1988. For all grades the average was \$470, with a high of \$535 in 1982 and a low of \$417 in 1985. The trend for the value of all grades of silicon carbide for the past 10 years was one of increase, a general decrease through 1985, then stabilization with 3 years essentially unchanged at 88% of the 1981 value. Then 1989 saw a significant increase of 13% compared with the average value of the past 3 years; 1990 and 1991 both were only slightly higher than the year proceeding them. Mineral price quotations in various December issues of trade magazines listed prices for metallurgical grades of silicon carbide of \$1,110 to \$1,388 per ton, while abrasive grade was quoted at \$1,573 to \$1,758 per ton.

Foreign Trade.—Exports plus reexports of silicon carbide in 1991 were 10,138 tons, a 24% increase compared with that

of 1990. While the total value of silicon carbide exported plus reexported increased only slightly, the value per ton decreased 16% to \$1,065, a 10-year low, and was only 57% of the 10-year high of \$1,865 in 1986. The average annual exports plus reexports for the past 10 years were 6,169 tons, with a high of 10,138 tons in 1991 and a low of 3,859 tons in 1986. The average annual value per ton of exports plus reexports for the past 10 years was \$1,454, with a high of \$1,865 in 1986 and a low of \$1,065 in 1991. The value of exports plus reexports fluctuated greatly during the past 10 years; values were up as much as 75% of the value at the beginning of the period and closed the period 20% less than at the beginning.

Imports of silicon carbide in 1991 decreased 8% in quantity to 69,891 tons, 14% in total value to \$45.3 million, and 7% in average value per ton to \$648. The average annual imports for the past 10 years were 76,244 tons, with a high of 101,600 tons in 1988 and a low of 56,250 tons in 1985. The average value per ton for the period was \$607, with a high of \$694 in 1990 and a low of \$539 in 1986. The trend of silicon carbide imports for the past 10 years was one that generally decreased to a low in 1985, followed by continuing increases until 1988, followed by continuing decreases until 1991 imports were 15% greater than those of 1982. (See tables 18 and 19.)

Alumina-Zirconia Oxide

One firm produced fused alumina-zirconia oxide in two plants, one each in the United States and Canada. Abrasive applications accounted for all of the production. Publishing production data would disclose company proprietary data. Export and import data were not available.

Metallic Abrasives

Production.—Eight firms produced metallic abrasives in nine plants at the end of 1991. During the year, one firm closed two plants and went out of business. The quantity and value of steel

shot and grit produced decreased about 10% and 8%, respectively. The average value per ton was \$394, a slight increase compared with that of 1990. The average annual production for the past 10 years was 178,617 tons, with a high of 213,879 tons in 1990 and a low of 135,843 tons in 1982. The average value per ton during the period was \$363, with a high of \$402 in 1982 and a low at \$310 in 1987. The trend of steel shot and grit production for the past 10 years was one of general growth until the 1991 decline. The 1991 production was equal to about 141% the 1982 production level. Michigan, Ohio, Pennsylvania, Virginia, and Indiana, in decreasing order of quantity, supplied the production of steel shot and grit. During 1991, two companies, one each in Indiana and Ohio, produced chilled and annealed iron shot and grit; by yearend, both plants were closed. Additionally, two firms, one in Michigan and one in New York, reported production of cut wire shot. Production of chilled and annealed iron and cut wire shot and grit declined significantly in 1991, 42% in quantity to 5,916 tons and 17% in value to \$5.5 million. The average value per ton increased about 45% to \$934. The average annual production of these types of shot and grit for the past 10 years was 14,980 tons, with a high of 10,770 tons in 1988 and a low of 5,916 tons in 1991. The average value per ton for the past 10 years was \$533, with a high of \$934 in 1991 and a low of \$388 in 1982. (See tables 20 and 21.)

Consumption.—The quantity of steel shot and grit sold or used decreased 4% to 201,170 tons, the total value decreased 5% to \$82.3 million, and the average value per ton decreased slightly to \$409. The average annual quantity of steel shot and grit sold or used for the past 10 years was 179,732 tons. The high was 214,787 tons in 1988, and the low was 133,275 tons in 1982. The trend for sold or used steel shot and grit for the past 10 years was one of fluctuating decreases and increases. The 1991 sold-and-used value was 49% greater than the value in 1982.

The quantity of chilled and annealed iron and cut wire shot and grit sold or

value decreased about 25% to \$5.8 million. The average value per ton decreased 32% to \$507. The average annual quantity of these shot and grit sold or used for the past 10 years was 14,955 tons, with a high of 18,192 tons in 1984 and a low of 9,152 tons in 1985. The trend for the sold-and-used value for the past 10 years was one of large individual increases and decreases. Changes were as much as 50% in 1 year, with the low in 1985. Since then, there was continued growth through 1989, followed by a significant decrease in 1990 and the small increase in 1991. The 1991 number was only 65% of that of 1982.

The estimated apparent domestic consumption of all types of metallic shot and grit decreased slightly in quantity to 196,090 tons, 8% in total value to \$79.7 million, and decreased 5% in average value per ton to \$406. The formula to calculate U.S. estimated apparent consumption is U.S. sold or used plus imports minus exports. The average annual estimated apparent consumption of metallic shot and grit for the past 10 years was 187,806 tons, with a high of 224,216 tons in 1988 and a low of 144,986 in 1982. The average value per ton for the same period was \$405, with a high of \$432 in 1985 and a low of \$375 in 1987. The trend of apparent consumption for the past 10 years was one of rapid increases and declines until 1985. This was followed by general growth until 1988 consumption was 55% greater than that of 1982, but with the declines in 1989, 1990, and 1991 consumption, it was only 35% greater than that of 1982.

Foreign Trade.—U.S. exports of metallic shot and grit increased slightly to 25,790 tons. The total value of exports increased 26% to \$16.3 million, and the average value per ton increased 25% to \$632. The average annual tonnage of metallic shot and grit exports for the past 10 years was 11,800 tons, with a high of 25,790 tons in 1991 and a low of 6,334 tons in 1986. The average value per ton for the past 10 years was \$731, with a high of \$948 in 1987 and a low of \$390 in 1989. The trend for metallic abrasive

exports for the past 10 years was one of general decline from 1982 through 1983, followed by fluctuating increases and decreases. The 1991 exports were 147% greater than those of 1982.

U.S. imports of metallic abrasives increased 25% in quantity to 9,207 tons, increased about 56% in total value to \$7.8 million, and increased 25% in value per ton to \$850. The average annual imports for the past 10 years were 5,010 tons, with a high of 9,207 tons in 1991 and a low of 2,699 tons in 1987. The average value per ton for the period was \$909, with a high of \$965 in 1988 and a low of \$280 in 1984. The trend for the quantity of imports for the past 10 years was one of up-and-down fluctuations resulting in a general decline through 1987, followed by an increase until 1991 imports were about 207% of those of 1982.

The United States was a net exporter of metallic abrasives in 1991, a position it has enjoyed by a significant ratio for the past 10 years with the exception of 1984.

^aEstimated. ²Revised. W Withheld to avoid disclosing company proprietary data.

¹Table includes data available through May 19, 1992. Total diamond output (gem plus industrial) for each country actually is reported, except where indicated by a footnote to be estimated. In contrast, the detailed separate production data for gem diamond and industrial diamond are U.S. Bureau of Mines estimates except for Australia (1987), Brazil (1987-90), and Central African Republic (1987-90), for which source publications give details on grade as well as totals. The estimated distribution of total output between gem and industrial diamond is conjectural, and for most countries, is based on the best available data at time of publication.

²Includes near-gem and cheap-gem qualities.

³Includes all synthetic diamond production.

⁴Reported figure.

⁵Figures are estimates based on reported exports and do not include smuggled diamonds.

⁶Figures do not include smuggled artisanal production.

⁷Other De Beers' Group output from the Republic of South Africa includes Kimberley Pool, Koffiefontein Mine, Namaqualand mines, and Venetia mines.

³Includes cut wire, aluminum, stainless steel shot, and items indicated by symbol W.

ADVANCED MATERIALS

By William J. McDonough and Robert D. Brown, Jr.

Dr. McDonough, physical scientist, Branch of Materials, has more than 25 years of experience and has been with various Departments of the Federal service for 18 years. Mr. Brown, physical scientist, Branch of Materials, has more than 21 years of experience and has been with the U.S. Bureau of Mines for the past 11 years.

Advanced materials are polymers, metals, and ceramics fabricated as intermaterial compounds, alloys, or composites. The resultant components have higher strength-to-density ratios, greater hardness and wear resistance, and one or more superior thermal, electrical, or optical properties, when compared with traditional materials. Advanced materials, the basis for many of today's emerging technologies, offer savings in total energy consumption, improved performance at reasonable cost, and less dependence on imports of strategic and critical mineral resources.

DOMESTIC DATA COVERAGE

Over the past 10 years, the publishers of Ceramic Industry magazine have conducted the only systematic survey of the industry, relying on voluntary reporting sales figures and their own estimates of those of nonreporting companies. The information on advanced ceramics reported here is from the results of the Ceramic Industry surveys of 1990 and 1991. These data were generously provided in advance of publication by Ms. Patricia Janeway, Editor in Chief and Associate Publisher.

Kline & Co., Inc. data are the basis for the reported 1990 and 1991 markets for advanced polymer, metal matrix, and carbon-carbon composites. Data for polymer composites are reported separately in the Bureau's Organic Materials chapter of the 1991 Annual Report. These data were provided by Mr. John M. Quarmlay, Project Manager of Advanced Materials for Kline & Co., Inc.

Some definitions of what constitutes advanced polymer, metal matrix, and carbon-carbon composites are required. For instance, the advanced polymer data include composites that are reinforced with advanced fibers. These fiber types include carbon, aramid, high-strength glass, and other high-performance fibers and are usually incorporated as continuous filaments in composites designed for structural applications. Therefore, by definition, chopped fibers and conventional E-glass (low-strength) fibers are not included.

Metal matrix composites are composed of a continuous metallic phase and a dispersed reinforcing phase. The reinforcements are limited to those materials whose physical form and chemical composition are not deleteriously changed during composite formation. Advanced metallurgical technologies such as exothermic dispersion reinforcement and mechanically alloyed metals fall outside this definition.

Carbon-carbon composites are a family of materials that can be produced from a variety of fibers (pan, pitch, or rayon) and carbon-producing matrix materials. Many types of carbon-carbon materials have been included; however, the more technically important carbon-carbons usually exhibit higher density (1.4 to 2.1 grams per cubic centimeter) and higher thermal conductivity. All composites markets are valued at the fabrication feedstock stage.

The Corporate Technology Directory, "Corp Tech," produced by Corporate Technology Information Services, Inc., Woburn, MA, is the primary source used

for domestic industry structure data in the advanced materials area. The 1992 Corporate Technology Directory is a reference on more than 35,000 U.S. entities that manufacture or develop high-technology products.

BACKGROUND

Advanced materials are critical to any nation's commercial competitiveness as evident today with numerous technologies under development by many industrialized nations, with the North American Community, the Pacific Rim Countries, and the European Community (EC) among the major competitors. Each of these three industrial groups have "Critical Technologies" lists to guide them toward future commercial development. At the top of most lists are (1) communications and information technologies, and (2) the synthesis and processing of electronic and advanced materials.

Products For Trade and Industry

Advanced materials technologies are highly competitive fields throughout the world's industrial commodities. The EC consortia are seriously challenging the United States through EC efforts to cooperatively develop "critical technologies" commencing with market driven R&D through incorporating state-of-the-art flexible manufacturing techniques. Also, the EC is working to unify industrial standards and to remove existing trade barriers throughout Western Europe and the newly democratic countries of Eastern Europe and the

former U.S.S.R. At the same time, the Pacific Rim countries, especially Japan, are challenging the United States with their prototype manufacturing and commercialization of advanced structural alloys, composites, ceramics, and superconductors. In particular, the Japanese challenge is being accomplished mostly through large investments in new factories and updated process technologies, with the latter based on total quality manufacturing concepts. Meanwhile, other developing countries and industrialized nations, such as Australia, Canada, and the Republic of South Africa, recognize the need to move from the status of commodity mineral and materials suppliers to full manufacturing participants in advanced materials technologies.¹

Economic Factors

The current recession has made the United States more aware of manufacturing competitiveness as this nation attempts to sustain the annual revenue values generated by exports.² Adding to the uncertain export revenues as this current recession is growing worldwide are changes in the domestic economy. The beginnings of cuts in the Defense budget, the bailouts in the savings and loan industry, and the huge interest on the national debt contribute to the scarcity of investment money necessary to fuel manufacturing growth.³ The nation or community that commercially emerges "first" from this current economic down cycle will be the one able to manufacture goods of very high quality at a marketable price while allowing a reasonable return on investment.⁴ The U.S. Government is committed to assisting manufacturing competitiveness, but the paths toward achieving this success are by no means clear. Many feel that a broad-based, progressive technology plan for government, industry, and university interaction is needed,⁵ but as 1991 ends, the actual role of the Federal Government is still being defined owing to the complexity of the economic and political problems inherent in such an undertaking.

Operating Factors

Large companies and the Federal Government use many small contractors, vendors, and consultants to achieve manufacturing or service goals. For example, General Motors Corp. uses more than 10,000 subcontractors in all its business and manufacturing endeavors. Department of Commerce data report that for the U.S. manufacturing sector, more than one-half of all goods is produced in companies with less than 500 employees. These small companies are limited in obtaining expensive upgrading such as automated machinery, just in time assembly, total quality management, etc. Besides, these original equipment manufacturers (OEM's) must compete, sometimes on a yearly basis, for contracts to continue or follow up with an already existing series of parts or assemblies. Often, both large corporations and governmental operations run on an annual fiscal year funding. For many contractors, there is no guarantee of additional funding, etc. All these factors and many more not mentioned contribute in keeping small U.S. manufacturing companies operating below maximum return on investment. Hence they are very susceptible when competing against the more modern manufacturing practices used by large and small foreign companies with or without assistance from their national Government.⁶

A small business situation exists in Japan where small companies (less than 300 employees) numbering more than 800,000 produce 60% of the goods and for the most part use new manufacturing technologies and other aids to maximize return on investment.⁷ The Japanese small manufacturers operate under a business climate of longer term contracts, and a nonserial, line management style of business planning; e.g., quality circles, and government-operated technical assistance centers. The longer term contracts have an obvious cost and quality payoff for both the OEM companies and the large assembler corporations. Furthermore, the Japanese operate more than 170 public assisted centers, called Kohsetsushi centers, that extend research

services, technical assistance, training, testing, and guidance to small companies. These Kohsetsushi centers initially started in the 1920's.

The EC was quick to copy the success of the Japanese economy and has expanded or set up more industry driven manufacturing service centers; for example, the thirteen centers of the Max Plank Institute in Germany.

Industry Structure

This chapter covers four broad-based technologies that make up the bulk of U.S. advanced materials manufacturing: advanced ceramics, advanced polymer composites, metal matrix composites, and carbon-carbon composites. The industry structure for the first three technologies is similar in their involvement of both large and small manufacturers. The carbon-carbon industry resulted from fabrication facilities established within large aerospace corporations that were initially primarily supported by the Federal Government for defense applications. The carbon-carbon industry structure will be discussed separately from the other three technologies.

The former three broad-based technologies grew from company internal R&D (IRAD), and once a technology was ready for commercialization, the fabrication was contracted out to smaller job companies or specific divisions of large companies. For example, advanced polymer composites companies include a few very large companies, but there are many small companies involved in the actual manufacture of the components. The Suppliers of Advanced Composites Materials Association (SACMA), with 30 members, reports that 90% of the world's production in 1990 was by its members: 12 in the United States, 10 in the EC, and a few in Japan. In the same timeframe, the Polymer Composites Institute listed approximately 450 members. Many of the small companies are subcontractors to the large companies. Today, many of these small companies are entrepreneurial companies, founded by engineers or scientists, and initially started with assistance from government

funding such as the Federal Government's Small Business Innovative Research Program (SBIR), which competitively awards funds to small companies.

Another example of a large company-small company interface occurs in the aircraft powerplant business. General Electric and Pratt and Whitney turbine engine divisions' R&D have led to the development of new heat-resistant metal alloy technologies. The actual fabrication of these new alloys into engine components is contracted out to smaller companies. To optimize the fabrication and quality testing, the turbine engine companies either set their own strict engineering specifications or work jointly with the smaller companies to optimize all technical specifications. As a second example, this same practice is followed by the American Telephone and Telegraph (AT&T) group in developing ceramic substrate technology. Once the process variables are controlled and the quality of a pilot line maximized in their research, development, and engineering laboratory, AT&T subcontracts the fabrication of the substrates to its engineered specifications to smaller companies.

In contrast to the aircraft powerplant business, the methodology of large company manufacturing components internally exists in advanced polymer composites. Recently, two large companies, Dupont Plastics and General Electric Plastics, built large processing plants in the metropolitan Detroit area to supply outer body panels and structural body panels for the automobile industry.⁸ Besides the plant costs, large development costs were necessary to fabricate these composite panels with quality, reproducibility, low cost, and in a timely manner. Advanced polymer processing has historically not been as time efficient a process as the metal fabrication with which it competes, and many production problems were solved. The use of polymer composite body panels was demonstrated on General Motors Corp. All Purpose Vehicles in 1989.

The existence of carbon-carbon composites is related to the Department of Defense's interest in faster and lighter as descriptive adjectives for its aircraft, tanks, ships, etc. The national laboratories, including National Aeronautics and Space Administration (NASA) facilities, and industry—assisted by Federal Government funding—collectively developed these composites to technical and engineering maturity. Carbon-carbon composites are still very expensive to fabricate; many reimpregnations with liquid matrix and refiring at high temperatures must be carried out on very expensive carbon fibers to produce reliable composites. Still, these composites have been successfully tested on combat and support aircraft for the military plus numerous applications for aerospace utilization.

The companies manufacturing carbon-carbon composites are usually spinoff or licensee companies from the large aerospace and aircraft assemblers. U.S. companies such as LTV, Kaiser Aerospace, and today, divisions of various large chemical companies, are all key players in the commercialization of carbon-carbon composites. Many small licensee companies exist today to supply finished components to the military aerospace industries, and the future of these companies and indeed, the future of carbon-carbon composites, are, for the near future, tied to the ongoing downsizing of the Department of Defense (owing to the ending of the cold war).

In summary, the advanced materials industry structure of the four broad-based technologies is a mixture of a few large companies (usually under 10 in number) along with many smaller companies that supply the actual components. The smaller companies range in technical capability from entrepreneurial/high-tech to OEM subcontractors with good technical skills, reliable component fabrication records, and a history of reasonable component costs to the large assembler company. The revenue mix of small companies versus large companies will be partially delineated in the individual subsections of this chapter.

ANNUAL REVIEW

The importance of advanced materials to the U.S. economy has been emphasized this year through increased activities: in Federal and State government participation, in industry awareness, and in university pronouncements. The Federal Government completed the establishment of presidential councils targeting advanced materials. It identified critical technologies for three groups: defense oriented, commercially driven, and scientifically defined. State governments increased their activities to create technology synergism among local industry, university, and state resources.

The industrial sector created more joint ventures with itself, Federal laboratories, and university consortia as well as international collaborations—all aimed at improving their competitive positions in the global marketplace.

The university sector, with funding assistance from various government agencies, continued to broaden R&D areas to include all aspects of manufacturing while graduating students skilled in solving and implementing advanced manufacturing techniques, especially as applied to manufacturing with advanced materials. The use of advanced materials and their complex processing to produce commercially marketable products are keys to the U.S. business success.

The following sections on the government programs highlight the increased interest by the Federal Government in assisting and technically facilitating the modernization of U.S. manufacturing companies to compete in global markets.

Presidential Councils

The Federal Government's role is established with the Office of Science and Technology Policy (OSTP) in the Executive Office of the President. The Director of OSTP, who is the Science Advisor to the President, also chairs the Federal Coordinating Council for Science, Engineering, and Technology

(FCCSET). FCCSET has Assistant Secretary level participation by all agencies having Federal programs involved with critical technologies. Input to both OSTP and FCCSET by industrial, State and local governments, and academia is accomplished through the President's Council of Advisors on Science and Technology (PCAST), again chaired by the Science Advisor. One subset of FCCSET is a Committee on Materials (COMAT), dedicated exclusively to the synthesizing and processing of advanced materials. Both FCCSET and PCAST report directly to the President.

"Critical Technologies" lists came forth from four different U.S. study groups in 1991, each group driven by its own individual missions. The following lists were generated: Defense Critical Technologies by Department of Defense (DOD), Emerging Technologies by the Department of Commerce (DOC), National Critical Technologies by the National Critical Technologies Panel of FCCSET, and the Commercial Airplane and Powerplant Critical Technologies by the Aircraft Industries Association. The three Federal Government lists, in short title form, are shown in table 1. The Aircraft Industries Association (AIA) list is similar in its "short form" headings and describes in detail definitive airframe, powerplant, and aerospace categories as critical technologies to its particular industry. (See table 1.)

All four lists designate similar technology subgroups such as materials, manufacturing, information and communications, biotechnology and life sciences, aeronautics and surface transportation, and energy and environment. Various crosscuts of these four lists, which are used in planning future funding requests, reside in the reports of the National Critical Technologies Panel of FCCSET. Altogether, about 20 technologies are identified as critical with more than 10 technologies categorized in the technical subgroups of materials and/or manufacturing.

During this same time period, the United States placed increasing emphasis

on the importance of critical technologies in the race for global technological leadership. The major outcome of this emphasis was the National Competitiveness Technology Transfer Act of 1989 (Public Law 101-189), which empowered industry, universities, and national laboratories to accelerate the commercialization of new technologies. The law makes provisions allowing national laboratories to enter into cooperative research and development agreements (CRADA's); negotiate licensing agreements for inventions; exchange personnel, services, and equipment with industry and universities; waive rights to inventions and intellectual property; and streamline the processing of agreements.

Department of Defense

Today, the goals and missions of the U.S. Department of Defense are being reassessed with the ending of the cold war and the beginning of democracies and market economies in both the old Warsaw Pact countries of Eastern Europe and the Republics belonging to the "Commonwealth of Independent States." Defense is the largest consumer of U.S. science and technology with efforts funded through the National Laboratories, industrial laboratories, nonprofit research centers, and science and engineering universities. Many legislators regard the breakup of the U.S.S.R. into separate nations coupled with a sluggish U.S. economy as ample reasons to justify reduced Defense expenditures. The Department, however, recognizes the importance of maintaining a level of expertise in critical technologies as necessary to keep the U.S. national defense second to none at a minimum of cost. The use of advanced technology in the Persian Gulf war in 1991, smart bombs, stealth airplanes, and interceptor missiles, led to a rapid conclusion of the hostilities with a minimum loss of U.S. personnel. Besides utility in weapons of war, some of these technologies have "dual use" modes; i.e., a definite defense application plus a marketable commercial/industrial component. The

industrial component is important because it can also be used to increase U.S. gross domestic product through improving our commercial competitiveness.

One example of the Department's critical technologies implementation is the Defense Advanced Research Projects Agency (DARPA) manufacturing "insertion" programs. Because advanced materials are essential components of many new technologies, they are to receive increased attention in the areas of precompetitive engineering, design, and prototyping segments that make up a total manufacturing facility. These DARPA programs are aimed at assisting companies by sharing the cost of developing new manufacturing skills; i.e., flexible manufacturing capabilities and/or total quality manufacturing techniques. These joint manufacturing insertion programs ensure DARPA that the latest state-of-the-art technologies will be available when needed for defense and for the same dollar; the transfer of these newly acquired manufacturing skills to the commercial sector will improve U.S. competitiveness.

Congressional Actions

Congressional bills, introduced in either 1989 or 1990, addressing and/or refining manufacturing competitiveness received funding during 1991. For example, DARPA's Precompetitive Consortia was funded in 1991 as a startup along with the Advanced Battery Consortium and the High Performance Computing Project. The DOC Advanced Technology Program (following in detail) and the National Center for Manufacturing Sciences funds were both increased in 1991 along with the National Science Foundation's Manufacturing Initiatives funds. Also from Congressional bills passed in 1991 will come the Department of Energy's (DOE) National Technology Initiative and the creation of the Critical Technologies Institute. The former will concentrate on increased technology transfer and cooperative research, development, and engineering between the U.S. Government and industry while the latter

will be an executive think tank focusing of facilitating civilian manufacturing and R&D. This Institute will be operated by civilian contractors under the aegis of the National Science Foundation.

Agency Programs

The Federal Government has always supported materials oriented "basic and applied R&D" through its various agencies and departments. The entire effort, loosely coordinated by oversight committees, contains agencies such as NASA, the National Science Foundation, Environmental Protection Agency (EPA), in addition to the Departments of Commerce, Energy, Interior, and Agriculture. Even nonclassified DARPA and Department of Defense projects are included. The 1990 funding level for all these materials-related projects is approximately \$1.5 billion annually, with an additional \$0.3 billion to \$0.4 billion for new facilities construction and equipment costs. In 1991, Cross Cut Strategy Plans were completed to focus and increase the effectiveness of this large multiagency effort in materials-related areas. This coordinated and refocused program was initiated in late 1991 as the Advanced Materials and Processing Program (AMPP).⁹ The AMPP will be coordinated by FCCSET and will contain industrial and university input as part of its planning and feedback mechanisms. Short-term goals are to make the AMPP market driven, improve the science of manufacturing know-how, and plan future R&D projects as national goals (similar in operating objectives to Japan's Ministry of International Trade and Industry). A preliminary Government document outlining the AMPP, released near the end of 1991, contained a chapter entitled "Introduction to the AMPP."

Tables 2, 3, and 4 are summary data from the AMPP showing present and projected funding levels. Table 2, Total AMPP R&D Funding, by Agency, covers fiscal year 1991, fiscal year 1992 (appropriated), and fiscal year 1993 (submitted budget) for the 10 agencies. Table 3 is AMPP R&D Funding, by

Research Component for the same 3 fiscal years covering the following components: (1) synthesis and processing, (2) theory, modeling, and simulation, (3) materials characterization, (4) education and human resources, and (5) national user facilities/other. Table 4 delineates fiscal year 1993 AMPP R&D Funding, by Material Class and Agency. There are 11 "classes" of materials ranging from bimolecular to superconducting, the class identification resulting from the crosscut workshops sponsored by FCCSET. Table 2 clearly shows the Department of Defense AMPP funding decreasing over the 3-year period while the Department of Energy and NASA funding, in particular, are increasing along with various other agencies. An approximate 9% increase overall in AMPP is projected from fiscal year 1991 to fiscal year 1993, assuming the fiscal year 1993 submitted budget is enacted. In the immediate past, Congress has, if anything, slightly increased this type of funding over the amount submitted by the White House Office of Management and Budget. (See tables 2, 3, and 4.)

Another example of U.S. competitive awareness is the Department of Commerce, Office of Technology Administration (DOC-OTA), established in 1989.¹⁰ This office works closely with the President's Science Advisor in coordinating precompetitive manufacturing strategies and programs as a logical followup to AMPP's market driven R&D. The DOC-OTA oversees the Advanced Technology Program (ATP) that focuses on precompetitive engineering, design, and prototyping for manufacturing technologies such as computer-assisted machining and flexible manufacturing. Demonstration facilities exist in various locales countrywide to assist manufacturers and provide incentives for a more rapid modernization of commercial technology in the United States. In 1991, the ATP office awarded, through competitive solicitations, more than \$36 million to various industrial/university consortia and Congress has voted funds for more than \$100 million in awards for 1992.

In addition to competitive awareness, the U.S. Government is responding to the shifting patterns of material use as more advanced materials enter the marketplace. These advanced materials represent an entire spectrum of finished products that did not exist 20 years ago. They range from a single material; e.g., polymer-based liquid containers, to complex composites made from polymer, ceramic, and metal. Examples of the latter are electronic circuit boards and outer-body panels for automobiles. The Government activities carried out by the U.S. Bureau of Mines' Branch of Materials consider material components from their sources of supply, lifecycle analyses, substitutional trends, recycling rates, and on through discards to the environment. This information is focused and summarized in the multi-volume series—The New Materials Society.¹¹ This Branch of Materials is the focal point for data gathering and analysis of overall raw and processed materials flows in our society and is specifically responsible for the collection and interpretation of data on the nonfuel use of organic materials, commodity ceramics, and advanced materials.

Industrial Production

The revenue created by U.S. manufacturing has been decreasing approximately 1% per year over the past 15 years, but over the past 3 years the adjusted annual revenue appears to be leveling out.¹² One reason for this revenue leveling is that U.S. companies are staying competitive, whenever possible, by investing in new equipment for design, engineering, prototyping, and manufacturing. They are using techniques such as computer aided design, computer aided engineering, stereolithography for prototyping, and employing "just in time," "design to assemble," and "total quality" concepts coupled to flexible manufacturing facilities.¹³

At the same time, the U.S. industry in 1991 continued the trend of making ventures and partnerships with foreign companies by jointly developing new

technology, especially technology requiring advanced manufacturing processes.¹⁴ In addition, the outright purchase of U.S.-based high-technology companies by foreign enterprises continued. For example, the top three U.S. companies involved in advanced ceramics (in sales and in R&D) are now foreign owned, with the Norton Co. sale being finalized in 1991.¹⁵ Also, more U.S. companies manufacture "offshore" to remain product cost competitive globally. One of the key reasons for these observed business trends is the large amount of investment capital necessary to develop advanced technology once an R&D idea is proven in the prototype stage. To bring these U.S.-derived R&D technologies to the marketplace at a competitive price requires multiple client partnerships in today's global economy.

World Review

The methodology of presenting data for this document has changed in the past 2 years because the world markets themselves are changing; the advanced materials marketplace is becoming more global as to both customers and suppliers. The international flavor of corporations has evolved to the point that these corporations are now "multinational." This definition causes data gatherers to concentrate on multinational companies with the hope that the data these corporations release contain revenue breakdowns according to country of origin. For instance, Ceramic Age magazine, which supplies this document with advanced ceramic materials data, changed over its sales and marketing questionnaire to reflect the uncertainty of country of origin for manufacturing the products in question. This document reflects these global trends by presenting data showing domestic coverage and world coverage for either revenue or weight of product produced and/or delivered.

For instance, table 5 shows domestic data coverage for 1990 and 1991 for the four technologies covered in this document while table 6 shows world data

coverage for the same parameters. In table 6, the worldwide revenue increase in advanced ceramics is in contrast to the worldwide revenue decrease in metal matrix composites, and carbon-carbon composites. These decreases may be explained: the U.S. military and its allies are the consumers for more than 80% of these three advanced materials technologies. Therefore, the slight decrease in revenues reflects the end of the cold war. The worldwide advanced ceramics revenue increase, at 9%, may be the best estimate of growth—discounting the effects of the end of the cold war. Since the advanced ceramics sector obtains 80% of its revenue from electronic components, the 9% reflects the increasing worldwide markets for communications and computer equipment (see U.S. DOC - 1991 Industrial Output). Also, the very slight increase in worldwide and domestic revenues for advanced polymers (1991 versus 1990) is reflecting the continued use of high-technology, high-cost structures in commercial aircraft applications and in specialty components for the automotive industry. (See tables 5 and 6.)

The projections of world markets for advanced materials (not included in this document) as projected in either sales revenue or tonnage of product sold have undergone drastic downward revisions. These downward revisions are the result of both technical and economic changes occurring in the world. For instance, technically "user friendly" advanced materials were projected to be economically available today based on R&D knowledge of 5 to 10 years ago. Even 5 years ago, positive incremental changes in the way some advanced materials yielded to processing innovations in the pilot plant stage led to under estimation of the technical problems involved in composites overall. The difficulty in assembling matrix materials and property enhancing reinforcements into large-volume, low-cost finished products was severely underestimated when the composites were in the R&D laboratories. Today, the process in making advanced materials

user friendly is occurring but not at the pace projected 5 to 10 years ago. On the economic side, changes brought about by the demise of the U.S.S.R. and other fiscal and economical factors caused recessionary times in 1991 for the United States, the EC, and the Pacific Rim countries. Unemployment in 1991 was running as high as 7% in the EC and 4% to 6% in the United States. These economic factors have caused market revenues for advanced materials to remain level or to decrease slightly. Downward trends can be expected to continue into the 1992-94 timeframe. Information obtained from the open literature indicates that feasibility and pilot plant studies for the commercialization of products using advanced materials are continuing. The ability to manufacture new products or retrofit an existing product to reduce its manufacturing costs or to enhance an existing products' consumer performance appeal can usually be accomplished by utilizing new materials; i.e., advanced materials.

OUTLOOK

The world and U.S. domestic outlook for increasing revenues from utilizing advanced materials will continue to be optimistic based on a number of factors. Open literature citations pertaining to the science and engineering aspects of advanced materials are continuing to increase as are the numbers of trade magazines devoted to the technology development of advanced materials. More universities and associate degree colleges list courses pertaining to advanced materials—both processing and manufacturing aspects. As a further example, trade magazine announcements inform us that more and more types of advance polymeric materials and composites are being studied in corporate laboratories and pilot plants of large chemical companies.¹⁶ Also, DOC data indicate that the slowly decreasing U.S. manufacturing revenues (total dollars for all areas) over the past 10 years have not affected chemical companies.¹⁷ These companies have remained competitive in

the marketplace and have indeed increased their revenues from successfully competing in global markets.

Additionally, advanced materials in the form of engineered composites allow the customer cost savings if the new structural component is designed to replace or combine two or three existing components (performance and cost driven). The continuing efforts toward lighter weight automobiles and aircraft, without sacrificing safety, offer new uses for composite materials, especially fiber-reinforced thermoplastic polymers.

The State of California law requiring 40,000 "zero pollution" passenger vehicles registered in the State by the year 1998 translates into urban/suburban electric vehicles. In fact, a European consortium won the initial contract to manage the earlier phases of this electric vehicle project.¹⁸ These vehicles are to be built in California utilizing advanced polymer composites, along with other advanced composites, and many people believe it will be the beginning of a large industry based on lightweight vehicle technologies.

A second technology related to the internal combustion engine and diesel engine is the "automotive ceramic gas turbine engine" program. The DOE and private industry have been funding this project, known under various project names, for more than 20 years. The successful commercialization of the ceramic gas turbine engine is estimated about 10 to 20 years from now. The timetable became shorter in 1988 when the Japanese announced their own country's effort to commercialize ceramic gas turbine engines for both the automobile and the diesel truck.¹⁹

ADVANCED CERAMICS

Background

Definitions, Grades, and Specifications.—Advanced ceramics are relatively new types of high-performance ceramics with significant potential for future economic impact. Advanced ceramics include electronic and electro-optical ceramics as well as structural

ceramics. Advanced ceramics range in component form from single-phase monoliths to complex composites. They differ from traditional ceramics by the nature of their specialized properties such as unique electrical, electronic, optical, or thermal characteristics. In addition, engineered properties such as high-temperature strength, high fracture toughness, and higher resistance to chemical corrosion are designed into advanced ceramic composites. These materials require more expensive, controlled particle size and impurity level powders as starting feedstocks. Additionally, sophisticated fabrication techniques are necessary to optimize their unique engineered physical properties.

Today, the marketplace potential for advanced ceramics has captured the interest and attention of scientists, engineers, and policymakers. This interest results from the current competition between the United States and other industrial nations to develop new commercial applications for advanced ceramics. The attention given advanced ceramics is most pronounced in Japan with their term "fine ceramics" symbolizing high-technology ceramics manufactured from very fine (small) powders of uniform size and shape. The EC is also interested in advanced ceramics. Worldwide, the development of advanced ceramic technologies by large numbers of nonceramic manufacturers, in competition with ceramic oriented companies, is evidence that advanced ceramics are nearing commercialization.

Ceramics are commonly defined as "inorganic, nonmetallic materials processed or consolidated at high temperatures." Traditional ceramics are primarily based on aluminosilicate compositions, more commonly known as clay minerals, such as the kaolin clays used in pottery, brick, and classical porcelain. Traditional ceramics are most often commodity minerals of the Earth with very little chemical alteration of the naturally occurring clays or minerals. On the other hand, advanced, high-technology ceramics include a wide variety of high-purity, single-phase

oxides, nitrides, carbides, borides, and others. Their feedstock powders usually result from chemical reactions designed to yield single-phase powders of high purity. Both cation and anion impurities must be minimized to realize their desired unique physical properties. Combinations of these high-purity materials into chemical compounds or in the form of second-phase additives (particulates, platelets, whiskers, and fibers) result in engineered advanced ceramics. The properties of these inorganic materials enable applications ranging from electronic components to heat- and wear-resistant parts to optical devices. Additional properties range from high-temperature strength to controlled thermal and electrical conductivity to resistance to high-temperature corrosion and erosion. Therefore, depending on the specific application, these materials can be engineered to exhibit optimum mechanical, electrical, electronic, magnetic, and optical properties.

The numbers of chemical compositions and processing variables necessary for high-performance advanced ceramics are quite large because both cations and anion species are involved in the chemical reactions. However, potentially important feedstock materials; i.e., powders, whiskers, and fibers, are often limited both in quantity and quality. The reasons for these limitations are attributed to (1) incomplete understanding of the complex chemical reactions, (2) very expensive scientific methods necessary to produce high-purity, single-phase feedstock materials, and (3) batch "pilot plant size" production runs (limited near-term market demand prevents massive economy of scale). Nevertheless, progress in producing high-purity, uniform, and batch repeatable feedstock materials at low cost is continuing. Advanced ceramic components of proven performance are today in many niche markets. Their entry into massive markets such as automotive engine components is expected in the near future as feedstock and processing costs decrease while performance and reliability characteristics increase.

Some of the more common high-purity powders available are alumina (Al_2O_3), boron carbide (B_4C), silicon carbide (SiC), silicon nitride (Si_3N_4), sialons (solid solutions of silicon nitride and alumina), and various forms of zirconia (ZrO_2). Other feedstock materials such as whiskers and fibers occur as atypical natural growth phenomena, meaning the materials capable of exhibiting this behavior are rare even in nature. Therefore, scientific techniques employed today to grow whiskers and fibers result in small yields, and the products tend to be very expensive. Today, this situation exists in carbon graphite fiber production where 1 kilogram of fibers costs more than \$1,000. Continued R&D on feedstock technologies offers the potential for low-cost powders, second-phase additives, whiskers, and fibers. This statement is based on similar history and feedstock cost reduction efforts such as aluminum and stainless steel in the metals industry and polymeric fibers (yarns) in the chemical industry.

Products for Trade and Industry.—Aluminum oxide (alumina) is traditionally used for a wide variety of ceramic products, including refractory brick, cements, and castable refractories. Higher purity aluminum oxide compositions, 75% to 99% Al_2O_3 , are high-value materials used because of their electrical resistivity for semiconductor and integrated circuit substrates, high-frequency insulators, holders and spacers for printed circuits, and spark plug insulators. Furthermore, the high strength and hardness of aluminum oxide make it suitable for a host of other applications requiring strength, hardness, and wear resistance. The high heat of formation of aluminum oxide gives it excellent chemical resistance to a variety of corrosive materials.

For high-temperature use, aluminum oxide retains about 90% of its mechanical strength up to $1,100^\circ\text{C}$. However, its high thermal expansion coefficient results in poor thermal shock resistance, which can be positively controlled in transformation-toughened aluminum oxide. Additionally, aluminum oxide

fibers are now commercially available. These fibers are spun from solutions of alumina-containing precursors (1% to 3% SiO_2), followed by heat treatment. They are available as woven preforms, papers, and mats and have use temperatures up to 800°C .

Boron carbide (B_4C) is harder than all known materials, other than diamond and cubic boron nitride. It is used mainly as an abrasive, in abrasion-resistant components, and in ceramic armor applications for airplanes and helicopters. Because of its high neutron cross section, boron carbide is used in the nuclear industry as reactor control elements, radiation shields, and control rod moderators.

Silicon carbide (SiC) is used traditionally as an abrasive and as a component of electrical heating elements. More recently, high-purity silicon carbide is used as a super refractory in many forms: as a monolith, as a fiber, or as a deposited coating. For example, high-purity silicon carbide, with less than 1% impurities, is a prime candidate for automotive engine structural applications requiring high strength at high temperatures with good wear resistance. In addition, high-strength silicon carbide fibers are produced by chemical vapor deposition techniques while platelets and whiskers are under development as second-phase reinforcements for ceramic, metal, and polymer composites.

Silicon nitride (Si_3N_4) exhibits corrosion and oxidation resistance over a wide temperature range and retains its high strength up to $1,300^\circ\text{C}$. Silicon nitride is being evaluated for components in gas turbine engines, heat engines, and high-temperature bearings; cutting tools; industrial wear parts; and ceramic armor. Sialons, solid solutions and compounds from oxynitrides of silicon and aluminum, are similar in physical structure and properties to silicon nitride but with slightly lower operating temperatures. While silicon nitride and sialons are still being developed, niche markets uses; e.g., as lubrication-free bearings, rocket nozzles, and gas shrouds for orbital welders, increase their commercialization potential.

Zirconium oxide (ZrO_2), produced from the mineral zircon (ZrSiO_4 , zirconium silicate) or recently from nuclear-grade zirconium metal, exists in three different crystalline forms, depending on temperature. Historically, this most refractory oxide was detrimentally restrained in optimizing its physical properties by the natural presence of low melting silicates or by its polymorphic transformations initiated at various temperatures. These solid-state transformations physically destroy any monolithic component in its natural state by massive spalling of the structure once a transformation temperature is reached. But by increased research on understanding its phase diagrams, scientists recently have learned to toughen zirconium oxide with small amounts of other oxides that are included in the crystal structure during synthesis. By incorporation of several percent of stabilizing oxides, a phenomenon called transformation toughening occurs. The resulting physical properties are enhanced over the naturally occurring zirconium oxide phases and are not degraded at prior transformation temperatures. This improved performance allows these transformation toughened materials to be used in low-temperature applications such as die draw heads, hot-metal scissors, etc., and cutting materials, especially where impact toughness is required. Hammerheads of zirconium oxide have been used to demonstrate that a metalliclike toughness in ceramics is obtainable by applying the principles of engineered materials. Both lower cost feedstocks and processing R&D efforts are underway in a number of countries—aimed at large-volume commercialization of these transformation toughened components.

A host of other advanced ceramic materials are being evaluated for applications that require optimization of electronic properties, mechanical properties, high-temperature properties, and erosion-corrosion properties. After laboratory pilot plant operations, the next steps in their commercialization are reduction in feedstock and processing costs while marketing efforts attempt to

move the components from low-volume to high-volume applications based on improved performance and pertinent total quality manufacturing practices.

Industry Structure.—The largest U.S. producers of advanced ceramics in 1991 were Corning Inc., Corning, NY, \$1,000.4 million; Cooper Industries, Houston, TX, \$456.0 million as Champion Spark Plug Co.; AC Spark Plug Div. of General Motors Corp., \$308.0 million, mostly spark plugs; GTE, Stanford, CT, \$275.3 million; and Allied Signal, Morristown, NJ, \$212.5 million, Autolite Spark Plug Div.

The largest worldwide producers of advanced ceramics in 1991 were Phillips Electronics N V, Netherlands, \$3,226.0 million; Kyocera Corp., Kyoto, Japan, \$2,557.7 million; Murata Manufacturing Co., Kyoto, Japan, \$1,967.1 million; Sumitomo Electric Industries, Osaka, Japan, \$651.0 million; and NGK Insulators, Ltd., Nagoya, Japan, \$600.0 million.

The top 10 worldwide advanced ceramics producers with 1991 sales of more than \$200 million are primarily manufacturers of spark plugs, optical fiber, electronic components, and porcelain insulators. The smaller companies with sales of less than \$50 million are the major producers of advanced structural ceramics. In the United States, many of these are privately held entrepreneurial companies. Many U.S. advanced materials companies, large and small, have changed owners through mergers and acquisitions with and by foreign companies. The Carborundum Co. and the Norton Co. are now divisions of BP America (United Kingdom) and Saint-Gobain (France), respectively. Additionally, large foreign companies such as Kyocera (Japan) and Hoechst (Germany) have set up research laboratories and manufacturing facilities in the United States. For example, Kyocera America Inc. has plants in nine locations within the United States and even more mergers and/or foreign plant startups are reported in trade magazines. Figure 1 shows the number of the largest

U.S. advanced ceramics producers for 1991.

The sales volume ranges shown in figure 1 represent the total sales of all U.S. advanced ceramics companies, including manufacturers of engineered ceramic products. The company data profiles, as depicted in figure 1, are useful in identifying how mature a particular industry is.²⁰ In the case for U.S. advanced ceramics companies, the company ranges of high, medium, and low sales volumes resemble a bell-shaped curve or for this data as a skewed bell-shaped curve. The shape of any bell curve (gaussian distribution in mathematics) allows comments to be drawn about the distribution. As shown in figure 1, a bell-shaped curve skewed toward the high range sales volume is indicative of a mature, more fully developed industry. (See figure 1.)

Technology.—**Solid Freeform Fabrication for Rapid Prototyping.**—The following three examples are emerging technologies that can impact the commercialization of advanced materials by allowing these materials to be prototyped and manufactured with greater technical reliability, product repeatability, and cost effectiveness than currently exists today.²¹ Advanced materials usually enter the marketplace as "niche market" products, and one advanced material may be the basis for four or more products. Because the number of parts per component is small in a niche market, the cost of prototyping is increased in relationship to manufacturing costs. The first successful attempt at rapid and lower cost prototyping is called "stereo lithography." Stereo lithography allows computer aided design, computer aided manufacturing (CAD CAM) designed components to be transformed rapidly from computer output into a geometric prototype in minutes. A photopolymeric liquid in a vat is turned into a point source solid under the controlled intermittent firing of a focused laser energy beam. The rastering and firing of the focused laser energy fashions the CAD CAM drawing into a three-dimensional prototype of any scale

desired. The resulting photopolymeric prototype can then be used to refine the component design and any new changes in the CAD CAM drawing rapidly turned into a new solid prototype. However, in many applications seeking to use rapid prototyping, the resultant photopolymeric materials are not resilient enough.

The next logical outgrowth of stereo lithography is to sinter powders into solid prototypes and thereby allow many more prototype applications. The new technique builds solid prototypes by selective laser sintering of powders. Starting at the bottom or base line, a thin layer of powder is machine spread over the constant area of the fabrication container. The computer-controlled laser beam selectively sinters the powders into the baseline prototype shape (CAD CAM designed), and then the next layer of powder is machine spread over the same constant area of the fabrication container. By repetitive actions, the selected laser sintering and the thin layer powder spreading result in the finished part. Any three-dimensional shape (with holes, cutbacks, channels, etc.) can be prototyped with a high degree of accuracy and repeatability. For example, using wax powder results in lost-wax patterns for investment castings, tools, molds, and short production runs of durable parts. Initially, wax, polycarbonate, and polyvinyl carbonate powders were successfully utilized. Today, nylon and other polymeric powders along with metal and ceramic powders are being investigated to increase the family of powders amenable to selected laser sintering. Preliminary results indicate parts can be produced 60% cheaper and 80% faster than machined prototype parts.

Continued R&D into rapid prototyping using advanced materials is ongoing today. The ability to go from CAD CAM three-dimensional solids generated on a computer to finished prototypes is a manufacturing asset. Also, using prototypes to test, evaluate, and provide feedback to structure-properties analysis programs allows for rapid optimization of the design and engineering aspects of any advanced material component. The total

cost savings and time savings are prime drivers for future applications involving rapid prototyping as many companies seek ways to optimize their return on investment.

Machinable Green State Billet Stock.—Technically, machinable billet stock(s) designed to produce high-quality parts are accomplished in the following manner. The billet stock is held together for the machining stage by polymeric materials. The polymeric material(s) must be removed, after machining, without degrading the chemistry of the ceramic sintering aids. Additionally, removal of the polymeric materials must not compromise the component shrinkage necessary to achieve fully dense ceramic parts. While firing the machined part to remove the polymeric binders, early stage (low-temperature) sintering must occur lest the machined shape sag under the force of gravity or worst case, just fall apart to powder. This technology requires multifunctional ceramic sintering aids (added initially as very fine wet powders designed to coat the matrix powders). The lower temperature sintering aids start to sinter the matrix powders together as the polymer binders decompose (as gases or as char) due to the rising temperature. The final-stage (high-temperature) sintering aids must replace or augment the low-temperature sintering aids without distortion of the part as the still rising temperature approaches the final ceramic sintering temperature. In reality, the ceramic sintering aids and their interactions with each other and the matrix powder(s), all as a function of rising temperature, are complex solid-state reactions being studied today as state-of-the-art science.

These machinable billets, as they become commercially available, will allow small companies interested in developing niche markets an opportunity to pursue these markets without being a fully integrated vertical producer. R&D is continuing in the area of machinable ceramics, and that fact will eventually allow more companies entry-level status to advanced ceramics.

Low-Cost In Situ Composites of Silicon Nitride.—Silicon nitride, a strong ceramic material with good chemical and oxidation resistance at elevated temperature (1,300° C), is the prime candidate material for advanced heat engines. The operation of any heat engine at a "higher temperature" results in improved thermal efficiency. Today, most heat engines employing metals use liquid or gas cooling to prevent meltdown of the metals. This external cooling lowers considerably the thermal efficiency of most metal heat engines and prevents engine designers from developing more thermal efficient heat engines. R&D continues to develop more thermal efficient engines through engineering newer high-temperature materials.

For instance, the DOE's Ceramic Automotive Gas Turbine Program utilizes silicon nitride materials in all critical components, including the turbine rotor. Silicon nitride, like most monolithic ceramics, has low resistance to fracture and must use reinforcements to improve its toughness to acceptable performance levels. R&D of the past 5 years has produced prototype silicon nitride materials reinforced with fibers and whiskers that, at 1,300° C, have both the strength and fracture toughness that mild steel exhibits at room temperature. The silicon nitride composite at 1,300° C has acceptable performance levels. Ongoing tests and evaluations in the ceramic gas turbine program are aiming at a 3,000-hour lifetime. The forementioned material is approaching 1,000 hours in today's tests. Even if this reinforced silicon nitride is technically successful, its costs are very prohibitive in the highly competitive heat engine business of today because it is a composite material.

Advanced ceramic composites require processing under high pressure at temperature to sinter the matrix phase together. The "inert" reinforcements (between 20 to 30 volume percent to optimize toughness) must be completely surrounded by matrix; i.e., no porosity. This can be accomplished by using high-pressure inert gases to squeeze the composite together at high temperature during processing.

The most favorable technical results of silicon nitride composites have lead many researchers to pursue making in situ composites of silicon nitride. Because most materials adhere to a structure-properties-process-performance paradigm, attempts to duplicate composite structure(s) through chemical and selective grain growth techniques have prior histories of success (citations in the technical literature). R&D funds from industry and government agencies to develop in situ composites of silicon nitride have produced preliminary results indicating limited success. Improved strength and fracture toughness data have been reported by tailoring the grain structure through annealing techniques using selective second-phase additions. The premise is: if composite-like microstructure(s) are produced by processing techniques not requiring high pressure at temperature, then low-cost, in situ composites of silicon nitride will rapidly advance the introduction of ceramic components in cost effective gas turbine engines.

Annual Review

Industrial Production.—The companies involved in the worldwide ceramics industry range from ceramics only producers to ceramic divisions within large multinational corporations. Tables 7, 8, 9, and 10 are a compendium of information available for calendar year 1991 (derived from the Ceramic Industry survey) compared with data for 1987, 1988, 1989, and 1990.²¹

Table 7 shows the emphasis change instituted by Ceramic Industry due to the emergence of multinational corporations. The U.S. sales data for subtechnologies of advanced ceramics; e.g., capacitors or substrates, are not available commencing with 1990. However, U.S. sales data for total advanced ceramics for 1990 and 1991 are shown in table 8, [Note a 3% sales increase in U.S. sales for 1991 versus 1990 (table 7) compared with a 12% sales increase in worldwide sales for 1991 versus 1990 (table 8)]. This fourfold differential may be reflecting the current recession in the United States or

show that the worldwide consumption of advanced ceramics is growing more rapidly in Japan and the EC than in the United States. (See tables 7 and 8.)

Table 9 shows a slight decrease in total sales of all U.S. ceramics with increases in advanced ceramics, whitewares, and refractories sales being offset by decreases in glass and porcelain sales. In contrast, table 10 shows worldwide sales increases in all ceramic categories with total worldwide sales increasing 12% for 1991 versus 1990. Comparing table 9 to table 10 indicates the possible effects of the U.S. recession on the total U.S. sales figures. At best, the U.S. sales data in table 9 exhibit a flatness in the U.S. economy, with certain ceramic technologies increasing sales revenues and others decreasing sales revenues for 1991. (See tables 9 and 10.)

Current Research.—Synthesis of New Matrix and Fiber Materials.—The R&D funds available for advanced ceramics technologies for structural, electronic, optical, magnetic, and medical uses are at a high level in the Federal, industrial, and academic sectors. The current recession has seen a slight decrease in industrial R&D funds. However, the Federal Government's Advanced Materials and Processing Program for 1991 reported an overall increase with a shift in emphasis toward nondefense programs.

The 1991 funding for ceramics is \$137.1 million plus an unknown percentage of \$185 million for composites funding. In addition, the DOC Advanced Technology Program (ATP) for R&D on precompetitive engineering, design, and manufacturing was funded at \$36 million this year with \$100 million allocated for 1992. An unknown percentage of the ATP is targeted for ceramic manufacturing depending on the proposals submitted for competitive awards. Summaries of selected technologies requesting R&D funds within advanced ceramics are listed below.

Current research is aimed at developing new matrix materials with improved properties, such as high-

fracture toughness, higher use temperatures, more erosion and corrosion protection, unique physical properties, etc., and low-cost processing for high-quality components. For advanced ceramics, current research is aimed to develop uniform and higher purity feedstock powders, alloy powders with sintering additives deposited on powder surface, and uniform and low-cost powder whisker or powder fiber blends. For colloidal state ceramics, research will target the development of many more low-cost sol gel powders from the solutions precursor routes, including alloys or coprecipitated powders. For advanced ceramic composites, researchers want to develop more homogeneous alloy powders suitable for blending with second-phase reinforcements, low-cost matrix deposition techniques for building matrix fiber preassembly tapes, and more refractory alloys systems for advanced gas turbine engines.

The effectiveness of fibers as reinforcements in any advanced material composites depends on the fiber(s) intrinsic strengths, surface condition(s) (failure is initiated at surface flaws), and the strength of the interfacial bond between the fiber and the matrix. Research efforts directed toward improved fiber reinforcements cover a variety of silica, aluminosilicate, boron, silicon nitride, silicon carbide, carbon, graphite, and organic fibers. Fibers are incorporated into matrix materials to improve the composites structural properties and occasionally to add other properties such as directional thermal conductivity. Research is ongoing to develop new fiber types and at the same time to lower the very high cost of most fibers.

Engineering, Design, and Prototyping.—R&D efforts are expanding into the upstream areas of product processing as international competition indicates total quality management is necessary for all phases of a product's manufacture. The steps of going from laboratory specimen to an acceptable prototype are now being investigated in a scientific fashion. The

use of finite element models for stress calculations coupled to CAD CAM software techniques is being optimized. Rapid prototyping through various techniques results in less time and capital spent on developing a final part for manufacturing. Flexible manufacturing lines allow companies an economy of scale as well as product versatility. Intelligent processing brings total quality management to a manufacturing process. And finally, computer numerically controlled (CNC) machining ensures product repeatability for finish machining and/or other steps in a manufacturing process requiring machining. These areas and many others necessary to bring a high-quality product to a competitive international marketplace are being researched in this country. The U.S. companies that are employing these cost effective and quality providing techniques are enjoying a marketplace advantage in the worldwide economy today. Soon, more U.S. companies will utilize these modern manufacturing techniques as these techniques prove themselves in the marketplace through a higher return on investment.

Nondestructive Evaluation (NDE).—Fiber breakage during fabrication, poor fiber-matrix adherence, and existence of voids and inclusions in advanced ceramic composites are potential causes of failure in service. Under normal conditions, these flaws are not readily detectable by visual inspection.

Adding to the extrinsic processing flaws aforementioned are failure modes caused by advanced ceramics undergoing stress-related formation of microcracks. These microcracks grow under stress and coalesce to cause brittle failure. In a fiber composite, the growth of the matrix microcracks is arrested by the fibers in the microcrack's path. But if the chemical bond between the fiber and the matrix is not optimized, the result is weakening of the fiber-matrix bond, and eventually, fiber breakage and complete brittle failure of the composite. Further mechanisms for brittle failure are caused by environmental conditions. Exposure

to chemical agents, ultraviolet radiation, heat, atomic oxygen (in space), and ionizing radiation, all contribute toward degrading the properties of advanced ceramic materials. Also, the lack of experience in longtime use of advanced ceramic materials contributes to an incomplete understanding of complex failure modes. This lack of understanding is coupled to today's lack of high-quality and fully characterized materials data bases necessary for engineering and designing reliable ceramic composites. Lastly, variability in the final properties and structures from one production run to the next run result from lack of complete understanding of the processing variables.

Inspecting each component prior to incorporation into a finished assembly requires nondestructive evaluation methods. Today, these methods include ultrasonic inspection, infrared thermography, thermographic stress analysis, X-ray tomography, eddy current measurement, acoustic emission measurement, fluorescence spectroscopy, magnetic resonance imaging (MRI), and pulsed nuclear magnetic resonance (a variation of MRI). New nondestructive evaluation methods are being developed both for initial inspection and for periodic inspection of components in use. For initial inspection, research on using X-rays from compact synchrotrons may be able to penetrate up to 6 centimeters of dense ceramic and identify flaws as small as 20 micrometers (typical flaw size that can grow to cause brittle failure). This technique would operate similar to computer aided tomography (CAT scans in medical profession). For in-service monitoring, two methods are presently under development. The first method involves incorporation of pressure sensitive detectors (piezoelectric or light emitters) coupled with wires or optical fibers to transmit data to a computer system. The second method involves sound detectors to receive acoustic emissions from critical stress-bearing regions in the component for transmittal to an analyzing computer (sound is emitted when microcracks grow).

Outlook

The recession in the industrial countries of the Northern Hemisphere makes the economic data reported for 1991 similar in total value to revenue data for 1990. The 1991 revenue highlights appear in niche areas such as modest revenue gains for engineered ceramics, fiber optics, and the category of other electronics. Total revenues for 1991 in advanced ceramics increased 13% over the previous year and are projected to increase 6% to 8% for the next year (Ceramic Age magazine). (See table 6.)

Ceramics and composites R&D funding, two separate classifications under the Government AMPP, increased in 1991. Larger increases in AMPP funds are projected for both 1992 and 1993. In addition, the ATP funding for precompetitive advanced manufacturing contains funds for ceramic processing utilizing intelligent processing techniques. Both of these governmental programs are expected to grow in the funding made available to advanced ceramics because advanced materials are always listed in the top four categories of the Nation's critical technologies lists. Critical technologies are targeted to receive more funding by both Government agencies and industrial R&D. These technologies represent commercial areas (determined by U.S. study groups) best suited to marketplace success in the near future by matching the best of our R&D talents with our rapidly increasing skills in modern manufacturing techniques.

The outlook for next year's advanced ceramic revenues is projected to be either flat or show a slight increase. Funding increases from both the Government and industry sectors for optimizing the techniques of modern manufacturing have been allocated for 1992. The United States appears poised to challenge global competitiveness in the area of advanced materials (ceramics).

POLYMER MATRIX COMPOSITES

Background

Today's composite market is dominated by polymer matrix materials, followed at some distance by metal matrix composites, with ceramic matrix composites just becoming commercialized. Advanced composite systems (ACS), in general, combine the desired characteristics of two or more materials to engineer a new material with a combination of properties not available by traditional methods of manufacture applied to the separate components. Initially developed for the aerospace and defense industries to achieve lighter weight, higher strength, greater toughness, etc., they enhance the efficiency and performance of many technical systems. ACS's are now being applied in the commercial airframe industry and special niche markets such as sports equipment that demand similar properties.

Definitions, Grades, and Specifications.—Polymers are classified as two basic types: thermoplastic and thermoset. Thermosets are those polymers that form by irreversible chemical reaction and consist of strongly cross-linked chains. Thermosets cannot be remelted and reformed but, rather, decompose at elevated temperatures. Because of the cross-linking, thermosets are strong and heat resistant but tend to be brittle. Examples of thermosets are epoxies, phenolics, vinyl esters, polyesters, and urethanes. Thermoplastics are polymers, with less cross-linking, that can be remelted and reformed. They tend to be less brittle (tougher), more flexible, and stronger in the direction along the strongly linked chains than between. Consequently, if the chains are aligned, the polymer is much stronger in one direction than the others.

A polymer composite is a combination of an organic resin and a reinforcing material in the form of fibers in a variety

of patterns and weaves or short fibers, whiskers, or particles. Generally, only composites containing continuous (i.e., relatively long, not short or chopped) fiber reinforcements are considered as advanced polymer composites. The fibers are typically high-strength glass (S-glass), carbon fibers, boron, ceramic, aramid, or other organic fibers.

Engineered polymers can be divided into two classes, polymer commodity materials and advanced polymer materials. Polymer commodity materials are characterized as high-volume, low-cost materials. Advanced polymer materials (AP's) are low-volume, high-cost materials that usually require specialized processing techniques. A composite containing short fibers in a matrix of advanced polymer material could be considered an advanced composite because of its matrix. This combination is of little interest. The continuous or long fiber composite is more important because of the resulting greater improvement in properties. The great bulk of polymer composites consist of short or chopped fibers or particulate incorporated in a "commodity" polymer matrix. These composites are not considered "advanced," but they will be included in this discussion for a complete picture and for comparisons in consumption.

Polymer composites reinforced with continuous fibers are generally referred to as advanced polymer composites (APC's). APC's exhibit excellent strength-to-density ratios, high stiffness, etc., developed from specialized processing techniques that result in properties approaching theoretical maximums attainable from the particular combination of materials used to form the composite. Organic resins used as matrix materials may consist of epoxies, polyimides, polyacrylates, polyesters, or a number of other high-temperature resins. Fibers may be of high-strength glass, carbon, boron, various ceramics such as alumina and silicon carbide, or high-strength organic materials. In general, the most important physical properties of APC's are determined by the properties of the fibers, so a myriad

of polymers, blends, and alloys may be used as matrix materials.

The matrix materials most often used for APC's are the epoxies and the engineering and high-performance thermoplastic polymers. The epoxies presently are used in more than 90% of APC's. Detailed definitions, grades, and specifications for the hundreds of available polymer matrix materials are beyond the scope of this work but can be readily obtained in the *Plastics Encyclopedia*.²² Specifications for the composites themselves (matrix plus reinforcement) are not written as with commodity materials; the specifications are written for each individual application.

The fact that the great majority of advanced polymer matrix composites manufactured today are composed of epoxy reinforced with carbon fiber or high-strength glass fiber is the result, mainly, of two factors. First, when property and performance specifications were written for current aerospace systems, about 15 years ago, epoxies were the only materials sufficiently developed and understood to be used successfully as composite matrix materials. Additionally, epoxy composites are relatively easy to fabricate because the resin-catalyst mixture has low viscosity and is suitable for a variety of prepregging and forming operations. Moreover, epoxies wet reinforcing fibers very effectively, producing a strong bond between them. Epoxies possess the strength, stiffness, corrosion resistance, and high-temperature stability needed for many high-tech applications.

Epoxies have some disadvantages, however. Though strong, they do not have high fracture toughness; i.e., they are brittle and do not resist high impacts. Epoxies are thermosets; they are difficult to recycle because they are formed by irreversible chemical reactions. They do not soften or melt upon heating but decompose instead.

Products for Trade and Industry.—One dominant use of polymer composites is in the area of corrosion-resistant equipment. In this sector,

polymer composites are used for piping, chemical storage and process tanks, pollution control equipment, walkways, platforms, etc. It has become possible to fabricate and field install large custom hoods and ducts for pollution control systems. Their high strength, low density, and relative ease of assembly, as well as resistance to corrosion, has resulted in the replacement of other materials. This was the third largest sector of nine for polymer composites and represented 15% of the total polymer composite market in 1991. Polymer composites in the other sectors involve mostly end uses, rather than industrial applications.

APC's, because of their high cost, have uses most notably in defense, aerospace, and sporting goods where performance benefits outweigh cost considerations. In defense and aerospace they are used in helicopter rotors, blades, and tail assemblies and in weapons systems as rocket motor cases on missiles and space vehicles. They are finding increasing use in secondary aircraft structures such as control surfaces (flaps, rudders, and stabilizers) or fairings (streamlining covers for aerodynamics) and more recently as primary structures such as wing, tail, and fuselage sections. Composites use in McDonnell Douglas aircraft's military planes, for example, has increased from about 2% in the F-15 to 27% on the AV-8B Harrier currently in production.²³ Boeing Co. has teamed with Sikorsky Aircraft to make the new LH helicopters, both with airframes and skins largely constructed of epoxy-carbon composites.

For commercial aircraft, the major manufacturers are planning to increase use of polymer composites in new generation planes. Boeing, for example, plans to increase the composite content of its highly successful 757 line from 3% in 1990 to 24.5% by the year 2000.²⁴

In sporting goods, the desire for better performance regardless of cost has created a market for fiberglass and carbon reinforced polymers in tennis rackets, golf club shafts, skis, sleds, and toboggans; fishing poles; and bicycles.

A particularly interesting aspect of trade in APC's is the use of "prepreg." This is short for "preimpregnated" composite. A prepreg is a combination consisting of a measured amount of polymer (matrix) and fiber (reinforcement) assembled (but not processed completely) to produce tows, fabrics, and tapes for parts producers. These manufacturers then form the composite to the desired shape and cure the resin to complete fabrication of the product. Thus a composites manufacturer has the option of purchasing polymer and fiber or purchasing prepreg and processing it to produce a part. A major portion of composite materials are traded as prepreg. Total prepreg shipments amount to slightly more than the total weight of fiber traded, worldwide.

The industrial market accounts for only about 5% of the use of APC's.²⁵ The primary use here is in tooling. The main purpose of tooling is to provide the contour configuration that a part assumes as it is finally cured. Metals such as aluminum and steel and electroformed nickel are commonly used as tooling materials. But composite tooling has advantages over metal. There is a better match of coefficient of thermal expansion between the composite being made and the tool. Composite tools are easy to prepare by lay up over a plaster mold. Their good heat transfer properties allow increased productivity through more rapid cycling of the process.

Other applications are developing. Robot arms, for example, with less inertial mass than metals, contribute to greater speed and lower systems and energy costs in automated manufacturing.

Industry Structure.—The industry structure in the polymer composite sector is such that the APC materials area is dominated heavily by a few large companies while there are many (and therefore, smaller) companies involved in the actual manufacture of commercial parts from polymer composites. In 1990, more than 90% of the world production of APC material was produced by the members of SACMA, less than 30 companies: about a dozen in the United

States, about 10 in Europe, and a few in Japan. On the other hand, the membership in the Composites Institute, the largest organization inside the Society of Plastics Industries, is at about 450 members. Intermediate in size and number are the companies that manufacture actual parts from APC's and those that produce polymer composite materials. A chart indicating the domestic companies producing APC materials is shown in figure 2. (See figure 2.)

Technology.—Processing.—Most polymer composite processing technologies influence the properties of the finished product, perhaps far more than metals or ceramics, whose properties are somewhat more intrinsic. Various fabrication technologies applicable to PMC's are listed and described briefly in tables 11 and 12.²⁶ These tables also list the predominant type of polymer processed, the form of the polymer prior to processing, and the typical shape of polymer composites made. The exact details of many of the techniques are proprietary.

The most widely used techniques for the fabrication of polymer composites are the open mold methods. The open mold methods include hand lay up or spray up (contact molding), pultrusion, filament winding, continuous laminating, and centrifugal casting. These technologies account for 65% of the polymer matrix composites produced. The closed mold methods include reaction injection molding, high-pressure laminating, and match die (low-pressure) molding. The closed mold methods are used to manufacture 35% of the domestic polymer matrix composite production.

The high-volume methods of hand lay up or spray up (open mold, contact molding) and continuous laminating are used to fabricate 62% of the production of the open mold class or slightly more than 40% of the total polymer matrix composite production. The remaining open mold techniques, filament winding, pultrusion, and centrifugal casting comprise 38% of the open mold production and 25% of the total.

The main closed mold technique is reaction injection molding, accounting for 58% of the closed mold production or 20% of the total. Other closed mold methods include high-pressure laminating and match die (low-pressure) molding, which are used for about 40% of the closed mold production or 14% of the total polymer matrix composites production.²⁷ (See tables 11 and 12.)

It is possible to control properties by varying conditions under which materials are processed. In particular, fibers and films can be made by processes that include close control of polymer chain orientation by drawing under controlled temperatures. Orientation of polymer chains affects strength, stiffness, and elevated temperature properties. For example, polyethylene terephthalate (PET) bottles can now be made under controlled conditions to achieve thermal stability at temperatures up to 88° C. This capability allows the use of PET in the hot-filled food packaging market. The old and new material are still chemically the same, PET. But changes in processing alter the internal structure of the material, resulting in greatly enhanced properties.

Mold design is a very important prefabrication step. The molding process must result in the desired surface appearance, and the mold must be able to withstand corrosiveness of both the material and the process. The process chosen must also match the flow properties of the resin, the geometry of the part, and the mold materials. An example showing the importance of proper processing and mold design is in the manufacture of continuous fiber reinforced thermosets. Because the long fibers in the thermosets are broken up and/or do not flow into the thinner sections, the use of transfer or plunger molding will result in degraded reinforcing fibers and lower strength compared to using compression molding. Furthermore, fibers may flow off into thin, intricate sections of a composite product during compression molding. In such a case, equal properties may be available from a less expensive material that can be injection molded, so it is

important to consider the desired properties of the part, the various materials that can be used to make it, the various mold materials available, and the molding process itself when designing a manufacturing process for a composite.

Joining Methods.—Although the number of component parts required for a system is generally fewer with polymer composites than with metallic systems, particularly in aerospace systems, parts must still be assembled with fasteners or adhesives. If the strength of the joint is less than that of the composite parts, much of the advantage of using the composite part is nullified. Hence, joining methods are receiving a great deal of attention. Improved polymer and metal materials for use as bolts and rivets are being developed, and high-strength adhesives and direct bonding methods are being researched. Perhaps more importantly, new computer-aided design methods have been utilized to predict stress levels within the composite and at the joints of assemblies. This enables engineers and designers to develop structures in which stresses are minimized in critical areas, such as joints.

Applications.—Polymers have been replacing glass, ceramics, metals, and paper in many applications. They are being used in applications from microwave food packaging to sporting goods and satellites. Their special properties have been exploited by design engineers in structural applications. Polymers have many favorable properties and characteristics. In general, they are corrosion resistant, higher in strength-to-density ratios, and usually allow fabrication of a complete assembly using fewer individual parts.

The first application of APC's was in the defense/aerospace industry, beginning in the 1970's. This is still the dominant area of application, with the current shift being from military to civilian aircraft and to the automotive industry in the future. APC's have been used extensively in smaller military aircraft and military and civilian rotorcraft. They are also used in stealth aircraft and the

Beech Starship. These advanced composites have superior strength-to-weight ratios and stiffness compared to the metals they replace in these applications. Resulting weight savings range from 10% to 60% over metallic designs, with a 30% saving being typical. Weight savings can be used to increase payload capacity, speed and maneuverability, and/or to reduce fuel consumption. The high value of weight reduction makes advanced aircraft the ideal market for these new materials. Because of its polymeric matrix, these composites have superior vibration-damping properties and resistance to fatigue and corrosion compared to metals.

The automotive industry becomes a more likely candidate for greatly increased use of APC's as regulations and consumer desire call for lighter cars. So far most applications of polymer composites have been in body panels, usually through the use of sheet molding compound (SMC). The Pontiac Fiero had an all-composite exterior. Composites have also found applications in automobile structural parts, in drive shafts and leaf springs. The roof and liftgate of the 1992 General Motors Saturn are made from SMC. Later models of the Camaro and Firebird will have composite body panels.²⁸

The latest American high-performance sports car, the Dodge Viper, will have glass-reinforced acrylic body panels. It will be Chrysler's first composite intensive vehicle.²⁹ APC's have also found applications in sporting goods, robotics, and medical devices.

Recycling.—Although relatively low recycling rates have been considered a problem for polymers in general (with about 60% of current production going to landfills annually) and with composites in particular, it is encouraging to note a high level of attention to finding solutions.³⁰ The number of composite industry executives who feel that recyclability is very important has risen steadily from 25% in 1988 to 55% in 1991.³¹

R&D engineers have begun to consider the desirability and feasibility of recycling in the early designs of new materials and

products. Some polymer composites are already being recycled in significant amounts. Azdel, a long, continuous glass-reinforced polypropylene composite produced by a joint-venture corporation formed through cooperation between the General Electric Co. and PPG Industries, Inc. is a good example. In tests to show recyclability, Azdel parts containing 40% glass fiber reinforcements were reheated and formed by compression molding five times, with property tests after each refabrication. There was no loss in tensile or flexural strength and only a minimal loss in toughness.³²

Ground sheet molding compound (containing fiberglass reinforcements) from Fiat body parts has been added to polypropylene along with a Union Carbide reinforcement promotion system of organosilicon chemicals. The resulting new composite did not completely match the properties of a similar composite made from polypropylene and virgin fiberglass, but the properties obtained make the recycled material worthy of consideration for applications.³³

For APC's, the main recycling problem is how to separate the fibers from the resin and reuse them economically. Recycling APC scrap may become economically feasible because of the high cost of carbon fibers. The matrix materials currently used are predominantly epoxy resins. Therefore, much of the research conducted has been for the recycling of this type of composite matrix.³⁴ In the uncured condition, epoxies are soluble in organic solvents such as acetone or methyl ethyl ketone. After the epoxy is dissolved, the recovered carbon fiber can be reused. After curing, however, epoxies are insoluble, so this procedure can only be used for prompt scrap and rejects.³⁵ Fortunately, most scrap consists of prepreg sections so this technique can be readily utilized. Cured epoxies can also be decomposed thermally below 400° C in air or at higher temperatures under an inert gas (to protect the fiber from oxidation), and the fiber may be recovered; the fiber surface, however, is affected so that lower fiber-matrix adhesion is observed in new products.

Fiber breakage may be sufficient to render fibers useful only as discontinuous reinforcement.

Fiber-matrix separation should be easier for the newer thermoplastic matrix APC's. Because the matrix material melts at high temperatures (rather than decomposing), separation is possible even after curing, and both the fibers and the matrix material may be recycled. A composite with a thermoplastic matrix can also be softened or melted and recycled simply by reprocessing while the matrix is fluid to fabricate a new component the same as or different from the original component.

Economic Factors.—The defense and aerospace industries have remained the principal driving forces behind the growth of advanced fiber composites. The next area for expansion will be in commercial transport aircraft.

Currently, the United States is the leader in applications of advanced fiber composites systems, but growing foreign activity is a definite threat to U.S. competitiveness in the commercial airplane industry. In 1990, the U.S. aerospace industry led all U.S. manufacturing sectors by posting a positive trade balance of almost \$30 billion. This decreased to a \$27 billion positive trade balance for 1991, still enough for first place by a wide margin. Figure 3 shows the trade balance in 1991 for various industry sectors.³⁶ (See figure 3.)

Survival in this industry depends on which airplane consortium produces the most reliable, fuel-efficient product. The consortium with advanced composites technologies that have been proven and tested will win the largest orders. Another factor that weakens U.S. competitiveness is the increasing U.S. dependence on foreign suppliers for such raw materials as advanced fibers. Japan and Western Europe are primary suppliers of both high-grade fine ceramic powders and advanced fiber reinforcements for composites; the new Department of Defense requirement for at least one-half of the polyacrylonitrile (PAN) carbon fibers purchased to be

domestically produced will not apply to commercial aircraft manufacturers. This is very important because it is hoped that anticipated Department of Defense budget cuts will be balanced by increases in commercial applications of advanced composites.³⁷

To compete effectively with traditional materials in the aerospace market (metal alloys based on aluminum, steel, and titanium), producers of advanced composites need to aggressively market their new materials. Current material use (by weight) in the Boeing 767 airliner's as follows: 80% aluminum, 14% steel, 2% titanium, and only 4% nonmetallics.

The DOC has reported that the consumption of advanced composites has been growing at a rate of 20% annually with 70% of that growth occurring in the aerospace industry.³⁸

Annual Review

Legislation and Government Programs.—Important governmental decisions may affect the polymers industry within the immediate future. The main factors are the Clean Air Act and the Resource Conservation and Recovery Act. Congress is currently considering the reauthorization of the Resource Conservation and Recovery Act. This will impact heavily on solid waste regulations. This act is ultimately likely to dictate national recycling goals. The 1990 version of the Clean Air Act is likely to require regulation of the polymer industry in general, including the production of composites. In light of these possibilities, a Society of the Plastics Industry task force is reviewing the industry's stand on workable policies regarding resource conservation, pollution abatement, and energy.

The Corporate Average Fuel Economy (CAFE) Act also affects the polymer composite industry. By requiring greater fuel economy in automobiles, this law encourages the use of lightweight polymer composites for body panels and structural components.

Production.—Generally, production has risen to meet increased demand in the polymer composite sector for the past decade, with an average annual growth rate of 5% for the 1980's. The composite growth process was mainly one of substitution for other materials in existing applications. Composite production grew at a rate twice that of the growth in gross domestic product (GDP) from 1983 to 1988.³⁹ The entire economy, world and domestic, has slowed in recent years, and composite production entered a near-no-growth phase. Production is expected to resume, growing at a rate twice that of the GDP in the 1990's.

The growth in production for APC's has been mostly a process of developing new applications or performing certain high-tech jobs at greater efficiency through lighter, stiffer, stronger, etc., materials. Production growth for this sector has been almost entirely for military and aerospace applications, where high costs were not a great concern. This dependence on military applications brought 20% annual growth rates to some areas but also a large volatility in demand due to current and anticipated cuts in defense acquisitions. Unless costs can be cut and products developed for the civilian consumer sector, the utilization of increased production capacity will only result in oversupply.

Consumption and Uses.—U.S. polymer composite markets can be divided into nine categories: aircraft-aerospace-military, construction, consumer products, appliance-business equipment, corrosion-resistant equipment, electrical-electronic, marine, transportation, and other. Table 13 presents the shipments of these materials by market category for the years 1987-91. Data for this table were compiled by the Society of the Plastics Industry.⁴⁰ (See table 13.)

The U.S. aircraft-aerospace-military market has remained somewhat stagnant during the past few years. After peaking at 41 million pounds in 1989, the 1990

market dropped to 39 million pounds. In 1991, this market was the same. The appliance-business equipment market used 153 million pounds of polymer composites in 1990, but shipments in 1991 dropped more than 12% to the same level as 1985-86, 135 million pounds. The U.S. construction industry did not recover from the recession. In 1990, polymer composite consumption dropped to 468 million pounds, down from 470 million pounds in 1989. Polymer composite use in this sector dropped further to 420 million pounds in 1991. These figures are significantly down from the previous highs in 1987 and 1988.

The U.S. consumer products market stood at 165 million pounds in 1990. Shipments decreased by 10% in 1991 to 149 million pounds. In 1990, the U.S. corrosion-resistant market stood at 350 million pounds. A modest rise was seen in 1991 to 355 million pounds. Polymer composites struggled to maintain position, but this was mainly due to general economic conditions rather than a reversal of the trend for composites to replace other materials in places where corrosion resistance, high strength, and ease of assembly are required.

Shipments to the electrical-electronic market reached 241 million pounds in 1990. A small decrease (less than 1%) was seen in 1991, with shipments falling to 231 million pounds. The popularity of fiberglass boats over the past decade made the marine market the fastest growing user of polymer composites at that time. The economic slump left retailers with excess inventories, resulting in a market decline starting in 1989. Continued high retail inventory caused the 1990 market to shrink even further. Composite purchases for the boating industry continued to decline in 1991 and dropped from 375 million pounds to 275 million pounds. In 1990, U.S. polymer composite use within the transportation market stood at 705 million pounds. In 1991, use decreased slightly to 682 million pounds.

Other products using polymer composites include medical equipment, orthopedic appliances, and dental materials. In 1990, consumption totaled

79 million pounds. This market decreased to 74 million pounds in 1991.

Kline & Co.'s estimated 1991 U.S. market for 17.1 million pounds of advanced polymer composites is \$2.4 billion or 53% of the world market. This represents no change in value but a decrease of 13.6% in weight from the 1990 amounts. Figure 4 (Kline & Co.) shows the 1991 U.S. market by end-use industry. These data show \$920 million (5.6 million pounds) for aircraft; \$1,080 million (4.1 million pounds) for missiles and space; \$52 million (2.4 million pounds) for armor; \$170 million (2.6 million pounds) for recreational; and \$155 million (2.4 million pounds) for other. An interesting point about figure 4 is that although the data show aircraft applications consuming more than 30% of the U.S. market, missile programs account for the majority of the parts used. The heavy use of advanced composites in these programs helps to explain why there was no change in value produced while there was a drop in how much was consumed. (See figure 4.)

World Review.—The estimated 1991 worldwide value for 31.1 million pounds of APC's is \$4.5 billion for three regions, North America, Western Europe, and the Pacific Rim (figure 5), according to Kline & Co. This represents an increase of 12.5% in value and a decrease of 5.8% in the amount consumed compared with the data for 1990. Again, according to Kline & Co., the estimated 1991 world market for APC's by end-use industry is shown in figure 6, as follows: \$1,450 million (9.4 million pounds) for aircraft; \$1,680 million (6.1 million pounds) for missiles and space; \$420 million (4.6 million pounds) for recreation; \$130 million (3.8 million pounds) for armor; \$35 million (0.6 million pounds) for automotive; and \$695 million (5.6 million pounds) for other. A notable feature in figure 6 is the difference in the missiles and space in terms of weight and dollar values: 20% by weight and almost 40% by cost. Higher costs are attributed to labor-

intensive fabrication and low-volume production. (See figures 5 and 6.)

Current Research.—**New Materials.**—The level of research effort in polymer technologies has shifted in areas of emphasis in recent years, according to Owens Corning's "Trends 1991."⁴¹ The survey of leading executives of the composites industry showed a steady decrease in the companies active in new materials development from 55% in 1988 to 39% in 1991. New applications development showed the quickest increase, from 21% to 32% of the companies polled from 1990 to 1991. This area of effort had dropped from 27% in 1988. R&D on new processing techniques held steady at about 25% of the companies from 1988 to 1991 whereas R&D on improving existing materials and efforts on quality control decreased from just less than 15% to slightly more than 10% for the same time period. Forty-seven percent of the executives expected a decrease in R&D expenditures in 1991. Although 36% expected an increase, this was the lowest level of optimism since the survey started in 1986, representing a 16% drop from that of 1990. All of these dampened expectations are a reflection of the general economic conditions and attempts to keep short-term profits up, quarter by quarter.

Current research to develop new matrix materials is aimed at overcoming the disadvantages of epoxies, such as low-fracture toughness, processing by irreversible reactions, and high viscosity. A number of epoxy blends with greater fracture toughness than single epoxies and lower viscosity than thermoplastics have been formulated and are being evaluated. These materials may find uses in areas demanding improved impact resistance, but they will still be difficult to repair or recycle.

Increased repairability and toughness are the main driving forces for the greater implementation of thermoplastic resins as matrix materials. Polyetheretherketone (PEEK), introduced in 1982, is a leading contender for more applications. Formable by heat and low pressures, it

also has a preprocessing advantage over thermosets (mostly epoxies) in that PEEK prepregs do not require refrigeration for storage and shipment. Thermoplastic processing technologies, being more automated, result in shorter cure and production times, resulting in increased productivity. Newer thermoplastic resins being developed as matrix materials are polyphenylene sulfide (PPS), thermoplastic polyimides, polyarylates, and polyetherimide (PEI).⁴²

Liquid crystal polymers are also being developed as matrix and even stand alone materials. Their internal structure is such that the molecular chains forming the resin become oriented parallel to each other so much that the material becomes "self reinforcing." This results in exceptionally high strengths. These materials can be processed at high temperatures, are thermally stable, and are solvent resistant. They are lower in density than epoxies. While it is expected that they will eventually find implementation in large structural applications, they are likely to be used first in large volumes as injection molded chip carriers in the electronics market.⁴³

New Fibers.—The effectiveness of fibers as reinforcements in APC's depends on their intrinsic strengths, surface condition (failure is initiated at surface flaws), and the strength of the interfacial bond with the matrix. Research directed toward finding improved reinforcements remains intense although development efforts have declined owing to general economic conditions. A variety of silica, aluminosilicate, boron, silicon nitride, silicon carbide, and organic fibers are being researched and evaluated for use as reinforcements for improved composite structural materials. A new high-performance E-glass, Star Stran 748, has been introduced commercially by Schuller International (formerly Manville). This fiber was designed specifically for injection molding, using PPS or PEI as matrix materials.⁴⁴

Nondestructive Evaluation (NDE).—Fiber breakage during

fabrication, poor fiber-matrix adherence, and existence of voids and inclusions in polymer composites are potential causes of failure in service and are not detectable by visual inspection because the flaws are internal. Because composite production methods do not yield 100% products at or above specifications, the only way to ensure complete quality control is to examine each component before the assembly of critical structural parts. Several methods are under development or are being used for this purpose. These include ultrasonic inspection, infrared thermography, thermographic stress analysis, X-ray tomography, eddy current measurement, acoustic emission measurement, fluorescence spectroscopy, magnetic resonance imaging (MRI), and pulsed nuclear magnetic resonance (a variation of MRI).

Because of the lack of experience in longtime use of APC's and the variability of properties resulting from lack of uniformity in processing, much effort is being expended to evaluate new materials for deterioration of properties while in service. Nondestructive evaluation methods are being developed for both periodic inspection of components in use, as well as methods based on continual monitoring during service. Two methods presently under development involve the incorporation of pressure sensitive detectors (piezoelectric or light emitters) into an assembly to detect deformation of a component or sound detectors to receive acoustic emissions from critical points in a component as a way to detect internal changes occurring in the component.

Although perfect adhesion at the fiber-matrix interface is generally thought of as the desirable condition, for certain applications the opposite may be true. For polymer composites used for ballistic armor, poor interfacial adhesion has been found to result in even better ballistic performance. S-2 glass fiber is used for reinforcement in this composite. In most cases, the desired phenomenon is for excellent fiber-matrix adhesion to allow stresses to be transferred from matrix to fibers. But in this application, controlled less-than-perfect adhesion maximizes the dissipation of impact energy because the

loosely bound fibers are able to "give" and absorb and distribute more of the impact energy from a ballistic projectile.⁴⁵ This composite offers the same structural performance and ballistic protection, has better corrosion resistance, and weighs 16% less than aluminum in the same application.⁴⁶ This is a good example of how control (achieved during processing) of structure can result in the improvement in properties desired for a specific application.

Outlook

The outlook for polymer composites is somewhat cloudy, reflecting the general economy. The transportation industry, however, as shown in table 13, is expected to continue to dominate the polymer composite market in the near term. The current recession, which has affected polymer composite shipments since 1988, may continue its negative effect in 1992 shipments. The largest slump is expected in the aerospace sector, which had been holding firm in spite of poor general economic conditions. The largest gain is expected in the construction area, which had slumped badly in 1991. Most sectors are expected to hold steady or achieve small increases for 1992. Major U.S. auto manufacturers plan to produce cars and small trucks with more plastic components ranging from fenders (some 1993 Chrysler models) to all-body panels (General Motor's planned electric cars for 1994) to meet the demands for fuel efficiency, which is most readily achieved by weight reduction. With the anticipated price reductions, due mostly to improved processing methods, polymer composites should resume penetration of the aerospace, corrosion-resistant products and electrical markets. The long-term outlook for polymer composites is continued growth.

The increased use of polymer composites in military aircraft during the past 20 years has proven that they can perform in critical applications. The concern for increased fuel efficiency in the commercial aerospace market is driving the penetration of APC's into this

field of application. Long-range projections for commercial aircraft indicate record growth. It is expected that almost 10,000 planes valued at \$626 billion will be delivered between 1990 and 2005 according to a Kline & Co. report.⁴⁷

Starting in 1992, after having increased percentages annually, the Department of Defense requires that a minimum of 50% of PAN carbon fiber procured for the military be obtained from domestic sources. This requirement has driven increases in domestic capacity. But expected cuts in defense orders have dampened expectations of continued growth at rates greater than 15% to 20% annually for this advanced reinforcing element.⁴⁸

Reduction of costs through more efficient production and the development of more nonmilitary applications are factors that should brighten the outlook for APC's.

ADVANCED ALLOYS, METAL MATRIX COMPOSITES, AND CARBON-CARBON COMPOSITES

Background

Definitions, Grades, and Specifications.—Metallic alloys are materials formed by combining one metal with other metal(s) or nonmetal(s) to develop a new material that has physical, mechanical, and/or thermal properties superior to the original materials. Steels (iron-carbon), stainless steels (iron-chromium-nickel), brasses (copper-zinc), bronzes (copper-tin), and aluminum alloys are the most widely known alloys. New compositions of these and other alloys are constantly being developed. Advanced alloys are usually highly complex materials, such as the superalloys that contain nickel or cobalt with significant amounts of chromium and are used frequently at temperatures above 500° C. The superalloys are perhaps the oldest of the advanced materials, originally developed for aircraft engines during World War II. Even though

alloys originated so long ago that we use some of them to name the ages of humankind, there have recently been major advances in developing superalloys, powder metal applications, light metal alloys, metal matrix composites (MMC's), and others, as well as new processing technology. These developments have been a major contributor to the current interest in advanced materials. Compositions of typical superalloys, their room temperature and high-temperature strengths, and their applications are shown in table 14.⁴⁹ (See table 14.)

For many years, aluminum alloys, superalloys, and titanium alloys have been the "backbone" high-performance metals used in both civilian and military aerospace systems. With the military applications leading the way, these systems have long represented the highest of "high tech" in structural materials. Aluminum alloys have been the main material for airframes, while the heavier superalloys and for some components, titanium alloys, have been the enabling technologies for aircraft engines. While new processing techniques have resulted in performance improvements in these alloys, they are currently approaching their technological limits. The development of a new generation of materials is necessary to achieve the dramatic performance improvements needed to sustain U.S. dominance in the worldwide aerospace industry. While ceramics and polymer matrix composites will undoubtedly be significant members of this new family of materials, new metal-based systems will also be important. Included among the most promising of these new metal systems are MMC's, intermetallics, and new aluminum alloys.

MMC's are metals or metal alloys reinforced with ceramic fibers, whiskers, or particulates. Because of their superior mechanical strength and unique physical characteristics, such as low thermal expansion, MMC's find applications in structural and nonstructural components alike. They combine metallic properties (ductility and toughness) with ceramic properties (high-temperature strength and

high stiffness) to offer greater strength in shear and compression and higher surface temperature capabilities. Some laboratory development of MMC's began in the 1960's, but the first commercial application was an MMC diesel engine piston introduced in 1983 by Toyota. Since then nearly every automobilemaker has done some R&D on this application. The continued increase in interest in MMC's for applications in aerospace, automotive, and other markets has been enhanced by the availability of relatively inexpensive reinforcements. For example, the average price for silicon carbide particulate used in aluminum MMC's is about \$2.50 per pound. Also helpful is the technique of simply "inserting" a part made of new material into an existing assembly when the match is close enough in geometry and properties between the old and new part. This technique gives a manufacturer valuable experience in utilization of the new material.

Aluminum alloys are heavily predominant as metal matrix materials, followed by magnesium, copper, and titanium alloys. Reinforcement materials for MMC's include the compounds silicon and boron carbides (SiC, B₄C), silicon and aluminum nitrides (Si₃N₄, AlN), and oxides (Al₂O₃, SiO₂), as well as elemental materials, such as carbon. Examples of use include silicon carbide in aluminum and magnesium MMC's in all three standard forms (fiber, whisker, and particulate). Carbon is ordinarily used as a continuous fiber reinforcement. Discontinuously reinforced MMC's employ particulates, whiskers, or short fibers as reinforcing components. Table 15 lists the currently available fibers, whiskers, and particulates for reinforcing aluminum in composites. The suitability of these materials for fabrication by standard metalworking processes has brought considerable attention to this class of MMC's in recent years.

Carbon-carbon composites have unique properties. They are lightweight, have high strength, and maintain their properties to temperatures above 2,000° C (3,650° F) in nonoxidizing atmospheres. Above 425° C (800° F),

they must be coated or contain oxidation inhibitors to be used long term in an oxidizing atmosphere. They have high modulus and low creep. (They are stiff and deform only slightly at high temperatures under load over time.) Their high strength and low coefficient of thermal expansion provide good thermal shock resistance. (See table 15.)

Industry Structure.—Neither metal matrix nor carbon-carbon composites have reached a mature industry level. Both are still growing, in the number of applications as well as in the amount and value of material produced. Figures 7 and 8 show that both industries are dominated by small- to medium-sized companies, an indication of continued growth potential. (See figures 7 and 8.)

Technology.—Processing.—Metal refining methods, such as vacuum induction melting, vacuum arc remelting, and electroslag remelting, have allowed metallurgists to produce alloys of high cleanliness and extremely low impurity levels. New processing methods, such as directional solidification, single crystal growth, hot isostatic pressing, mechanical alloying, and rapid solidification, have been used to fabricate alloys with refined and controlled microstructures, resulting in the achievement of tailormade properties.

In some cases these new processes enable the production of "impossible alloys." Just as oil and water "do not mix," some metallic elements do not form solutions with each other. Through ordinary solidification, these insoluble metals would separate into at least two separate phases, and any product made would likely be brittle. But by using rapid (through millions of degrees per second) solidification, atoms of the different metals are "frozen" together before they have time to separate, forming a solid solution that could never be produced with conventional processing.

The fabrication of MMC's can range in complexity, from simple pouring of molten metal into molds containing

preformed fiber reinforcement skeletons, to intricate methods involving partially solidified metal, vigorous agitation, and/or the use of high pressure or vacuum to quickly force the molten metal into a mold. Each method offers its own particular advantages in terms of cost, protection of reinforcement, and adaptability. A number of processing methods suitable for advanced structural ceramics are also applicable to MMC's.

MMC's are often processed in two stages. First, a special process is used to produce a composite "preform" containing the specified amounts of reinforcement and matrix. Then standard metalworking processes are used to shape the composite to the desired configuration. For example, composite preforms can be fabricated by coating carbon fibers with condensed aluminum vapors using either chemical or physical vapor deposition. These carbon-reinforced aluminum preforms are subsequently consolidated using hot pressing techniques. Hot rolling or hot isostatic pressing could also be used for the consolidation step.

"Compcasting" is another technique for preparing MMC's. The reinforcing particles are introduced into a vigorously agitated, nearly solidified melt or slurry. The viscosity of the melt or slurry is controlled to maintain a uniform distribution of the reinforcement.

The Duralcan process involves adding SiC powder to aluminum alloys. Proprietary pretreatment of the particles and a specially designed stirrer to mix the particles in the melt are the technical keys to the process. After mixing, the composite is solidified relatively quickly using a direct chill water cooled mold. This preserves the uniform distribution of reinforcement particles. The ingots produced are then remelted and cast into the desired shapes. More than 70 foundries have successfully remelted and cast ingots from this process.⁵⁰

Applications.—MMC's are already used in several applications. Boron-fiber-reinforced aluminum tubes are used as cargo bay struts in the space shuttle and some sporting and recreational goods

such as skis and bicycle frames. Aluminum-base MMC's are finding additional applications in airframes and other aircraft applications.

Lockheed is using MMC's in the vertical tail fins for the Advanced Tactical Fighter. This application results in a 25% weight reduction over current tail fins. Pratt and Whitney Aircraft is developing a fan blade for jet engines, utilizing an aluminum matrix composite with continuous boron fiber reinforcement wrapped around a titanium core. Aerospace optical systems requiring high stiffness and low coefficient of thermal expansion (CTE) have been produced using Duralcan composites.

Duralcan automotive brake rotors save one-third of the weight of cast iron rotors and have low thermal expansion, better wear resistance, and excellent thermal conductivity. Automotive pistons take advantage of this composite's high wear resistance, low CTE, and high-temperature strength. Additional automotive applications will include rocker arms and cylinder heads.

Other products fabricated in foundries using Duralcan include microelectronics packaging, electro-optical platforms, ballistic armor, and various structures requiring stiffness and good high-temperature properties.⁵¹

The future will bring titanium-base MMC's now being developed for turbojet compressors and superalloy-base MMC's for thrust turbine airfoils. Potential commercial applications of MMC's are listed along with their special properties in table 16. (See table 16.)

Recycling.—In the metals industry, making use of alloy scrap is common practice. Scrap metal is usually less expensive than primary metal and sometimes more available. There can be a problem, however, with contamination in any complex alloy, especially the superalloys. The recycling chain begins with scrap produced from alloy production with contributions of "prompt scrap" from parts fabricators and other users of superalloys, mainly builders of engines for commercial airliners or military aircraft. A user is any

organization that uses a finished product until the product is retired from service owing to wear, corrosion, inefficiency, or obsolescence. The user generates "obsolete scrap" when equipment is overhauled and parts replaced, or when equipment is dismantled at the end of its useful "lifecycle." The scrap is usually in the form of solids, such as turbine blades and vanes. A recent U.S. Bureau of Mines study indicates that while most of the superalloy scrap generated is recycled into new superalloys, up to 30% of it is downgraded or discarded. This represents an area where research is needed to maximize conservation of these valuable materials.⁵²

Because the reinforcement elements would become a contaminant if allowed to remain mixed with the matrix material during remelting, segregation of MMC's from nonreinforced alloys is necessary before recycling. Bureau research has shown that it is possible to separate conventional Ti-6Al-4V alloy from the same alloys reinforced with SiC or B₄C fibers using eddy current measurements. Bureau researchers have succeeded in separating aluminum alloys from aluminum-lithium alloys using eddy current measurements. Because these techniques make use of differences in electrical conductivity to make the separation, they should work for separating aluminum metal matrix composites from unreinforced aluminum alloys.

If the metal and reinforcement do not interact chemically at the melting point of the metal, a physical separation, such as filtration, would be effective in separating matrix material from reinforcements. The U.S. Bureau of Mines has conducted preliminary research on this approach using various filter media.⁵³ However, if significant chemical reactions occur, the fibers usually will be damaged, and often special techniques would be needed to clean up the now contaminated melt. Currently, the amount of MMC's producing obsolete scrap is very low, but recycling is expected to increase significantly as the acceptance of these materials increases.

Significant amounts of recycling already occur with certain MMC's. Contrary to the commonly held impression that MMC's are always difficult to recycle, the Duralcan MMC foundry ingot is inherently recyclable because when it is remelted and cast to shape in the foundry, after original purchase, the reinforcing particles remain well distributed with only gentle stirring and there is no loss of properties. Theoretically, when its useful life is completed, the product could be remelted and cast still another time. Currently, most of the scrap recycled is prompt scrap, gates and risers from foundry ingot, extrusion butts, cut extrusion scrap, etc. This material is recycled back through the basic Duralcan composite stirring process.

If desired, the reinforcing particulate can be removed from the molten composite by the same fluxing methods, such as salt fluxing, used to remove oxide films, etc., from ordinary aluminum alloys. The result is an aluminum alloy, free of particulate, "reclaimed" to its original alloy state before the composite was produced.

Annual Review

Consumption and Uses.—The estimated 1991 U.S. market for 330,000 pounds of metal matrix composites is \$33 million or 61% of the world market. This represents an 8.3% decrease in value and weight compared with those of 1990. Figure 9 (Kline & Co.) shows the 1991 U.S. market by end-use industry. These data show \$4 million (170,000 pounds) for automotive; \$26 million (145,000 pounds) for aerospace; \$2 million (10,000 pounds) for recreational; and \$1 million (5,000 pounds) for other. The heavy use of metal matrix composites in aerospace programs and current and anticipated cutbacks in these programs helps explain why there was a decrease in value produced and a drop in how much material was consumed. (See figure 9.)

Kline & Co.'s estimated 1991 U.S. market for 375,000 pounds of carbon-carbon composites is \$125 million. This represents a 16.7% decrease in value and

a 25% drop in weight compared with those of 1990. Figure 10 (Kline & Co.) shows the 1991 U.S. market by end-use industry. These data show \$32 million (265,000 pounds) for aircraft brakes; \$67 million (50,000 pounds) for nose tips and ablatives; \$22 million (25,000 pounds) for rockets and nozzles; \$2 million (20,000 pounds) for racing brakes; and \$2 million (15,000 pounds) for other. The heavy use of carbon-carbon matrix composites in aircraft brakes helps explain why there was a decrease in value produced and material consumed. (See figure 10.)

World Review.—The estimated 1990 worldwide market for 1.2 million pounds of metal matrix composites was \$60 million for four different applications (figure 11): automotive (\$15.6 million), aerospace (\$42.0 million), recreation (\$1.2 million), and other (\$1.2 million), according to Kline & Co. In 1991, Kline & Co. reported that the world market dropped to \$54 million (10% decline), paralleling the sluggish domestic and world economies. Total usage also dropped to 980,000 pounds (18% decline) in 1991. Figure 12 shows data for the four applications: automotive (\$11 million), aerospace (\$40 million), recreation (\$1.5 million), and other (\$1.5 million). (See figures 11 and 12.)

A notable feature in figure 11 is the difference in the aerospace industry's share in terms of weight and dollar values; only 15% by weight, the aerospace share accounts for 70% of the value. This indicates that the average cost of MMC's for aerospace applications is an order of magnitude higher than those for automotive and other applications. These higher costs are attributed to labor-intensive fabrication and low-volume production.

Again, according to Kline & Co., in figure 13, North America accounted for 56% of the 1991 worldwide value of MMC's, mainly due to the high cost of composite materials used by the aerospace industry. The Pacific Rim (mostly Japan) share is only 20% of this worldwide market in terms of value.

However, it should be noted that Japan is the leading consumer of MMC components, in terms of weight, mainly because of its production of MMC engine pistons. For 1991, the Pacific Rim production was 45% of the world total by weight. North America was rated at only 36% on the same basis. It appears that a variety of aerospace applications will become large markets for MMC's. Military jet and rocket structures are specific target areas for MMC's. (See figure 13.)

The estimated worldwide market in 1990 for carbon-carbon composites was \$200 million for four different applications (figure 14): aircraft brakes (\$50 million), rocket nozzles (\$70 million), nose tips-ablatives (\$64 million), and other (\$16 million). According to Kline & Co., the United States represented 75% of the 1990 worldwide carbon-carbon composite market, primarily owing to its dominance in military and aerospace technology. Western Europe and Japan account for the remaining 25% of market share. (See figure 14.)

In spite of recent predictions of more than 10% growth per year, the estimated world market for carbon-carbon composites in 1991 is estimated as shown in figure 15 to be only \$175 million, with aircraft brakes and rocket nozzles dropping down below \$40 million, while nose-tips and ablatives increased to \$90 million and other uses held steady. The total usage dropped from 675,000 to 515,000 pounds. This decrease is due to an overall sluggish economy combined with current and anticipated cuts in defense spending owing to the winding down of the cold war and the quick success in the Persian Gulf war. Figure 16 shows that the United States maintained its position holding 74% of the market share. (See figures 15 and 16.)

Current Research.—Matrix fiber adherence is an important factor in determining MMC properties. Optimum adherence of the matrix to the reinforcement often involves some degree

of chemical reaction between the matrix and the reinforcement. However, if the reaction is too extensive, degradation of the reinforcement may limit the strength of the composite. The lithium added to aluminum alloys to enhance wetting during the formation of aluminum-alumina fiber composites (in addition to adding strength and stiffness to the matrix) reacts strongly with the fibers. The composite must be infiltrated and cooled quickly or the Al_2O_3 fibers will lose their integrity and will add nothing to the properties of the composite. In another example, nonheat-treated boron-fiber-reinforced aluminum fails during fracture through debonding at the fiber-matrix interface. After heat treatment of the composite at 300° C, in an inert atmosphere, the room temperature strength increases and fracture occurs within the fiber itself, rather than along the fiber-matrix interface. Through a properly controlled reaction, the interface has become stronger than the fiber. Additional research is necessary to improve the ability of the materials engineer to control the reactions at the fiber-matrix interface to develop optimum adherence between the reinforcing phase and the matrix.

The most recent developments in MMC technology utilize the wrought alloy series rather than the casting alloys as a basis for matrix materials. BP Metal Composites in England is developing composites based on Alloy 2124, a high-strength, fracture tough alloy, and Al-Li Alloy 8090, a new, strong, stiff alloy with lithium, using 17% SiC particles for reinforcements for both. The resulting composites have excellent stiffness. Composite billets are made using powder metallurgy techniques. Conventional and superplastic metalworking techniques are then used to form sheet, plate, extrusions, forgings, or specific parts. Access panels, extruded floor-beam struts, and missile control fins have been fabricated as demonstration aerospace parts.⁵⁴

Advanced Composite Materials Corp. (ACMC) of Greer, SC, is also developing aluminum composites based on the wrought alloy series. Their composite 2009/SiC has the strength and density of

high-strength 7XXX aircraft alloys and the stiffness of titanium. Alloy 2009 contains 3.6% copper and 1.3% manganese. Powder metallurgy techniques are used to produce billets, which are then extruded, rolled, or forged. They can be processed by any metalworking operation that does not require melting. The finished products are stronger and more ductile than equivalent ones made from cast billets. Any desired product can be fabricated using conventional shop procedures. Lockheed is currently testing prototypes of a vertical tail stabilizer for an advanced jet fighter made from this material.⁵⁵ ACMC is also exploring the 6XXX series aluminum alloys (which contain magnesium and silicon as alloying elements) and high-temperature aluminum alloys made by rapid solidification for use as matrix materials for composites.⁵⁶

Outlook

The already intense intermaterial competition between different materials systems for the various sectors of industry will increase in the near and long term due to anticipated decreases in defense spending. For the materials systems that have been able to take advantage of the performance at any price philosophy of military procurement, there is danger of near-term downturns in applications because this philosophy can no longer prevail. In the ordinary consumer world, the materials that provide adequate performance at the best price will prevail; the continued success of much of the new materials industry will be dependent on the ability of developers to find effective nonmilitary applications of these materials. For any materials that are heavily dependent on military applications, the picture has become cloudy, at best. The bright side of this phenomenon is that more work in the development of commercial applications will become imperative, rather than an afterthought. With more emphasis on commercial applications of these new materials the United States is more likely to succeed in the economic "wars."

New alloys that are lighter, stronger, tougher, more fatigue and corrosion resistant will always find increasing use if they can be manufactured at competitive prices. Thus, new aluminum and magnesium alloys will continue to chip away at the dominance of steel where lower density has become a desired property as in the automobile industry. New titanium alloys will be applied in cases where lightweight and good high-temperature properties are important.

MMC's saw a drop in nearly all areas in 1991. The only bright spot was in the recreation area, where performance at any price is second only to defense applications. In this area, an excellent 25% increase in sales occurred, overcoming a 10% drop for the entire MMC sector. As more commercial applications are developed, the MMC industry should resume its growth.

Because of its heavy use in defense applications, perhaps the picture for carbon-carbon composites is the most cloudy. To meet the mandated requirement for a 50% domestic supply of PAN fibers, domestic capacity has been increasing over the past few years. Demand has not kept up. Capacity has outstripped demand both domestically and worldwide. At slightly more than \$300 per pound for an average price, this material is quite expensive. Accordingly, most of its growth must occur in sectors where no competing material can come close to doing the job. Therefore, opportunities for growth appear to be somewhat limited for the near term, until more varied applications of this material can be found.

POWDER METALLURGY

Powder metallurgy (P/M) is an ancient technique. The tungsten filament produced in 1910 for the electric light was the first modern P/M product. More recently, the 1970's saw rapid solidification processing (RSP) become a powder production method, and the 1990's have seen the development of metal injection molding (MIM) as a parts production method.

Background

Definitions, Grades, and Specifications.—P/M is a high precision method of forming metal components. The use of P/M permits the fabrication of complex metal shapes with little or no machining, provides excellent control over dimensional tolerances and surface finishes, and decreases scrap losses when compared to conventional metalworking processes.

Products for Trade and Industry.—Iron, stainless steels, aluminum, copper, brasses, bronzes, nickel, and tin are the most commonly used powder metals and alloys. Other important factors in the P/M industry are titanium, the compound tungsten carbide, and the refractory metals tungsten, molybdenum, and tantalum.

Industry Structure.—There are about 50 domestic producers of powder metals and about 200 fabricators of parts using these materials. About 70 fabricators manufacture specialty P/M products like superalloys, tool steels, porous alloy products, magnetic materials, RSP and MIM products, alloy strip for electronic applications, and tungsten carbide cutting and wear parts, etc. The majority of P/M fabricators produce conventional P/M products from mostly iron- and copper-base powders.

Technology.—Processing.—The most common methods of powder production are reduction of oxides or other chemicals, electrolysis, and atomization of molten metal. RSP is a newer method for powder metal production. In this process the molten alloy is solidified at rates equivalent to millions of degrees per second. RSP is used to produce wrought aluminum alloys that are stronger and have greater fracture toughness, corrosion, and fatigue resistance than conventionally produced aluminum alloys.

The basic method used to produce parts from powder metals involves high

pressures and heat. The powder is pressed in a precision die at pressures up to 50 tons per square inch to form a useful shape such as a gear. Ordinarily, the powder is pressed at room temperature and then heated in a controlled atmosphere so that a metallurgical bond is formed between the powder particles. No melting occurs during this sintering process. The bulk density of the powder increases during both the pressing and sintering processes so that the finished product is as dense or nearly so, compared to a product made using a molten metal step.

Other processes used for powder metal consolidation include hot or cold isostatic pressing, forging, direct powder rolling, and MIM, a newly developed method. In MIM processing, fine metal powders are injected into a mold along with an organic binder, such as wax. The organic binder is burned off from the molded part, and the component is sintered to final shape. It is possible to produce very complex parts of many sizes and shapes using MIM.

Design engineers are becoming more comfortable with MIM and are designing parts for high-performance components. With the full implementation of MIM by the automotive industry, P/M could return to steady growth for some years. Current MIM automotive applications include ignition lock and truck manual transmission parts. GM and Chrysler are contemplating the use of MIM parts for small truck transmissions, fuel injection systems, and brakes. Even without major cost breakthroughs, total sales in the MIM area could reach \$100 million before the turn of the century.

Applications.—P/M parts are currently used in many different kinds of items, from lock hardware to Canadian nickels. P/M is utilized in various small- to medium-sized appliances such as power tools and hardware, copiers and postage meters, washing machines, garden tractors, snowmobiles, automatic transmissions for automobiles, and sporting equipment such as fishing rods and guns. Current domestic passenger cars contain about 25 pounds of P/M

parts. Although some of these applications appear mundane, it is the fabricator's use of advanced processing of new materials that gives them a competitive edge over other makers of similar products.

Annual Review

More than 800,000 tons of metal powder is produced annually, worldwide. The total value of domestic metal powder shipments, including paste and flake, was \$1.2 billion in 1990 when the amount produced in North America was slightly less than 300,000 tons. The powder metal parts and product industry is a \$2 billion business in North America, indicating that the value added during fabrication is nearly equal to that of the powder as a raw material. Shipments in the P/M industry decreased uniformly during 1991 as shown in table 17.⁵⁷ The slight decrease for each major area of the industry reflected continued downturns or slow recovery in the national economy. (See table 17.)

Outlook

The slight downturn for 1991 for powder metals was due to general economic conditions rather than a real softening of demand for powder metal products. The general trend for annual increases should resume in 1992, unless the general economy proves to be very sluggish. With greater implementation of new processes and the resulting increases in efficiency, growth should continue in this sector of the materials industry.

TABLE 1
COMPARISON OF GOVERNMENT LISTS OF IMPORTANT TECHNOLOGIES

National critical technologies	Commerce emerging technologies	Defense critical technologies
Materials:		
Materials synthesis and processing and electronic and photonic materials	Advanced materials, advanced semiconductor devices, superconductors	Composite materials, semiconductor materials and microelectronic circuits, superconductors.
Ceramics, composites, high-performance metals and alloys	Advanced materials	Composite materials.
Manufacturing:		
Flexible computer-integrated manufacturing, intelligent processing equipment, micro- and nanofabrication, systems management technologies.	Flexible computer-integrated manufacturing and artificial intelligence.	Machine intelligence and robotics.
Information and communications:		
Software	High-performance computing	Software producibility.
Microelectronics and optoelectronics	Advanced semiconductor devices	Semiconductor materials and microelectronic circuits.
	Optoelectronics	Photonics.
High-performance computing and networking	High-performance computing	Parallel computer architectures.
High-definition imaging and displays	Digital imaging	Data fusion.
Sensors and signal processing	Sensor technology	Data fusion, signal processing, passive sensors, sensitive radars, machine intelligence and robotics.
Data storage and peripherals	High-density data storage	Photonics.
Computer simulation and modeling	High-performance computing	Simulation and modeling, and computational fluid dynamics.
Biotechnology and life sciences:		
Applied molecular biology and medical technology	Biotechnology and medical devices and diagnostics	Biotechnology materials and processes.
Aeronautics and surface transportation:		
Aeronautics and surface transportation technologies		Air-breathing propulsion.
Energy and environment:		
Energy technologies and pollution minimization, remediation, and waste management		No national critical technologies counterpart: high energy density materials, hypervelocity projectiles, pulsed power, signature control, and weapon system environment.

Note.—National critical technologies were designated by the National Critical Technologies Panel; emerging technologies were designated by the U.S. Department of Commerce; defense critical technologies were designated by the U.S. Department of Defense.

TABLE 11
POLYMER MATRIX COMPOSITES FABRICATION METHODS OPEN MOLD TECHNIQUES

Process	Predominate polymer processed	Materials type or form	Shape characteristics	Process description
Open mold (contact molding)	Thermosetting (primary reinforced polymer forming process 40% of total)	Liquid resin (spray, hand applied) or thermoplastic sheet; reinforcing material	Large complex	Reinforced shapes are formed by using open molds, and room-temperature curing resin is brushed, poured, or sprayed onto reinforcing material laid up in a mold. Spray up method resin and chopped fibers sprayed onto mold. Reinforced vacuum formed sheet method—mainly acrylic sheet is vacuum formed and reinforced resin applied to back surface. The process also includes encapsulating or potting.
Continuous laminating	Polyester	Resin, reinforcement	Thin, flat or curved profiles	Reinforcement is passed through a resin bath, faced with cellophane, passed through squeeze rolls, and heated.
Filament winding	Epoxy, polyester	Resin	Round, rigid	Continuous filament (usually glass) in form of roving is saturated with resin and machine wound onto mandrels having shape of desired finished part. Once winding is completed, part and mandrel are placed in oven for curing. Mandrel is then removed through porthole at end of wound part.
Pultrusion	Thermosetting (polyesters, some epoxies, and others)	Liquid resins, fiber reinforcement	Uniform cross section	Resin-swelled fibers are pulled through a heated shaping die, which initiates cure in the thermosetting resin and forms the shape of the continuous length of pultruded product.
Centrifugal casting	Thermosetting	Liquid resin, fiber reinforcement	Uniform wall thickness	Resin is applied to the inside of a rotating cylindrical mold and is uniformly forced against the reinforcing material. Heating aids flowing and curing.

TABLE 12
POLYMER MATRIX COMPOSITES FABRICATION METHODS CLOSED MOLD TECHNIQUES

Process	Predominate polymer processed	Materials type or form	Shape characteristics	Process description
Reaction injection molding (RIM)	Thermosetting (urethanes)	Liquid	Large, intricate, high-performance, solid, or cellular	Reactive components are generally mixed by impingement in a chamber and then injected into a closed mold.
Laminates, high pressure-industrial and decorative	Thermosetting	Reinforcement—fiber sheet/prepregs, liquid resin	Thick walled, simple shapes	Reinforcing material (layers) is preimpregnated or soaked with resin (sometimes a thermoplastic). Compressed under pressure over 1,000 pounds per square inch into a flat sheet. Tube and rod shapes also made from rolled or closed mold methods. Prepregs are semicured reinforced materials used to make above forms. Decorative laminates may have a separate patterned face-sheet laminated to the structure.
Match die molding (low pressure)	Thermosetting (epoxy, polyester, and others)	Reinforced plastic compounds or resin and reinforcing material	Contoured, medium wall thickness	Either preforms (chopped glass fibers/resin shape) or a premix molding compound (resin and short glass fiber strands) are placed in mold, heated, and pressed to shape.

ALUMINUM, BAUXITE, AND ALUMINA

By Patricia A. Plunkert and Errol D. Sehne

Ms. Plunkert, a physical scientist with 23 years U.S. Bureau of Mines experience, has been the commodity specialist for aluminum since 1987. Domestic survey data for aluminum were prepared by Shonta E. Osborne, statistical assistant; and international data tables were prepared by Audrey D. Wilkes, international data coordinator.

Mr. Sehne is a physical scientist with 18 years of minerals industry and U.S. Bureau of Mines experience. Domestic survey data for bauxite and alumina were prepared by Susan M. Copeland, statistical assistant; and international data tables were prepared by Harold D. Willis, international data coordinator, and William L. Zajac, Chief, Section of International Data.

Aluminum is the second most abundant metallic element in the Earth's crust after silicon, yet it is a comparatively new industrial metal that has been produced in commercial quantities for just over 100 years. It weighs about one-third as much as steel or copper; is malleable, ductile, and easily machined and cast; and has excellent corrosion resistance and durability. Measured either in quantity or value, aluminum's use exceeds that of any other metal except iron, and it is important in virtually all segments of the world economy.

In 1991, the aluminum market was characterized by weak demand, a high metal production level in the Western World, and increased exports from the former U.S.S.R. As a result, the price of primary aluminum metal fell throughout the year and world inventories rose, especially those held by the London Metal Exchange (LME). The United States continued to be the world leader in primary metal production, producing more than 4.1 million metric tons of metal with an estimated value of \$5.4 billion.

World production of bauxite and alumina, feedstocks for the aluminum industry, declined slightly during 1991 in response to a stagnating demand for primary aluminum metal. Mine production of bauxite was reported from 27 countries, and alumina was produced in 24 countries.

DOMESTIC DATA COVERAGE

Domestic production and consumption data for aluminum, bauxite, and alumina are developed by the U.S. Bureau of Mines from five separate, voluntary surveys of U.S. operations. Typical of these monthly, quarterly, and annual surveys is the "Aluminum" survey. Of the 13 companies canvassed by this form, all responded, representing 100% of the total domestic primary aluminum production.

BACKGROUND

Definitions, Grades, and Specifications

Bauxite is a heterogeneous material chiefly composed of the aluminum oxide minerals gibbsite [$\text{Al}(\text{OH})_3$], the trihydrate, and boehmite and diaspore (AlOOH), the monohydrates.¹ Domestic bauxites and those imported from Brazil, Guyana, and Suriname are of the trihydrate gibbsitic type. Imports from the Sangaredi deposits of Guinea and the north coast of Jamaica are predominantly gibbsitic, but they also contain 4% to 10% of the monohydrate mineral, boehmite. In most European and northern Asian bauxite deposits, boehmite is the principal alumina mineral. Recovery of the aluminum oxide in boehmite requires a higher temperature and higher caustic concentration than is

needed in processing gibbsite. Major impurities in bauxite ores include iron oxides, silica, aluminum silicates, and titanium oxides.

Free moisture in crude bauxite, as mined, may range from 5% to 30%. To produce dried bauxite, most of the free moisture is removed by heating crude bauxite in rotary drying kilns at about 315° C. Calcined bauxite is produced by heating bauxite to 925° to 1,040° C to reduce total volatile matter, including chemically combined water, to less than 1%. Approximately 2 tons of crude ore is required to produce 1 ton of calcined bauxite.

Aluminum metal has a relatively low density, high electrical and thermal conductivity, good resistance to corrosion, and good malleability. It is nonmagnetic, nonsparking, and highly reflective. It may be alloyed and treated to yield a high strength-to-weight ratio.

Ingot is a cast form of primary or secondary metal that is convenient to handle and store and is suitable for fabricating or remelting. Commercial-size ingots normally weigh about 30 pounds; however, some ingots weigh up to 9 tons. A portion of both primary and secondary metal is sold and transported in molten form.

Commercially pure aluminum usually contains about 99.7% aluminum. In the annealed condition, it has low strength and is relatively soft. However, it is available in strain-hardened conditions of

higher strength and reduced ductility. Metal with more than 99.7% and up to 99.85% aluminum is available at higher cost than standard commercial metal. Superpurity aluminum contains a minimum of 99.99% aluminum.

Aluminum alloys have been developed that, after cold rolling, heat treating, annealing, or age hardening, have strengths approaching those of mild steels. More than 100 commercial alloys are available, and several new alloys are developed each year. The alloys offer a wide variety of combinations of mechanical strength, ductility, electrical conductivity, and corrosion resistance.

Aluminum alloys are generally divided into two major groups: wrought and casting. The Aluminum Association uses a code to designate the purity and alloy content of wrought alloys and to register the composition of casting alloys and ingot.

New aluminum-base scrap, generated in the production of intermediate and end products of aluminum metal, may be pure (unalloyed), segregated (one alloy type), or mixed (two or more alloys). It includes solids, such as new casting scrap; clippings or cuttings of new sheet, rod, wire, and cable; borings and turnings from the machining of aluminum parts; and residues, drosses, skimmings, spillings, and sweepings.

New scrap is further defined as either "runaround" (home) scrap or purchased scrap. Runaround or home scrap is new scrap that is recycled by the same company that generates it; such scrap by definition never leaves the company generating it and, therefore, is never marketed as scrap. Purchased scrap is new scrap that is purchased, imported, or treated on toll by secondary smelters, the original aluminum product suppliers, or others. New aluminum scrap that is purchased from manufacturers of end products may be referred to as consumer scrap. Purchased new scrap is sometimes referred to as prompt industrial scrap.

Old scrap, all of which is considered as purchased, comes from discarded, used, and worn out products. It includes aluminum pistons or other aluminum engine or body parts from junked cars,

aluminum used beverage cans (UBC) and utensils, and old wire and cable. Sweated pig is scrap that has been sweated or melted into a pig or ingot form for convenience and economy in shipping and storage. Obsolete scrap is new, unused, but technologically obsolete aluminum end products, outdated inventory materials, production overruns, and spare parts for machines and equipment no longer being used. In the United States, both sweated pig and obsolete scrap are considered old scrap.

Geology-Resources

Bauxite is formed by the weathering of aluminum-bearing rocks under conditions conducive to the chemical breakdown of minerals within the parent rock. In the weathering process, the aluminum is retained as hydrated aluminum oxide minerals and other constituents are leached from the parent rock. Conditions favorable for the formation of bauxite existed in areas and geological periods that provided warm wet climates, aluminous parent rocks with high permeability and readily soluble minerals, good subsurface drainage, and long periods of tectonic stability that permitted deep weathering and preservation of land surfaces.

Major bauxite deposits that supported the U.S. aluminum industry for almost 100 years were formed in central Arkansas by weathering of nepheline syenite intrusives during late Paleocene and early Eocene time.² The predominant aluminum oxide mineral that occurred within these now-depleted bauxite deposits was the trihydrate form, gibbsite. Some deposits were residual on the igneous rock and clay, while others were the result of transportation and accumulation of eroded deposits. Most of the deposits were subsequently covered by sand and clay beds. Bauxite ore ranged in thickness from a few feet to 65 feet and was overlain by a 40- to 150-foot layer of overburden. The composition of the ore mined in the Arkansas region varied widely within a range of 40% to 52% Al_2O_3 , 7% to 17% SiO_2 , and 6% to 12% Fe_2O_3 . Permanent closure of the

last remaining bauxite mining operations in Arkansas occurred in 1990.

The bauxite deposits currently mined throughout the coastal plain of Alabama and Georgia are found as lenses within flat-lying beds of kaolinitic clay, which are overlain by sand and clays of early Tertiary age. Average ore thickness is 10 feet, though locally 33-foot ore thicknesses have been encountered. Overburden, especially in the Alabama sinkhole deposits, can exceed 120 feet in thickness. The grade of the bauxite is 48% to 56% Al_2O_3 , 12% to 16% SiO_2 , and less than 2.5% Fe_2O_3 . The low iron oxide content permits this ore to be used in refractory and chemical applications. These specialty products often incorporate a natural mixture of bauxite and bauxitic kaolin.

In Jamaica, the bauxite deposits fill sinkholes and channels and blanket uneven depressions in the karst surface of a limestone of middle Tertiary age. Individual ore bodies range from pockets containing a few hundred tons of bauxite to basins containing millions of tons. The soil overburden is only 1 to 2 feet thick. Jamaican bauxite is largely gibbsitic, although mixtures containing up to 20% monohydrate alumina occur in some ores. Ore grade is 45% to 49% Al_2O_3 , 0.8% to 8% SiO_2 , 17% to 22% Fe_2O_3 , and 2.5% TiO_2 . The bauxite deposits in the Dominican Republic and Haiti are similar in grade, age, and genesis and are identified as "Jamaica-type" bauxites.

Bauxite deposits in Guyana and Suriname are scattered throughout a narrow belt extending along the contact between the Precambrian crystalline rocks of the Guyana Shield and the sedimentary beds of Tertiary or later age that form the coastal plain. These deposits usually rest on kaolinitic clay and range from exposed outcrops to ore bodies overlain by as much as 200 feet of sand and clay, although the average overburden is about 60 feet. Other deposits of bauxite and laterite occur in these countries at higher elevations south of the coastal belt. The alumina mineral is gibbsite and the ore is high grade; typically 55% to 60% Al_2O_3 , 2% to 5% SiO_2 , and less than 3% Fe_2O_3 .

Both countries have been exporters of refractory- and abrasive-grade bauxite.

In the large deposits discovered within northern Brazil since 1967, the bauxite occurs as a residual capping on dissected plateaus several hundred feet above the Amazon or other nearby rivers. The ore has developed on unconsolidated Tertiary sediments and is covered by 12 to 30 feet of kaolinitic clay. Ore thickness averages about 16 feet. The approximate grade after washing is 55% Al_2O_3 , 3.5% SiO_2 , and 11% Fe_2O_3 . Bauxites in northern Brazil and Venezuela are of the gibbsitic type and contain little monohydrate alumina.

The Weipa bauxite deposit in Queensland, Australia, occurs in the upper portion of a flat-lying laterite that extends for more than 100 miles along the west coast of the Cape York Peninsula. The bauxite ranges in thickness from a few feet to 30 feet and is covered by a soil overburden 1 to 3 feet thick. Average ore thickness is about 14 feet. The ore is basically gibbsitic, but some of the alumina is also present in the form of boehmite. The deposits are associated with Tertiary kaolinitic sands, from which they were probably derived. The grade of the beneficiated bauxite is 53% to 58% Al_2O_3 , 4% to 7% SiO_2 , and 12% Fe_2O_3 .

The Darling Range bauxite deposits in Western Australia occur as a residual capping on Precambrian granites, gneiss, and intrusive crystalline rocks. A thin, 1.5-foot blanket of soil mixed with loose pisolites covers the deposits. The top of the ore is characterized by a ferruginous hardcap about 6 feet in thickness. The deposits are characterized by a low alumina and a high quartz sand content; however, the reactive silica is typically less than 2%. General composition is 38% to 46% Al_2O_3 , 10% to 23% SiO_2 , 11% to 16% Fe_2O_3 , and about 4% TiO_2 .

In Guinea, the large Sangaredi bauxite deposits occur as laterite caps on inland plateaus at elevations of 900 feet or more above sea level. The deposits have been dissected by stream drainage systems. Most of the bauxite is believed to have formed through weathering of schists and sandstones of Devonian or post-Devonian

age. The thickness of the Sangaredi bauxite ore averages more than 65 feet and exceeds 130 feet in some places. Overburden, where present, consists of a thin topsoil. Typical ore contains 57% to 60% Al_2O_3 , less than 1% SiO_2 , and 2% to 4% Fe_2O_3 . The upper zone of the Sangaredi deposit contained only a few percent boehmite, but mining has progressed to lower benches where the monohydrate content has increased to almost 10%. To extend the overall life of the mining project, operations are currently being expanded to the adjacent Bidikoum ore body.

Many of the European bauxite deposits are associated with pockets and depressions in the karst weathering surface of Mesozoic limestone beds that have been buried, folded, and faulted subsequent to the development of the bauxite. European bauxites are composed predominantly of monohydrate alumina minerals, although some gibbsitic deposits are mined in Hungary and a few other countries.

In the past, the commercial production of primary aluminum has been based almost entirely on the use of bauxite. However, deposits containing aluminum in the other mineral forms are widespread and virtually inexhaustible. The average aluminum content of the Earth's crust has been estimated at 8.3% (15.7% on an Al_2O_3 basis), and deposits containing more than 13% aluminum (25% Al_2O_3) are common.

Information on bauxite reserves and resources varies from reports based on thorough exploration for some deposits to reports giving only a total quantity estimate based on unspecified fieldwork for other deposits. The reserve and reserve-base estimates in table 3 are the result of evaluating data and information obtained from many sources. The quality of bauxite deposits cannot be assessed by the alumina content alone because the mineralogical form in which the alumina occurs; its extractability in the Bayer process; the quantity of reactive silica present; iron content, including the ratio of ferric to ferrous iron; and other chemical and physical properties all affect the process cost and the alumina

recoverable from a given bauxite. The classification of undeveloped bauxite deposits as either reserves or subeconomic resources also is a matter of judgment because many factors other than grade influence the economics of mining, transporting, and processing the bauxite to alumina. The definitions of reserves and reserve base are published in U.S. Geological Survey Circular 831, "Principles of a Resource/Reserve Classification for Minerals."³

Past estimates of world bauxite reserves were about 1 billion metric tons in 1945, almost 3 billion tons in 1955, 6 billion tons in 1965, and about 21 billion tons in 1985. In 1991, they were estimated at approximately 23 billion tons. Guinea and Australia together possess nearly one-half of the world's known reserves. More than 25% occurs in the Western Hemisphere, principally in Brazil, Jamaica, Guyana, and Suriname. Estimates of additional bauxite classified as subeconomic, hypothetical, or speculative resources bring the total world resources of bauxite to within the range of 55 to 75 billion tons. Growth in reserves has roughly paralleled the expansion of world bauxite production capacity. Major new discoveries are the primary factor in reserve increases; however, production economies resulting from technological advances and large-scale operations have also permitted the inclusion of lower grade bauxite previously considered subeconomic.

Historically, the principal domestic sources of bauxite were in central Arkansas, where reserves were estimated to have been about 15 million metric tons prior to the permanent closure of the last mining operations in 1990. An additional 2 to 5 million tons of bauxite reserves in Alabama and Georgia are the principal source of domestic refractory and chemical bauxites.

The resources of bauxite in the United States, other than the present reserves, are chiefly in (1) large low-grade deposits containing substantial quantities of clay minerals in Arkansas, Alabama, and Georgia; (2) ferruginous bauxite deposits in Oregon and Washington; and (3) deposits of low-grade ferruginous bauxite

in soils and weathered basalts on Kauai and Maui, Hawaii. Inclusion of these low-grade resources increases the total estimated bauxitic resource in the United States to 290 to 315 million tons. The mining of some of these deposits may be restricted or prohibited because of environmental considerations such as their proximity to populated or scenic areas.

Nonbauxitic aluminum-bearing deposits in the United States that have received the most attention as potentially economic sources of aluminum include kaolinitic clays, anorthosite, and alunite. Other types of clays, shales, schists, nepheline syenite, and saprolite are also potential aluminum raw materials. In addition, the production of certain other mineral products yields aluminous materials that may be considered potential sources of metal. These include coal ash and coal mining refuse, copper leach solutions, aluminum phosphate rock, and dawsonite produced in conjunction with the mining of oil shales. (See tables 1, 2, and 3.)

Technology

Exploration.—The first stage of planning a bauxite exploration program usually entails a thorough study of regional geology, physiography, and any previous reports on exploration or mining operations within the area of interest. The initial regional appraisal should include a review of topographic maps (rarely available for remote tropical areas), aerial photographs, satellite imagery, and mosaics prepared from aerial side-looking radar (SLR) surveys. In the Amazon Basin of Brazil, where the dense rain forest canopy completely masks stream valleys, scarps, and plateaus, SLR methods have proven effective in revealing the hidden topography. Geobotanical techniques using true- or false-color air photos and satellite images have been used to identify vegetation types associated with aluminous laterites. Airborne radiometric surveys are useful in delineating exposed laterites by their typically elevated levels of radioactivity.

After specific target areas have been defined, reconnaissance by helicopter or fixed-wing aircraft can provide valuable accessibility and logistical support information. Surface prospecting for float samples in river drainage systems has long been a reliable guide in the discovery of bauxite deposits. Vertical channel sampling of indurated resistant outcrops exposed in stream valleys can often provide the first positive identification of the presence of bauxite. Detailed evaluation and development require drilling, pitting, or trenching to provide samples for chemical analysis. Surface mapping is essential to document drill collar and test pit locations and elevations.

Bauxite minerals are difficult to identify visually and require sophisticated laboratory techniques for quantitative analysis. Because of this requirement, exploration samples and development samples are often shipped to a major chemical laboratory for analysis. The most significant determinations are for alumina and silica content. Both "total alumina" and "available alumina" (alumina recoverable by both low- and high-temperature Bayer processes) are normally determined. In addition to "total silica," it is important to analyze for "reactive silica" because the latter combines with alumina and soda in the Bayer process to form sodium aluminum silicates that are lost in the red mud wastes. Iron oxides, titania, and loss on ignition are also routinely determined.

Mining.—Open pit mining has accounted for all of the bauxite mined in the United States in recent years and for approximately 95% of the world bauxite production. Restoration of the land surface at depleted bauxite mines is being accomplished in many parts of the world by preserving the topsoil stripped from the mine sites for later replacement on the reclaimed areas.

Before the closure of mining operations in Arkansas, draglines, scrapers, shovels, and trucks were used in the stripping of overburden. Stripping ratios as high as 13 feet of overburden to 1 foot of ore were utilized, and some surface pits in

Arkansas reached depths of approximately 200 feet. The pit walls of unconsolidated sand and clay were relatively stable; however, some slumping did occur. In the earlier phases of the mining operations, flat-lying ore was recovered by room-and-pillar mining along a retreating line of controlled rock collapse. Underground bauxite mining ceased in Arkansas in 1976, and the remaining surface mining operations were closed in 1990.

Surface mining methods and a similar mix of equipment are presently employed at the nonmetallurgical bauxite mining operations in the Eufaula district of Alabama and Andersonville district of Georgia.

In Jamaica, the bauxite deposits lie closer to the surface, and the overburden of vegetation and topsoil is easily stripped. The ore usually requires no blasting. Shovels, draglines, and scrapers are used to load the ore. Haulage is by truck, railroad, or aerial tramline to the alumina plants and port facilities. In Suriname and Guyana, up to 200 feet of overburden is stripped by draglines, scrapers, bucket wheel excavators, or hydraulicking. The ore is broken by blasting and loaded into ore cars or trucks with power shovels, backhoes, or draglines.

At Weipa, Australia, bulldozers and scraper loaders remove the few feet of overburden. Front-end loaders, each mining in excess of 500 tons per hour, then load the uncemented pisolitic ore into trucks for a relatively short haul to a beneficiating plant for sizing and washing. At the deposits in the Darling Range of Western Australia, forest clearing of vegetation and overburden removal are followed by blasting of the hardcap that comprises the top few feet of the bauxite deposits. Front-end loaders load dump trucks for haulage to a mobile crushing plant. Bauxite is carried from the crusher to an alumina plant by conveyer belt.

The Sangaredi deposits mined for the Boké project in Guinea have little overburden but require blasting. Loosened ore is loaded by electric shovels directly onto railcars for shipment

85 miles to the Kamsar treatment (drying and calcining) facility and port site.

Underground mining accounts for much of the current Greek and Hungarian bauxite production and is also employed in other parts of Europe, including the U.S.S.R. Room-and-pillar and various stoping methods are used. Underground water problems are common—especially in the Hungarian mines, where bauxite deposits are associated with the weathering of limestone. Here dewatering of underground workings has accounted for 10% to 15% of the mining cost.

Beneficiation.—Bauxite treatment is usually confined to crushing, washing, and drying operations. Most of the bauxites that are mined do not require the more costly beneficiation techniques used on some other metal ores. Moreover, most impurities such as iron, silicon, and titanium are frequently so finely dispersed in the bauxite that they cannot be readily separated by physical methods. Many bauxites are upgraded, however, by washing or wet screening to remove sand and some of the clay minerals (reactive silica).

Metallurgical and chemical grades of bauxite that must be transported appreciable distances are normally dried before shipment. Drying facilitates the handling of some bauxites, and the degree to which a specific bauxite is dried depends in part on its handling and dusting characteristics. Because crude bauxite may contain 10% to 30% free moisture, drying results in savings in freight charges that may more than offset drying costs. Bauxite from Guinea usually is dried to 3% to 6% moisture, whereas Jamaican bauxite is shipped with about 15% moisture. Bauxite for use in refractories and abrasives is calcined to remove both free moisture and chemically combined water.

Alumina Production.—Virtually all alumina produced commercially from bauxite is obtained by a process patented by Karl Bayer in 1888 (German Patent 43,977), although research on aluminum extraction from other mineral raw

materials has continued for many years. The Bayer process involves a caustic leach of the bauxite at elevated temperature and pressure, followed by separation of the resulting sodium aluminate solution and selective precipitation of the aluminum as the hydrated aluminum oxide [$\text{Al}(\text{OH})_3$].

The actual processing conditions such as the leach temperature, holding time, and caustic concentration, as well as the costs, are influenced by the type of bauxite to be processed. As a result, a Bayer alumina plant is designed to treat a specific type of ore and, in general, cannot use a bauxite that is markedly different from the one the plant was originally designed to use without major plant modifications. The Bayer process is initiated by mixing crude bauxite with preheated spent leach solution. Lime is added during this initial step to control the phosphorus content and to increase the solubility of alumina within the plant feed. The resulting slurry, containing 40% to 50% solids, is pumped with additional caustic leach solution to pressurized digesters where high-pressure steam is used to raise the temperature. Alumina and some of the silica are dissolved during this step, soluble sodium aluminate is formed, and a complex sodium aluminum silicate is precipitated from the process stream.

Digestion, in tanks 10 to 15 feet in diameter and up to 90 feet high, takes up to 5 hours. Leaching temperatures range from about 105° C to about 290° C, with corresponding pressures ranging from about 60 pounds per square inch (psi) to more than 1,000 psi. The lower temperature ranges are used for bauxites in which nearly all of the available alumina is present as gibbsite. The higher temperatures are needed to digest bauxites having a large percentage of boehmite. Caustic concentration of the spent leach solution, expressed as grams per liter of sodium carbonate (Na_2CO_3), averages about 200 grams per liter for gibbsitic bauxite and about 300 grams per liter for bauxites with a high boehmite content.

The resulting slurry of sodium aluminate solution and insoluble red mud from the digesters is cooled to

atmospheric boiling temperature, and a coarse sand waste fraction is removed by gravity separators or wet cyclones. The fine solids in the red mud are then separated by decantation of the overflow in settling tanks measuring about 15 feet in depth and 50 to 125 feet in diameter. A flocculant such as starch is added to increase the settling rate of the red mud particles. The overflow from the settling tanks containing the alumina in solution is clarified by filtration and placed into precipitating tanks ranging in size from 25 to 30 feet in diameter and up to 80 feet in height.

The clarified sodium aluminate liquor is cooled until it becomes supersaturated, then seeded with fine crystals of alumina trihydrate. The alumina is precipitated as the trihydrate, separated by sedimentation or filtration, and washed. The spent leach solution containing caustic soda is regenerated in the precipitation step, and together with the alumina remaining in solution, is recycled to the digesters. The filtered and washed alumina trihydrate is calcined for use in making aluminum metal. A portion of the washed alumina may be left in the trihydrate form for chemical uses or it may be further processed under controlled conditions to produce a variety of chemical aluminas, such as activated or tabular alumina for uses other than metal production.

Two forms of calcined alumina are used to produce aluminum. European Bayer plants have traditionally produced a fine-grained, highly calcined, flourey alumina while North American Bayer plants have always produced a coarser grained, porous, sandy alumina that has not been totally calcined to the alpha alumina stage (artificial corundum). The relatively large surface area of the sandy alumina particles compared with the flourey alumina particles permits their use as an absorbent in dry scrubber units at primary aluminum smelters. Fluorine in the gases emitted from the smelter's potlines is trapped by the alumina and is later recycled when this sandy alumina is used as feed for metal production in the facility's reduction cells. Pressure from environmental regulations and improved economics through recovery of fluorine

have been important factors in the conversion of world alumina plants to produce a sandy rather than a floury alumina product.

The red mud waste stream contains Fe_2O_3 , TiO_2 , the sodium aluminum silicate complex, and small quantities of other metal oxides. Because the insoluble sodium aluminum silicate complex represents a loss of both alumina and soda, a low reactive silica content in the bauxite is desirable. Reactive silica contents of more than 8% are usually uneconomic for treatment by the Bayer process because approximately 1.1 units (weight unit) of alumina and 1.2 units of soda are lost for each unit of reactive silica in the ore. The loss of soda is made up by adding caustic soda or soda ash and lime to the spent leach solution to bring it up to the appropriate caustic concentration before it is recycled.

Bauxite with 8% to 15% silica may be treated by the combination Bayer-sinter process developed by the Aluminum Co. of America (Alcoa). In this process, the bauxite is first subjected to a Bayer leach. The resulting red mud, containing sodium aluminum silicate, is sintered with limestone and soda ash and then leached with water to recover alumina and soda. Alumina produced by this combination process is of relatively high purity and commands a premium price. The insoluble residue (brown mud) resulting from leaching the sintered materials has a composition somewhat similar to that of portland cement.

The upper limit of silica for use in the combination Bayer-sinter process is about 15%. However, in practice, bauxite containing some clay and as much as 25% silica has been mined and blended with low-silica ore in proportions that gave a feedstock of approximately 12% to 13% silica. At present, variations of the combination process are reportedly used by plants in China and the U.S.S.R.

In the U.S.S.R., alumina has been extracted from nepheline $[(\text{Na},\text{K})\text{AlSiO}_4]$ flotation concentrates and other nonbauxitic materials containing about 30% alumina. Nepheline syenite has been mined at Belogorsk in Siberia and obtained as a byproduct of apatite

recovery from syenite deposits in the Kola Peninsula. The process employed involves sintering the nepheline with lime followed by leaching. Alumina reportedly has also been produced from alunite $[\text{KAl}_3(\text{OH})_6(\text{SO}_4)_2]$ in the Azerbaijan region.

In the past, a small tonnage of alumina has been commercially extracted in Norway from high-iron bauxites by the Pedersen process. In this process, bauxite, limestone, coke, and iron ore were smelted in an electric furnace to produce pig iron and calcium aluminate slag containing 30% to 50% alumina. The slag was leached with sodium carbonate solution, and alumina trihydrate was then precipitated by carbon dioxide. During World War II, the process was also used at a Swedish plant to treat andalusite (Al_2SiO_5).

Smelting.—Primary Aluminum Production.—Primary aluminum is produced by the reduction of alumina by electrolysis in a molten bath of natural or synthetic cryolite (Na_3AlF_6), which serves as an electrolyte and as a solvent for the alumina. The reduction cells or pots containing the bath are about 10 to 15 feet wide, 20 to 40 feet long, and about 3 to 4 feet deep, lined with carbon, and connected in electrical series of 100 to 240 cells to form a potline. From 800 to 3,000 pounds of aluminum is produced per day in each pot. The carbon lining is in contact with the molten aluminum metal and serves as the cathode. It usually must be replaced after 3 to 4 years.

Cryolite and aluminum fluoride are added to the electrolyte to maintain the desirable ratio of sodium and aluminum fluoride and to replace fluorine lost from the cell in pot linings or through volatilization. The melting point of the bath is lowered by the addition of small quantities of fluorspar or, in some instances, lithium compounds. The carbon anode, which is consumed during the operation, is replaced using the Soderberg continuous method or the prebaked method.

In the Soderberg method, a reinforced rectangular steel shell, approximately 3 to

5 feet high and open at the top and bottom, is suspended above the furnace. The carbon mass of paste or briquets of coke and pitch within the shell forms the anode and is added periodically as the anode is consumed. Current enters the anode through rows of pins inserted into the carbon mass either vertically or horizontally. The heat of the bath and the heat resulting from the electrical resistance of the carbon bake the anode mass so that it becomes a hard monolithic mass from the surface of the electrolyte to a point approximately 20 inches above the bath. As the carbon anode is consumed and additional carbon descends through the rectangular steel shell and is consumed, the lowest pins are withdrawn and replaced at higher levels in the carbon mass. The optimum anode-cathode distance is maintained by raising or lowering the pins, which become baked into the lower part of the carbon block.

In the prebaked anode system, sets of 16 to 24 prebaked carbon blocks are used for the anode. The size of the blocks varies from plant to plant; typical blocks are about 20 inches wide, about 30 inches long, and 12 to 18 inches high. They weigh 400 to 600 pounds. Steel stubs or rods, which suspend the block in the bath and conduct the current to the carbon, are sealed in the anode block by pouring molten iron around the rod and allowing it to solidify. The blocks are raised or lowered separately to maintain proper position with respect to the bath and are replaced individually as they are consumed.

The Soderberg system requires less labor and, except for moving the steel pins, is a continuous method of feeding anode carbon. The prebaked system results in better electrical efficiency in the reduction cell but requires separate anode fabricating and rodding facilities not required in the Soderberg system. The prebaked system permits efficient collection of the cell offgases for subsequent treatment to remove fluorine; the off gases from a Soderberg cell are difficult to collect, necessitating fluorine recovery from a larger volume of gas than that generated in prebaked systems.

The molten bath or electrolyte may be as deep as 14 inches, but the anode is usually only 2 inches from the pad of molten aluminum collecting on the carbon cathode. The optimum operating temperature is between 950° to 985° C. At this temperature range, the alumina content of the bath ranges from 3% to 10%. When the alumina concentration drops to about 2%, the electrical resistance of the cell increases sharply, chiefly because of a gas film that envelops the anode, and the voltage drop across the cell increases from 5 volts to 30 to 40 volts. The phenomenon is known as the "anode effect," and as soon as it occurs, the crust of frozen cryolite on top of the bath is broken and more alumina is added to the cell, which then returns to normal operating condition.

Every 1 or 2 days the molten aluminum is removed from the bottom of the cell by a vacuum siphon technique. Thermally insulated cast-iron pots with airtight lids and downward-sloping spouts are used to withdraw the molten metal. The pot is evacuated, and the molten metal is sucked into the cast-iron pot. The molten metal is blended in a holding furnace with other batches and alloyed and cast into various solid forms or transported molten to fabricating plants as far as 300 miles away.

Utilizing direct current, cells operate at 65,000 to 150,000 amperes; the majority of plants have 80,000- to 100,000-ampere cells. Anode current densities range from 600 to 800 amperes per square foot. The voltage drop across a single cell is 4.5 to 5.0 volts; across a potline, it may be as high as 1,000 volts.

The larger cells require less labor per pound of aluminum produced, but special problems are encountered in cells designed to operate at 100,000 or more amperes. The larger currents cause powerful magnetic fields in the molten aluminum metal and the bath, resulting in violent agitation. This agitation causes aluminum to be dispersed in the bath, increasing the possibility of reversing the reduction reaction. Another detrimental effect is that the molten metal piles up toward the negative leads, causing a variation in the anode-cathode spacing.

Moreover, localized thermal effects may distort the carbon lining.

Production cells normally have current efficiencies ranging from 85% to 93%. Metal losses are principally caused by reoxidation of aluminum in the electrolyte and by physical loss of metal through vaporization from the bath or spillage. The resistance of the bath is sufficient to maintain the operating temperature. However, heat energy is lost by radiation, thermal conductance through electrode connections, in exhaust gases and tapped metal, and in electrodes removed from the cells.

To prevent atmospheric pollution, fumes evolved from the cells during electrolysis are removed from plant offgases by a collection and wet-scrubbing system or by a dry process whereby the fluorine is absorbed by alumina and recycled.

Superpurity Aluminum Processing.—The production of superpurity aluminum, 99.99+ % purity, requires special procedures, such as a continuous electrorefining of commercially pure aluminum in a Hoopes cell. This cell employs three molten layers of metals or bath materials of different densities. The bottom layer is the anode, a relatively impure aluminum alloyed with copper to increase its density. The intermediate layer is molten cryolite electrolyte with alkaline earth metal fluorides added to give the desired density, always greater than pure aluminum. The top layer, which serves as the cathode, is the molten superpurity aluminum that floats on the electrolyte layer.

Recycling.—In recycling, aluminum-base scrap is usually melted in gas- or oil-fired reverberatory furnaces of 30,000- to 100,000-pound capacity, sometimes with primary ingot metal. The furnaces have one or two charging wells separated from the main bath by a refractory wall that permits only molten metal into the main bath. The principal refining of aluminum-base scrap is the removal of magnesium by treating the molten metal with chlorine or with

various fluxes such as aluminum chloride, aluminum fluoride, or mixtures of sodium and potassium chlorides and fluorides. To facilitate handling, a significant proportion of the old aluminum scrap, and in some cases new scrap, is simply melted to form a solid ingot called "sweated pig," which must be further treated to produce specification-grade ingot.

Aluminum drosses containing about 30% metallics are usually crushed and screened to bring the metallic content up to about 60% to 70%. They are then melted in a reverberatory furnace, with the molten aluminum metal collecting on the bottom of the furnace. Salt slags containing less than 30% metallics may be leached with water to separate the metallics.

ANNUAL REVIEW— ALUMINUM

Domestic production of primary aluminum has been just over the 4-million-ton-per-year level since 1989. In 1991, domestic and world producers continued to operate their smelters at or near rated capacity levels during most of the year despite the economic recession, falling metal prices, and rising inventories. It was not until late in the year that producers began announcing temporary smelter closures and cutbacks in production. However, by then, prices were hovering around the 50-cent-per-pound range, their lowest level since late 1986.

The domestic secondary aluminum industry also fell victim to this economic squeeze of falling prices and rising inventories in 1991. Despite these problems, more than 2.5 million tons of metal was recovered from purchased new and old scrap during the year. Aluminum recovered from discarded aluminum products (old scrap) accounted for about 60% of this total. Almost 30% of the apparent demand for aluminum was met by metal recovered from old scrap.

The domestic consumption of aluminum decreased slightly in 1991. The overall weakness of the economy and

cutbacks in the construction and transportation industries contributed to this decline. Although U.S. imports decreased slightly in 1991, U.S. exports continued to grow, but at a much slower pace than at the end of the past decade.

The slowdown in worldwide aluminum demand, rising inventories, and declining metal prices led many companies to begin to reevaluate the status of their higher cost aluminum reduction facilities around the world. Many companies also began to reassess their primary aluminum expansion plans that were made during the high growth period of the late 1980's. The startup of this planned new capacity may well be delayed from the originally proposed timetables. (See table 4.)

Production

Primary.—Domestic primary aluminum production increased slightly compared with 1990 production levels. In 1991, 13 companies operated 23 primary aluminum smelters, and most of these smelters continued to be operated at or near their rated capacity levels during most of the year.

In February, Ravenswood Aluminum Co. reported the restart of one of two idled potlines at its primary aluminum plant in Ravenswood, WV. The restart brought production at the plant to about 75% of its 166,000-ton-per-year capacity. The potline had been closed since 1981.

In August, Reynolds Metals Co. announced the shutdown of three of the five potlines at its primary aluminum smelter in Troutdale, OR, curtailing about 70,500 tons per year of production capacity. In December, Reynolds Metals reported the temporary closure of the remaining two potlines at its 121,000-ton-per-year facility.

The Environmental Protection Agency (EPA) granted Reynolds Metals' petition to exclude kiln residue, derived from the processing of spent potliner, from EPA's list of hazardous wastes. Reynolds' process reportedly blended the potliner with limestone and a sandy material prior to roasting at elevated temperatures in a rotary kiln, converting the spent potliner into environmentally acceptable landfill

material. In 1988, the EPA had listed spent potliner as a hazardous waste. Reynolds' proposed plant in Arkadelphia, AR, the site of a dismantled primary aluminum smelter, reportedly would have the capacity to process 120,000 to 130,000 tons of spent potliner per year.

Alumax Inc. reported the closure of its aluminum rolled products plant in Hawesville, KY. The plant reportedly housed a single cold mill and produced aluminum sheet products for the building and construction industry.

Kaiser Aluminum & Chemical Corp. entered the automotive aluminum casting business with the announced purchase of the Winters Industries Div. of Whitaker Corp. Winters Industries produced manifolds and other cast aluminum components for cars and trucks and was one of four companies reportedly selected to supply aluminum engine components for the V-10 engine going into Chrysler Corp.'s Viper sports car. Winters Industries, which operated three plants in and around Canton, OH, would probably become part of Kaiser Aluminum's forgings division.

Reynolds Metals reported an increase in capacity at its Bellwood, VA, aluminum extrusion plant with the startup of a new, fully automated, 5,000-ton extrusion press. The new press resulted in a 25% increase in plant capacity to 100 million pounds per year.

Alcan Aluminum Corp. announced the opening of its new wire and cable facility in Roseburg, OR. The plant would produce aluminum transmission and distribution cable and aluminum building wire.

J W Aluminum Co. reported the completion of a 30-million-pound expansion at its Mount Holly, SC, fabrication facility. The plant produced foil, finstock, and coiled sheet for a number of applications, including cable wrap and litho sheet. (See table 5.)

Secondary.—According to a survey conducted by the Aluminum Association Inc., the Institute of Scrap Recycling Industries, and the Can Manufacturers Institute, a record 56.85 billion aluminum UBC's were recycled in the United States

in 1991, about 227 cans for every man, woman, and child in the Nation. This was the 20th consecutive year that the number of recycled aluminum beverage cans has increased. The recycling rate for 1991 was 62.4%, down slightly from the 1990 rate of 63.6%.

Golden Aluminum Corp. announced that construction had been completed at its new 130-million-pound-per-year canstock plant in San Antonio, TX. The company noted that the rolling mill would use continuous casting technology to manufacture aluminum sheet products for the food and beverage can market. The feedstock for this plant would be recycled material, primarily UBC's. The company expected the plant to come on-line by the end of the year and to begin full-scale operations early in 1992.

Roth Brothers Smelting Corp. announced plans to increase capacity at its East Syracuse, NY, secondary aluminum smelter by 25,000 tons per year. The company said the decision was based on projections for increased use of secondary aluminum in the automotive market.

Two companies announced plans to build plants to process saltcake, a byproduct of aluminum dross processing. Imco Recycling Inc. planned to build a salt recovery plant at its Morgantown, KY, plant, and Solar Aluminum Technology Services announced plans for a facility in Wendover, UT. Both plants were expected to recover both aluminum metal and reusable fluxing salts. (See tables 6, 7, and 8.)

Consumption and Uses

The container and packaging industry remained the largest domestic consumer of aluminum products and increased its share of the domestic aluminum market to 29%. The Can Manufacturers Institute reported that more than 91 billion aluminum beverage cans were shipped in 1991, representing about 97% of the total metal beverage can shipments.

Reynolds Metals announced the introduction of a new generation of canmakers, which it claimed operated at speeds one-third greater than the fastest

canmaker currently in wide commercial use. The new Mark IV draw-and-iron press reportedly could produce two-piece can bodies at the rate of more than 400 cans per minute. Prototype and production models were in operation in Greece and the United States.

Alcoa announced the development of a new high-strength aluminum alloy 7055-T77 for compression-dominated structures in the aircraft industry. The new alloy targets such applications as upper wing structures, cargo rails, and seat tracks. Boeing Co. announced that the new alloy had been specified for the upper wing skins on its new 777 wide-body aircraft.

Aluminum also found increased application as a major construction material in specialized marine crafts. A new rescue vessel designed for the U.S. Coast Guard contains about 7 tons of aluminum. The Coast Guard announced that Textron Marine Systems had been awarded a contract to construct five of these 47-foot crafts as an intermediate step to building up to 100 of the vessels. Textron reported that aluminum alloy sheet and extrusions used in the hull, keel, and engine foundations gave the vessel the strength to withstand wave impacts that were three times the acceleration of gravity. The craft was also designed to survive 360-degree side rollovers and end-over-end flips, to handle hurricane-force winds, to travel at speeds greater than 25 knots, and to have a range of 220 nautical miles.

Another marine application for aluminum was in high-speed catamaran passenger vessels, such as the new Seacat ferry that was put in service on the English Channel. For vessels such as catamarans, hydrofoils, and hovercraft/air cushion catamarans, light weight is particularly important, and aluminum has long been a favored construction material.

Aluminum continued to compete with other metals and plastics for an increased share of the automotive market. Reynolds Metals reported that it had been awarded a 5-year contract by the Ford Motor Co. for aluminum driveshaft tubes. The contract covered delivery of 500,000 tubes per year requiring an estimated

1,200 tons of aluminum annually. Both General Motors Corp. (GM) and Chrysler announced plans to begin switching from copper and brass radiators to aluminum radiators in various car and truck models over the next few years.

Ford reported that it had received commitments from Alcoa, Reynolds Metals, and Alcan Aluminium Ltd. to help in the development of body panel applications for aluminum in the next generation of the midsize Taurus cars scheduled to be introduced in 1995. These subassemblies—inner and outer hood panels, deck lid panels, and front fenders—would be evaluated against conventional steel units on the basis of weight, dent-resistance, appearance, corrosion-resistance, price, and other factors.

Chrysler announced plans to develop a two-stroke, low-profile, three-cylinder engine for passenger car use by 1995 that could contain as much as 100 pounds of aluminum versus the 50 to 55 pounds of aluminum contained in Chrysler's conventional four-cylinder, four-stroke engine. A similar type of engine reportedly was being developed by Orbital Engine Co. USA Inc. for use by Ford in Europe.

GM announced that it was developing a low-displacement engine for introduction in some of its intermediate and larger cars in 1994 that would employ an estimated 165 pounds of aluminum in the cylinder blocks, heads, water pumps, pistons, intake manifolds, and other components.

Creative Industries, Auburn Hills, MI, reported that it was teaming up with Alcan Aluminium to engineer a lightweight aluminum frame for GM's first production electric cars, which the company expected to be introduced in 1994.

Alcan Rolled Products announced plans to construct two pilot-processing lines for automotive sheet products at its Warren, OH, rolling mill. A company spokesman said that this marked a first stage in the product development phase and eventually would include joint testing and other procedures with the automobile companies.

Alcoa announced plans to build a plant to produce components and sub-assemblies for aluminum spaceframes in Soest, Federal Republic of Germany. The plant, scheduled for completion by 1993, was expected to have the capacity to produce more than 100,000 units annually. Alcoa also announced that an agreement had been signed with Audi AG under which Alcoa would supply aluminum spaceframe components for a new Audi model. (See tables 9, 10, 11, and 12.)

Stocks

Inventories of aluminum ingot, mill products, and scrap at reduction and other processing plants, as reported by the U.S. Department of Commerce, decreased from a revised total of 1.820 million tons at yearend 1990 to 1.788 million tons at yearend 1991.

On February 1, the LME began accepting metal at its first U.S. warehouse in Baltimore, MD. By the end of the year, the LME had approved warehouses for the receipt of aluminum metal in six additional locations in the United States—Long Beach, CA; Bridgeport-New Haven, CT; Chicago, IL; Louisville, KY; St. Louis, MO; and Toledo, OH. The LME reported that its U.S. warehouses held a total of 167,550 tons of aluminum metal at yearend 1991.

Markets and Prices

The monthly average U.S. market price of primary aluminum trended downward throughout the year. The December monthly average was more than 18 cents per pound lower than the January price level. The LME and New York Commodity Exchange (COMEX) prices for aluminum futures followed the same general trend as the U.S. market price.

Purchase prices for aluminum scrap, as quoted by the American Metal Market (AMM), fluctuated during the year, but closed the year at much lower levels than those at the beginning of the year. The yearend price ranges for selected types of aluminum scrap were as follows: mixed

low-copper-content aluminum clips, 38 to 39 cents per pound; old sheet and cast aluminum, 33 to 35 cents per pound; and clean dry aluminum turnings, 34 to 36 cents per pound.

Prices for UBC's fluctuated during the year, but closed 10 cents per pound lower than prices at the beginning of the year. Aluminum producers' buying prices for processed and delivered UBC's, which began the year in a range of 42 to 46 cents per pound, reached a high for the year of 49 to 53 cents per pound in March. The price range at the end of the year was 32 to 37 cents per pound.

Secondary aluminum ingot prices, as quoted by AMM, fluctuated during the year, but generally trended downward and closed much lower than prices at the end of 1990. The yearend 1991 price ranges for selected secondary aluminum ingots were as follows: alloy 380 (1% zinc content), 59.5 to 61 cents per pound; alloy 360 (0.6% copper content) and alloy 413 (0.6% copper content), 62.5 to 63.5 cents per pound; and alloy 319, 61 to 62.5 cents per pound.

The LME continued its investigations into the potential for an LME secondary aluminum ingot contract. A final decision on the introduction of such a contract was expected by mid-1992. (See table 13.)

Foreign Trade

Exports of all forms of aluminum from the United States increased slightly from those of the previous year. Canada and Japan continued to be the major recipients of U.S. aluminum materials, accounting for slightly more than 70% of the U.S. exports. Exports of UBC's, which were included in the scrap category, were at about the same level as those of the previous year. UBC exports in 1991 totaled 2,805 tons compared with 2,854 tons in 1990. Japan and the United Kingdom were the principal destinations of UBC's exported, accounting for almost 60% of the total in 1991.

Imports for consumption of aluminum decreased slightly compared with those of 1990. Canada remained the major shipping country to the United States,

supplying almost 84% of the total imports in 1991. UBC imports in 1991 totaled 31,602 tons compared with 37,028 tons in 1990. Canada also continued to be the major source of UBC imports, accounting for more than two-thirds of the total in 1991. (See tables 14, 15, 16, 17, and 18.)

World Review

With the slowdown in the world economy, which began during the latter half of 1990 and continued through 1991, world demand for primary aluminum remained relatively unchanged from that of the previous year. World inventories rose, especially those held by the LME. LME inventories at the beginning of the year totaled 318,000 tons. By the end of the year, inventories held by the LME had more than tripled and totaled 987,150 tons.

This oversupply of metal was exacerbated by a larger than normal influx of aluminum metal from the U.S.S.R. onto the world market. In previous years, Eastern European countries, including the U.S.S.R., shipped between 100,000 and 350,000 tons of metal per year to the Western World market. In 1991, however, it was estimated that these shipments exceeded 800,000 tons of metal.

Primary aluminum inventories held by members of the International Primary Aluminium Institute (IPAI), which represent the bulk of stocks held outside the former centrally planned economy countries, increased from 1.527 million tons at yearend 1990 to 1.754 million tons at yearend 1991. IPAI reported that total metal inventories, including secondary aluminum, increased from 3.138 million tons at yearend 1990 to 3.349 million tons at yearend 1991.

The slowdown in demand accompanied by rising inventories caused world aluminum prices to fall sharply. Even though it appeared that many of the world's smelters were operating at a loss, it was not until late in the year that companies began to announce temporary capacity shutdowns. The current oversupply of metal and the uncertainty

surrounding future exports from the U.S.S.R. has caused many companies to delay or postpone previously announced smelter expansion plans.

Capacity.—The data in table 19 are rated annual capacity for plants producing primary aluminum as of December 31 for the years shown. Rated capacity is defined as the maximum quantity that can be produced on a normally sustainable, long-term operating rate, based on the physical equipment of the plant and given acceptable routine operating procedures for labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure. (See table 19.)

Argentina.—In October, Aluminios Argentinos S.A.I.C. (Aluar) announced plans to decrease production by 9% at its 160,000-ton-per-year primary aluminum smelter at Puerto Madryn. The cutback reportedly was in response to low world metal prices.

Australia.—Vereinigte Aluminium-Werke AG (VAW) reported that the Government of Australia had approved a proposed expansion of the consortium-owned Tomago Aluminium Co. Pty. Ltd. primary aluminum smelter in New South Wales. The addition of the proposed third potline would increase capacity at the smelter to 380,000 tons per year. The company reported that construction was scheduled to begin this year and that initial production from the new potline was expected in the first half of 1993.

The State government-owned Aluminium Smelters of Victoria Pty. Ltd. (Aluvic) and the wholly owned subsidiary of U.S.-based Adolph Coors, Golden Aluminum, announced the signing of a joint-venture agreement to build a 105,000-ton-per-year aluminum can sheet rolling mill at Bendigo. The new venture, Golden Pacific Aluminium, reportedly would use continuous casting technology developed by Launer

Engineering Ltd., the same technology developed for Golden Aluminum's rolling mill in San Antonio, TX. One major difference between the two plants, however, was that the San Antonio plant would use recycled metal as feedstock, while the Australian plant would use primary metal. Golden Pacific reported that it was proceeding with preliminary engineering plans and applications for environmental permits. If technical, financial, and permitting activities were resolved, construction could begin in the fourth quarter of 1992 with commissioning scheduled for late 1994.

Austria.—Reynolds Metals announced the completion of a \$16 million expansion that doubled the capacity of its Austria Dosen can plant at Enzesfeld, near Vienna. Capacity of the two-line plant increased to 900 million cans per year. Reynolds Metals said that the company was now positioned to grow in the future and to become a major supplier in the European market that consumed 58 beverage cans per capita compared with 350 cans per capita in the United States.

Austria Metall AG announced plans to close its 80,000-ton-per-year Ranshofen primary aluminum smelter by the end of 1992. The company planned to close the smelter in five stages, the first of which was scheduled for the end of 1991.

Bahrain.—Bahrain Aluminium Extrusion Co. (Balexco) announced the signing of a technical cooperation agreement with Finleader Group of Italy to expand Balexco's production from its current capacity of 6,000 tons per year to 18,000 tons per year. The company reported that work on the plans was scheduled to begin in 1992 and would include three units, an aluminum extrusion press, a casting remelt plant, and an aluminum die manufacturing plant.

Brazil.—Alumínio do Maranhão S.A. (Alumar) announced that the new third potline at its primary aluminum smelter in São Luis was fully operational. The addition of the 83,000-ton-per-year

potline increased the annual capacity of the smelter to 328,000 tons.

Alumínio Brasileiro S.A. (Albras) announced the completion of the Phase II expansion of its primary aluminum smelter, which increased capacity to 320,000 tons per year. In early March, a blackout that cut electrical power to the plant for 12 hours severely damaged the smelter. By the end of September, Albras reported that 814 of the plant's 864 pots were fully operational as opposed to 131 operating pots immediately following the blackout.

In November, Alcan Alumínio do Brazil S.A. announced the closure of one of three potlines at its 60,000-ton-per-year smelter in Saramenha. The closure reduced capacity at the plant by 9,000 tons per year.

Reynolds Metals announced plans to expand capacity at Latas de Alumínio S.A. (Latasa), a joint-venture can manufacturing plant. The \$30 million project reportedly would increase the plant's existing 800-million-can-per-year capacity to 1.3 billion cans per year.

Canada.—In February, Aluminerie de Bécancour Inc. (ABI) reported that the smelter's third 120,000-ton-per-year potline was fully operational, 4 months ahead of the planned completion date. Capacity at the plant rose to 360,000 tons per year.

Reynolds Metals announced the startup of a new 120,000-ton-per-year potline at its primary aluminum smelter in Baie Comeau, Quebec. With the addition of this potline, capacity at the plant increased to 400,000 tons per year, making this one of the largest smelters in the world.

Alcan Aluminium announced the temporary reduction of capacity at three of its smelters in Quebec. Effective November 1, one 21,000-ton-per-year potline at Shawinigan and one 24,500-ton-per-year potline at Isle Maligne were closed. In addition, one 22,000-ton-per-year potline at the Arvida smelter was closed at the beginning of December.

Kaiser Aluminum announced plans to build an extrusion plant in London, Ontario, at a cost of \$21 million. The

plant reportedly included three presses—4,000 tons, 2,400 tons, and 1,800 tons. The company expected the project to be completed in 1993 and to eventually replace the company's present extrusion plant in Scarborough.

Chile.—Noranda Aluminum Inc. announced that it reached an agreement with Proyectos de Aysen, a small Chilean company, to proceed with a proposed primary aluminum smelter in southern Chile. The \$1.5 billion Alumysa project reportedly included a 230,000-ton-per-year smelter, a hydroelectric plant, and a port facility near Puerto Aysen. Financing of the project was incomplete, and construction was expected to take about 6 years to complete.

China.—China reported that construction had begun on the first phase of the Pingguo Aluminium Co. in the Guangxi Zhuang Autonomous Region. The first stage, which the Government expected to be completed in 1994, called for a production facility with an annual capacity of 300,000 tons of alumina and 100,000 tons of aluminum. Upon completion of the project, Pingguo reportedly would have an annual production capacity of about 1.2 million tons of alumina, 500,000 tons of aluminum, and 300,000 tons of aluminum products.

Dubai.—In January, Dubai Aluminium Co. (Dubal) announced that its new 70,000-ton-per-year potline came on-stream 6 weeks ahead of schedule. Capacity at the smelter increased to 240,000 tons per year.

France.—Pechiney announced the permanent closure of two of its older primary aluminum smelters, Noguères and Riouperoux, at the end of October. The plant at Noguères, which had an original capacity of 114,000 tons per year before it was reduced to 75,000 tons per year in 1987, had reportedly been producing only 38,000 tons annually since October 1990. The Riouperoux smelter had an initial capacity of 25,000 tons per

year, which had fallen to 14,000 tons per year prior to the shutdown.

Germany.—Alusuisse Lonza Holdings Ltd. announced the closure of its 64,000-ton-per-year primary aluminum smelter in Rheinfelden. A combination of the age of the smelter, which was one of the oldest in Europe (startup 1897), the downturn in world aluminum markets, the high cost of energy, and increased environmental expenditures were cited as reasons for the closure. The company reported, however, that the casthouse at Rheinfelden would continue to produce primary aluminum casting alloys, impact extrusion semis, and items from the specialty foundry.

Alusuisse also announced a temporary 40,000-ton-per-year cutback in production at its 130,000-ton-per-year smelter in Essen.

At the end of October, VAW announced the temporary closure of 33,000 tons per year of capacity at two of its smelters in Germany. Most of the reduction was reported to be at its Töging smelter and the remainder at its Norf facility.

Subject to the approval of the German Federal Cartel Office, Klockner and Co. and SMG Sommer Metallwerke GmbH announced an agreement to merge their secondary aluminum activities and to form a new company, Sekundäraluminiumwerke GmbH (SAW). Sommer Metallwerke would own 80% of the new company, and the remainder would be owned by Klockner. Included in the merger were Sommer Metallwerke's three secondary aluminum plants, which produced about 130,000 tons per year of aluminum, and Klockner's 38,000-ton-per-year secondary aluminum plant.

Hungary.—Hungarian Aluminium Corp. (Hungalu) announced plans to close all three of its primary aluminum smelters in Hungary. The company indicated that the 18,000-ton-per-year Tatabánya smelter would close at the end of the year. The 25,000-ton-per-year Ajka smelter and the 35,000-ton-per-year

Inota smelter were scheduled for closure in 1992.

Iceland.—The Atlantal Aluminium consortium reported that attempts to secure financing for its greenfield smelter had been postponed. The partners cited low aluminum metal prices, weak demand, and uncertainty arising from developments in Eastern Europe as reasons for the decision, which could push back the originally proposed timetable for the project (1994) by as much as 3 years. The group said, however, that preliminary environmental and other preparatory work would continue.

India.—National Aluminium Co. Ltd. (Nalco) announced plans for a \$1.2 billion expansion program. According to company officials, the plan included a 50% expansion of capacity at its primary aluminum smelter in Orissa to 330,000 tons per year, a 25% increase in alumina refinery capacity, and a doubling of bauxite mine capacity.

Hindustan Aluminium Co. Ltd. (Hindalco) reported the commissioning of a sixth potline at its Renukoot smelter, raising capacity at the plant to 150,000 tons per year. The company also announced plans to double the capacity of this smelter and to expand the capacity of its captive powerplant by 360 megawatts.

Iran.—Almahadi Aluminium Corp. announced the signing of a construction contract for a new \$1.5 billion primary aluminum project at Bandar Abbas near the Straits of Hormuz. The 220,000-ton-per-year smelter was expected to come on-stream in mid-1994 and to be fully operational by mid-1995. The company also announced the possible future expansion of this smelter to 330,000 tons per year. Almahadi Aluminium was a joint venture between the Iranian Government (60%) and the Dubai-based International Development Corp. (40%).

The Government also reported that work was proceeding on the addition of a new fourth potline at the primary smelter in Arak. The new potline was due on-

stream in October. Installation of a fifth potline reportedly was underway and due to come on-stream in 1992. Completion of the fifth potline was expected to increase capacity at the smelter to 120,000 tons per year.

Italy.—Alumix S.p.A. announced the closure of its 30,000-ton-per-year primary aluminum smelter at Porto Marghera. The closure was the first step in a major reorganization plan announced by the State-owned aluminum producer.

Japan.—Kobe Steel Ltd. and Alcoa announced the formation of two more joint-venture companies, one in the United States and the other in Japan. The companies were expected to focus on expanding the use of aluminum in the automotive industry and to include joint research and development in aluminum sheets, extrusions, castings, and forgings, as well as production and sales.

Nippon Steel Corp. reported an agreement to purchase 26.25% of Sky Aluminium Co. from Mitsui and Co. Ltd., increasing Nippon's share of the company to 36.25%. Sky Aluminium reportedly produced approximately 117,000 tons per year of aluminum sheet.

Yet another joint venture between a steel company and an aluminum producer was announced. Kawasaki Steel, Furukawa Electric, and Furukawa Aluminium announced plans to set up aluminum sheet production facilities to serve the automobile industry.

Sumitomo Corp. announced the merging of two of its subsidiaries, Kansai Light Metals and Sumi-Al Alloys. The new company, Summit Aluminium, was expected to have an aluminum alloy capacity of 120,000 tons per year. Because Sumi-Al produced alloy from primary ingot and Kansai produced alloy from scrap, the new company was expected to vary its raw material intake based on price fluctuations between primary and secondary materials. Summit also announced a 5-year expansion plan that was expected to increase alloy capacity by 5,000 tons per month.

Korea, Republic of.—Adolph Coors Co. announced the signing of a joint-venture agreement with Jinro Ltd., a large food and beverage company in Seoul. The joint venture, Jinro-Coors Brewery Co., reportedly included a 1.8-million-barrel-per-year brewery and an on-site aluminum can plant.

Alcoa and Sam Sun Industrial announced the formation of a joint venture to produce aluminum extrusions and tube products principally for the South Korean aerospace market.

Mexico.—Aluminio SA announced the closure of two of the three potlines at its 66,000-ton-per-year primary aluminum smelter in Vera Cruz. By the end of the year, operating capacity at the smelter had been reduced to 22,000 tons per year.

Netherlands.—Late in the year, Hoogovens Aluminium BV announced an 18,000-ton-per-year decrease in primary aluminum smelter capacity. Hoogovens operated smelters at Delfzijl in the Netherlands and Voerde in Germany.

Pechiney Nederland NV announced a 12.5% decrease in production capacity at its 170,000-ton-per-year smelter in Vlissingen.

Norway.—Norsk Hydro AS joined the list of companies that announced temporary cutbacks in production owing to rising world inventories and declining metal prices. In November, Norsk Hydro announced temporary cutbacks of 45,000 tons per year, equivalent to 7.5% of capacity, to take effect by the end of the year. All four of the company's Norwegian smelters would be included in the reductions.

Alcoa announced the purchase of Elkem AS's 50% interest in Alcoa Nederland Holdings BV. By purchasing Elkem's share, Alcoa became the sole owner of the rolled and extruded aluminum products company. The purchase included fabrication facilities in the Netherlands, Spain, and the United Kingdom, but did not affect the Elkem-

Alcoa partnership that operated primary aluminum smelters at Lista and Mosjoen.

South Africa, Republic of.—Alusaf Pty. Ltd. announced plans to build a new 466,000-ton-per-year primary aluminum smelter in the Republic of South Africa. The company also reported that a technology agreement had been signed with Pechiney, whereby the French company would design the facility and provide 2 years of operational support. A final decision on the project was expected in 1992. If the go-ahead is given, the company said that full commercial production could be achieved within 3 years.

Spain.—Pechiney announced plans to construct an aluminum beverage can plant near Barcelona. The company expected the facility to be completed in the first quarter of 1992 and to produce 1.2 billion cans per year.

Turkey.—Etibank announced plans to expand capacity at its 60,000-ton-per-year smelter in Seydisehir to 100,000 tons per year.

United Kingdom.—Alcan Aluminium announced a temporary reduction in production at two of its primary aluminum smelters. In July, 10,000 tons per year of production was curtailed at Lochaber. In November, Alcan Aluminium closed one 66,000-ton-per-year potline at Lynemouth Works.

Alcan Aluminium also announced the opening of a UBC recycling plant in Warrington. The 50,000-ton-per-year plant reportedly was the first recycling plant in the European Community dedicated solely to the recycling of aluminum beverage cans.

Cookson Aluminium announced that construction had begun on a new secondary aluminum smelter at Repton near Derby. Although the new smelter would have a design capacity of 30,000 tons per year, the net increase in capacity for Cookson would be only 5,000 tons per year. The new smelter was to replace the recently mothballed 10,000-

ton-per-year smelter at North Cave on Humberside and the existing 15,000-ton-per-year smelter at Repton. The company expected the new smelter to be completed in 1992.

Nacanco reported the completion of a third production line at its Wakefield aluminum beverage can plant. The new line reportedly increased the annual capacity of the plant by 50%, from 1.2 billion cans to 1.8 billion.

CMB Packaging announced that it had converted one of the five canmaking lines at its Carlisle plant from the production of tinsplate soft drink cans to aluminum beer cans. The modified line reportedly had a production rate of 800,000 cans per day. A spokesperson for the company said that, because of a growing preference for aluminum, the plants' three remaining steel lines could be switched to aluminum in the future.

Venezuela.—The Government of Venezuela announced the selection of three new aluminum smelter projects to participate in its debt-for-equity financing program. The projects selected were: Alcoven, a 300,000-ton-per-year Alcoa-based project; a 240,000-ton-per-year Orinoco project, which included Kaiser Aluminum and Korean interests; and Aluyana, a 215,000-ton-per-year smelter, which included Italian interests. Also qualified under this debt-equity program was the Quintametall Project (Alcasa V), the addition of a fifth potline, equivalent to 215,000 tons per year of capacity, at the Aluminio del Caroni SA (Alcasa) smelter in Puerto Ordaz. (See table 20.)

Current Research

Intermetallic compounds containing aluminum, such as nickel aluminide (NiAl), offered new opportunities for developing low-density, high-strength structural alloys, which might be used at temperatures higher than currently possible with conventional titanium- and nickel-base alloys. An article describing the physical and mechanical properties of NiAl, its application potential, and the progress made in improving its mechanical properties was published.⁴

Under a program funded by the U.S. Air Force, the manufacture of discontinuously reinforced aluminum composites was being scaled up to commercially useful sizes and production rates. An integral part of the attempt to scale up the production of these composites was the evaluation of the properties of the materials produced so that specifications could be maintained. Among the composites being tested were 6090/SiC/25p, which was designed for ambient-temperature applications, and X8019/SiC/12.5p, which was designed for elevated-temperature applications.⁵

The performance requirements of advanced naval aircraft, weapons, and propulsion systems have necessitated the development of a new category of hybrid materials: HYMATS. The Naval Air Development Center was actively engaged in research and development on several HYMAT materials, including macrolaminates; polymets; conductive, segregated-network composites; and reinforced ceramics.⁶

The Minerals, Metals, and Materials Society (TMS) published the proceedings of the Light Metals Committee technical sessions presented at the 120th TMS Annual Meeting held in New Orleans, LA, February 1991. More than 100 papers, in such topic areas as alumina and bauxite, reduction technology, carbon technology, and cast shop technology, were presented. The proceedings, entitled, "Light Metals 1991," were available from TMS, 420 Commonwealth Drive, Warrendale, PA 15086.

OUTLOOK—ALUMINUM

Demand for aluminum, both domestically and worldwide, continued to be weak during the first half of 1992. The oversupply of metal, the economic recession, and the uncertainty surrounding future metal export levels from the former U.S.S.R. should continue to depress the world aluminum market. This slowdown should continue into 1993 before beginning a slow gradual rise in the second half of the year. Once the market adjusts itself to the flow of metal from the former

U.S.S.R. into the world marketplace and the world economies begin to recover, the aluminum market should also begin to recover. Thereafter, aluminum metal demand should show an average annual growth rate of about 2% per year over the next few years.

ANNUAL REVIEW—BAUXITE AND ALUMINA

World production of bauxite and alumina declined throughout 1991 in a marked response to the worldwide slowdown in demand for primary aluminum metal. Mine production of bauxite was reported from 27 countries. Domestic consumption of bauxite, contrary to world production trends, once again continued its upward movement during the year, with the majority of this growth driven by requirements resulting from the sustained high operating rates of U.S. aluminum smelters and alumina tolling operations. Within the specialty products area, consumption of chemical-grade bauxite increased by a small amount above 1990 levels, but bauxite consumption by the abrasive and refractory industries declined slightly in 1991. In spite of a protracted national economic recession in 1991, domestic demand for alumina remained firm through most of the year, chiefly in response to the continued high level of primary aluminum smelter operation. Total U.S. alumina production remained relatively constant in comparison with that of 1990, while shipments of smelter-grade alumina continued the upward progression that has been their pattern for the past 2 years. U.S. consumption of bauxite for alumina production increased slightly above 1990 levels; however, a significant softening of the alumina market developed for alumina priced on contracts tied to the depressed primary aluminum metal prices. This resulted in a pronounced weakening of the spot prices quoted for alumina on world markets in 1991. Alumina reportedly was produced in 24 countries around the world. (See table 21.)

Legislation and Government Programs

On June 13th, 1991, the EPA issued a final determination that 20 special wastes from ore and mineral processing operations should not be regulated as hazardous materials.⁷ This finding included red and brown muds generated from Bayer-process production of alumina. All of the wastes had been identified for temporary exemption from regulation as hazardous materials under the Mining Waste Exclusion of the Resource Conservation and Recovery Act (RCRA) pending an EPA study and ruling. The EPA decision allows these wastes to be included within a special regulatory category being developed for mining extraction and beneficiation wastes.

There were no announced additions or withdrawals of bauxite from the National Defense Stockpile (NDS) in 1991. The NDS goals for bauxite remained unchanged at 21.3 million tons of Jamaica-type and 6.2 million tons of Suriname-type metallurgical-grade bauxite. The goal for calcined refractory-grade bauxite remained at 1.26 million tons. The Defense Logistics Agency (DLA), manager of the NDS, listed an inventory of 12.7 million tons of Jamaica-type and 5.4 million tons of Suriname-type metallurgical-grade bauxite at yearend. The NDS calcined refractory-grade bauxite inventory was listed as 280,500 tons at the close of 1991.

The Defense Logistics Agency (DLA) issued a solicitation on June 3, 1992, for the conversion of approximately 166,400 tons of NDS bauxite into aluminum metal. In this offering, the second of a planned series of contracts to upgrade NDS metallurgical-grade bauxite ore, compensation for fulfillment of the contract was stipulated to be by payment-in-kind with 1.6 million tons of NDS bauxite. The final award of a contract for this DLA solicitation was not announced by the end of the year.

Production

The total U.S. bauxite production during 1991 was markedly lower than that reported for 1990. The significant reduction in domestic mine production was partly attributed to the permanent closure of the last bauxite mining operation in Arkansas during mid-1990. The only currently active bauxite mines remaining in the United States are the surface operations in Alabama and Georgia that produce bauxitic materials, a natural mixture of bauxitic clay and bauxite with a very low iron oxide content, primarily used for the production of alumina calcines. Demand for these domestic ores remained relatively weak during 1991, and mine output was intermittent. The current proprietary nature of U.S. bauxite production data precludes the disclosure of this information in a nonaggregate form. Within this market sector, the Harbison-Walker Refractories Div. of Dresser Industries Inc. shipped bauxite from mines in Alabama to its local calcining plant and to Carbo Ceramic Co.'s proppant plant at Eufaula, AL. Throughout the year, C-E Minerals continued to operate and maintain its mines in Alabama and Georgia, with the raw ore shipped to its Andersonville, GA, facility for the production of high-alumina refractory materials. American Cyanamid Co. continued to produce calcined bauxitic clays for the production of aluminum sulfate at its Andersonville, GA, operation. In early 1991, Alcoa announced a major cost-cutting plan for its alumina chemicals plant at Benton, AR, a program that could result in a staff reduction of up to 40%. The labor force cuts were scheduled to begin by midyear, with completion of the total restructuring plan projected to take approximately 1 year. Additionally, later in the year, Alcoa announced plans to expand its facilities for drying alumina trihydrate at its Point Comfort, TX, alumina plant.

In December 1991, LaRoche Chemicals Inc. announced that it planned to construct a new activated alumina plant and expand two existing activated alumina

plants at its Baton Rouge, LA, facility. The total cost of the project was estimated at \$19 million, with startup for the new state-of-the-art plant scheduled for June 1993. Upon completion of the project, LaRoche's total production capacity for activated alumina should reach 27,000 tons per year.

During the second half of 1991, in order to balance its alumina supply system, Reynolds Metals temporarily reduced production at its Sherwin alumina plant near Corpus Christi, TX. On December 31, 1991, the Sherwin plant was reported to be operating at 69% of its annual rated capacity.

The merger of Vista Chemical Co. of the United States into RWE A.G. of Germany reportedly was completed in June 1991. The merger, originally announced in December 1990, was delayed by the Federal Trade Commission (FTC) until arrangements were developed to separate Vista Chemical's ultrahigh-purity alumina production, a byproduct of its Ziegler synthetic linear alcohol production process, from the remainder of Vista Chemical. The FTC-mandated solution to the separation issue was achieved when Discovery Chemicals Inc., of Port Allen, LA, and RWE formed a separate joint-venture company to market the monohydrate alumina byproduct obtained from Ziegler-process production of linear alcohols. This unique ultrahigh-purity alumina is one of the raw materials used in the manufacture of catalysts. (See tables 22 and 23.)

Consumption and Uses

A continued, firm domestic requirement for smelter-grade alumina moved the consumption of crude and dried metallurgical-grade bauxite to a level moderately above that of 1990. Consumption of bauxite by the chemicals industries increased very slightly during 1991, while consumption within the abrasive and refractory industries decreased by modest amounts for the year. Approximately 90% of the bauxite consumed in the United States during 1991 was refined to alumina, and an

estimated average of 2.17 tons of dried bauxite was required to produce 1 ton of calcined alumina. Twenty-two of the 23 active primary aluminum smelters reported a consumption of 8.1 million tons of calcined alumina in 1991, a slight increase from the consumption level reported for 1990. This greater level of consumption, coupled with the sustained high U.S. alumina production rates, resulted in an increased level of smelter-grade alumina imports into the domestic alumina market. An estimated 92% of the alumina shipped by U.S. refineries went to domestic primary smelters for metal production. Consumption in various forms by the abrasives, chemicals, refractories, and specialties industries accounted for the balance of the alumina usage. (See tables 24, 25, 26, 27, and 28.)

Markets and Prices

Contract terms for the purchase of metallurgical-grade bauxite and smelter-grade alumina in world markets are not normally made public, and, consequently, prices for these commodities are not published by trade journals. Price quotes are generally limited to certain specialty forms of bauxite and alumina for nonmetallurgical uses.

In 1991, the U.S. Bureau of Mines estimated the average value of domestic crude bauxite shipments, f.o.b. mine or plant, to be \$17 per ton. The average value of calcined domestic bauxite was estimated to be \$100 per ton. Base prices quoted by Industrial Minerals magazine and independent sources for imported calcined refractory-grade bauxite were as follows: Chinese, typical 85% alumina (Al_2O_3), f.o.b. barge, Burnside, LA, \$85 to \$125 per ton; and Guyanese, f.o.b. rail car, Baltimore, MD, or f.o.b. barge, Gulf Coast, \$175 per ton. Abrasive-grade bauxite, minimum 86% Al_2O_3 , c.i.f. main European ports, was priced at \$95 to \$108 per ton. Base prices were subject to adjustment for various grain-size specifications, size of order, and fuel cost factors.

The extremely low aluminum metal prices of 1991 resulted in a correspondent

easing of alumina prices from the record-high levels that were established during the late 1980's. The average value of domestic calcined alumina shipments was estimated to be \$230 per ton. Trade data released by the Bureau of the Census indicated the average value of imported calcined alumina was \$234 per ton, f.a.s. port of shipment, and \$248 per ton, c.i.f. U.S. ports. Beyond these current prices, medium-term projections support a reasonably buoyant market outlook for alumina toward the mid-1990's.

For 1991, the International Bauxite Association (IBA) recommended that its members set their minimum c.i.f. price for metallurgical-grade bauxite at between 2% and 2.5% of the composite reference price for primary aluminum ingot, and for metallurgical-grade alumina between 13.5% and 15.5% of the composite reference price for primary aluminum ingot. The IBA members account for approximately 85% of the bauxite output from the market economy countries and about 57% of the alumina production. (See tables 29 and 30.)

Foreign Trade

Dried bauxite exports from the United States totaled 37,800 tons in 1991, a continuation of the upward trend recorded in 1990; Canada received 32,100 tons and Mexico 5,000 tons. U.S. exports of calcined refractory-grade bauxite totaled 6,900 tons for 1991; Mexico received 5,800 tons and Canada 1,000 tons. Exports of all other grades of calcined bauxite (chiefly abrasive-grade) amounted to 6,000 tons for the year. Mexico received 5,600 tons of this total. Specialty aluminum compounds exported included 4,400 tons of aluminum sulfate, 10,800 tons of aluminum oxide abrasives, and 24,000 tons of various fluorine-base compounds of aluminum, including synthetic cryolite and aluminum fluoride.

Imports for consumption of crude and dried bauxite decreased from 1990 receipts, and the three primary suppliers were Jamaica, Guinea, and Brazil, in order of shipments. Australia's shipments to the United States decreased by approximately 70% during the year,

and Australia took up the fifth place position on the list of countries that supplied bauxite to U.S. markets in 1991. (See tables 31, 32, 33, and 34.)

World Review

World production of bauxite and alumina declined in response to a marked sluggishness in demand for primary aluminum metal. Twenty-seven countries reportedly mined bauxite in 1991, and the total world production of bauxite was slightly more than 109 million tons, a very slight decrease (less than 1%) below 1990 production. Australia, Guinea, Jamaica, and Brazil, in order of volume, accounted for slightly more than 70% of the total bauxite mined during the year. The corresponding world output of alumina decreased to 39.8 million tons, which was almost 1% below the 1990 production level. The traditional principal producing countries, Australia, the U.S.S.R., and the United States, once again supplied 50% of the total world production. Jamaica's reopened alumina capacity and plant expansions have allowed that nation to once again hold a principal position within the ranks of the world's premier alumina producers.

Capacity.—The 1991 world annual rated capacity of plants producing alumina was placed at 1% above last year's record-setting level. Apparent worldwide refinery capacity utilization for the year was estimated at approximately 90%. Any further free market increases in smelter-grade alumina production capacity are expected to develop from incremental expansions of existing plants and only in very special circumstances from new greenfield refineries, which normally require a 4- to 5-year design, engineering, and construction period, plus a rather substantial capital investment.

Australia.—In 1991, the world's largest bauxite- and alumina-producing country achieved a new alumina production record for the ninth consecutive year. Australian bauxite production in 1991, however, was below

the level recorded for 1990. This was the first drop in bauxite production levels for Australia since 1982.

In the latter part of 1991, it was reported that the Gladstone alumina plant in Queensland, operated by Queensland Alumina Ltd. (QAL), had reached a production level near 3.3 million tons per year. The successful introduction of a trihydrate-grade "sweetener" from the Weipa bauxite mining operations of Comalco Ltd. into the QAL Bayer circuit and the conversion from fuel oil to natural gas for calcination had contributed to this improvement in production.

During 1991, the Mineral Products Div. of Comalco reported that, in an effort to maintain its market competitiveness, it had instituted a series of work force reductions. The cutbacks included staff at the Weipa bauxite mining operations and the group's headquarters in Brisbane.

Australia announced that it intended to resign as a member of the Jamaica-based International Bauxite Association (IBA), which it had helped to create in 1974. Australia's Minister of Resources reportedly indicated the country had found that participation in the IBA was no longer justifiable on a cost versus benefits basis. Australia reportedly had tentatively set the date for withdrawal from the association as October of 1992.

Brazil.—Billiton International Metals BV and Alcoa reportedly decided not to proceed with their planned joint-venture development of a 2.25-million-ton-per-year bauxite mine near Oriximiná in the Brazilian State of Pará. Alternatively, Alcoa intends to become a shareholder in Mineração Rio do Norte's (MRN) Trombetas bauxite mining operation. In a related action, Alcan will exchange 12% of its participation in MRN for a 10% interest in the Alcoa-Billiton 1-million-ton-per-year São Luís alumina plant in Maranhão State.

In a related issue, the Brazilian Government granted Alumar approval to invest \$450 million for the expansion of its alumina plant at São Luis to the 2.1-million-ton-per-year level, with

completion of the project expected by 1994.

Cia. Brasileira de Alumínio (CBA) reportedly has decided to invest \$200 million to build a 200,000-ton-per-year alumina plant in east-central Minas Gerais State. The project had been on hold since 1989 because CBA was required to obtain both State and Federal authorization for the proposed development plan.

Canada.—During 1991, Alcan Aluminium commissioned a superwhite hydrate facility at its alumina plant at Jonquiére, Quebec. The new installation will produce commercial alumina-based chemicals for markets within North America.

In addition, Alcan announced that it had placed its Bayer Experimental Centre in Quebec into operation. The pilot plant provides a facility for carrying out experiments associated with the processing of bauxite and alumina. The research installation was designed to enable Alcan and its partner, Comalco, to develop the design of a new joint-venture alumina plant being considered for the Weipa area of Australia.

China.—As previously indicated, according to Chinese officials, the first phase of construction at the Pingguo Aluminium facilities in Guangxi Zhuang Autonomous Region was reported to have begun in 1991. Under this initial phase of the project, scheduled for completion in 1994, a 300,000-ton-per-year alumina plant and a 100,000-ton-per-year aluminum smelter are reportedly being constructed at a cost of \$519 million. It was planned that the bauxite feed for this aluminum complex would be drawn from five nearby mining areas where ore reserves have been estimated at 200 million tons.

Greece.—The Greek Government was reportedly seeking private investors to participate in the Hellenic Alumina Industry SA (ELVA) alumina plant planned for construction at Thisvi, in Boeotia. In the past 2 years, the cost of

this project has escalated from \$650 million to approximately \$850 million, owing in part to design modifications that have increased the plant's originally planned capacity from 600,000 tons per year to the currently contemplated 700,000 tons per year.

Guinea.—Mine planning and development for the Bidikoum bauxite deposit commenced in late 1991. The blending of ores from this newly opened mine site in the Boké region, with those from the adjacent Sangaredi Mine, will extend the overall life of the 12-million-ton-per-year Compagnie des Bauxites de Guinée (CBG) mining operation.

Guyana.—Aroaima Mining Co., a 50-50 joint venture of Reynolds Metals and the Government of Guyana, attained its full annualized mine production capacity of 1.5 million tons in 1991. The consortium, based in Barbados, has developed two mining sites along Guyana's Berbice River, with combined bauxite reserves of 25 million tons. The project's initial bauxite output was mined for sale to third-party buyers, as well as for purchase by Reynolds.

The Bauxite Industry Development Co. Ltd. (Bidco) and its subsidiary Guyana Mining Enterprise, Ltd. (Guymine) announced that they were considering the appointment of an engineering or mining company to undertake the management and restructuring of their principal bauxite production facilities at Linden. The Guymine Linden operations reportedly has a capacity of approximately 400,000 tons per year of mostly refractory-grade bauxite.

Hungary.—On June 30, 1991, Hungalu, a state-owned enterprise, was transformed into a public limited company according to the provisions of Hungarian Act XIII of 1989 dealing with the reorganization of economic organizations within Hungary.

As earlier noted, in the painful process of transition to a free market industry, Hungalu at midyear announced that it

planned to phase out its primary aluminum production, but would maintain operations at its three alumina plants and its semifabricating facilities. Hungalu intended to maintain these operations as profit centers for the attraction of investors into various privatization ventures.

Hungalu's bauxite production base shrunk in 1991 when two of five mines, both underground operations, were closed to ease the strain of mine dewatering procedures on the level of the regional water table.

India.—It was announced that India's state-owned Nalco received formal Government approval to expand existing operations at its Orissa complex by 50%. Nalco indicated that work on the expansion was scheduled to commence in 1992, with final completion of the project in 1995. The program reportedly includes a doubling of bauxite output from 2.4 to 4.8 million tons per year at its Panchapatmali mines in Koraput District, plus an increase of alumina production from 0.8 to 1.35 million tons per year at its Damanjodi plant, Koraput District.

The Government of India reportedly has decided, under its new liberal economic policies, to open bauxite mining to the private sector. This has led to the States of Gujarat and Andhra Pradesh providing invitations to private firms for the development of their respective bauxite deposits. The Gujarat Mineral Development Corp. released plans for the establishment of a 50,000-ton-per-year bauxite calcination plant.

Indonesia.—It was announced that Indonesia's state-owned PT Aneka Tambang intended to expand bauxite production by developing a deposit at Lomesa on Bintan Island, contingent upon approval from the local authorities. Under a 30-year contract, the company holds the exclusive mining rights for a 10,470-hectare mining concession on Bintan Island. Ore reserves for the Lomesa area reportedly have been estimated at 4 million tons of bauxite.

The PT Indonesia Asahan Aluminum (Inalum) smelter reportedly canceled contracts for 48,000 tons of alumina due to a 25,000-ton-per-year cutback in aluminum metal production. Inalum was forced to reduce its power usage, and as a result its metal output, because light rainfall had limited hydroelectric production at its affiliated power facilities on the Asahan River.

Iran.—The Iranian Ministry of Mining and Metal Industries reportedly awarded a \$357.2 million contract for the construction of a 250,000-ton-per-year alumina plant in Iran to the Hungarian aluminum industry's Planning and Research Institute (ALUTERV).

Italy.—In June 1991, Sardabauxiti S.p.A., a subsidiary of the Sardinian state-backed Ente Minerario Sardo, officially inaugurated its 350,000-ton-per-year Olmedo underground bauxite mine in the Nurra region of northwestern Sardinia. In addition to Olmedo, Sardabauxiti reportedly was developing plans to mine the near-surface bauxite deposits at Montigiù de Su Cossu.

Jamaica.—The Alumina Partners of Jamaica (Alpart) alumina plant, owned by Kaiser Aluminum (65%) and Hydro Aluminium (35%), reportedly produced 1.3 million tons of alumina in 1991. This was an increase of 110,000 tons compared with that of 1990. In conjunction with this production increase, the first phase of a modernization and expansion program to increase Alpart's capacity to 1.45 million tons per year was being implemented during 1991, with completion of the capacity increase expected for yearend 1992. A further expansion of annual capacity to 2 million tons per year was reportedly being considered by the participants in Alpart.

It was announced that Alcan would spend \$200 million to upgrade and expand its bauxite mining and alumina production facilities in Jamaica. The expansion program included the construction of a 2.5-mile cableway for

the transportation of bauxite from mines in the Comfort area to the Alcan Jamaica Ltd. alumina plant at Kirkvine, Manchester.

In 1991, it was reported that Jamaica's Government-owned Bauxite and Alumina Trading Co. (Batco) had signed a new 3-year agreement with Pechiney for the supply of 150,000 tons per year of bauxite.

Political changes within the U.S.S.R. late in 1991 reportedly resulted in the premature termination of a \$125 million, 5-year agreement for Jamaica to provide 1 million tons per year of bauxite to the U.S.S.R.

Netherlands.—It was announced that the Dutch aluminum smelter, Aluminium Delfzijl BV, a unit of Hoogovens, entered a new 7-year alumina supply contract with Royal Dutch/Shell's metals subsidiary, Billiton Marketing & Trading BV.

Sierra Leone.—It was announced that Alusuisse Lonza continued its negotiations in 1991 with the Sierra Leone Government regarding the updating and modification of existing bauxite mining contracts. The talks that commenced in 1990 apparently were open-ended and the existing mining agreement remains in effect until the parties reach a new agreement.

Suriname.—Suriname Aluminium Co. (Suralco) announced that its Coermotibo bauxite mine in Suriname was scheduled to come on-stream in mid-September. When fully operational, this mine should replace the Moengo mining operations, where reserves reportedly are nearly exhausted.

Additionally, in further mining developments, a new 500-ton bucket wheel excavator with its support equipment was delivered to Suriname in early 1991 to be used by Billiton Maatschappij Suriname (BMS) for overburden removal at the new Accaribo Mine near Paranam, a joint-venture operation between BMS (76%) and Suralco (24%).

U.S.S.R.—The Government of the U.S.S.R. reportedly ceased financing capital improvements at the Severoural'sk bauxite mine in Sverdlovsk Oblast. The underground mining operations reportedly exploit bauxite ores from depths of over 1,000 meters with substandard equipment and under very dangerous operating conditions. This disruption in funding may require the mothballing of the 12 projects that were under construction by the Boksitstroy Trust to make up for recently declining production levels. The new equipment and facilities, worth an estimated \$22 million, were due to come on-stream in 1992.

Venezuela.—It was reported that C.V.G.-Interamericana de Alumina, C.A. (Interalumina) of Venezuela had completed a \$350 million expansion program that increased its alumina production capacity from 1.3 to 2 million tons per year. In addition, Venezuela's C.V.G. Bauxita Venezolana C.A. (Bauxiven) announced that its 1991 ore production reached approximately 2.0 million tons, an exceedingly significant increase over 1990's 771,000 tons. During 1991, Bauxiven reportedly invested \$85 million to increase efficiency at its Los Pijiguaos mining operations, and it estimated a similar investment for 1992. (See tables 35, 36, and 37.)

Current Research

In 1991, Alcan International Ltd. announced the results of research into pilot plant tests for the conversion of Bayer-process-produced sodium oxalate to oxalic acid by an ion-exchange process.⁸ During Bayer processing of bauxite ores, organic carbon contaminants within the ores undergo degradation to sodium oxalate that builds up to equilibrium concentrations and remains in the recycled Bayer liquor of an alumina plant. This sodium oxalate causes processing and product quality problems in the production of alumina and, therefore, must be removed from the liquor when its concentration approaches the supersaturation point. Oxalic acid is

a commodity with extensive industrial applications; i.e., as a laundry bleach, a cleansing agent for metals, a textile finishing agent, and in the manufacture of dyes. The concept of converting sodium oxalate derived from the Bayer process to oxalic acid is not a new industrial strategy; VAW was granted a patent in 1977 for a similar byproduct approach based on the reaction of oxalate with lime at elevated temperature. Alcan's tests were conducted on a pilot plant scale for the preparation of a concentrated solution of oxalic acid as well as the recovery of acid dihydrate by the ion-exchange process, a less complicated and possibly safer method than that tested by VAW. The Alcan research work determined that the ion-exchange technique was a technically viable process for the transformation of Bayer sodium oxalate into oxalic acid. The method was simple to operate and required little maintenance and was found capable of generating some degree of cash-flow.

In related research, associated with seeking improvements to the Bayer process, Aluminium Oxid Stade GmbH (AOS), a 50-50 joint venture of VAW and Reynolds Metals, reported on its methods for the removal of organic carbon from Bayer liquor by wet oxidation in tube digesters.⁹ This research work, on an industrial scale, at AOS's Stade, Germany, facility, determined that maintaining less than 1% oxygen in the waste gases of the tube-digester units resulted in safe wet oxidation during oxygen injection into superhigh temperature tube digestion systems. The primary reason for this application of wet oxidation methods at AOS has been to slowly reduce, over a long period; i.e., years, the organic carbon content of the plant's Bayer circuit liquors.

OUTLOOK—BAUXITE AND ALUMINA

Known world bauxite reserves are sufficient to meet cumulative world demand well into the 21st century. Considering the high degree of

probability for discovering additional bauxite deposits and assuming reasonable energy costs, plus the added possibility of utilizing lower grade bauxite deposits and other alternative sources of alumina, world resources of aluminum are more than adequate to fulfill demand for the foreseeable future.

The shift of alumina production facilities from the aluminum-producing industrial countries with high energy costs, in North America and Europe, to the bauxite-producing countries of the world is expected to continue in the future. If the costs of imported bauxite and alumina increase for U.S. companies, alternate domestic sources of alumina may become economically more attractive feedstocks for the aluminum industry. Alternatively, high fuel prices tend to make nonbauxitic materials less competitive because the processes for treating substitute materials require considerably greater amounts of energy than that for Bayer-processed bauxite. It therefore seems evident that nonbauxitic sources of aluminum would become viable only within the context of a prolonged national emergency or international embargo extending over a period of several years. Imports of primary aluminum metal from countries with low electrical energy costs and secondary production from recycled aluminum appear likely to be used in ever-increasing proportions to meet the domestic demand for aluminum.

In addition, the future economic restructuring of Eastern Europe and the U.S.S.R. may greatly expand the potential market opportunities available to the firmly established bauxite- and alumina-producing countries of the world. The quality and quantity of bauxite resources within the former Eastern bloc nations are estimated to be incapable of sustaining an economically sound market-based aluminum industry. To become competitive in the "new global economy," major amounts of imported bauxite and alumina feedstocks will be required to support the aluminum industries of the U.S.S.R. and Eastern Europe.

Beyond alumina's principal use in the production of aluminum metal, the future will see an increased demand for alumina within specialty markets (abrasive, chemical, new materials, and refractory applications). Economic forecasts project that these very specialized markets will become significant profit centers for the aluminum industry of the future.

TABLE 7—Continued
**U. S. STOCKS, RECEIPTS, AND CONSUMPTION OF PURCHASED NEW AND OLD ALUMINUM
 SCRAP¹ AND SWEATED PIG IN 1991**

(Metric tons)

Class of consumer and type of scrap	Stocks, Jan. 1	Net receipts ²	Consumption	Stocks, Dec. 31
Sweated pig	1,788	28,005	27,969	1,825
Total of all scrap consumed ⁶	<u>84,016</u>	<u>2,700,258</u>	<u>2,686,735</u>	<u>97,538</u>

¹Revised.

²Includes imported scrap. According to reporting companies, 3.60% of total receipts of aluminum-base scrap, or 97,228 metric tons, was received on toll arrangements.

³Includes inventory adjustment.

⁴Includes data on foil, can stock clippings, and other miscellaneous.

⁵Used beverage cans toll treated for primary producers are included in secondary smelter tabulation.

⁶Includes municipal wastes (includes litter) and fragmentized scrap (auto shredder).

⁷Data may not add to totals shown because of independent rounding.

TABLE 8
PRODUCTION AND SHIPMENTS OF SECONDARY ALUMINUM ALLOYS BY
INDEPENDENT SMELTERS IN THE UNITED STATES

(Metric tons)

	1990		1991	
	Production	Net shipments ¹	Production	Net shipments ¹
Die-cast alloys:				
13% Si, 360, etc. (0.6% Cu, maximum)	60,935	61,918	60,690	59,909
380 and variations	273,432	272,270	308,968	310,083
Sand and permanent mold:

No. 12 and variations	W	W	W	W
No. 319 and variations	57,284	55,577	49,308	51,491
F-132 alloy and variations	8,693	11,279	13,770	17,294
Al-Mg alloys	695	700	723	719
Al-Zn alloys	2,648	2,489	2,761	2,789
Al-Si alloys (0.6% to 2.0% Cu)	11,896	11,906	8,608	8,420
Al-Cu alloys (1.5% Si, maximum)	1,753	1,745	1,195	1,249
Al-Si-Cu-Ni alloys	1,174	1,178	1,278	1,272
Other	1,468	1,357	890	1,006
Wrought alloys: Extrusion billets	125,604	125,937	67,922	68,827
Miscellaneous:				
Steel deoxidation	4,866	5,437	6,690	6,690
Pure (97.0% Al)	29	29	117	4,865
Aluminum-base hardeners	1,478	1,520	100	445
Other ²	34,407	34,787	29,060	27,571
Total	602,980	604,735	564,667	575,283
Less consumption of materials other than scrap:				
Primary aluminum	43,336	—	15,881	—
Primary silicon	29,127	—	26,979	—
Other	3,320	—	1,888	—
Net metallic recovery from aluminum scrap and sweated pig consumed in production of secondary aluminum ingot³	527,197	XX	519,919	XX

W Withheld to avoid disclosing company proprietary data; included with "Sand and permanent mold: Other. XX Not applicable.

¹Includes inventory adjustment.

²Includes other die-cast alloys and other miscellaneous.

³No allowance made for melt-loss of primary aluminum and alloying ingredients.

TABLE 9
U.S. APPARENT ALUMINUM SUPPLY AND CONSUMPTION
(Thousand metric tons)

	1987	1988	1989	1990	1991
Primary production	3,343	3,944	4,030	4,048	4,121
Change in stocks: ¹					
Aluminum industry	+341	+11	+61	+2	+32
LME stocks in U.S. warehouses	—	—	—	—	-168
Imports	1,850	1,620	1,470	1,514	1,490
Secondary recovery: ²					
New scrap	1,134	1,077	1,043	1,034	979
Old scrap	852	1,045	1,011	1,359	1,522
Total supply	7,520	7,697	7,615	7,957	7,976
Less total exports	917	1,247	1,615	1,659	1,762
Apparent aluminum supply available for domestic manufacturing	6,603	6,450	6,000	6,298	6,214
Apparent consumption ³	5,469	5,373	4,957	5,264	5,235

¹Revised.

²Positive figure indicates a decrease in stocks; negative figure indicates an increase in stocks.

³Metallic recovery from purchased, tolled, or imported new and old aluminum scrap expanded for full industry coverage.

⁴Apparent aluminum supply available for domestic manufacturing less recovery from purchased new scrap (a measure of consumption in manufactured end products).

¹Detailed information on the individual aluminum reduction plants is available in a two-part report that can be ordered from Aluminum Specialist, U.S. Bureau of Mines, 810 7th Street NW, MS #5208, Washington, DC 20241. Part 1 of "Primary Aluminum Plants, Worldwide" details location, ownership, and production capacity for 1988-95 and sources of energy for foreign and domestic primary aluminum plants, including those in centrally planned economies. Part 2 summarizes production capacities for 1988-95 by smelter and country.

TABLE 20—Continued
ALUMINUM, PRIMARY: WORLD PRODUCTION,¹ BY COUNTRY

(Thousand metric tons)

Country	1987	1988	1989	1990	1991 ^a
Venezuela	428	437	540	590	600
Yugoslavia ^b	244	260	331	349	315
Total	16,514	17,548	18,199	17,977	18,194

^aEstimated. ^bRevised. NA Not available.

¹The U.S. Bureau of Mines defines primary aluminum as "The weight of liquid aluminum as tapped from pots, excluding the weight of any alloying materials as well as that of any metal produced from either returned scrap or remelted materials." International reporting practices vary from country to country, some nations conforming to the foregoing definition and others using different definitions. For those countries for which a different definition is given specifically in the source publication, that definition is provided in this table by footnote. Table includes data available through May 27, 1992.

²Reported figure.

³Primary ingot.

⁴Excludes high-purity aluminum containing 99.995% or more as follows, in metric tons: 1987—12,099; 1988—13,628; 1989—15,696; 1990—16,292; and 1991—19,652.

⁵Primary unalloyed ingot plus secondary unalloyed ingot.

⁶Primary unalloyed metal plus primary alloyed metal, thus including weight of alloying material.

⁷Data do not add to total shown because of independent rounding.

TABLE 21
SALIENT BAUXITE STATISTICS

(Thousand metric tons and thousand dollars)

	1987	1988	1989	1990	1991

³Table includes data available through June 16, 1992.

⁴Reported figure.

⁵Dry bauxite equivalent of crude ore.

⁶Dry bauxite equivalent of ore processed by drying plant.

⁷Less than 1/2 unit.

⁸Bauxite processed for conversion to alumina in Jamaica plus kiln-dried ore prepared for export.

⁹Public-sector production only.

¹⁰In addition to the bauxite reported in the body of the table, the U.S.S.R. produces nepheline syenite concentrates and alunite ore as sources of aluminum. Nepheline syenite concentrate production was as follows, in thousand metric tons: 1987—1,660; 1988—1,639; 1989—1,697; 1990—1,650 (estimated); and 1991—1,500 (estimated). Estimated alunite ore production was as follows, in thousand metric tons: 1987—625; 1988—625; 1989—600; 1990—550; and 1991—500. Nepheline syenite concentrate grades 25% to 30% alumina, and alunite ore grades 16% to 18% alumina; these commodities may be converted to their bauxite equivalent by using factors of 1 ton of nepheline syenite concentrate equals 0.55 ton of bauxite and 1 ton of alunite equals 0.34 ton of bauxite.

³Reported figure.

⁴Hydrate.

⁵Data presented are for alumina for metallurgical use. Gross weight of aluminum hydrate for all uses was as follows, in thousand metric tons: 1987—711; 1988—778; 1989—863; 1990—890; and 1991—864.

⁶Data may not add to totals shown because of independent rounding.

ANTIMONY

By Thomas O. Llewellyn

Mr. Llewellyn, a physical scientist with more than 30 years of industry and U.S. Bureau of Mines experience, has been the commodity specialist for antimony since 1987. Domestic survey data were prepared by Elsie Isaac, statistical assistant; and international data were prepared by Ronald Hatch, international data assistant, Section of International Data.

The production and reported consumption of primary antimony products decreased in 1991 compared with that of 1990 as a result of a general softening of demand in the antimony market. Exports and imports of antimony products were also down from those of the previous year. A coalition of five U.S. antimony trioxide producers and/or manufacturers of antimony trioxide-based products filed an antidumping petition with the U.S. International Trade Commission (ITC) and the U.S. Department of Commerce, charging China with unfair trade practices.

DOMESTIC DATA COVERAGE

Domestic production data for antimony are developed by the U.S. Bureau of Mines from two voluntary surveys of U.S. operations. Typical of these surveys is the "Primary Antimony" survey. Of the six operations to which a survey request was sent, all responded, representing 100% of the primary smelter production shown in table 1 and 100% of the total antimony content of primary antimony production by class shown in table 2. (See table 1.)

BACKGROUND

Antimony, from the Greek *anti plus monos*, means "a metal seldom found alone." Although the name was intended to describe the metal's mineralogical association in ores, it also properly describes the use of antimony in modern industry because the metal is usually used

as an alloy with other metals. The natural sulfide of antimony, stibnite, was known and used in Biblical times as medicine and as a cosmetic for eyebrow painting. A vase found at Tello, Chaldea, reportedly cast in metallic antimony, indicates that in about 4000 B.C. the Chaldeans knew the art of reducing the sulfide to metal.

The known domestic deposits of antimony ore have generally been small and uneconomical when compared to foreign producers, resulting in a dependence on foreign sources of supply by the United States. Bolivia, China, Mexico, and the Republic of South Africa have historically been the principal sources of supply.

Definitions, Grades, and Specifications

Antimony is seldom found in nature as native metal because of its strong affinity for sulfur and the metallic elements such as copper, lead, and silver. Antimony in its elemental form is a silvery white, brittle, crystalline solid that exhibits poor electrical and heat conductivity properties. The National Stockpile Purchase Specification P-2a-R4, June 10, 1980, covered two grades of refined antimony metal ingot form. Grade A has a minimum antimony content of 99.8% and the following impurity maximums: arsenic, 0.05%; sulfur, 0.10%; lead, 0.15%; and other elements (copper, iron, nickel, silver, and tin), 0.05% each. Grade B material is composed of 99.5% antimony as a minimum with maximum impurity levels of 0.1% arsenic, 0.1%

sulfur, 0.2% lead, and 0.1% each of other elements.

Chemical-grade ore is that which is sufficiently pure to be used directly in producing the trioxide, chloride, or other industrial chemical compound. For chemical-grade sulfide ore, total impurities, including arsenic and lead, must not exceed 0.25%, and no single metallic impurity can exceed 0.1%.

Antimony trioxide, the most important of the antimony compounds, is used in flame-retarding formulations for many materials. Most commercial grades of antimony trioxide contain between 99.2% and 99.5% antimony trioxide with varying amounts of impurities such as arsenic, iron, and lead. Commercial suppliers offer various grades of antimony trioxide based on the relative tinting strength of their product, which is related to average particle size. In general, the tinting strength increases as the particle size decreases.

Industry Structure

Antimony was produced from ores and as a byproduct of the smelting of base metals ores in about 23 countries. China, the world's leading producer, accounted for about 54% of the total world estimated mine production during 1991. China together with the other four major producing countries, Bolivia, Mexico, the Republic of South Africa, and the U.S.S.R., accounted for about 90% of the total world antimony production. In 1991, antimony production from domestic source materials was largely derived from

recycling of lead-antimony batteries. Recycling plus mine output supplied less than one-half of the estimated domestic demand. Primary antimony was recovered as a byproduct from the smelting of domestic lead and from silver-copper ores.

Antimony metal and trioxide producers in the United States are essentially large, integrated companies with a variety of activities in marketing and manufacturing of base metals and chemical compounds. A few producers and processors of antimony have interests in foreign operations. Most purchase raw materials from mine and smelter operations either directly or through dealers.

Geology-Resources

Estimates of the abundance of antimony in the Earth's crust range from 0.2 to 0.5 parts per million. Antimony is chalcophile, occurring with sulfur and the heavy metals, copper, lead, and silver. More than 100 minerals of antimony are found in nature. Stibnite (Sb_2S_3) is the predominant ore mineral of antimony.

Simple antimony deposits consist principally of stibnite or, rarely, native antimony in a siliceous gangue, commonly with some pyrite, and in places a little gold and small amounts of other metal sulfides, principally silver and mercury. Antimony ores commonly are associated with igneous activity and have common genetic association with such intrusives as granite, diorites, and monzonites. The mineralogy of the veins and their almost invariably shallow depth suggest a low temperature of formation at near-surface positions, possibly related to the configuration of the water table at the time of deposition. Most of these geologically simple stibnite deposits do not individually contain more than several thousand tons of ore. Deposits of this type are found in the world's most productive antimony districts, including those of Bolivia, China, Mexico, and the Republic of South Africa.

Complex antimony deposits consist of stibnite associated with pyrite, arsenopyrite, cinnabar, or scheelite, or of antimony sulfosalts with varying amounts

of copper, lead, and silver, as well as common sulfides of these metals and zinc. Ores of the complex deposits generally are mined primarily for gold, lead, silver, tungsten, or zinc.

Most of the antimony produced in the United States is from complex deposits. The tetrahedrite ores found in the Coeur d'Alene district of Idaho are outstanding examples of complex deposits.¹

Principal identified world antimony resources, at about 5 million tons, are in Bolivia, China, Mexico, the Republic of South Africa, and the U.S.S.R. U.S. resources are mainly in Alaska, Idaho, Montana, and Nevada.

Technology

Antimony deposits are seldom explored in advance of actual mining because the deposits are generally small, irregular, and difficult to appraise.

Many of the typically small mines contain irregular and scattered ore bodies that cannot be readily exploited by large-scale mining methods. Mining methods used in mines that recover metalliferous ores, of which antimony is a minor constituent, are designed for producing the principal metals such as gold, lead, or silver.

The antimony content of ores determines the method of recovery. In general, the lowest grades of sulfide ores, 5% to 25% antimony, are roasted; 25% to 40% antimony ores are smelted in a blast furnace; and 45% to 60% antimony ores are liquated. At some mines in Bolivia and the Republic of South Africa, the high-grade sulfide ore is concentrated by hand-cobbing and sold as lump sulfide ore, 60% antimony content. As higher grade deposits have become depleted, increasing emphasis has been placed on upgrading low-grade ores by flotation.

Roasting of the ore to yield a volatile trioxide or the stable nonvolatile tetroxide is the only pyrometallurgical procedure suitable for low-grade ores (5% to 25% antimony content). The sulfur is oxidized and removed from waste gases, and the volatilized antimony oxide is recovered in flues, condensing pipes, a baghouse, precipitators, or a combination of the

above. The temperature and quantity of available oxygen determine the kind and quantity of the oxide produced. The oxide produced by this method is generally impure and can be reduced to metal. However, careful control of volatilization conditions will produce a high-grade oxide that can be sold directly to consumers.

Water-jacketed blast furnaces are used in several plants to reduce ores containing 25% to 40% antimony. Oxides, sulfides, or mixed ores, residues, mattes, slags, and briquetted fines or flue dusts can be used as blast furnace charges. A high smelting column and comparatively low air pressure are used, and the slag and metal are separated in the hearth.

Antimony sulfide can be separated from the gangue of sulfide ores by melting in a reverberatory furnace. A reducing atmosphere is kept to prevent oxidation. The solidified product is called liquated or needle antimony and may be used as sulfide or converted to antimony metal by iron precipitation.

Some complex ores can be treated by leaching and electrowinning to recover the antimony. A typical process uses an alkali hydroxide or sulfide as the solvent. The filtered leach solution containing sodium thioantimonate, Na_3SbS_4 , is electrolyzed in a diaphragm cell using an iron or lead anode and an iron or mild-steel cathode. The cathode metal obtained is 93% to 99% pure antimony.² Antimony metal is also produced as antimonial lead, which is an important product of the secondary lead smelter. A blast furnace charge containing used or discarded battery plates, type metal, and bearing metal is reduced to a lead bullion. The bullion is refined in reverberatory furnaces and melting pots to meet specifications.

Byproducts and Coproducts

Most of the domestic primary antimony production is a byproduct or coproduct of mining, smelting, and refining other metals and ores that contain relatively small quantities of antimony. In 1991, domestic production of antimony was mainly a byproduct of treatment of

tetrahedrite, a complex silver-copper-antimony sulfide ore. An undisclosed amount of antimony was also recovered as a byproduct of the processing of lead ores.

The antimony deposits of the Republic of South Africa contain gold. High-grade Bolivian antimony ores contain variable and minor values of gold and tungsten and objectionable amounts of arsenic, copper, and lead in some deposits. Chinese ores contain some tungsten.

Substitutes

Compounds of chromium, tin, titanium, zinc, and zirconium substitute for antimony chemicals in paint, pigments, frits, and enamels. A combination of cadmium, calcium, copper, selenium, strontium, sulfur, and tin can be used as substitutes for hardening lead. Selected organic compounds and hydrated aluminum oxide are widely accepted alternative materials in flame-retardant systems.

Economic Factors

Antimony and antimony trioxide are taxed under the new Superfund Amendments and Reauthorization Act of 1986, Public Law 99-499. The taxes, to be collected from producers and importers, were \$4.90 per ton of antimony metal and \$4.13 per ton of antimony trioxide. The taxes have been rescheduled to end on December 31, 1995.

Antimony producers are granted a depletion allowance of 22% on domestic production and 14% on foreign production.

Under the new Harmonized Tariff Schedule of the United States, which took effect January 1, 1989, antimony ore and concentrates imports from most favored nations (MFN) and non-most-favored nations (non-MFN) were duty free. Antimony and articles thereof, including waste and scrap, and antimony oxide were duty free for MFN. However, from non-MFN a statutory duty of 4.4 cents per kilogram was imposed.

Operating Factors

Environmental and ecological problems associated with the processing of antimony metal and ores are minimal because emissions and effluents are controlled at the processing site.

The major conservation practice of the antimony industry is the recycling of the metal in used storage batteries, type metal, and babbitt. Antimony metal and antimonial lead from intermediate smelter products such as slags, drosses, flue dusts, and residues generated at copper and lead smelters are recovered at lead smelters.

Energy requirements for the production of antimony metal and antimony trioxide from stibnite ores are 163 million British thermal units (Btu's) per net ton of antimony metal and 186 million Btu's per net ton of antimony trioxide.³

An estimated 210 persons are employed in the domestic production of antimony ores and in conversion of antimony ores and raw materials to antimony metal and compounds.

ANNUAL REVIEW

Legislation and Government Programs

On April 25, 1991, a coalition of five U.S. antimony trioxide producers and/or manufacturers of antimony trioxide-based products filed an antidumping petition with the United States ITC and the U.S. Department of Commerce, charging China with unfair trade practices.

The coalition members requesting the initiation of an investigation, on behalf of the U.S. refining antimony trioxide industry, were: Anzon Inc. and Atochem North America, Inc. of Philadelphia, PA; Laurel Industries Inc. of Cleveland, OH; U.S. Antimony Corp. of Thompson Falls, MT; and U.S. Antimony Sales Corp. of Natick, MA.⁴

On June 5, 1991, the ITC's preliminary investigation determined that there was a reasonable indication of material injury or threatened material injury to the domestic antimony trioxide refining industry as a result of

Chinese-refined antimony trioxide imports.⁵

On October 9, 1991, the Commerce Department announced its preliminary determination that all Chinese antimony trioxide entering the United States should be assessed a dumping margin of 3.18%.⁶

On October 23, 1991, the ITC established a schedule for its final antidumping duty investigation of refined antimony trioxide imported from China. At the request of Chinese officials on November 6, 1991, the Department of Commerce extended the date for its final determination in the investigation from December 16, 1991, to February 21, 1992. To conform with the new schedule by the Department of Commerce, the ITC also revised its schedule for the final investigation, and the hearing scheduled for December 19, 1991, was rescheduled to be held on February 25, 1992, at the ITC building, 500 E Street, SW, Washington, DC.⁷

Strategic Considerations

Antimony was included in the National Defense Stockpile because of its strategic uses in flame-retardant compounds, friction bearings, and batteries.

No inventory acquisitions or sales were made during the year, and, as of December 31, 1991, the stockpile inventory was 32,658 metric tons of antimony metal.

Domestic Production

Mine Production.—Sunshine Mining Co. produced antimony as a byproduct of the treatment of tetrahedrite, a complex silver-copper-antimony sulfide ore, from the Coeur d'Alene district of Idaho.

Smelter Production.—Primary.—The producers of primary antimony metal and oxide products were ASARCO Incorporated, Omaha, NE; Amspec Chemical Corp., Gloucester City, NJ; Anzon Inc., Laredo, TX; Laurel Industries Inc., La Porte, TX; Sunshine Mining Co., Kellogg, ID; and U.S.

Antimony Corp., Thompson Falls, MT. (See table 2.)

Secondary.—Old scrap, predominantly lead battery plates, was the source of most of the secondary antimony output. New scrap, mostly in the form of drosses and residues from various sources, supplied the remainder. The antimony content of scrap was usually recovered and consumed as antimonial lead. (See table 3.)

Consumption and Uses

Reported domestic consumption of primary antimony products decreased in 1991 compared with 1990 as a result of a general softening of demand in the antimony market. Lead-antimony alloys were used in starting-lighting-ignition batteries, ammunition, corrosion resistant pumps and pipes, tank linings, roofing sheets, solder, cable sheaths, and antifriction bearings.

Antimony compounds were used in plastics both as stabilizers and as flame retardant. Antimony trioxide in an organic solvent was used to make textiles, plastics, and other combustibles flame retardant. Antimony was used as a decolorizing and refining agent in some forms of glass, such as special optical glass. The estimated distribution of antimony uses was flame retardants, 73%; transportation, including batteries, 9%; chemicals, 9%; ceramics and glass, 4%; and other, 5%. (See tables 4, 5, and 6.)

Markets and Prices

The New York dealer antimony metal price, published by Metals Week, started the year ranging from \$0.78 to \$0.80 per pound, held steady during January, and increased to a range of \$0.84 to \$0.85 per pound by mid-March. At yearend, the dealer price range was listed at \$0.82 to \$0.84 per pound.

The price range for high-tint antimony trioxide was \$1.10 per pound at the beginning of the year and remained constant for the rest of 1991.

The European price range quotation for clean antimony sulfide concentrate (60% antimony content), published by Metal Bulletin (London), which was \$15 to \$17 per metric ton unit at the beginning of 1991, decreased to a range of \$14.50 to \$16.50 per metric ton unit at the beginning of the second quarter, and remained constant for the rest of the year. The European price range quotation for lump antimony sulfide ore (60% antimony content) held steady at \$15.50 to \$17 per metric ton unit during 1991. (See tables 7, 8, 9, 10, and 11.)

World Review

Capacity.—The data in table 12 represent rated annual production capacity for mines and refineries on December 31, 1991. Rated capacity was defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable, long-term operating rate, based on the physical equipment of the plant and routine operating procedures for labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure.

The rated capacity of mines and refineries for antimony was estimated based on discussions with some officials from private industry, past and present production rate, and published capacity data. (See tables 12 and 13.)

Bolivia.—Once more antimony producers from Bolivia and China attempted to control the prices of antimony through a bilateral agreement. Both countries agreed to set a quarterly minimum reference price of \$1,760 per metric ton for metal and \$15.20 per metric ton unit of concentrate (60% antimony content), c.i.f. Rotterdam. This new antimony agreement was signed on May 15, 1991. The previous agreement signed between these two countries was on January 7, 1989; but in May 1990, Bolivian officials withdrew their

participation in the joint Bolivian-Chinese effort to control producer prices as, in their opinion, the agreement failed to achieve its objective of coordinating policies of the two countries on antimony production and trade.⁸ The new antimony agreement was seen by American and European traders as another possible failure.

Japan.—Antimony trioxide production, mainly from imported materials, was 11,908 tons, an increase of about 8% compared with 1990 production. Antimony metal production also increased from 216 tons in 1990 to 262 tons in 1991.

Current Research

Antimony content in the aluminum scrap supply could become an increasing problem as more Japanese and European cars, as well as other consumed materials, enter the waste-recycling stream. Japan and Europe use antimony to modify the physical properties of aluminum alloys while the United States usually does not. Aluminum-bearing antimony should not be used to manufacture cooking utensils. Stibine (SbH_3), a gaseous poisonous binary compound of antimony with hydrogen, could form when a cooking utensil is exposed to an acidic environment. Researchers at the Argonne National Laboratory in Argonne, IL, have successfully removed about 99.9% of the antimony content from a molten aluminum-antimony alloy by adding calcium metal to the melt. It is believed that the calcium and antimony combined to form an insoluble intermetallic compound that reports to the aluminum oxide surface slag.⁹

OUTLOOK

Mining, beneficiation, and metallurgical procedures for antimony have changed little in the past 30 years. No new technological developments that would affect productivity are foreseen for the future.

The oversupply of antimony products from China that has saturated the market in the past 3 years will continue during 1992, and unless China's policy of offering discounts from the world market price shows signs of changing, the prospects for Western antimony trioxide producers will remain not very good.

ARSENIC

By J. Roger Loebenstein

Mr. Loebenstein, a physical scientist with 17 years industry and U.S. Bureau of Mines experience, has been the commodity specialist for arsenic since 1987. Domestic survey data were prepared by Evangeline Hemphill, mineral data assistant; and international data tables were prepared by Harold Willis, international data coordinator.

Aside from small amounts of arsenic trioxide shipped from remaining stocks at ASARCO Incorporated's closed plant at Tacoma, WA, the United States imported all of the arsenic it required in 1991. More than 93% of the arsenic was imported as the trioxide, another 2% as arsenic acid and arsenic sulfide, and less than 5% as metal.

A major producer of arsenic trioxide in Sweden, Boliden Mineral AB, permanently shut down production, reportedly because of environmental problems. At about the same time, China emerged as the world's largest producer of both arsenic trioxide and arsenic metal, selling large amounts of both commodities to the United States.

ANNUAL REVIEW

Legislation and Government Programs

In 1991, the Environmental Protection Agency (EPA) announced its preliminary decision to cancel the registration of products containing arsenic acid used as a desiccant on cotton. The Agency provided for a period of hearings before making its final decision.¹ EPA estimated that current usage of arsenic acid is 2 to 3 million pounds per year, representing 5% to 10% of total U.S. cotton acreage.² It suggested that another chemical, paraquat, possibly could be used as a substitute for arsenic acid. A final ruling by EPA on the use of arsenic acid as a desiccant on cotton was not expected until sometime in 1992.

California's Department of Health Services received a recommendation to lower its drinking water standard for arsenic severely, from 50 parts per

billion, the current Federal standard, to 2 parts per billion. A new risk assessment by the State's Environmental Protection Agency indicated that lifetime consumption of drinking water with levels of arsenic at 50 parts per billion presents a 1% risk of cancer.³

In California, hazardous water has been found primarily in 200 deep wells in Kings, Kern, San Joaquin, and Sonoma Counties. The arsenic is believed to enter water supplies from underground deposits in highly porous rock where wells are often drilled—particularly in desert areas and near mountains.

Issues

In January 1992, a Panamanian ship traveling from New York to Baltimore via Delaware Bay encountered a storm off the coast of Cape May, NJ, and lost four containers of arsenic trioxide weighing a total of 75 metric tons. Subsequently, the Justice Department filed suit against the owner of the Panamanian freighter to help pay for the cleanup. About \$2.7 million in Superfund cleanup money was approved by EPA to help cover the costs of the extensive search and recovery of the arsenic-containing drums. Total cost of recovery was estimated at about \$5 million. The Commerce Department prohibited fishing in the vicinity of the spill.

The U.S. Coast Guard reportedly recovered three of the four shipping containers that were lost at sea, but the fourth container was never located. Of the 440 drums of arsenic trioxide that were lost, 329 were recovered, but not all of the recovered drums were found with

their contents intact.

The U.S. Bureau of Mines began a study of the flow of arsenic-containing materials in the United States. Aspects of materials flow considered in this study include arsenic generated as a result of processing other metals, manufacturing wastes, dissipative uses, and disposal of products.

Consumption

Arsenic trioxide was converted to arsenic acid for use in the production of arsenical wood preservatives by three principal companies, Hickson Corp., Chemical Specialities, Inc., and Osmose Corp. Chromated copper arsenate (CCA) is the most common arsenic-base wood preservative. Other arsenic-base wood preservatives include ammoniacal copper arsenate (ACA) and fluor chrome arsenate phenol (FCAP).

The only two remaining major agricultural uses for arsenic are as herbicides (monosodium methanearsonate or MSMA and disodium methanearsonate or DSMA) for control of weeds and arsenic acid to aid in the mechanical harvesting of cotton in Oklahoma and Texas. ISK Biotech (formerly Fermenta Corp.), Mentor, OH, produced the arsenical herbicide MSMA at a plant in Houston, TX. Atochem Corp., Bryan, TX, was a major producer of arsenic acid for use by cotton growers and wood preservative companies.

Minor amounts of arsenic acid were used by glass companies such as Corning Glass, Corning, NY. Arsenic acid is used as a fining agent to disperse bubbles that tend to form when certain types of glass are produced. As a result of EPA

regulations that became effective in 1986, arsenic emissions from glass furnaces have been sharply reduced.

Commercial-grade arsenic metal, 99% pure, was used in lead- and copper-base alloys as a minor additive (about 0.01% to 0.5%) to increase strength in the posts and grids of lead-acid storage batteries and to improve the corrosion resistance and tensile strength in copper alloys.

Relatively small quantities of high-purity arsenic metal, of 99.99% or higher purity, were used in the manufacture of crystalline gallium arsenide, a semiconducting material used in optoelectronic circuitry, high-speed computers, and other devices. Convex Computer Corp., Richardson, TX, shipped seven of its C3800 model computers in 1991. According to the company, this is the first supercomputer to be fully implemented with gallium arsenide semiconductor technology.

Prices

Prices for arsenic trioxide, 99% pure from Mexico, and arsenic metal, 99% pure from Mexico, are shown in table 2. The average price for Mexican arsenic trioxide increased slightly in 1991 to \$0.25 per pound, while the price of arsenic metal imported from China was down substantially to \$0.68 per pound, a decline from a record-high level in 1990. In 1990, a disruption in supply of arsenic metal from China caused prices to temporarily skyrocket.

Prices for arsenic trioxide are not readily available from published sources, although historical prices from 1955 to 1990 are published in the Chemical Economics Handbook published by SRI International, Menlo Park, CA. Normally, producers quote two prices, one for high-grade (minimum 99%) arsenic trioxide and one for low-grade (minimum 95%) arsenic trioxide. There is a spread of \$0.08 to \$0.12 per pound between the prices of the two grades. The U.S. Bureau of Mines has published yearend arsenic metal prices from 1921 through 1988.⁴

Foreign Trade

The United States imported more than 7,000 metric tons of arsenic trioxide from China in 1991, a large increase from no imports at all in 1989, as shown in table 3. China was also the largest supplier of arsenic metal to the United States in 1991.

Chile was the second largest source of arsenic trioxide imports in 1991, providing slightly less than one-quarter of total U.S. imports. Cia. Minera San José Ltd. produced arsenic trioxide as a byproduct of gold-copper ores roasted at its El Indio smelter. The company was expected to increase production when a new roaster is added to its smelter, sometime in 1992.

World Review

Arsenic was recovered as arsenic trioxide from the smelting or roasting of nonferrous metal ores or concentrates in about 16 countries, as shown in table 4. Annual arsenic trioxide refinery production capacities for the three leading countries were as follows: China, 12,000 tons; Chile, 10,000 tons; and the U.S.S.R., 10,000 tons. Of the producing countries, only Chile and China have countered the trend in recent years toward decreasing arsenic production.

Several changes occurred in producing countries in 1991. Historically, Sweden has been an important producer, but production was shut down permanently in 1991, reportedly for environmental reasons. In France, one of the two major producers of arsenic trioxide from gold ores, Mine et Produits Chimiques de Salsigne, declared bankruptcy. The producers in Belgium and Mexico were under increased pressure to reduce production by Governments concerned with environmental problems associated with arsenic and its potential release to the environment.

Consumers reported that the Chinese arsenic trioxide was generally poor in quality, 97% to 98% pure, and contained a high degree of moisture and foreign material, such as rocks and pebbles. China is believed to be the only country

in the world that produces arsenic trioxide directly from arsenic ores.

Arsenic metal, which accounts for only 3% of world demand for arsenic, was produced by the reduction of arsenic trioxide. Commercial-grade arsenic metal, 99% pure, which accounted for the majority of arsenic metal production, was produced only in China. High-purity arsenic, 99.99% pure or greater, for use in the semiconductor industry was produced in about 10 companies. Furukawa Electric Co. Ltd. in Japan and Preussag AG in Germany were believed to be the world's largest producers, with reported capacities of 30 and 15 tons per year, respectively. Other high-purity arsenic producers included Mitsubishi Metal Corp. and Rasa Industries Ltd. in Japan and Johnson Matthey Ltd. and MCP Electronic Materials Ltd. in the United Kingdom. In Canada, Johnson Matthey Ltd. reportedly stopped production of high-purity arsenic metal early in 1992. The company is continuing to produce gallium arsenide wafers for use in the electronics industry.

OUTLOOK

The anticipated shortfall in arsenic trioxide supplies in 1991 due to Boliden's decision to shut down production in Sweden did not materialize because other producers, most notably Chile and China, made up for the shortfall.

The major market for arsenic is in wood preservatives. The future for arsenic consumption is therefore tied to new housing, where wood decks containing arsenical preservatives have become almost standard items in recent years. Treated wood is also used in decks added to existing houses. The growth of wood preservatives is expected to average 1% to 2% per year for the duration of the current economic recession. No major environmental problems associated with the use of arsenicals in wood preservatives is anticipated because of the small amounts of arsenic used and the fact that arsenic does not readily leach from treated wood.

The use of arsenic in agricultural chemicals has been under close scrutiny

by EPA for many years. Many pesticide uses for arsenical chemicals have been banned by EPA or voluntarily withdrawn by their manufacturers, while the use of the arsenic acid as a cotton desiccant could be banned as early as 1992 (see section under Legislation and Government Programs). The outlook for agricultural chemicals is expected to continue to be negative over the next 5 years.

Gallium arsenide components compete with silicon components in electronic applications. Gallium arsenide components are faster, but silicon components are cheaper. Advances in computer technology have led to the move from linear to parallel arrangement of processors, thus minimizing the relative slowness of silicon. For this reason, it is unlikely that gallium arsenide will replace silicon in most electronic applications, despite growth in gallium arsenide production capacity.

⁵Output of Tsuneb Corp. Ltd. only.

⁶Output of Empresa Minera del Centro del Peru (Centromin Peru) as reported by the Ministerio de Energia y Mines.

⁷Based on arsenic trioxide exported plus the arsenic trioxide equivalent of the output of metallic arsenic exported.

ASBESTOS

By Robert L. Virta

Robert L. Virta, a physical scientist with 16 years U.S. Bureau of Mines experience, has been the commodity specialist for asbestos since 1986. Domestic survey data were prepared by Joseph Daniels, statistical assistant; and international data tables were prepared by Ron Hatch, international data assistant.

The U.S. Court of Appeals for the Fifth Circuit overturned the Environmental Protection Agency (EPA) ruling that would have phased out most uses of asbestos by 1997. The court indicated the EPA did not sufficiently evaluate the health risks posed by substitutes or adequately assess the costs and benefits of less burdensome options to a total ban. Domestic asbestos production increased slightly from that of 1990, but consumption decreased 16%, from 41,348 to 34,765 tons. Asbestos was consumed domestically for roofing products, 44%; friction products, 28%; asbestos-cement pipe, 11%; packing and gaskets, 8%; and other, 9%.

DOMESTIC DATA COVERAGE

Domestic production data for asbestos are developed by the U.S. Bureau of Mines by means of a voluntary industry survey. Of the two canvassed operations to which a survey request was sent, both responded, representing 100% of the total production data shown in table 1. (See table 1.)

ANNUAL REVIEW

Legislation and Government Programs

The U.S. Court of Appeals for the Fifth Circuit overturned EPA's 1989 ruling that would have phased out most uses of asbestos by 1997. The court indicated that EPA did not adequately evaluate the health risks posed by asbestos substitutes or adequately assess the costs and benefits of alternatives to a total ban on the use of asbestos. EPA

can ban asbestos-containing products that were not manufactured or imported prior to July 12, 1989, under the court decision.¹ EPA did not appeal the decision to the U.S. Supreme Court.

EPA issued a final rule on January 30 amending national primary and secondary drinking water regulations. The maximum contaminant and maximum contaminant level goals for asbestos were both set at 7 million fibers (longer than 10 micrometers) per liter. The standard becomes effective in July 1992.²

The Mine Safety and Health Administration continued reviewing its proposed revisions to existing standards for air quality and chemical substances, including the lowering of permissible exposure levels to asbestos from 2.0 fibers per cubic centimeter to 0.2 fibers per cubic centimeter.³

The Occupational Safety and Health Administration (OSHA) issued a final rule on June 8, 1992, removing the nonasbestiform varieties of actinolite, anthophyllite, and tremolite from the scope of its asbestos standard. The nonasbestiform varieties will be regulated according to limits set for "particulates not otherwise regulated."⁴

Strategic Considerations

A wide variety of asbestos-containing civilian products also have military applications. Examples include friction materials (brakes and clutches), electrical and thermal insulations, packings and gaskets, asbestos-reinforced plastics, etc., for use on military vehicles, ships, rockets, missiles, and in military construction. During World War II and

the Korean War, strict controls were placed on the export of asbestos because the United States was dependent on foreign sources for about 90% of its requirements of all grades of asbestos. The United States was totally dependent on foreign sources for low-iron, spinning-grade chrysotile. Since that time, equipment components have been redesigned, new products have been introduced, and substitutes for asbestos are being used more frequently. Because of the trend toward lower asbestos consumption, the Department of Defense has authorized the disposal of 6,155 tons of chrysotile, 30,844 tons of amosite, and 33 tons of crocidolite from the National Defense Stockpile.

Issues

The safe use of asbestos is one of the major concerns of the asbestos industry. In response to these concerns, representatives from several countries established the International Fibre Safety Group. The purpose of the organization is to promote the safe and controlled use of asbestos and other industrial fibers and the adoption of International Labor Organization recommendations. Representatives from Belgium, Brazil, Canada, France, Thailand, the United States, the former Soviet Union, and Zimbabwe were founding members of the organization.⁵

A major concern among the public is the health risk posed by asbestos-containing materials in buildings. The Health Effects Institute-Asbestos Research, cosponsored by EPA, conducted a study of asbestos in

commercial and public buildings. The panel reported that it is unlikely that indoor asbestos concentrations would be greater than outdoor concentrations when asbestos-containing materials were in good condition. It also concluded that other pollutants posed a greater lifetime risk and that arbitrary removal of asbestos-containing material is unwarranted in well-maintained buildings.⁶ Similarly, the American Medical Association's Council of Scientific Affairs recommended the use of better management, containment, and disposal methods to prevent asbestos-related injury and disease.⁷

Production

Asbestos was produced in the United States by two companies, KCAC Inc., San Benito County, CA, and Vermont Asbestos Group Inc. (VAG), Orleans County, VT. Domestic production was limited to chrysotile, one of six commercial varieties of asbestos. KCAC operated a mine in a highly sheared serpentinite composed of matted, short-fiber chrysotile and unfractured serpentinite (also referred to as a mass fiber deposit). The ore was stripped, and wet processing was used to beneficiate the fiber. VAG operated an open pit mine in a serpentinite-containing cross-fiber veins of chrysotile. Dry milling was used to process the fiber. While the California company produced only short fiber chrysotile, the Vermont company produced a wide range of chrysotile grades.

Domestic production increased slightly from that of 1990. While domestic markets for asbestos continued to weaken, foreign markets remained strong.

Consumption and Uses

Asbestos was used in a wide variety of products because of its high tensile strength, chemical and thermal stability, high flexibility, low electrical conductivity, and large surface area. Products made from asbestos were more heat resistant (and often incombustible), more resistant to chemical attack

(particularly for alkalis), stronger (asbestos acted as a physical reinforcer), and less conductive (asbestos had a low dielectric constant). In addition, they were more viscose (asbestos stiffened compounds and coatings), faster setting (asbestos hastened water drainage in asbestos-cement pipe production), and more cost efficient than many nonasbestos products.

U.S. consumption of asbestos decreased 16% in 1991. Approximately 83% of the asbestos consumed domestically was chrysotile, 1% was crocidolite, and 16% was an unspecified fiber type, most likely chrysotile. Approximately 79% of the chrysotile consumed in the United States was grade 7, followed by grades 4, 6, 5, and 3. (See table 2.)

The construction industry is the major consumer of asbestos fiber in the form of asbestos cement pipe, asbestos cement sheet, coatings, compounds, packings, and roofing products. These end uses accounted for 70% of the asbestos consumed in the United States.

Consumption has declined dramatically from 800,962 tons in 1973 to 34,765 tons in 1991. Two factors have been responsible for the decrease. First, many U.S. markets are maturing so the demand for asbestos-containing materials has declined. Second, the controversy surrounding the health risks posed by asbestos have prompted many manufacturers to stop producing asbestos-containing products. Manufacturers gradually have been replacing asbestos with substitute materials, redesigning old products to eliminate the need for asbestos, or designing new products that require neither asbestos nor asbestos substitutes. Economic, manufacturing, performance, and/or technical difficulties were considered before asbestos was replaced by a substitute material or product.

Examples of materials substituted for asbestos include aramid fiber, calcium silicate, carbon fiber, cellulose fiber, ceramic fiber, fibrous glass, graphite flake and fiber, steel fibers, and wollastonite. Examples of alternative products include aluminum, vinyl, and wood siding; aluminum and fiberglass

sheet; asphalt coatings; ductile iron pipe; polyvinylchloride pipe; prestressed and reinforced concrete pipe, and semimetallic brakes.

Markets and Prices

The average unit value of domestically produced asbestos increased slightly from that of 1991. Unit values for imported asbestos ranged from \$154 per ton to \$1,927 per ton and averaged \$256 per ton. Unit values for exported asbestos ranged from \$169 per ton to \$2,350 per ton and averaged \$290 per ton. Approximate equivalents, in dollars per metric ton, of price ranges quoted in Industrial Minerals (London), December 1991, for Canadian chrysotile, f.o.b. mine, were \$1,320 to \$2,125 for Group 3, \$918 to \$1,275 for Group 4, \$604 to \$714 for Group 5, \$442 for Group 6, and \$136 to \$264 for Group 7. (See table 3.)

Foreign Trade

The total value of asbestos fibers and asbestos products exported and reexported from the United States was \$123,439,041. This is a slight decrease from that of 1990. Exports and reexports of brake linings and disk pads accounted for 75% of the value of all manufactured asbestos products. Canada remained the largest importer of unmanufactured fibers and manufactured products, followed by Japan, Mexico, the United Kingdom, and the Federal Republic of Germany.

Canada provided 99% of the asbestos imported into the United States, and the Republic of South Africa provided less than 1%. Zimbabwe supplied the remaining amount. Approximately 99% of the asbestos fiber imports was chrysotile. (See tables 4, 5, and 6.)

World Review

World production of asbestos, which has been fairly stable for many years, decreased again in 1991. Since 1982, production has dropped from 3,910,592 tons to 3,489,529 tons in 1991. Most of the decline occurred in the past 3 years when opposition to the use of asbestos

intensified. Consumption in more mature North American and European markets has declined. Sales in other countries continued to grow because of the need for asbestos-base construction materials.

Canada continued to be the largest market economy producer of asbestos, followed by Brazil, Zimbabwe, and the Republic of South Africa. The U.S.S.R. was the world's largest producer of asbestos. Canada and the U.S.S.R. accounted for 77% of the world production. Canada continued to be the largest exporter of asbestos. (See table 7.)

Greece.—The Northern Greece Asbestos Mines Co. in Kozani closed owing to financial difficulties. The work force at the mine was reduced from 380 to 250 employees, and the company was refinanced with Government backing. The operation may be leased to private interests in the future.⁸

South Africa, Republic of.—Msaulii Asbes Beperk, which has experienced a drop in profits in recent years, began studying the feasibility of recovering asbestos fiber from its tailings dump. The recovery would require the construction of a new mill plant.⁹

Swaziland.—The Swaziland Government and Consolidated Mining Corp. of the Republic of South Africa have taken control of the Havelock asbestos mine. Ownership is 15% and 85%, respectively. The mine is expected to have an operating life of 8 years, at a production rate of 2,500 tons per month.¹⁰

OUTLOOK

Domestic consumption will continue to decrease although the decrease should not be as great as in recent years. The overturning of the EPA phaseout of asbestos is not likely to result in a reversal of this trend. Foreign markets for asbestos fiber should remain strong because of the demand for proven, low-cost construction materials.

BARITE

By James P. Searls

Mr. Searls, a physical scientist and economist with 15 years of institute, Government, and U.S. Bureau of Mines experience, is the commodity specialist for barite. Domestic survey data were prepared by Maria Rosa Arguelles, statistical assistant; and international data were prepared by Virginia Woodson, international data coordinator.

Domestic production of barite increased 4% to 448 thousand metric tons¹ while apparent consumption decreased 12% to about 1.27 million tons. Exports rose fourfold to 43,000 tons while imports declined about 14% to 841 thousand tons. Production from Nevada was about 78% of the U.S. total. Twelve production facilities closed during the year, but the remaining facilities increased output, which kept the total production slightly above that of 1990. The principal use for barite, as a weighing agent in oil- and gas-well-drilling fluids (muds), accounted for 92% of U.S. apparent consumption. In 1991, oil prices trended downward to a range that did not encourage deep drilling (below 10,000 feet) for oil and gas. Deep drilling declined 13% while total oil and gas wells drilled rose by 13%.

DOMESTIC DATA COVERAGE

Domestic production data for barite are developed by the U.S. Bureau of Mines from a voluntary survey of U.S. operations. Of the 55 operations to which a survey request was sent, all responded, representing 100% of the crushed and ground production sold or used shown in table 1. (See tables 1 and 2.)

BACKGROUND

Definitions and Specifications

The term "primary barite," as used in this report, refers to the first marketable product and includes crude barite, flotation concentrate, and other

beneficiated material such as washer, jig, heavy media, table, or magnetic separation concentrate. Most primary barite requires fine grinding before it is used for drilling muds. This grinding may or may not be done at the mine site.

Barite is the mineralogical name for barium sulfate and was derived from the Greek word "barus," meaning heavy. In commerce, the mineral is often referred to as "heavy spar" or "barytes." "Spar" means almost any transparent or translucent, readily cleavable, crystalline mineral having a vitreous luster.² Specifications for barite vary according to different uses. Material for weighing muds must be finely ground, dense, and chemically inert; consequently, barite for this purpose must have a specific gravity of 4.2 or higher, it must be free of soluble salts, and 90% to 95% of the material must pass through a 325-mesh screen. A small percentage of iron oxide is not objectionable. In chemical manufacturing, purity is the principal concern, and a maximum of 1% each of ferric oxide (Fe_2O_3) and strontium sulfate (SrSO_4) and a trace of fluorine usually are specified, with a minimum of 94% barium sulfate (BaSO_4). If the mineral is to be used in the production of lithopone, the SrSO_4 content may be somewhat higher. Mesh size is important to chemical manufacturers; if the material is too fine, dust is lost, and if it is too coarse, mixing with carbonaceous material is poor. Most chemical manufacturers specify a size range of 4 to 20 mesh; some purchase lump barite and grind it to their own needs.

Products for Trade and Industry

The principal use for barite, as a weighing material in well drilling muds, accounted for more than 92% of total U.S. consumption in 1991. Drilling muds have five main functions: (1) transport drill cuttings to the surface, (2) control formation pressures, (3) maintain borehole stability, (4) protect producing zones, and (5) cool and lubricate the bit and drill string. Barite's lack of hardness (Mohs scale 2 to 3.5) is a plus in this application. The principal function of the barite constituent is as a weighing agent to suppress high formation pressures and prevent blowouts. The deeper the hole, the more barite is needed as a percentage of the total mud mix because hydrocarbon pressures rise strongly with increasing depth. The added weight of the barite in the column of mud is used to counteract the dangerous pressures when deep pockets of hydrocarbons are encountered. High-pressure hydrocarbons can cause extremely dangerous explosions or fires at the drilling rig if uncontrolled.

The use of barite as a filler or extender and other uses accounted for about 7% of total U.S. consumption in 1990. Barite has a high specific gravity, low oil absorption, easy wettability by oils, and good sanding qualities. Unbleached barite may be substituted for bleached barite when brightness is not a factor. In painting automobiles, barite is used as a filler for the primer coats. The barite contributes to the gloss of the topcoat. When the primers are applied by the electrodeposition process, the body structure is dipped into a tank containing water and paint primer. The method

eliminates one of the primary coats, thus reducing the quantity of barite used.

Barite is also used as a filler or extender in some plastic and rubber products. Processors of polyurethane foam use barite in manufacturing such products as floor mats and carpet-backings to add weight and improve processing qualities. Barite is used in white sidewalls for tires; sidewalls consist mainly of rubber, zinc oxide, and a small quantity of barite.

Other industries use small quantities of barite fillers. In the paper industry, the white and dense barite coatings serve as a base for the sensitized layers in photographic prints. In the printing industry, barite is used in inks.

In glassmaking, barite is added to the glass melt to reduce the heat-insulating froth that forms on the melt surface, thus saving fuel, and to act as an oxidizer and decolorizer, making the glass more workable and increasing its brilliance. Glass manufacturers usually require a minimum of 95% BaSO_4 with a maximum of 2.5% silicon dioxide (SiO_2) and 0.15% Fe_2O_3 . The particle size range generally preferred is -30 to +140 mesh. Finely ground barite can be substituted when crushed material is not available. Barium-base glass (using barium carbonate) is considered to be more brilliant than lime glass and more durable than lead glass.

Minor uses include ballast for ships, heavy concrete aggregate for radiation shielding and pipe-weighting in low-lying areas, friction products, and applications in foundries.

Barite is also a raw material for barium chemical manufacturing. The major barium chemicals are the carbonate, chloride, oxide, hydroxide, nitrate, peroxide, and sulfate.

The most important barium chemical is precipitated barium carbonate, which is a raw material for production of many of the other compounds. It is also used in brick and tile manufacturing to control scum caused by gypsum or magnesium sulfate in the clay and to diminish porosity and prevent discoloration in brick. Other uses are in television picture tubes as a radiation barrier,

optical glass, ceramic glazes, porcelain enamel, ferrites, and miscellaneous ceramic products.

Blanc fixe, chemically precipitated barium sulfate, is used as a white filler in paints, rubber, inks, and other materials where a degree of purity higher than natural barite is required. Lithopone (a white pigment composed of a mixture of barium sulfate, zinc sulfide, and zinc oxide), formerly manufactured in large tonnages for use as a white pigment in paints, has been largely replaced by titanium dioxide.

Barium chloride is used in case-hardening and heat-treating baths, in leather and cloth, in making magnesium metal, in preventing scum on brick, in water treatment, and as a laboratory reagent. Fused barium chloride may be electrolyzed to produce barium metal.

Barium nitrate is used in green signal flares, tracer bullets, primers and detonators, and enamels. Barium oxide is used in electric furnace ferrous metallurgy to increase the life of acid furnace linings, to give a quieter and steadier arc, to reduce the sulfur content of the iron, and to lower the slag viscosity.

Barium hydroxide is used to make barium stearate for lubricating greases. Barium-base greases are excellent for load bearing, water resisting applications. It is also used as a rust preventative because it is extremely sticky and resistant to even steam cleaning. Barium titanate finds use in miniature electronic and communication equipment.

Barium metal is also produced by reduction of barium oxide. The metal is used as a "getter" to remove traces of gas from vacuum tubes, or in alloys for spark plugs and electronic emission elements in electronic tubes.

Industry Structure

Domestic barite production began in 1845 in Fauquier County, VA. About 5 years later, production began in Missouri. In 1880, Tennessee became the third barite-producing State, and 1901 and 1903 saw Georgia and Kentucky, respectively, become producers.

California began producing in 1914, Nevada in 1916, and Arkansas in 1941.

Barite was first used as a filler in white paints; however, in 1842, with the advent of the domestic lithopone industry, a second important market opened. In 1908, Chicago Copper Refining Co. began manufacturing barium chemicals at Blue Island, IL. The first washers and jigs used in the industry were installed in Georgia and Tennessee in 1914-16 and in Missouri in 1923-24. A fourth market for barite came into existence in 1916 when a patent was obtained on the use of barite as a weighing agent in rotary drilling muds; today this is the largest consumer of barite. In 1941, the deposit of barite at Malvern, AK, was opened when Magnet Cove Barium Corp. successfully separated barite from associated minerals by flotation. In 1977, IMCO Services Co. completed a multimillion dollar plant at Mountain Springs, NV, that produced barite concentrate using jigs, concentration tables, and flotation. This combination of beneficiating methods was unique in the barite industry.

Geology

Barite is the only commercial source of barium and barium compounds in the United States. Witherite (BaCO_3) has been produced from the Settlingstones Mine in England, and small quantities enter the United States every year.

Pure barite has a specific gravity of 4.5. Barite varies considerably in appearance depending on source and treatment. It is a moderately soft crystalline material with a Mohs' hardness between 2 and 3.5. In residual deposits, it ranges in size from large boulders to fines. Shades of white to dark gray and black, depending on impurities and surficial coating, are common in commercial deposits.

Vein and cavity-filling deposits are those in which barite occurs along faults, joints, bedding planes, and other solution channels or sink structures. These deposits are found most often in limestone. Most of the vein deposits are believed to be of hydrothermal origin.

In central Missouri, barite occurs in circular deposits in karst or collapse and sink structures. These ores are rich, but the deposits are generally small in overall extent. These deposits are also important as the source of the residual ore upon weathering.

Residual barite deposits are formed by weathering of preexisting deposits. The principal residual deposits are found in southeastern Missouri; the Appalachian region; Sweetwater, TN; Cartersville, GA; and in the Rio Grande area of Texas. A concentration of at least 100 to 300 pounds of barite per cubic yard is required in a commercial deposit. In Washington County, MO, the residuum is 10 to 15 feet thick, while in Cartersville, GA, the ore is 150 feet thick in some spots. This form of deposit has been of considerable economic significance.

The most important commercial deposits are of bedded barite. These are principally in Arkansas, California, and Nevada. The barite in these areas is generally dark gray to black and has a characteristic fetid odor when struck with a hammer. The beds, which vary in thickness from several inches to more than 50 feet, occur interbedded with dark chert and siliceous siltstone and shale. In most of the deposits, the barite is laminated. In some areas, barite nodules and rosettes make up a large part of the beds. Many of the beds contain 50% to 95% barite. Originally it was thought that these deposits were the result of the replacement of carbonate rocks; however, current thought is that the deposits are of sedimentary origin. The actual environment of deposition has not been established, but theories range from submarine volcanic emissions to hydrothermal solutions to recycling of barite from preexisting rocks.

Technology

Exploration.—In the past two decades, geological exploration has led to the discovery of bedded barite deposits in Canada, India, Mexico, and the United States. Bedded deposits have not been sought in many parts of the world. As the search for barite expands in the

coming years, it is likely that more bedded deposits will be discovered.

Mining.—Residual deposits of barite are generally mined by draglines in open pits after removal of overburden by conventional methods using elevating scrapers, trucks, dumpers, bulldozers, and front-end loaders. The ore is then beneficiated in washer plants equipped with rotary breakers, log washers, trommel screens, and jigs to separate barite from other material. Fine barite in the overflow from the log washers is recovered by tabling and flotation while the jig concentrate is magnetically separated.

Bedded and vein deposits may be mined by open pit or underground methods depending on local conditions. The bedded deposits of Arkansas have been mined by both methods. The ore is crushed and ground for beneficiation by flotation. Bedded barite in Nevada is mined by open pit methods using a combination of bulldozers with ripping teeth and conventional blasting. The ore is picked up by front-end loaders and hauled in dump trucks to a processing plant. In some deposits, the ore is of sufficient grade to be either screened and direct shipped or washed, crushed, screened, and shipped to a grinding plant; however, much of the ore requires beneficiation by jigging or flotation.

Quantities of barite have been recovered by underwater mining off Castle Island near Petersburg in southeastern Alaska. The ore is blasted, recovered by a crane equipped with a special digging bucket, and loaded into barges.

Processing.—Barite grinding is usually accomplished by heated airswept Raymond mills, a type of roller mill; however, ball mills are used when iron contamination is not important, as in drilling muds. Barite is ground either wet or dry. For use in well drilling, barite is ground dry. If the barite requires upgrading by flotation, it is ground wet. Barite is also ground wet when it is to be bleached for filler use; impurities are subsequently removed by

treatment with sulfuric acid. The bleached barite pulp is then settled and separated, washed, dried, sized, and bagged.

A small amount of barite is converted into a soluble form before its use in the manufacture of lithopone or other chemicals. Crushed barite is roasted with coke in a kiln at about 1,200° C to reduce the barium sulfate to the more soluble compound, barium sulfide, commonly called black ash. The sulfide is leached from the clinker with hot water. By adding zinc sulfate to the leach liquor, an intimate mixture of barium sulfate and zinc sulfide called lithopone is precipitated.

The leach liquor is also a precursor of a number of barium chemicals. Addition of sodium sulfate precipitates a pure barium sulfate (called blanc fixe). Barium carbonate is precipitated by either carbonating or adding sodium carbonate to the leach liquor. Hydrochloric acid added to the leach liquor produces a solution of barium chloride. Barium carbonate and barium chloride are the starting compounds for the manufacture of many other barium chemicals.

ANNUAL REVIEW

Legislation and Government Programs

The U.S. Environmental Protection Agency (EPA) announced the discovery of a series of anaerobic and aerobic processes that could conceivably occur in a hydrocarbon drill site waste pit and convert inert barite to a form with mobile barium ions. Barium ions, when mobile, are considered to be a toxic heavy metal.

Production

Run-of-mine barite output, the lowest cost primary barite sold or used by producers and representing 65% of total production, decreased 7% from that of 1990. The remainder of total production was flotation concentrate and other beneficiated material. The lower cost crude barite and jigged beneficiated materials were used chiefly in drilling

muds; the higher valued floated and other beneficiated material was used mostly in chemical and glass manufacturing and in filler applications.

Reported primary production increased almost 4% from a revised 430,000 tons in 1990. Nevada and Georgia remained the two leading barite-producing States. Other producing States, in descending order, were Missouri, California, Illinois, and Montana. Illinois production was as a coproduct of fluor spar mining and milling; in all other States, barite is the primary product.

The leading domestic barite producers were M-I Drilling Fluids Co., a Dresser-Halliburton Co. division, with mines in Nevada; Milpark Drilling Fluids, a Baker Hughes Inc. division, also with mines in Nevada; and Baroid Drilling Fluids Inc., a NL Petroleum Services Inc. division, with mines in Missouri and Nevada. (See tables 3 and 4.)

Consumption and Uses

Consumption of crushed and ground barite decreased about 12% to 1.3 million tons in 1991. The oil- and gas-well-drilling industry completed less than 22,000 wells of all types³ and drilled almost 112 million feet of hole,⁴ which represented an 8% and 11% increase, respectively, compared with those of 1990. The relationship between barite production, consumption, and well drilling, especially deep well drilling, is illustrated in figure 1. (See figure 1.)

Note that there is a generally common shape between the tops of the barite tonnage bars and the number of wells drilled below 10,000 feet curve. The regression of "total number of wells drilled" (not shown) on "tons of barite used" results in an R^2 (adjective) of .76 while the regression of "number of wells drilled below 10,000 feet" and "year" on "tons of barite used" results in an R^2 (adjective) of .82 for 21 years of data. The "component plus residual" plot for time (year) shows a downward trend for barite. Apparently the well drilling industry has learned to use less barite per well over time.

Total drilling footage exceeded 6 million feet in four States: Texas, 46.9 million feet; Oklahoma, 12.3 million; Louisiana, 9.0 million; and Kansas, 7.0 million. Generally, the deeper a hole is drilled after 5,000 feet, the more barite is used per foot of drilling.

Another barometer of drilling activity at the end of 1991, the Baker Hughes rig count, showed the cumulative average number of operating domestic rigs in 1991 decreased almost 15% to 859. The end of the year count was 770, below the yearly cumulative average.⁵ The Smith rig count, from the same source, reported 310 rigs drilling to below 10,000 feet, down 31% from 1990's count of 451 rigs at the end of the year.

The low rig count at the end of the year can be explained by the generally low price of oil. This price is discussed using a common marker grade, West Texas Intermediate. West Texas Intermediate oil reached a peak price of about \$37 per barrel in October 1990 then fell continuously to below \$20 per barrel in March 1991.⁶ West Texas Intermediate oil prices then trended up to a high point of about \$24 per barrel in October and fell below \$20 per barrel by the end of the year. Saudi Arabia, the United Arab Emirates, and Venezuela had increased their production in the latter half of 1990 to make up for lost production during the Iraqi invasion of Kuwait and the loss of Kuwaiti and Iraqi oil on the world market. "With lost production replaced, formerly idle capacity in use, and demand stalling for economic reasons, the market spent 1991 nearly in balance, which moderated the volatility characteristic of crude prices in recent years."⁷ "Estimated" total well drilling in the United States declined from about 7,800 wells in the first quarter to 6,450 wells in the fourth quarter of 1991, according to the American Petroleum Institute. (See tables 5 and 6.)

Prices

Price quotations in such trade publications as the Chemical Marketing Reporter, Industrial Minerals, and Engineering and Mining Journal for barite

remained unchanged throughout the year. The quoted prices are in nominal dollars and do not show any increase to reflect inflation. The quoted prices may serve as a general guide but do not reflect actual transactions, some of which are on long-term contracts and some are at confidential, negotiated prices.

The reported average value per ton of domestic barite, based on reported value of direct-ship, beneficiated, and floated material, increased almost 28%, f.o.b. plant, from \$37.21 per ton in 1990 to \$47.57. The average value of ground barite, sold or used by producers, was \$81.24 per ton, a 6% decrease from the \$86.36 per ton reported in 1990. Within this group the average value of barite for well drilling end use was \$75.45 per ton while the average value for barium chemicals, filler and extender, and glass, was \$148.08 per ton. The average customs value of exported barite was \$76.84 per ton. The average c.i.f. value of imported crude barite was \$43.67 per ton, and the c.i.f. value of imported ground barite from Mexico was \$65.55 per ton.

Foreign Trade

Exports of natural barium sulfate or barite increased strongly from about 9,200 tons to about 43,300 tons. Export data provided by the Bureau of the Census did not indicate the grades of barite traded; however, based only on the dollars per ton of individual shipments, which varies from about \$40 to almost \$2,000 per ton, drilling-, filler-, glass-, chemical-, and pharmaceutical-grade were all exported. Historically, barite exports were predominantly ground drilling-mud-grade material with less than 5% of the tonnage as specialty ground barites. Canada and Mexico have been traditionally either first or second among export recipients of U.S. ground barite, but Brazil received the largest quantity in 1991 and Venezuela was second. (See table 7.)

Imports for consumption of crude barite declined about 15% from those of 1990 to less than 0.9 million tons. The principal source countries, in descending

order, were China at 710,000 tons of crude barite, India at 123,000 tons of crude barite, and Mexico at 37,000 tons of ground barite. The higher priced material was chiefly crude filler and extender-quality barite. High-quality barite, generally material with a specific gravity greater than 4.2, is usually blended during grinding with lower grade ore, foreign or domestic, to meet American Petroleum Institute specifications for a minimum density of 4.2 for drilling-mud-grade barite. Most of the crude barite entered through customs districts along the gulf coast for delivery to grinding plants in the area. (See tables 8, 9, 10, and 11.)

World Review

Capacity.—The data in table 13 are rated capacity for mines as of December 31, 1991. Rated capacity is defined as the maximum quantity of product that can be produced on a normally sustainable long-term operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period with minimum capital expenditure.

Mine capacity for domestic barite production was aggregated from data voluntarily supplied by the producers. The rated capacity data for the foreign mines were estimated from the previous year's production in cooperation with the Division of International Minerals. (See tables 12 and 13.)

Little change occurred around the world as China, India, and Morocco dominated the international market with large capacity and good quality, low-priced product.

United Kingdom.—Minworth Group went into receivership early in the year due to losses at the Strontian Mine (and involvement in a fluorspar mine).

OUTLOOK

With the end of the Persian Gulf War and confidence in the continuation of world peace and the tranquility of world oil supplies and prices, the demand for drilling rig usage is declining. Saudi Arabia and Kuwait may be interested in keeping oil prices relatively low over the next several years in appreciation of the war fought on their behalf by many countries from around the world. They may also know that higher oil prices will bring in other technologies and fuel sources in the long run, so they may be interested in letting a free market establish oil prices. Demand for petroleum products may be sluggish as several large countries deal with financial problems. The United States must pay for the savings and loan bailout, infrastructure replacement, environmental concerns, and social concerns. Japan has had its own contraction in the stock market and banking circles that may leave it short of cash for several years. The Federal Republic of Germany must put much of its cash into reintegrating the former East Germany and replacing its infrastructure and capital goods for future production and environmental protection. The Commonwealth of Independent States, formerly the U.S.S.R. and countries of East Europe, have to reorganize their economic systems, form entrepreneurial groups, and invest in large amounts of capital goods to reemploy, even retrain, millions of workers. World economic growth may be slow for several years as these several problems are worked through, meaning slow growth in petroleum consumption and prices that will not encourage aggressive drilling for new reserves. Slow growth in petroleum consumption will lead to less drilling and lowered demand for barite, tempered by the search for ever deeper new resources that do use more barite.

The U.S. Department of Energy (DOE) has forecast crude oil prices out to the year 2010 recently.⁸ A simple regression of barite consumption for hydrocarbon well drilling on (U.S. Refiner's

Acquisition Cost of Imported Crude Oil) oil prices was performed. The R^2 equaled 0.827 for the regression. The forecast into the future for the DOE model considered \$23 per barrel (1990 \$s) for a low case, \$33 per barrel for a medium case, and \$40 per barrel for a high case by the year 2010. The corresponding barite demand quantities would increase smoothly from 1990's consumption level of 1,409,000 tons to 1,626,000 tons of barite per year for \$23 per barrel in the year 2010, 2,277,000 tons of barite for \$33 per barrel in the year 2010, and 2,733,000 tons of barite per year for \$40 per barrel in the year 2010.

BERYLLIUM

By Deborah A. Kramer

Ms. Kramer is a physical scientist with the Branch of Industrial Minerals. She has covered beryllium for 8 years. Domestic survey data were prepared by Shonta Osborne, statistical assistant; and the international data table was prepared by Ron Hatch, international data assistant.

Since its first commercial production in the United States in the early 1920's, beryllium has become an important material in many industrial and defense applications. Properties such as its high strength, light weight, and high thermal conductivity allow beryllium to be used for components in aircraft, satellites, electronic circuits, oil drilling equipment, and consumer goods.

The United States is the only market economy country with an integrated beryllium industry. Bertrandite, mined and processed in Utah, is the primary ore source for the end products—beryllium metal, beryllium alloys, and beryllium oxide—that are produced in Ohio and Pennsylvania. Imported beryl ore, mainly from Brazil, supplements domestic ore supply.

U.S. mine production continued to decline in 1991, a trend that began in 1988. Beryl imports continue to decrease, and the United States supplied a greater share of domestic demand. Brush Wellman Inc. was the sole U.S. beryllium mine producer with the capability to convert this ore and beryl into beryllium products.

Although the general economic downturn partially was responsible for a decline in U.S. beryllium consumption, not every end-use market was affected. A persistent decline in computer applications that began in 1989 resulted in weak demand for beryllium copper alloys, but a greater consumer demand for air-bag restraint systems led to an increase in beryllium-nickel consumption. Metallic beryllium consumption dropped because of a decrease in production of some defense components.

During 1991, however, manufacturers developed new products, such as beryllium-aluminum alloys that contain up to 40% beryllium, which were targeted toward the aerospace market. In addition, beryllium and beryllium-base alloys were used in new applications in the energy field, ranging from oilfield components to experimental fusion reactors.

DOMESTIC DATA COVERAGE

Beryllium data are collected from two voluntary surveys of U.S. operations. In 1990, there were eight responses to the "Beryllium Mineral Concentrate and Beryllium Ore" survey, representing 100% of the total canvassed. These respondents produced 100% of total domestic mine shipments, shown in tables 1 and 9. A small number of unidentified producers may have shipped insignificant quantities of byproduct beryl, which have not been included. (See table 1.)

BACKGROUND

Products for Trade and Industry

Beryllium-Copper Alloys.—Beryllium-copper alloys are used in a wide variety of applications and average about 65% of annual U.S. consumption on a beryllium metal equivalent basis. These alloys, most of which contain approximately 2% beryllium, are used because of their high electrical and thermal conductivity, high strength and hardness, good corrosion and fatigue resistance, and nonmagnetic properties. Beryllium-copper strip is manufactured into springs, connectors, and switches for use in applications in

automobiles, aerospace, radar and telecommunications, factory automation, computers, home appliances, and instrumentation and control systems. The principal use of large-diameter beryllium-copper tubing is in oil and gas drilling equipment and in bushings and bearings in aircraft landing gear and heavy machinery. Connectors in fiber-optic telecommunications systems are the main application for beryllium-copper rod. Small, pluggable sockets for joining integrated circuits to printed circuit boards are the main application for beryllium-copper wire. Beryllium-copper bar and plate are used in resistance-welding parts, components for machinery and materials-handling systems, and for molds to make metal, glass, and plastic components.

Beryllium also is used in small quantities in nickel- and aluminum-base alloys. Miniature electronic connector components that operate at high temperatures are the main use for beryllium-nickel alloys. Beryllium-aluminum alloys are used as castings in the aerospace industry. Addition of small quantities of beryllium to magnesium alloys inhibits oxidation.

Beryllium Metal.—Beryllium metal, which averages about 20% of annual U.S. demand, is used principally in aerospace and defense applications. Its high stiffness, light weight, and dimensional stability over a wide temperature range make it useful in satellite and space vehicle structures, inertial guidance systems, military aircraft brakes, and space optical system components. Because beryllium is transparent to X-rays, it is used in X-ray

windows. In nuclear reactors, beryllium also serves as a canning material, as a neutron moderator, in control rods, and as a reflector. In the past, the metal had been used as a triggering device in nuclear warheads. Other applications for metallic beryllium include high-speed computer components, audio components, and mirrors. In the U.S. space shuttles, several structural parts and brake components use beryllium.

Beryllium Oxide.—Beryllium oxide (beryllia) is an excellent heat conductor, with high hardness and strength. This material also acts as an electrical insulator in some applications. Beryllium oxide, averaging about 15% of domestic demand, serves mainly as a substrate for high-density electronic circuits for high-speed computers, automotive ignition systems, lasers, and radar electronic countermeasure systems. Because it is transparent to microwaves, microwave communications systems and microwave ovens may use beryllium oxide.

Industry Structure

The United States is the only country that can process beryllium ore and concentrates into beryllium products and supplies most of the rest of the world with these products. Brush Wellman mines bertrandite and converts this ore, along with beryl, to beryllium hydroxide at its facility in Delta, UT. Beryllium hydroxide is shipped to the company's plant in Elmore, OH, where it is converted into beryllium alloys and metal. Brush Wellman also produces beryllium oxide at a plant in Tucson, AZ, from the beryllium hydroxide recovered at Delta.

One other company in the United States has the capability to produce beryllium alloys. NGK Metals Corp., a subsidiary of NGK Insulators of Japan, produces beryllium alloys at a plant in Reading, PA. Because NGK Metals does not have facilities to process the raw materials, the company purchases imported beryl, and Brush Wellman converts the beryl into beryllium hydroxide under a tolling arrangement.

Ore production from labor-intensive operations outside the United States is sporadic, except for the largest producers—Brazil, China, and the U.S.S.R. Most of the beryl recovered in Brazil is exported to the United States, and that country is the largest U.S. beryl import source. Some beryl from China has been imported into the United States in the past, but it is assumed that China has some capability to process beryl because products, including beryllium-copper master alloy, originating there have appeared in the world market. Although little is known about the U.S.S.R., it is assumed that it has an integrated beryllium industry because little, if any, beryl produced in that country has been traded. With the separation of the U.S.S.R. into independent states, beryllium alloys, metal, and oxide have appeared on the world market. (See table 2.)

Geology

Because of its strategic importance, beryllium mineral occurrences in the United States were studied extensively in the years after World War II, particularly by the U.S. Geological Survey and the U.S. Bureau of Mines. During this period, the United States did not have a reliable domestic supply of beryllium minerals and was reliant on imports to supply most of its requirements. Most domestic beryllium was recovered from beryl produced as a byproduct of mining other pegmatite minerals. After production of bertrandite began in Utah in 1969, providing the United States with a secure beryllium source, little effort was made to evaluate additional beryllium mineral deposits.

Granitic pegmatites are the world's principal source of beryl. Beryl has been mined from zones, fracture-filling units, and replacement bodies in heterogeneous pegmatites. The principal beryl deposits are zones. Most beryl-rich zones contain only a few thousand metric tons of rock, but a few may contain as much as 1 million tons. Beryl occurs in concentrations of approximately 2% in zones containing plagioclase, quartz, and

muscovite mica, the principal product. It also is as abundant in zones from which spodumene, amblygonite, and feldspar are recovered.

Beryl tends to be finer grained in outer zones than in inner zones of pegmatites. Much of the fine- and medium-grained beryl of pegmatites in the Black Hills, SD, contains abundant inclusions of other minerals. Large masses of beryl containing almost no inclusions have been found in inner zones and may extend across several zones. Beryl is evenly distributed in some deposits, but in others it is irregularly distributed in rich aggregates in various parts of a zone.

None of the other beryllium minerals in pegmatites are of commercial importance. Chrysoberyl is concentrated in parts of some pegmatites but is much less abundant than beryl. Other beryllium minerals are exceedingly rare.

Beryl has been found in quartz veins containing cassiterite, wolframite, molybdenite, and other minerals. The concentration of beryl in the outer parts of these veins, just as beryl is concentrated in the outer part of quartz zones in some pegmatites, suggests that these quartz veins are genetically similar to pegmatites. Beryl crystals in quartz veins are normally less than 1 inch long. Beryl has been studied in the tin veins in South Dakota, England, and elsewhere. Beryl also has been reported in a tungsten vein in New Mexico and in quartz veins in Colorado; however, the mineral has not been reported in the more important tin and tungsten deposits of the world.

Replacement deposits that contain beryllium are primarily tactites and emerald-bearing schists. Helvite is the chief beryllium mineral of tactites and related rocks, but idocrase, grossularite, chlorite, and possibly other minerals also contain beryllium. The most thoroughly documented beryllium deposits in tactites in the United States are in New Mexico and Alaska, although the Alaskan deposits are of minor significance.

Nepheline syenite and other nepheline rocks have been reported to contain as much as 0.1% beryllium oxide. Deposits of this type have not been studied thoroughly enough to determine the

commercial feasibility of their development, although small quantities of beryllium-rich deposits have been found in Arkansas and Colorado.

Beryllium also has been found in coals. Sampling of a variety of U.S. coal ashes indicated a significant distribution pattern for beryllium, with an average of 46 parts per million for all of the samples. Accumulation of beryllium in coal was determined to be a syngenetic process, and the beryllium content of the coal primarily is dependent on the rocks that contributed material to the coal-depositional sites.

Technology

Exploration.—In many cases, the presence of beryl is visible by the naked eye. It appears as greenish-white crystals, and because it is usually associated with colorless quartz, large crystals are easily distinguished. For other beryllium minerals and finely disseminated beryl crystals, a beryllometer is normally used in the field for detecting beryllium mineralization. The beryllometer uses a gamma radiation supplied by an antimony 124 radioisotope to generate neutrons when the radiation field comes into contact with a beryllium-bearing mineral. This equipment is similar to a Geiger counter used to detect uranium. Beryllometers can be made with a sensitivity of 0.01% beryllium or less. Detection of beryllium in ore is usually followed by diamond drilling and assaying to delineate beryllium deposits further.

Mining.—Most of the beryl produced outside the United States is from Brazil, where labor-intensive, pick-and-shovel mining of weathered pegmatites is the primary method used. Garimpeiros (laborers) perform all of the mining and cobbing of the ore. Because the garimpeiros mine on private land and sell directly to ore buyers, information concerning mining methods and production is scarce.

Pegmatite mining in Brazil essentially consists of stoping into exposed, weathered pegmatites with picks and

shovels. Mines are established wherever beryl-rich pegmatites exist. Each stope is worked by three to five men who pick beryl crystals out of the host rock and muck out the waste. Other garimpeiros (usually women and children) sort through the mucked-out material for beryl crystals that were overlooked. Stopes are approximately 1.5 meters high and 1 meter wide. A mine can contain as many as 40 stopes.¹

In Utah, Brush Wellman mines bertrandite by open pit methods. Unlike beryl, in which the mineral can be identified by color and crystal structure, bertrandite mineralization cannot be recognized by the naked eye. Consequently, Brush Wellman conducts geologic and geochemical evaluations on a specific area, followed by a drilling program to determine if an economic ore body exists.

After delineating an ore body, overburden is removed to within 2 meters of the ore by a local earth-moving contractor during the winter and spring. This stripping operation usually requires about 9 months for completion. In the 2-meter cover remaining, drill benches are constructed on 7.5-meter centers to take samples of the ore body at 0.6-meter intervals. Information obtained from analyzing the samples allows cross-sectional and contour maps to be developed. These maps are used to plan the mining and processing operations.

After the maps are prepared, the remainder of the overburden is removed, and the ore is mined, typically with a self-loading scraper. Because of the irregular ore-grade distribution in the ground, the ore is mined from predetermined areas and placed in a stockpile in layers to obtain a homogeneous blend. Drilling, sampling, and assaying the stockpiled ore generate a map that identifies ore-grade distribution throughout the stockpile. Stockpiled ore is trucked to the mill, which is about 80 kilometers away, for further processing.

Beryllium Hydroxide Production.—Beryllium is recovered commercially from two ores—beryl and

bertrandite. Beryllium hydroxide, the intermediate product recovered from these ores, is subsequently converted to beryllium metal, alloys, or oxide. Brush Wellman is the only company with facilities to extract the beryllium values from both ores. Because of the difference in beryllium content of beryl and bertrandite, the ores are treated separately until the beryllium is dissolved, then the two solutions are combined.

Bertrandite is crushed and wet-milled to yield a slurry at about -20 mesh. The slurry then is leached with a sulfuric acid solution at about 95° C to dissolve the beryllium, forming a beryllium sulfate solution. In contrast, after crushing, beryl ore is heated to 1,700° C and quenched rapidly in water to form a frit. Heat treating the frit at 1,000° C, grinding to about -200 mesh, and then leaching with a concentrated sulfuric acid solution at 250° C to 300° C dissolves the contained beryllium, forming a beryllium sulfate solution.

After separating the solids from both beryllium sulfate solutions, the two solutions are combined. Solvent extraction is used to remove additional impurity elements that were extracted with the beryllium. In solvent extraction, the beryllium sulfate solution contacts an organic solution of di-2-ethylhexylphosphoric acid in kerosene. Beryllium is selectively dissolved in the organic solution. The slow rate of extraction at room temperature is accelerated by warming the extractant and leach solution. The loaded organic phase is treated with an aqueous ammonium carbonate solution, and beryllium is stripped from the organic phase forming $(\text{NH}_4)_2\text{Be}(\text{CO}_3)_2$.

In addition to beryllium, the solvent extraction step dissolves iron, aluminum, and fluoride. Heating the strip solution to about 70° C separates the iron and aluminum as hydroxide or carbonate precipitates. Two hydrolysis steps at 95° C and 165° C, respectively, remove the ammonia and carbon dioxide, resulting in the formation of beryllium hydroxide, which is filtered and then drummed for shipment. Approximately 80% of the

beryllium content of both the beryl and bertrandite is recovered by this process.²

Beryllium-Copper Alloy Production.—To produce beryllium-copper master alloy, beryllium hydroxide, electrolytic copper, and carbon are combined in an electric arc furnace. The resultant melt, containing about 4% beryllium, is cast into ingots. Remelting master alloy ingots with additional copper and other alloying elements yields the desired beryllium-copper alloy, which is then cast into slabs or billets. Slabs of beryllium-copper alloys are processed further into strip or plate, and billets are extruded into tube, rod, bar, and wire products.

Beryllium Metal Production.—To produce beryllium metal, beryllium hydroxide is dissolved in an ammonium bifluoride solution. Filtering and treating the solution with ammonium sulfide removes impurities such as iron, lead, manganese, and zinc. The purified solution is concentrated in an evaporator to yield an ammonium beryllium fluoride salt. After the salt is removed with a centrifuge and dried, it is fed to a continuous induction furnace. Decomposing the salt at 700° C to 900° C in the induction furnace produces molten anhydrous beryllium fluoride and ammonium fluoride gas, which is captured in scrubbers for reuse. Cooled beryllium fluoride is reacted with magnesium in batch induction furnaces to produce metallic beryllium and magnesium fluoride. Cooling the mixture produces a solid cake that contains beryllium pebbles, magnesium fluoride, and unreacted beryllium fluoride. Crushing this mixture followed by water leaching yields beryllium metal and magnesium fluoride. After separating the magnesium fluoride, the pebbles are vacuum melted to remove any slag trapped in them and cast into ingots.

Vacuum-cast ingots are normally further processed into a powder, produced by machining the ingot into chips. Chips cut by the lathe are removed by a vacuum system, and after passing through a cyclone, are automatically loaded into drums.

Grinding in a ball mill, impact grinding, or attrition grinding reduces the size of the chips. Each of these methods produces a different particle-size powder. In attrition grinding, chips are ground into a powder between a fixed, grooved beryllium plate and a rotating, grooved beryllium plate. In impact grinding, a high-velocity stream of air blasts a mixture of chips and oversize powder onto a solid beryllium target. Upon impact, the chips break into small particles that are removed from the chamber by vacuum conveying. A ball mill is used when extremely fine powder is required. After grinding, the beryllium powder is sized, either with screens or an air classifier. Beryllium powder is formed into billets by vacuum hot-pressing, hot-isostatic pressing, or cold-isostatic pressing, depending on the end use of the material.

Beryllium Oxide Production.—Beryllium oxide powder is produced by dissolving beryllium hydroxide in sulfuric acid. The resulting beryllium sulfate solution is concentrated by evaporation and cooled until the solution is supersaturated. During cooling, beryllium sulfate tetrahydrate crystals are produced. Wet salt crystals are removed from the mother liquor in a centrifuge. Calcining these crystals in a car-hearth furnace at temperatures up to 1,430° C decomposes the salt to beryllium oxide, water vapor, and SO₂ and SO₃ gases. The gases are fed through scrubbers, and the beryllium oxide is cooled, screened, and bagged for shipment.

Substitutes

Because of its high cost compared to those of other materials, beryllium is used in applications in which its properties are crucial. Steel, titanium, or graphite composites substitute for beryllium metal in some applications, and phosphor bronze substitutes for beryllium-copper alloys, but these substitutions result in substantial loss in performance. In some cases, aluminum nitride may be substituted for beryllium oxide.

Operating Factors

Beryllium dust and fumes have been recognized as the cause of beryllosis, a serious chronic lung disease. In the 1940's, the disease was diagnosed among industry employees and their relatives, who had handled dusty workclothes prior to the establishment of suitable hygienic procedures. Cases were also reported among residents of communities surrounding beryllium-processing plants. Although uncertainties related to the cause of the disease still exist, the problem appears to be controlled when established preventative measures are exercised. In beryllium-processing plants, harmful effects are prevented by maintaining clean workplaces; requiring the use of safety equipment such as personal respirators; collection of dust, fumes, and mists at the source of deposition in dust collectors; medical programs; and other procedures to provide safe working conditions. Control of potential health hazards adds significantly to the final cost of beryllium products.

Under the Clean Air Act, the Environmental Protection Agency (EPA) has issued standards for certain hazardous air pollutants, including beryllium. Beryllium emissions for plants that process beryllium materials are limited to 10 grams of beryllium over a 24-hour period. EPA also established water quality criteria for beryllium under the Clean Water Act. The Clean Water Act is intended to ensure a water quality sufficient to protect a use for which the water body has been designated. Typical designations include protection of aquatic life and wildlife habitat and protection of human health. A concentration level of 130 micrograms per liter of beryllium was established to protect aquatic organisms from acute health effects, and a level of 5.3 micrograms per liter was established for protection of chronic health effects. For human health, EPA established a concentration of 3.7 nanograms per liter to protect human health during the ingestion of water and fish, and a concentration of 64.1 nanograms per liter was established to

protect human health during the ingestion of fish only. Beryllium currently is not regulated by EPA under the Safe Drinking Water Act.

The Occupational Safety and Health Administration (OSHA) also issues standards for airborne beryllium particles. Current OSHA standards limit the 8-hour exposure level to an average of 2 micrograms per cubic meter, with a peak of 25 micrograms per cubic meter not to exceed 30 minutes, and a ceiling concentration of 5 micrograms per cubic meter. Mine Safety and Health Administration regulations affect only Brush Wellman's operation in Utah and are the same standards as those of OSHA.

ANNUAL REVIEW

Legislation and Government Programs

The Defense Logistics Agency extended its contract with Brush Wellman to convert beryl ore in the National Defense Stockpile (NDS) to vacuum-hot-pressed beryllium billets. The extension called for an additional 19,500 kilograms of beryllium, worth about \$13 million, to be delivered to the NDS in 1993. The contract was originally awarded in 1990, and this extension brings the total quantity of billet to 60,782 kilograms over a 3-year period. Some of the ore has been delivered to Brush Wellman in Utah for conversion to metal, but the NDS retains title to the material until the metal is delivered to the NDS. Because of this, the official yearend 1991 inventories in the NDS, shown in table 3, did not change from those at yearend 1990.

EPA reportedly planned to set Federal water-quality standards for 22 States that have not set their own standards. Under the 1987 amendments to the Clean Water Act, the 50 States and 5 territories were required to adopt specific water-quality standards for priority toxic pollutants, including beryllium, by February 4, 1990. Only 31 States complied with these amendments, which prompted EPA to announce its intent to impose Federal standards. (See table 3.)

Production

U.S. mine production of bertrandite declined in 1991, and inventories were drawn down slightly to meet world demand for beryllium products. Production of beryllium-copper master alloy, beryllium oxide, and beryllium-aluminum alloys dropped significantly in 1991. Production of metallic beryllium declined slightly. The only products that registered an increase in production were beryllium-nickel alloys, for which production nearly doubled from that of 1990.

Brush Wellman was the only integrated producer of beryllium in the United States. The company mined bertrandite at its open pit near Delta, UT, and processed this ore, imported beryl, and small quantities of domestically produced byproduct beryl into beryllium hydroxide at its facility in Delta. Beryllium hydroxide was shipped to Brush Wellman's plant in Elmore, OH, where it was manufactured into beryllium metal, beryllium alloys, and beryllium oxide. NGK Metals also produced beryllium alloys at its plant in Reading, PA, from beryllium hydroxide supplied by Brush Wellman.

Consumption and Uses

The general U.S. economic slowdown affected consumption for all beryllium products, continuing the drop in demand that began in 1988. In particular, a decline in demand was affected by a prolonged recession in the computer and electronic equipment markets, the principal end-use market for beryllium-copper alloys. Reduced demand for strategic defense systems because of recent world events primarily were responsible for the drop in beryllium metal consumption.

The Defense Reutilization and Marketing Service (DRMS) continued to be a source of beryllium scrap. Almost 3,800 kilograms of beryllium aircraft brake disks and assemblies was sold during 1991 at prices between \$25 and \$40 per kilogram. Brush Wellman was the principal purchaser of these materials.

DRMS also sold small quantities of beryllium-copper alloys and beryllium oxide.

In a bulletin issued on March 12, the U.S. Department of Defense clarified its position on the use of beryllium oxide ceramic materials in new applications. The bulletin stated that health hazards occur only from fine airborne particles that are encountered in the manufacturing process and not during the use of a finished device. Defense recognized that beryllium oxide was a safe product when handled in a solid form. In 1989, Defense had curtailed the usage of beryllium oxide because of perceived health hazards.³

Markets and Prices

Yearend prices for beryllium products are shown in table 4. Because of the economic conditions in 1991, prices for most beryllium products remained stable throughout the year, with the exception of beryllium metal. Powder and vacuum-cast lump prices rose about 4% and 37%, respectively. (See table 4.)

Foreign Trade

The Bureau of the Census does not separately identify all imports and exports of beryllium-copper alloys. The Journal of Commerce Port Import/Export Reporting Service (PIERS) provides some data on materials that are transported by ship. According to PIERS, 116,995 kilograms (gross weight) of beryllium-copper alloys in the forms of ingot, rod, and strip was exported. Japan was the destination for 79% of these exports, with the Federal Republic of Germany as the second largest recipient with 8% of the total. A small quantity of beryllium-copper master alloy was exported to Brazil.

PIERS reported that 177,234 kilograms (gross weight) of beryllium-copper alloys was imported in 1991. Sources of these imports were Japan, 69%; France, 18%; the Netherlands, 8%; and the United Kingdom, 5%. A total of 30,642 kilograms (gross weight) of beryllium-copper alloy scrap was imported from the

United Kingdom (62%) and Japan (38%).
(See tables 5, 6, 7, and 8.)

World Review

India.—According to Indian officials, a pilot plant for the production of beryllium metal was set up at the Bhabha Atomic Research Centre in Turbhe, New Bombay. The plant was designed to produce up to 2 kilograms per batch of beryllium for eventual conversion to vacuum hot-pressed beryllium metal and beryllium-copper alloy ingots. Both of these metals were expected to be used by India's Department of Space and Department of Atomic Energy.

Japan.—Demand for beryllium-copper alloys in Japan was estimated to have been reduced to 1,400 metric tons, a 10% decrease from the 1990 level. Most of the drop in demand occurred at the end of 1991 as a result of a recession in the Japanese economy. The principal end use for beryllium-copper alloys in Japan was in electrical and electronic components for motor vehicles and electronically controlled machine tools.⁴
(See table 9.)

OUTLOOK

Demand for beryllium-copper alloys should continue to be affected mainly by changes in the U.S. economy. Because these alloys are used in diverse applications, a downturn in only one or two end-use sectors is unlikely to have a significant effect on U.S. consumption. A prolonged recession, however, will continue to depress beryllium-copper alloy demand. The use of beryllium-nickel alloys should continue to grow. The predominant use of beryllium-nickel alloys is in automobile airbag systems, and more and more consumers are demanding these passive restraint systems in their new automobiles.

Metallic beryllium usage is unlikely to increase significantly. Beryllium's principal use is in defense applications, and because of decreased funding for some defense programs, production of new defense systems has been cut back.

Manufacturers are attempting to increase usage of beryllium components in other applications by developing new beryllium production methods to reduce the overall cost of the material. In addition, the manufacturers also are developing new families of intermetallic beryllium compounds, metal-matrix composites, and aluminum alloys that contain up to 40% beryllium. If these materials prove successful, new nondefense applications for beryllium may open up in the future.

The supply of beryllium ores could change drastically in the next few years. It is believed that the former U.S.S.R. has significant beryllium ore production capabilities and that much of the ore production was converted into beryllium metal and used within the country for military applications. With the recent changes in the former U.S.S.R. and that country's need for hard currency, it is likely that some of the beryllium ore will appear on the open market. With a reduction in the need for metals for its defense industry, beryllium metal produced in the former U.S.S.R. also may appear on the world market. (See table 10.)

BISMUTH

By Stephen M. Jasinski

Mr. Jasinski, a physical scientist with 5 years of U.S. Bureau of Mines experience, has been the commodity specialist for bismuth since 1988. Domestic survey data were prepared by Carolyn Crews, mineral data assistant. International Data were prepared by Harold Willis, international data assistant.

Increased production of bismuth chemicals boosted domestic consumption of bismuth 12% over that of 1990, according to the U.S. Bureau of Mines. Fusible alloy consumption also increased, but metallurgical additive uses dropped slightly. Consumers relied more on existing stocks of bismuth and less on imports, as shipments of bismuth to the United States declined from those of 1990.

Bismuth has become a leading candidate for replacing lead in many metallurgical and pigment applications. In 1991, it was announced that a bismuth-containing brass had been developed to replace leaded brass in some plumbing fixtures. Bismuth has also been tested as a replacement for steel shot in shotgun shells used in hunting waterfowl. Steel shot is currently used as a substitute for lead shot, but bismuth performs similarly to lead and is nontoxic.

Other recent developments include nontoxic ceramic glazes, bismuth-containing lubricating greases, and pharmaceuticals.

ANNUAL REVIEW

Legislation and Government Programs

The Defense Logistics Agency (DLA) which maintains the National Defense Stockpile (NDS), sold 56,880 kilograms of bismuth from the NDS in 1991. The Department of Defense proposed revising the goal for bismuth and other metals in the NDS. In its Annual Materials Plan, the Department of Defense has proposed reducing the goal for bismuth from 480,808 kilograms to zero.¹

The rate of disposal for fiscal years 1992 and 1993 will be 90,718 kilograms; the same amount is to be disposed of annually until the supply is exhausted. The inventory on December 31, 1991, was 828,280 kilograms.

Production

ASARCO Incorporated was the only domestic producer of primary bismuth. Production of bismuth at the company's Omaha, NE, refinery decreased slightly in 1991. To avoid disclosing company proprietary information, the data are not published. Several firms produced small quantities of secondary bismuth, mainly from fusible alloy scrap, but data on the quantities produced are not available.

Consumption and Uses

Domestic consumption of bismuth increased 12% over that of 1990. The largest increase was for bismuth chemicals mainly for industrial chemicals and pigments. The other chemical categories, pharmaceutical uses and cosmetic pigments, also grew in usage. Metallurgical additive use dipped slightly in the aluminum and steel industries.

Markets and Prices

The domestic dealer price was about \$3.00 per pound throughout the year, ranging from a brief low of \$2.70 in January to a high of \$3.25 per pound in July. The steady price was attributed to an adequate supply of bismuth and fairly level demand throughout the year.

Foreign Trade

Imports for consumption of bismuth metal were down 12% from those of 1990. The main sources were Mexico, Belgium, Peru, and China. Compared to those of 1990, imports from Belgium dropped almost 50% and imports from Peru, 35%. These decreases were offset partly by increased imports from Mexico and China. Exports were down 39% from those of 1990 owing to less bismuth-containing material being shipped to the United Kingdom for reprocessing.

World Review

Although world production of bismuth in 1991 was about the same as that in 1990, several companies stopped producing bismuth in 1991. RTZ Ltd. closed its Capper Pass tin smelter in the United Kingdom. The facility also produced bismuth and other minor metals. The closure was blamed on two major economic reasons, higher exchanges rates for the pound sterling, which increased toll refining charges, and a shortage of tin concentrates caused by low tin prices. The smelter has an annual production capacity of 4 metric tons of bismuth.

Capacity.—The data in table 5 are the rated annual capacity for mines and refineries as of December 31, 1991. Rated capacity is defined as the maximum quantity of material that can be produced in a given period of time on a normally sustainable long-term operating rate. It is based on the physical equipment of the plant and given acceptable routine

operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period with minimum capital expenditure.

Mine and refinery capacities for bismuth are based on combination of data on engineering capacity provided by some companies and estimates by the U.S. Bureau of Mines.

Bolivia.—Hexagon Resources, Flagstaff, AZ, began negotiations with Corporacion Minera de Bolivia (COMIBOL), the state-run mining company, to produce bismuth at the Tasna Mine. Bolivia is the only country where bismuth has been mined as a primary product on a large scale. COMIBOL closed Tasna in 1979 because of mounting losses. It was reopened briefly in 1985, but declining bismuth prices have kept it closed since then.

Canada.—Brunswick Mining and Smelting Co., Ltd., a subsidiary of Noranda Minerals Inc., produced about 100 tons of bismuth contained in bismuth-lead alloys, averaging 6% bismuth. This was down from that of previous years owing to a strike by the smelter employees that was not settled until May. The alloys were shipped to Belgium and the U.S.S.R. for refining; however, with the dissolution of the U.S.S.R., the company has had trouble finding a steady buyer for their product. Bismuth production will remain small, unless there is an increase in demand.

Cominco Ltd. recovered bismuth sporadically in 1991 as a byproduct of its lead refining circuit. Total output was about 100 tons. Cominco and Noranda have both resigned as sponsoring members of the International Bismuth Institute because of each company's reduced output and sales of bismuth.

France.—Les Mines de Salsigne, which recovered bismuth as a byproduct of gold production, ceased operations because of mounting losses. The mine produced

about 60 to 80 tons of crude bismuth annually, which was sent to Sidech in Belgium for refining.

Korea, Republic of.—Korea Tungsten Mining Co. suspended production of bismuth in the second half of the year. Bismuth was recovered as a byproduct of tungsten, but dwindling reserves and the depressed price of tungsten forced the company to stop production. Korea Tungsten has an annual production capacity of 200 tons per year, but production has been less than 100 tons for the past 3 years, most of which was exported to Japan.

Current Research

The application of bismuth as a nontoxic substitute for lead in a variety of uses dominated research news on bismuth in 1991. The most prominent announcement came from AT & T Bell Laboratories, which announced the development of a lead-free brass for use in plumbing fixtures. Lead is usually added to the brass to allow it to be machined easily, as it provides lubrication and allows the chips of metal to break off readily. Increased concerns about lead possibly leaching into drinking water from faucets and pending legislation to ban lead in many applications prompted research in this area. The only drawback to using bismuth was its brittleness, but this was alleviated by adding a small amount of either tin or phosphorus, which gave the brass nearly the same characteristics as leaded brass.

Actual widespread substitution is highly unlikely because the world supply of bismuth is limited. World production is about 4,000 tons per year and annual refinery capacity is more than 8,000 tons, but it would require at least 5 to 10 years for new mines and refineries to begin production. An increase of 2,000 tons in 2 to 3 years seems to be achievable. Bismuth is also much more expensive than lead, and new products would reflect this increase. Nibco Inc., Elkhart, IN, has begun production of a full line of lead-free plumbing fixtures, marketed for use in new homes only.²

There is also a problem with mixing bismuth brass scrap with lead brass scrap. Bismuth is considered a contaminant in brass mills, and measures would have to be taken to prevent this from occurring.

Bismuth is being investigated as a replacement for steel shot in shotgun shells. Steel shot is used as a replacement for lead shot, which was used for hunting waterfowl. Lead was banned for use in shot because some birds were found to be suffering from lead poisoning from ingesting the shot that had accumulated in the wetlands. Steel has some disadvantages; first, it is much harder than lead and is much more detrimental to the gun barrel; second, the steel shot often passes through birds and just wounds them, whereas bismuth and lead deform slightly upon impact; third, steel shot is much lighter than lead, requiring a larger size pellet. As with the brass, issues of availability and price must be assessed before any action will take place. Bismuth shot has not been approved for use, but it is being tested by the Canadian Wildlife Service.³

Drakenfeld Colors has patented a new bismuth pigment that will be used as replacement for lead pigments in certain ceramic enamels. The pigment has shown the same degree of durability as the lead pigments; however, it is not compatible with certain cadmium-bearing yellow-orange and red pigments.⁴

American Superconductor Corp. has produced a bismuth-silver superconductor that can be drawn into flexible wire up to 40 meters in length. The total amounts of bismuth used in this and other superconductor uses has been very small and used for experimental purposes only.⁵

OUTLOOK

The future for bismuth is optimistic, evidenced by the increase in consumption and the variety of new applications that have been developed. The release of NDS bismuth and the resumption of production in Bolivia could help supply bismuth for some of the more promising new uses in the next 5 years. World production could also increase in other countries if economic conditions are

favorable. Bismuth has the advantage of being nontoxic, which is expected to keep demand rising gradually in the next decade.

*Estimated. Revised. W Withheld to avoid disclosing company proprietary data; excluded from "Total."

¹Table includes data available through Apr. 2, 1992. Bismuth is produced primarily as a byproduct of other metals, mostly lead, and only in Bolivia is it mined for itself.

²Figures listed under mine output are reported in Canadian sources as production of refined metal and bullion plus recoverable bismuth content of exported concentrate.

³Mine output figures have been estimated based on reported metal output figures.

BORON

By Phyllis A. Lyday

Mrs. Lyday has covered boron for 13 years. Domestic survey data were prepared by Pam Shorter, statistical assistant; and international data were prepared by Harold Willis, international data coordinator.

U.S. production and sales of boron minerals and chemicals decreased during the year. Domestically, glass fiber insulation was the largest use for borates, followed by sales to textile-grade glass fibers, sales to distributors, and borosilicate glasses.

California was the only domestic source of boron minerals. The United States continued to provide essentially all of its own supply while maintaining a strong position as a source of sodium borate products and boric acid exported to foreign markets.

Supplementary U.S. imports of Turkish calcium borate and calcium-sodium borate ores, borax, and boric acid, primarily for various glass uses, continued.

DOMESTIC DATA COVERAGE

Domestic data for boron are developed by the U.S. Bureau of Mines from two separate, voluntary surveys of U.S. operations. Of the three operations to which a sold and used survey request was sent, three responded, representing 100% of the total boron sold or used shown in tables 1 and 10. A Bureau canvass of the three U.S. producers also collected data on domestic consumption of boron minerals and compounds shown in tables 4 and 5. (See table 1.)

BACKGROUND

Definitions, Grades, and Specifications

Few of the many minerals that contain boron are commercially valuable. Only colemanite and ulexite minerals, primarily imported from Turkey, are

marketed in the United States. The boron oxide content of both minerals is usually marketed at about 40%. (See table 2.)

Tincal and kernite ore and brines are the U.S. source of refined borate chemical compounds. The most common refined borates, borax pentahydrate and its derivative anhydrous borax, are marketed in technical and agricultural grades. Lesser quantities of borax decahydrate are produced in technical, United States Pharmacopeia and special quality grades.

Boric acid is a white, odorless, crystalline solid sold in technical national formulary and special quality grades as granules or powder. Boron oxide is a hard, brittle, colorless solid resembling glass that is ground and marketed most often under the name anhydrous boric acid.

Elemental boron is a dark brown powder in the amorphous form and a yellowish-brown, hard, brittle solid in the monoclinic crystalline form. Boron is marketed in grades from 90% to 99% purity.

Ferroboron is a name given to a variety of boron-iron alloys containing 0.2% to 24% boron used primarily to introduce small quantities of boron into specialty steels.

In the boron hydride series are diborane, a gas; pentaborane, a liquid; and decaborane, a solid. These compounds range from 31,220 British thermal units (Btu) per pound for diborane to 27,850 Btu per pound for decaborane. A history of the boron fuels project was told in a recent book. The book describes the pilot-plant production at the Malta Rocket Test Station.¹ Sodium borohydride is marketed in powder or

pellet form and in sodium hydroxide solution.

Boron nitride, a soft, white, highly refractory solid resembling graphite, can withstand significant oxidation to temperatures up to 650° C. Boron nitride produced in fibrous form equals glass fibers in strength and modules of elasticity, but is lighter in weight and more resistant to high temperature. When subjected to extremely high pressure and temperature, boron nitride forms cubic crystals that rival the harness of diamond.

Boron carbide, produced by reacting carbon and boric acid at 22,600° C, is a highly refractory material and one of the hardest substances known. Most commonly used for both abrasive and abrasion-resistant applications as well as nuclear shielding, boron carbide is marketed in technical and high-purity grades.

Byproducts and Coproducts

More than four-fifths of the U.S. production comes from mineral deposits mined only for their boron content. The remainder is produced from lake brines, which also supply sodium carbonate, sodium sulfate, potassium sulfate, and potassium chloride. Turkish colemanite, ulexite, and tincal ores are worked only for their boron content. Most Soviet borates are also mined only for their boron content, but the Gulf of Kara-Bagaz-Gol and the Sivash (lagoon) borates are extracted with coproduct chloromagnesium from brines. South American boron has been mined from ores and also has been produced as a coproduct of nitrate and iodine production.

Economic Factors

Costs.—Energy costs are especially high for producing anhydrous products. The anhydrous products were originally introduced to decrease freight costs per ton of contained boron oxide. Both domestic producers now use cogeneration facilities to reduce the cost of energy for processing and supplying excess electricity for sale. (See table 3.)

Depletion Provisions.—The domestic and foreign depletion allowances for boron are 14% of gross income and may not exceed 50% of net income without the depletion deduction.

Operating Factors

Naturally occurring boron compounds have relatively low toxicity for humans and other mammals. U.S. Borax & Chemical Corp. submitted a Toxic Substance Control Act Section 8(e) risk report (No. 2002) to the U.S. Environmental Protection Agency (EPA). Results of a teratology study of boric acid reported no observed adverse effects.²

Occupational Safety and Health Administration's (OSHA) Hazard Communication Standard went into effect November 1985 and May 1986. It is OSHA's most comprehensive worker protection regulation. It provides for information and training for workers encountering chemical exposures in the workplace. The standard requires the use of labels and material safety data sheets for all regulated chemicals. Part of the standard includes the Threshold Limit Values (TLV) from the American Conference of Governmental Industrial Hygienist. TLV's refer to airborne concentrations of substances and represent conditions under which nearly all workers might be repeatedly exposed day after day without adverse effect. The only hazard listed for boron chemicals produced at the mine site was a Time Weighted Average for borax decahydrate, listed as 5 milligrams per cubic meter per 8-hour workday, 40-hour workweek, to which nearly all workers may be repeatedly exposed without adverse

effect. Sodium borates, boric acid, and boron oxide are not present to any significant degree in air and are placed in the same hazard category as general dust.³

Small quantities of boron are essential for all plant life. Boron is added in trace levels to fertilizers; however, quantities well below concentrations affecting humans and animals are so extremely toxic to vegetation that boron compounds are also used commercially as herbicides. Concentrated boric acid is used to control certain insects and in dilute solutions as a preservative to control the growth of bacteria.

ANNUAL REVIEW

Legislation and Government Programs

Debate opened before the full House Interior Committee on the California Desert Protection Act. Under the proposed bill, 4.3 million acres of public land would be designated wilderness. In addition to the wilderness designation, the bill would add 1.3 million acres of Federal lands to the existing Death Valley National Monument and 200,000 acres to the Joshua Tree National Monument. The land under discussion contains numerous mineral deposits, including most known boron reserves. At yearend, H.R. 2929 had passed the House and was sent to the Senate for further consideration.

The Department of Commerce (DOC) published in the January 7, 1991, Federal Register that the DOC will soon publish a regulation amending the national security export controls on pyrolytic boron nitride (PBN). Initially, the Department intended to remove national security-based validated licensing requirements to all noncontrolled destinations. Following multilateral review by the Coordinating Committee for Multilateral Export Controls (COCOM), the Department published in the Federal Register on September 1 an announcement of the decontrol of PBN licensing requirements for exports to controlled countries.

Production

The majority of boron production continued to be from Kern County, with the balance from San Bernardino and Inyo Counties, CA.

American Borate Co. (ABC), a wholly owned subsidiary of Owens-Corning Fiberglass Corp., was sold in December of 1990 to a private firm. ABC renewed its mine permits and began to mine small amounts of colemanite and ulexite from the Billie Mine during 1991. Colemanite was processed at Lathrop Well, NV. Storage and grinding facilities were at Dunn, CA.

North American Chemical Co. operated the Trona and Westend plants at Searles Lake, in San Bernardino County, to produce refined sodium borate compounds and boric acid from the mineral-rich lake brines. At the Trona plant, a differential evaporative process produced borax with potash as a byproduct. Boric acid was produced by solvent extraction. The Westend plant continued production of sodium borates by a carbonation process. Brines used in the process were pumped to the Argus plant to produce sodium sulfate.

United States Borax & Chemical Corp., a part of Borax Consolidated Ltd. of the RTZ Corp. PLC of London, United Kingdom, continued to be the primary world supplier of sodium borates. RTZ is traded on the New York Stock Exchange.

U.S. Borax mined and processed crude and refined sodium borates, their anhydrous derivatives, and anhydrous boric acid at Boron, in Kern County, CA. A second plant at Boron used a proprietary process to produce technical-grade boric acid from U.S. Borax's extensive kernite ore reserves. The boric acid was produced to compete with imported colemanite used in glass manufacture.

The majority of material was shipped to U.S. Borax's storage, Wilmington, CA. Products made at Wilmington included ammonium borates, potassium borates, sodium metaborates, and zinc borate.

During 1991, experiments to grow natural-type plants on the mine wastes were begun. The experiments will

establish the proper slopes, vegetation, and methodology for reclaiming and resurfacing the mine waste.

During 1991, U.S. Borax, Boron, CA, received a runner-up award for the Sentinels award. To be eligible for the award, a mine must have accrued at least 30,000 injury-free hours. During 1991, all runners-up worked the entire calendar year without a lost-time injury.⁴

Consumption and Uses

U.S. consumption of borates decreased. Glass fiber insulation and glass fiber primarily used as reinforcement for plastics continued to be the largest consuming industries.

The use of borates in glass fiber thermal insulation, primarily used in new construction, was the largest area of demand for borates. Cellulosic insulation, the seventh largest area of demand, decreased.

The second major market for borates, manufacturing high-tensile-strength glass fiber materials for use in a range of products, showed an increase in demand. The nonconductive and low dielectric properties of high-strength glass-reinforced materials make them transparent to radar and thus valuable for "stealth" applications. Carbon-fiber-reinforced resins can be stronger than metals and, with higher modules, more stable. Although composites can be 10 times more expensive than typical aerospace-grade aluminum, the flexibility they offer in design and consolidation of parts allows large complex structures to be fabricated to exacting specifications. In addition, their light weight and ability to withstand high temperatures have made them the material of choice for a variety of aerospace applications.

A boron-reinforced epoxy patch was used to reinforce structural cracks in the B-1 bomber. The material was supplied by Textron Specialty Materials of Lowell, MS. The boron-epoxy patch technique was chosen after more traditional methods failed. The titanium longerons will be reinforced with two boron-epoxy patches that are about five times stronger and six times stiffer than aluminum

alloys. The patches must be applied in thinner layers, which is important for aerodynamic surfaces, to achieve the same amount of reinforcement.⁵

Consumption of borates in borosilicate glasses remained the third major end use, and demand decreased. Boron added in amounts of between 4% to 15% to glass reduced the viscosity of the melt, assisted with fiber formation during processing, and allowed for improved specific optical properties, increased resistance to aqueous or chemical attack, enhanced certain mechanical properties, and reduced the thermal expansion coefficient and thermal shock resistance of the product. Boron oxide provides a range of favorable benefits to the melting of nonspecialty and container glass and the final glass properties. Each 1% of boron oxides reduces the melting temperature of the glass 20° C.⁶

Boron compounds continued to find application in the manufacture of biological growth control chemicals for use in water treatment, algicide, fertilizers, herbicides, and insecticides. Boron can be applied as a spray and incorporated in herbicides, fertilizers, and irrigation water. The Potash & Phosphate Institute recommended one-half pound of boron for every ton of expected yield of alfalfa in the Spring 1992 Agri-Briefs. The brief recommended that micronutrient levels in the soil be monitored by soil testing.

A growing and important use of borax and boric acid was as a fire-retardant-treatment wood to be used as an alternative to noncombustible materials for building applications. Fire retardant chemicals reduce the rate at which flames travel across the wood surface, thereby reducing the capacity of the wood to contribute to a fire. The chemicals increase the amount of char and reduce the amount of flammable volatiles, but also lower the temperature at which thermal degradation occurs.⁷ The amount of degradation depends upon the chemical species present, elevated temperature levels, duration of exposure, and moisture content.⁸ Most fire retardant treatments significantly reduce the strength and stiffness of the treated wood product.⁹ ASTM is in the process of developing a

protocol for assessing impregnated chemical effects on long-term properties of wood products.¹⁰

Boron compounds were also used in metallurgical processes as fluxes, shielding slag in the nonferrous metallurgical industry, and components in electroplating baths. Small amounts of boron and ferroboration were constituents of certain nonferrous alloys and specialty steels, respectively.

Boron is also used as a bleaching agent in detergents and cleaning products, such as compact washing powders. Interlox America started up a plant in Texas for production of 45 million pounds per year of sodium perborate monohydrate. The other U.S. supplier is E.I. Du Pont de Nemours & Co. With the added capacity, imports will not be necessary to supply demand.¹¹ (See tables 4 and 5.)

Prices

Prices for anhydrous, pentahydrate, and decahydrate borax and technical boric acid decreased. Only the price for Turkish ulexite increased. (See table 6.)

Foreign Trade

The majority of material from the U.S. Borax facility in Boron was shipped to storage, loading, and shipping facilities at Wilmington, CA. A large part of the output was exported to Western Europe from Wilmington to Botlek, Netherlands. (See tables 7 and 8.)

World Review

Corning Inc. and Vitro, Sociedad Anonima, Mexico's largest glass manufacturer, have signed a letter of intent to create a new worldwide joint venture dedicated to consumer housewares. The alliance will combine annual sales in excess of \$800 million. Under the terms of the proposed transfer, Corning would transfer its worldwide consumer assets and business to a newly formed U.S. subsidiary called Corning Vitro Corp. Likewise, Vitro will form a Mexican subsidiary to be called Vitro Corning S.A. de C.V.¹²

Capacity.—The data in table 9 are rated capacity for mines and refineries as of December 31, 1991. Mine capacity for boron was based on rated capacity as reported by the company, by another government agency, or another published source. Capacity outside of the United States was limited by the availability of loading and transportation equipment and market demand, rather than limitations of ore grade. (See table 9.)

Argentina.—Boroquimica SA continued production of tincal and boric acid from a deposit at Tincalayu.

Bolivia.—Compania Minera Tierra Ltd., a small company formed in 1988 for producing borates in an area of the Department of Potosi, obtained a loan of \$1.6 million from the Inter-American Investment Corp. The firm has important concessions of ulexite and sulfur near the Chilean border in the southwestern tip of the country. About 120,000 tons of ulexite per year is exported to Brazil and other neighboring countries. In 1990, the company employed 120 persons.

The company has interest in ulexite mineral concessions at the following locations: Kapina, Chalviri, Pastos Grandes, Chiguana, Leguani, and Empexa. The concessions cover an area of 4,800 hectares, and reserves have been estimated by the company to exceed 13 million tons of raw ulexite with grades ranging from 20% to 37%.

Ulexite is extracted and dried by turning by tractor. The dried ulexite is washed and roasted. The processed ulexite of about 42% borate content is bagged and exported by trucks and rail.

The loan received will finance a boric acid plant at Apacheta, Department of Potosi. The plant is near the location of a geothermal field that plans electric generation beginning in 1993. The boric acid will be produced by combining ulexite with sulfur dioxide produced by burning sulfur.

A new compendium of information on the geology and mining in Bolivia was released at the National Western Mining Conference and Exhibit. The compendium was the result of studies

commissioned by the Ministry of Mining and Metallurgy under the direction of the Bolivian Geological Survey and funded by the U.S. Trade and Development Programs. The compendium contains details of more than 700 mines and mineral occurrences, including the geology and metallogenesis of each locality. A section on investment conditions and recent changes to the Bolivian Mining Law was also included.¹³

Chile.—Quiborax is the main producer of boric acid and concentrated ulexite. Minera del Boro, Minera Ascotan, and Boroquimica are smaller local producers. Quiborax and Minera del Boro planned capacity increases. By 1994, Minsal planned to have completed a boric acid expansion of 18,000 tons per year.

Compania Minera Salar de Atacama (Minsal), a joint-venture project between AMAX of the United States, Molibdenos Y Metales (Molymet) of Chile, and Corporacion de Fomento de la Produccion (CORFO). CORFO established the joint venture as a result of an international public licitation in 1986, in which the Lithium Corp. of America (LITHCO) was the only other bidder. The project was designed to produce lithium carbonate, potassium chloride, potassium sulfate, and boric acid from the Salar de Atacama in the Second Region. Future production was expected to be 26,000 tons of boric acid per year. In February 1991, the project was placed on hold for a second year, under the terms of AMAX's original contract.¹⁴

China.—The borates in the salt lakes of China are mainly found on the Qinghai-Xizang (Tibet) Plateau. Boron is distributed in many saline lakes from the southern side of the Gilian Mountains in the north side of the Gangdisi-Tanggula mountains. Most borates exist in the Holocene sediments, some in the late Pleistocene. Most are concentrated on the hot spring side of the lake basin. Borax and tincalconite are mainly found in the salt lakes of carbonate-type, and the pinnoite, kurnakovite, and other Mg-borates in the lakes of sulfate-type.

Investigations on the source of borate are as follows: Geothermal water and acid magmatic rock weathering are the source of the forming borates; the borates can be formed in various brines of the different concentrating stages of sulfate and carbonate types; the precipitation of borates requires a rather stable environment; the mixing process and low-temperature condition are fairly beneficial for the borate formation; and the formation of borates is closely related to the chemical type, pH value, and B-content of those brines.¹⁵

Boron mineralization occurs in Yuanjiaguo iron ore bodies of Kuandian-type. One of the features of the Kuandian-type iron ore deposits is that they consistently occur at the same position in the stratigraphy. The Precambrian metamorphic systems in the east Liaoning region can be divided into the Anshan Group (Archaen), the Kuandian Group (Lower Proterozoic), and the Liaohe Group (middle Proterozoic). The iron ore and associated boron deposits occur in the Yangmugan Series and the Baiciadi Series of the Kuandian Group, all of which consist of tourmaline granulite, biotite, garnet, magnesium marble, and plagioclase hornblende. The boron-magnesite minerals were formed from the remnant solution after rock-forming and iron-ore-forming stages. Therefore, all iron deposits are associated with deposits of boron, phosphorous, sulfides, and rare earths.¹⁶

Iran.—At Deh-e-Shotoran near Sirjan, the region is of tourmaline-rich granites that have invaded metamorphosed sandstones. Ulexite is found in depressions. At Tonkar near Sabzevar, there are several sources of borates in consolidated sediments of thin beds of limestone, marl, and clays. Ulexite also occurs close to the village of Ashin near Anarak.¹⁷

Mexico.—U.S. Borax and Vitro Corp. operated a pilot plant to evaluate a borate deposit near Magdalena in Sonora during 1991.

Negotiation began that could lead to a North American Free-Trade Agreement among Canada, Mexico, and the United States. The talks concerned the investment and ownership of corporations.

Turkey.—Turkey's boron operations are under the control of the Government corporation, Etibank, that mines boron from major deposits at Bigadic, Kirka, and Emet. Etibank operates refining facilities to produce refined sodium borates and boric acid from tincal concentrates at Bandirma. Boron minerals and compounds are shipped from the port of Bandirma on the Sea of Marmara and Izmir on the Aegean Sea.

During 1991, studies on the beneficiation of boron minerals by flotation were investigated. Calcium-containing borates are relatively insoluble, while sodium-containing borates are highly soluble. Flotation tests were conducted to elucidate the mechanism involved in the flotation of boron minerals.¹⁸

U.S.S.R.—Several distributors were marketing boron compounds produced in the U.S.S.R. Among the materials listed were boric acid, borax decahydrate, anhydrous borax, sodium perborate, and calcium borate.¹⁹

United Kingdom.—A high-speed composite lifeboat, the first prototype of a successor to the Royal National Lifeboat Institution Arun boat, began sea trials. The new craft is almost 1.5 tons lighter while increasing the design strength. The reinforcement was a woven combination of a amid nylon with e-glass, which is a borosilicate-type glass. The first prototype exceeded contract speeds.²⁰

Yugoslavia.—Boron in the Janando basin in Serbia occurs as haulite (44% boron oxide), and in the Kremna basin in Serbia and the Lopari-Sibosnica basin in Bosnia as searlesite.

In the volcanic sedimentary series of the Jarando Neogene basin, haulite mineralization was discovered near the Pobrdjski Potok, about 1 kilometer north

of the magnesite deposit at Bela Stena. Haulite occurs in a series of lenses up to 1 meter thick and 10 meters long. In the sedimentary deposit of pellitomorphic magnesite and dolomite at Kremna (Serbia) of Neogene age, searlesite appears in the form of ball-shaped grains. In some magnesite layers, the percentage of searlesite is as much as 40%, with an average boron oxide content of 1.6%. In Bosnia, in the Miocene lacustrine sediments of the Lopari-Sibosnica basin, ellipsoidal lumps of searlesite are found in shale-marl series with interlayers of tuffs and tuffaceous sandstone.²¹ (See table 10.)

Current Research

Atochem S.A. granted Morton International worldwide licensing rights to a new pulp process. The process combines the use of a reducing agent, such as "Boral," which contains sodium borohydride, with Atochem's hydrogen peroxide. The new process enables economic achievement of brightness levels of 1% to 2% International Standards Organization (ISO) over those obtained by the conventional process.²²

The occurrence of boracite and other boron-bearing minerals in the Gulf Coast Salt Basin was reported in 1987. In Wayne County, MS, 72 wells have been drilled to the Louann Salt formation at depths of between 12,000 and 15,000 feet. Cuttings from nine wells have provided boron-bearing minerals. Boracite occurs as small euhedral crystals in clear, pale yellow, or pale bluish-green. The apparent consistent occurrence of the boron-bearing minerals in the study area suggests that their presence may be pervasive at the top of the Louann Salt throughout the entire Salt Basin.²³

A study of 78 wells from a 4-county area of Mississippi provided borocite group crystals from only 5 wells. The boracite-containing wells are distributed randomly.²⁴

Argonne National Laboratory won a 1991 Research and Development 100 Award for the development of boric acid lubricant. The lubricant is extremely versatile with applications in moving

mechanical seals; sliding, rolling, and rotating engine parts; and metal-forming and metal-curing machines. It can be used to prevent damage to heavily loaded gears and to railroad trucks and wheels. It also has value for high-precision motion drives where stick-slip is a major concern, as well as magnetic data storage media and many other applications.²⁵

A new composite thermal-protection system was developed by Ames Research Center that used silica and boron oxide powders, which form borosilicate glass, and silicon tetraboride powder, which gives the requisite emittance. The ingredients are mixed in an alcohol carrier to make a slurry, which is strayed on a tile, dried, and sintered to form a hard, protective surface. The resulting system had thermal insulating properties comparable to existing systems but with 20 to 100 times more resistance to impact.²⁶

The use of "thinnings," the small trees cut in commercial forest that are cut so that the best trees may grow larger, were used in two revolutionary new buildings in Dorset, England. Thinnings are considered too small for construction and are usually used for wood-burning stoves or for mulch. The new building approach can spare and preserve forest by making productive use of their thinnings. Norway spruce used in the buildings was borate-treated for longer working life. The preservative was a strong, warm solution of disodium octaborate tetrahydrate. The debarked trees were dunked in groups of three or four in 30-foot tanks. Longer trees were sprayed three times to achieve 100% borate penetration.

The green flexibility of newly felled treated wood was considered an asset. Stored in polythene, the thinnings retain flexibility for a month. While sawing wood weakens the grain, which gives tensile strength to the beam, thinnings have the same strength as sawn wood twice its age. The new buildings were designed to exploit the strength in tension of roundwood and reduce the strength demands at midpoint.²⁷

Studies on the role of boron in granitic magmas demonstrated that boron is

concentrated in late-stage magmas until lost through aqueous vapor. Boron clusters in the melt scavenge water and alkalis. The effects on magmas may influence the concentration and precipitation of metal ores and the development of crystals in granite-pegmatite systems.²⁸

The texts of the plenary and invited lectures presented at the 7th International Symposium on Boron Chemistry (IMEBORON) held in Torun, Poland, July 30-August 3, 1990, were published in the March 1991 issue of *Pure and Applied Chemistry*. More than 100 participants from 13 countries attended the meeting. The scientific program consisted of 7 plenary and 18 invited lectures and 35 oral and 32 poster presentations. A panel discussion focused on current trends in practical applications of boron compounds. The 8th IMEBORON was scheduled at the University of Tennessee for July 11-15, 1993.

OUTLOOK

Production and consumption of boron minerals and compounds have decreased between 1982 and 1991. There are several factors that may lead to misleading outlooks in consumption. One is that production and imports reported in 1 year may be utilized over a period of years. In addition, environmental concerns may change the demand for boron significantly in a short period. The regulation of fire retardants in products have resulted in changes in boron usage as a fire retardant. More recent decreases in domestic consumption have been attributed to decreases in glass consumption because of less demand resulting from a recession.

Agriculture

Boron usage in agriculture reached a low in 1982 and has continued to decline. The primary reason was attributed to the decline of the number of farms during the same time period. Farming exports are showing increased strength and demand for boron usage in agriculture.

Ceramics and Glass

Boron usage increased over the 1980's, reaching a peak in 1984 that was a 36% increase over that of the prior year. This spike was probably a demand to balance the sharp decline of 1982 of 41%. Ceramics and glass have both faced competition with polymers. The U.S. fiberglass industry was reported to be feeling the effects of recessionary pressures. The sagging economy produced a decline in demand for fiberglass reinforcements that was expected to be long term. Fiberglass is closely related to construction and transportation, which continue to be depressed.

Coatings and Plating

Primarily used as a protective coating for steel products and as a glazing on ceramic tiles, usage has experienced a decline. This decline was a result of the demand for polymers that replace many of the coatings and plating uses.

Fabricated Metal Products

Boron usage decreased in metal products during the past decade. Many traditional metal products that require soldering now are produced from polymers as one piece. Usage in specialized metal was expected to increase at the rate of 2% per year.

Soaps and Detergents

This usage declined primarily as chlorine bleaches and cold water washes replace boron soap powders. Recent concern for environmental effects of chlorine may reverse the decline. Perborate bleaches have returned to name brand soap products. The usage of boron in soaps and bleaches was expected to increase by 4% per year over the next 5 years.

BROMINE

By Phyllis A. Lyday

Mrs. Lyday, a physical scientist with the U.S. Bureau of Mines, has been the commodity specialist for bromine for 13 years. Domestic survey data were prepared by Gail Mason, statistical assistant; and international data tables were prepared by Doug Rhoten, international data assistant.

Production of bromine worldwide in 1991 was as follows: United States, 42%; Israel, 32%; the U.S.S.R., 12%; the United Kingdom, 7%; and other countries, 7%. The U.S. portion of world production has decreased steadily since 1973, when the United States produced 71% of the world supply. The decrease in world share has been a result of environmental constraints and the emergence of Israel as the world's second largest producer. Domestic capacity decreased 14% during the same period of time. The quantity of bromine sold or used in the United States was 170 million kilograms (kg) valued at \$167 million. Exports of elemental bromine and bromine contained in compounds amounted to 17 million kg. The price of elemental bromine in bulk was 56 cents per kg. Primary uses of bromine compounds were in flame retardants (27%), agriculture (15%), petroleum additives (15%), well-drilling fluids (10%), and other (33%).¹

DOMESTIC DATA COVERAGE

Domestic production data for bromine were developed by the U.S. Bureau of Mines from a voluntary survey of U.S. operations. Of the six operations to which a survey request was sent, two responded, representing 41% of total elemental bromine sold or used. Production at the other four operations was estimated by using quantity of brine produced and estimated bromine concentration. (See table 1.)

BACKGROUND

Definitions, Grades, and Specifications

In the elemental form, bromine is a very dark, reddish-brown liquid. Bromine is the only nonmetallic element that is liquid at ordinary temperature and pressure. The natural form of bromine is a solution of sodium bromide in natural brines, saline deposits, salt lakes and seas, and oceans.

Elemental bromine is marketed in a "purified" grade with the following specifications: Specific gravity not less than 3.1 at 10° C to 20° C; bromine, not less than 99.7%; iodine, none; and chlorine, not more than 0.1%. Specifications for the various grades of bromine compounds include technical bromine, 99.5% pure, with the chief impurities consisting of chlorine, traces of moisture, and organic matter. Specifications of the United States Pharmacopoeia and the American Chemical Society Committee on Analytical Reagents allow 0.3% chlorine, 0.05% iodine, 0.0002% sulfur (0.006% as sulfate), and no more organic matter in 1 milliliter than will saturate 50 milliliters of 5% sodium hydroxide solution. The term "chemically pure" signifies a minimum of impurities.

Geology-Resources

Bromine is widely distributed in the Earth's crust, but in small quantities. By far the largest potential source of bromine in the world exists in the oceans. At a

concentration of only 65 parts per million (ppm), large amounts of seawater are processed to obtain the bromine.

Arkansas brines contain about 5,000 ppm at depths of 2,286 meters (7,500 feet) in limestone of the Smackover Formation of Jurassic age. In Michigan, brines containing about 2,600 ppm of bromine occur in the Sylvania Sandstone Formation of the Detroit River Group of Devonian age.

In Israel, bromine is produced as a byproduct of salt, sodium chloride, and potash production from the Dead Sea. The waste brines contain 14,000 ppm bromine.

Technology

Processing.—The Arkansas Geological Commission report three east-west bromine-rich brine fields. Wells are drilled down to the brine level, and a submersible pump is lowered to pump the liquid to the surface. Brine is separated by gravity from any residual gas at the surface and pumped to one of six processing facilities.

At the processing facility, bromine is separated from the brine by a steaming-out process. The brine is pumped into the top of a tower constructed of granite and filled with ceramic packing. As the brine falls through the packing material, it reacts with chlorine and steam that are injected at the bottom of the tower. One pound of chlorine yields 1 kg of bromine. About 95% of the bromine, or about 0.7 to 0.8 kg of bromine per barrel of brine, is recovered if the raw brine is first acidified to a pH of 3.5. The chlorine

replaces the bromine in the brine, and the gaseous bromine rises with the steam out of the top of the tower; there it is condensed to a reddish-brown liquid. Bromine is separated from gases. The bromine liquid can be further purified or reacted with other materials to form bromine compounds. Bromine vapor, a little chlorine, and water vapor are captured at the top of the tower. Hot bromine-free liquor emerges from the bottom of the tower. After neutralizing with lime, the waste liquor is pumped through a heat exchanger to a waste pond. Brine from the pond is reinjected into the same producing zone to maintain hydrostatic pressure.

Seawater contains about 60 ppm to 70 ppm of bromine as sodium bromide or magnesium bromide. Production of bromine from seawater uses the blowing-out process. Raw seawater is acidified by adding sulfuric acid and then chlorine. Air was drawn into the base of the tower and rises as the brine descends. Air containing bromine passes to the absorption tower. In the absorption tower, bromine reacts with sulfur dioxide to form a hydrogen bromide. The bromine is separated by adding acid to the solution and is distilled by steam. The gaseous bromine is condensed, separated, and purified.

Recycling.—Great Lakes Chemical Corp. (Great Lakes) announced the beginning of what is claimed to be the first halon reclamation and recycling facility. Great Lakes planned to collect and recycle used halon from the fire services industry through E/M Corp., a wholly owned subsidiary. The first facility was to be in the Los Angeles basin and will serve west coast and Pacific Rim markets. A second site was to be at El Dorado, AR.²

Byproducts and Coproducts

Some bromine-bearing brines contain hydrogen sulfide gas. This gas has a disagreeable odor, is highly toxic, and when burned, will oxidize to sulfur dioxide, an acid-producing gas. To prevent the emission of the gas to the

atmosphere where sulfur dioxide may form, environmental regulations require the recovery of the sulfur. Hydrogen sulfide gas was chemically removed from the incoming brine and converted into elemental sulfur or other nontoxic sulfur-containing compounds. The cost of recovery was greater than the selling price of the sulfur, but recovery prevented emission of a gas that may contribute to the formation of acid rain.

Substitutes

Various materials are used in flame retardants as replacements for bromine in engineering and high-performance thermoplastic polymers and blends, and polymeric composites. The distinguishing characteristic of engineering polymers is that they have properties that lend themselves to structural applications over a wide range of temperatures, high mechanical stress, and harsh chemical and physical environments. The high-performance polymers are also distinguished by their special properties such as extremely high-temperature tolerance and outstanding optical properties or conductivity, but they are not necessarily designed for structural integrity.³ (See table 2.)

Economic Factors

Costs.—Oil & Gas Journal published in the December 30, 1991, issue that drilling and/or equipping costs for gas wells in Arkansas averaged \$486,000 for wells 1,524 to 2,286 meters deep (5,000 to 7,499 feet). Chlorine, the largest manufacturing cost factor, represented about 30% of the manufacturing cost of bromine. Other cost factors include brine (22%), operating cost (15%), utilities (14%), overhead (12%), and other (7%).

Taxes.—During 1991, brines produced in Arkansas required the payment of \$2 per 1,000 barrels in severance taxes, and capital equipment was subject to the payment of property taxes. Bromine produced in the United States was subject to Superfund taxes of \$4.91 per metric

ton (\$4.45 per short ton). Bromine was manufactured using chlorine, which was subject to a Superfund tax of \$2.98 per metric ton of chlorine (\$2.70 per short ton).

Depletion Provisions.—Bromine producers (domestic and foreign) are granted a 5% depletion allowance under the Federal Income Tax Law on the value of bromine produced from brine wells. The depletion allowance can be calculated by the actual cost method.

Operating Factors

Toxicity.—Bromine is highly toxic and corrosive and must not be allowed to escape into the atmosphere. Many bromine compounds are also poisonous or irritating and must be packaged in leakproof containers to avoid personal injury. If bromine spills on paper, rags, wood shaving, etc., it will generate considerable heat, which may lead to spontaneous combustion. Bromine reacts with living tissue and must be removed immediately to avoid serious injury.

Bromine vapors are hazardous to the eyes and lungs. Any concentration above 1 ppm in the air for an 8-hour exposure is considered a health hazard. Bromine can be detected by its odor even at this level. Exposure to concentrations of 500 to 1,000 ppm for as little as one-half hour is lethal. The Occupational Safety and Health Administration regulates the working conditions of bromine plants.

When handling bromine, a person should use safety goggles, face shield, rubber gloves, rubber boots, and under some conditions, a self-contained breathing apparatus. Bromine spills are neutralized with a solution of sodium thiosulfate. Gaseous bromine is neutralized with controlled amounts of gaseous ammonia. All metal, such as electrical switches and connections, that may be exposed to bromine vapors should be made of corrosion resistant materials and/or completely sealed from contact with the room air.

Employment.—The U.S. bromine chemical industry employed directly an average of 20 personnel for each \$1 million of sales. The employees work in production, packaging, transportation, marketing, product and process development, quality control, and administration. More than two-thirds of these jobs was concentrated in Union and Columbia Counties of south Arkansas.

Energy Requirements.—The manufacturing cost of bromine was heavily dependent on chlorine and brine cost. Of the total brine cost, 46% was power related and 53% was maintenance cost. Brine cost is dependent on well maintenance cost and energy cost associated with well pumping. Approximately 14% of the bromine manufacturing cost was energy related.

Transportation.—The Research and Special Programs Administration (RSPA), U.S. Department of Transportation (DOT), published rules for hazardous substances (49 CFR, parts 171 and 172). The action complies with a 1986 amendment (Public Law 99-499) to section 306(a) of the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) of 1980 (Public Law 96-510). The law mandates that RSPA regulate all Environmental Protection Agency (EPA)-designated hazardous substances. The amendment required shippers and carriers to identify CERCLA hazardous substances, to comply with the Hazardous Materials Regulations, and to make the required notifications if a discharge of a hazardous substance occurs.

ANNUAL REVIEW

Legislation and Government Programs

The Federal Trade Commission (FTC) opposed Great Lakes's proposal to acquire the remaining 50% interest in Arkansas Chemicals Inc., which is a joint venture with PPG Industries Inc. The FTC objected because the sale could

lessen competition in the bromine markets.⁴

The DOT RSPA listed a final rule for performance-oriented packaging standards that included several bromine compounds under Hazardous Material Regulation (HMR) (49 CFR, parts 173.193 and 228). The rule comprehensively revises the HMR with respect to hazard communication, classification, and packaging requirements.⁵ On January 1, 1991, the new DOT/United National Performance Oriented Packaging Standards (POPS) were phased into the current DOT HMR. On that date, compliance with domestic shipping was voluntary. However, shipping materials internationally or domestically by air or international waters must comply with the POPS regulations. POPS involves changes to every aspect of shipping activities, including selecting packages; preparing shipping documents; and labeling, marking, and placarding shipments of hazardous materials and waste.⁶

The Department of Health and Human Services and EPA listed a revised priority list of hazardous substances that was to be the subject of toxicological profiles that included brominated compounds. The CERCLA, as amended by the Superfund Amendments and Reauthorization Act (SARA), established certain requirements for a list of at least 100 hazardous substances that are most commonly found at facilities on the National Priorities List.⁷

An EPA-funded computer network began in May that would allow States to exchange technical and legal information about Superfund programs. Through a computer bulletin board, users would have access to four data bases: a listing of more than 650 EPA policies and guidance documents; State Superfund program information; State settlement, including information on contaminants, technologies, costs, and timetables; and a record of State decisions.⁸

Methyl bromide was dropped by EPA as an inert product on List 2 and was classified as a List 1 inert. The Agency stated that all products containing methyl bromide as an inert have been canceled.⁹

EPA announced in the Federal Register a final rule for the pesticide tolerances for inorganic bromide resulting from fumigation with methyl bromide on May 1, 1991. Tolerances contained in 40 CFR 180.123 and 199 for residues of inorganic bromides in or on ginger roots was amended to 100 ppm.

A section 18 exemption was granted by the EPA to the U.S. Department of Agriculture (USDA) for the use of methyl bromide to control various plant pests not currently established in the United States on imported cherimoya. The exemption provisions included: application under tarpaulins or in other temporary enclosures at the rate of 3 pounds per cubic foot, held for 2 hours; detection of leaks using masks and monitoring; limitation of 30-ppm maximum residue for inorganic bromides and 0.01 ppm for residues of ethyl bromide; aeration of treated commodities to allow dissipation of methyl bromide residues; an expiration date of October 10, 1994.¹⁰

A notice of proposed rulemaking was published by the EPA in the Federal Register September 30, 1991, to conform its stratospheric ozone protection regulations (40 CFR, part 82) to the requirements of title VI of the Clean Air Act Amendments of 1990, Public Law 101-549. The notice proposes amended regulations implementing the 1992 and later requirements of section 604, as well as the related provisions of sections 603, 607, and 616, in a manner consistent with the United States' continuing obligations under the Montreal Protocol as amended.

A proposed rule was published by the EPA in the Federal Register on June 25, 1991, for a test under section 4(a) of the Toxic Substances Control Act (TSCA) in response to the Interagency Testing Committee (ITC) designation of five brominated flame retardants (BFR). The testing would include environmental and health effects and chemical fate testing. EPA has concluded that activities involving these BFR may pose an unreasonable risk of injury to human health or the environment as suggested by certain preliminary data, existing data are inadequate to assess the risks to human health and the environment posed by

exposure to these substances, and testing of each of the five BFR's is necessary to develop such data.

Production

Ethyl Corp. and Great Lakes produced and marketed bromine chemicals from plants in Arkansas. Small amounts of unpurified bromine were produced as a byproduct of magnesium production in Michigan and reprocessed for consumption in Arkansas. The Arkansas plants accounted for 97% of U.S. elemental bromine capacity at yearend 1991 and 100% of bromine sold or used.

Plant capacity was dependent upon brine supplies, concentration of the bromine in the brine, and individual plant extraction processes. In Arkansas, one supply and one disposal well were required for each 4.5 million kg per year of bromine produced.

Bromine concentrations in the brine decrease as waste brine depleted of bromine is returned to its source. New wells must be drilled to provide adequate reserves to ensure future demands of elemental bromine. Each supply well requires an investment in excess of \$1 million and has an average life of about 10 to 15 years. (See table 3.)

Consumption and Uses

Fire retardants were primarily tetrabromobisphenol-A (TBBA) and decabromodiphenyl oxide. Great Lakes announced plans to expand TBBA production capacity at its El Dorado, AR, facility to meet growing demand as a flame retardant for acrylonitrile-butadiene-styrene (ABS) polymers. The expansion increased Great Lakes' capacity by 25%.

The U.S. International Trade Commission (USITC) publication entitled "Synthetic Organic Chemicals, 1990" listed Ethyl Corp. as the only producer of hexabromocyclododecane. Sales of flame retardants account for one-half of the worldwide plastic additives market and are growing. Brominated hydrocarbons are the major materials used to make flame retardants.

Demand for ethylene dibromide (EDB) is in gasoline additives as a scavenger for lead antiknock. The USITC's "Synthetic Organic Chemicals, 1990" listed Great Lakes and Ethyl as the only producers of EDB used in gasoline additives during 1991.

The USITC reported that the Dyes & Pigments Div. of Mobay Chemical Corp. produced pigment red 168, dibromoanthranthrone orange. Red 168 was used in automotive metallic applications because of its transparency.

Bromine was used in clear brine drilling fluids used in work-over and completion fluids and other uses. Hoechst Celanese Corp. (U.S.) sold bromine compounds as intermediates in the production of antibiotics, disinfectants, anti-inflammatory, and analgesic products. One bromine compound is a useful intermediate under both alkaline and acidic conditions. Another compound is useful for heteroatomic ring closures of organic chemicals. In addition, the company used bromine in dyes.

Halogenated synthetic rubber consumption has grown between 1980 and 1992. Exxon Chemical Co. is the only domestic manufacturer of bromobutyl rubber. This rubber is more heat resistant than other types of rubber and is used primarily in truck tires. The International Institute of Synthetic Rubber Producers in Houston, TX, projected growth rates of 2.1% per year through 1996 for all synthetic rubber consumption, with the exception of polychloroprene.

Prices

Bromine was sold under contracts negotiated between buyer and seller. Price quotations do not necessarily represent prices at which transactions actually occurred, nor do they represent bid and asked prices. They were quoted in table 4 to serve only as a guide to yearend price levels. (See table 4.)

Foreign Trade

Israel received duty-free treatment on its bromine products in all major world

markets except the United States, where duties are paid on three significant bromine products. The duty on all bromine products will drop to zero in 1995. (See tables 5 and 6.)

World Review

Capacity.—The data in table 7 are rated capacity for mines and refineries as of December 31, 1991. (See tables 7 and 8.)

Canada.—Ethyl Corp. applied for permits to double and modernize its 22,680-metric-ton-per-year plant for tetraethyl lead (TEL) at Corunna, Ontario, by 1992. TEL uses a bromine compound as a scavenger for the lead. Farm vehicles and light aircraft are exempt from a phaseout of leaded gasoline passed in 1988 that took effect in December 1990. Local unions are in favor of the plant expansion because it will employ 350 for the construction and create 70 to 80 new plant jobs. The plant presently employs 165 people. The expansion was expected to cost \$67 million. The modernization would decrease lead emissions by 23% and improve air quality emissions from the plant by a 53% decrease.¹¹

China.—The Qaidam Basin in northwest China's Qinghai Province covers an area of 25,000 square kilometers and contains reserves of 40 types of salt minerals that include bromine, lithium, and magnesium. A potash plant was in operation in the southern portion of the basin, and a soda ash plant was planned to begin production in 1991.¹²

Germany, Federal Republic of.—The closure of eastern and western potash mines was proposed by a federal-state commission. BASF Corp.'s minerals subsidiary Kali und Salz announced plans to cooperate with eastern German potash and salt producer Mitteldeutscher Kali (MDK). Almost 5,000 jobs were to be eliminated in the German potash industry by 1994, including 1,400 out of 7,300 jobs at Kali und Salz and 3,500 out of

12,000 at MDK. Bromine was produced from the bitterns of potash production from mines that also have bromine production plants. The production of bromine could be adversely affected by the closures.¹³

Great Lakes acquired the chemical plant at Konstanz of Degussa AG effective October 1. Plans were underway to relocate the research and development from Aycliffe, United Kingdom, to Konstanz. Great Lakes planned to continue to make amino acid derivatives for Degussa and expand into new bromine and nonbromine products at the newly acquired plant.¹⁴

Israel.—Dead Sea Bromine (DSB), a subsidiary of Israeli Chemicals Ltd. (ICL), announced capacity increases in chlorine and bromine output. The addition of chlorine is necessary to produce bromine. The company planned to increase bromine capacity from 135,000 to 170,000 metric tons per year by 1993. Plans were to reach 200,000 metric tons per year by 1997. DSB planned to invest about \$40 million per year over the next 5 years to increase bromine capacity.¹⁵

The Government began efforts to sell a share of ICL to offset an investment program in 1985. In 1986, ICL announced privatization of some of the 189 State-owned companies. Much of the organic and inorganic chemical activity takes place within the framework of the massive ICL, which in 1986 was composed of 28 companies with a work force of 7,000. During 1990, formal bids were accepted for 50% of ICL, but a number of Government representatives favored a public sell rather than to a foreign investor. Great Lakes was part of the only foreign consortium that had a bid on ICL at yearend 1990.

In August 1991, privatization terms for ICL were agreed to by a committee with representatives from the finance, trade and industry, and justice ministries of the Israeli Government. Some conditions for the privatization appear to conflict in terms of how much control the Government will exercise over ICL. The State retained the "power of supervision"

over the natural resources controlled by ICL, such as bromine and reserves of potash in the Dead Sea. The State has to approve any buyer of a 15% or greater holding or a 26% or larger stake by a strategic partner, such as an international chemicals concern.¹⁶ The plans to sell 51% to a private investor was opposed by company management and members of the Government.

ICL authorized Bromine Compounds to proceed with a \$14 million investment program at Ramat Hovav in the Negev Desert. The investment forms part of a \$45 million plan to produce specialty chemicals for the plastics industry. Technology for the project was developed by ICL's research and development division.¹⁷

DSB Group planned to expand its TBBA used in fire retardants at Beer Sheva by 4,600 metric tons annually. The \$3 million project was to be completed by 1992. In addition to production at Beer Sheva, DSB also produces TBBA at a subsidiary, Broomchemie BV, Terneuzen, Netherlands.¹⁸

Jordan.—The Arab Potash Co. announced that the feasibility study begun in June 1990 was progressing and was expected to be completed by 1992. The initial study was for a \$2 billion complex. The plans were modified to be a \$700 to \$800 million complex to include production of elemental bromine, magnesium oxide, potassium sulfate fertilizers, polyvinyl chloride, soda ash, and some bromine derivatives. The first phase of technical studies was completed and involved three international consultants.¹⁹

U.S.S.R.—The Union of Soviet Socialist Republics (U.S.S.R.) intended to increase production of specialty materials to meet internal demand and win export markets. Alexei Pavlovich, director of the State rubber organization Giprokautchuk, outlined trends at the recent international rubber conference in Ottawa, Canada, organized by the International Rubber Study Group.

The recent opening of the Soviet economy to outside ventures has led to

several projects in the rubber industry. The furthest advance is the Sovbutital joint venture, based in Tobolsk, where a plant is under construction with capacity for butyl rubber and halobutyl rubber.²⁰ The chemical industry was in a recession during 1991. The gross national product was down an estimated 15%, industrial output fell almost 10%, and gross output of chemicals dropped more than 10%.²¹

United Kingdom.—Great Lakes began the purchase of 37% of Associated Octel from Shell, United Kingdom. The purchase will increase Great Lakes' share of Octel to 51%. Octel will continue to diversify, with emphasis on bromine-related specialties. Great Lakes planned to cut the cost of bromine production with retrofits at the company's seawater-based facilities. Bromine from the plant was used in TEL used as an octane booster in leaded gasoline. TEL accounts for 90% of Octel's business.²²

Current Research

Chemists synthesized a reagent by treating a reagent with primary bromides to produce hydroperoxides and peracids. Naturally occurring hydroperoxides are active against cancer, bacteria, and parasites.²³

Ethyl S.A., the European subsidiary of Ethyl Corp., planned to locate a new research and development facility in the Scientific Park at Catholic University of Louvain near Brussels, Belgium. Initial investment will be \$8 million. The company purchased approximately 8 hectares with options to buy an additional 2 hectares in the park.²⁴

Corning Process Systems announced a nonexclusive license to produce bromine from weak solutions of bromide or hydrobromic acid or seawater concentrations.²⁵

Extraction, recovery, and economics for two refractory concentrates of gold were investigated using cyanide and bromine reagents. Gold extractions for cyanide leaching (24 to 48 hours) and bromine leaching (6 hours) were the same and ranged from 94% to 96%. Gold recoveries from bromine pregnant

solutions using carbon adsorption, ion exchange, solvent extraction, and zinc and aluminum precipitation methods were better than 99.9%. A preliminary economic analysis indicates that chemical costs for cyanidation and bromine processes are \$11.70 and \$11.60, respectively, per metric ton of calcine processed.²⁶

Gold was leached with a bromine solution from a very rich (6.2 kg per ton) black sand concentrate and its subsequent recovery by ion exchange resins and solvent extraction. The dissolution of gold from black sand ranged from 94% to 96%. Gold loadings and recoveries of almost 100% were achieved by both ion exchange and solvent extraction methods. The kinetics and equilibrium of loading gold onto ion exchange resins and its elution from the resin were studied. An organic solution was used in all the solvent extraction work for gold recovery from the bromine leach solution. The consumption of the solution was about 130 kg per metric ton of the concentrate processed. The costs of lixiviation to extract 0.0311 kg of gold from the black sand was about \$1.00. The economics of bromine process versus cyanidation were investigated, based on the electrochemical regeneration of bromine.²⁷

The loading characteristics of gold-tetrabromide species onto activated carbon were evaluated using a completely mixed batch reactor system. Although loading continued slowly after several days, abnormally high loading capacity values could be attained within 72 hours. Elution of gold from the loaded carbon was feasible provided the carbon had not been overloaded. If loading is carried to high levels, complete elution becomes impractical and the gold may be recovered by ashing the carbon. The ashing of the carbon appeared to be cost effective. Ashing leads to considerable savings by the elimination of the conventional elution and precipitation methods. Such savings may offset the cost for the high demand of reagent, which is a major disadvantage of the bromine process. Ashing may make the process economically competitive with the cyanide process.²⁸

Ferlini/General Atomics Development Corp. announced plans to transfer its patented flue gas desulfurization process to the commercial market. The process operates in a closed-loop system based on bromine. The sulfur dioxide-containing flue gases are contacted with a dilute solution of commercially available bromine. Sulfur dioxide reacts with the bromine in the solution to form sulfuric acid and hydrogen bromide. Bromine is regenerated from the hydrogen bromide by electrolysis, leaving sulfuric acid and hydrogen, two salable chemicals. Bromine is completely recycled and does not contaminate the environment.

FMC Corp. introduced a calcium peroxide substitute for potassium bromide in dough conditioning formulation. The new material has a finer, more uniform particle size that results in better distribution of the oxidizer with flour and other ingredients. The processing technology also results in reduced moisture content of the stored calcium peroxide, providing better stability and longer shelf life prior to use.²⁹

Chemists at Pennzoil Products Co. developed a new class of synthetic lubricants for extreme service conditions. The lubricants are prepared using alkyl halides such as bromine. The new substance has proved to be effective at extreme temperatures. Although most extreme service applications for lubricants occur in aerospace and military service, there are significant civilian applications in arctic and desert construction projects.³⁰

A new variation of a standard technique to detect amplified DNA sequences was developed using a bromine compound. The technique allows detection of a DNA sequence from outside the reaction tube. The process allows more widespread use of the technique because of high sample count.³¹

OUTLOOK

Sales of bromine, primarily in compounds, have decreased about 25% since 1979. This represents an annual rate of decrease of about 2% per year. These decreases have been offset by

increased use of bromine in fire retardants, sanitizers, and well-drilling fluids. Bromine is expected to increase in demand at the same 1.1% rate through the next 5 years. Demand as a fire retardant will offset any decreases in other uses. Bromine usage in well-drilling fluids was expected to increase.

Petroleum

Demand for bromine as a gasoline additive has declined each year since the EPA issued regulations in the 1970's to reduce the lead in gasoline. Bromine in the form of ethylene dibromide is used as a "scavenger" for the lead to keep the lead from depositing in the engine. In 1979, the amount of bromine sold reached a peak of 225 million kg. The rapid decline to 141 million kg in 1986 was a direct result of the limits on lead in leaded gasoline. During 1991, the European Community continued discussions to reduce lead levels in gasoline.

Federal laws enacted to encourage alternative forms of power in automotive engines are likely to have a depressive effect on increases in petroleum demand. The Clean Air Act Amendments of 1990 (Public Law 101-549) has an amendment that will require mobile sources, such as cars and trucks, to use the most effective technology possible to control emission. Electric cars that do not require bromine gasoline additives are already on the market in California.

Sanitary Preparations

Bromine has found usage in swimming pools, hot tubs, and whirlpools. The sanitary preparation field is an area where bromine has been found to be safer than its substitutes. The use of bromine will continue to grow in this area closely following the gross national product in real growth.

Fire Retardants

Federal regulations covering flammability of private and public building materials and furnishings have

required greater amounts of fire retardant chemicals to be used in these materials and furnishings. Fire retardants are expected to grow as organic materials replace metals in transportation, infrastructure, and packaging. Several State governments continue to support strong consumer laws that protect State residents from products with potential fire hazards produced in other States. Growth during 1991 was reported to be at about 3% to 4%, with sales at about \$860 million in 1990.³²

Other Uses

Usage of calcium bromide and zinc bromide in well-drilling fluids decreased during the 1980's as the domestic petroleum industry suffered a severe recession. Both the Baker Hughes and the Smith rig count published each week in the Oil & Gas Journal showed a 33% to 35% decrease in activity during 1991 when compared with that of 1990. Oilfield chemicals used in drilling, completion and workover, and production operations have remained significantly more profitable internationally than in U.S. operations. The competition market, which includes corrosion inhibitors, bactericides, viscosities, and defoamers, as well as commodities such as calcium chloride and calcium bromide brines used to maintain well productivity, was estimated at about \$100 million, while the cementing and stimulation segments are about \$2.5 billion.³³

CADMIUM

By Thomas O. Llewellyn

Mr. Llewellyn, a physical scientist with over 30 years of industry and U.S. Bureau of Mines experience, has been the commodity specialist for cadmium since 1987. Domestic survey data were prepared by Giovanni Jacarepaqua, statistical assistant, Section of Metals Data; and international data were prepared by Ted Spittal, international data assistant, Section of International Data.

Domestic production of cadmium metal in 1991 was at about the same level as that of the previous year, according to the U.S. Bureau of Mines. Four companies operating four plants produced all of the domestic cadmium. The price of cadmium metal declined, continuing a trend that began in mid-1989.

DOMESTIC DATA COVERAGE

Domestic production data for cadmium metal and compounds are developed by the U.S. Bureau of Mines from a voluntary survey of U.S. operations. Of the four metal-producing plants to which a survey request was sent, all responded, representing 100% of the total cadmium metal production shown in tables 1 and 3. Of the 11 operations that produced cadmium compounds to which a survey request was sent, all responded, representing 100% of the cadmium content of production of cadmium compounds shown in table 2. (See tables 1, 2, and 3.)

ANNUAL REVIEW

Legislation and Government Programs

On February 6, 1990, the Occupational Safety and Health Administration (OSHA) published a proposed rule to reduce the existing limit for occupational exposure to airborne cadmium. Public hearings were held, one in Washington, DC, in June and the other in Denver, CO, in July.

The posthearing comment period closed on October 18, 1990.¹ OSHA announced on September 18, 1991, the reopening of the rulemaking record on cadmium for 45 days. The reopening allowed additional information into the record on cadmium sulfide pigments concerning their relative insolubility in biological systems. OSHA also received written comments on those additional comments that were submitted after the posthearing comment period closed and were not publicly discussed.²

On September 24, 1991, the U.S. Department of Commerce notified the public of its determination not to revoke the antidumping on cadmium metal from Japan, as was proposed the month before. Special dumping duties were established in August 1972.³

An updated draft toxicological profile for cadmium published by the Agency for Toxic Substances and Disease Registry, Department of Health and Human Services, was issued in October 1991, and the public comment period will end on February 8, 1992.⁴

Strategic Considerations

Cadmium is included in the National Defense Stockpile (NDS) because of its importance in specialized military applications such as plating where substitutes may be in short supply or unsatisfactory. In addition, the United States depends on imports to meet part of its requirements. Purchase of cadmium under the Strategic and Critical Minerals Stockpiling Act began in 1948, and the

initial stockpile requirements were completed in 1955. Cadmium was also acquired for supplemental stockpile from 1956 through 1963 under provisions of the Agricultural Trade Development and Assistance Act of 1954, which enabled the U.S. Department of Agriculture Commodity Credit Corp. to barter surplus perishable goods for foreign-produced cadmium metal. Government shipments from stockpile excesses for 1964-76 totaled 3,918 tons. In April 1980, the stockpile goal for cadmium was set at 5,307 metric tons. At the end of 1991, the NDS cadmium inventory was 2,871 metric tons.

Production

Primary cadmium was produced by ASARCO Incorporated, Denver, CO; Big River Zinc Corp., Sauget, IL; Jersey Miniere Zinc Co., Clarksville, TN; and Zinc Corp. of America, Bartlesville, OK. The companies in Illinois, Oklahoma, and Tennessee recovered cadmium as a byproduct of smelting domestic and imported zinc concentrates. The company in Colorado recovered cadmium from other sources such as lead smelter baghouse dust.

Consumption and Uses

Apparent consumption of cadmium increased compared with that of 1990. Although the U.S. Bureau of Mines does not collect actual consumption data, apparent consumption by use categories in

1991 was estimated as follows: batteries, 45%; coating and plating, 20%; pigments, 16%; plastic and synthetic products, 12%; and alloys and other, 7%.

Stocks

Total inventories of cadmium metal and cadmium compounds increased about 71% and 26%, respectively, compared with those of 1990. (See table 4.)

Markets and Prices

The New York dealer price range for cadmium metal, published by Metals Week, at the beginning of 1991 was \$3.00 to \$3.22 per pound, about 40% less than the price range quoted at the beginning of 1990. The prices for cadmium metal fluctuated slightly during the first 6 months of the year, but followed a downward trend and reached a low range of \$1.50 to \$1.60 per pound by June 6, 1991. However, during the next 3 months the cadmium market showed signs of recovery, and the price range at the end of October was \$1.90 to \$2.05 per pound; this price range prevailed through yearend. The price decline was due to a lower market demand for end uses of cadmium such as coating and plating, and alloys and other.

Foreign Trade

Cadmium is taxed under the Superfund Amendments and Reauthorization Act of 1986, Public Law 99-499. The tax, to be collected from producers and importers, was \$4.45 per ton of cadmium metal. The tax, which was scheduled to expire on December 31, 1991, has been rescheduled to end on December 31, 1995. Cadmium producers are granted a depletion allowance of 22% on domestic production and 14% on foreign production.

Under the new Harmonized Tariff Schedule of the United States, which took effect January 1, 1989, cadmium sulfide and pigments and preparations based on cadmium compounds imports from most favored nations (MFN) are subject to a 3.1% ad valorem duty; for non-MFN a

25% ad valorem duty was retained. Imports of unwrought cadmium, waste and scrap, and powders, are duty free for MFN, whereas a statutory duty of 33 cents per kilogram was imposed on these materials for non-MFN. (See tables 5 and 6.)

World Review

Industry Structure.—World refinery production of cadmium was estimated at 20,673 metric tons in 1991. Japan was the largest producer of refined cadmium in 1991, followed by the U.S.S.R., Belgium, the United States, Canada, China, and Germany. These seven countries accounted for approximately 61% of the world's refined cadmium production in 1991. Because cadmium is recovered mainly as a byproduct of zinc ore processing, many producers of zinc and zinc compounds produce primary cadmium as an integral part of their operation. In some cases, residues and flue dusts from zinc producers are used directly by cadmium producers. Some cadmium may also be recovered from flue dust generated at various lead and copper smelters; however, the amount of this production is not known.

Capacity.—The data in table 7 represent rated annual production capacity for mines and refineries on December 31, 1991. Rated capacity was defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable, long-term operating rate, based on the physical equipment of the plant and routine operating procedures for labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure. (See tables 7 and 8.)

Reserves.—Cadmium reserves were obtained by applying an average recovery factor of 0.36% to zinc reserve data. On this basis, the domestic reserves of cadmium were estimated at 72,000 metric

tons. Total world reserves were estimated to be about 535,000 metric tons. The world's largest reserves of cadmium were in the United States and Canada.

Cadmium minerals are not found in commercial viable deposits, and its abundance in the Earth's crust is about 0.2 parts per million. Greenockite (CdS) is the only cadmium mineral of importance; it is not found in any isolated deposit, but is nearly always associated with zinc sulfide. Cadmium is usually produced as a byproduct in the recovery of primary zinc from zinc ores and also from some lead ores or complex copper-lead-zinc ores. However, it is generally agreed that the cadmium in lead and copper ores is associated with the zinc sulfide present rather than with the other minerals.

Current Research

The U.S. Bureau of Mines investigated hydrometallurgical processing techniques to recycle metals from semiconductors and other advanced materials. Cadmium and tellurium were recovered from cadmium telluride (CdTe) scrap produced in the manufacturing of both infrared optic devices and thin-film photovoltaic devices. Leaching the crushed CdTe infrared optic scrap for 75 minutes at 110° C in dilute sulfuric acid under 120 psig oxygen yielded 99.5% cadmium extraction. Tellurium remained in the leach residue as tellurium oxide and elemental tellurium. The cadmium in the leach liquor was purified of coextracted metals such as gallium and iron by adjusting the pH to 5.3. The cadmium was recovered as cadmium sulfate crystals by evaporating the solution.⁵

Bacteria operate on metals through bioleaching, biosorption, and bioreduction mechanisms. Based on these mechanisms, the U.S. Bureau of Mines developed a promising technique to extract metal contaminants from wastewaters using porous polymeric beads containing nonliving biological materials. Biomass materials used in the beads included algae, duckweed, sphagnum moss, and yeast.

Batch and continuous tests demonstrated that beads selectively remove metal contaminants, such as cadmium, mercury, copper, lead, and zinc, from a variety of wastewaters. Treated effluents often met the federally established National Drinking Water Standards.⁶ The Environmental Protection Agency established an interim Maximum Contamination Level (MCL) of 10 micrograms per liter for cadmium in drinking water.

Developments in cadmium technology during the year were abstracted in *Cadscam*, a quarterly publication available through the Cadmium Association, 42 Weymouth Street, London, WIN 3LQ, England.

OUTLOOK

The short-term demand for cadmium in the United States was expected to fall below the level of 1990. This decline was expected to be the result of continuing lower demand for cadmium in coating and plating and pigments during the next 2 to 4 years. There was a strong indication that the world demand for primary cadmium will follow the same trend, for the reasons aforementioned, which are a consequence of stricter environmental and health controls now under consideration in North America and Europe.

*Estimated. ¹Revised. NA Not available.

²This table gives unwrought production from ores, concentrates, flue dusts, and other materials of both domestic and imported origin. Sources generally do not indicate if secondary metal (recovered from scrap) is included or not; where known, this has been indicated by a footnote. Data derived in part from World Metal Statistics (published by World Bureau of Metal Statistics, Ware, United Kingdom) and from Metal Statistics (published by Metallgesellschaft Aktiengesellschaft, Frankfurt am Main, Germany). Cadmium is found in ores, concentrates, and/or flue dusts in several other countries, but these materials are exported for treatment elsewhere to recover cadmium metal; therefore, such output is not reported in this table to avoid double counting. This table includes data available through Apr. 2, 1992.

³Reported figure.

⁴Includes secondary.

CALCIUM AND CALCIUM COMPOUNDS

By M. Michael Miller

Mr. Miller, a physical scientist with 14 years of minerals experience with the U.S. Department of the Interior, has been the commodity specialist for calcium and calcium compounds since 1989. Domestic survey data were prepared by Joseph C. Daniels, statistical assistant. All units are in metric tons, unless otherwise noted.

Calcium, the fifth most abundant element in the Earth's crust, is chemically very active and is found in a host of minerals that occur in nearly every geologic environment. The U.S. Bureau of Mines publishes reports for a variety of calcium-containing minerals and compounds because of their commercial significance and contribution to the quality of human life. Calcium fluoride is sold as fluorspar; calcium sulfate as gypsum or anhydrite; calcium oxide and hydroxide as lime; calcium phosphate as phosphate rock; and natural calcium carbonate as either limestone, marble, calcareous marl, or shell. Information on these commodities can be obtained in the U.S. Bureau of Mines annual reports entitled, "Fluorspar," "Gypsum," "Lime," "Phosphate Rock," "Crushed Stone," and "Dimension Stone." Other calcium compounds are discussed in the report concerning the element with which calcium is combined; for example, calcium bromide is covered in the "Bromine Annual Report." This "Calcium and Calcium Compounds Annual Report" includes calcium metal, calcium chloride, precipitated calcium carbonate, and various other calcium compounds not covered elsewhere.

DOMESTIC DATA COVERAGE

The U.S. Bureau of Mines develops domestic production data for calcium chloride from a voluntary survey of U.S. operations entitled, "Calcium Chloride and Calcium-Magnesium Chloride." Of the seven operations polled, all responded, representing about 21% of the total production shown in table 1.

Production for two producers not polled was estimated using data from previous years, published plant capacity, and contacts within the industry. (See table 1.)

BACKGROUND

Grades and Specifications

Calcium metal is usually sold in the form of crowns, broken crown pieces or nodules, or billets, which are produced by melting crowns in an argon atmosphere. The metal purity in these forms is at least 98%. Higher purity metal is obtained by redistillation. Calcium metal is usually shipped in polyethylene bags under argon in airtight steel drums. Table 2 shows typical specifications for commercial grade, melted grade, and redistilled grade. (See table 2.)

The American Society for Testing and Materials (ASTM) issues a standard specification for calcium chloride designated D 98. It covers technical-grade calcium chloride to be used for road conditioning purposes, ice removal, concrete curing, acceleration of the set of concrete, and as a desiccant. D 98 covers two types of calcium chloride, solid (Type S) and liquid (Type L). Solid occurs in flake, pellet, granular, and powder form in concentrations of 77%, 90%, and 94% minimum. Liquid occurs as water solutions of calcium chloride in concentrations varying from 30% to 45%. Calcium chloride is divided into three grades: Grade 1—77% minimum, Grade 2—90% minimum, and Grade 3—94% minimum. Within each grade there are

sieve-size requirements for flake, pellet, granular, and powder forms.¹

Technology

Calcium Metal.²—In 1808, Davy produced elemental calcium as a mercury amalgam by the electrolysis of calcium chloride in the presence of a mercury cathode. He and others were only marginally successful in attempts to isolate the pure metal by distilling the mercury. In 1855, Bunsen and Matthiessen attempted to produce calcium metal by the electrolysis of a mixture of calcium, strontium, and ammonium chlorides to lower the electrolyte melting point, but produced only finely divided calcium alloys. This process was slowly improved, and by 1904, Rathenau obtained calcium by the electrolysis of molten calcium chloride held at a temperature above the melting point of the salt but below the melting point of calcium metal. An iron cathode just touched the surface of the bath and was raised slowly as the relatively chloride-free calcium deposited on its end. This process accounted for virtually all calcium metal production from 1904 to 1940.

Prior to 1939, calcium was manufactured exclusively in France and Germany. With the outbreak of World War II, an electrolytic calcium plant was constructed at Sault Ste. Marie, MI, by the Electro Metallurgical Corp. Large quantities of calcium were required as the reducing agent for uranium production. In addition, the U.S. Army Signal Corps used calcium to produce calcium hydride, which could easily be transported to

remote areas and used as a source of hydrogen for meteorological balloons. To satisfy these needs, an aluminothermic reduction process was developed. Developed earlier on a laboratory scale in 1922, the process was improved and commercialized by the New England Lime Co. in Canaan, CT, which later became a division of Pfizer Inc.

The aluminothermic process, or Pidgeon process as it is sometimes called, begins with quarried high-calcium limestone calcined to form calcium oxide. The calcium oxide is ground to a small particle size and dry-blended with finely divided aluminum. The mixture is compacted into briquets to ensure good contact of reactants. The briquets are placed in horizontal metal tubes, called retorts, made of heat-resistant steel and heated in a furnace to 1,100° C to 1,200° C under high vacuum, and the calcium oxide is reduced to calcium metal. The calcium metal vapor is collected in the water-cooled condenser section of the retort at about 700° C. After the reaction has proceeded for about 24 hours, the vacuum is broken with argon, and the condensed blocks of 98%-pure calcium metal, called "crowns," and the calcium aluminate reaction product are removed.

For certain applications greater than 98% purity is required, which is achieved by redistillation. Crude calcium is placed in the bottom of a large vertical retort equipped with a water-cooled condenser at the top. The retort is sealed and evacuated to a pressure of less than 6.6 pascal (0.05 millimeters of mercury), while the bottom is heated to 900° C to 925° C. The calcium quickly distills into the condensing section, leaving behind the bulk of the less volatile impurities. Subsequent processing must take place under exclusion of moisture to avoid oxidation. Redistillation does not greatly reduce the impurity level of volatile materials such as magnesium.

Calcium Chloride.³—Domestic calcium chloride is produced from natural brines and by reacting hydrochloric acid with limestone. Most U.S. production is natural from brine wells in Michigan,

with a small amount from dry lake beds in California.

Initial efforts to stimulate the development of Michigan salt and brine deposits took place in 1859. The State legislature passed a bill authorizing payment for Michigan salt. By 1870, saw mill operators were augmenting their income by using waste lumber as fuel to evaporate brines. In 1882, solution mining of rock salt began, and Michigan soon became the leading salt-producing State.

By 1914, an integrated process was developed using three vacuum evaporators to extract various brine components. Bromine was extracted first in an electrolytic cell, and the debrominated brine was then processed through a heated vacuum evaporator. This process precipitated sodium chloride, which was used to produce chlorine, hydrogen, and sodium hydroxide. The brine was then sent to a second evaporator where magnesium chloride was precipitated out. The brine from the second evaporator went to a third evaporator, which produced precipitated hydrates of calcium chloride and a 38% calcium chloride product.

Today the process has been expanded and improved to extract, in sequence, iodine, bromine, magnesium chloride, and calcium chloride. The calcium chloride is derived from the brine left over after processing the magnesium chloride into magnesium hydroxide. This brine is about 25% calcium chloride, and it is processed through double- or triple-effect vacuum evaporators to make a 32% to 45% solution. Unwanted alkali chlorides are precipitated here and can be removed by settlers and centrifuges. The brine undergoes further evaporation to attain an anhydrous product of 78% to 94% calcium chloride concentration.

Precipitated Calcium Carbonate.⁴—Calcium carbonate occurs in two crystalline forms—aragonite and calcite. These forms possess different physical properties. There are three basic processes for the manufacture of calcium carbonate as a precipitate. The processes include the lime-soda process, the lime-

ammonium chloride process, and the carbonation process. All three start with a dilute lime hydrate in aqueous suspension, descriptively called milk-of-lime.

In the lime-soda process, milk-of-lime is reacted with sodium carbonate to produce calcium carbonate and sodium hydroxide. The commercial alkali manufacturers used this process, which produced as a byproduct a coarse calcium carbonate precipitate. Production of a uniform, fine-particle-size precipitate could only be achieved at the expense of the primary goal, caustic soda recovery.

In the lime-ammonium chloride process, milk-of-lime is reacted with ammonium chloride to produce calcium chloride. The calcium chloride is purified and then reacted with soda ash to form calcium carbonate. The process can be fine tuned by modifying the addition times, method and rate of agitation, pH, concentrations, and reaction temperatures. This process requires a low-cost source of sodium carbonate and calcium chloride, and production, historically, has been as a satellite to Solvay process synthetic soda ash plants. The last domestic synthetic soda ash plant closed in 1986.

The most common production process used in the United States is the carbonation process. Carbon dioxide is bubbled through milk-of-lime to form a precipitate of calcium carbonate and water. The reaction conditions determine the particle size and shape of the resulting aragonite or calcite. To modify the dimensions and performance characteristics of the precipitate, it is necessary to adjust a range of variables that include concentration, starting temperature, pH, degree and type of mixing, solution rates, and the addition of additives. Calcite, aragonite, or a mixture of both can be produced, although commercial forms are usually exclusively one form or the other. The carbonation process is the most complex of the three processes. Because of the low cost availability of raw materials, it has become the process of choice and forms the foundation of the expanding network of satellite precipitated calcium carbonate plants adjacent to pulp and paper mills.

ANNUAL REVIEW

Strategic Considerations

Redistilled-grade calcium metal was used to reduce uranium dioxide, a fuel in some types of fission reactors. The nuclear applications of calcium metal gave it strategic significance; the U.S. Department of State would not permit sales to countries not signatory to the United Nations Nuclear Nonproliferation Treaty.

Production

Pfizer Inc. produced calcium metal at Canaan, CT, by the Pidgeon process, in which high-purity calcium oxide (produced by calcining limestone) and aluminum powder are compacted into briquets and heated in vacuum retorts. The vaporized calcium metal product collects as a "crown" in a water-cooled condenser. Production was up slightly compared with that of 1990.

Pfizer produced commercial-grade 98.5% calcium in eight shapes and high-purity redistilled 99.2% metal in three shapes, with other shapes available on request. They produced an 80% to 20% calcium-magnesium alloy, a pure calcium wire used in the steel industry to modify inclusions, and a 73% to 27% calcium-aluminum alloy or unalloyed calcium-aluminum briquette. Elkem Metals Co., a Norwegian-owned company with headquarters in Pittsburgh, PA, produced a calcium-silicon-barium-aluminum alloy at its plant in Niagara Falls, NY, and imported several other calcium alloys.

Michigan was the leading State in natural calcium chloride production; California was a distant second. The Dow Chemical Co. and Wilkinson Corp. (formerly Wilkinson Chemical Corp.) recovered calcium chloride from brines in Mason and Lapeer Counties, MI. Dow's Ludington plant produced calcium chloride pellets, flake, and liquid; Wilkinson marketed calcium chloride solutions only. National Chloride Co. of America, Cargill's Leslie Salt Co., and Hill Brothers Chemical Co. produced

calcium chloride from dry-lake brine wells in San Bernadino County, CA. Hill Brothers Chemical also produced from a second operation near Cadiz Lake, CA, and marketed material produced by Magnesium Corp. of America as a byproduct of magnesium production in Rowley, UT.

Tetra Chemicals produced synthetic calcium chloride from a plant near Lake Charles, LA, and from its liquids plant at Norco, LA. Allied Signal Inc. recovered calcium chloride as a byproduct at its Baton Rouge, LA, plant using hydrochloric acid and limestone. Occidental Chemical Corp. manufactured calcium chloride at Tacoma, WA, using limestone and hydrochloric acid. Standard Chlorine of Delaware discontinued production of synthetic calcium chloride in 1991.

At the end of 1991, there were 26 precipitated calcium carbonate (PCC) plants operating in the United States. Pfizer Inc. had 17 satellite PCC plants in operation in the United States plus 2 additional plants in Canada and 1 in Japan. English China Clay International (ECCI) operated three satellite plants in the United States and one in Canada in 1991. The ECCI plants operated in 1990 under the name GK Carbonate. There are reportedly three additional companies operating satellite PCC plants. There are three companies that produce PCC for the open market: Pfizer Inc. at Adams, MA, Mississippi Lime Co. at Ste. Genevieve, MO, and Continental Lime Inc. at Tacoma, WA. The 26 U.S. plants have an estimated capacity in excess of 1 million tons.

Calcium hypochlorite was produced by Olin Corp. at Charleston, TN, and PPG Industries Inc. at Natrium, WV. Sales were relatively unchanged from those of 1990. Total domestic calcium hypochlorite capacity was 106,000 tons. In early 1991, Olin Corp. started production from a new 9,000-ton-per-year plant in Charleston, TN.

Consumption and Uses

Calcium metal was used in the manufacture of maintenance-free and

sealed lead-acid batteries, as an aid in removing bismuth in lead refining, and as a desulfurizer and deoxidizer in steel refining. It was used to reduce oxides of the rare earth neodymium and boron for alloying with metallic iron for use in neodymium-iron-boron permanent magnets. It was used as a reducing agent to recover many of the less common metals such as hafnium, plutonium, thorium, tungsten, uranium, and vanadium and the rare earths from their oxides or fluorides. Some minor uses were in the preparation of vitamin B and chelated calcium supplements and as a cathode coating in some types of photoelectric tubes. Domestic consumption of calcium metal increased in 1991. This was evidenced by increased imports reported by the Bureau of the Census, U.S. Department of Commerce.

Calcium chloride was used to deice pavements, to control dust, to stabilize road bases, to thaw coal and other bulk materials, in oil and gas drilling, for concrete-set acceleration, as tire ballasting, to deink newspaper, and in miscellaneous other uses. The principal use of calcium chloride was to melt snow and ice from roads. Calcium chloride is more effective at lower temperatures than rock salt and was used mainly in the Northern and Eastern States. Because of its considerably higher price, it was used in conjunction with rock salt for maximum effectiveness and economy.

Precipitated calcium carbonate was used as a pigment for brightness and opaqueness in premium-quality coated papers and as a filler in uncoated papers. In coated paper, PCC was used in the coating to improve paper brightness and print clarity. In uncoated papers, it was used as a filler and extender in the paper to improve the optical, physical, and price-performance characteristics of the paper. The plastics industry used a fine and ultrafine grade of PCC to lower raw material costs, increase impact resistance, improve surface smoothness, and enhance color stability. Its major use was in polyvinyl chloride (PVC), but it was also used in such polymers as polystyrene, polypropylene, and polyethylene. The paint industry used it as a replacement for

expensive TiO₂ pigment and to control flow properties, provide body, and maintain dispersion.⁵

Calcium hypochlorite was used to disinfect swimming pools, which accounted for more than 85% of domestic demand. Municipal sanitation and industrial bleaching accounted for the remainder. It was used as an algicide, bactericide, deodorant, water purifier, disinfectant, fungicide, and bleaching agent.

Calcium nitrate was used as a concrete additive to inhibit corrosion of steel reinforcement bars, accelerate setting time, and enhance strength.

Calcium carbide and calcium-silicon alloy were used to remove sulfur from molten pig iron as it was carried in transfer ladles from the blast furnace to the steelmaking furnace.

Prices

The published price of calcium metal last changed April 19, 1990, according to the Metal Bulletin. The yearend published price range for calcium metal, minimum 98%, was \$2.25 to \$2.75 per pound, U.S. free market.⁶ This was equivalent to \$4.96 to \$6.06 per kilogram. The published price did not change in 1991. Calcium metal is sold on a contract basis, and the contract price may vary greatly from the published price. The published price range only serves as a guide to the prices obtained by dealers and producers.

Solid calcium chloride prices were quoted by Chemical Marketing Reporter for Grade 1 (minimum 77%) and Grade 3 (minimum 94%), generally in flake or pellet form. Liquid prices were quoted for a range of 30% to 42% concentration and for 45% concentration. Although actual prices are negotiated and usually discounted, yearend 1991 published prices and specifications are shown in table 3.

Precipitated calcium carbonate prices as reported by Chemical Marketing Reporter did not change in 1991. List prices for technical grade, (0.5 microns), bags, bulk, f.o.b. works, were \$212.00 per short ton (about \$234.00 per metric ton). List prices for ultrafine, (0.05 to 0.5

microns), bags, bulk, f.o.b. works, were \$540.00 per short ton (about \$595.00 per metric ton). List prices for surface treated, bags, bulk, f.o.b. works, were \$320.00 per short ton (about \$353.00 per metric ton).⁷ (See table 3.)

Foreign Trade

U.S. exports of calcium chloride increased by 31% in 1991, with a substantial portion of the increase going to Canada. The United States exported 31,306 tons of calcium hypochlorite to many countries for an export value of about \$33,796,000. More than 9,703 tons of calcium carbide was exported to 17 countries for an export value of more than \$5,299,000. Exports of 3,716 tons of calcium cyanamide went predominantly to Mexico. (See table 4.)

Imports of calcium metal increased by more than 26% compared with those of 1990. The majority of shipments came directly from China, France, and Canada, in descending order. According to Bureau of the Census import data, the average c.i.f. unit value of imported calcium metal was \$6.38 per kilogram (\$2.89 per pound), which exceeded the published price range. There was a tremendous disparity between the value of material from China and the U.S.S.R. and the value of material from Canada and France. The material from Canada and France included calcium alloys and powdered or granulated calcium. (See tables 5, 6, and 7.)

OUTLOOK

The major end uses of calcium metal are in the lead industry primarily in maintenance-free and sealed lead-acid batteries; in the steel industry; and as a reducing agent of rare-earth oxides for permanent magnet manufacture. These three areas each account for roughly one-third of domestic calcium metal consumption.

The majority of the maintenance-free and sealed lead-acid batteries go into the U.S. starter battery market primarily as replacement batteries for automobiles. The replacement battery market is

weather dependent, as temperature extremes tend to damage batteries. Owing to the recession and the mild winter in 1991, calcium metal consumption decreased in this market. Based on projections made for the battery industry and assuming no growth in overall lead consumption and the continuation of sluggish economic conditions, it is estimated that consumption will be flat in 1992. Beyond 1992, calcium metal consumption in this market segment is expected to grow by 2% to 3% annually through 1994.

Despite the 13% decrease in raw steel production in 1991, calcium metal consumption for steel refining was strong. This market is expected to remain strong in 1992 and beyond. This optimism is based on the increased efficiencies achieved by using calcium.

Calcium metal's use as a reducing agent of rare-earth oxides for permanent magnet manufacture was a strong market in 1991. Consumption in this area should increase during the next few years due to an expanding permanent magnet market.

Calcium chloride consumption is still very dependent on the vagaries of the weather. The mild winter in 1991 hurt the deicing market, which was also the case in 1990. The deicing, dust control, and road stabilization markets are dependent on the weather. These markets are mature, and consumption levels should be flat except for fluctuations caused by year-to-year changes in precipitation levels. A decline in oil drilling activity has slowed expected growth in the drilling fluids market. Calcium chloride is added to specially designed oil muds to deal with plastic flowing shale encountered offshore Louisiana, in Wyoming, and in other locations. Passage of the Intermodal Transportation Efficiency Act and a pickup in the construction industry should boost the market for its use as a concrete-set accelerator. A niche market that should grow is newsprint deinking. Some industry sources believe that a future growth market is in the agricultural sector, where it would be used as a growth enhancing macronutrient.

There is already an excess of capacity in the calcium chloride industry. This excess capacity is likely to become more acute as additional synthetic or byproduct capacity comes on-line in the next few years. Calcium chloride production utilizing hydrochloric acid is seen as a solution to an oversupply of hydrochloric acid and the need for deep well disposal. In addition, Dow Chemical Co. is considering converting its propylene oxide manufacturing process from the use of caustic soda to the use of hydrated lime. If the conversion is made, the new process could generate approximately 225,000 tons of byproduct calcium chloride.

The outlook for precipitated calcium carbonate consumption continues to be driven by the pace of conversions to alkaline sizing by the paper industry. The North American market has the potential for 35 to 40 satellite plants. Construction of satellite plants slowed down in 1991; only a few were built. Pfizer has an additional 13 plants under construction or planned for North America and overseas. Demand for both ground and precipitated calcium carbonate fillers is expected to grow at a rate of 10% per year.

The many benefits of PCC use by the paper industry have recently been balanced by criticism that, as paper filler levels increase, PCC performance will deteriorate because of poor drainage and increased water retention. Pfizer, which has reinvested much of its PCC profits into research and development, is continuing to work on new product development and is currently field testing new products with increased filler-loading levels.

Although most paper markets slowed down during 1991, long-term growth is expected when the economy turns around. Because paper accounts for the largest portion of PCC consumption, this growth will be reflected by increased PCC sales. The outlook for PCC consumption in paints and plastics is tied to the health of the economy, the construction industry, and the automobile industry. Both markets are expected to be flat through

most of 1992 and then grow when the economy recovers.

CEMENT

By Cheryl Solomon

Ms. Solomon, a physical scientist with 6 years of U.S. Bureau of Mines experience, has been the commodity specialist for cement since 1992. Domestic survey data were prepared by Gail Mason, statistical assistant; and international survey data were prepared by Ron Hatch, international data coordinator.

Cement is the most widely used construction material in the United States. The industry's main product, portland cement, makes up 96% of the total domestic production. The remainder comes from masonry, hydraulic, and aluminous cements.

In 1991, U.S. demand for cement declined, as the basic trend set over the past 4 years continued. Domestic production of portland cement declined by 6%. Cement imported for consumption declined for the fourth year to 8.7 million short tons. Portland cement prices declined marginally due to decline in demand.

The Department of Commerce determined that gray portland cement and clinker from Japan were being sold in the United States at less than fair value. The U.S. International Trade Commission determined that the U.S. cement industry was being injured by imports from Japan.

DOMESTIC DATA COVERAGE

Domestic production and consumption data for cement are developed by means of the portland and masonry cement voluntary survey. Of the 119 cement manufacturing plants to which an annual survey collection request was made, 95 responded, representing 80% of the cement production and consumption data shown in table 1. Estimates were made for nonrespondents using monthly survey data and data received from previous annual surveys.

BACKGROUND

Definitions, Grades, and Specifications

Section 4 of the Annual Book of the American Society for Testing and Materials (ASTM) publishes standards, test methods, definitions, recommended practices, classifications, and specifications for cement, lime, and gypsum.¹

Following is a brief discussion of various types of hydraulic cements and the materials from which they are made.

Clinker.—Clinker is produced by heating a properly proportioned mixture of finely ground raw materials containing calcium carbonate, silica, alumina, and iron oxide in a kiln to a temperature of about 2,700° F at which partial fusion occurs. The fused material, which ranges from fine sand grains to walnut size, is ground with small amounts, 3% to 5%, of calcium sulfate, usually gypsum or anhydrite, to make portland cement.

Portland Cement.—ASTM specification C-150 covers five types of portland cement: Type I, for use when special properties specified for other types are not required; Type II, for general use, especially when moderate sulfate resistance or moderate heat of hydration is desired; Type III, for use when high early strength is required; Type IV, for use when a low heat of hydration is desired; and Type V, for use when high sulfate resistance is required. ASTM specifications also include Type IA, Type IIA, and Type IIIA for the

same uses but with the addition of air entraining compounds to protect concrete against freeze-thaw damage.

White Cement.—White cement is made from iron-free materials of exceptional purity, usually limestone, china clay or kaolin, and silica. The clinker is burned with a reducing flame in the kiln and rapidly quenched in a water spray to keep any iron in the ferrous state to avoid coloration by ferric ions. The clinker is then ground with high-purity white gypsum using ceramic balls and liners in grinding mills. White cement is used in decorative concrete, including terrazzo, highway lane markers, and architectural concrete.

Masonry Cement.—Masonry cement is a hydraulic cement used in mortars for masonry construction. It contains one or more of the following materials: portland cement, portland-pozzolan cement, slag cement, or hydraulic lime, usually with hydrated lime, limestone, chalk, calcareous shale, talc, slag, or clay interground for plasticity. ASTM designation C-91 contains specifications for masonry cement.

Blended Hydraulic Cement.—ASTM designation C-595 covers four kinds of blended hydraulic cements, each with an optional provision for air entraining.

Portland-Blast Furnace Slag.—This is essentially an intimately interground mixture of portland cement clinker and granulated blast furnace slag, or an intimate and uniform blend of portland

cement and fine granulated blast furnace slag in which the slag constituent ranges between 25% to 70% of the total weight of the cement.

Pozzolan.—Pozzolan is a siliceous and aluminous material that in itself possesses little or no cementitious value but will, in a finely divided form and in the presence of moisture, chemically react with calcium hydroxide at ordinary temperatures to form compounds possessing cementitious properties. Fly ash is a pozzolanic material obtained from flue gases produced by coal combustion. Natural pozzolans are naturally occurring materials such as diatomaceous earths, opaline cherts and shales, tuffs, volcanic ash, and pumicites. ASTM C-618 covers fly ash and natural pozzolans.

Portland-Pozzolan Cement.—Portland-pozzolan cement is produced by intergrinding portland cement clinker and pozzolan, by blending portland cement or portland-blast furnace slag cement and finely divided pozzolan, or a combination of intergrinding and blending in which the amount of the pozzolan is between 15% and 40% of the total weight of the cement.

Pozzolan-Modified Portland Cement.—The constituents in this type of cement are the same as those for portland-pozzolan cement, and the methods of production are also the same. However, pozzolan makes up less than 15% of the total weight of the blended cement.

Slag Cement.—Slag cement is a finely divided material made from a uniform blend of granulated blast furnace slag and hydrated lime. The slag constitutes at least 70% of the total weight of the blended cement.

Oil-Well Cement.—Oil-well cement was developed to seal oil and gas wells under pressures of 18 to 20,000 pounds per square inch and temperatures up to 400° F in oil and gas wells and 500° F in

steam wells. This cement must remain fluid up to about 4 hours to be effective. The cement is modified by service companies to fit individual well conditions using additives. The average well depth is 4,600 feet, but can range from grass roots depth to 30,000 feet.

The American Petroleum Institute (API) specifications cover requirements for manufacturing eight classes of well cements—A, B, C, D, E, F, G, and H—and Grades O-Ordinary, MSR-Moderate Sulfate-Resistant Grade, and HSR-High Sulfate Resistant Grade.² Changes in the API Specification were set down in 1991, including the elimination of specific well depths in classes A-H cement and the abolition of mandatory testing for classes A, B, and C cement among other changes. The physical and chemical requirements set down previously remained the same.

Expansive Cement.—Expansive cement is a hydraulic cement that tends to increase in volume after setting during the early hardening period. There are three types of expansive cements, types K, M, and S. Expansive cements are used primarily in shrinkage-compensating concrete. ASTM specification C-845 covers all expansive cements.

Aluminous Cement.—Sometimes known as calcium aluminate cement, high-alumina cement, or "Ciment Fondu," aluminous cement is a hydraulic nonportland cement. Special applications of aluminous cement are based on its rapid-hardening qualities, resistance to sulfate action, and refractory properties when used as "castable refractories" and mortars for furnaces and kilns.

Concrete.—Concrete is a proportioned mixture of coarse mineral aggregates of sand and gravel or crushed stone, bound together by a paste of hydraulic cement and water. Volume 04.02 of ASTM standards covers concrete and aggregates.

Admixtures.—Admixtures allow the concrete to be altered to the particular job. Factors such as the durability,

appearance, versatility, and cost effectiveness of the concrete can be manipulated. Most additives modify the hydration of portland cement in some way, by changing the speed of reaction or by dispersing the cement particles more thoroughly throughout the mix. Admixtures reduce the water-cement ratio required in the concrete mix. The following are admixtures in cement:³

Plasticizers.—Plasticizers are water-reducing agents that effectively reduce the quantity of cement required to achieve certain strength or workability characteristics.

Superplasticizers.—Superplasticizers produce highly workable flowing concrete that can, for example, be used for pumping applications. Superplasticizers can also produce high-strength concrete that has a reduced water content and a high compressive strength.

Air-Entraining Agents.—Air-entraining agents cause microscopic air bubbles to be distributed uniformly throughout the concrete. These then act as reservoirs for the water when it freezes, allowing it to expand without harming the structure of the concrete. They can also act as crack inhibitors by preventing small cracks enlarging beyond the extent of the nearest air void. Concrete may be air-entrained to give protection from freeze-thaw cycles. Air-entraining mixtures may entail loss of compressive and tensile strength and thus may be used with plasticizers to restore the strength properties. Fly ash and slag have an air-entraining effect.

Accelerators.—Accelerating admixtures increase the hardening rate of concrete, giving high early strength development. Calcium chloride is the most common accelerator and has been in use since 1885. Accelerators are mainly used in cold weather to normalize the setting time for concrete in a similar way that retarding plasticizers may be used in hot weather to slow down the process.

Waterproofing Aids.—Waterproofing aids are chemical admixtures that provide protection against the wind and rain, and reduce the intake of ground water. Waterproofing aids form a water repellent surface on the concrete and thin hydrophobic layers and voids within the concrete structure.

Polypropylene Fibers.—Polypropylene fibers can inhibit cracks. The fibers take up the stress from drying concrete, thus reducing the tendency for it to crack. They add little to the overall strength of the hardened concrete; however, they impart elasticity during the initial plastic stage of the concrete, which is important for the inhibition of cracks.

Products For Trade and Industry

Portland cement makes up 96% of total domestic output; the remainder is mostly masonry cement with white, expansive, portland slag and pozzolan, waterproof, and a variety of miscellaneous cements accounted for a small percentage of the remainder.

Industry Structure

The industry is composed of 119 cement-producing plants in 39 States. Multiplant operations were being run by 23 companies. Because of overall poor financial performance by the industry during the 1980's and 1990's, many companies have left the cement business or closed plants and began importing finished cement or clinker for grinding into finished cement. Seventeen independent importers have constructed terminals to receive foreign cement for markets near coastal areas.

In the mid- to late 1980's, changes in U.S. cement company ownership to overseas companies were very active. Due to the downturn in the U.S. cement industry and the possibilities to acquire cement companies in Europe, there has been much less interest in foreign acquisition of U.S. cement companies. However, at the end of the year there was still 65% foreign ownership.⁴ In 1991, Blue Circle Industries of London,

England, acquired the Beazer Harleyville, SC, plant and Lafarge Coppee of France finalized its acquisitions of Davenport Cement Co. and Missouri Portland Cement Co. A 50% interest of Riverside Cement of Diamond Bar, CA, was acquired by SsangYong Cement Industrial Co. of Seoul, Republic of Korea. Other overseas companies that have acquired U.S. cement companies in prior years⁵ are S.A. Cimenteries CBR of Belgium, Cementos Mexicanos of Monterrey, Mexico, Holderbank Management and Consulting of Zurich, Switzerland, Onoda Cement of Tokyo, Japan, Ciments Francais of Paris, France, RMC of England, Tarmac PLC of Wolverhampton, England, Titan Cement Co. of Athens, Greece, and a consortium of Spanish cement producers consisting of Asland Cement, Cementos Molins, and Uniland Cement.

The cement industry is forward integrated into the ready-mixed concrete, concrete products, and aggregate industries. Cement industries have also acquired interests in waste management companies.

Resources

Primary raw materials required for cement clinker production are, in order of importance, limestone, clay and shale, and iron ore. In instances where essential chemical components are not present in primary raw materials in the required amount, other mined materials or industrial products may be used as additives to correct these deficiencies. Gypsum is added during the clinker grinding process to make finished portland cement.

Although raw materials for cement manufacturing have not been quantified, they are abundant in most countries. Some countries deficient in raw materials meet their requirements by importing. Many domestic companies have reported reserves of raw materials exceeding 100 years of supply.

Technology

Principal steps in manufacturing portland cement consist of crushing, grinding, mixing, and burning raw materials and grinding the resultant clinker. About 1.8 tons of raw materials is required to make 1 ton of cement.

Raw Material Grinding.—Both dry and wet grinding are used to obtain a fineness that may range from 75% to 90% passing through a 200-mesh sieve. In wet milling, water is added with the mill feed to produce a slurry containing about 65% solids. The raw material is then dried and ground for burning.

Burning.—Burning is the most important operation in manufacturing cement because fuel consumption is a major expense, plant capacity is measured by kiln output, and strength and other properties of cement depend on the quality of the clinker. Burning takes place in a rotary kiln that is a refractory-lined steel cylindrical shell. It rotates on an axis inclined at 3/8 to 1/2 inch per foot toward the discharge end. U.S. kilns range in size from 116 to 760 feet long and 8 to 24 feet in diameter.

Byproducts and Coproducts

There are no major byproducts and coproducts in manufacturing hydraulic cement in the United States. Flotation, a method of beneficiation used by some companies to remove undesirable constituents from raw materials and usually to increase the calcium carbonate content of the kiln feed, produces waste such as silica sand or mica fines that may be marketed. Waste rock quarried in selective mining of usable raw material has been sold for riprap and fill materials or crushed and sold as aggregate for concrete or for road base. Some kiln dusts with high alkali content have been collected and used as fertilizer or processed to recover potash.

Economic Factors

Prices.—Cement prices are greatly influenced by local or regional markets and by the availability of energy and raw materials required for cement manufacturing. Discounts for cash and large-quantity purchases, absorption of freight charges, and the cost of packing bags and pallets add to the complexity of cement price patterns. Competition among producers and, in some instances, stiff competition from imports are also factors that contribute to depressed prices and ultimately limit investment dollars available for capital improvement or expansion.

Costs.—In 1990, the national average total operating costs per ton of cement was \$32.99. These costs did not include sales and corporate management expenses.⁶

Tariffs.—For countries with most-favored-nation status, duties are imposed only on white cement in the amount of 22 cents per metric ton, including the weight of containers. Other hydraulic cement and clinker are duty free. The statutory import duty for countries without most-favored-nation status is \$1.76 per metric ton and \$1.32 per metric ton for all other types of cement and clinker, respectively.

Operating Factors

Environmental Requirements.—The cement industry is faced with environmental challenges in the form of carbon dioxide, sulfur dioxide, and nitrogen oxide emissions. Carbon dioxide, as one of the principal gases contributing to the greenhouse effect, has been an important emissions challenge facing the cement industry. Burning of fossil fuels and calcination, the process in which carbon dioxide is driven from calcium carbonate and magnesium carbonate, leaving free lime and magnesia, contributes roughly one-half of the carbon dioxide generated by cementmakers. Sulfur dioxide emissions also have required emissions control

although they have declined since their peak in the early 1970's.⁷ Sulfur is introduced into the process of cement manufacture in the raw materials and fuel in three forms, as sulfates, sulfides, and organic sulfur compounds, and may leave as sulfates in the dust or clinker, or as gaseous sulfur dioxide contained in the exhaust gas. The problems with nitrogen oxide emissions are more complicated than for sulfur dioxide emissions due to complex mechanisms of nitrogen oxide formation. The clinker burning process causes nitrogen oxides to form, which are harmful to the environment. Reduction in nitrogen oxide emissions has been achieved by using such primary measures as an optimized kiln burner and secondary measures to decompose nitrogen oxide that has already formed.⁸

Another source of pollution associated with cement production is controlling dust from kilns and clinker coolers. That requires the installation of dust collectors such as bag houses and electrostatic precipitators, both of which add considerably to operating costs without improving production. In addition to meeting air quality standards, the industry must also comply with water quality, land use, health and safety, and noise requirements. It has been estimated that capital costs for meeting these requirements can account for 20% to 25% of the capital expenditures for new plants and major additions.

Employment.—In 1990, the average U.S. cement plant employed approximately 135 persons, including clerical but excluding sales and corporate management. By regions, the East North Central had the highest average with 169 employees and the West South Central the lowest, with 96 employees.⁹

Energy Requirements.—The U.S. cement industry consumed an average of 4.127 million British thermal units per ton (Btu/ton) in 1990. The fuel cost per unit of clinker was \$5.84.¹⁰ Substantial energy savings have been achieved since the Federal Government implemented the voluntary energy conservation program in

1972. The installation of improved raw material grinding and processing technology, the use of preheater-precalciner systems for burning raw materials, the conversion from wet to dry process, and the conversion from oil and gas to coal for kiln firing all contributed to improved energy efficiency. Further improvements in energy consumption will result as the cement industry continues to increase its use of municipal, industrial, and hazardous wastes for firing the kiln.

ANNUAL REVIEW

Legislation and Government Programs

The Intermodal Surface Transportation Efficiency Act of 1991 was to provide a significant increase in authorizations for new transportation spending over the next 6 years. The new bill implied a more than 40% increase in highway and mass transit funding compared to the period from 1987 to 1991.¹¹

The Boiler and Industrial Furnace Rule (BIF), under the Resource Conservation and Recovery Act (RCRA), sets emission limits and operating standards for cement kilns and other facilities that burn wastes. Cement companies that burn wastes are covered by BIF.

The Environmental Protection Agency has a mandate under the Beville Amendment of RCRA to study cement kiln dusts and to present a Report to Congress by mid-1993.

Issues

Issues facing the cement industry included those relating to the environment such as the use of alternate fuels, among those hazardous wastes, tire-derived fuels, and others; the use of cement kiln dust as fertilizer or in other applications; and the recycling of cement and concrete. Other issues were the lack of capital for new cement plants, cement dumped in the United States by foreign companies, and foreign ownership of U.S. cement plants.

With respect to the use of alternate fuels, cement kilns offer the capacity to burn large amounts of hazardous wastes

that would otherwise go to an incinerator. The cement kilns use the fuel as opposed to merely burning it up as would an incinerator. In addition, the alternate fuels can mean significant reduction in the use of fossil fuels. The use of tire-derived fuel is another example of the recycling of a product that would otherwise go to landfills. According to the Portland Cement Association, 38% of the plants used waste fuel in 1991, up from 33% in 1990.¹²

Issues relating to cement dumping are covered in the Foreign Trade section of this report. Issues relating to foreign ownership of cement plants are covered under the Industry Structure section of this report.

Production

One State agency and 49 companies operated 119 plants in 39 States. In addition, two companies operated two plants in Puerto Rico, manufacturing hydraulic cement. The production data obtained are arranged by State or groups of States that form cement districts. A cement district may represent a group of States or a portion of a State. The States of California, Illinois, New York, Pennsylvania, and Texas are divided to provide more definitive marketing information within those States as follows:

California, Northern.—Points north and west of the northern borders of San Luis Obispo and Kern Counties and the western borders of Inyo and Mono Counties.

California, Southern.—All other counties in California.

Chicago, Metropolitan.—The seven Illinois counties of Cook, DuPage, Kane, Kendall, Lake, McHenry, and Will.

Illinois.—All other counties in Illinois.

New York, Western.—All counties west of a dividing line following the eastern boundaries of Broome, Chenango,

Lewis, Madison, Oneida, and St. Lawrence Counties.

New York, Eastern.—All counties east of the aforementioned dividing line, except Metropolitan New York.

New York, Metropolitan.—The five counties of New York City (Bronx, Kings, New York, Queens, and Richmond) plus Nassau Counties, Rockland, Suffolk, and Westchester Counties.

Pennsylvania, Eastern.—All counties east of the eastern boundaries of Centre, Clinton, Franklin, Huntingdon, and Potter Counties.

Pennsylvania, Western.—All other counties in Pennsylvania.

Texas, Northern.—All counties north of a dividing line following the northern borders of Burnet, Crockett, Jasper, Jeff Davis, Llano, Madison, Mason, Menard, Milam, Newton, Pecos, Polk, Robertson, San Jacinto, Schleicher, Tyler, Walker, and Williamson Counties.

Texas, Southern.—All counties south of the aforementioned dividing line.

Clinker Capacity.—Clinker capacity in the United States, excluding Puerto Rico, increased slightly to 81.9 million tons. California continued to lead all States in clinker capacity, followed by Texas, Pennsylvania, Michigan, and Missouri. Together these five States accounted for 44% of total U.S. clinker capacity.¹³

By yearend, multiplant operations were being run by 23 companies. The size of individual companies, as a percentage of total U.S. clinker production capacity, ranged from 0.3% to 12%. The 5 largest companies with clinker capacity provided 38% of total clinker capacity; the 10 largest companies with clinker capacity provided a combined 59%. The 10 largest companies, in decreasing order of size of clinker production, were Holnam Inc., Lafarge Corp., Southdown Inc., Lone Star Industries Inc., Blue Circle Inc., Ash Grove Cement Co., Lehigh Portland

Cement, Essroc Materials, Medusa Cement Co., and California Portland Cement Co.

Portland Cement.—Portland cement production decreased by 6% to 69.4 million tons. The decrease was attributed to declines in the construction markets in 1991.

The industry operated 119 plants, including 8 grinding facilities, to produce various types of finished hydraulic cement compared with 120 plants in 1990. California continued to lead all States in the production of cement, followed by Texas, Pennsylvania, Michigan, and Missouri. Together these five States accounted for 45% of total U.S. cement production.

The size of individual companies, as a percentage of total U.S. finished cement production capacity, ranged from 0.4% to 11.8%. The top 10 producing companies, in declining order of production, were Holnam Inc., Lafarge Corp., Lone Star Industries Inc., Southdown Inc., Lehigh Portland Cement Co., Ash Grove Cement, Blue Circle, Essroc, Medusa Cement Co., and California Portland Cement.

Masonry Cement.—At yearend, 80 plants were manufacturing masonry cement in the United States. One plant producing masonry exclusively was Riverton Corp., Riverton, VA.

Aluminous Cement.—Aluminous cement continued to be produced by Lehigh, Buffington, IN; Lone Star Lafarge, Chesapeake, VA; and Aluminum Co. of America, Bauxite, AR.

Fuel Consumption.—According to the Portland Cement Association, a survey of its members indicated that coal and coke accounted for 70.8% of the fuel used.¹⁴ The consumption of electrical energy represented 10% of the fuel used. Fuel used in wet-process plants was 6.3 million Btu/ton, or 29% higher than the dry process of 4.5 million Btu/ton. Kilns without preheaters averaged 5.4 million Btu/ton, those with preheaters averaged

4.4 million Btu/ton, and those with precalciners averaged 3.9 million Btu/ton.

Corporate Changes.—C.H. Beazer PLC was acquired by Hanson Trust PLC.¹⁵ Both companies are based in the United Kingdom. Beazer had owned Gifford-Hill, which therefore ceased to exist as a cement company. Hanson gained a 50% interest in North Texas Cement and Riverside Cement Co. North Texas Cement was a joint venture with Pioneer. Gifford-Hill's Harleyville, SC, plant was purchased by Blue Circle Industries PLC.¹⁶ Lafarge Corp. took over the U.S. assets of Cementia Holdings SA, which will bring an additional 2.5 million tons of capacity to Lafarge, plus 16 cement terminals and more than 30 ready-mix and aggregate operations.¹⁷ SsangYong, the largest player in the Republic of South Korea, which operated the largest clinker production facility in the world, purchased a 50% interest in a joint venture with Beazer of the United Kingdom construction building group to own and operate the plants and terminals of the Riverside Cement Co. in California.

The four plants owned by RC Cement have been grouped under the parent name. Tarmac merged its two plants in Florida and Virginia under the corporate name Roanoke Cement. South Dakota Cement changed its name to Dacotah Cement.¹⁸

Consumption and Uses

Consumer demand for cement in the United States, excluding Puerto Rico, decreased by 11% to 79.4 million tons. This was the fourth year of decline after the 20-year low experienced at the depth of the recession in 1982. According to U.S. Department of Commerce data, housing starts declined 15% to 1.0 million units. The value of new construction put in place declined 9% to \$401 billion. The value of residential construction put in place declined 14% to \$158 billion, primarily in single-unit structures. The value of nonresidential construction put in place declined 17% to

\$97.8 billion, owing primarily to decreases in office and other commercial building construction. Public construction experienced an increase of 9% or \$50.4 billion, caused primarily by spending for public buildings, conservation and development, sewer systems, and water supply facilities.¹⁹

Among the consuming States, California continued to lead all areas in the amount of portland cement consumed followed by, in order of shipments received, Texas, Florida, Illinois, Ohio, and Pennsylvania. Together, these States consumed 40% of total U.S. tonnage.

On a regional basis, all of the nine census regions experienced decreases in consumption. The largest decreases were experienced by the South Atlantic, Pacific, Middle Atlantic, and New England regions, with decreases of 17.5%, 16.3%, 14.0%, and 12.7%, respectively. However, the East North Central, East South Central, and West North Central all experienced declines of between 6.6% and 10.0%. The West South Central and Mountain Regions experienced moderate declines of slightly more than 3%.²⁰

Shipments of domestically produced portland cement from U.S. mills decreased by 8%, while masonry cement shipments decreased by 13%. Cement imported for consumption declined by 34%. This was the fourth consecutive year that imports declined.

Ready-mix concrete producers were the primary consumers of cement, accounting for about 71% of the total, followed by concrete product manufacturers with 13%, highway contractors with 5%, building material dealers with 4%, and other contractors with 3.5%. Smaller amounts were consumed by Federal, State, and other government agencies and by a variety of other miscellaneous users.

Markets and Prices

The average mill value of portland cement declined slightly to \$49.37 per ton while the value of masonry cement increased slightly to \$68.91 per ton.

The average value of cement as reported by Engineering News—Record (ENR) by yearend was \$62.43 per ton. The ENR prices are based on an average per ton value of cement delivered to 20 cities. The prices ranged from a low of \$62.10 in January to a high of \$64.11 in August. The average price change for portland cement for November 1991 increased by 1.6% compared with November 1990.²¹

Foreign Trade

The International Trade Commission (ITC) made a final determination that gray portland cement and clinker from Japan were being sold in the United States at less than fair market value and that the cement industry was materially injured by reason of these imports. This determination followed the investigation that was initiated when a committee of Southern California cement producers filed an antidumping petition with the U.S. ITC and the U.S. Department of Commerce.

In July, the ITC determined that there was reasonable indication that imports of gray portland cement and clinker from Venezuela were being sold in the United States at less than fair value under section 733 of 19 U.S.C. 1673b. In December, the ITC gave notice of the institution of the final antidumping investigation.

A panel of the General Agreement on Tariffs and Trade (GATT) ruled that the United States improperly applied stiff antidumping duties to imports of Mexican cement and recommended that the United States return the more than \$30 million in duties it had collected. In August 1990, the ITC had ruled that imports of Mexican cement were harming U.S. producers, which allowed antidumping duties as high as 57% to be imposed on Mexican cement imports. Mexico and the United States negotiated over the ruling for 1 year. When those negotiations did not lead to a resolution, Mexico asked GATT, the world trade organization based in Geneva, to review the dispute. GATT, however, does not have the power to enforce this recommendation, and it was unlikely that

the United States would return any antidumping tariffs.²²

According to trade data reported by the U.S. Department of Commerce, Bureau of Census, cement imported for consumption in the United States and its possessions and territories was 8.7 million tons or 34% below the level of 1990. This was the fourth year of decline following 3 consecutive years of record-high imports. The decline corresponded to the marginal decrease in total demand resulting from reduced construction activity. Canada, Colombia, Mexico, and Venezuela were the principal import sources accounting for 72% of the total. Clinker accounted for 17% of total imports compared with 32% reached in the peak year of 1985. The average value of foreign cement and clinker, including cost, insurance, and freight, delivered to American ports averaged \$46.27, up 11% from that of 1990.

Florida led all States in the amount of imports received, accounting for 19% of the total. Sixty-four percent or 1.0 million tons of the Florida imports was shipped through the Tampa Customs District. Imports made up about 31% of Florida's portland cement consumption compared with 9% of apparent consumption nationally. Fifty-three percent of imports into Florida came from Venezuela. Los Angeles was the second largest recipient of imported cement, receiving 1.0 million or 12% of the total, about one-half of which was received from Mexico.

Exports of hydraulic cement and clinker as reported by the Bureau of Census increased 26% to 698,000 tons. Canada received 74% of the total.

World Review

World cement production was up slightly at 1.3 billion tons. China continued to lead all nations with 21% of production, followed by the U.S.S.R. with 11%, Japan with 7%, and the United States with 6%. Countries with excess capacity continued to export cement to the United States. Twenty-two countries exported cement to the United

States in 1991, six less than those in 1990. The amount of cement imports declined by 35% because of increased demand within exporting countries and because of a continued decline in demand in certain U.S. markets.

There was considerable activity in plant modernization or expansion by industry throughout the world. The May issue of World Cement magazine gives a world roundup of cement plants.²³

Capacity.—Data in table 9 are estimated and were obtained from a number of different sources, including Government representatives, cement associations, producers, and consultants. Capacity is defined as the maximum quantity of cement that can be produced in a period of time on a normally sustainable basis taking into consideration downtime required for maintenance and repair. Capacity includes operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure.

During 1991, clinker-producing plants in an estimated 132 countries had a combined annual capacity of about 1.4 billion tons. The seven leading countries, China, the U.S.S.R., Japan, the United States, India, Brazil, and the Federal Republic of Germany, Western states, controlled 52% of world capacity.

In the United States, 46% of the clinker production capacity was concentrated in five States: California, Texas, Pennsylvania, Michigan, and Missouri. At yearend, 207 kilns at 111 plants were being operated, excluding Puerto Rico. The average annual kiln capacity increased to 388,000 tons compared with 365,000 in 1990.²⁴

Canada.—Canada produced 9.4 million tons of cement in 1991, with cement consumption at 6.8 million tons. Canada was the largest exporter of cement to the United States, having exported 3.1 million tons of hydraulic cement and clinker. The Canadian cement industry is highly integrated both vertically and horizontally compared to

that in the United States. There were eight Canadian cement companies, the largest being Lafarge Canada, a subsidiary of France's Lafarge Coppee. Foreign owners controlled 77% of Canadian cement capacity. Canada experienced a worsening of its recession in 1991, with construction down sharply.

Czechoslovakia.—Total cement production was more than 8 million tons with a production capacity of 11.2 million tons. The Czechoslovakian cement industry is relatively modern. Three cement plants used the wet process and 14, the dry process. Total heat consumption on average was 1,026 kilocalories/kilogram. Energy consumption was 109 kilowatt hours/ton. Solid and waste fuels were replacing applied fuels. The use of preheaters was intensified, and environmental protection was improved.²⁵

Greece.—Heracles General Cement Co., Greece's leading cement producer and one of its largest industrial companies, was privatized by the Greek Government according to the Financial Times. Heracles is 70% owned by Greece's state-owned industrial holding company.

India.—The Indian cement industry continued to aggressively expand its production capacity through new plant construction, modernization, and expansion activities. It is anticipated that demand will continue to increase. Cement production in India reached an alltime high of 48.5 million tons. This was the eighth consecutive year of reported production growth.

Japan.—The Japanese Ministry of International Trade and Industry removed that country's cement industry from Government protection. The removal was based on the Ministry's assessment that the Japanese cement industry no longer required favorable tax treatment and low-interest loans to help the industry. In a separate action, Japan's Fair Trade Commission fined 12 leading cement producers a total of \$90 million

after the discovery of illegal cartel arrangements in the Chugoku and Hokkaido regions.²⁶

The U.S. Department of Commerce determined in March 1991 that imports from Japan of gray portland cement and clinker were sold in the United States at less than fair value. The ITC ruled in April 1991 that U.S. cement producers had been injured by dumped Japanese cement. The duties imposed on the Japanese cement industry were 84.7% for Nihon Cement Co., 47.79% for Onoda Cement Co., and 65.22% for all other Japanese producers and exporters of cement and clinker. The duties were effective May 1991.²⁷

Hungary.—Cement production in Hungary was approximately 2.5 million tons, with capacity of about 5 million tons per year, giving a utilization of production capacity of about 42%. Exports of cement, about 53,000 tons, were minimal; imports were about 130,000 tons. Natural gas was the main fuel, utilized at 54%, followed by heavy oil at 38% and coal at 8%.²⁸

Korea, Republic of.—The Republic of Korea has the fifth largest cement industry in the world. Korea's cement production increased 54% over the past 6 years to 40 million tons in 1991. Although the country operated more than 120,000 tons per day of dry-process clinker, which represented an increase in capacity, imports of three million tons were expected to be needed to meet the continuing domestic shortage. China continued to provide the imported cement in the form of bagged cement delivered to Seoul markets. There are eight cement plants that are on the northeast coast near Kangnung on the Sea of Japan and in the region around Chongju. The cement industry in the Republic of Korea is extremely advanced and modernized due to the relative youth of the industry (established only 30 years prior) and to the incorporation of new ideas and processes. The country's entire production capacity is based on dry-process technology. With the rate of

growth in capacity and with expected flattening of demand, it was expected that the Republic of Korea would be exporting more.²⁹

Mexico.—In 1991, the Mexican cement industry produced 25.1 million tons of grey cement, 5.4% more than that in 1990. The national market consumed 23.3 million tons that represented 93% of the total production; 1.8 million tons of cement was exported. The apparent national consumption of grey cement increased by 9.7% in relation to that of 1990. The consumption of cement has remained closely correlated with the behavior of the gross national product; the changes in the latter have an immediate effect on the consumption.

Cementos Mexicanos announced plans to spend about \$1 billion to expand some of its plants and built two new ones to increase its cement production capacity by 35% or 8.8 million tons. Cement demand in Mexico has increased by 10% per year, reportedly. Plants were expected to be built in Guadalajara, Hidalgo, Mexico, Puebla, and the Yucatan.³⁰

The Mexican cement industry is made up of 30 cement plants controlled by 8 industrial groupings, of which CEMEX, formerly known as Cementos Mexicanos, is the largest, controlling about 63% of the market.

Imports of cement from Mexico dropped to 12%, down from 28%, 28%, and 17% in 1988, 1989, and 1990, respectively. The decrease was presumably due to the determination by the ITC that domestic cement producers were being injured by cement from Mexico and the subsequent duties ranging from 3.7% to 58.4% placed on cement imported from Mexico.

Poland.—The cement industry had large, modern dry-process plants working alongside outdated plants with small capacity. The wet process predominated, accounting for 60% of clinker production, which resulted in high heat consumption for clinker burning or 1,330 kilocalories/kilogram of clinker in the whole Polish

cement industry. Therefore, the industry had limited automation of the production process, high labor costs for plant operation and maintenance, relatively high levels of environmental pollution, and high energy consumption. The consumption of cement was low, approximately 10 million tons, or about 60% of total capacity, with 1.8 million tons of exports. In addition, seven plants were reorganized as single joint stock companies—Gorazdze, Oazrow, Strzelce Opolskie, Kujawy, Rudniki, Malogoszcz, and Warta.³¹

Romania.—Clinker production capacity was about 15 million tons per year and cement production capacity more than 23 million tons per year. The cement industry is relatively modern. Seven of the 10 plants in operation had production capacities greater than 2 million tons per year and 2 had more than 1 million tons per year. One plant produced white cement. Eighty-five percent of the kilns was dry kilns with preheaters. Over the past 2 years, however, the capacity utilization has been between 30% and 40%.³²

Saudi Arabia.—The eight cement companies of the Saudi cement industry produced approximately 12 million tons of clinker and sold about 13 million tons cement and clinker during 1991. Industry installed production capacity was rated at about 14.0 million tons per year. More than 1.54 million tons of clinker was exported, along with 492,000 tons of cement, to seven countries in the region and the Far East. The key industry development during 1991 was the establishment of the Saudi Consolidated Cement Co., a merging of the Saudi Bahraini Cement Co. and the Saudi Cement Co. The new venture was to operate about 3.2 million tons of combined annual production capacity.

Taiwan.—Demand for cement in Taiwan reached 19.6 million tons with local producers capable of only outputting 18.9 million tons, leaving a sizable

shortfall to be met from imports from Japan and Indonesia.³³

U.S.S.R.—As of January 1, 1990, there were 398 kilns in service, including 3 kilns with precalciners and 18 shaft kilns. The wet process predominated, with the dry process accounting for only 18% of the kilns. Gas was the main fuel, utilized at 73%, heavy fuel oil at 17.4%, and coal at 9.6%. But it was expected that more coal and also waste fuels would be used in the future. The cement industry faced a number of challenges. Plants needed to be converted to the dry process. However, in Russian and Ukrainian areas, there were deposits of raw material with high moisture content, on average greater than 16%. Modernization of cement mills, with the introduction of closed circuits with new generation classifiers, needed to be accomplished.³⁴

Current Research

The use of supplementary materials has become of increasing importance in concreting practice. These materials can be incorporated in concrete to facilitate several benefits, including the modification and improvement of certain material properties, the conservation of nonrenewable natural resources, and the utilization of industrial byproducts. Blast furnace slag has been widely used in concretes for many years, both as a cementing medium and aggregate.

In the study conducted at the Department of Construction Engineering at the National Taiwan Institute of Technology, the effect of blast furnace slag and fly ash on cement paste was investigated. Blast furnace slag, with a high content of glassy phase, possessed cementitious ability and could be used as a partial substitute for cement. Fly ash is a pozzolanic material and is suitable for massive concrete structures because its addition as a partial substitute for cement would reduce thermal hydration and bleeding, thereby improving the overall durability of the concrete.³⁵

The use of steel slag has been investigated in recent years for use as

aggregate in instant-chilled slag (I.C.S.) The tensile splitting strength of the slag aggregate itself was higher than that of limestone. Compressive, indirect tensile and flexural strengths of I.C.S. slag concretes were greater than those of corresponding control concretes containing limestone aggregate.³⁶

Experimental results at the Department of Silicate Engineering, at the Nanjing Institute of Chemical Technology in China, indicated that alkali slag cements had high strength and durability. The hydration of alkali slag cements is controlled by alkaline activators and is different from that of portland cement. Some activators act as reactants, such as calcium hydroxide and gypsum, but others act simply as catalysts, such as sodium hydroxide.³⁷

The effect of hot weather on the flexural and compressive strength of concrete containing different percentages of granulated blast furnace slag and ground rhyolite tuff for partial replacement of cement was studied at the Hungarian Institute for Building Science in Budapest, Hungary. Hot weather can increase the water demand, the rate of slump loss, the velocity of setting and hardening, and plastic shrinkage. The results indicated that concretes containing blast furnace slag as a partial replacement of cement (up to 40%) cast and cured at 42° C had about the same compressive and flexural strengths at later age as those made with portland cement alone.³⁸

Engineers at the Research Institute of Civil Engineering in Czechoslovakia studied the impact of fly ash fineness on concrete strength. Economy of cement could be reached only with sufficiently fine fly ash.³⁹

The influence of fly ash on the basic characteristics of lightweight and ordinary concretes subject to heat treatment was studied at the Research Institute for Building Structures, Kiev, U.S.S.R. The studies were made of fly ash-containing concretes intended for precast products subject to heat treatment, including lightweight concretes with porous aggregates. The use of fly ash increased the strength of lightweight concretes, reduced cement consumption by 15% to

20%, and permitted a decrease in concrete mean density and heat conduction. The study provided fly ash specifications and characteristics in the U.S.S.R.⁴⁰

The corrosion of steel in concrete with and without silica fume was studied at the Division of Building, Construction and Engineering in Australia. A corrosion cell based on constant impressed voltage of 400 megavolts was developed to study corrosion rate of steel in concrete of different strength levels and in concrete with different silica fume contents. The results indicated that corrosion rate of steel embedded in saturated concrete could be reduced by increasing concrete strength, particularly in a chloride-contaminated environment. The use of 10% silica fume as cement replacement material in making 70 megapascals concrete could have beneficial effects in terms of reduced corrosion rates.⁴¹

An experimental investigation, which was part of a larger research program, studied the relationship between gypsum content porosity and strength in cement. It was hypothesized that total porosity is the main microstructural parameter governing the influence of SO₃ content on the compressive strength of portland cement mortars.⁴²

The rheology and thickening time of high sulfate-resistant class G oil well cement slurries consisting of cement, water, and glycerin were evaluated experimentally at Rogaland Research in Stavanger, Norway. Glycerin contents of 26% by volume or less were found to accelerate the hydration process. At the same time, glycerin was found to act as a viscosifier to the slurry.⁴³ A study that was still in the trial stage was a method to contain and control ocean-based oil spills using portland cement. Usually, oil spills in the ocean are contained through the use of booms and skimmers that recover the spilled oil. Chemical dispersants are another well-known method. However, both of these oil abatement techniques are limited in their application. The new containment technology uses a portland cement-based reagent that is sprayed on an oil spill to form interlocking crystals of calcium

silicate hydrate. Because the calcium silicate hydrate is heavier than the water, it sinks to the bottom, dragging with it the oil particles entrapped in the crystal lattices.⁴⁴

In recent years, the demands for high-quality cement concretes and mortars have greatly increased. This has been due to the problem with the durability of concrete structures. One of the weakest spots in concrete is the interface between cement paste and inserts, such as aggregates. It has been known that the addition of polymers to concretes and mortars in the form of polymer dispersions improved adhesion to substrates and decreased permeability. The aim of the study at the Delft University of Technology in the Netherlands was to investigate the influence of polymer modification on the adhesion of cement paste to aggregates. Three kinds of polymers and two kinds of aggregates were used in the study. In addition, the influence of silica fume on adhesion of cement paste to these aggregates was explored. The strength results were found to be strongly affected by the polymer nature, their contents, aggregate type, and the curing conditions of the composites.⁴⁵

OUTLOOK

The North American Free Trade Act is expected to change the way cement is traded in North America. Increased trade between America, Europe, and Asia, has caused a new distribution of wealth.

Increased emphasis on rebuilding the Nation's infrastructure and transportation has come from the Intermodal Surface Transportation Efficiency Act of 1991. The act provides for authorization of \$155 billion in spending in the 5-year period from 1992 to 1997. The new bill implied more than a 40% increase in highway and mass transit funding compared to the amount spent in 1987-91. The act is likely to increase the demand for cement. How large that increase will be depends on the amount of funds that is actually allocated to highway spending.⁴⁶

It is expected that there will be continued consolidation of plants and companies as well as integration of cement companies into downstream industries, such as in other construction materials industries. There are approximately 2 million tons of new clinker capacity and 860,000 tons of new finish grinding capacity expected to be completed in 1992 and 1993.

The Portland Cement Association forecasts portland cement consumption to be 84.7, 90.6, and 94.2 million tons by 1993, 1994, and 1995, respectively.

Additives to cement, such as slag and fly ash, will continue to play an important role in the cement industry by providing substitutes to the use of cement and imparting special properties to the cement such as sulfate resistance, high strength, etc. Use of alternate fuels such as waste fuel, tires, etc. will also continue to play an important role in the cement industry. Studies conducted by various agencies such as the Environmental Protection Agency and other associations will indicate which regulations the cement industry will need to be concerned about when using alternate fuels.

W Withheld to avoid disclosing company proprietary data; included in "Total."

¹Includes Puerto Rico. Includes data for three white cement facilities as follows: California (1), Pennsylvania (1), and Texas (1). Includes data for grinding plants (8 in 1990-91) as follows: Alaska (1), Florida (2), Iowa (1), Michigan (1), Pennsylvania (1), and Texas (2).

²Grinding capacity based on fineness necessary to grind Types I and II cement, making allowance for downtime required for maintenance.

³Includes cement produced from imported clinker (1990—1,759,197 tons, 1991—2,056,394).

⁴Includes imported cement. Source of imports withheld to avoid disclosing company proprietary data.

¹Estimated. ²Revised. NA Not available.

³Table includes data available through June 28, 1992.

⁴In addition to the countries listed, Cameroon produces cement, but available information is inadequate to make reliable estimates of output levels.

⁵Reported figure.

⁶Data are for the year ending June 30 of that stated.

CHROMIUM

By John F. Papp

Dr. Papp, a physical scientist with 20 years' U.S. Bureau of Mines experience, has been the commodity specialist for chromium since 1983. Domestic survey data were prepared by Steve Frauenheim and Robin Johnson, mineral data assistants; chromite world production data, by country, were prepared by Audrey D. Wilkes, international data coordinator. Cost of production data was prepared by Edward H. Boyle, Minerals Availability Field Office, Division of Statistics and Information Services. (All tonnages are in metric tons unless otherwise specified.)

Chromium has a wide range of uses in metals, chemicals, and refractories. It is one of the Nation's most important strategic and critical materials. Chromium use in iron, steel, and nonferrous alloys enhances hardenability and resistance to corrosion and oxidation. The use of chromium to produce stainless steel and nonferrous alloys are two of its more important applications. Other applications are in alloy steel, plating of metals, pigments, leather processing, catalysts, surface treatments, and refractories.

Because the United States has no chromite ore reserves and a limited reserve base, domestic supply has been a concern during every national military emergency since World War I. World chromite resources, mining capacity, and ferrochromium production capacity are concentrated in the Eastern Hemisphere. The National Defense Stockpile (NDS) contains chromium in various forms, including chromite ore, chromium ferroalloys, and chromium metal in recognition of the vulnerability of long supply routes during a military emergency.

Research is conducted by the Federal Government to reduce U.S. vulnerability to potential chromium supply interruption. That research covers both domestic resource utilization and alternative materials identification. Domestic chromium resources include mineral deposits and recyclable materials. The U.S. Geological Survey and the U.S.

Bureau of Mines evaluate U.S. territory for chromium mineral deposits. The U.S. Bureau of Mines also studies minerals extraction and processing and materials substitution and recycling. Alternative materials research is also conducted by the National Aeronautics and Space Administration, the National Institute of Standards and Technology, the Department of Defense, and the Department of Energy.

World chromite ore reserves are more than adequate to meet anticipated world demand.

DOMESTIC DATA COVERAGE

Domestic data coverage of the primary consuming industries—chemical, metallurgical, and refractory—are developed by the U.S. Bureau of Mines by means of the voluntary monthly "Chromite Ores and Chromium Products" survey. The companies listed in table 11 by industry accounted for 100% of the chromite consumption data by industry in the current year of table 13. All of the refractory companies and all of the chemical companies that consumed chromite in 1991 reported to the Bureau, while 75% of the metallurgical companies reported. Consumption was estimated for the remaining 25% of the metallurgical firms.

Domestic production data for chromium ferroalloys and metal are developed by the U.S. Bureau of Mines by means of two separate, voluntary

surveys. These two surveys are the monthly "Chromite Ores and Chromium Products" and the annual "Ferroalloys." Production by the metallurgical companies listed in table 11 represented 100% of the domestic production shown in the current year of table 12. Seventy-five percent of those companies responded to both surveys. Production for the remaining 25% was estimated.

BACKGROUND

Chromium owes its prominence as a commodity to its use in stainless steel. Stainless steel was invented in the early 1900's. Soon thereafter electric furnaces evolved that could smelt chromite into ferrochromium. Before about 1960, ferrous alloys required the addition of as little carbon as possible because carbon could not efficiently be removed from molten steel. Thus, the production of low-carbon, high-chromium alloys (typically less than 0.1% carbon and more than 65% chromium) in or near steel producing centers, was the common practice. To make this ferrochromium, high chromium-to-iron ratio ores were required (ratios greater than about 2:1).

Since 1960, major changes have occurred in the chromium industry because of changes in steelmaking technology. The development of ladle refining techniques (i.e., processes that permit the chemical modification of liquid metal) such as argon-oxygen decarburization, permitted the steel

industry to shift from the more costly low-carbon ferrochromium to the less costly high-carbon ferrochromium as its major source of chromium units. This shift in ferrochromium grade has been accompanied by a shift in quantity of production among ferrochromium-producing countries. Since the 1970's, chromite ore-producing countries have developed their own ferrochromium production capacities. As a result, ferrochromium production has moved from the major stainless steel-producing centers, Japan, the United States, and Western Europe, to chromite-producing countries, Finland, the Republic of South Africa, Turkey, and Zimbabwe. With the exception of Japan, only minor ferrochromium production remains in the major stainless steel-producing countries. In particular, the Republic of South Africa, whose ores have a chromium-to-iron ratio of about 1.2:1, has increased its high-carbon ferrochromium production dramatically. Significant, but declining, quantities of ferrochromium continue to be produced in Japan.

Once chromium is incorporated into stainless steel, it is used in many different ways. Stainless steel is used in many industrial applications that benefit from oxidation or corrosion resistance or in applications that benefit from the ease with which stainless steel may be cleaned. Uses that are common to the experience of many people include kitchen and eating utensils, sinks, and automobile exhaust components or systems. Chromium is also used in chemicals for a variety of purposes.

Chromite, the mineral from which chromium is derived for use in the metallurgical and chemical industries, is used directly by the refractory industry to produce heat-, spalling-, corrosion-, and abrasion-resistant bricks for metallurgical and high-temperature industrial mineral processing applications. Chromite is not mined domestically; thus, the United States is 100% import dependent to meet domestic chromite demand. Some domestic chromium demand is met by recycling. Chromium is a critical and strategic material contained in the NDS to

ensure adequate supply in the event of a national defense emergency.

Definitions, Grades, and Specifications

U.S. industry sets chemical and physical specifications for chromium materials through the American Society for Testing and Materials (ASTM). Other organizations also make specifications for chromium materials. The Defense Logistics Agency (DLA), in cooperation with the Department of Commerce, maintains purchase specifications for chromium materials contained in the NDS. The Treasury Department, in cooperation with the Department of Commerce and signatories to the General Agreement on Tariffs and Trade, maintains definitions of chromium materials for the purpose of recording trade and applying tariff duties. (See table 1.)

The import category "chromite ore and concentrates made therefrom" is subdivided by chromic oxide content as follows: containing not more than 40% chromic oxide, containing more than 40% and less than 46% chromic oxide, and containing 46% or more chromic oxide. Producers of chromite ore and concentrate typically specify chromic oxide content; chromium-to-iron ratio; and iron, silica, alumina, magnesia, and phosphorous contents. They also specify the size of the ore or concentrate. Typically, chromic oxide content ranges from 36% to 56%, with values in the 40% to 50% range being most common. Chromium-to-iron ratios typically range from about 1.5:1 to about 4.0:1, with typical values of about 1.5:1 to 3.0:1. In trade, the chromite ore is also called chromium ore, chromite, chrome ore, and chrome.

The import category "chromium ferroalloys" is subdivided into ferrochromium and ferrochromium-silicon. Ferrochromium-silicon, also called ferrosilicon-chromium and chromium silicide, is not further classified. Ferrochromium is classified by its carbon content as containing not more than 3% carbon, more than 3% but not more than 4% carbon, or more than

4% carbon. Producers of ferrochromium typically classify their material as low- or high-carbon or charge-grade ferrochromium. Charge-grade ferrochromium is also called charge chrome. Producers of chromium ferroalloys typically specify chromium, carbon, silicon, phosphorous, and sulfur contents and material size. Ferrochromium-silicon typically contains 24% to 40% chromium, 38% to 50% silicon, and 0.05% to 0.1% carbon. Ferrochromium typically contains 50% to 75% chromium and 0.05% to 8% carbon. Low-carbon ferrochromium typically contains 55% to 75% chromium and 0.02% to 0.1% carbon. High-carbon ferrochromium typically contains 60% to 70% chromium and 6% to 8% carbon. Charge-grade ferrochromium typically contains 50% to 55% chromium and 6% to 8% carbon.

Products for Trade and Industry

Chromium is primarily used in the metallurgical industry as an alloying element. Small quantities of chromium are alloyed with (i.e., added to) a base metal to achieve certain desired properties not attainable with the base metal alone. Before its use as an alloying element, chromium was used predominantly in chemicals to make pigments or to plate metals. Chromite is used as a refractory material. Refractories resist degradation when exposed to heat. As a pigment, chromium provides color to many end products and corrosion protection to ferrous metals. As a plating material, chromium provides a lustrous or a hard finish and corrosion protection to the substrate metal. As a refractory, chromite found major use in blast furnace iron production. The decline in use of this process has resulted in a corresponding decline in chromite refractory use. Environmental concern over hexavalent chromium contamination has resulted in reduced use or increased expense of chromium use in pigments and plating. Chromium is traded primarily as chromite ore or as ferrochromium. Substantial amounts of chromium

chemicals, pigments, and metal are also traded.

Industry Structure

Stainless steel was developed in about 1900. Since then, stainless steel has grown to become the major end use of chromium. Chromium is used in stainless steel production in the form of ferrochromium, a product of smelting chromite ore with a carbonaceous material (chemical reductant) and siliceous materials (flux material). The production of stainless steel evolved in association with the major steel-producing centers. The production of ferrochromium developed in conjunction with the production of stainless steel at those steel-producing locations.

In a trend toward vertical integration, chromite-producing countries have been developing ferrochromium and stainless steel production capacity. This trend has worldwide impact. Formerly, ferrochromium was produced mainly by Europe, Japan, and the United States, the major steel producers. The U.S. trend to obtain chromium in the ferroalloy form is a result of the world trend to produce ferrochromium in chromite-producing countries.

The structure of the chromium industry from a material processing perspective begins with mining of chromite ore. (See figure 1, chromium material flow.) Once mined, the ore is beneficiated. The resulting chromite ore or concentrate made therefrom may be consumed in the refractory, chemical, or metallurgical industry. Chromite ore is consumed in the refractory industry for its chromite mineral content. The chromite is typically crushed, ground, and sized. It is then mixed with magnesite to make chrome-magnesite bricks that are subsequently consumed in the steel, glass, or cement industry. The chromite refractories are used to line steelmaking furnaces, cement kilns, or heat exchangers associated with glass production. (See figure 1.)

Chromite ore consumed in the chemical or metallurgical industry is processed to extract the chromium from

the chromite mineral. Chromite ore consumed in the chemical industry is kiln roasted, and the chromium is leached out in the form of sodium bichromate. The sodium bichromate is further processed to make chromic acid and other chromium chemicals and pigments. Chromic oxide is a chemical industry product. Chromite ore consumed in the metallurgical industry is smelted to produce ferrochromium. In effect, the oxygen is removed from the iron-chromium-oxygen mineral, leaving an iron-chromium alloy, ferrochromium. Ferrochromium is produced to meet a variety of chemical and physical specifications. Several variations of the ferrochromium production process are practiced; the submerged electric arc furnace is central to each process. Ferrochromium is the source of chromium units for alloys, especially ferrous alloys. When nonferrous alloys require chromium and the iron is undesirable, chromium metal is used. Chromium metal is produced from ferrochromium by an electrolytic process or from chromic oxide by an aluminothermic process.

The major vertical structure of the chromium industry is mining-smelting-stainless steelmaking. In some instances, the ownership of mining operations, smelters, and stainless steel production facilities is integrated. In many other cases, integration is limited to mining and smelting or to smelting and stainless steelmaking. Often the ownership of operations is shared. Major mining, smelting, or stainless steel production facilities are typically privately owned by large companies or groups of companies. (See tables 2 and 3.)

Geology-Resources

The geology of many chromium deposits has been characterized.¹ The data in table 23 are rated reserves and reserve base for major chromite ore-producing countries.² The data on chromite reserves and resources are categorized according to a general U.S. Bureau of Mines-U.S. Geological Survey classification system applicable to all minerals. The definition of reserves and

reserve base are published in Geological Survey Circular 831, "Principles of a Resource/Reserve Classification for Minerals." The distribution of chromite deposits into reserves, reserve base, and resources categories is determined by the physical and chemical nature of the ore (physical factors) and by mining and market economics (economic factors). Resources are a concentration of naturally occurring material from which a commodity may currently or potentially be extracted. Resources are divided into identified and undiscovered. As used here, resources refers only to identified resources that are further subdivided into demonstrated and inferred resources. The reserve base is the in-place demonstrated (measured plus indicated) resource from which reserves are estimated. The reserve base includes those resources that are currently economic, marginally economic, and some of those that are currently subeconomic.

Reserves are that part of the reserve base that could be economically extracted or produced at the time of determination. Reserves include only recoverable materials. Reserve values are included in reserve base values.

The term "reserves" is commonly used with a variety of definitions. Even when the definition given here is used, the quantitative value of reserves could vary owing to differing physical and economic criteria applied to a deposit by different analysts.

Technology

Mining.—A wide variety of mining technology is applied to the surface and subsurface mining of chromite ore. Most ore comes from large mechanized mines. However, small labor-intensive mining operations contribute to world supply.

Beneficiation.—The amount of beneficiation required and the techniques used depend on the ore source and end-use requirements. When the chromite is clean, only hand sorting of coarse material and gravity separation of fine

material may be required. When the ore is lumpy and mixed with host rock, heavy-media separation may be used. When the chromite mineral occurs in fine grains intermixed with host rock, crushing may be used in conjunction with gravity separation and magnetic separation.

Smelting.—The smelting of chromite ore to produce ferrochromium requires electric arc furnace technology. Early electric furnaces having power ratings in the kilovolt-ampere range have developed into modern furnaces having power ratings of about 50 megavolt-amperes. Closed and partially closed electric arc furnaces replaced open furnaces in the 1970's to improve pollution control, efficient furnace operation, and safety.

Ferrochromium is produced from chromite ore by smelting a mixture of the ore, flux materials (e.g., quartz, dolomite, limestone, and aluminosilicates), and a carbonaceous reductant (wood, coke, or charcoal) in an electric arc furnace. If the ore is lumpy, it can be fed directly into the furnace. However, if the ore is not lumpy, it must be agglomerated before it is fed into the furnace. (See Energy Requirements under Operating Factors.) Efficient operations recover chromium lost to furnace fume by collecting and remelting the dust and recover chromium lost to slag by crushing and beneficiating the slag. The chromium content of the ferrochromium is determined by the chromium-to-iron ratio of the chromite ore.

The shift from high-chromium, low-carbon ferrochromium to low-chromium, high-carbon ferrochromium, commonly called charge-grade ferrochromium, permitted the use of low chromium-to-iron ratio ore for smelting to ferrochromium. The Republic of South Africa is the most abundant and low-cost source of such ore. Unfortunately, this ore is friable (breaks easily into small pieces), and the finer fractions of such ore are blown out of a furnace before it can be smelted. Agglomeration technology has been developed to permit the use of fine chromite ore in the

electric arc furnace. Both briquetting and pelletizing are practiced. Efficient production technology uses prerduced and preheated pelletized furnace feed. Industry is developing new production technologies using high-temperature plasmas or using alternatives to electrical power supply. The new production technologies are expected to be more cost competitive than traditional production technology under some conditions. Advanced smelting technologies that use abundant friable ore have been and are being developed. Plasma processes, including both transferred and nontransferred arc processes, have been applied to ferrochromium production. The kiln roasting prerduction process is being applied to ferrochromium production.

Recycling.—Recycling is the only domestic supply source of chromium. Stainless steel and superalloys are recycled, primarily for their nickel and chromium contents. As much as 50% of electric furnace stainless steel production can result from recycled (i.e., new and old) stainless steel scrap. Advanced stainless steel production technology like continuous casting reduces prompt scrap generation and permits a higher product yield per unit of raw material feed. See figure 2 depicting the general recycling of chromium material flow industry structure. (See figure 2.)

Byproducts and Coproducts

Chromite ore is mined as a primary product. Chromite is not a byproduct or coproduct of the mining of any mineral, nor are there byproducts or coproducts associated with chromite mining. Chromite has the potential of becoming a byproduct of platinum mining in the Republic of South Africa or of lateritic nickel mining. Platinum and chromite are both present in the UG2 seam of the Bushveld Complex in the Republic of South Africa. At present, most platinum mining is from the Merensky Reef. However, as platinum mining from the UG2 seam continues and as new mining operations that exploit the UG2 seam are

developed, chromite-containing tailings will continue to grow. The feasibility of utilizing these resources has been demonstrated, and new ferrochromium production facilities under development by Samancor Ltd. are designed to permit the use of these resources. It appears to be only a matter of time before economic conditions favor the use of those tailings, thereby making chromite a byproduct of some platinum operations.

Economic Factors

Prices.—Inadequate supplies of ferrochromium in the late 1980's resulted from strong demand for stainless steel in all three major producing regions: the United States, Japan, and Europe. This inadequate supply resulted in increasing ferrochromium prices until mid-1989, when supply exceeded demand and prices began to decline. In 1989 and 1990, new ferrochromium plants and plant expansions were under construction or being completed. Reduced stainless steel production permitted ferrochromium producers, traders, and consumers to rebuild stocks after about 3 years of generally increasing production. Reduced demand for ferrochromium, resulting from decreased stainless steel production, and increased supply of ferrochromium, resulting from producer expansions and new plant construction, have resulted in declining ferrochromium prices since 1990.

The historical value of chromite ore by grade, ferrochromium by grade, and chromium metal imported to the United States is shown in tables 4 and 5. These values show that as chromite ore is processed to ferrochromium and to chromium metal, the added value is quite large. On a per unit of contained chromium basis for recent years, the value of ferrochromium is about 5 times that of chromite ore; the value of chromium metal is about 30 times that of chromite ore. Variations of the value of ore are shown to follow those of ferrochromium, indicating values of chromite ore change in response to demand with ferrochromium value first to reflect demand changes.³ Ferrochromium

values show greater variation than those of chromite ore. The unit value of chromium materials has increased by 10% to 15% per year in actual value since 1963. (See tables 4 and 5.)

Costs.⁴—Operating and transportation are the two major components of chromite ore cost in the marketplace. Operating cost includes mining (the production of run-of-mine ore) and beneficiation (the production of marketable chromite ore or concentrate from the run-of-mine ore). Mining cost is typically in the range of 70% to 90% of operating cost but exceeds 90% in some cases. Labor cost is the major component of mining and of beneficiation cost. Labor cost is typically in the range of 20% to 70% of mining cost and from 25% to 90% of beneficiation cost, but can be higher.

Excluding the delivered cost of chromite ore, electrical energy, other raw materials, and labor are the major components of smelting (i.e., production of ferrochromium from chromite ore) cost. (Note that smelting cost excludes the cost of chromite ore feed material.) Electrical energy cost is in the range of 20% to 55% of smelting cost; raw materials (excluding chromite ore), 15% to 35%; and labor, 10% to 30%.

The U.S. Bureau of Mines has studied the availability of chromium. The Bureau analyzed the cost and availability of chromium materials. The chromium materials included exportable chromite products (metallurgical, chemical, refractory, and foundry sands) and chromium ferroalloy products in 10 market economy countries (MEC's). These various chromium materials were simultaneously analyzed for cost and availability. The product breakdown among chromium materials was based on mine and smelter production capacities and known operating relationships circa the 1987-88 time period.

A total of about 874 million tons, gross weight, of in situ material containing about 203 million tons of chromium was analyzed. Extraction and beneficiation of this material was estimated to yield about 475 million tons

of chromite products, of which 289 million tons would be available for export and the remaining 187 million tons would be smelted in the country in which it was mined to produce about 80 million tons of chromium ferroalloys. The chromium ferroalloys would then be available for use in the country of production or for export. The 80 million tons of chromium ferroalloys included about 74 million tons of high-carbon ferrochromium, 4 million tons of low-carbon ferrochromium, and 2 million tons of ferrochromium-silicon.

The countries of the Republic of South Africa and Zimbabwe contained about 80% of the in situ chromium contained in chromite ore. Finland and India accounted for an additional 11% of the contained chromium; another 8% of the contained chromium was fairly evenly split among Brazil, the Philippines, Turkey, and the United States; and the remainder was in Greece and Madagascar.

Based on Cr_2O_3 content of in situ chromite ore, the 10 MEC's split into 2 groups, a high-grade group and a low-grade group. The high-grade group, those with ore grades ranging from 34% to 43% Cr_2O_3 , included India, Madagascar, the Republic of South Africa, Turkey, and Zimbabwe. The low-grade group, those with ore grades ranging from 9% to 27% Cr_2O_3 , included Brazil, Finland, Greece, the Philippines, and the United States. The grade differences between the two groups resulted in a wide disparity in their respective weighted average Cr_2O_3 contents. The high-grade group averaged 39% Cr_2O_3 , and the low-grade group, only 16% Cr_2O_3 .

Table 6 shows the results of the Bureau's analysis. Chromium material costs were calculated on a weighted average basis, f.o.b. ship at the port of export. Chromite costs shown in table 6 include chromite ore mining and beneficiating (including mine capital and operating costs and taxes) and chromite product transportation to port facilities. Chromium ferroalloy costs include chromite ore but exclude smelter capital cost. On a weight basis, the Bureau's analysis shows that the Republic of South

Africa and Zimbabwe could produce about 78% of metallurgical chromite ore, 93% of chemical chromite ore, 85% of refractory chromite ore, and 93% of foundry chromite ore that could be produced at their respective estimated break-even cost. The Republic of South Africa and Zimbabwe could also produce about 69% of the high-carbon ferrochromium, 89% of the low-carbon ferrochromium, and 100% of ferrochromium-silicon that could be produced at their respective estimated break-even cost. (See table 6.)

The low-carbon ferrochromium availability curve is shown in figure 3; the high-carbon ferrochromium is shown in figure 4. The costs shown in figures 3 and 4 include mining and beneficiation operating and capital costs, transportation to specific smelters, smelting operating costs, taxes, and transport costs to specific port cities for export. Recovery of initial capital costs at the ferrochromium smelters has not been included. Figure 3 shows that the MEC's studied support total production of 4 million tons of low-carbon ferrochromium at a cost ranging from about \$0.42 to \$0.95 per pound, contained chromium, for 0% discounted cash-flow rate of return. Figure 4 shows that the same MEC's studied support total production of about 74 million tons of high-carbon ferrochromium at a cost of about \$0.28 to \$1.07 per pound, contained chromium, at a 0% discounted cash-flow rate of return. (See figures 3 and 4.)

Tariffs.—Import tariffs are typically imposed to protect the domestic industry. Where there is no domestic industry, such as chromite ore production in the United States, there is no tariff. (See Foreign Trade section of this report for U.S. tariff duties on chromium materials.) In some cases, such as ferrochromium imports to the European Community, import tariffs are used with import quotas. That is, a duty-free quota is allocated to member countries. The quotas may be revised as necessary to meet the needs of domestic consumers and producers. Only in a few cases, such as ferrochromium exports from China and certain grades of

chromite ore exports from India, are export duties applied.

Operating Factors

Environmental Requirements.—Chromium releases into the environment are regulated by the Environmental Protection Agency (EPA). Workplace exposure is regulated by the Occupational Safety and Health Administration.

Toxicity.⁵—The effect of an element on the human body depends on several factors. These factors include the chemical or class of chemical, the route of exposure, the quantity and duration of exposure, and characteristics of the exposed subject.

Human Toxicity.—The chemical distinctions typically made about chromium chemicals include whether the compound is synthetic or naturally occurring. Synthetic chromium compounds are typically classified by their oxidation state. Trivalent and hexavalent chromium compounds are two such classifications. Exposure to chromium compounds could typically occur through one or more of three routes: skin contact, ingestion, or inhalation. Exposure can also vary in intensity (concentration of the chemical) and duration (length of time for which exposure occurs). Response to chemical exposure is dependent on such human characteristics as age, sex, general health, and sensitivity. The effect of chemical exposure on the human body can be good or bad. Chromium is one of those elements that is both essential to good health and detrimental to good health. The detrimental effects of chemical exposure are classified as acutely toxic when small amounts of the chemical cause significant damage in a short time; chronically toxic when exposure over a long time causes measurable damage; and carcinogenic when exposure can result in cancer.

Background levels of chromium may be estimated from natural abundances. At about 185 parts per million, chromium

is the 13th most common element in the Earth's crust, and at 0.2 parts per billion, the 26th most common element in seawater.

Under some conditions chromium compounds cause systemic damage to the human body.⁶ Because experimentation on human subjects is morally unacceptable, most toxicity data results from workplace, coincidental, or accidental human exposure or animal experimentation. EPA concluded that there is sufficient evidence in animals and humans for the carcinogenicity of chromium (VI) compounds, while evidence for the carcinogenicity of chromium (III) compounds in humans and animals is largely nonpositive. The acute toxicity of chromium (III) compounds is low whereas the acute toxicity of chromium (VI) compounds is in the high to moderate range. Chronic toxicity of chromium (III) is considered low.

Chromium generally forms chemical compounds in which chromium has either the hexavalent or trivalent oxidation state. Hexavalent chromium compounds are generally recognized as toxic. Chronic occupational exposure to hexavalent chromium has been associated with an increased incidence of bronchial cancer. The toxic status of trivalent chromium compounds is not clear. However, trivalent chromium compounds are less toxic than hexavalent chromium compounds. Chemical compounds containing chromium in lower valence states are generally recognized as benign.

Human Health.—Chromium is a trace mineral required by the human body for good health.⁷ A daily intake in the range of 50 to 200 micrograms has been recommended. Chromium is a cofactor for insulin, a hormone that participates in carbohydrate and fat metabolism. A cofactor is a material that acts with the material. The dietary chemical compound form of chromium is trivalent. Because humans cannot convert trivalent (III) chromium to hexavalent (VI) chromium, the carcinogenicity of hexavalent chromium compounds bears no relevance to the nutritional role of trivalent chromium.

Environmental Releases and Transfers.⁸—The EPA regulates and monitors industrial impact on the environment. As part of its monitoring activity, EPA collects data on toxic chemicals. That information is made available in the Toxic Release Inventory (TRI). TRI is mandated under title III of the Superfund Amendments and Reauthorization Act (SARA) of 1986.

Chromium has been identified as a toxic material by the EPA. As a toxic material, companies that release chromium-containing materials into the environment are required to report those releases to EPA. In turn, EPA collates the reported information and makes it publicly available in the form of the TRI data base.

EPA has been collecting environmental release information since 1987 from manufacturing facilities that employ 10 or more persons and used a threshold amount of chromium contained in chromium compounds. (A manufacturing facility is one whose product is included in Standard Industrial Classification Division E (SIC) Codes 20 through 39. EPA does not cover Division B, Mining, Groups 10 through 14.) The threshold amount decreased from 1987 to 1989, after which time it remained constant. The threshold limit for a facility that manufactured or processed chromium compounds was about 34 tons of contained chromium in 1987, about 23 tons in 1988, and about 11 tons in 1989 and subsequent years. The threshold limit for facilities that otherwise used chromium compounds has been and remains about 5.4 tons. (Note that EPA has definitions for the terms manufacture, process, and otherwise use for the purpose of reporting releases.) When reporting chromium releases, a facility must add up the chromium released from all sources that exceed a de minimis amount. The de minimis amount for chromium compounds is 0.1%. Facilities report the amount of chromium released to the air, water, and earth environment; the amount of chromium recovered on site; and the amount transferred to offsite locations. The collected data are called the TRI.

EPA reported total releases and transfers of chromium in chromium and chromium compounds in 1987 to have been 41,362 tons; 1988, 56,051 tons; 1989, 51,894; and 1990, 35,129 tons. By materials destination, land releases and offsite transfers accounted for the largest share of reported releases and transfers. By reporting industry, chemical and allied products and primary metals industries accounted for the largest shares of releases.

Energy Requirements.—Electric arc furnace ferrochromium production is an electrical energy intensive process (requiring about 3,500 to 3,800 kilowatt-hours per ton of ferrochromium produced) that produces similar volumes of ferrochromium and slag. However, heat recovery can reduce energy requirements. Energy efficient processes using preheating can reduce the energy requirements to about 2,500 to 2,800 kilowatt-hours per ton of ferrochromium produced. Typically, all of the energy required to smelt chromite is supplied in the form of electricity. Electrical energy requirements can be reduced by preheating or prereducing charge material using alternative energy sources such as coal, natural gas, or fuel oil. Advanced production technology permits the use of liquid or gas fuel to substitute for part of the energy required. Alternative production technology is being developed that would permit nonelectrical energy sources to supply a significant fraction of the energy required to smelt chromite ore.

Transportation.—Chromite ore is typically transported by trackless truck or conveyor belt from the mine face to storage or processing facilities on the mine site. From there, it is transported by truck from the mine site to the local railhead. It is then transported by rail to ports or to smelters. Smelters that do not have associated loading and unloading facilities for ships transport their product by rail to ports. Following transport by ship to consumer countries, chromium materials are typically barged or hauled

by truck to end users who have no loading and unloading facilities for ships.

ANNUAL REVIEW

In 1991, chromium apparent consumption was about 366,000 tons of contained chromium. The reported consumption of chromite by the chemical and metallurgical industry and by the refractory industry decreased. Chemical and metallurgical industry chromite consumption includes material consumed as part of the NDS program to convert chromite ore to ferrochromium. Imports of chromite decreased as did chromium ferroalloys compared with those of 1990. (See table 7.)

U.S. supply consisted of recycled and imported chromium materials. The United States recycled about 540,000 tons, gross weight, of stainless steel scrap and imported about 641,000 tons of chromite ore, ferroalloys, chemicals, and pigments valued at about \$328 million. The United States exported about 87,000 tons of chromium materials valued at about \$56 million. In 1991, both quantity and value of imports of chromium materials decreased, and exports of chromium materials increased compared with those of 1990.

Legislation and Government Programs

The President terminated sanctions, implemented under the Comprehensive Anti-Apartheid Act of 1986 (Public Law 99-440), against the Republic of South Africa. In July, the President found that the Government of South Africa had taken all of the steps specified in section 311(a) of the act, and, therefore, that title III and sections 501(c) and 504(b) of the act had terminated. He ordered executive departments and agencies to terminate sanctions and revoked previous Executive orders regarding the sanctions effective July 10, 1991. As a critical and strategic material unavailable from other reliable suppliers, chromium materials were exempt from the sanctions against imports from South Africa.⁹

In accordance with the President's November 1982 directive and Public Law

99-591, the DLA continued to upgrade NDS chromite ore to high-carbon ferrochromium. The Agency reported conversion of chromite ore to ferrochromium on a calendar year contract basis. DLA signed a contract with Macalloy Corp., Charleston, SC, in 1990 to upgrade NDS chromite ore. The contract period covers the years 1990-94, the last 2 years of which are optional for DLA. (See table 8.)

As part of its plan to modernize the NDS, DLA contracted with Elkem Metals Co., Marietta, OH, to upgrade NDS nonspecification-grade low-carbon ferrochromium into electrolytic (vacuum melting-grade) chromium metal. Elkem converted low-carbon ferrochromium to chromium metal in 1989 and 1990. In 1991, DLA contracted with Elkem to convert low-carbon ferrochromium to about 1,100 tons of chromium metal. DLA also exercised its option to have Macalloy convert chromite ore to ferrochromium in 1992. (See table 9.)

EPA promulgated its final rule on chromium contained in primary drinking water. EPA set the maximum contaminant level goal (MCLG) and the maximum contaminant level for chromium contained in primary drinking water at 0.1 milligram per liter. EPA identified the best available technologies to remove chromium III compounds to be coagulation with filtration, ion exchange, lime softening, and reverse osmosis. EPA identified the best available technologies to remove chromium VI compounds to be coagulation with filtration, ion exchange, and reverse osmosis. EPA concluded that chromium contained in drinking water should be minimized in recognition of its biological reactivity, including its potential for being a carcinogenic hazard. EPA set the chromium III and chromium VI MCLG based on the reference dose concept. The safe dose to which EPA refers is the National Academy of Sciences recommended daily intake of 50 to 200 micrograms per day. EPA commented that should new data demonstrate a cancer risk by ingestion of chromium VI, it would reconsider the chromium VI MCLG.¹⁰

EPA denied a petition to remove chromium III compounds and chromic oxide in particular from the chemicals covered by the Emergency Planning and Community Right-to-Know Act of 1986, in particular from the section 313 list of toxic chemicals. The petition to remove chromium III compounds was based on the contention that chromium III compounds are considered nonhazardous wastes under the Resource Conservation and Recovery Act (RCRA). EPA denied the petition based on EPA's determination that the conversion of chromium III to chromium VI has been demonstrated to occur in soils and in water-treatment processes that use chlorine.¹¹

EPA announced that treated residue from roasting and leaching of chromite ore is to be regulated under section D of RCRA, its final rule on the regulation of this material. RCRA was amended in 1980 to exclude solid waste generated by the extraction, beneficiation, and processing of ores and minerals from being regulated as hazardous waste under subtitle C of RCRA until those wastes could be studied to determine the manner in which they should be regulated. EPA was directed in 1988 by a court order to restrict the scope of exclusion to large volume, low hazard waste. An EPA study determined that treated residue from roasting and leaching of chromite ore does not pose an actual or potential danger to human health and the environment. EPA therefore decided to regulate treated residue from roasting and leaching of chromite ore under section D of RCRA.¹²

EPA started the 33/50 Program, a voluntary program to reduce environmental release and transfer of 17 toxic chemicals, including chromium and chromium compounds. The program is so named because its objective is the voluntary one-third reduction of chromium and chromium compound releases and transfers by 1992 and one-half reduction by 1995. Reductions are to be measured against 1988 TRI data.¹³

Strategic Considerations

Supply Security.—There is no production of chromite ore in the United States; primary consumption of chromium by U.S. industry is by companies that use chromite ore to produce ferrochromium, chromium chemicals, and chromite refractories and by chromium metal producers that use ferrochromium. Chromite ore reserves are abundant, ensuring adequate long-term supply. However, supply sources are few and remote from the United States, making supply vulnerable to disruption. The problem for the United States is one of national security. Ferrochromium is essential to stainless and some alloy steel production, which are in turn essential to both the domestic economy and to the production of military hardware.

Stockpile.—The NDS contains the following chromium materials: chromite ore, chromium ferroalloys, and chromium metal. The purpose of the NDS is to supply military, essential civilian, and basic industrial needs of the United States during a national defense emergency; by law, the stockpile cannot be used for economic or budgetary purposes. In addition to private and Government stocks, there exists a large unreported inventory of chromium contained in products, trader stocks, and scrap. The amount of these stocks varies with demand and price of the material. Under severe price pressures resulting from primary chromium shortages, recycling of consumer materials could add to the supply.

Chromite ore must be converted to ferrochromium before it can be used to make steel. Prompt response during a national defense emergency requires that conversion be carried out by domestic industry. However, domestic ferrochromium production capacity is not adequate to meet anticipated domestic demand under mobilization conditions. To ensure prompt NDS response to a national defense emergency, the President chose to convert stockpiled chromite ore to ferrochromium. Changes in industrial

capacity and new manufacturing and technological developments have rendered selected chromium materials in the NDS inventory obsolete, either in quality or form or both, and in need of upgrading. Subsequent to legislative mandate, DLA began modernizing chromium materials in the NDS by converting nonspecification-grade low-carbon ferrochromium into chromium metal. (See Legislation and Government Programs section of this report.) (See table 10.)

Issues

World ferrochromium production capacity in 1991 significantly exceeded demand, resulting in low capacity utilization. Major restructuring of the chromium industry occurred in India and the Republic of South Africa. (See India and Republic of South Africa under World Review section of this report.) Strong demand for ferrochromium, resulting from high levels of stainless steel production worldwide in 1987-89, resulted in ferrochromium plant expansions and new plant construction. Since 1970, the trend has been for ferrochromium production capacity to move from major stainless steel-producing countries (e.g., Japan, the United States, and Western Europe) to major chromite ore-producing countries (e.g., Finland, the Philippines, the Republic of South Africa, Turkey, and Zimbabwe). This has occurred through the creation of new plants or furnaces in chromite ore-producing locations and the closure of furnaces in other geographic areas where ferrochromium production was formerly strong. The increase in and change in location of world annual gross weight production capacity has continued that trend. Most of the added capacity was in chromite ore-producing countries. All of the capacity contraction was in nonchromite-producing countries. The largest addition to national annual capacity was in the Republic of South Africa, increasing the Republic of South Africa's capacity by about 30% in the 1989-90 time period. The supply shortage in 1988 was estimated to have been about 200,000 tons or about 5% of

1988 world production capacity. The expansion of 1989 and 1990 represented about 16% of 1988 world production capacity.

Stainless steel is the major chromium end use. Despite strong stainless steel production in 1991, ferrochromium production capacity exceeded demand, and weak prices resulted. Ferrochromium producers limited production and planned plant closings to reduce supply of ferrochromium in the expectation that reduced supply would stimulate prices to increase.

With stainless steel production growing at a long-term average annual rate of 3% to 4%, it is estimated that it will take until 1995 (about 5 years of average industry performance) for demand to catch up with added capacity. Experience shows that short-term variations in chromium consumption and production can be significantly larger than long-term trends.

Production

The major marketplace chromium materials are chromite ore and chromium metal, ferroalloys, and chemicals. In 1991, the United States produced chromium metal, ferroalloys, and chemicals, but no chromite ore. (See tables 11 and 12.)

Chrome Corp. of America, a subsidiary of Boulder Gold (Australia), continued to study possibilities for the development of its chromite resources in Montana. Chrome Corp. reportedly studied the possibility of producing stainless steel using Montana chromite ore.

Macalloy Corp. converted chromite ore to high-carbon ferrochromium for the NDS under a contract with the DLA. Elkem Metals Co. converted nonspecification-grade low-carbon ferrochromium into chromium metal for the NDS under a contract with the DLA. (See Legislation and Government Programs section of this report.)

Macalloy planned to construct a plasma arc furnace in cooperation with the South Carolina Research Authority at a cost of about \$10 million. The new furnace was

planned to have a daily production capacity to about 60 tons and electrical capacity in the range of 7 to 25 megavolt-amperes. The furnace was planned to become operational in 1993.

Chromium chemicals industry and production capacity were reviewed. American Chrome and Chemicals produced sodium bichromate with an annual capacity of about 45,000 tons. Occidental Chemicals Corp. produced sodium bichromate with an annual sodium bichromate production capacity of about 103,000 tons.¹⁴ (See chromium chemicals under Outlook section of this report.)

Consumption and Uses

Domestic consumption of chromite ore and concentrate was 375,084 tons in 1991. Of the total chromite consumed, the chemical and metallurgical industry used 339,068 tons, and the refractory industry, 36,016. Much of the chromite consumed and ferrochromium produced by the metallurgical industry were part of the NDS conversion program. (See Legislation and Government Programs section of this report.)

Chromium has a wide range of uses in the three primary consumer groups. In the metallurgical industry, its principal use in 1991 was in stainless steel. Of the 367,220 tons of chromium ferroalloys, metal, and other chromium-containing materials reported consumed, stainless steel accounted for 80%; full-alloy steel, 7%; superalloys 3%; and other end uses, 10%. The primary use of chromium in the refractory industry was in the form of chromite to make refractory bricks to line metallurgical furnaces.

The chemical industry consumed chromite for manufacturing sodium bichromate, chromic acid, and other chromium chemicals and pigments. Sodium bichromate is the material from which a wide range of chromium chemicals are made. (See tables 13 and 14.)

Stocks

Reported consumer stocks of chromite in the United States decreased from 354,661 tons in 1990 to 321,225 tons in 1991. Chemical and metallurgical industry stocks decreased as did refractory industry stocks. At the 1991 annual rate of chromite consumption, consumer stocks represented about 11 months of supply in the chemical and metallurgical industry and 4 months of supply in the refractory industry. Producer stocks of chromium ferroalloys, metal, and other materials decreased from 14,935 tons in 1990 to 11,832 tons in 1991. Consumer stocks increased from 17,598 tons in 1990 to 18,772 tons in 1991. At the 1991 annual rate of chromium ferroalloy and metal consumption, producer plus consumer stocks represented about a 1-month supply. (See table 15.)

Prices

The price of chromite decreased steadily in 1991. The published price of the Republic of South African Transvaal chromite, 44% Cr₂O₃ (no specific chromium-to-iron ratio), decreased from a range of \$50 to \$55 per ton, f.o.b. the Republic of South African ports, to a range of \$42 to \$50 in August, where it remained for the rest of the year. The published price of Turkish ore changed from a range of \$120 to \$135 per ton, f.o.b. Turkish ports, to a range of \$130 to \$135 in February. It then decreased to a range of \$120 to \$130 in August, where it remained for the rest of the year.

Ferrochromium prices generally began the year in a decline and then increased toward midyear. The published price of domestic high-carbon ferrochromium (50% to 55% chromium) decreased from 54.5 to 49 cents per pound of chromium content (¢/lb-Cr) in August, where it remained for the rest of the year. The published price of domestic low-carbon [0.05% and 0.015% (Simplex) carbon] ferrochromium remained unchanged.

The published price of electrolytic chromium metal remained at 370 ¢/lb throughout the year. The price of

elchrome-grade electrolytic chromium metal increased from 422.5 ¢/lb to 450.0 ¢/lb in March, where it remained for the rest of the year. (Elchrome is a vacuum degassed chromium metal product produced by Elkem Metals Co.)

The published price of imported high-carbon (50% to 55% and 60% to 65% chromium) ferrochromium varied throughout the year. The published price of 50% to 55% high-carbon ferrochromium started at a range of from 46 to 47.5 ¢/lb-Cr and ended the year at 48 to 48.5 ¢/lb-Cr. The price varied frequently, especially at yearend. The published price of imported 60% to 65% high-carbon ferrochromium started the year at a range of 42.25 to 45.5 ¢/lb-Cr from which it increased to a high of 51 to 52 ¢/lb-Cr in March, after which it declined to a low of from 42.5 to 43.75 ¢/lb-Cr in September. The price then increased to a range of from 46.75 to 47.5 ¢/lb-Cr in December. The published price changed monthly. The published price of imported low-carbon (0.05% carbon) ferrochromium increased from a range of from 100 to 105 ¢/lb-Cr to a high of from 104 to 107 ¢/lb-Cr in April, after which it steadily declined to a low from 85 to 86.5 ¢/lb-Cr in December. (See table 16.)

Foreign Trade

Chromium material exports from and imports to the United States included chromite ore and chromium metal, ferroalloys, chemicals, and pigments. (See tables 17 through 22.)

World Review

Industry Structure.—The chromium industry is composed primarily of chromite ore producers, ferrochromium producers, and stainless steel producers. Other industry components are chromium chemical and chromite refractory producers. Brazil, Finland, India, the Republic of South Africa, and the U.S.S.R. are countries that mine chromite, produce ferrochromium, and produce stainless steel. In Finland, Outokumpu Oy, a major share of which

is state-owned, owns and operates chromite mining, ferrochromium production, and stainless steel production facilities, making it completely vertically integrated. In the Republic of South Africa, major restructuring occurred. (See Republic of South Africa section.) Samancor is vertically integrated from chromite mining through ferrochromium and stainless steel production. Consolidated Metallurgical Industries and Chromecorp Technology are vertically integrated from chromite mining through ferrochromium production. Chromium-related companies in the Republic of South Africa are privately owned. Typically, major shares of a company are owned by other companies, and the remainder, if any, is openly traded. In Brazil, the mining and smelting of chromium is vertically integrated, but stainless steel production is independent of the mining-smelting operations. The major mining companies are subsidiaries of Cia. de Ferro Ligas da Bahia S.A. Stainless steel is produced primarily by Companhia Aços Especiais Itabira. Other chromite operations in Brazil are also vertically integrated. Bayer AG (Federal Republic of Germany) owns a chromite mine and chromium chemical plant. Refractory chromite operations are also vertically integrated from chromite production through refractory material production. Chromite mining and ferrochromium production in India is mostly vertically integrated. Ferro Alloys Corp. is the only stainless steel producer in India that is integrated from chromite ore mining through ferrochromium and stainless steel production. In the former U.S.S.R., chromite mining, ferrochromium production, and stainless steel production were state-owned.

The chromium industry of Japan consists primarily of the production of ferrochromium and stainless steel. Chromite ore production in Japan is small relative to consumption. In Japan, industrial companies may group together to meet common needs such as insurance, banking, transportation, international trade, real estate, etc. Companies within a group are frequently part owners of other companies within the group, but

share holding between groups is also common, especially by banking and trust companies. The Japanese ferrochromium producers are typically associated with stainless steel producers and may be part of a group. Association means the stainless steel producer takes the output of the ferrochromium producer. Because Japanese industry is typically both forward and backward integrated, stainless steel and ferrochromium producers may each be partial owners of one another. (See figure 5.)

The chromium industry of Turkey is composed of both large and small chromite ore producers, with one major producer, Etibank, integrated from mining through ferrochromium production. The chromium industry of Zimbabwe is composed of large companies vertically integrated from chromite mine production through ferrochromium production, small independent chromite mines, and chromite mines operated independently on behalf of the large vertically integrated companies.

Capacity.—The data in table 23 are rated capacities for major countries that mine chromite ore and produce ferrochromium, primary chromium chemicals, and chromium metal as of December 31, 1991. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time at a normally sustainable long-term operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure. Because not all countries or producers make production capacity information available, historical chromium trade data have been used to estimate production capacity. Rated production capacity changes result both from changes in facilities and changes in knowledge about facilities.

Reserves.—The United States has no chromite ore reserves. However, the United States has a reserve base and resources that could be exploited. (For further information on domestic reserves, reserve base, and resources, see Geology-Resources section of this report.) (See table 23.)

Albania.—Eight chromite ore-producing mines were reported operating. The mines and the districts in which they are located were: Kam in Tropojë, Vlahne and Kalimash in Kukës, Bulqize and Ternove in Peshkopi, Bater in Mat, Katjel in Librazhd, and Pojske in Pogradec. Production and exports by grade were reported and are shown in table 24.

The Bulqize Mine was mechanizing its ore transport in the process of increasing production capacity from 200,000 to 300,000 tons per year. Chromite reserves in the Kukës region were estimated at 14 million tons.

Civil unrest and some chromite ore mine strikes were reported. Albania reported its intention to develop its chromium industry—chromite ore and ferrochromium production. The European Community, Union Carbide (United States), and Samancor (South Africa) were involved in development discussions at various times during the year. No specific development arrangement had been made by yearend. Electrical energy availability that has limited ferrochromium production in the past was not a problem. Hydroelectric power was sufficiently abundant to have been exported. (See table 24.)

Australia.—Australia reported its demonstrated, subeconomic resources of chromite ore to have been 2.37 million tons of paramarginal and 0.52 million tons of submarginal resources and inferred, subeconomic resources to have been 20 million tons.

The Coobina chromite deposit was reviewed. The deposit, in Western Australia (23°29'S latitude, 120°16'E longitude), was found to have a chromite reserve base of about 124,000 tons

graded at 39.3% Cr₂O₃. It was reported that surface mining between 1950 and 1957 resulted in the production of 14,610 tons of ore that was used to produce refractories after smelting tests proved unsuccessful. More recent analysis of the ore showed that crushing and gravity separation of run-of-mine ore could produce metallurgical-grade (43% Cr₂O₃, Cr:Fe=1.6, lumpy) and chemical-grade (46% Cr₂O₃, fines) products. The economics of production (i.e., the price of chromite ore relative to the cost of selective mining, beneficiation, and transportation) was not good enough to choose mine development at the time of the evaluation.¹⁵

Brazil.—Brazil started a new economic plan in February. The new plan calls for a 75.45% increase of electric utility rates, increasing rates for ferrochromium producers from a range of 15 to 16 (US)mills per kilowatt-hour to a range of 26 to 27 (US)mills per kilowatt-hour. An antidumping case was filed against imports of ferrochromium from Albania, Greece, Turkey, and the U.S.S.R. At yearend, a decision had not yet been made.

Brazil received a \$62,000 contract through the International Development Fund of the United Nations Industrial Development Organization to treat tannery waste and to set up a specialized pollution control laboratory and training program. Recycling and recovery of chromium tanning material was one of the program objectives to reduce pollution in Franca, São Paulo State, where 4,500 to 12,000 hides were being processed daily with the expectation of tripling that rate.

Associação Brasileira Dos Produtores de Ferroligas (ABRAFE), the Brazilian ferroalloy producers association, reported 1991 production as follows: high-carbon ferrochromium, 74,788 tons; low-carbon ferrochromium, 7,437 tons; and ferrochromium-silicon, 4,524 tons. ABRAFE reported 1991 exports as follows: high-carbon ferrochromium, 27,015 tons; low-carbon ferrochromium, 20 tons; and ferrochromium-silicon, none. ABRAFE reported Brazilian

chromium ferroalloy production capacity to have been 120,000 tons of high-carbon ferrochromium, 14,000 tons of low-carbon ferrochromium, and 10,000 tons of ferrochromium-silicon. Brazilian chromium ferroalloy production capacity totaled 144,000 tons with production at 86,749 tons, giving a capacity utilization of 60% in 1991.

Cia. de Ferro Ligas da Bahia S.A. reported idling one of six high-carbon ferrochromium and one of three low-carbon ferrochromium furnaces owing to reduced demand.

Companhia Ferroligas do Amapá's Vila Nova Mine produced chromite in Amapá Territory. The Vila Nova Mine estimated its inferred chromite reserves at 7 million tons. Chromite production capacity was 50,000 to 60,000 tons per year of beneficiated product. The company started up a new beneficiation plant. The new plant was expected to reach full production capacity of 120,000 tons per year in 1992.

Companhia Ferroligas do Amapá (CFA) converted its furnaces to ferromanganese production in late 1990 because of the low ferrochromium price. CFA did not restart ferrochromium production in 1991.

Canada.—Canada studied its chromite occurrences in British Columbia. Geographic location of chromite occurrences were reported along with geology, mineralization, history, and current claims where possible.¹⁶

Sherwood Metallurgical Corp. continued development of a Canadian-based low-carbon ferrochromium smelter. The plant was planned to have an initial production capacity of 30,000 tons per year of low-carbon ferrochromium containing 60% to 65% chromium. Producing at full capacity, the plant was planned to annually consume 300,000 megawatt-hours of energy, 61,000 tons of chromite ore, 12,500 tons of low-sulfur reductant, and 22,000 tons of low-lime silica sand. The project was reported to have been seeking financing and a location.

China.—China reported chromite ore imports of 544,648 tons in 1991 (641,267 tons in 1990 and 700,076 tons in 1989). China imported chromite ore as feed material for its ferrochromium production industry. Ferrochromium producers included Hunan Ferro Alloy Works (Hunan Province), Jiangyang Ferro Alloy Works (Jiangsu Province), Jilin Ferro Alloy Works (Jilin Province), Liaoyang Ferro Alloy Works (Liaoning Province), and Shanghai Ferro Alloy Works.

European Community.—In 1990, the European Commission (EC) started an investigation when European ferrochromium producers requested them to investigate U.S.S.R. and Albanian high-carbon ferrochromium imports to determine whether or not the ferrochromium was being dumped in the European Community. The EC reportedly terminated its investigation in April after European producers did not respond in writing to an EC request for information. The EC set duty-free quotas for ferrochromium at 28,100 tons, the same as 1990 quotas.

The transition of the U.S.S.R. from a centrally planned economy starting in 1990 and the transition of the Soviet Union to independent States at the end of 1991, along with European commitment to assist the Eastern bloc countries and the former U.S.S.R. countries, posed a difficult problem for the European Community. Owing to high levels of stainless steel production in the 1989-90 time period, ferrochromium experienced short supply, resulting in production capacity expansions worldwide. Thus, former Eastern bloc and Soviet ferrochromium producers entered the European market at a time of excess supply, competing with European producers. The U.S.S.R. was thought to export about 40% of its ferrochromium production to European markets before 1989. Complicating this situation was the decline in production in the former Soviet States, resulting in their seeking external markets for even more ferrochromium than in previous years.

Finland.—Outokumpu Steel Oy planned to dredge port facilities at Kemi, the port through which it exports ferrochromium produced at its Tornio works, to permit larger volume vessels to use the port.

Greece.—Hellenic Ferroalloys SA (HFA) purchased the Domokos Mine from Financial-Mining Industrial and Shipping Corp. (FIMISCO), a Greek refractory producer. The mine has been producing refractory-grade chromite ore since World War II. Output from this mine was expected to eliminate HFA's need to import Albanian and Turkish chromite. The mine was reported to have reserves of 2 million tons and to have a production capacity of 100,000 tons per year. HFA's power supply was stopped in June by the Public Power Corp. While shut down, HFA relined its furnaces in June, and the Greek Government decided to liquidate the company in September, at which time the plant was closed. Ferrochromium production in 1991 was estimated at about 25,000 tons.

India.—National.—The Indian Government devalued the Indian Rupee to encourage foreign trade. The devaluation was expected to make ferrochromium production profitable which would, in turn, stimulate ferrochromium exports. The devaluation was about 20%.

Chromite Ore.—Industrial Minerals & Ferro Alloys Ltd. reportedly developed its chromite ore mining resources in the Boula region by leasing about 400,000 square meters of mining property from Serajuddin and Co.

Ferrochromium.—Ferro Alloys Corp. (FACOR) commissioned a captive electrical power generating facility (including a fuel oil storage facility) at its ferrochromium plant at Shreeramnagar in Andhra Pradesh State. The electrical powerplant consisted of three 10.5-megawatt diesel powered electrical generators. This captive power station is capable of supplying about one-half of FACOR's needs at Shreeramnagar.

FACOR continued construction of two 10.5-megawatt electrical generators at its charge-grade ferrochromium plant in Orissa State. This fuel oil fired powerplant has the capacity for addition of a third generator.

Indian Charge Chrome Ltd., a subsidiary of Indian Metals and Ferro Alloys Ltd., experienced transformer failures at its two captive power generators (108-megawatts total capacity) causing temporary reduction in production rate.

Ispat Alloys Ltd. planned to construct a ferrochromium plant in Dhenkanal District of Orissa State. Ispat planned to complete construction of the ferrochromium plant along with a captive powerplant in 1993.

Jindal Ferro Alloys obtained financing for and planned the expansion of its current production facilities estimated to have a capacity of about 6,000 tons per year. Jindal planned to construct crushing and grinding operations followed by kiln roasting and smelting in a 12-megavolt-ampere electric furnace having a production capacity of about 15,000 tons per year. Jindal planned to convert the existing furnace to low-carbon ferrochromium production.

Mandsaur Ferro Alloys sought capital investment to set up a high-carbon ferrochromium production facility in Madhya Pradesh. Capacity was to be about 6,000 tons per year. Nav Bharat Ferro Alloys converted one of its three 16.5-megavolt-ampere ferrosilicon furnaces to ferrochromium production, giving itself an estimated annual ferrochromium production capacity of about 20,000 tons per year. Sarada Ferro Alloys sought financing to add 5,000 tons per year of high-carbon ferrochromium production capacity to its current 6,000 tons per year at Srikakulam, Andhra Pradesh. Standard Ferro Chrome planned to expand its ferrochromium production capacity by 1995, based on an agreement with Tata Iron & Steel Co.

Tata Iron and Steel Co. entered the ferrochromium markets in 1990 with the acquisition of Andhra Ferro Alloys, Vizianagaram District, Andhra Pradesh State, and the conversion of part of Joda

Ferro Alloys, Kendujhar District, Orissa State, from ferromanganese production capacity to ferrochromium production capacity. Andhra provided capacity of about 5,000 tons per year, and the conversion of one of Joda's 9-megavolt-ampere ferromanganese furnace to a 12-megavolt-ampere ferrochromium furnace by Elkem (Norway) yielded about another 20,000 tons per year. Tata started marketing ferrochromium produced for itself on a conversion basis by Indian Charge Chrome Ltd. (ICCL), which provided Tata an effective additional ferrochromium production capacity of about 20,000 tons per year. ICCL, an export-oriented subsidiary of Indian Metals and Ferro Alloys, has a production capacity of about 50,000 tons per year. In 1991, Tata purchased OMC Alloys from Orissa Mining Corp., adding about another 50,000 tons per year to its capacity. Tata further made marketing agreements with Saida (about 11,000 tons per year of capacity), Standard Ferro Chrome (about 1,500 tons per year of current capacity and planned expansion to 120,000 tons per year), Nav Bharat Ferro Alloys (15,000 tons per year of capacity), and VBC Ferro Alloys (about 15,000 tons per year of capacity). Tata has thus, over a period of about 2 years, acquired an annual production capacity of about 140,000 tons to make it the largest single ferrochromium producer in India and of major size by world standards. This status will last as long as the conversion contracts, about 5 years, if Tata does not extend them or acquire production facilities. Tata holds the largest share of chromite ore reserves in Orissa. It has mechanized its Sukinda Chromite Mine and added a beneficiation plant, increasing production capacity to about 750,000 tons per year. Tata's moves into the ferrochromium market thus provide demand for its chromite ore production and take advantage of its existing public-sector marketing expertise.

Unimetal Alloys, a steel producer, sought financing to establish a ferrochromium plant at Hyderabad, Andhra Pradesh, to produce 60% to 65% and 70% to 75% high-carbon ferrochromium with chromite ore from

Orissa. Unimetal planned an annual capacity of about 25,000 tons from one 16.5-megavolt-ampere furnace, to be in production in 1994. VBC Ferro Alloys converted one furnace from ferrosilicon to ferrochromium to do toll conversion for Tata Iron and Steel Co. The conversion gave VBC an annual ferrochromium production capacity of about 20,000 tons for use against the 5-year conversion agreement with Tata. VBC planned to acquire a second furnace for the production of ferrochromium. When the new furnace is commissioned, the old furnace was planned to be converted back to ferrosilicon production.

Chromium Chemicals.—India supports an old and currently growing leather tanning industry. About 2,000 tanneries have the capacity to process 500,000 tons of hides and skins annually, and 80% of the tanneries use a tanning process that utilized basic chromium sulfate (BCS). India consumes about 25,000 tons of BCS annually for tanning, of which about 15,000 tons is absorbed in the hides and skins and 10,000 tons is discharged to wastewater.

Iran.—Faryab Mining and Chrome Smelting Co., a state-owned company, was producing chromite ore graded at 46% to 52% Cr₂O₃ and chromium-to-iron ratio of 3:1 at the rate of about 100,000 tons per year. Faryab started construction of a ferrochromium smelter consisting of two Chinese-made electric furnaces each with 15-megavolt-ampere electrical capacity and combined production capacity of 14,000 tons per year.

Italy.—Ferroleghé SpA was sold by Montedison SpA to Finanziaria Metallurgica, a member of the Indel Group. Ferroleghé operates three 12-megavolt-ampere furnaces with annual production capacity of 38,000 to 40,000 tons at its Milan plant. Ferroleghé has not been producing since 1990, but plans to restart production in 1992 using ore supplied by Albania, Turkey, and the former U.S.S.R. Ferroleghé is now

owned 98% by Indel and 2% by Finanziaria Metallurgica. Italcromo, a major shareholder of which is Finanziaria Metallurgica, continued construction of a ferrochromium plant at Termoli. Italcromo planned to install two furnaces, one in 1992 and a second in 1993, with a total annual production capacity of 100,000 tons of ferrochromium. Acciaierie e Ferriere Lombarde Falck SpA stopped production in January owing to weak market conditions and then resumed in July to take advantage of low-cost summer season electrical energy rates. Falck produces low-carbon ferrochromium at Novate Mezzola with an annual capacity of about 13,000 tons. Falck negotiated with SA des Minerais (Luxembourg) and Consolidated Metallurgical Industries (CMI) (Republic of South Africa) to restructure its production facilities. CMI was to provide technological consultation, and Minerais was to provide cash and marketing expertise.

Japan.—Japan operated a two-part stockpiling program, Government and private. Japan's goal was to acquire a stockpile of chromium materials adequate to serve the needs of Japanese industry for 60 days. Japan planned to have the Government finance and stockpile 70% of the material; and the private sector the remaining 30%. Metal Mining Agency of Japan, under the supervision of the Ministry of International Trade and Industry, operated the Government stockpile, while Japan Rare Metals Stockpiling Association operated the private stockpile. Japan planned to purchase about 2,000 tons of ferrochromium (1,500 tons high-carbon ferrochromium, 500 tons low-carbon ferrochromium) for its stockpile by March 1992. These purchases were expected to increase the stockpile quantities to the equivalent of 32.72 days of Japanese consumption. Japan planned to sell stockpiled materials up to 20% of holdings during price surges then to use the profits to finance additional purchases. Japan also planned to change the basis of estimating equivalent days of consumption from 1986 consumption to

an average of consumption over the 1986-90 time period.

Japan Metals and Chemicals Co. (JMC) closed one of three furnaces at its Oguni ferrochromium plant. The closure reduced the plant's annual production capacity from about 24,000 tons to about 15,000 tons. JMC's Kyushu plant was unaffected and continued to operate with an annual capacity of about 70,000 tons. Pacific Metals upgraded and increased the production capacity of its rotary kiln to match the capacity of its furnaces.

Japan reported stainless steel production of 2,839,472 tons in 1991, an increase of 6.8% compared with that of 1990. Japan's ferroalloy industry produced about 301,706 tons of ferrochromium, a decline of 7.5% compared with that of 1990. Japan's ferrochromium production has ranged from 260,000 tons to 360,000 tons per year in the 1980-91 time period. Japan imported 578,073 tons of ferrochromium in 1991, while it exported 1,928 tons, giving imports a 66% market share. Japan imported 755,059 tons of chromite ore and 794 tons of chromium metal.

Korea, Republic of.—Consumption of ferrochromium in 1991 exceeded that of 1990 by 40%, an increase that reflected growth of the Korean stainless steel production industry. (See table 25.)

Madagascar.—Kraomita Malagasy (Kraoma) mined 122,276 tons of chromite ore in 1990. Madagascar exported 79,269 tons of chromite in 1990. Beneficiation changes for Andriamena Mine chromite have enabled Kraoma to produce a chromite graded at 0.002% to 0.003% phosphorous, an improvement over the typical chromite grade of 0.007% phosphorous.

Norway.—Elkem Rana AS, a subsidiary of Elkem AS (Norway), started ferrochromium production from a second electric furnace. The furnace started this year is the same as the one started last year. Each furnace has an annual production capacity of about 70,000, giving Elkem Rana a total annual

high-carbon ferrochromium production capacity of 140,000. Elkem Rana's high-carbon ferrochromium production was estimated at 35,000 tons in 1990, 90,000 tons in 1991, and was projected to reach 140,000 tons in 1992. Elkem Rana has two more smelting furnaces at its Mo-i-Rana plant site that have not yet been dedicated to ferroalloy production.

Oman.—Oman planned the formation of a private company to exploit its chromite resources. Oman reported 425 deposits, one-half of which were in the Al Batinah, Ash Sharqiyah, and Az Zahirah regions. Oman did not produce chromite in 1991, but exported 12,500 tons from stocks.

Pakistan.—North West Frontier Province auctioned 5,000 acres in the Kohistan district. Leases were for a 5-year period and are renewable. The area was thought to have chromite deposit potential.

Philippines.—National.—The National Power Corp. of the Philippines reported the worst drought conditions since 1983. As a result of the drought, water levels were low and hydroelectric power use had to be curtailed early in the 1991 dry season (March through May). Water levels are typically restored during the rainy season, which starts in July. Rain volume was inadequate to restore water reserves, so power limitations were expected again at yearend. About 93% of Mindanao Island power supply is hydroelectric generated from water stored in Lake Lanao.

The National Resources Development Corp. (Philippine Government) started a program to make safety equipment available to small-scale mining operations on Dinagat Island through Government recognized miners' associations. The program was initially funded with \$10,500.

Chromite Ore.—Benguet Corp. agreed with the Department of Environment and Natural Resources (Philippine Government) and Consolidated Mines

(owners) to mine three refractory-grade chromite deposits on 616.12 hectares in Zambales Province, Luzon Island, at an annual production rate of about 60,000 tons. The mineral production-sharing agreement between the Government and Benguet entitles the Government to 1% of gross mining revenue in addition to a 5% excise tax, an annual occupation tax of \$3.75 per hectare, and 12.5% of net revenue at the start of commercial operations. Reserves were estimated to have been equivalent to about 25 to 30 years of production. Benguet already contracts with Consolidated to operate the Masinloc deposit in the same area. However, the Masinloc Mine was closed owing to financial difficulties of Consolidated Mines, its owner. The Securities and Exchange Commission (Philippine Government) authorized Consolidated to plan to reopen the Masinloc Mine. Plans must be agreed to by creditors, some of whom object to reorganizing. CPO Mineral Resources and Development Corp. received approval from the Board of Investment (Philippine Government) to invest \$600,000 to develop a chromite deposit on a 972-hectare site in Bukidnon Province, Mindanao Island. CPO planned to start production in 1992 at the rate of 36,000 tons per year and to increase the production rate to 60,000 tons per year after 5 years.

Ferrochromium.—Ferrochrome Philippines Inc., after closure in November 1990 over a power supply dispute, relined its furnace, repaired the furnace electrodes and roof, and repaired its pelletizing plant. The smelter restarted production in October only to face power cutbacks, then closure because of inadequate power supply.

Following damage to its furnace that caused plant closure in June, Integrated Chrome Corp. retained Nippon Denko (Japan) to plan plant expansion to coincide with plant repair. The damaged furnace was designed for ferrosilicon production. However, it had been converted to ferrochromium production. It had an electrical capacity of 20 megavolt-amperes and a production

capacity of about 24,000 tons per year of high-carbon ferrochromium.

Metro Alloys constructed a ferrochromium furnace. The furnace was being constructed by China Metallurgical Consulting Corp. and was planned to be completed in 1992. The furnace was planned to have an electrical capacity of 12.5 megavolt-amperes and a high-carbon ferrochromium production capacity of 30,000 tons per year.

Poland.—Poland introduced a 15% tariff on imported ferrochromium. The Laziska ferroalloy plant planned to start producing high-carbon ferrochromium in 1992.

South Africa, Republic of.—Major restructuring occurred in the South African chromium industry in 1991. The high price of ferrochromium in 1988-89 that resulted from stainless steel demand that could not be met by existing ferrochromium producers put working capital in the producers' hands. These high prices stimulated investment in new ferrochromium plants and equipment. In 1990, existing ferrochromium producers increased their production capacity by acquiring smaller producers or by expanding their production facilities. At this time, CMI added a furnace and acquired Purity Ferrochrome, a new producer; Samancor added furnaces at its Tubatse smelter; MS&A constructed a new ferrochromium production facility that uses a new production process (kiln furnace prereduction followed by electric furnace smelting) at Middelburg and increased the transformer capacity of its direct current transferred plasma arc furnace at Krugersdorp; and Chromecorp Technology added a furnace. (Ferroalloys made no changes.) During and following the introduction of this new ferrochromium production capacity in South Africa and other capacity around the world, ferrochromium supply exceeded demand, causing ferrochromium prices to decline.

With annual ferrochromium production capacity of almost 1.5 million tons (gross weight) per year, nearly one-third of

world ferrochromium production capacity, South Africa is greatly impacted by these changes. Ferrochromium accounts for nearly one-half of South African ferroalloy export earnings, and ferroalloys are about the third largest export earner following gold and coal. Ferroalloy export earnings of South Africa about equal those of platinum-group metals.

By yearend 1990, South African ferrochromium producers ranked, by production capacity, as follows: Samancor, 620 thousand metric tons, gross weight, per year (kt/yr); MS&A, 380 kt/yr; CMI, 320 kt/yr; CCT, 180 kt/yr; and Ferroalloys, 100 kt/yr. In 1991, Samancor acquired MS&A, increasing its capacity to about 1 million tons per year. MS&A, South Africa's only stainless steel producer, also sold its stainless steel operation, MS&A Stainless (previously Southern Cross Steel), with an annual production capacity of 120 kt/yr, to Columbus, a joint venture between Samancor and Highveld Steel and Vanadium (an Anglo American company). Columbus plans to increase its stainless steel production to about 400 kt/yr, putting them in the production range of current major world stainless producers in the Federal Republic of Germany, France, Japan, and the United States. Samancor also acquired the chromite ore mining operations of Rand Mines. (Both MS&A and Rand Mines were subsidiary companies of Barlow Rand.) The addition of Rand Mines' chromite ore mining annual capacity of about 1,700 kt/yr to Samancor's previous annual capacity of about 2,200 kt/yr gives Samancor the current annual chromite ore production capacity of about 4,000 kt/yr or nearly one-third of world annual production.

South Africa's Minerals Bureau reported 1990 chromite ore production (excluding Bophuthatswana) at 4,081,248 tons, a decrease of 4.5% over that of 1989. The Minerals Bureau reported 1990 chromite ore sales to have been as follows: domestic, 2,463,000 (down 3% from that of 1989); and foreign, 1,096,000 tons (down 20% from that of 1990). The Minerals Bureau reported

1990 chromium ferroalloy production at 1,022,026 tons, a decrease of 1.2% from that of 1989. The Minerals Bureau reported 1990 sales to have been as follows: domestic, 26,080 tons (down 57% from that of 1989); and foreign, 923,934 (down 2.8% from that of 1989). The large decreases in reported 1990 export sales of chromite ore and ferrochromium reflect lower consumer demand and world excess supply relative to demand.

Chromite Ore.—Weak demand for chromite ore in 1991 made economic chromite production for small- and medium-size mines difficult. Some closures were anticipated if demand continued to be weak. As indicated by reported sales aforementioned, about two-thirds of chromite production is consumed internally, mostly for ferrochromium production. Major chromite ore producers are associated with ferrochromium producers.

Chromium Chemicals.—Chrome Chemicals Ltd., a subsidiary of Bayer AG (Federal Republic of Germany), closed its chromium chemical production facility in Durban, Natal. Production reportedly was stopped because of weak demand and low prices worldwide.

Ferrochromium.—Chromecorp Technology (CCT) operated one ferrochromium plant at Rustenburg with an annual ferrochromium production capacity of about 150,000 to 180,000 tons from three electric furnaces. CCT planned the installation of equipment to recover chromium from slag and to install a fourth furnace for which floor space was provided during original plant construction. Slag beneficiation equipment was planned to be operational in 1992 and to provide a production capacity of about 16,200 tons per year. CCT also operated a captive chromite mine, the Chroombronne Mine. CCT planned to start up a new chromite mine with annual production capacity of about 250,000 tons to meet projected demand of its planned fourth furnace. Weak market conditions lead CCT to plan the

temporary closure of its furnaces at yearend.

Consolidated Metallurgical Industries Ltd. (CMI), a subsidiary of Johannesburg Consolidated Investment Co. Ltd., operated two ferrochromium plants: CMI at Lydenburg with about 210,000 tons annual production capacity and Purity at Rustenburg with about 120,000 tons annual production capacity. CMI also operated Purity Chrome Mine, a captive chromite mine associated with its Rustenburg plant. CMI experienced a brief labor strike in October, which was settled through a negotiated pay increase. CMI negotiated with CCT for the purchase of CCT. No purchase agreement was reached. CMI planned to close one furnace at Lydenburg and one at Rustenburg owing to weak demand.

Feralloys, a subsidiary of Associated Manganese Mines of South Africa, operated a ferrochromium plant at Machadodorp with annual production capacity of about 100,000 tons. The plant experienced a brief labor strike in September.

Samancor operated five ferrochromium plants: Batlhako with an annual production capacity of about 20,000 tons; Ferrometals at Witbank with an annual production capacity of about 300,000 tons; Tubatse at Steelpoort with an annual production capacity of about 300,000 tons; Middelburg plant at Middelburg with an annual capacity of about 280,000 tons (including the yet to go into commercial production kiln process); and Krugersdorp plant at Krugersdorp with an annual capacity of about 100,000 tons. Samancor has a total ferrochromium production capacity of about 1,000,000 tons. Owing to weak demand, Samancor reduced its production by closing some furnaces. Samancor planned further closures in 1992 should demand not improve. Samancor planned to improve energy efficiency of its transferred arc furnace at Krugersdorp by improving heat recovery. Samancor planned to restart the kiln at Middelburg after pollution control equipment was repaired and market conditions improved.

Sentrachem, previously a calcium carbide producer, planned to convert its

30-megavolt-ampere furnace to charge-grade ferrochromium production with annual capacity of 60,000 to 70,000 tons at a cost of \$10 million. The conversion was planned to be completed in 1992.

Spain.—Ferroaleaciones Españoles (Fesa) produced ferrochromium at its Medina del Campo plant, Valladolid, with an annual production capacity of about 32,000 tons. Electrical power cost and availability limited production. The plant ceased ferrochromium production in August of 1991 owing to high power cost. Fesa planned to continue ferrochromium production by recovering ferrochromium from stockpiled slag and to review its ferrochromium production decision in 1993, when it was anticipated that countries of the European Community would be exchanging electrical energy without tax, thereby reducing electrical energy cost to Fesa. Fesa was granted legal protection in September covering a 3-year period, during which the company planned to restructure.

Swaziland.—Australian Overseas Mining Ltd. (Australia) (AOM) has been planning to construct a smelter with production capacity of about 120,000 tons per year. AOM holds interest in the joint venture and manages the project. In 1991, AOM planned to construct the plant near the Emaswati coal mine. The plant was planned to use the CODIR production process developed by Krupp (Germany) for application to ferrochromium production, currently owned by Mannesmann Demag (Germany) and implemented by Middelburg Steel & Alloy (South Africa) (MS&A). AOM planned to start construction after Demag evaluated the operation of the MS&A plant. The project may be delayed because Samancor (South Africa), the new owner of MS&A, postponed startup of the new MS&A plant owing to excess world ferrochromium production capacity.

Sweden.—Vargön Alloys AB produced ferrochromium from chromite ore

supplied by Brazil, India, the Philippines, Turkey, the United States, and the U.S.S.R. Vargön produced high-carbon ferrochromium from three furnaces with an annual production capacity of about 155,000 tons. Vargön was founded in 1874 under the name Wargön Alloys as part of an agricultural-industrial complex. Airco (United States) acquired the complex in 1968, retaining only the ferroalloy division. Airco sold the complex to Fides (a subsidiary of Credit Suisse, Switzerland) in 1979, which subsequently sold it to a consortium of management and Mellanfonden (Sweden) in 1987. Vargön produces high-carbon ferrochromium graded at 4% to 6% carbon and 58% to 59% chromium.

Turkey.—Etibank completed construction of two new furnaces in 1989. One of those furnaces was started up that year and achieved production status in 1990. The second furnace was then started up on a trial basis. Etibank operated two smelters in 1991, one producing low-carbon ferrochromium at Antalya, with annual production capacity of about 10,000 tons, and one producing high-carbon ferrochromium at Elazığ, with annual production capacity of about 150,000 tons. Etibank petitioned the U.S. Trade Representative to make low- and high-carbon ferrochromium eligible for duty-free treatment. A decision was expected in 1992.

U.S.S.R.—In an effort to become better known in the West and following common practice among market economy businesses, the former planned economy country industries have made information about their operations known to the West through publicly available industry reports and news services. Through these reports and direct interaction among industry, government, and news reporting representatives, information about chromium-related industry in the former U.S.S.R. is becoming better known in the West. The chromium industry of the former U.S.S.R. that is currently actively interacting with the West includes

producers of chromite ore and chromium ferroalloys and metal.

Chromite ore and chromium ferroalloy and metal producers in the former U.S.S.R. developed their commercial contacts with market economy countries. The Donskoy Ore Dressing Complex and the Aktubinsk Ferroalloy Works (Kazakhstan Republic) developed commercial relations with Japan. Donskoy has exported through the Black Sea port of Poti (Georgia Republic) but developed transportation by train through Siberia to the Eastern port of Nakhodka, a more convenient port from which to ship to Japan. Since 1982 chromite ore and ferrochromium exports from the U.S.S.R. to Japan have increased. Chromite ore from the U.S.S.R. has represented from 2% to 10% of Japanese imports, with no clear trend, while ferrochromium from the former U.S.S.R. has represented from 0% to about 2.5% of Japanese imports with an increasing trend over the time period.

Chromite Ore.—The Donskoy Ore Dressing Complex operated surface and underground chromite mines and an ore beneficiation plant. Proven reserves were estimated to have been about 300 million tons with inferred and estimated reserves at about 1 billion tons. Production at Donskoy was reported to have been about 3.6 million tons per year, with plans to increase that rate to 4.0 million tons per year in 1993. Donskoy surface mines included three working faces: 40 Years of Kazakh SSR, Mirny, and Objedinyonny. A fourth face, Dehgiz Agach, was being planned. The largest operation is the 40 Years of Kazakh SSR, where a 1,270-meter by 1,100-meter by 220-meter volume is mined in 16-meter by 20-meter benches to produce about 1.7-million-ton-per-year run-of-mine ore graded at 47% to 49% Cr₂O₃, with production planned to increase to 2.0 million tons per year. Donskoy underground mines included the Molodyozhnaya and Tsentraljinaya. A third underground operation, Glubokoe, was being planned. Production from the Molodyozhnaya Mine was about 1.5 million tons per year at an average grade

of about 44.8% Cr₂O₃. The beneficiation facilities included two ore dressing plants. One plant produced about 1.3 million tons per year while the other produced about 0.7 million tons per year. The 0.7-million-ton-per-year plant was being renovated to produce about 2.0 million tons per year with a target completion date of 1992. Donskoy was also constructing a briquetting facility targeted for completion in 1992. The briquettes were planned to be used within the country to produce ferrochromium. Chromite ore product from Donskoy ranges in grade from 42% to 57% Cr₂O₃, Cr:Fe from 2.8 to 4.2, in a variety of sizes up to about 300 millimeters. Donskoy has exported through Poti, Republic of Georgia, which is 2,800 meters by rail from the complex. More recently, Donskoy has exported through Nakhodka on the east coast of Russia, which is about 6,000 kilometers from the complex by the trans-Siberian railroad. Donskoy planned to develop an export option through the Ukraine Republic.

Chromium Ferroalloy and Metal.—Aktubinsk Ferroalloy Works, Kazakhstan, operated 14 shaft furnaces, 3 vacuum furnaces, 2 grain refining furnaces, and 2 converter furnaces to produce high-, medium-, and low-carbon ferrochromium, ferrochromium-silicon, and nitrogen-bearing ferrochromium with an annual capacity of about 340,000 tons per year. Chelyabinsk Elektrometallurgical Works, Russia, produced low-carbon ferrochromium and ferrochromium-silicon. Production in 1989 was reported to have been about 210,400 tons of high-carbon ferrochromium, 37,700 tons of foundry-grade ferrochromium, and 135,000 tons of ferrochromium-silicon. Klyuchevsk Ferroalloy Works, Sverdlovsk Region, Russia, produced low-carbon ferrochromium and chromium metal. Serovsk Ferroalloy Works, Sverdlovsk Region, Russia, operated two chromium ferroalloy plants, each consisting of nine electric furnaces that produced high-, medium-, and low-carbon ferrochromium and ferrochromium-silicon. Production in 1989 was reported to have been about

90,000 tons of high-carbon ferrochromium, 34,000 tons of medium-carbon ferrochromium, 121,000 tons of low-carbon ferrochromium, and 12,700 tons of ferrochromium-silicon. Yermakovskiy Ferroalloy Works, Pavlovsk Region, Kazakhstan, produced ferrochromium and ferrochromium-silicon. Zaporozhye Ferroalloy Works, Ukraine, produced ferrochromium.

Chromite Refractories.—Krasnoarmeiskiy Silica Works, Donetsk Region, Russia, produced chromite-periclase refractories with an annual production capacity of about 50,000 tons. Nikitovskiy Dolomite Works, Donetsk Region, Russia, produced unshaped chrome-magnesia refractories.

Vietnam.—International Mineral Research (Australia) reported that Vietnam was seeking foreign investment in its mining industry since it introduced new mining laws in 1988. Chromite production in Vietnam peaked at 36,000 tons in 1968 but has been only 4,000 tons in recent years.

Yugoslavia.—Political changes resulted in armed conflict in Yugoslavia following the separation of Slovenia, Croatia, and Bosnia and Hercegovina from Yugoslavia. Hemijsko-Elektrometallurški Kombinat Jugohrom, which had been a major ferroalloy producer, is in the Macedonia region of Yugoslavia, but did not produce ferrochromium in 1991. Tvornica Karbida i Ferolegura Dalmacija has an annual high-carbon ferrochromium production capacity of about 70,000 tons and is in Dugi Rat, Croatia. Tovarna Dušika Ruše has an annual low-carbon ferrochromium capacity of about 5,500 tons and is in Slovenia. Civil strife interfered with production.

Zimbabwe.—It was reported that 62 chromite mines were operating in Zimbabwe in 1991, most of which were small mining cooperatives. The mining industry reportedly generated about 45% of Zimbabwe's foreign exchange earnings with ferrochromium accounting for the

largest single share in 1988 at about 15%.

The Government of Zimbabwe, Union Carbide (owner of Zimbabwe Mining and Smelting), Anglo American Corp. (owner of Zimbabwe Alloys) and Atlas Copco-Eickhoff (Germany) studied the potential of mechanized mining of chromite from the northern great dyke, a thin seam deposit. Zimbabwe Alloys produced ferrochromium-silicon, with an annual capacity of about 55,000 tons, about one-half of which was used within the plant to produce low-carbon ferrochromium, and low-carbon ferrochromium, with an annual capacity of about 36,000 tons per year. Zimbabwe Mining and Smelting operated six electric arc furnaces, five at 17 megawatts and one at 12.5 megawatts, and one induction furnace at 3.5 megawatts to produce high-carbon ferrochromium with an annual production capacity approaching 200,000 tons and containing chromium in the range of 65.5% to 66%. Zimbabwe Mining and Smelting planned the installation of a second induction melting furnace and the possible addition of a seventh smelting furnace contingent upon development of an efficient mechanized mining method for northern dyke chromite deposits. Zimbabwe Mining and Smelting was installing dust collection equipment. All of the furnaces were to have dust control equipment by 1995. (See tables 26 and 27.)

Current Research

U.S. Bureau of Mines research provides fundamental scientific and technical information essential for advancing mineral science, processing technology, and conserving and developing domestic mineral resources. This research is conducted in support of the Strategic and Critical Materials Stock Piling Act of 1946 as amended, the Defense Production Act of 1950 as amended, the Mining and Minerals Policy Act of 1970, and the National Materials and Minerals Policy, Research and Development Act of 1980. Recent research related to chromium includes the study of chromite recovery from domestic

deposits, the development of analytic techniques to study chromium alloys, and the recovery of chromium from waste.

The U.S. Bureau of Mines studied domestic chromite ore resources from the Pennsylvania-Maryland area. The Bureau conducted magnetometer traverses in the State line district of Pennsylvania and Maryland to determine the geophysical response of the area. While chromite only rarely can be detected directly by magnetic methods, there is a possibility that geophysical signatures in the host rock could provide some guidelines for further exploration. The study did not find this method to be useful nor did it rule out the method for the study of chromite deposits in this area.¹⁷

The U.S. Bureau of Mines studied eutectic formation (formation of a mixture of phases that do not form solid solutions) in white cast irons and the recovery of chromium from superalloy scrap. The Bureau used electron microprobe analysis, X-ray diffraction, and scanning electron and optical microscopy to study the effect of chromium and other elements on the structure and morphology of the eutectic carbides. Differential thermal analysis was used to study the effects of alloying additions on the solidification reactions. Effects observed were explained in terms of the effects of alloying elements on the liquidus surface of the metastable iron-chromium-carbon phase diagram.¹⁸ The Bureau developed a procedure to recover chromium from mixed and contaminated superalloy scrap that uses both pyrometallurgical and hydrometallurgical methods. Chromium and iron were recovered together by precipitation.¹⁹

The U.S. Bureau of Mines analyzed the chromium and other elemental contents of U.S.-produced stainless and heat-resisting steel. The Bureau found that the 1962-83 average chromium fraction of U.S.-produced stainless and heat-resisting steel to have been about 0.17 ± 0.01 . The unit consumption of chromium was found to have declined with the increased use of Type 409, a ferritic stainless grade that is also one of the lowest chromium-containing stainless alloys. Type 409 was adopted for use in

automobile exhaust systems when that industry elected to meet EPA air emission standards through the use of catalytic converters.²⁰

A refractory metals symposium recently reviewed several aspects of chromium. Chromium recovery from mixed contaminated superalloy scrap as a ferroalloy was demonstrated. Treatment included pyrometallurgical and hydrometallurgical processes.²¹ Chromium recovery in the form of sodium chromate from Egyptian chromite ore was studied using a process that first sinters and then roasts the sinter. Chromium recoveries of near 100% dependent on roasting time and temperature and sodium carbonate and calcium oxide additions were achieved.²² The reduction of chromium (VI) to chromium (III) in a liquid fluidized bed electrochemical reactor was studied. The process is a possible alternative to one of several used by electroplaters to meet EPA effluent requirements. The effect of varying anode materials and mixing electrolyte streams were determined.²³

The Department of Agriculture developed a process that separates chromium from solid leather waste. Chromium sulfate is applied to animal hides to stabilize and preserve the hides. Separation of chromium from leather waste contributes both to chromium recovery and the reduction of waste disposal cost.²⁴

The Council for Mineral Technology (MINTEK) of the Republic of South Africa conducts government-sponsored and commercially sponsored and cosponsored research and development on chromite ore and ferrochromium. Recent MINTEK research has included chromite beneficiation, agglomeration, and smelting. MINTEK reported on the development, up to industrial scale, of a transferred plasma-arc smelting process for the production of ferrochromium. MINTEK commercial-scale transferred plasma-arc furnace and furnace control technology was industrially implemented.²⁵

MINTEK reported on the effect of technology and cost on the Republic of South Africa's international

ferrochromium market. The major ferrochromium operating production costs were identified to be about 30% for chromite ore feed, 20% for other material feed (reducing agents, fluxes, electrodes, and fuel), 40% for electrical energy, and 10% for labor and maintenance. Capital costs were found to be process sensitive. Capital cost of the traditional submerged-arc furnace was lowest, followed by plasma-arc then kiln roasting direct reduction. It was found that from 1970 to 1989 ferrochromium annual production capacity in the Republic of South Africa grew from about 0.1 to 1 million tons, an average annual rate of about 15%. In the 1990-91 time period, an additional 0.5 million tons of production capacity was added. It was projected that South African ferrochromium production would increase from an annual rate of about 1 million tons in 1989 to about 2.1 million tons in the year 2000.²⁶

The application of nickel sulfide to a reduction process of Canadian chromites (Bird River, Manitoba) was reported. Nickel was used in the smelting process to produce a high-carbon ferrochromium-nickel product usable as a master alloy for stainless steel production. A major condition for master alloy production is that contaminant levels be acceptable to stainless steel production. Laboratory-scale master alloy was produced, suggesting that a master alloy containing 40% chromium, 19% nickel, 0.04% sulfur, 0.5% carbon, and 0.5% silicon could be produced at commercial scale.²⁷

Private industry researched more economic production and utilization processes. Industry studied the application of hollow cathode technology to the production of ferrochromium from chromite ore fines. Hollow cathode use permits the direct use of fine ore, avoiding the need for agglomeration. Several process and product improvements were achieved.²⁸

Environmental concerns about chromium have resulted in a wide variety of studies to determine the natural background levels, sources of environmental emissions, movement of chromium in the environment, interaction of chromium with plants and animals,

effect of chromium on plants and animals, measurement methods, and recovery technology. A broad review of many environmental factors and the role of chromium, among other metals, in the environment was published.²⁹

OUTLOOK

On average in the United States, about 70% of chromium is consumed by the metallurgical industry, and about 70% of metallurgical industry chromium consumption is for stainless steel production. Stainless steel, by definition, contains at least 11% chromium but may contain up to 36% chromium. Thus, stainless steel production accounts for about one-half of the chromium consumed in the United States. The remainder is consumed in the production of other ferrous and nonferrous alloys, chemicals, and refractories. Some of the chemical and refractory products are consumed in the steel production process.

On average internationally, about 79% of chromium is consumed by the metallurgical industry, 13% by the chemical industry, and 8% by the refractory industry. Of the chromium consumed in the metallurgical industry, about 60% is consumed in stainless steel. Thus, stainless steel production accounts for about one-half of the chromium consumed internationally.³⁰

The outlook for chromium consumption in the United States and internationally is the same as that for stainless steel. Stainless steel is estimated to be the major end use for chromium worldwide. Thus, stainless steel industry performance determines chromium industry demand worldwide. (See table 28.)

The trend to supply chromium in the form of ferrochromium by chromite mining countries is expected to continue. The rate at which new ferrochromium plants come into production is expected to diminish now that all major chromite producers have such facilities. With new, efficient ferrochromium production facilities and excess capacity in chromite-producing countries, both production and capacity are expected to diminish in

traditional ferrochromium-producing countries, except where domestic industries are protected by quotas and tariffs. Further upward integration of the chromium industry is expected as chromite-producing countries expand current capacity or develop new stainless steel production capacity.

Stainless Steel

As pointed out above, chromium demand is driven by stainless steel demand. Stainless steel demand is price sensitive and an important part of stainless steel cost is nickel cost (about 70% of stainless steel requires nickel). One factor that could effect chromium demand is the availability of inexpensive nickel. Nickel availability is adequate to meet current demand and anticipated stainless steel demand until about 1995, at which time new nickel production capacity may be needed to meet demand. Projected cost of new nickel production capacity could be substantially higher than that of currently available material.³¹ After 1995, the increasing cost of nickel may result in increased stainless steel cost, which could result in reduced demand for stainless steel. Thus, just when stainless steel demand for chromium is anticipated to come into equilibrium with ferrochromium production capacity, demand may decline, reducing chromium industry growth after 1995. Several factors could modify this scenario. The role of the previously centrally planned economy countries both in terms of nickel supply and stainless steel demand are ambiguous. The balance between reduction in cost owing to greater production rates may offset some nickel increases. Stainless steel producers could substitute manganese for nickel, thereby reducing the impact of nickel cost increases. Short-term fluctuations in demand could exceed these longer term average projections.

Chromium Chemicals³²

Chromium chemical markets were reviewed. U.S. demand for sodium bichromate was reported to have been

130,200 tons in 1990 and was projected to be 130,800 tons in 1991 and 133,400 tons in 1995. The domestic chromium chemicals market showed -0.7% growth from 1981 through 1990 and was expected to show a positive 1% growth from 1991 through 1995. Reported prices for sodium bichromate crystals was \$0.60 per pound of sodium bichromate dihydrate equivalent content (for pricing purposes, sodium bichromate dihydrate equivalent content of crystals is 100%) and sodium bichromate liquor was \$0.55 per pound of sodium bichromate dihydrate equivalent content (typically the sodium bichromate dihydrate equivalent content of liquor ranges from 69% to 70%). Sodium bichromate was used as follows: chromic acid, 55%; chromium oxide, 10%; leather tanning, 8%; pigments, 7%; wood preservatives, 2%; drilling mud additives, 2%; other uses (including metal finishing, water treatment, textiles, and catalysts), 3%; and export, 13%. Environmental concerns were seen as driving the chromium chemicals markets.

Demand for chromic acid was expected to continue to grow at an annual rate of about 2% to 3% through 1995. Domestic chromic acid producers, American Chrome and Chemicals and Occidental Chemicals, increased their chromic acid production capacity to the current annual rate of 71,000 tons to meet increasing demand. Chromic acid prices were about \$1.10 to \$1.15 per pound in 400-pound drums. Chromic acid was consumed for the production of wood preservatives, metal finishing, and chromium dioxide. Wood preservation currently accounts for about 70% of chromic acid demand and was expected to increase even though chromium chemicals account for about 70% of the U.S. wood treatment market. Environmental restrictions on the use of creosote (in marine pilings) and pentachlorophenol (in utility poles) are expected to result in greater use of chromic acid for wood preservation. The most widely used chromium-containing wood preservative is chromium copper arsenate (CCA). CCA-treated wood is resistant to decay and termite attack, and wood treated with CCA is easier to paint

than wood treated with oil-base formulations. CCA-treated wood thus finds use in roofing, outdoor decks, and house foundations. Metal finishing accounts for about 27% of chromium oxide demand. Metal finishing includes chromium plating, aluminum anodizing, and other metal treatments. No growth was anticipated for metal finishing. The remaining 3% of chromic acid consumption included the production of chromium dioxide, a growth market that included the production of magnetic particles for use in magnetic recording media (audio and video tapes and computer disks).

EPA regulation limiting chromium releases have encouraged recycling of chromium chemicals and the use of substitutes to reduce releases. As a result, demand is expected to be reduced for many end uses.

¹Preliminary.

²Customs value per ton of chromium contained in imported material.

NOTE.—Constant dollar value is actual value multiplied by gross domestic product (GDP) ratio. GDP ratio is annual GDP index divided by 1987 GDP index. GDP ratio calculated as the ratio of GDP indices reported in Economic Report of the President, U.S. Government, Feb. 1992, available from Superintendent of Documents, U.S. Government Printing Office.

[†]Preliminary. [‡]Revised. NA Not available.

¹Customs value per ton of chromium contained in imported material.

²Carbon not more than 4%.

³More than 4% carbon.

NOTE.—Constant dollar value is actual value multiplied by gross domestic product (GDP) ratio. GDP ratio is annual GDP index divided by 1987 GDP index. GDP ratio calculated as the ratio of GDP indices reported in Economic Report of the President, U.S. Government, Feb. 1992, available from Superintendent of Documents, U.S. Government Printing Office.

**TABLE 6
AVAILABILITY OF CHROMITE AND CHROMIUM FERROALLOYS
FROM 10 MARKET ECONOMY COUNTRIES**

Chromium materials	Quantity available (million metric tons, gross weight)	Cost ¹ (dollars per metric ton)	
		Weighted average	Range
Chromite:			
Chemical grade	64.3	53	\$35- 174

TABLE 21
U.S. IMPORTS FOR CONSUMPTION OF CHROMIUM MATERIALS, BY TYPE

Type	1989	1990	1991		Principal sources, 1991
	Gross weight (metric tons)	Gross weight (metric tons)	Gross weight (metric tons)	Value (thousands)	
METALS AND ALLOYS					
Chromium metal:					
Waste and scrap	50	85	18	\$104	China (92%); Brazil (8%).
Other than waste and scrap	4,152	6,579	5,747	43,617	United Kingdom (32%); France (24%); China (22%); Japan (19%).
Ferrochromium-silicon	16,803	23,801	35,301	3,517	Zimbabwe (100%).
CHEMICALS					
Chromium oxides and hydroxides:					
Chromium trioxide	661	1,677	1,196	2,285	Italy (57%); Netherlands (18%); Japan (10%); Federal Republic of Germany (10%).
Other	3,880	3,512	3,976	1,141	Federal Republic of Germany (44%); Japan (25%); China (16%); Italy (9%).
Sulfates of chromium	313	192	186	108	Turkey (83%); Mexico (10%); United Kingdom (6%).
Salts of oxometallic or peroxometallic acids:					
Chromates of lead and zinc	607	425	334	698	Poland (48%); Norway (19%); Federal Republic of Germany (13%); France (13%).
Sodium dichromate	5,489	1,661	4,895	2,483	United Kingdom (79%); Mexico (8%); Republic of South Africa (5%).
Potassium dichromate	827	680	464	977	Federal Republic of Germany (35%); U.S.S.R. (32%); United Kingdom (31%).
Other chromates and dichromates; peroxochromates	1,010	1,860	859	2,424	United Kingdom (73%); France (21%).
Chromium carbide	108	123	77	759	United Kingdom (40%); Japan (34%); Federal Republic of Germany (25%).
PIGMENTS AND PREPARATIONS BASED ON CHROMIUM					
Chrome yellow	3,688	3,643	3,468	7,422	Canada (78%); Hungary (11%); Mexico (6%).
Molybdenum orange	1,046	916	812	2,399	Canada (99%).
Zinc yellow	542	436	218	435	Norway (58%); Poland (29%); Mexico (12%).
Other	687	657	441	3,197	Federal Republic of Germany (51%); Japan (17%); Canada (14%); Netherlands (13%); United Kingdom (5%).

¹Contained 2,756 tons of chromium.

²Contained 1,459 tons of chromium.

³Contained 2,046 tons of chromium.

¹Estimated. ²Revised.

³Table includes data available through May 14, 1992.

⁴In addition to the countries listed, Bulgaria and North Korea may also produce chromite, but output is not reported quantitatively, and available general information is inadequate for formulation of reliable estimates of output levels. Figures for all countries represent marketable output unless otherwise noted.

⁵Average Cr₂O₃ content was as follows: 1987—40.0%; 1988—39.0%; 1989—39.5%; 1990—39.2%; and 1991—39.0% (estimated). Brazil also reports run-of-mine crude ore production and Cr₂O₃ content in metric tons as follows: 1987—829,739 (172,215); 1988—779,258 (208,812); 1989-91—not available.

⁶Direct-shipping lump ore plus concentrate.

⁷Reported figure.

⁸Exports of direct-shipping ore plus production of concentrates.

⁹Includes production by Bophathatswana, which was as follows, in metric tons: 1987—522,900; 1988—536,500; 1989—676,154; 1990—468,262 (revised); and 1991—500,000 (estimated).

¹⁰Revised to zero.

*Estimated. ²Revised. NA Not available.

¹Reported figure.

²Includes Eastern and Western states.

³Includes production from Boputhatswana. Includes net production of ferrochromium-silicon if there was any.

⁴Soviet production of electric furnace ferrochromium is not reported; estimates provided are based on crude source material production and availability for consumption (including estimates) and upon reported ferroalloy trade, including data from trading partner countries.

⁵U.S. output of ferrochromium includes high- and low-carbon ferrochromium, ferrochromium-silicon, chromium metal, and other chromium materials.

⁶Data may not add to totals shown because of independent rounding.

⁷Ferrochromium includes ferrochromium-silicon (if any was produced) for Republic of South Africa and the United States.

CLAYS

By Robert L. Virta

Mr. Virta, a physical scientist with 16 years of U.S. Bureau of Mines experience, has been the acting commodity specialist for clays since 1991. Domestic survey data were prepared by Maria Arguelles, statistical assistant. The international tables were prepared by Ron Hatch, Douglas Rhoten, and Ted Spittal, international data coordinators.

The amount of clay sold or used by domestic producers increased 3% in tonnage to 44 million metric tons and decreased 7% in value to \$1.5 billion. Production of ball clay, bentonite, and fire clay decreased in 1991. Common clay and shale, fuller's earth, and kaolin production increased. Common clays accounted for 62% of the tonnage, and kaolin accounted for 61% of the value of clays produced in 1991. Imports increased 17% in tonnage to 35,000 tons and 11% in value to \$13 million. Exports decreased 3% in tonnage to 4 million tons and increased 1% in value to \$590 million. (See table 1.)

Clays were produced in 44 States and Puerto Rico. The seven leading producer States, in descending order, were Georgia, Wyoming, Texas, Ohio, Alabama, California, and North Carolina. (See table 2 and 3.)

DOMESTIC DATA COVERAGE

Domestic production data for clays are developed by the U.S. Bureau of Mines from one voluntary survey of U.S. operations. Of the 1,799 operations covered by the survey, 1,240 responded, representing 75% of the total clay and shale production sold or used shown in table 1. (See table 1.)

BACKGROUND

Definitions, Grades, and Specifications

Clays are categorized into six groups by the U.S. Bureau of Mines. The

categories are kaolin, ball clay, fire clay, bentonite, fuller's earth, and common clay and shale. The definitions listed in this work for the high-alumina clays, kaolin, ball clay, and fire clay are similar to those in U.S. Bureau of Mines Information Circular 8335.¹

Kaolin, or china clay, is defined as a white, claylike material composed mainly of kaolinite and other kaolin-group minerals, such as halloysite and dickite. Kaolin has a specific gravity of 2.6 and a fusion point of 1,785° C. Kaolin is classified according to the method of preparation (crude, air-separated, water-washed, delaminated, air-dried, calcined, slip, pulp, slurry, or water suspension) and on specific physical and chemical properties.

Ball clay is a plastic, white-firing clay used mainly for bonding in ceramicware. The clays are of sedimentary origin and consist mainly of the kaolinite, sericite mica, and organic matter. Ball clays usually are much finer grained than kaolins and are renowned for their plasticity. They are classified according to the method of preparation (crude, shredded, air-floated, water-washed, or slurry) and specific physical and chemical properties.

Fire clay is defined as detrital material, either plastic or rocklike, that commonly occurs as underclay below coal seams. Low concentrations of iron oxide, lime, magnesia, and alkalis in fire clay enable the material to withstand temperatures of 1,500° C or higher. It is composed mainly of kaolinite. Fire clays also contain other clays such as diaspore,

burley, burley-flint, ball clay, and bauxitic clay and shale. Fire clays generally are used for refractories or to raise vitrification temperatures in heavy clay products. The fired colors of fire clays range from buffs to grays. Fire clays are classified according to their physical and chemical properties and the characteristics of the products made from them.

Bentonite is a clay composed primarily of smectite minerals. The primary smectite mineral is usually montmorillonite. Swelling-type bentonite has a high-sodium ion concentration. Its volume increases 15 to 20 times its dry volume when wetted with water. Nonswelling bentonites usually are high in calcium. Bentonite is classified according to its physical and chemical properties, with particular emphasis on particle size and swelling index.

The term "fuller's earth" is derived from the first major use of the material, which was for cleaning textiles by fullers. Fuller's earth does not refer to a clay with a specific composition or mineralogy. It is defined as a nonplastic clay or claylike material, usually high in magnesia, that is suitable for decolorizing and purifying mineral and vegetable oils. They are composed mainly of the needle- and/or lath-shaped clay mineral attapulgite or varieties of montmorillonite. Fuller's earths containing opal or other forms of colloidal silica also are produced. Fuller's earths are classified according to their physical and chemical properties. Sepiolite-type clays are grouped with

fuller's earths under the Bureau classification system.

Common clay is defined as a clay or claylike material that is plastic enough to mold easily. Its vitrification point is usually below 1,100° C. Shale is a laminated sedimentary rock that is formed by the consolidation of clay, mud, or silt. The common clays and shales are composed mainly of illite or chlorite. They also may contain kaolin and montmorillonite. Common clays and shales usually contain more alkali, alkaline earth, and ferruginous minerals and less aluminum than high-quality kaolins, fire clays, and ball clays. Iron present in the clay usually imparts a reddish color to the final product after firing. There is no formal classification of common clays and shales, although a clay may sometimes be referred to as common, brick, sewer pipe, or tile clay. Clay and shale are used in the manufacture of structural clay products such as brick, drain tile, portland cement clinker, and expanded lightweight aggregates.

The American Society for Testing and Materials, American Foundrymen's Association, American Oil Chemist's Society, American Petroleum Institute, Technical Association of the Pulp and Paper Industry, and other national organizations have developed tests and set standards for some applications. Many producers and consumers, however, use nonstandardized tests that are applicable to their specific needs. Individual companies often set the acceptable limits of mineralogical composition, particle size, and other physical and chemical properties. Detailed data on specifications have been published by the U.S. Bureau of Mines.²

Products for Trade and Industry

Because of the many types of clay and different qualities within each type, the consumption pattern and the products for trade and industry are constantly changing. Consumption of kaolin in refractories has been growing since 1970 because of the increasing popularity of castable, ramming, gunning, and plastic

mixes that use calcined kaolin aggregates (grog) in their formulations.³ The consumption of calcined kaolin grogs also has increased in refractory brick manufacturing, replacing imported calcined refractory-grade bauxite grogs. Bentonite products for waterproofing and sealing in construction and reservoir uses also have gained in popularity. Attapulgite-type fuller's earth production, like bentonite, is finding increasing applications in the premium drilling mud industry.

Industry Structure

An estimated 319 companies operating more than 1,000 clays pits or mines reported production in 1991; of these, 103 companies, most with multiple operations, accounted for approximately 66% of the tonnage and 75% of the value for all types of clay produced and sold or used. Clay production was reported in all States and Puerto Rico except Alaska, Delaware, Hawaii, Rhode Island, Vermont, Wisconsin, and the District of Columbia.

The leading clay-producing States were Georgia, 9.5 million tons; Wyoming, 2.5 million tons; Texas, 2.3 million tons; Ohio, 2.2 million tons; Alabama, 2.1 million tons; North Carolina, 2.1 million tons; and California, 2.1 million tons. (See table 2.) Most of the clay is mined by open pit methods. Less than 2% of U.S. clay output is from underground mines in 1991. Most of the underground production is in Pennsylvania, Ohio, and West Virginia, where the clays are mainly underclays associated with coal and suitable for refractory uses.

Forty-two firms operated 141 kaolin mines in 14 States. In 1991, three large, diversified firms accounted for about 60% of total domestic kaolin output. Most large kaolin producers have operations in Georgia, which accounted for 79% of the kaolin production.

The ball clay industry is small, with 6 producers operating 36 mines in 5 States in 1991. Three of the producers were large, diversified firms with widespread foreign and domestic mineral interests.

Tennessee ball clay production represented about 66% of the total output.

Fireclay producers were mostly refractories manufacturers that used the clay in firebrick and other refractories. Seventy-eight mines were operated in 1991 by 19 firms in 7 States.

Firms producing bentonite operated 144 mines in 11 States. Four producers were large, diversified firms with international mineral operations; three of the firms had interests in other types of clay in the United States. Wyoming was the leading State, accounting for 73% of the total output. Swelling-type bentonite is produced mainly in Montana and Wyoming and nonswelling-type bentonite is produced in Mississippi and Texas. The United States is the world's largest producer and exporter of bentonitic clays.

Nineteen companies produced fuller's earth from 37 mines in 10 States. Eleven of the mines were in the attapulgite-fuller's earth areas of Florida and Georgia. These two States accounted for 35% of domestic production. Most producers were small, independent firms, but three were large, diversified corporations with international mineral interests. The world's fuller's earth needs are supplied from relatively few areas. The United States is the world's largest producer and user of fuller's earth.

Firms producing common clay and shale in 1991 were manufacturers of structural clay products, clay pipe, lightweight aggregates, and cement. Most companies mined the clays used in making their products. Private mining contractors and haulers were employed in many of the operations. Some producers were diversified firms having interests in metals and other nonclay products. Some companies owned and operated several clay pits and plants in order to cover a large market area. The economic radius for shipment of common clay or shale products is usually 200 miles or less. The high cost of transport promotes the development of local ownership companies, or in the case of a large firm, the ownership and operation of several strategically located pits and associated fabricating plants.

Geology-Resources

Clay is formed by the mechanical and chemical breakdown (weathering) of rocks. The weathering products consist of mineral grains and rock fragments of different size and different physical and chemical properties. The nonplastic portion consists of altered and unaltered rock fragments (grit), which are usually quartz, micas, feldspar, and iron oxides. The plastic portion usually is composed of clays and is low in grit.

Clays may be classified as residual or sedimentary. Residual clays are deposited in the same location in which they were formed. Sedimentary clays are those that have been transported, usually by water, and deposited elsewhere.⁴ Sedimentary clays often undergo further alteration and classification during transport. Kaolin deposits in Georgia and South Carolina are sedimentary. Kaolin deposits in North Carolina and English china or kaolin clay deposits are residual.⁵ The Kentucky and Tennessee ball clays and the Missouri fire clays are sedimentary deposits. Most bentonites, montmorillonites, and fuller's earth were formed in place through the weathering of volcanic ash or tuff. The attapulgite-type fuller's earth deposits of Florida and Georgia were probably not formed from volcanic ash or tuff. Geologists have never found any evidence of volcanic materials associated with these deposits.⁶

The definitions of reserves and reserve base are published in U.S. Geological Survey Circular 831, "Principles of a Resource/Reserve Classification for Minerals." Reserves are the part of an ore body that can be economically extracted at the time of evaluation. Reserve base is the part of an ore body that meets specified minimum physical and chemical criteria related to current mining and production practices. Reserve base includes reserves, marginal reserves, and subeconomic resources.

Common clays and shale deposits are found throughout the United States. Clays and shale were mined commercially in 43 States and Puerto Rico. Domestic resources are almost unlimited. Not all deposits, however, are near potential

markets, and most deposits are not suitable for all applications. For example, most common clay or shale deposits can be used to manufacture common brick, but the color or strength of the final product may not meet the requirements of the local market. Relatively few deposits are suitable for manufacture of lightweight aggregate. Even with these limitations of location and use, resources of common clay and shale are "virtually unlimited."

U.S. reserves of other types of clays that are owned or controlled by domestic producers are estimated to be about 700 million tons. U.S. reserves of kaolin are estimated to be 400 million tons; ball clay, 30 million tons; fire clay, 100 million tons; bentonite, 120 million tons; and fuller's earth, 60 million tons.

Large quantities of high-quality kaolin suitable for paper-coating and paper-filler are found in Georgia. A small area in Florida and Georgia contains sizable reserves of attapulgite-type fuller's earth. Most bentonite for iron ore pelletizing and oil-well-drilling muds is mined in Wyoming. Fire clay deposits, such as those found in Missouri, are widespread. Deposits of high-quality fire clay are nearing depletion. Kentucky and Tennessee are two of only a few States that have sizable deposits of ball clay.

Technology

Exploration.—Exploration begins with an understanding of the geological occurrence of the clays of interest. With this knowledge, potential economic deposits can be located. Auger or core drills are then made to delineate the size and shape of the deposit and to obtain material for testing.

Kaolins usually are evaluated for filler and ceramic applications. The grit, particle size, brightness, and leachability are determined. Air-floated clays normally require only grit and brightness determinations. Kaolin, ball clay, and fire clay for ceramic and/or refractory applications are analyzed for grit, brightness, green and dry strengths, fired color, and iron and alumina contents. The common clays and shales usually are

tested according to the intended end use, such as brick, structural-drain tile, or lightweight aggregate. Usually, prepared specimens are tested for plasticity, green strength, shrinkage, vitrification temperature range, etc. For lightweight aggregates, the bloating range is determined. Bentonites and fuller's earth clays are difficult to evaluate because there is no standard testing procedures or specifications. Generally, they are processed to meet the purchaser's specifications.

Mining.—Most clays are mined from open pits using modern surface mining equipment such as draglines, power shovels, front-end loaders, backhoes, scraper-loaders, and shale planers. Some kaolin is extracted by hydraulic mining and dredging. A few clay pits are operated using crude hand-mining methods. A small number of clay mines, principally in underclays in coal mining areas, are mined underground using room-and-pillar methods. Clays usually are transported by truck from the pit or blending areas to the processing plants. Rail, conveyor belt, and in the case of kaolin, pipelines also are used.

About 100% of the clay is recovered from the minable beds in most open pit operations. Approximately 75% is recovered in underground operations. The waste-to-clay ratio is highest for kaolin, about 7:1, and lowest for common clay and shale, about 0.25:1.

Processing.—Clays are used in a large number of products so they must be treated in many different ways. Processing can consist of very simple and inexpensive crushing and screening for some common clays. It also can consist of very elaborate and expensive grinding, sizing, bleaching, delamination, etc., for paper-coating clays and high-quality filler clays for use in rubber, paint, plastic, and other products. In general, processing does not appreciably alter the chemical or mineralogical characteristics of the clays. The two exceptions are calcining and cation exchange.

Significant processing losses occur with kaolin and fuller's earth. About 40% of the kaolin and 30% of the fuller's earth delivered to the processing plants is discarded. Waste material from processing consists mostly of off-grade clays and small quantities of quartz, mica, feldspar, and iron-bearing minerals.

Kaolin.—Processing involves one or more of the following: crushing, blunging with dispersant, rough sedimentation, water fractionation, magnetic separation, ultraflotation, acid treatment, calcination, air floating, and attrition grinding, slurring, and delaminating. Kaolins used for paper-coating applications may be bleached and further delaminated by grinding, deflocculation, and elutriation to special sizes. Ultraflotation or wet magnetic separation treatment may be used to remove iron- or titanium-bearing minerals to obtain a whiter product.

Ball Clay.—Processing involves drying, shredding, pulverizing, air floating, and slurring.

Fire Clay.—Processing involves crushing, calcining, and blending.

Bentonite.—Processing involves weathering, drying, grinding, sizing, granulation, and the use of additives for cation exchange.

Fuller's Earth.—Processing involves blunging, extruding, drying, crushing, grinding, sizing, and dispersing.

Common Clay and Shale.—Processing involves crushing, blunging, extruding, and drying. Common bricks, tile, lightweight aggregate, etc., require firing in a kiln. The kiln firing or drying operation produces a finished manufactured product.

Processing costs for clays range from a few cents per ton for some common clays to more than \$400 per ton for some special paper-coating clays and high-

quality clays that require very elaborate and expensive treatments.

Price schedules, although not complete, are available and are published regularly in trade journals such as the American Paint and Coatings Journal, Chemical Marketing Reporter, and Industrial Minerals (London).

Federal tax laws allow clay producers a depletion allowance on both domestic and foreign gross income not to exceed 50% of net income with depletion deduction. Depletion allowances are as follows: ball clay, bentonite, kaolin or china clay, sagger clay, and clay used or sold for purposes dependent on its refractory properties, 14% domestic and 14% foreign; fuller's earth, 14% domestic and 14% foreign; clay used for extraction of alumina or aluminum compounds, 22% domestic; clay used or sold for use in manufacturing drainage and roofing tile, flower pots, and kindred products, 5% domestic and 5% foreign; and clay and shale used for making brick, tile, and lightweight aggregate, 7.5% domestic and 7.5% foreign. Severance taxes are levied by some producing States.

Byproducts and Coproducts

Firms in California, Florida, and Texas produce silica glass sand as a coproduct of its kaolin production. Flake mica is a byproduct in one kaolin operation in North Carolina. Bauxite is a coproduct in kaolin operations in Alabama and Georgia. Clay and limestone for cement manufacture are often produced from the same property and reported as coproducts or byproducts even though they are usually mined separately from different formations or beds. Sand, gravel, and stone aggregates are occasionally produced together with common clays.

Economic Factors

Economic factors affecting clays vary in importance with type, quality, and intended end use. The cost of transportation is an important factor for the common clay and fire clay industries;

mines must be close to consumers to be cost competitive. Other types of clays are less abundant and have higher unit values. They can be shipped greater distances from the mines and still be cost competitive. For example, paper-coating clay from Georgia and attapulgitic-type fuller's earth from Florida and Georgia can be shipped nationwide. Bentonite for iron ore pelletizing from Montana and Wyoming can be shipped a considerable distance to the iron ore centers. In some of these cases, the shipping costs exceed the value of the clays at the mine or processing plant.

Because most clays are relatively low-cost materials in the crude state, mining costs must be kept as low as possible. Cost of the crude clays ranges from less than \$3 per ton for some common clays to more than \$20 per ton for some of the higher quality materials.

Very little clay is imported because transportation costs would make the clays noncompetitive in price. Consequently, import duties have little impact on the amount of clays imported.

Operating Factors

To manufacture finished clay products, producers require equipment to mine and process the crude clay and a kiln for firing or drying their products. Mining, processing, and manufacturing are all energy-intensive operations. Many clay producers converted to coal from oil firing and gas firing. However, the conversion to coal and/or wood as a kiln fuel is gaining in popularity where feasible in heavy clay and refractory products manufacturing and in bentonite processing.

Losses in mining are extremely small, except in underground mining where recovery will average about 75%. Processing losses for material receiving, crushing, grinding, mixing, shredding, blending, and drying also are insignificant. Losses from washing, sizing, etc., reach 30% or 40%.

Clay mining lacks many of the hazards associated with other types of mining because only a few deposits require the use of explosives and most mines are

open pit earth-moving operations. Domestic mine employment in 1991 was estimated to be 2,000 workers. Domestic mill employment was estimated to be 9,100 workers.

ANNUAL REVIEW

Issues

Clay mining has an environmental impact because of the disturbance to the land. Overburden is moved and clays are removed, leaving a depression or pit. State laws usually require leveling or recontouring of the disturbed area and planting trees or grasses to minimize erosion. For processing, the impoundment of slimes and dust control are usually required. The rules for disposal of coarse tailings are similar to or included with those laws governing reclamation of the mined area.

Many local governments are enacting stricter regulations. In some cases they change the land use zoning. New regulations and land use changes sometimes force a mine to close or relocate to a more distant deposit, increasing costs to the community because of increased transportation charges.

An issue that continues to interest a segment of the clay industry is the classification of crystalline silica as a probable human carcinogen. Mineral products containing 0.1% or more crystalline silica must be labeled in accordance to the Occupational Safety and Health Administration's Hazard Communication Standard (HCS), and employers must comply with the terms of HCS with regard to worker training. Some States are enacting stricter regulations with regard to crystalline silica based on the health findings.

Although domestic clay resources are more than adequate and clay is a mature industry, the average price for clays is expected to rise steadily. The increased prices reflect the demand for higher quality specialty clay by consumers and increased costs associated with land acquisition, severance taxes, land rehabilitation, energy requirements, and

environmental factors. These rising prices, if unchecked, will have an adverse affect on the clay industry by making competing materials more cost competitive.

Production, Prices, and Foreign Trade

ECC Group PLC, United Kingdom, announced the sale of Southern Clay Products Inc. to Laporte PLC. Southern Clay Products mines ball clay from a mine near Gonzales, TX, and bentonite from a mine in Kaycee, WY.⁷

Approval was granted for the expansion or creation of several mines, including a kaolin mine near Belview, MN, and common clay operations near Lewiston, ME, and Quinton, NJ.⁸

Kaolin.—Domestic production of kaolin increased 5% to 9.5 million tons. The value of production decreased 3% to \$9.2 billion. The unit value of kaolin decreased 8% to \$96 per ton. Filler- and refractory-grade kaolin had the highest reported values. Kaolin was produced in 14 States. Georgia accounted for 79% and South Carolina accounted for 6% of total production. Georgia accounted for more than 94% of the total production value. (See table 4.) Filler, refractory, chemical- and water-washed, air-floated, and unprocessed grades were produced in Georgia. South Carolina produced only air-floated and unprocessed grades of kaolin. (See tables 5, 6, 7, 8, 9, and 10.) Arkansas and California produced refractory- and chemical-grade kaolins. Kaolin producers reported major domestic end uses as paper-coating, 34%; paper-filling, 14%; refractories, 21%; fiberglass and insulation, 5%; face brick and rubber, 3% each; and paint and chemicals, 3%. (See table 11 and figure 1.)

Asea Brown Boveri Inc. sold Dry Branch Kaolin Co. to Imetal. The Dry Branch operation produces kaolin for the ceramics, ink, paint, paper, and rubber industries.⁹

Despite the overall slow economy, kaolin production increased. Domestic sales of paper-grade kaolin decreased 5%

from those of 1990. However, the trend toward the use of high-quality coated papers resulted in a growth of 4% for coating clay. Exports increased 35% because of a continued weak U.S. dollar. U.S. sales of unprocessed kaolin declined 35% because of the completion of a major project that required large tonnages of low-value unprocessed kaolin. Calcined and water-washed kaolin production increased 76% and 9%, respectively. This contrasts with an 18% decrease in sales of delaminated and 21% decrease in sales of air-float kaolin. (See tables 5, 6, 7, 8, 9, 10, and 11.)

Exports of kaolin reported by the U.S. Department of Commerce increased 1% to 2.86 million tons valued at \$430 million. The unit value of the exported kaolin decreased slightly to \$150.71 per ton. Kaolin, including calcined material, was exported to 65 countries. The major importers, in descending order, were Japan, Canada, Finland, the Netherlands, Italy, and Mexico. Kaolin producers reported end-use markets for their exports as follows: paper-coating, 68%; paper-filling, 20%; rubber, 2%; and other, including ceramics, paint, and refractories, 9%. (See tables 11 and 26.)

Kaolin imports for consumption increased about 1% to 3,373 tons valued at \$1.6 million. The unit value increased about 7% to \$476.43 per ton, reflecting the continuing strong worldwide demand for premium-quality kaolin. (See table 27.)

Kaolin prices quoted in the trade journals generally were unchanged from those of the previous year. (See table 12.)

The Food and Drug Administration amended the food additive regulations to allow the use of modified kaolin in paper and paperboard intended for use in contact with food.¹⁰

Ball Clay.—Production of domestic ball clay decreased 1% to 784,000 tons valued at about \$33 million. Tennessee supplied 66% of the Nation's output, followed by, in descending order of production, Kentucky, Mississippi, Texas, and Indiana. Production decreased in all the major producing

States. The principal ball clay markets were dinnerware, floor and wall tile, and sanitaryware. (See tables 13 and 14.)

The average unit value for ball clay reported by domestic producers increased slightly to \$42.63 per ton. Listed prices in the Chemical Marketing Reporter, January 6, 1992, per short ton, were unchanged from those of 1991. (See table 12.)

Ball clay exports decreased 16% to 58,000 tons valued at \$2.9 million. The unit value increased to \$50.15. Shipments were made to 24 countries. The major importer was Mexico, with 79% of the exports. (See tables 14 and 26.)

Ball clay imports for consumption, almost entirely from the United Kingdom, also decreased 53% to 750 tons valued at \$262,000. The unit value of these clays increased more than 21% to \$347.94 per ton. (See table 27.)

Fire Clay.—Fire clay sold or used by domestic producers decreased 24% in tonnage to 474,000 tons and 18% in value to \$13.1 million. Missouri was the leading producing State followed by Ohio, Alabama, New Jersey, Pennsylvania, and New Mexico. (See table 15).

The clay refractory industry had been in a period of low production because of decreased demand brought about by technological changes and lower consumption levels by its major users—steel, nonferrous metals, ceramics, glass, and minerals processing industries. The technological changes in steelmaking, away from integrated pig iron systems and toward electric furnaces and/or minimills, further compounded the problem by employing shapes and specialty refractories requiring less fire clay.

Fire clay was produced from mines in six States. Missouri, Ohio, and Alabama, in descending order of volume, accounted for more than 89% of the total domestic production.

North American Refractories Co. merged with Didier Taylor Refractories Corp. The combined companies will

operate under the North American Refractories name.¹¹

Exports of fire clay decreased 7% to 199,000 tons. The unit value of exported clay increased 9% to \$95.48 per ton. Fire clay was exported to 33 countries. The major recipients, in descending order, were the Netherlands, Mexico, Japan, Australia, and Taiwan. Fire clay imported from two countries amounted to 425 tons valued at \$80,000. (See tables 26 and 27.)

The unit value for fire clay, reported by producers, ranged from about \$5 to \$43 per ton.

Bentonite.—Bentonite production decreased more than 3% to 3.4 million tons, while the value increased 2% to \$125.4 million. Wyoming was the largest bentonite producer, accounting for 73% of production. Wyoming also was the leading producer of swelling bentonite. (See table 16.) The three major end uses were drilling mud, foundry sand, and iron ore pelletizing with 20%, 17%, and 21%, respectively, of total sales. Sales of bentonite to the foundry sand and iron ore pelletizing industries increased 5% in 1991. (See figure 17.)

For the past 2 years, bentonite producers have reported that about 700,000 tons of bentonite was sold to the iron ore pelletizing industry, more than that in previous years. Domestic bentonite consumption, based on data provided by the domestic iron ore pelletizing industry, was estimated to be between 510,000 and 520,000 tons. Bentonite exports to Canadian iron ore pelletizers were estimated to be between 110,000 to 130,000 tons, making sales to U.S. and Canadian pelletizers between 620,000 to 650,000 tons. Bentonite also was exported to other countries for pelletizing iron ore.

Bentonite was produced in 11 States. Most of the high-swelling or sodium bentonite was produced in Wyoming. Mines in Alabama and Mississippi produced more than one-half of the low-swelling or calcium bentonite. Calcium bentonite produced in Alabama and

Mississippi was suitable for the production of absorbent, acid-activated, and foundry products. (See table 16.)

American Colloid Co. built a new blending facility in Alabama. The facility processes bentonite for use by the foundry industry.

The quoted price in the Chemical Marketing Reporter, January 6, 1992, for domestic bentonite, carload lots, f.o.b. mines, was \$28.60 per ton. The average unit value reported by domestic producers increased 3% to \$36.54 per ton.

Bentonite exports decreased 6% to 660,000 tons valued at \$63.6 million. The unit value of exported bentonite increased about 18% to \$96.32 per ton. Bentonite was exported to 61 countries, 37 more than those in 1990. The six major recipients, in descending order, were Japan, Canada, Taiwan, United Kingdom, Venezuela, and Australia. Domestic bentonite producers reported their exports were foundry sand, 62%; drilling mud, 24%; and others, 14%. (See tables 17 and 26.)

Bentonite imports for consumption consisted mostly of untreated bentonite clay and chemically or artificially activated materials. Bentonite imports increased 9% to 2,224 tons. Canada was the largest supplier of bentonite. The chemically activated category decreased 3% to 1,084 tons valued at \$1.8 million. Mexico accounted for 62% of the chemically activated bentonite imported into the United States. This was an increase of 9% over that of 1990. (See table 27.)

Fuller's Earth.—Production of fuller's earth increased 19% to 2.74 million tons valued at \$270 million. Reported production of fuller's earth is greater than that of 1990 because two producers were included under the fuller's earth category for the first time. They were reported under other clay categories in the past. The average unit value increased 2% to \$98.70 per ton. Production was reported in 10 States. Florida and Georgia accounted for nearly one-half of domestic production. Pet waste absorbents

accounted for 65% of consumption. (See table 18 and figure 3.)

Production from the region that includes Attapulugus, Decatur County, GA, and Quincy, Gadsden County, FL, is composed predominantly of the lathshaped amphibolelike clay mineral attapulugite. Most of the fuller's earth produced in other areas of the United States contains varieties of montmorillonite and/or other clays.

Attapulugite, a fuller's earth-type clay, finds wide application in both absorbent and gelling and/or thickening areas. The thixotropic properties of attapulugite clays provide the important thickening and viscosity controls necessary for suspending solids. Mineral thickeners are used in such diverse markets as paint, joint compound cement, and saltwater drilling mud.

Fuller's earth was exported to 29 countries, 1 less than that in 1990. The quantity decreased 59% to 27,000 tons. The unit value of exported fuller's earth increased 27% to \$164.44. The increase was attributed to a larger percentage of high-cost gelling and drilling mud grades shipped. Most of the fuller's earth was shipped to Canada (22%) and the Netherlands (33%). Small amounts of decolorizing fuller's earth were imported from Canada and the Federal Republic of Germany. (See tables 19, 26, and 27.)

Common Clay and Shale.—Domestic sales or use of common clay and shale increased 5% in tonnage to 27.2 million tons and increased 4% in value to \$141 million. Of the nine major producing States, production increased in Alabama, California, Michigan, Missouri, South Carolina, and Texas and decreased in Georgia, North Carolina, and Ohio. Common clay and shale represented about 62% of the quantity but only 9% of the value of total domestic clay production. (See table 20.)

Domestic clay and shale are generally mined and used captively to fabricate or manufacture products. Less than 10% of the total output is usually sold. The average unit value for all common clay and shale produced in the United States

and Puerto Rico decreased 11% to \$5.18 per ton. The reported unit value ranged from \$2 per ton to \$36 per ton.

Consumption and Uses

The manufacture of heavy clay products, including (1) building brick; sewer pipe; and drain, roofing, structural, terra cotta, and other tile; (2) portland cement clinker; and (3) lightweight aggregate, accounted for 29%, 23%, and 8%, respectively, of total domestic consumption. (See table 21.)

Kaolin has many industrial applications, and many grades are specifically designed for use as a filler in paper, paint, rubber, plastics,¹² and ceramics.¹³ New uses are constantly being developed. Kaolin is a unique industrial mineral because it is chemically inert over a relatively wide pH range, is white in color, and has good covering or hiding power when used as a pigment or extender in coated films and filling applications. It also is soft and nonabrasive, has low conductivity of heat and electricity, and costs less than most materials with which it competes. Fillers and extenders must meet very rigid specifications such as particle size, color, brightness, and viscosity.¹⁴

Ball clays are extremely refractory and their use, largely in whitewares, imparts a high green strength as well as plasticity to the bodies. Although white-firing ball clays are preferable, fired products that range to cream or buff colors do not generally impair the quality of the whiteware products.

Fire clays are used mostly in commercial refractory products such as firebrick and block of many shapes, insulating brick, saggars, refractory mortars and mixes, ramming and gunning mixes, grog and crude aggregates, and many other products. Fire clays are also added to common clays to increase the vitrification range of sewer pipes and bricks.

The swelling sodium bentonites are used largely in drilling muds, in foundry sands, and in pelletizing taconite iron ores. The nonswelling or calcium bentonites are used mostly in conjunction

with the swelling bentonites in foundry sand mixes in which the sodium bentonites provide dry strength and the calcium bentonites provide high green strength. Fuller's earth and calcium bentonites find application in decolorizing and purifying mineral, vegetable, and animal oils. Clays used to process animal or vegetable oils usually are activated by acid treatment. Acid treatment produces a highly absorbent sievelike structure. Attapulugite is used in drilling muds instead of sodium bentonites for drilling saltwater formations. Sodium bentonite flocculates in brine, thereby destroying the colloidal suspension required for drilling. The major uses for attapulugite and montmorillonite types of the fuller's earths are in pet waste and oil and grease absorbents because of their absorbent properties.

Bentonite also is used for foundry casting by the steel, iron, and nonferrous casting. The bentonite provides good green strength and desirable dry strength characteristics. Sodium bentonites are used in steel casting. Ion-exchanged bentonites are used for iron and nonferrous casting. There is increased use of mixtures of ion-exchanged and sodium bentonites to meet the more stringent demands of the casting industry.¹⁵

Construction.—Common clays and shales are used to manufacture a wide variety of construction materials such as structural clay products, cement, and expanded aggregates.

Structural Clay Products.—Structural clay products such as building brick, drain tile, and vitrified sewer pipe are used in building construction, for sewer systems, to drain farmers' fields, and for many other uses. Other clays, such as kaolin, fire clay, or ball clay, could in many cases be used to produce equally suitable "heavy clay" products, but they are generally more refractory and valuable for other uses. Of the total clay produced, about one-third is consumed in the manufacture of these structural products.

Hydraulic Cement.—The portland cement industry requires alumina and silica as constituents in the manufacture of portland cement. Common clays provide a low-cost source of these materials.

Expanded Clay and Shale.—For this purpose, certain bloating qualities and strength are required. Lightweight concrete blocks, floors, walls, and other shapes made from expanded clay and shale have a lower overall weight, which results in savings in the design of the supporting framework. Also, products made from expanded clay and shale have better insulating qualities than equivalent products made with sand and gravel and crushed stone aggregates.

Refractories.—Refractories require strength at high temperatures, resistance to corrosion, low coefficient of expansion, and many other physical and chemical properties, depending on the application. Clays with physical properties most suitable for general refractory use have been classed as fire clays. The current trend is for refractories designed for a specific use and castable mixes containing refractory aggregates and calcium aluminate cements.¹⁶

Paper Products.—Demand for clays for use as filler and coater in paper has followed the rapid increase in demand for paper. Kaolin is the principal clay used.

Other Uses.—Pottery and related products require good ceramic qualities, including plastic formation, desirable firing temperatures, color, etc. The principal clays meeting these and other specifications are ball clay and kaolin. Kaolin also is used as a raw material feed in formulating bottle and plate glass batches. Drilling mud is a scientifically designed mixture of several items. It contains, in addition to bentonite or attapulgite, ground barite for its high specific gravity.¹⁷ Demand for bentonite in iron and steel production is based on

its ability to form strong iron ore pellets from fine-grained taconite concentrates. Easily handled hard pellets are essential for efficient blast furnace operation.

Heavy Clay Products.—The value reported for shipments by the Bureau of the Census for heavy clay products decreased 20% to \$1.4 billion. The million standard brick count for building or common face brick decreased 20%. Shipments of clay floor and wall tile decreased 16% while vitrified clay and sewer pipe fittings decreased 15%. (See tables 22 and 23.)

Lightweight Aggregates.—Consumption of clay and shale in the production of lightweight aggregate decreased 5% to 3.6 million tons. Concrete block, the largest category, (67% of total production), decreased 3% while the second biggest consuming area, structural concrete (20% of total production), decreased 10%. The third largest segment, highway surfacing (8% of production), increased slightly. The other category, the smallest segment consisting essentially of market areas such as recreational and horticultural uses, decreased 20%. (See table 24.)

Refractories.—All types of clay, except for fuller's earth, were used in manufacturing refractories. Kaolin, bentonite, and fire clay accounted for 57%, 26%, and 13%, respectively, of total clay used for this purpose. (See table 21.) The remainder, ball clay and common clay and shale, was used chiefly as bonding agents. Bentonite, both swelling and nonswelling, was used as a bonding agent in proprietary foundry formulations imparting both hot and green strength to the sand.

The tonnage of clays used for refractories increased 6% and constituted 7% of total clay produced. The continued use of high-alumina, clay-based refractories, mostly calcined kaolin grogs in monoliths, and the upturn in demand for the more conventional refractory bricks and shapes were largely responsible. (See table 25.) The major

refractory consuming industries—cement, foundry, glass, and ferrous and nonferrous metals—continued to undergo major changes in technology and production levels for their products.

Filler.—Bentonite, fuller's earth, and kaolin are the principal filler clays. Kaolin, either air-floated, water washed, low-temperature calcined, and/or delaminated, was used in the manufacture of adhesives, paint, paper, plastics, and rubber. Fuller's earth was used primarily in pesticides and fertilizers. Clays were used in pesticides and fertilizers as either thickeners, carriers, dilutents, or prilling agents. Bentonites were used mainly in animal feeds.

Of the total clay produced, 12% was used in filler applications; of this, kaolin accounted for 86%; fuller's earth, 7%; bentonite, 3%; and ball clay, common clay and shale, and fire clay, 4%. Kaolin consumed as fillers decreased 14% to 4.4 million tons. Use of paper-coating-grade kaolin increased 4%, and the use of paper-filler-grade kaolin decreased 22%. These two categories accounted for 71% of the total filler and extender category. (See table 21.)

Absorbent Uses.—Absorbent uses for clays accounted for about 2.4 million tons or 5% of total clay consumption. Demand for absorbents increased 14%. Fuller's earth was the principal clay used for absorbent purposes. This application accounted for 88% of its entire output. Demand for clays in pet waste absorbents increased significantly. The use of fuller's earth in floor or oil and grease absorbents, chiefly to absorb hazardous oily substances, accounted for 16% of the absorbent demand. (See table 21.)

Drilling Mud.—Demand for clays in rotary-drilling muds decreased to about 724,000 tons and accounted for 2% of total clay production. Swelling-type bentonite remained the principal clay used in drilling mud mixes, although fuller's earth, used mostly in saltwater drilling techniques, and nonswelling sodium-activated bentonites were also used to a

limited extent. Bentonite and fuller's earth accounted for 100% of the total amount of clays used in this category. (See table 21.)

Floor and Wall Tile.—Common clay and shale, ball clay, and kaolin, in order of volume, were used in manufacturing floor, wall, and quarry tile. This end-use category accounted for 19% of the total clay production. (See table 21.)

Pelletizing Iron Ore.—Bentonite continued to be used as a binder in forming indurated iron ore pellets. Demand decreased 2% to 717,000 tons. (See table 21.)

Ceramics and Glass.—Total demand for clay in the manufacture of pottery, sanitaryware, china and dinnerware, and related products (excluding clay flower pots) accounted for 3% of the total clay output. This demand, principally ball and kaolin clays, decreased 28% to 1.01 million tons. The downturn in new residential housing construction, large consumers of whiteware and sanitaryware, was partially offset by the strong demand for these products in the remodeling areas. (See table 21.)

World Review

Capacity.—The data in tables 28, 29, and 30 are rated capacity for mines as of December 31, 1991. Rated capacity is defined as the maximum quantity of product that can be produced on a normally sustainable long-term operating rate based on physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure.

Mine capacity for domestic clay production was aggregated from data voluntarily supplied by producers. The rated capacity data for the foreign mines were estimated from previous years'

production in cooperation with the Division of International Minerals. (See tables 31, 32, and 33.)

Czechoslovakia.—Czechoslovakia produces bentonite and kaolin. Bentonite is produced primarily from North and West Bohemia. Bentonite is used in metallurgical, oil drilling, and paint applications. Czechoslovakia is the sixth largest producer of kaolin. Five grades of kaolin are produced: chinaware or porcelain grade, ceramics grade, paper grade, titaniferous grade, and feldspathic grade.¹⁸

Egypt.—A kaolin deposit with estimated reserves of 30 million tons has been discovered in the Kalbafha district by the Geological Survey and Minerals Projects Authority.¹⁹

Finland.—Engelhard Corp. announced plans to construct a plant for blending imported kaolin near Kotka. The plant will be able to provide papermakers with 40,000 tons of hydrated calcined kaolin per year.²⁰

France.—Coframines acquired a majority shareholding in Kaolins d'Arvor. Kaolins d'Arvor operates a mine and processing plant near Lorient. The company produces kaolin for paper and ceramics applications. Production capacity is 32,000 tons per year.²¹

Societe Kaoliniere Armoricaine (SOKA) mines kaolin from a deposit near Quessoy. The deposit consists of two kaolin layers, a white layer and a grey layer containing 0.2% organics. A mixture of 20% white kaolin and 80% grey kaolin is used for ceramic applications. The kaolin is washed and sized using hydrocyclones. The slurry is thickened and dried to about 30% moisture content. Driers reduce the final water content to about 12%. Besides ceramics applications, the company also produces kaolin for adhesive, animal feed, fertilizer, insecticide, and rubber applications.²²

Germany.—The Fuchs-Ton Division of Watts, Blake, Bearne & Co. PLC acquired a major share in the clay operations of Didier-Werke AG. The acquisition is expected to increase the company's clay sales by one-third. The clays are sold to the wall tile, floor tile, refractory, pipe, brick, and tableware industries.²³

Redland PLC, through its German subsidiary Braas, began negotiations for the purchase of brickworks and clay reserves in eastern Germany. The company will build a clay tile plant to supply the growing roof tile market.²⁴

Spain.—Spain currently produces attapulgite, ball clay, bentonite, kaolin, and sepiolite. Attapulgite and sepiolite are mined by nine companies. Attapulgite is sold primarily for animal feed and salt water drilling applications. Some of the major applications for sepiolite are pet litter, animal feed products, catalysts, absorbents, fertilizers, and fillers. There is only one major producer of bentonite, Minas de Gador SA. The company mines calcium bentonite in Almeria and Madrid. Untreated, ion-exchanged, and acid activated bentonites are produced for foundry applications, vegetable oil bleaching, animal feed, ceramic, and wine clarification. Ball clay is produced by SA Minera Catalono-Aragonesa for applications such as stoneware, bricks, and roof tiles. Kaolin is produced by six companies, primarily for paper, glass, and ceramic applications.²⁵

United Kingdom.—Laporte PLC announced plans to construct a clay processing facility in Cheshire. The plant capacity will be 200,000 tons per year of activated earth-based material and absorbent granules.²⁶

Current Research

The U.S. Bureau of Mines completed a study of the bonding mechanism between montmorillonite and high molecular weight polymers using infrared spectrophotometry. High molecular

weight polymers such as polyacrylamide (PAM) and polyethylene oxide (PEO) are used as flocculating agents. The results suggested that PAM was adsorbed to the clay by nitrogen atom of the polymer. PEO was bonded to the clay through a water bridge. PEO was thought to be adsorbed directly onto the surface of the bentonite.²⁷

OUTLOOK

U.S. clay demand between 1982 and 1992 has rebounded slowly from 32 million to 44 million tons. This is well below the levels of the early 1970's. In general, there has been a decrease in construction activity in the public, private, and commercial sectors. Higher mortgage rates in the late 1970's and early 1980's and the limited availability of affordable housing and funds for public and business ventures contributed to the problem. The slow economy of recent years continued to depress construction activities despite declining interest rates. Demand for common clay and shale, which are strongly tied to the construction industry, has declined over the past 10 years. Kaolin, ball clay, and fuller's earth have fared better than their common clay and shale counterparts because they are used in more diversified applications and industries. Domestic demand for specialty clays should remain strong in the near future.

The weak U.S. dollar in the latter part of the decade encouraged specialty clays producers to expand their share of export markets. Exports of domestic clays, mostly kaolin, bentonite, ball clay, and fuller's earth, are restricted to the higher valued specially treated varieties for use in drilling muds, papercoating, and iron ore pelletizing and by the foundry industry. Export markets should continue to remain strong in the near future. Imports of clays, except for English china and ball clays and acid-activated bentonites, are minor. The English clays enjoy a small prestige-dictated market, while the activated clays are confined to use in the Southern and Northern States.

¹Revised. W Withheld to avoid disclosing proprietary data; included with "Total" and/or "Miscellaneous."

²Includes high-temperature calcined.

³Includes low-temperature calcined and delaminated.

⁴Data may not add to totals shown because of independent rounding.

⁵Includes soil conditioners and mulches.

⁶Less than 1/2 unit.

**TABLE 12
PRICE QUOTATIONS FOR KAOLIN AND BALL CLAY, 1991**

	Per metric ton
Kaolin:	
Water-washed, fully calcined bags, carload lots, f.o.b. Georgia per ton	323.00
Calcined, paper-grade, same basis, per ton	470.00
Paper-grade, uncalcined, bulk, carload lots, f.o.b. Georgia, per ton:	
No. 1 coating	110.00
No. 2 coating	87.00
No. 3 coating	85.00
No. 4 coating	82.00
Filler, general purpose, same basis per ton	64.00
Delaminated, water-washed, uncalcined, painted-grade, 1-micrometer average, same basis, per ton	284.00
Dry-ground, airfloated, soft, same basis per ton	52.00
National Formulary, powder, colloidal, bacteria controlled, 50-pound bags, 5,000-pound lots, per ton	273.00
Ball clay:	
Domestic, airfloated, bags, carload lots Tennessee, per ton	49.00
Domestic, crushed, moisture-repellent, bulk carload lots, Tennessee, per ton	24.00

TABLE 25
SHIPMENTS OF REFRACTORIES IN THE UNITED STATES, BY PRODUCT

Product	Unit of quantity	1989 ^a		1990	
		Quantity	Value (thousand)	Quantity	Value (thousand)
CLAY REFRACTORIES					
Superduty fire clay brick and shapes, other fire clay, including semisilica brick and shapes, glasshouse pots, tank blocks, feeder parts, upper structure parts used only for glass tanks	1,000 9-inch equivalent	59,725	\$49,177	55,536	\$50,085
High-alumina (50% to 60% Al ₂ O ₃) brick and shapes made of calcined diaspor or bauxite	do.	92,082	163,719	92,590	168,559
Insulating firebrick and shapes	do.	49,006	57,879	48,587	53,985
Ladle brick sleeves, nozzles, runner brick, tuyeres, hot-top refractories	short tons	62,972	48,839	56,072	47,316
Kiln furniture, radiant heater elements, potter's supplies, other miscellaneous-shaped refractory items	do.	35,701	37,261	32,975	37,997
Refractory bonding mortars	do.	80,139	43,189	81,175	73,595
Plastic refractories and ramming mixes, containing up to 87.5% Al ₂ O ₃	do.	227,633	92,779	228,599	96,388
Castable mixes	do.	299,292	128,721	283,500	114,323
Gunning mixes	do.	171,453	49,928	158,261	46,980
Other clay refractory materials sold in lump or ground form	do.	412,907	86,937	352,763	72,523
Miscellaneous refractories	do.	XX	64,837	XX	40,779
Total clay refractories	do.	XX	823,266	XX	802,530
NONCLAY REFRACTORIES					
Silica brick and shapes	1,000 9-inch equivalent	12,823	24,252	18,340	26,933
Magnesite and magnesite-chrome brick and shapes	do.	(¹)	(¹)	(¹)	(¹)
Chrome and chrome-chrome brick and shapes	do.	(¹)	(¹)	(¹)	(¹)
Shaped refractories containing natural graphite	short tons	23,197	44,575	21,145	47,778
Zircon and zirconia brick and shapes; other carbon refractories: Forsterite, pyrophyllite, dolomite-magnesite molten-cast, other brick and shapes	1,000 9-inch equivalent	31,341	183,446	33,484	200,074
Other mullite, kyanite, sillimanite, or andalusite brick and shapes	do.	3,231	26,279	3,269	25,809
Other extra-high (over 60% alumina) brick and fused bauxite, fused alumina, dense-sintered alumina shapes	do.	6,679	103,387	5,753	96,576
Silicon carbide brick, shapes, kiln furniture	do.	1,688	44,579	1,558	45,823
Refractory bonding mortar	short tons	W	19,474	W	19,068
Hydraulic-setting nonclay refractory castables	do.	31,022	32,778	30,538	40,293
Plastic refractories and ramming mixes	do.	123,934	90,462	123,199	92,333
Gunning mixes	do.	W	W	W	W
Dead-burned magnesia or magnesite	do.	322,023	82,736	295,167	79,185
Dead-burned dolomite	short tons.	202,692	12,073	224,280	13,457
Other nonclay refractory material sold in lump or ground form	do.	310,878	110,423	329,589	109,608
Miscellaneous nonclay refractories	do.	XX	413,219	XX	426,575
Total nonclay refractories	do.	XX	1,187,681	XX	1,223,512
Grand total refractories	do.	XX	2,010,947	XX	2,026,042

Revised. W Withheld to avoid disclosing company proprietary data, value included in total. XX Not applicable. Included in miscellaneous nonclay refractories.

COBALT

By Kim B. Shedd

Ms. Shedd is a physical scientist (geologist) with more than 12 years of combined experience working for the U.S. Bureau of Mines in research and mineral commodities. She has been the commodity specialist for cobalt since 1988. Domestic survey data and trade data were prepared by Robin A. Johnson, mineral data assistant. International production tables were prepared by William L. Zajac, Chief, Section of International Data, and Ronald Hatch, international data assistant, in coordination with the Bureau's country specialists.

Cobalt is a strategic and critical metal used in many diverse industrial and military applications. The largest use of cobalt is in superalloys, which are alloys designed to resist stress and corrosion at high temperatures. The main use for superalloys is in jet engine parts. Another important use of cobalt is to make permanent magnets, which are used in a wide range of electrical devices. Cobalt acts as a binder in cemented carbides and diamond tools, which are used for metal cutting and forming, mining, and oil and gas drilling. Cobalt chemicals have diverse uses, including catalysts for the petroleum and chemical industries; drying agents for paints, varnishes, and inks; additives to ground coats for porcelain enamels; and pigments for ceramics, paints, and plastics.

The United States is the world's largest consumer of cobalt, but has no domestic production, so it relies on imports to meet its primary cobalt needs. The United States stocks significant quantities of cobalt metal in the National Defense Stockpile (NDS) for military, industrial, and essential civilian use during a national emergency.

For the fourth year in a row Western World cobalt demand exceeded Western World production. Zaire and Zambia, the world's two leading producers, began the process of democratization following decades of single-party rule. Zambia had a smooth transition to a new Government late in the year. Zaire, however, suffered from political discord resulting

from delays in converting to a multiparty system. In addition to political tensions, economic conditions in Zaire worsened, resulting in social unrest. In this framework of political and economic problems, La Générale des Carrières et des Mines du Zaire (Gécamines), the world's largest cobalt producer, tried to bring back production levels reduced by a major mine collapse that occurred in 1990. The company was unable to meet its production targets for cobalt, resulting in a further drawdown of already low producer stocks and an inability to complete its 1991 deliveries.

Concern over adequacy of supply caused free market prices to double in the latter part of the year. During the year, Japanese consumers built up significant stocks in fear of a shortage, resulting in a 50% increase in demand from that country. The Western World supply-demand imbalance would have been worse, were it not for recessionary economic conditions in consuming countries and a significant influx of cobalt from the U.S.S.R., which sold both Russian-produced and Government-stockpiled cobalt to Western markets.

DOMESTIC DATA COVERAGE

Domestic data on cobalt processing and consumption are developed by the U.S. Bureau of Mines from three separate, voluntary surveys of U.S. operations. In the cobalt processors survey, seven of the eight companies canvassed responded.

Most of the data on cobalt used in chemicals were obtained from this survey. The second survey covers a broad range of metal-consuming companies, such as superalloy producers, magnetic alloy producers, and tungsten carbide producers. The U.S. Bureau of Mines also surveys superalloy scrap recyclers to determine the consumption of secondary cobalt in superalloy production. Seven of the 13 recyclers on the survey responded to requests concerning the quantity of cobalt contained in scrap processed and sold to superalloy producers. The data in tables 3 through 6 contain estimates to account for nonrespondents.

BACKGROUND

Definitions, Grades, and Specifications

Cobalt is a metallic element. It is silvery gray in color, hard, ductile, somewhat malleable, and magnetic. Other properties include atomic number, 27; atomic weight, 58.93; melting point, 1,493° C; boiling point, 3,100° C; and Curie temperature, 1,121° C. Cobalt-60 (⁶⁰Co) is produced by irradiating cobalt metal in a nuclear reactor. This radioactive isotope is used in radiation therapy and sterilization of medical supplies.

Currently, there are no internationally recognized specifications for cobalt metal. The two leading Western World producers, Gécamines and Zambia

Consolidated Copper Mines Ltd. (ZCCM), have proposed specifications for five grades of cobalt.¹ The U.S. Government has purchase specifications for NDS cobalt. The current NDS specification, P-13-R6, provides physical and chemical requirements for three grades of refined cobalt metal. Grades A and B must be in the form of electrolytic cathode; grade C can be either cathode or granules. Chemical requirements specify the weight percentage, in order of abundance, of cobalt, nickel, iron, and manganese, as well as maximum levels of 26 impurities.

Products for Trade and Industry

Roughly one-half of the cobalt used in the United States is consumed as primary cobalt metal. Most of this metal is in the form of electrolytic cobalt (cathode or rounds), granules (shot), or metal powder. Some of the Russian cobalt metal is in ingot form and some of the Zambian cobalt is produced as crushed bar. Secondary cobalt is cobalt recovered from scrap. Purchased scrap constituted about 22% of U.S. reported consumption in 1991. The remainder of the cobalt used, about 30%, is in the form of cobalt chemical compounds. This includes cobalt oxide, which can be either gray oxide, with 75% to 78% cobalt content, or black oxide, with 70% to 74% cobalt content. The percent cobalt content in the oxides depends on the relative amounts of cobalt(II)oxide, CoO, and cobalt(II)dicobalt(III)tetroxide, Co₃O₄, present. Commercially available inorganic cobalt compounds include carbonate, chloride, hydroxide, nitrate, and sulfate (either as heptohydrate or monohydrate). Most of the inorganic compounds are sold in crystalline form, but some are also available in solution. A variety of organic cobalt compounds are also available.

Industry Structure

Cobalt mine and refinery production are limited to a few countries. The United States is not currently a cobalt producer. U.S. mine production of

cobalt ceased at the end of 1971, and the sole U.S. cobalt refinery discontinued processing imported nickel-cobalt matte in late 1985. In 1991, Zaire was the world's leading producer of refined cobalt, followed by Zambia, the U.S.S.R., Canada, Norway, and Finland. These six countries represented 96% of world cobalt refinery production. Zairian and Zambian production was from domestic ores. Canada and the U.S.S.R. produced cobalt from both domestic and imported raw materials. All of the cobalt produced in Norway and most of the cobalt produced in Finland was from imported raw materials. World producers of refined cobalt and producers of intermediate cobalt-containing products are listed. (See tables 1 and 2.)

Cobalt processors represent an important source of supply for various industries. Processors differ from producers primarily in the feed materials they use. Cobalt producers refine cobalt from ores, concentrates, mattes, or residues originating from mining or refining operations. A few refiners supplement their feedstock with secondary cobalt (scrap). Producer products include cobalt cathode, granules, metal powder, oxide, and salts. In contrast, cobalt processors begin with refined cobalt metal or cobalt-containing scrap and make metal powder, oxide, and/or salts, but not cathode or granules. The world's largest cobalt processor is Metallurgie Hoboken-Overpelt S.A. (MHO) in Belgium. Other cobalt processors are in Asia, Europe, and the United States (see Production section of this report).

Byproducts and Coproducts

Cobalt is rarely produced as a primary product from a mining operation. Most of Western World cobalt supply is produced as a byproduct of copper production in Zaire and Zambia. With the exceptions of Morocco, where small amounts of cobalt are produced as a primary product, and the Republic of South Africa, where cobalt is produced as a byproduct of platinum mining and refining, cobalt production in most other

countries is a byproduct of nickel production.

Economic Factors²

Most of cobalt's production costs are attributed to the primary metal produced at a given operation. The incremental costs applied to cobalt production include costs to separate cobalt from the primary metal, usually during the refining stage; transportation costs; and marketing costs. The U.S. Bureau of Mines Minerals Availability Program estimated 1989 direct operating costs for cobalt refining in market economy countries to range from less than \$1.00 per pound for cobalt cathode production at Falconbridge Ltd.'s Kristiansand, Norway, refinery to about \$3.00 per pound for production of cobalt metal powders at Sherritt Gordon Ltd.'s refinery in Alberta, Canada. Cobalt refining costs in Zaire and Zambia are estimated to average about \$2.50 per pound. However, additional capital improvements, transportation, and marketing expenses in these two countries may increase total costs to about \$4.00 per pound. Most of the nonproducing properties evaluated in the study would require a total cost per pound, including a 15% discounted cash-flow rate of return, in excess of January 1989 market prices for the primary commodities (\$1.50 per pound for copper, \$7.50 per pound for nickel, or \$8.65 per pound for cobalt).

Operating Factors

The Environmental Protection Agency (EPA) regulates releases of cobalt into the environment under various programs. Workplace exposures are regulated by the Occupational Safety and Health Administration (OSHA).

ANNUAL REVIEW

Legislation and Government Programs

The Defense Logistics Agency (DLA) reported a yearend NDS cobalt inventory of 24,126 metric tons, contained cobalt. This included cobalt received from

Sherritt-Gordon Ltd. during the 1990 cobalt upgrading program that underwent a final accounting transfer during 1991.

The NDS goal of 38,737 metric tons of cobalt metal remained in effect during 1991. However, in July, the DLA submitted an interim report to Congress that proposed new goals for 39 materials, including cobalt. The new goals were intended to reflect a reduction in the potential threat to U.S. national security. They were developed using 1989 supply and demand data, following the existing statutory requirement that NDS planning be based on a 3-year global conventional war with a 1-year mobilization period. The proposed goal for cobalt was 20,593 metric tons of cobalt metal. Adoption of this goal would result in an excess of about 3,500 metric tons of cobalt. Before any sales of excess materials could occur, Congress must approve the proposed goals, and, in the case of cobalt, pass legislative authority for the disposals. By law, disposals of NDS materials must be made in a manner to avoid undue market disruption. Goals proposed in the interim report are subject to revision in the 1992 Report to the Congress on National Defense Stockpile Requirements.

In July, the President terminated sanctions against the Republic of South Africa implemented under the Comprehensive Anti-Apartheid Act of 1986 (Public Law 99-440). The President determined that the Government of South Africa had taken all of the steps specified in section 311(a) of the act, and therefore, that title III and sections 501(c) and 504(b) of the act had terminated.³ Cobalt had been certified as a strategic mineral by the U.S. State Department, so that it had been exempt from the prohibition of imports of products "produced, manufactured by, marketed, or otherwise exported by a parastatal organization of South Africa."

Strategic Considerations

Cobalt is considered a strategic and critical metal because of its many industrial and defense-related uses and because the United States is highly dependent on imports for its supply. The

United States is the world's largest consumer of cobalt. In 1991, the United States consumed about 30% of estimated world refinery production. There was no domestic production, so demand was met primarily from imports, with the exception of about 20% from purchased scrap.

To ensure an adequate supply for military, industrial, and essential civilian needs, cobalt metal is included in the NDS. Stockpile quantities are intended to sustain the United States for a period of not less than 3 years during a national emergency situation. Most of the cobalt in the stockpile was purchased prior to 1980 and does not meet current quality requirements for vacuum-melted superalloys.

World cobalt production is concentrated in a limited number of geographic areas. More than one-half of the world's supply of refined cobalt comes from central Africa, primarily Zaire and Zambia. Since 1987, all of the cobalt produced in Zaire has been transported through the Republic of South Africa. Cobalt produced in Zambia was formerly transported through the Republic of South Africa, but has been exported through Dar es Salaam, Tanzania, in recent years. Therefore, while the Republic of South Africa is not a major cobalt producer, its potential influence on supply is great because of the large amounts of cobalt exported using its transportation system. The United States formerly prohibited imports of products "produced, manufactured by, marketed, or otherwise exported by a parastatal organization of South Africa" as part of the Comprehensive Anti-Apartheid Act of 1986. However, cobalt was identified as strategic and critical mineral by the U.S. Department of State and exempted from this prohibition. In July, the President lifted the sanctions against South Africa (see Legislation and Government Programs section of this report).

Production

There was no domestic mine or refinery production of cobalt in 1991. Blackbird Metals Inc. of New York

continued with its efforts to initiate U.S. cobalt production. The company postponed its plan to purchase and reopen the former Blackbird cobalt mine in Idaho, but continued with plans to build a cobalt refinery with an annual capacity of 5,000 metric tons per year. The company intended to use a variety of cobalt-containing materials as feed for the refinery.

The State of Maine's Department of Environmental Protection finalized new regulations for the exploration and mining of metallic minerals in August. During the third quarter, Black Hawk Mining Inc. of Toronto, Canada, began the permitting process for its Knox nickel-copper-cobalt deposit near Warren, ME. The company recalculated the ore reserves at a 0.8% nickel cutoff grade, with the following results: 3,970,000 metric tons geological ore reserves grading 1.40% nickel, 0.64% copper, and 0.12% cobalt.⁴ The company planned to mine the deposit by both open pit and underground methods at the rate of 420,000 tons of ore per year. Knox Nickel would produce a bulk concentrate that would be exported to be refined. Annual production of payable metals was estimated at 3,400 metric tons of nickel, 2,000 metric tons of copper, and 160 metric tons of cobalt.

U.S. cobalt supply included secondary cobalt from the recycling of superalloy and other forms of scrap. Cobalt was recovered from spent petroleum catalysts at the AMAX Metals Recovery plant in Braithwaite, LA, and by Gulf Chemical and Metallurgical Corp. in Freeport, TX.

Two cobalt processors produced extra-fine cobalt metal powder in the United States. Carolmet, owned by MHO of Belgium, produced extra-fine powder from imported primary metal at its Laurinburg, NC, plant. GTE Products Corp. produced extra-fine powder from recycled materials in Towanda, PA. Production and shipments of extra-fine cobalt metal powder are withheld to avoid disclosing company proprietary data.

Domestic cobalt processors produced 2,039 metric tons of cobalt oxide and hydroxide, inorganic cobalt compounds, and organic cobalt compounds in 1991.

Because this figure includes production of intermediate forms, it does not represent net production. Shipments are defined as sales, transfers, or consumption to make end-use products such as paint driers or catalysts. In 1991, domestic cobalt processors shipped 1,886 metric tons of cobalt oxide and hydroxide, inorganic cobalt compounds, and organic cobalt compounds. Production and shipments each decreased 4% in 1991 as compared with production and shipments in 1990.

Consumption and Uses

Apparent consumption, as calculated from net imports, consumption from purchased scrap, and changes in Government and industry stocks, was 7,786 metric tons. (See table 3.)

The data for cutting and wear-resistant materials in table 4 have been revised. The category titled "Cutting and wear-resistant materials" now represents only those products made from cobalt metal powder—such as cemented carbides and diamond tools. Wear-resistant alloys such as stellites have been removed from this category and are combined with similar alloys under the category titled "Welding materials (structural and hardfacing)." As a result of this revision, cemented carbides and diamond tools now average about 7% of total reported consumption and wear-resistant alloys about 2%. (See table 4.)

U.S. reported cobalt consumption decreased 4% in 1991 compared with that of 1990. Total reported consumption has been relatively level since 1988. In 1991, the amount of cobalt consumed as metal decreased to below 50% of all forms consumed, while cobalt consumed in scrap increased to more than 20% and cobalt consumed as chemicals remained about 30%. (See table 5 and figure 1.)

Metallurgical industries (producers of cemented carbides, magnetic alloys, mill products, steels, superalloys, etc.) consumed 3% less cobalt in 1991 as compared with consumption in 1990. Superalloy melters used 8% less cobalt than the record-high amount used in 1990. However, the amount of cobalt consumed in superalloys remained above

consumption levels reported prior to 1990. Producers of cutting and wear-resistant materials used slightly less cobalt in 1991 than they did in 1990. In contrast, producers of magnetic alloys used basically the same amounts of cobalt in both years.

Cobalt consumption by chemical industries decreased 4% in 1991. As compared with consumption in 1990, in 1991 more cobalt was consumed as glass decolorizers, ground coat frits, and paint driers, while less cobalt was consumed to make catalysts, feed, and pigments.

Stocks

Total yearend cobalt stocks held by U.S. processors and consumers decreased 12% as compared with 1990 yearend stocks. The largest decrease was in cobalt metal stocks, at 20% below yearend 1990 levels. Yearend chemical stocks were only slightly below 1990 yearend levels. In contrast, yearend scrap stocks were 43% greater in 1991 than at yearend 1990. (See table 6.)

Stocks held by producers' sales agents in the United States were believed to be very low during 1991.

Markets and Prices

In 1991, Western World cobalt demand exceeded Western World production for the fourth consecutive year. During previous years, the deficit was met primarily from producers' stocks. In 1991, the remaining producer stocks continued to be drawn down, but imports of cobalt from the U.S.S.R.—both Russian-produced and cobalt from the Soviet strategic stockpile—made a significant contribution to Western cobalt supply. Estimates of the quantity of cobalt from the U.S.S.R. that entered Western markets in 1991 ranged from 1,000 to 3,000 metric tons. The combined effects of increased imports from the U.S.S.R. and reduced consumption because of recessionary economic conditions lessened the impact of the imbalance between production and demand. The effect of economic conditions on Western World

consumption was obscured somewhat by strong Japanese demand resulting from stockbuilding (see Japan section of this report).

The producer price of cobalt was maintained at \$11.00 per pound throughout 1991. In contrast, free market prices doubled during the latter part of year, approaching levels last seen during the "cobalt crisis" of 1978-79. Free market prices in January ranged from \$15.25 to \$16.50 per pound. In spite of ongoing concerns over cobalt supplies in general, and the impact of the worsening political situation in Zaire in particular, prices steadily decreased during the first half of 1991. In late July, free market prices dropped below \$13.00 per pound, before increasing to \$13.50 to \$14.00 in August. During the second week in September, prices increased to about \$15.00 per pound, reportedly because of renewed demand, speculation over the upcoming announcement of the 1992 producer price, and concern over increased unrest in Zaire. In late September/early October, free market prices jumped sharply to almost \$20.00 per pound following reports of looting and rioting in Zaire, which caused the evacuation of foreign nationals and a temporary halt in copper and cobalt production. At this time, Gécamines reduced its 1991 production forecast to 12,000 metric tons from the 13,500 metric tons originally targeted for the year.

During the second week of October, Gécamines and ZCCM announced a new 1992 producer price of \$13.00 per pound, effective January 1, 1992. Unlike past years when the producer price was effective for 1 to 2 years, the 1992 price was to be reviewed in June 1992 and subject to change at that time. Free market cobalt prices dropped back to the \$17.00 to \$18.00 range, but then rapidly increased to almost \$30.00 per pound during November because of concerns over future supply from both Zaire and Zambia. News from Zaire of renewed violence and a second production stoppage in late October was followed by reports of suspended cobalt deliveries. In Zambia, the election of a new president

in the country's first multiparty elections since independence caused speculation that new ZCCM management might change the company's cobalt marketing policy.

In mid-December, Gécamines and ZCCM revised their 1992 producer price to \$25.00 per pound. The new price superseded the \$13.00 price announced in October, and like the earlier price, was subject to evaluation and possible revision in mid-1992. The increase was intended to bring producer prices closer to free market prices, which were then in the \$30.00 to \$35.00 per pound range. The new price would bring much-needed income to producer countries in the short term, but could result in substitution in some applications and decreased markets in the long term.

At yearend, market concerns continued to focus on Gécamines' production levels. The company estimated 1992 refinery production at 8,000 to 9,000 metric tons, but industry analysts suggested that production could be lower. As a result of the lower production, Gécamines informed contract customers that 1992 deliveries would be only 60% of 1991 contracted amounts.

The weighted average market price for the year was \$16.92 per pound. Prices for cobalt-containing materials are presented. (See tables 3 and 7 and figure 2.)

Foreign Trade

U.S. imports of unwrought cobalt and cobalt in chemicals increased in 1991 to an estimated 6,924 metric tons valued at \$174 million. (See tables 8 and 9.) This represents an 8% increase over imports for consumption in 1990, excluding 1990 imports for the NDS. Fifty-eight percent of U.S. cobalt imports in 1991 was from ores originating in the south-central African countries of Zaire and Zambia. This included cobalt imported from Belgium, where Zairian cobalt metal was processed into metal powder, oxides, and salts by MHO. Twenty-eight percent of U.S. imports was from Canada and Norway. Much of the cobalt produced in Norway was from Canadian ores.

Imports of cobalt metal from the U.S.S.R. increased to 285 metric tons or 4% of total imports. The U.S.S.R. is a major cobalt producer, but did not export cobalt to the United States before 1990. U.S. cobalt imports by source are presented in figure 3.

U.S. net import reliance as a percentage of apparent consumption was estimated to be 80% in 1991. The net import reliance would be 100% if no cobalt were recovered from secondary sources (scrap). (See tables 8, 9, 10, and 11 and figure 3.)

In 1991, the United States exported an estimated 1,536 metric tons of unwrought cobalt and cobalt contained in chemicals valued at \$30.5 million. This represented a 15% increase as compared with exports in 1990. One-half of this cobalt was shipped to five countries: Canada (13%), Mexico (13%), Japan (11%), Italy (7%), and the United Kingdom (6%). The remaining 50% was shipped to 41 other countries. (See table 12.)

Exports also included 323 metric tons, gross weight, of wrought metal and cobalt articles valued at \$13.4 million. Ninety percent of these materials was sent to seven countries: the Netherlands (25%), Canada (14%), France (13%), Sweden (12%), Japan and the United Kingdom (each 10%), and the Republic of Korea (7%). The remainder was shipped to 18 other countries. In addition, the United States exported 9 metric tons, gross weight, of material under the category entitled, "Cobalt ores and concentrates." Canada received 4.5 metric tons of this material valued at \$40,568. A shipment to Belgium of 4.3 metric tons valued at \$190,040 could not be verified by the Bureau of Census.

World Review

World cobalt production decreased in 1991. Refinery production reported by the seven Cobalt Development Institute (CDI) member producers⁵—Falconbridge, Gécamines, Inco Ltd., Outokumpu Oy, Sherritt Gordon, Sumitomo Metal Mining Co. Ltd., and ZCCM—decreased 4% from production in 1990. The decrease was the result of a significant decrease in

production by Gécamines—the world's largest cobalt producer. Production in 1991 by Inco Ltd. and ZCCM was essentially unchanged from that of 1990. In contrast, Sherritt Gordon, Outokumpu Oy, and Falconbridge each produced significantly more cobalt in 1991 than in 1990. The CDI estimated total 1991 world production at 25,300 metric tons, with nonmember production primarily from Russia (4,300 metric tons) and China (300 metric tons) and the remaining 400 metric tons from miscellaneous other countries. The CDI estimated world consumption at about 25,500 metric tons, roughly in balance with world production.

Capacity.—The data in table 13 are rated capacity for refineries as of December 31, 1991. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable long-term operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure. Because not all countries or producers make production capacity information available, historical reported or estimated cobalt production data have been used to estimate refinery capacity in some cases. Changes in refinery capacity can result from changes in facilities or from changes in knowledge about the facilities. (See table 13.)

Australia.—Nickel-cobalt sulfide and cobalt sulfide were produced as byproducts of nickel mining and refining by Western Mining Corp. (WMC) in Western Australia and Queensland Nickel Pty. Ltd. in Queensland, respectively. Minor amounts of cobalt oxide were produced as a byproduct of zinc production by Pacific Smelting and Mining Co. Ltd. in Risdon, Tasmania.

Dallhold Investments Pty. Ltd., owner of 72% interest in the Queensland Nickel Joint Venture, went into receivership in July. Operation of Queensland Nickel's Yabulu nickel-cobalt refinery continued under the control of a consortium of financial institutions—Hongkong and Shanghai Corp., Bank of New Zealand Ltd., and Tricontinental Corp. Ltd. In October, the consortium put its 72% interest up for sale. The remaining 28% interest, owned by the Queensland government, was not affected by the sale. Cobalt sulfide produced at the Yabulu refinery was refined by Outokumpu Oy in Finland.

MIM Holdings Ltd. continued work on a pilot circuit to recover cobalt from its Mount Isa copper concentrates. The circuit would use bioleaching technology to produce cobalt as hydroxide. The hydroxide would then be sold for further refining. Trial runs were expected to begin during the third quarter of 1992. If the pilot circuit proved successful, an annual production of between 600 and 1,200 metric tons of cobalt might be possible by mid-1994.⁶

Belgium.—In December, MHO, the world's largest cobalt chemical and metal powder processor, informed its customers that it would withdraw from the cobalt salts market in 1992. The company planned to continue producing cobalt oxides and metal powders, but would no longer produce cobalt salts such as acetates, chlorides, sulfates, carbonates, and nitrates. Industries using cobalt salts would have to obtain them from other sources. Applications for cobalt salts include catalysts, ceramics, enamels, magnetic recording media, metal finishing, rubber additives, and feed for the manufacture of other chemicals, including driers for paints and inks. MHO's decrease in production was the result of reduced supplies of raw materials. Gécamines is the primary source of cobalt metal feed for MHO's cobalt plant at Olen. The company was expected to resume salts production when raw materials supply problems were resolved.

Botswana.—BCL Ltd. mined nickel-copper ores from company mines in the Selebi-Phikwe district. Copper-nickel-cobalt matte produced by BCL Ltd. was sent to refineries in Norway and Zimbabwe to be refined.

Brazil.—Cia. Niquel Tocantins produced cobalt cathode at its nickel refinery in Sao Miguel Paulista, Sao Paulo State.

Canada.—Cobalt is produced as a byproduct of nickel by three Canadian companies, Falconbridge, Inco, and Sherritt-Gordon.

In 1991, Falconbridge produced approximately 700 metric tons of cobalt from nickel ores at its Sudbury, Ontario, operations. In addition, 700 metric tons of cobalt was produced from custom feed smelting.⁷ Falconbridge also researched the pyrometallurgical treatment of cobalt-bearing scrap with the goal of increasing its custom feed business. Cobalt-containing nickel-copper matte from Sudbury was refined at the Falconbridge Nikkelverk refinery in Norway.

Inco produced cobalt oxide at its Thompson, Manitoba, refinery and cobalt cathode at its Port Colborne refinery. Feed materials for the two refineries originated from nickel mines in Thompson, Manitoba, and Sudbury, Ontario, respectively. Inco's production of refined cobalt was essentially the same as production during the previous year. The company produced 1,385 metric tons of cobalt in 1991 as compared with 1,380 metric tons in 1990.⁸ Inco's 1991 cobalt deliveries, including cobalt contained in alloys and engineered products, decreased 4% from deliveries in 1990 to 1,393 metric tons.⁹

In December, Inco signed an agreement with Le Bureau de Recherches Géologiques et Minières (BRGM) of France to evaluate the feasibility of developing nickel-cobalt laterites in New Caledonia (see New Caledonia section of this report).

Sherritt Gordon refined cobalt-containing materials from Canada and elsewhere at its nickel-cobalt refinery at

Fort Saskatchewan, Alberta. Production in 1990 was limited by a lack of nickel-cobalt feed. In April 1991, Sherritt reportedly was forced to reduce allocations to U.S. consumers because of the feedstock shortage. By May, Sherritt had secured a long-term source of feed and was able to operate its refinery at close to capacity during the second half of the year. As a result, Sherritt's production of cobalt metal powder in 1991 increased 19% to 821 metric tons.¹⁰

Although Sherritt does not disclose feed sources, industry analysts believed that the new feed included nickel-cobalt sulfides from Cuba's Moa Bay refinery. The sulfides, containing about 55% nickel and 5% cobalt, began appearing in Canadian import statistics in April 1991 under the trade category "nickel oxide sinters and other intermediate products of nickel metallurgy." Canada's other two nickel producers denied receiving Cuban feed. The source of the feed is significant because the United States has a trade embargo on materials originating in Cuba, which would affect nickel and cobalt produced from Cuban feedstock. By summer, Sherritt was reported to have withdrawn from the U.S. market.

Sherritt developed a proprietary process to refine the new feed, which was relatively rich in cobalt. Adaptations to the refinery began in 1991 and were expected to be completed by mid-1992, raising the refinery's cobalt capacity to approximately 1,350 metric tons per year (3 million pounds per year). Sherritt researchers also worked on the development and marketing of value-added materials, including extra-fine cobalt powder for the cemented carbide industry.

Cuba.—Cuba produces nickel-cobalt sulfides at its Moa Bay plant and nickel-cobalt oxide and oxide sinter at its Nicaro and Punta Gorda plants. All three plants use lateritic ore as their feedstock. The nickel-cobalt sulfides contain a greater percent of cobalt than the oxide and sinter, roughly 5% as compared with about 1%. Historically, all of the nickel-cobalt sulfides were refined at the Orsk nickel refinery in the southern Ural

mountains in the U.S.S.R. In 1991, Cuba began sending some of the sulfides to Canada.

Finland.—In October, Outokumpu Metals and Resources Oy and Mooney Chemicals, Inc., a U.S. cobalt chemical processor, merged their chemical businesses into a newly incorporated Delaware holding company named OM Group Inc. OM Group will produce a wide range of cobalt and nickel products, including cobalt metal powders, inorganic cobalt salts, and cobalt carboxylates. The company will operate from three locations: the Outokumpu cobalt refinery in Kokkola, Finland; the Vasset S.A. chemical processing plant in Paris, France; and the Mooney Chemicals processing plant in Franklin, PA. Vasset, a producer of cobalt carboxylates, was purchased by Outokumpu in 1990. At yearend, ownership of OM Group was divided as follows: 49% held by a consortium of Finnish companies (Nova Insurance, the Industrial Mutual Insurance Co., and Investa Oy), 47% held by Outokumpu, and 4% held by Mooney.

Outokumpu produced 1,503 metric tons of cobalt in powders and salts in 1991, a 16% increase over production in 1990.¹¹ The total production of cobalt in cobalt products by OM Group companies during 1991 was 2,115 metric tons.¹²

Japan.—Sumitomo produced electrolytic cobalt, cobalt oxide, cobalt sulfate, and other cobalt salts as a byproduct of nickel production at its Niihama Nickel Refinery in Ehime Prefecture.

According to Japan's Ministry of International Trade and Industry (MITI),¹³ 1991 Japanese reported cobalt consumption was relatively unchanged at 3,015 metric tons, as compared with 2,994 metric tons in 1990. With the exception of a 6% increase in cobalt used to make hard metal tools, cobalt consumption in all industry sectors was basically the same as consumption in 1990. In 1991, reported consumption by industry was as follows: 416 metric tons

in catalysts, 365 metric tons in hard metal tools, 631 metric tons in magnetic materials, 896 metric tons in special steels, and 707 metric tons in other uses. Total Japanese cobalt consumption was estimated to be about 4,500 metric tons. The MITI statistics do not include cobalt use in magnetic tapes—estimated at 900 to 1,000 metric tons per year of cobalt sulfate, welding materials, or diamond tools. Japanese demand for cobalt was met primarily from imports, which increased almost 50% in 1991 to 6,674 metric tons.

During 1991, the Japanese built up significant inventories of cobalt to avoid potential shortages resulting from tight market conditions.¹⁴ As compared with purchases in 1990, Japanese buyers purchased 23% more cobalt from producers and increased their purchases from the free market more than 300%. Total imports of cobalt metal and metal powder were about 6,700 metric tons. Domestic production from Sumitomo was 185 metric tons. Assuming a domestic consumption of 4,400 to 4,600 metric tons and a 300-metric-ton inventory drawdown to cover a supply deficit during the fourth quarter of 1990, roughly 2,000 metric tons of cobalt would have accumulated as inventory. The yearend inventory was larger than expected because of a slowdown in the Japanese economy beginning in the second quarter of 1991, increased use of cobalt scrap, and forward buying by consumers in early 1991. The inventory was expected to be drawn down during 1992. The long-term effects of tight cobalt supplies and high prices were projected as reduced consumption and substitution of cobalt-containing products. For example, ongoing decreases in production of samarium-cobalt and Alnico magnets were expected to continue.

New Caledonia.—In December, Inco Ltd. of Canada signed an agreement in principle with BRGM of France to investigate the feasibility of developing lateritic nickel-cobalt resources in southern New Caledonia. Under the agreement, Inco would purchase Société de Promotions de Mines (Sopromines),

the BRGM subsidiary that holds mining titles to the deposits. Inco would also buy patents and technical expertise on the processing of nickel oxide ores owned or developed by BRGM. These purchases were subject to approval by the French Government. Also considered was the formation of a joint venture between Inco and BRGM, in which Inco would have the majority interest. The feasibility study was expected to take several years, after which a decision would be made on whether to proceed with mining.

Norway.—The Falconbridge Nikkelverk refinery produced a record 1,983 metric tons of cobalt cathode in 1991, an 8% increase from the 1,830 metric tons produced in 1990.¹⁵ Feedstock for the refinery was in the form of matte from company operations in Sudbury, Canada; BCL Ltd. in Botswana; and Norilsk in the U.S.S.R.

Philippines.—During the year, the Philippine Nickel Co. continued rehabilitation of the idled Nonoc Mining and Industrial Corp. nickel production facility and sought financing for the project.

South Africa, Republic of.—Cobalt was produced as a byproduct of the Republic of South Africa's platinum industry. Refined cobalt was produced by two companies: Rustenburg Base Metal Refiners Pty. Ltd. produced cobalt sulfate, and Impala Platinum Ltd. produced cobalt metal powder. A third company, Western Platinum Ltd., produced nickel sulfate containing minor amounts of cobalt.

South Africa's Minerals Bureau reported cobalt production, domestic sales, and exports for the years 1986-90.¹⁶ The refinery production figures in table 15 have been revised to include these reported figures. The breakdown between cobalt sulfate and metal powder production was estimated as 70% sulfate and 30% powder, based on the capacities of the two refineries. Mine production estimates in table 14 were also revised. Most of the cobalt produced in the

Republic of South Africa is exported. In 1990, 88% (219 metric tons) of the 249 metric tons produced was exported, and the remaining 12% was sold domestically. Cobalt production was expected to increase in the future as a result of increases in platinum mine production.

Uganda.—BRGM completed a prefeasibility study on the recovery of cobalt from concentrates stockpiled at the Kilembe copper mines near Kasese in western Uganda. The study investigated the viability of extracting the cobalt by bioleaching methods. Previous studies estimated that more than 1 million metric tons of cobaltiferous pyrite concentrates with an average grade of 1.2% cobalt was stockpiled during copper mining and concentrating operations that ceased in 1982. In October, BRGM and United Kingdom-based Barclays Metals proposed setting up a joint venture with the Ugandan Government to prepare a detailed feasibility study, including resource evaluation and pilot plant tests, followed by the construction of a full-scale processing plant.

Venezuela.—Corporacion Federal de Minas (Cofeminas)—a joint-venture between Jordev Resources Inc., of Vancouver, British Columbia, and Corporacion de Caracas of Venezuela—secured exploration and mining rights and completed a prefeasibility study on the Loma de Hierro deposit. Loma de Hierro is a lateritic nickel deposit south of Caracas reported to contain 38.5 million metric tons of ore, grading 1.55% nickel and 0.05% cobalt.

Zaire.—Gécamines remained the world's largest cobalt producer, providing almost 35% of estimated world refinery production. The company's cobalt production decreased 18% in 1991, at least partly because of the loss of concentrates following the September 1990 cave-in at the Kamoto underground mine. The Kamoto Mine, in Gécamines Western Group near the town of Kolwezi,

is the company's largest underground copper-cobalt mine. Prior to the collapse, the mine had been a significant source of cobalt because of its high output levels and the high cobalt content of its ores. Rehabilitation of the mine has taken longer than anticipated, causing delays in restoring production to former levels. During the year, Gécamines offset some of the loss of cobalt from the Kamoto Mine by reprocessing stockpiled cobalt hydrates. The hydrates had been precipitated from Gécamines' hydrometallurgical plants' cobalt leach circuits during periods of oversupply and stockpiled for later use.

Gécamines' operations were further hampered by Zaire's declining economic condition, a continuing political stalemate, and increased social unrest. On September 23, rioting and looting by soldiers and civilians spread from Kinshasa to other urban areas, including towns in the copper-cobalt mining area. Belgian and French troops were sent to Zaire on September 24th to protect foreign residents and to evacuate those that wanted to leave. Thousands of foreign nationals were reported to have left the country. Gécamines' offices in Kolwezi were demolished, and mining operations there were interrupted for several days. Violence recurred in late October in Kinshasa and in the Copperbelt, where production was again suspended. While no intentional damage occurred to the mines or refineries during the looting, the facilities suffered from the lack of proper maintenance during interruptions in production.

Zaire's political situation caused Western governments and international financial institutions to withdraw all financial aid, including that to state-owned Gécamines. By yearend, the company was unable to fulfill its delivery quotas for 1991. In December, Gécamines and ZCCM revised their 1992 producer price for cobalt, with the hope that the added income would help to increase future production. Gécamines continued seeking financing and estimated that \$300 to \$400 million would be needed to rehabilitate the Kamoto Mine, repair Gécamines facilities, and bring

copper and cobalt production back to former levels. The company hoped to maintain production at 8,000 to 9,000 metric tons in 1992, but industry analysts cautioned that production could be lower than 1991 levels.

The project with Techpro Mining and Metallurgy of the United Kingdom for the recovery of cobalt and copper from leach residues was delayed and downsized. Originally, Techpro was to construct a horizontal belt filter and two flotation columns at the Shituru plant and a horizontal belt filter at the Luilu plant. Progress on the project was slowed by a delay by Gécamines in providing downpayment to Techpro. In addition, the project scope was reduced to construction of a horizontal belt filter at Shituru.

Zambia.—Zambia had its first multiparty elections since its independence in 1964. The newly elected President replaced ZCCM's top management and began an examination of company financial records for alleged corruption. The President was also reported to be considering various means of encouraging foreign investment, including privatization of some state-owned companies. ZCCM produced 4,817 metric tons of refined cobalt metal between January and December 1991.¹⁷ This production was basically the same as the 4,844 metric tons produced in calendar year 1990.

Zimbabwe.—Minor amounts of impure cobalt oxide were produced in Zimbabwe as a byproduct of nickel mining and refining. The cobalt oxide was exported to be refined. (See tables 14 and 15.)

Current Research

The U.S. Bureau of Mines researched the recovery of individual metals from mixed superalloy scrap.¹⁸ A combined pyrometallurgical and hydrometallurgical process was used. The superalloy scrap was melted, then sulfur was added to form a matte. The matte was then granulated and ground to an appropriate

particle size for leaching with a chloride leach solution. Molybdenum was recovered from the leach solution by solvent extraction. Chromium and iron were recovered by precipitation. The remaining purified leach solution contained the cobalt and nickel, which could be recovered by a commercial solvent extraction-electrowinning process.

The CDI of Wickford, Essex, United Kingdom, published abstracts on cobalt research, articles on selected cobalt uses, and annual and semiannual data on cobalt production by institute members in quarterly issues of Cobalt News.

OUTLOOK

The future cobalt market will depend on the balance between several supply and demand factors. Even at reduced production levels, Zaire is still the world's largest cobalt producer, and the quantity and quality of cobalt it produces will continue to be important factors in world supply. Political and economic conditions in Zaire have not yet been resolved. Gécamines' ability to bring its production back to former levels and rebuild stocks of cobalt metal both in Zaire and in consuming countries will be determining factors in the cobalt market. Since the collapse of the Kamoto mine, a significant portion of Gécamines' cobalt production has been from the reprocessing of stockpiled cobalt hydrates. Steady production of cobalt in the future will depend on Gécamines' success in rehabilitating the Kamoto Mine and improving production at its other copper-cobalt mines before stocks of cobalt hydrates are depleted. These improvements will depend on the company's ability to acquire financing.

In 1991, cobalt from the U.S.S.R. contributed significantly to alleviate the tight supply situation. Supplies to Western markets included cobalt from strategic stockpiles and cobalt produced in the U.S.S.R. The amount of cobalt remaining in the stockpiles is not known. In terms of domestically produced cobalt, Russian production is expected to decrease in 1992, and some of the cobalt will be reserved for domestic use. An

estimated 1,000 metric tons of Russian-produced cobalt may be available for export in 1992. However, cobalt exports are controlled by the state, which had not granted export licenses to producers by mid-1992.

Sales of cobalt by the U.S. Government could provide a steady addition to supply for several years. During 1991, the DLA proposed reducing the size of the NDS. Adoption of the proposed stockpile goal for cobalt would result in excess cobalt available for disposal. Before sales of excess materials could occur, Congress must approve the proposed goals and pass legislative authority for the disposals. The DLA proposal recommended sales at a rate of 1,360 metric tons per year.

In the longer term, current high prices give added incentive to potential new producers. The Government of Uganda, in conjunction with BRGM, and MIM of Australia are each investigating the production of cobalt by bioleaching byproduct cobalt from former or present-day copper production. Blackbird Metals continues with its plans to build a U.S. cobalt refinery, although it has decided to postpone the purchase and reopening of the Blackbird Mine in Idaho and is considering other feed sources. Potential new producers such as Knox Nickel in Maine, or former producers such as Nonoc in the Philippines, would produce cobalt as a byproduct of nickel, and their success will depend to a large extent on the nickel market.

In addition to the quantity of future cobalt supply, quality is also a concern. Not all cobalt metal available is suitable for all applications. Zaire and Zambia each produce several grades of refined cobalt. Zaire's projected 1992 production includes cobalt contained in matte and alliage blanc (an alloy of copper, cobalt, and iron), which are intermediate products that require further refining. Russian cobalt ingots are not as high grade as cobalt from other sources and must be cut to a smaller size before they can be used by some consumers. NDS cobalt to be offered for sale will be cobalt purchased prior to 1980, when purchase specifications were not as stringent as

those in effect today. This cobalt has been identified as unsuitable for the most demanding uses, in particular, vacuum-melted superalloys.

On the demand side, increases in consumption will depend on the economies of the major consuming countries. Continued high prices are likely to result in increased use of cobalt scrap and substitution where possible. Future demand could be negatively impacted if engineers choose to avoid cobalt in products now under development—both price and future availability are important in materials selection.

Overall Western World cobalt supply and demand are currently close to being in balance. However, a decrease in Western World production without added cobalt from non-Western producers or strategic stockpiles, or an increase in consumption without increased supply, could upset the balance. In addition to overall supply and demand, the supply-demand balance of higher quality grades of cobalt also bears watching. Once producers rebuild their stocks, short-term disruptions in supply can be reduced. Cobalt prices are expected to decrease to more typical levels when increased supply brings the market into a more comfortable balance.

TABLE 1
WORLD PRODUCERS OF REFINED COBALT¹

Country	Company	Cobalt products
Albania	Government-owned	Oxide.
Brazil	Companhia Niquel Tocantins	Cathode.
Canada	Inco Ltd.	Cathode, oxide.
Do.	Sherritt Gordon Ltd.	Metal powder, briquettes.
China	Government-owned	NA.
Finland	Outokumpu Oy	Metal powder, oxide, salts.
France	Eramet-SLN	Chloride.
Japan	Sumitomo Metal Mining Co. Ltd.	Cathode, oxide, salts.
Norway	Falconbridge Ltd.	Cathode.
South Africa, Republic of	Impala Platinum Ltd.	Metal powder.
Do.	Rustenberg Base Metal Refiners Pty. Ltd.	Sulfate.
U.S.S.R.	Government-owned	Ingot, cathode, oxide, salts.
Zaire	La Générale des Carrières et des Mines.	Cathode, granules.
Zambia	Zambia Consolidated Copper Mines Ltd.	Cathode, crushed bar.

NA Not available.

¹Companies with production during 1991.

TABLE 2
WORLD PRODUCERS OF INTERMEDIATE COBALT PRODUCTS¹

Country	Company	Cobalt-containing products
Australia	Queensland Nickel Pty. Ltd.	Cobalt sulfide.
Do.	Western Mining Corp.	Nickel-cobalt sulfide.
Do.	Pacific Smelting and Mining Co. Ltd.	Impure cobalt oxide.
Botswana	BCL Ltd.	Nickel-copper matte.
Cuba	Union de Empresas del Niquel	Nickel-cobalt oxide, ² nickel-cobalt sulfide.
Morocco	Compagnie de Tifnout Tiranimine	Cobalt concentrate.
New Caledonia	Société Metallurgique le Nickel	Nickel matte.
South Africa, Republic of	Western Platinum Ltd.	Nickel sulfate, nickel matte.
Zimbabwe	Bindura Nickel Corp. Ltd.	Cobalt-nickel hydroxide.
Do.	Rio Tinto (Zimbabwe) Ltd.	Do.

¹Companies with production during 1991; excludes companies producing refined cobalt.

²Cobalt may not be recovered.

Refinery	'27,995	'26,407	'25,181	'25,316	'23,922

¹Estimated. ²Revised.

¹Stocks held by consumers and chemical processors.

²Market price based on weighted average of Metals Week prices.

TABLE 4
U.S. REPORTED CONSUMPTION OF COBALT,¹ BY END USE

(Metric tons, cobalt content)

End use	1988	1989	1990	1991
Steel:				
Full-alloy	W	W	W	W
High-strength, low-alloy	W	—	—	—
Stainless and heat-resisting	26	74	41	51
Tool	180	219	123	W
Superalloys	'2,865	'2,860	'3,345	3,066
Alloys (excluding alloy steels and superalloys):				
Cutting and wear-resistant materials ²	'522	'538	'541	523
Magnetic alloys	'878	'870	'710	713
Nonferrous alloys	'64	27	31	32
Welding materials (structural and hard-facing) ³	'206	'136	'180	135
Other alloys	'86	'52	'74	62
Mill products made from metal powder	W	W	W	W
Drier in paint or related usage	892	718	'751	781
Miscellaneous and unspecified ⁴	'1,590	'1,680	'1,717	1,876
Total⁶	'7,308	'7,172	'7,512	7,238

¹Revised. W Withheld to avoid disclosing company proprietary data; included with "Miscellaneous and unspecified."

²Includes estimates.

³Includes diamond bit matrices, cemented and sintered carbides, and cast carbide dies or parts.

⁴Includes wear-resistant alloys.

⁵Data not comparable with those prior to 1990 because of a change in reporting method.

⁶Includes catalysts, feed or nutritive additive, glass decolorizer, ground coat frit, pigments, and data indicated by symbol "W."

Data may not add to totals shown because of independent rounding.

Total	41,245	43,819	36,000	35,709	26,583

*Estimated. Revised.

¹Table includes data available through June 5, 1992. Figures represent recoverable cobalt content of ores, concentrates, or intermediate products from copper, nickel, platinum, or zinc operations. Morocco was the only country where cobalt was mined as a primary product.

²In addition to the countries listed, Bulgaria, China, the Eastern states of the Federal Republic of Germany, Indonesia, and Poland are known to produce ores that contain cobalt, but information is inadequate for reliable estimates of output levels. Other copper-, nickel-, platinum-, or zinc-producing nations may also produce ores containing cobalt as a byproduct component, but recovery is small or nil.

³Calculated from reported and estimated weight of nickeliferous ore.

⁴Figures represent quantities of cobalt contained in intermediate metallurgical products (cobalt oxide and nickel-cobalt sulfide). Cobalt content of lateritic nickel ore, nickel concentrate, and zinc concentrate was as follows, in metric tons: 1987—2,715; 1988—2,574 (estimated); 1989—2,375 (estimated); 1990—2,375 (estimated); and 1991—2,400 (estimated).

⁵Reported cobalt content of pelletized nickel-copper matte.

⁶Figures represent total cobalt content of all products derived from ores of Canadian origin, including cobalt oxides shipped to the United Kingdom for further processing and nickel-copper-cobalt mattes shipped to Norway for further processing. Actual mine production was reported as follows, in metric tons: 1987—5,490; 1988—6,234; 1989—6,167; 1990—5,470; and 1991—5,629.

⁷Reported figure.

⁸Determined from reported nickel-cobalt content of granular and powder oxide, oxide sinter, and sulfide production.

⁹Cobalt content of concentrates.

¹⁰Series represents estimated recoverable content of ores and intermediate metallurgical products exported from New Caledonia to France and Japan. The estimated cobalt content of total ores mined is as follows, in metric tons: 1987—5,800; 1988—6,000; 1989—6,000; 1990—6,000; and 1991—6,000.

¹¹In addition to concentrates, cobalt hydrates and scrap are used as feed to the refineries. Cobalt content of these materials was as follows, in metric tons: Hydrates: 1987—1,042; 1988—0; 1989—0; 1990—3,194; and 1991—5,483. Scrap: 1987—33; 1988—31; 1989—27; 1990—49; and 1991—516.

¹²Fiscal years beginning Apr. 1 of that stated. Cobalt content of ore milled was as follows, in metric tons: 1987—11,198; 1988—10,687; 1989—10,590; 1990—10,870 (revised); and 1991—10,880 (estimated).

¹³Estimated cobalt content of ore.

COLUMBIUM (NIOBIUM) AND TANTALUM

By Larry D. Cunningham

Mr. Cunningham, a physical scientist with 12 years U.S. Bureau of Mines experience, has served as the commodity specialist for columbium and tantalum since 1983. Domestic survey and trade data were prepared by Cheryl M. Mack, statistical assistant; and columbium and tantalum world production data, by country, were prepared by Audrey D. Wilkes, international data coordinator.

Columbium (Cb) is vital as an alloying element in steels and in superalloys for aircraft turbine engines and is in greatest demand in industrialized countries. Columbium is critical to the United States because of its defense-related uses in the aerospace, energy, and transportation industries. Acceptable substitutes are available for some columbium applications, but in most cases they are less desirable.

Tantalum (Ta) is used mostly in the electronics industry, mainly in capacitors, and in aerospace and transportation applications. Tantalum is also critical to the United States because of its defense-related applications in aircraft, missiles, and radio communications. Substitution for tantalum is made at either a performance or economic penalty in most applications.

Domestic columbium and tantalum resources are of low-grade and are not commercially recoverable. The last significant mining of columbium and tantalum was during the Korean conflict when increased military demand resulted in columbium and tantalum ore shortages.

The metric system is the official system of measurement of most countries. The U.S. Bureau of Mines, in an effort to provide statistical data on columbium and tantalum that are consistent with international usage, will henceforth report data in kilograms and metric tons unless otherwise noted. For comparison to previous years' data, kilograms can be converted to pounds by multiplying the published number by 2.20462, and metric tons can be converted to short tons by

multiplying the published number by 1.10231.

The United States continued to be dependent on imports of columbium and tantalum materials, with Brazil being the major source for columbium imports and Germany the major source for tantalum imports. Columbium and tantalum price quotations remained stable.

National Defense Stockpile (NDS) goals and inventoried stocks for columbium and tantalum remained the same. However, to ensure future tantalum availability to the United States, the Defense Logistics Agency (DLA) awarded a contract for purchase of the product "tantalum oxide" for the NDS.

Overall reported consumption of columbium in the form of ferrocolumbium and nickel columbium was down, with demand for columbium in superalloys up slightly. Demand for tantalum was flat, with the consumption of capacitor-grade powder on the decline.

DOMESTIC DATA COVERAGE

Domestic production data for ferrocolumbium are developed by the U.S. Bureau of Mines from the annual voluntary domestic survey for ferroalloys. Of the four operations to which a survey request was sent, two responded. Thus, ferrocolumbium production data for 1991 were incomplete at the time this report was prepared.

BACKGROUND—COLUMBIUM

Columbium and niobium are synonymous names for the chemical element with atomic number 41; columbium was the first name given, and niobium was the name officially designated by the International Union of Pure and Applied Chemistry in 1950. The metal conducts heat and electricity relatively well, has a high melting point (2,480° C), is readily fabricated, and is highly resistant to many chemical environments. Columbium exhibits superconductivity at about 9° K, a temperature still too low for most commercial applications. (Superconductivity is the virtual loss of electrical resistance that occurs at a specific material dependent temperature and results in energy conservation and more rapid operation of electrical circuits.)

Definitions, Grades, and Specifications

Columbium pentoxide (oxide) is a stable, white- to buff-colored compound that is produced in metallurgical, ceramic, and optical grades. Purity of oxide generally exceeds 99%.

Ferrocolumbium is categorized into three grades by American Society for Testing and Materials (ASTM) Specification A550: low-alloy steel grade, alloy and stainless steel grade, and high-purity grade. For all grades, the composition is approximately 65% columbium, with the balance iron; principal impurities are aluminum, silicon, and tantalum. Nickel

columbium typically contains 63% columbium, with the balance nickel. Aluminum, iron, silicon, and tantalum are the principal impurities.

Columbium carbide is available as a powder containing about 87% columbium and the balance carbon.

Columbium metal is available in many forms and shapes. Purity of unalloyed metal is usually more than 99%, with attention mainly given to iron, tantalum, and zirconium as metallic impurities and carbon, hydrogen, nitrogen, and oxygen as interstitial impurities. Alloys with hafnium, tantalum, titanium, tungsten, and zirconium are of most commercial importance. Chemical and physical standards for columbium and columbium alloy mill shapes are given in ASTM Specifications B391-B394, B652, and B654-B655.

Products for Trade and Industry

Columbium, in the form of ferrocolumbium, is used worldwide, principally as an additive to improve the strength and corrosion resistance of steel. Columbium-containing high-strength and corrosion resistant steel is used in applications such as high-strength linepipe, structural members, lightweight components in cars and trucks, and exhaust manifolds. Because of its refractory nature, appreciable amounts of columbium in the form of high-purity ferrocolumbium and nickel columbium are used in nickel-, cobalt-, and iron-base superalloys for applications such as jet engine components, rocket subassemblies, and heat-resisting and combustion equipment. Columbium-base alloys are also used in aerospace applications such as rocket nozzles. Columbium carbide is used in cemented carbides to modify the properties of the cobalt-bonded tungsten carbide-base material. It is usually used with carbides of metals such as tantalum and titanium. Columbium oxide is the intermediate product used in the manufacture of high-purity ferrocolumbium, nickel columbium, columbium metal, and columbium carbide.

Geology-Resources

Columbium is almost always found in nature as an oxide in association with other minerals, but not in elemental form nor as a sulfide. Columbium has an overall crustal abundance estimated as 20 parts per million and a strong geochemical coherence with tantalum. Pyrochlore and bariopyrochlore (also known as pandaite), its barium analog, have become the main sources of columbium. The minerals contain little tantalum, having a columbium oxide-to-tantalum oxide ratio of 200:1 or greater. Pyrochlore and bariopyrochlore are commonly found in the interior parts of alkalic rock complexes, frequently in association with minerals of such other elements as thorium, titanium, uranium, and those of the rare earths. Columbite, the columbium-rich member of the columbite-tantalite isomorphous series, is normally found in intrusive pegmatites and in biotite and alkalic granites. However, because most such deposits relatively high in columbium content are small and erratically distributed, most columbite has been obtained as a byproduct of mining for other commodities, mainly tin.

Reserve and reserve base data for columbium are shown in table 1 and are based on a judgmental appraisal of current information. Reserve base is defined as the in-place demonstrated (measured plus indicated) resource from which reserves are estimated. The reserve base may encompass those parts of the resources that have a reasonable potential for becoming economically available within planning horizons beyond those that assume proven technology and current economics. Reserves are defined as that part of the reserve base that could be economically extracted or produced at the time of determination.

Technology

Exploration.—Columbium deposits of economic interest are most likely to be found in alkalic rock complexes and associated carbonatites. Aerial photography and geological mapping can

be used to reveal alkalic complexes, which frequently occur with circular geometry and concentric rock arrangement. Test pitting and panning can be used to explore placer deposits for columbium by virtue of the high specific gravity of columbium minerals. The columbium content of samples can be determined rapidly by means of truck-mounted spectrographic equipment and X-ray fluorescence spectroscopy.

Mining.—Pyrochlore has been mined mainly by mechanized open pit, underground stoping methods, or a combination of both. Currently, all mining for pyrochlore in Brazil is open pit, whereas in Canada, underground mining is being done via a large-diameter blasthole method. Ore, with host rock, is usually dislodged from a working face with explosives. Beneficiation of the ore, after it has been finely ground, is achieved primarily by various flotation procedures combined with magnetic separation to remove iron minerals. A chloridizing and leaching process can also be employed to lower barium, lead, phosphorus, and sulfur contents. Methods used to mine columbite have ranged from simple hand operations in small pegmatite mines to hydraulic monitors and dredges at placer deposits.

Beneficiation.—Pyrochlore concentrates are used solely in the manufacture of ferrocolumbium for steelmaking. Aluminothermy, the process being used for making steelmaking-grade ferrocolumbium from pyrochlore concentrates, is carried out in batches. As practiced by Cia. Brasileira de Metalurgia e Mineração (CBMM) in Brazil, a mixed charge of concentrate, iron oxide (as hematite), fine aluminum powder, and slagging agents is reacted to produce ferrocolumbium in a refractory-lined, cylindrical steel shell open at the top and resting upon a lined silica sand bed. Also, processes have been developed for production of columbium oxide through treatment of ferrocolumbium produced from pyrochlore concentrates. This technology is being used to produce commercial

quantities of columbium oxide suitable for the manufacture of high-purity ferrocolumbium, nickel columbium, and columbium metal.

In the extraction of columbium from other mineral concentrates and tin slags, modern technology makes use mainly of digestion with hydrofluoric acid followed by liquid-liquid extraction with methyl isobutyl ketone (MIBK). This procedure efficiently recovers both columbium and tantalum in the form of separate streams that then can be further processed individually into oxides and metal. Columbium oxide is precipitated from the columbium stream by ammonia and then purified and calcined.

Columbium oxide is aluminothermally reduced batchwise to produce high-purity ferrocolumbium, nickel columbium, and columbium metal. Aluminothermally produced columbium metal is commonly purified to remove aluminum and other contaminants by remelting it in an electron-beam furnace. Several remelts may be required before the desired level of purity is reached and a ductile ingot has been produced. The basic method for production of columbium carbide is reduction of columbium oxide by carbon at high temperature under vacuum or a protective atmosphere.

Recycling.—Columbium used in steelmaking and in superalloy manufacture is essentially a dissipative use, and little is reclaimed. However, when strict scrap segregation practices are followed, small quantities of columbium-bearing superalloy scrap are recycled. Aside from sales to alloy melters, columbium metal scrap has not been recycled to any extent other than in-house as home scrap by processors.

Byproducts and Coproducts

In Africa, Australia, Brazil, Malaysia, and Thailand, columbium, as well as tantalum, is produced as a byproduct and/or coproduct of tin mining. Columbium and tantalum can also be recovered economically from some tin slags, which constitute an important raw

material source for high-purity columbium and tantalum. Other elements frequently associated with columbium deposits include rare earths, thorium, titanium, and uranium; some of these have been recovered along with columbium in the past and may be coextracted in the future.

Substitutes

For established applications of both columbium-bearing steels and superalloys, substitution of some alternative steel or alloy requiring less columbium ordinarily lowers performance and/or cost effectiveness. In some high-strength low-alloy (HSLA) steels, use of columbium as a microalloying element competes with use of such elements as molybdenum, titanium, and vanadium. In other HSLA steels, it may be desirable to use one or more of these elements along with columbium in complementary fashion. Tantalum is a costly potential substitute for columbium in superalloys. Titanium can be used instead of columbium in stainless steel to improve corrosion resistance.

Economic Factors

Prices.—Time-price relationships for columbium contained in concentrates in terms of actual prices and in constant 1987 dollars are shown in table 2 and figure 1. Actual prices reported are based on historical price quotations or best available information from producers.

By the end of World War II, new columbium-bearing superalloys were being used in jet airplane engines. Subsequently, the involvement of the United States in the Korean conflict, and the rapid expansion of jet-engine production during this period resulted in columbium concentrate shortages and increased prices. Additionally, the demand for ore to produce ferrocolumbium had outstripped the available supply of columbium-bearing materials. However, a significant activity during this period was the U.S. Government-guaranteed worldwide 100% bonus

purchase program under title III of the Defense Production Act. The program was initiated to encourage increased production of columbium-tantalum ore and concentrates of both domestic and foreign origin.

In May 1952, the Defense Materials Procurement Agency (DMPA) announced its schedule for the purchase of columbium concentrates for the National Stockpile at an average price of \$3.40 per pound of combined columbium-tantalum oxides. The program was such a success in the expansion of supply that in only 3 years the stockpile had acquired 15 million pounds of columbium and tantalum oxides contained in columbium concentrates.

Having achieved its basic objectives, the U.S. Government stopped buying foreign material under the program in May 1955. Small-lot purchases of domestically produced material continued until 1958. The DMPA purchase price had largely governed the market quotations for columbium concentrates, and termination of the program was followed by lower prices and reduced production worldwide.

With the trend of increasing columbium demand, concentrate prices began to escalate in the mid-1970's with the peak year occurring in 1977. The price increase was attributed to inflation, higher labor costs, and resulting higher raw material costs.

In 1980, an important change in the nature of columbium supply occurred with the commercialization both in Brazil and the United States of plants for producing columbium oxide from pyrochlore-based materials. This event resulted in the lowering of prices for columbium oxide and high-purity columbium products. Columbium prices were lowered in much of the 1980's, owing to the large quantities of pyrochlore produced in Brazil and Canada, and the products produced from this feed material.

Depletion Provisions.—U.S. columbium-producing companies are granted a depletion allowance of 22% for domestic

production of columbium minerals and 14% on foreign production.

BACKGROUND—TANTALUM

Tantalum is a refractory metal that is ductile, easily fabricated, has a high melting point (2,996° C), is highly resistant to corrosion by acids, and is a good conductor of heat and electricity. It combines readily with other refractory metals such as hafnium and tungsten to form alloys having high-temperature strength and stability. Tantalum forms highly stable anodic films and exhibits a rectifying, or electronic valve, action in an electrolyte. Tantalum is twice as dense as steel with a specific gravity of 16.6.

Definitions, Grades, and Specifications

Metallic forms of tantalum are produced chiefly in unalloyed form or alloyed with up to about 10% tungsten. Unalloyed metal and alloys with tungsten are available as ingot, plate, sheet, strip, bar, rod, wire, and tubing in accordance with ASTM Specifications B364, B365, and B521. Allowable impurity levels do not exceed 0.3% in most cases; the main impurities are columbium and oxygen, plus tungsten in the case of unalloyed tantalum. Purity of tantalum metal powder is usually about 99.9%. Depending on powder usage, impurities that must be controlled consist mainly of calcium, carbon, columbium, iron, nickel, nitrogen, oxygen, silicon, and sodium. Commercial tantalum carbide usually contains about 93% tantalum and about 6.3% carbon.

Products for Trade and Industry

The major end use for tantalum, as tantalum metal powder, is in the production of electronic components, mainly tantalum capacitors. Applications for tantalum capacitors include computers, communication systems, and instruments and controls for aircraft, missiles, ships, and weapon systems. The tantalum capacitor exhibits reliable performance and combines compactness

and high efficiency with good shelflife. Because of its high melting point, good strength at elevated temperatures, and good corrosion resistance, tantalum is combined with cobalt, iron, and nickel to produce superalloys that are employed in aerospace structures and jet engine components. Tantalum carbide, used mostly in mixtures with carbides of such metals as columbium, titanium, and tungsten, is used in cemented-carbide cutting tools, wear-resistant parts, farm tools, and turning and boring tools. Because of its excellent corrosion resistant properties, tantalum mill and fabricated products are used in the chemical industry in applications such as heat exchangers, evaporators, condensers, pumps, and liners for reactors and tanks.

Geology-Resources

The principal source of tantalum is an isomorphous series of minerals containing columbium, iron, manganese, and tantalum oxides. Tantalum and columbium have strong geochemical affinity and are found together in most rocks and minerals in which they occur. Tantalite-columbite occurs mainly as accessory minerals disseminated in granitic rocks or in pegmatites associated with granites. The microlite-pyrochlore mineral series is also a source of tantalum. These minerals consist essentially of complex oxides of calcium, columbium, sodium, and tantalum in combination with hydroxyl ions and fluorides. Microlite occurs mainly in the albitized zones of granite pegmatites, often associated with tantalite or columbite. Struverite is a low-grade source of tantalum recoverable from tin-mining wastes in Southeast Asia. Struverite is a variation of the titanium mineral rutile. Tantalum is also obtained through byproduct recovery from tantalum-bearing tin slags, principally from smelters in Brazil and Southeast Asia.

Reserve and reserve base data for tantalum are shown in table 3 and are based on a judgmental appraisal of current information. Reserve base is defined as the in-place demonstrated

(measured plus indicated) resource from which reserves are estimated. The reserve base may encompass those parts of the resources that have a reasonable potential for becoming economically available within planning horizons beyond those that assume proven technology and current economics. Reserves are defined as that part of the reserve base that could be economically extracted or produced at the time of determination.

Technology

Exploration.—Exploration for tantalum is generally pursued on the basis of its known frequent association with tin and certain other elements in pegmatite environments, some features of which can be distinguished by aerial photography. Application of X-ray fluorescence analysis techniques has been helpful in measuring tantalum at the low concentrations at which it occurs. The high specific gravity of tantalum minerals makes it possible to reveal their presence in placer deposits by test pitting and panning.

Mining.—Most tantalum-related mining developments in the past generally were small, relatively high-cost intermittent operations that depended on the recovery of byproduct or coproduct minerals for economic viability. Future mine development will shift more to primary tantalum sources, notably operations in Australia.

Both alluvial and residual tantalum and tantalum-containing tin deposits are normally mined by hand, by hydraulic monitors, by dredges, or by mechanized open pit mining. The mining of pegmatite deposits, which may be either open pit or underground, is carried out by blasting, transporting, and crushing the rock to free the tantalum and associated coproduct minerals. The materials are then concentrated by wet gravity methods (sluices, jigs, spirals, and tables) and finally separated from associated minerals by gravity and electrostatic and electromagnetic processes.

Tantalum is recovered from slags produced at tin smelters throughout the world. Tantalum content varies in tin slag depending on ore and smelting practice.

Beneficiation.—Tantalum mineral concentrates and tin slags are the predominant feed materials for preparation of tantalum metal and compounds. Both raw materials usually contain recoverable amounts of columbium as well. Depending on circumstances, tin slags may be used directly for extraction of tantalum or they may be first upgraded. Upgrading is typically performed by means of an electric furnace process that yields a synthetic concentrate.

In the extraction of tantalum from these source materials, technology makes use mainly of digestion with hydrofluoric acid followed by liquid-liquid extraction with MIBK. This procedure efficiently recovers both tantalum and columbium in the form of separate streams that then can be further processed individually into salts, oxides, and metal. The two streams are produced by a series of countercurrent extractions that also remove impurities. The tantalum product stream is a fluotantallic acid solution from which either potassium fluotantalate (K-salt), by addition of potassium chloride or fluoride, or tantalum pentoxide, by addition of ammonia, can be precipitated. Reducing K-salt by sodium is the standard commercial method for making tantalum metal. The product of sodium reduction is a powder that is consolidated by a pressing, vacuum sintering, and melting sequence.

Tantalum carbide can be manufactured by several methods, the most common being solid-state reaction between tantalum oxide and carbon. Tantalum carbide can also be made by reacting metallic tantalum directly with carbon.

Recycling.—Recycling of tantalum largely takes place within the processing and product producing industry and is mostly runaround or home scrap that is consumed internally. In addition,

quantities of tantalum are recycled indirectly in the form of used tantalum-bearing cutting tools and high-temperature alloy melting scrap.

Byproducts and Coproducts

Economic exploitation of tantalum minerals often is dependent on the price of associated recoverable byproduct or coproduct minerals, principally tin and columbium. Tantalite-columbite minerals occur in deposits associated with beryllium, lithium, rare-earth, tin, titanium, tungsten, uranium, and zirconium minerals. Minerals associated with tantalum in pegmatite deposits include beryl, feldspar, lepidolite, mica, pollucite, and spodumene. Tantalum and columbium can also be recovered economically from some tin slags, which constitute an important raw material source for tantalum and high-purity columbium. Tantalum is usually extracted in conjunction with columbium in much the same type of equipment.

Substitutes

Substitution for tantalum is usually made at a performance or economic penalty for most uses. Also, substitution requires both investment and experimentation and does not necessarily occur quickly. Aluminum and ceramics compete strongly with tantalum for use in electronic capacitors. In cemented carbides, columbium carbide and columbium-hafnium carbide can take the place of tantalum carbide in some cutting tools. Replacements for tantalum in corrosion-resistant equipment are columbium, glass, platinum, titanium, and zirconium. Columbium, hafnium, molybdenum, tungsten, and some platinum-group metals can be substituted for tantalum in high-temperature applications.

Economic Factors

Prices.—Time-price relationships for tantalum contained in concentrates in terms of actual prices and in constant

1987 dollars are shown in table 4 and figure 2. Actual prices reported are based on historical price quotations or best available information from producers. The prices show large swings between the high and low in response to market conditions.

The Korean conflict in 1950 increased demand for tantalum in military requirements. Thus, consumption rose sharply with resulting ore shortages. During this period, the U.S. Government-guaranteed worldwide 100% bonus purchase program was initiated to increase production of columbium-tantalum ore and concentrates of both domestic and foreign origin. In May 1952, a schedule was announced for the purchase of 15 million pounds of the combined columbium-tantalum oxides at prices about double prevailing world prices. The program had the effect of increasing tantalum ore prices to a high of \$8 per pound of oxide.

Having achieved its basic procurement objectives, the purchase of foreign material was stopped in May 1955. Small-lot purchases of domestically produced material continued until December 1958. When Government purchase of domestic ore stopped, the immediate effect was a confused market in which production and prices of ore began to drift downward. By 1959, prices for tantalum ore had dropped to about \$4 per pound of oxide.

By 1960, tantalum demand for use in capacitors, high-temperature alloys, corrosion-resistant chemical applications, machine cutting tools, and aerospace applications had increased substantially. During the 1960's, the variations in supply and demand resulted in a repetition of 2 or 3 years of oversupply with lower prices followed by 2 or 3 years of high demand with higher prices. Price peaks in 1961 and 1966 were occasioned by a sudden increase in demand for tantalum, which outstripped the supply, driving prices up. This cyclical trend continued into the 1970's.

The 1970's can be characterized as a decade of increasing tantalum demand, ore shortages, escalating prices, and substitution. A 7-year trend of declining

price, 1967-73, was followed by a trend of rapid price increase that was sustained through midyear 1980. The record price levels during this period were attributed in part to a state of panic buying influenced by anticipated greater tantalum demand, amidst concerns at the time of a shrinking world tantalum supply. The high prices brought about substitution for tantalum and more widespread search for and development of new tantalum sources. However, prices began declining by yearend 1980 and by midyear 1986 were the lowest since first quarter 1977, hastened by a weak tantalum demand and an increase in tantalum material stockpiles. Subsequently, prices rebounded through yearend 1988 and were at the highest level since the third quarter of 1981, responding to increased demand for feed materials along with the drawdown of stockpiles. The price of tantalum continued its cyclic pattern, and the 1991 average price quote was about \$30 per pound of oxide.

Depletion Provisions.—U.S. tantalum-producing companies are granted a depletion allowance of 22% for domestic production of tantalum minerals and 14% on foreign production.

ANNUAL REVIEW— COLUMBIUM AND TANTALUM

Legislation and Government Programs

At yearend, Government stocks of columbium and tantalum in the NDS were the same as those in 1990 (table 7). The overall goal of the columbium group, on a recoverable basis, was 5.68 million kilograms (12.52 million pounds). The overall goal for the tantalum group, on a recoverable basis, was 3.25 million kilograms (7.16 million pounds). Under the offset concept for the NDS, less than 25% of the goal for columbium concentrates and 37% of the goal for tantalum minerals were met.

In July, the Department of Defense issued a report to Congress recommend-

ing revisions to stockpile material goals, including those for the columbium and tantalum groups. The goal for the columbium group would increase from 6.02 million kilograms (13.27 million pounds) to 7.99 million kilograms (17.6 million pounds). The goal for tantalum minerals would decrease from 3.81 million kilograms (8.4 million pounds) to 2.88 million kilograms (6.34 million pounds). The proposed goals, based on 1989 supply and demand data, were said by the Department to continue to meet a 3-year global conventional war. At yearend, Congress had not yet approved the proposed goal revisions.

In its "Strategic and Critical Materials Report To The Congress, April 1991-September 1991," the Department of Defense reported that 59,251 kilograms (130,626 pounds) of tantalum material had been accepted and received into the stockpile. However, status (inventory) of the material had not been determined. The material was part of the 90,718 kilograms (200,000 pounds) of tantalum oxide contained in tantalum natural minerals and concentrates contracted for in 1990 from Sogem-Afrimet, New York, NY, and O'Dell Construction Co., Prattville, AL.

In September, the DLA awarded a contract to purchase 90,718 kilograms (200,000 pounds) of the product "tantalum oxide" for the NDS. The material will conform to the requirements for Grade 2 tantalum oxide, as modified, stated in National Stockpile Purchase Specification P-113a, Tantalum Source Materials, dated August 3, 1981. The award was made to O'Dell Construction, one of eight bidding firms.

The award was for eight 11,340-kilogram (25,000-pound) allotments at a purchase price of \$55.00 per pound of tantalum oxide for each of the eight lots. Bid prices for the eight allotments, under varying bid conditions, ranged from \$47.88 to \$145.00 per pound of tantalum oxide. The material shall be delivered between January 1, 1992, and March 31, 1994, to be placed equally in NDS storage depots at New Haven, ID, and Somerville, NJ. Payment for the tantalum oxide, including transportation,

will be made with excess material available for disposal under the Stockpile Disposal Program.

In its revised fiscal year 1992 Annual Materials Plan for the NDS, the Department of Defense provided for the acquisition of 113,400 kilograms (250,000 pounds) of columbium for the columbium group and 28,576 kilograms (63,000 pounds) of tantalum metal. Additionally, some existing columbium and tantalum stockpile materials would be upgraded: 204 metric tons (225 short tons) of columbium-tantalum concentrates to columbium and tantalum metal, 18,144 kilograms (40,000 pounds) of tantalum powder to vacuum-grade metal, and 20,412 kilograms (45,000 pounds) of columbium powder to vacuum-grade metal.

In August, the Memphis region of the Defense Reutilization and Marketing Service reportedly sold two lots of tantalum capacitor scrap at a sale of nonferrous recyclables at Warner Robbins Air Force Base, GA. EDS Enterprises Co., Upland, GA, was the high bidder for both lots. One 268-kilogram (590-pound) lot of tantalum capacitor scrap, silver coated, attracted a high bid of \$13.88 per pound. The other 488-kilogram (1,075-pound) lot of tantalum capacitor scrap attracted a high bid of \$4.48 per pound.¹

Strategic Considerations

The high degree of import reliance for columbium and tantalum continues to be the principal strategic problem faced by the United States. Summaries of important columbium and tantalum statistics are shown in tables 5 and 6, respectively. In the case of both columbium and tantalum, there has been no significant mining since the 1950's. Domestic columbium and tantalum resources are of low grade, some mineralogically complex, and most are not currently commercially recoverable. To ensure a supply of columbium and tantalum during an emergency, goals for both materials have been established for the NDS. However, inventories for both materials are substantially under set

goals. Consequently, a degree of vulnerability still remains.

The NDS goals and inventory for both columbium and tantalum are mostly for source materials (feedstocks). However, the United States has become more reliant on the processing capability of foreign sources and the availability of intermediate products from those sources. At the start of the 1980's, there were four major processors of columbium- and tantalum-bearing source materials. One of the operations was shut down in 1985, and another shut down its processing operation at yearend 1989. Of the remaining two companies, one is dedicated solely to the processing of columbium materials, whereas the other company processes both columbium and tantalum materials. Thus, there is concern whether the United States would have on hand in an emergency adequate processing capacity for conversion of the stockpile materials to an upgraded form and quality required by the critical end uses.

Production

In 1991, there were two processors of columbium- and tantalum-bearing source materials that were integrated from raw material processing to columbium and tantalum end products: Cabot Corp. for columbium and tantalum processing and Shieldalloy Metallurgical Corp., dedicated solely to columbium processing. NRC Inc., a major supplier, and Thai Tantalum Inc. produced tantalum products. Reading Alloys Inc. and Teledyne Wah Chang Albany were major producers of high-purity columbium products. Kennametal Inc. was the major producer of columbium and tantalum carbides. Major domestic columbium and tantalum processing and producing companies are shown in table 8.

Early in the year, Shieldalloy, a Metallurg Inc. subsidiary, announced that all management functions previously located at the Metallurg headquarters in New York had been transferred to its Newfield, NJ, plant effective January 1. The consolidation of management and

operation functions was said to be for the overall improvement in communications and efficiency at the company. Additionally, Metallurg reported that a new division, Metallurg International Resources, had been created early in the year to conduct all export and trading activities previously conducted by the company.

In April, the Unocal Corp. announced that its Molycorp Inc. subsidiary and parts of its chemical businesses were still up for sale. Molycorp, based in Los Angeles, CA, holds a 45% interest in the world's largest producer and supplier of columbium products, CBMM of Brazil.

Consumption and Uses

Overall reported consumption of columbium as ferrocolumbium and nickel columbium was down by 7% compared with that of 1990 (see table 10). Consumption of columbium by the steelmaking industry was down by 9%, in line with an 11% decrease in raw steel production. There was a small increase in the percentage of columbium usage per ton of steel produced. Columbium consumption in carbon steel decreased by 35%, while columbium consumption in HSLA steel advanced by 20%. Demand for columbium in superalloys was up slightly. That portion used in the form of nickel columbium increased to more than 280,000 kilograms, reflecting a significant shift from ferrocolumbium. U.S. columbium consumption in 1990, by end use, is shown in figure 3.

Overall consumption of tantalum was down from that of 1990. Factory sales of tantalum capacitors were up by 9%, as reported by the Electronic Industries Association. However, the amount of capacitor-grade powder consumed was on the decline owing to the continued use of higher capacitance tantalum powders. U.S. tantalum consumption in 1990, by end use, is shown in figure 4.

Markets and Prices

A published price for pyrochlore concentrates was not available. The published price for pyrochlore produced

in Canada was suspended in early 1989. However, industry sources indicated that Canadian pyrochlore was about \$2.75 per pound of contained Cb_2O_3 , f.o.b. Canada. A price for Brazilian pyrochlore has not been available since 1981 when exports were stopped. The Metals Week published price for regular-grade ferrocolumbium was unchanged throughout the year at \$6.58 per pound of contained columbium, f.o.b. shipping port.

The Metals Week published spot price for columbite ore, quoted since July 1989 at a range of \$3.00 to \$3.50 per pound of contained Cb_2O_3 and Ta_2O_5 , c.i.f. U.S. ports, was suspended in February. The Metal Bulletin published price for columbite ore, on the basis of a minimum 65% contained Cb_2O_3 and Ta_2O_5 , remained unchanged at a range of \$2.60 to \$3.05 per pound. For the year, the Metals Week published price for high-purity ferrocolumbium containing 62% to 68% columbium was quoted at \$18.50 per pound of contained columbium, f.o.b. shipping point, and the published price for nickel columbium was quoted at \$20.50 per pound of contained columbium. Metals Week's published price for columbium oxide was \$8.17 per pound of oxide, and its published price for columbium metal was at a range of \$30 to \$50.

The Metals Week published spot price for tantalite ore fell from a range of \$31 to \$35 per pound of contained Cb_2O_3 and Ta_2O_5 , c.i.f. U.S. ports, to a range of \$27.50 to \$29.00 in early October, where it remained through December. The Metal Bulletin published price for tantalite remained unchanged at a range of \$34 to \$37 per pound of contained Ta_2O_5 . The Metal Bulletin published price for tantalite produced by Greenbushes Ltd. of Australia, quoted since February 1989 at \$50 per pound on the basis of 40% contained Ta_2O_5 , fell to \$40 per pound in mid-April, where it remained through December. A published price for tantalite from the Canadian producer, Tantalum Mining Corp. of Canada Ltd. (TANCO), was not available. Industry sources indicated that tantalum mill products sold at an average

of \$170 per pound, depending on specification, and that tantalum capacitor-grade powder sold at an average of \$145 per pound.

Foreign Trade

Net trade for columbium and tantalum continued at a deficit, but closed to the lowest level since 1986. Overall trade value for exports rose by 11%, with total volume up by 17% owing to significant increases in the volume of ferrocolumbium and wrought tantalum exports. For imports, trade value was down by 8%. Data for exports and imports are summarized in table 11.

Imports for consumption of columbium mineral concentrates increased by 12% from those of 1990 (see table 12). Canada was the leading supplier, providing about 90% of both total quantity and total value. Imports at an average grade of approximately 58% Cb_2O_3 and 3% Ta_2O_5 were estimated to contain 1.01 million kilograms of columbium and 60,000 kilograms of tantalum.

Imports for consumption of tantalum mineral concentrates continued to decline, with the average unit value for overall imports decreasing by 16% (see table 13). Imports from Germany and Japan, both nonproducing countries, together accounted for about 40% of total quantity and about 36% of total value. Imports at an average grade of approximately 37% Ta_2O_5 and 23% Cb_2O_3 were estimated to contain 280,000 kilograms of tantalum and 150,000 kilograms of columbium.

Imports for consumption of synthetic tantalum-columbium concentrates totaled 63,000 kilograms valued at \$741,000, compared with 51,000 kilograms valued at \$1.5 million in 1990. These figures are not included in the salient statistics data.

Brazil continued as the major source for U.S. columbium imports, and Germany continued as the major source for U.S. tantalum imports (see figures 5 and 6). The schedule of tariffs that applied during 1991 to U.S. imports of selected columbium and tantalum materials is given in table 14.

World Review

Industry Structure.—Principal world columbium and tantalum raw material and product producers are shown in tables 15 and 16, respectively. Brazil and Canada remained as the major producers of columbium raw materials feedstock, while tantalum raw materials continued to be produced mainly in Australia, Brazil, Canada, and in Thailand in the form of high-grade tantalum-bearing tin slags. Synthetic concentrates, produced from low-grade tin slags from Germany, were an additional source of columbium and tantalum raw material supply. Annual world production of columbium and tantalum mineral concentrates, by country, is given in table 18. World tantalum supply in 1981-91 is shown in figure 7.

Capacity.—The data in table 17 are rated capacity for mines and mills as of December 31, 1991. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable long-term operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgement of the author, can be brought into production within a short period of time with minimum capital expenditure. Mine capacity for columbium and tantalum is based on published reports, maximum production statistics, and estimates where capacity information is either incomplete or unavailable.

Australia.—For its fiscal year ending June 30, 1991, Gwalia Consolidated Ltd. reported that tantalite output at its Greenbushes Mine, southwest Western Australia, had increased gradually during the year from annual rates of 122,470 kilograms in the first quarter to 181,437 kilograms in the fourth quarter. Ore treated at Greenbushes almost doubled to 2.985 million tons, with tantalum oxide

production in tantalum concentrates increasing to about 146,000 kilograms. Tantalum oxide contained in tantalum glass (slag) production fell to 37,430 kilograms.²

A feasibility study to evaluate and consider the various alternatives and requirements necessary to operate and/or upgrade existing operations at Greenbushes to maximize production at the lowest possible cost was completed. Results of the study reportedly indicated sufficient positive returns to enable Gwalia to proceed with recapitalization of the mine. The study concluded that "tin/tantalum and spodumene ores should continue to be produced from open pits, with the transition from weathered to fresh pegmatite ores for the tin/tantalum sector." Construction of a new tantalum processing facility for treating the harder ores would be required. Thus, a decision was made to proceed with development of the tantalum hard-rock operations and to construct new tantalum processing facilities. Plans were made for commencing plant construction by yearend, with commissioning of the new facilities scheduled for about October 1992.

Additionally, Gwalia announced that the company had entered into contracts with two of the world's largest tantalum processors, Cabot Corp. and Hermann C. Starck, for the long-term supply of tantalite concentrates. The initial contracts are for a period of 5 years, with concentrates to be supplied at fixed volumes and prices to be set on an annual basis. Quantities to be delivered under the secured contracts are for a minimum of 0.907 million kilograms of contained Ta_2O_5 and a maximum of 1.089 million kilograms of Ta_2O_5 over the next 5 years.

As reported by Pancontinental Mining Ltd. for its fiscal year ending June 30, 1991, tantalum production at the Wodgina Mine was about 127,000 kilograms of Ta_2O_5 contained in concentrate. A total of 88,172 tons of ore grading 0.1892% Ta_2O_5 was processed in the treatment plant yielding 286.2 tons of concentrate grading 44.4% Ta_2O_5 , with a metallurgical recovery of 76%. The mine, 120 kilometers south of Port

Hedland in the Pilbara region of Western Australia, is a 50-50 joint venture between Pancontinental and Goldrim Mining Australia Ltd. Pan West Tantalum Pty. Ltd., a wholly owned subsidiary of Pancontinental, is the operator of the joint venture. A small metallurgical laboratory was constructed and commissioned on-site to monitor plant performance and to test new techniques and/or equipment that have potential for improving recoveries.³ The 1991 reporting period was the first full year of operation at Wodgina, which was officially opened by the Western Australian Minister for Resources in February 1990.

Brazil.—CBMM was reported to have installed a new semicontinuous autothermic reduction process to produce standard-grade (steelmaking-grade) ferrocolumbium at its facility in Araxa. CBMM had relied on the conventional batch thermite process, developed during the 1960's, to produce the ferrocolumbium. The new process, designed and constructed by CBMM, was said to have led to the elimination of atmospheric pollution and minimized the impact of cost increases. As reported previously, the new plant will have an annual ferrocolumbium capacity of about 25,000 tons.

Associação Brasileira dos Produtores de Ferroligas (ABRAFE), the Brazilian ferroalloy producers association, reported 1991 production of ferrocolumbium as 18,959 tons, up from the 16,643 tons produced in 1990. ABRAFE reported exports of ferrocolumbium totaled 15,163 tons compared with 13,360 tons exported in 1990.

Canada.—As reported by Teck Corp., production of Cb_2O_5 at the Niobec Mine at St. Honoré, Quebec, decreased slightly to about 3.37 million kilograms. Niobec is a 50-50 joint venture between Teck, operator, and Cambior Inc., product marketing. Ore milled increased to 805,000 tons, as the mill operated on the average of 2,242 tons of ore per day. Average recovery was down to 60.2%

with Cb_2O_5 grade of concentrate at 70%. Due to the frequent changes in the character of the ore, which can complicate the milling process, an on-stream analyzer costing \$650,000 was installed to improve ore process control. Exploration drilling during 1991 established new ore reserves that essentially replaced ore processed during the year. Thus, yearend ore reserves remained at 10.1 million tons averaging 0.65% Cb_2O_5 .⁴

Japan.—Production of ferrocolumbium was 710 tons, down significantly from the 984 tons produced in 1990. With the exception of Japan Metals & Chemicals Co. Ltd., it was reported that all other ferrocolumbium producers had ceased production by July. However, The TEX Report reported that Japan's demand for ferrocolumbium for steelmaking was 4,398 tons, an alltime high. Columbium ore imported for ferrocolumbium production increased by 15% to 1,347 tons, with Canada continuing to provide more than 80% of the total. Ferrocolumbium imports rose to 4,526 tons from the 3,516 tons reported in 1990. The bulk of ferrocolumbium imports continued to come from Brazil. Columbium consumption in Japan reportedly continues to increase owing to demand from its automakers.

Roskill's Letter from Japan reported that Japan's demand for tantalum materials rose to 274 tons from the 264 tons reported for 1990.

Thailand.—To compensate for the decrease in Thailand's tin concentrate output, the Thailand Smelting and Refining Co. Ltd. (Thaisarco) tin smelter was reported to have purchased concentrates from the Laos state-owned Société de Exploitation des Mines D'Etaine. Thaisarco, with an annual tin capacity of 38,000 tons, sought to find alternate sources of supply in light of Thailand's declining tin concentrate production. However, Thai tin concentrates are high in tantalum content from which the Thaisarco smelter produces a

tantalum-bearing slag containing up to 17% Ta_2O_5 . Increasing the throughput of imported concentrates could result in reduced tantalum content of the slags. Thaisarco-produced tantalum-bearing tin slags have been a major source of world tantalum supply for years. The smelter has an annual capacity to produce from Thai concentrates about 318,000 kilograms of tantalum contained in slags.

Thai Tantalum Co. Ltd. was reported to have revised the scheduled startup of its tantalum processing plant, to occur by yearend 1992. The plant is being constructed at the Map Ta Phut Industrial Estate in Rayong Province east of Bangkok. When operational, the new facility reportedly will have an annual capacity of 300 tons of intermediate tantalum products.

OUTLOOK

Columbium

Columbium is used principally as an additive in steelmaking, which continues to account for about 80% of the reported consumption in the United States. No significant change to this trend is expected in the near term for there are few other growth markets and/or uses for columbium. Thus, future columbium demand growth will continue to be directly related to the worldwide performance of the steel industry. U.S. apparent consumption of columbium has been in the range of 3,200 to 3,600 tons of contained columbium for the period 1987-91, and any major future variations from this trend will depend on future activities of the domestic steel industry. The outlook for steel is discussed in the annual report for "Iron and Steel." The outlook for columbium will also be dependent to a lesser degree on the performance of the aerospace industry. Domestic reported consumption of columbium in the production of superalloys continues to be no more than 20%. Future growth for this end use will be affected mainly by the demand for columbium-containing superalloys from the aircraft industry. However, industry sources indicate that continued reduction

in military spending is expected to lead to reduced aerospace shipments throughout the decade. The major components of U.S. supply-demand relationships for columbium in 1981-91 are given in table 19.

Tantalum

For the past decade, more than 60% of the tantalum consumed in the United States was used to produce electronic components, mainly tantalum capacitors, with major markets in recent years being computer and communication systems. However, overall tantalum demand growth in this sector has been slowed owing to the industry's continued emphasis on higher capacitance powders and the miniaturization of electronic components resulting in less tantalum used per unit. Also, tantalum demand in the cemented carbide sector continues to be affected by the growing use of mixed carbides, coated cutting tools, improved tool life, and the down-sizing of components. Additionally, the price for tantalum has had a cyclical and somewhat volatile history that has adversely impacted demand. However, major tantalum processors have entered into long-term contracts for the supply of tantalum concentrates. Under terms of the contracts, material would be supplied at fixed volumes and prices on an annual basis for a period of 5 years. With the award of these contracts, future stability in the supply and price of tantalum is anticipated. The major components of U.S. supply-demand relationships for tantalum in 1981-91 are given in table 20.

World: Production of columbium-tantalum concentrates⁵	275	291	378	¹366	423

⁵Estimated. ⁶Revised. NA Not available. W Withheld to avoid disclosing company proprietary data.

¹A small unreported quantity was produced.

²Includes reexports.

³Exclusive of waste and scrap.

⁴Receipts reported by consumers; includes synthetic concentrates and other miscellaneous materials, after deduction of reshipments.

**TABLE 7
COLUMBIUM AND TANTALUM MATERIALS IN GOVERNMENT
INVENTORIES AS OF DECEMBER 31, 1991**

(Thousand kilograms of columbium or tantalum content)

Material	Stockpile goals	National Defense Stockpile inventory		
		Stockpile grade	Nonstockpile grade	Total
Columbium:				
Concentrates	6,019	522	394	¹ 916
Carbide powder	45	10	—	10
Ferrocolumbium	—	271	151	¹ 422
Metal	—	20	—	¹ 20
Total	(²)	823	545	1,368
Tantalum:				
Minerals	3,810	765	—	¹ 1,288
Carbide powder	—	13	(⁴)	¹ 13
Metal	—	91	—	¹ 91
Total	(²)	869	523	1,392

¹All surplus ferrocolumbium and columbium metal were used to offset columbium concentrates shortfall. Total offset was 520,700 kilograms.

²Overall goals, on a recoverable basis, total 5,679,100 kilograms for the columbium metal group and 3,247,800 kilograms for the tantalum metal group.

³All surplus tantalum carbide powder and tantalum metal were used to offset the tantalum minerals shortfall. Total offset was 122,900 kilograms.

⁴45 kilograms.

STOCKS		
December 31:		
Consumer	NA	NA
Producer ³	NA	NA
Total stocks⁴	NA	NA

¹Estimated. ²Revised. NA Not available.

³Includes columbium and tantalum in ferrotantalum-columbium, if any.

⁴Included with "Steel: High-strength low alloy."

⁵Included with "Steel: Unspecified."

⁶Included with "Miscellaneous and unspecified."

⁷Ferrocolumbium only.

TABLE 11
U.S. FOREIGN TRADE IN COLUMBIUM AND TANTALUM METAL AND ALLOYS, BY CLASS

(Thousand kilograms, gross weight, and thousand dollars)

Class	1990		1991		Principal destinations and sources, 1991
	Quantity	Value	Quantity	Value	
EXPORTS¹					
Columbium:					
Ores and concentrates	48	337	8	55	Mexico 6, \$34; Japan 1, \$8; India 1, \$7; Costa Rica (°), \$4; Canada (°), \$2.
Ferrocolumbium	585	5,495	741	6,952	Canada 649, \$6,144; Mexico 88, \$772; Trinidad and Tobago 2, \$19; China 1, \$14.
Tantalum:					
Synthetic concentrates	13	131	—	—	—
Ores and concentrates	1	7	11	248	Barbados 7, \$168; United Kingdom 3, \$70; Germany (°), \$10.
Unwrought and waste and scrap	89	3,862	121	3,651	Germany 114, \$3,111; Canada 3, \$281; United Kingdom 1, \$108; Austria 1, \$79; Netherlands 1, \$71.
Unwrought powders	82	21,638	66	19,659	United Kingdom 20, \$6,265; Japan 16, \$4,414; Germany 14, \$4,387; France 15, \$4,167; Italy 1, \$262.
Unwrought alloys and metal	12	3,700	21	4,336	Canada 15, \$3,380; Netherlands (°), \$279; Spain 2, \$270; Japan (°), \$172; United Kingdom (°), \$75; Mexico (°), \$75.
Wrought	60	20,068	77	26,580	Japan 39, \$13,330; Germany 9, \$3,657; United Kingdom 10, \$3,459; France 6, \$1,860; Canada 6, \$1,519; South Africa 3, \$1,324.
Total	XX	55,238	XX	61,481	Japan \$17,900; Canada \$11,300; Germany \$11,200; United Kingdom \$10,000; France \$6,000. ³
IMPORTS FOR CONSUMPTION					
Columbium:					
Ores and concentrates	2,251	7,898	2,515	8,445	Canada 2,241, \$7,598; Nigeria 64, \$253; Netherlands 51, \$167; Germany 37, \$164; Belgium 68, \$88.
Oxide	973	15,348	603	10,210	Brazil 521, \$7,951; Germany 82, \$2,253; United Kingdom (°), \$7.
Ferrocolumbium	2,919	24,685	3,282	27,415	All from Brazil.
Unwrought alloys, metal, and powders	2	149	1	103	Canada 1, \$66; Brazil 1, \$22; Germany (°), \$8.
Tantalum:					
Synthetic concentrates	51	1,464	63	741	All from Germany.
Ores and concentrates	1,016	25,589	937	19,868	Germany 296, \$5,653; Australia 113, \$4,360; Canada 133, \$3,458; Japan 78, \$1,496; Zaire 48, \$901; Thailand 40, \$861.
Unwrought waste and scrap	77	6,990	120	8,558	Germany 37, \$4,344; Japan 28, \$2,296; France 16, \$781; Mexico 27, \$381; China 4, \$292; United Kingdom 3, \$185; India 1, \$106.
Unwrought powders	13	2,038	16	2,645	Germany 10, \$1,561; Japan 2, \$695; China 3, \$388; Peru (°), \$2.
Unwrought alloys and metal	6	733	1	259	Germany 1, \$242; Japan (°), \$13; United Kingdom (°), \$4.
Wrought	3	1,028	2	765	Germany 1, \$572; Japan (°), \$54; Canada (°), \$54; Austria (°), \$30; United Kingdom (°), \$28; Switzerland (°), \$22.
Total	XX	85,922	XX	79,009	Brazil \$35,800; Germany \$15,500; Canada \$11,200; Japan \$4,600; Australia \$4,400. ³

¹Revised. XX Not applicable.

²For columbium, data on exports of metal and alloys in unwrought and wrought form, including waste and scrap, are not available; included in nonspecific tariff classifications.

³Less than 1/2 unit.

⁴Rounded.

¹Estimated. Revised. NA Not available.

²Excludes columbium- and tantalum-bearing tin concentrates and slags. Production of tantalum contained in tin slags was, in thousand kilograms: 1987—246; 1988—519; 1989—362; 1990—343; and 1991—244 according to data from the Tantalum-Niobium International Study Center. Table includes data available through July 2, 1992.

³In addition to the countries listed, Bolivia, China, the U.S.S.R., and Zambia also produce, or are believed to produce, columbium and tantalum mineral concentrates, but available information is inadequate to make reliable estimates of output levels.

⁴Data on gross weight generally have been presented as reported in official sources of the respective countries, divided into concentrates of columbite, tantalite, and pyrochlore where information is available to do so, and reported in groups such as columbite and tantalite where it is not.

⁵Unless otherwise specified, data presented for metal content are U.S. Bureau of Mines estimates based on, in most part, reported gross weight and/or pentoxide content.

⁶Reported in and/or by official country sources.

⁷Less than 1/2 unit.

Data may not add to totals shown because of independent rounding.

COPPER

By Janice L. W. Jolly

Mrs. Jolly is a physical scientist (geologist) with more than 30 years in the mining industry, including 18 years with the U.S. Bureau of Mines. She worked as a research geologist on mineral deposits with the U.S. Geological Survey and Roan Selection Trust, Ltd. of Zambia and as a consultant on mineral affairs with the U.S. House of Representatives Armed Services Committee and the World Bank. Mrs. Jolly is currently the copper specialist for the U.S. Bureau of Mines, a position she has held since 1983. Domestic survey data were prepared by Lisa Conley, Lisa Christian, Marleese Collins, and Wannette Davis, mineral data assistants, and Jean Moore, data controller. The world production tables were prepared by country and data specialists in the Division of International Minerals.

World copper mine production of 8.8 million metric tons¹ and refined consumption of 10.8 million tons were at record levels in 1991. Though world copper supply and demand was in balance most of the year, the year ended with a surplus and an increase in refined stocks. Copper demand by U.S. semifacturers was lower during the first half of the year, but by yearend had increased as domestic markets recovered. Increased world demand continued to be driven by increased consumption in the Asian countries. Increased supplies from new capacity in Chile, Indonesia, Portugal, and the United States were offset by disruptions at other sources and the continued closure of the Bougainville Mine, Papua New Guinea. Production disruptions caused by mine closures, political problems, industry deterioration, and sporadic labor disputes also restrained the flow of copper. In addition, localized smelter shortages developed that were to both constrain refined production and increase processing charges for smelting and refining to record heights. At yearend, visible world refined inventories increased to an estimated 969,000 tons, an increase of 42% over that of 1990 and equivalent to about 5.6 weeks of market economy countries (MEC) consumption. As a result of the softer market, the U.S. producers' average annual price, at \$1.09 per pound, was lower than that of 1990. U.S. exports of scrap, concentrates, and refined copper continued to be high; most

were destined for Far Eastern markets in China, Japan, South Korea, and Taiwan.

DOMESTIC DATA COVERAGE

Domestic production data for copper were developed by the U.S. Bureau of Mines from seven separate surveys of U.S. operations. Typical of these surveys is the mine production survey. Of 123 operations to which a survey request was sent in 1991, 93% responded and 74 reported copper production, representing an estimated 99.8% of the mine production shown in tables 1, 12, 14, and 15. Production for the remainder was estimated using other surveys.

BACKGROUND

Definitions, Grades, and Specifications

Copper is traded in many forms that relate to differing stages of processing. For example, at the mine, copper may be sold as ore, concentrates, or precipitates. *Copper ore* may contain as little as 0.40% copper or more than 10% copper, depending on its source. *Copper concentrates* are produced by milling and concentrating copper ore and may contain between 18% and 40% copper. *Copper precipitate, or cement copper*, is recovered from leach solutions by chemical precipitation with scrap iron and may contain as much as 90% copper.

Smelter products include *copper matte, blister, slag, and anode*. *Slag* is the waste formed in smelting through the

combination of a *flux*, such as limestone and silica, with the gangue or waste portion of the ore and, though it may contain small amounts of copper, is high in silicon and iron. *Copper matte* contains between 15% and 65% copper, together with much of the sulfur and other nonferrous and precious metals. The newer flash smelting technologies result in a much lower sulfur content in the matte than was possible in reverberatory furnaces. Copper matte is transferred to a converting furnace where the sulfur and iron are oxidized and removed as sulfur dioxide gas and slag, respectively; the enriched copper melt (97% to 98.5% copper) is poured as *blister copper*. The blister is then *fire refined* by oxidizing the impurities in a reverberatory furnace, followed by removal of the excess oxygen by a process called *poling*. Poling may be done by insertion of green logs or a reducing gas into the melt. The blister is then cast into *anode* shape and further treated in an electrolyte bath to form *refined copper cathode* through electrolysis, a process in which the copper ions of the anode are transferred by electrical current to the negatively charged cathode. Impurities in the copper anode, such as gold, selenium, and silver, are collected at the bottom of the electrolytic tank as a residue and are recovered in a later process. Cathode copper also may be obtained from an *electrowinning* process. In this process, cathode copper is plated directly from copper-bearing solutions obtained from

leaching copper-bearing ore, matte, scrap, or other material and enriched by solvent extraction methods. Alternatively, *fire-refined* copper, or scrap, may be cast into ingots, bars, billets, or cakes and not processed electrolytically in a refining tank before direct use.

Refined copper cathode, which contains greater than 99.3% copper, is the predominant form traded. *Tough-pitch copper* is refined copper cast into shapes. *Oxygen-free copper*, which is preferred for special electrical uses, is refined copper melted and recast in a deoxidizing atmosphere. *Deoxidized copper* is refined copper treated with deoxidizers to reduce cuprous oxide and remove oxygen. Normal refinery shapes cast from cathodes and fire-refined copper are wirebars, billets, slabs, ingots, and bars. Since the late 1970's, the *continuous cast wire rod* has almost eliminated the wirebar as an intermediate shape used for making wire rod from refined copper. *Wire rod* is used to make wire. *Wirebar* currently comprises less than 1% of the copper market. *Billets* typically are large cylindrical shapes often used for extruding tubing, or sometimes wire rod. *Slabs* are the precursors to flat products such as sheet. *Ingots* are small shapes that are usually remelted and used for making alloys.

There are more than 370 copper and copper alloys divided into broad categories of wrought and cast metals. A Unified Numbering System (UNS) for Metals and Materials was developed by the American Society for Testing and Materials (ASTM) and the Society of Automotive Engineers. This system designates each copper alloy by five digits preceded by the letter C. The UNS system is administered by the Copper Development Association (CDA) and is widely used by ingotmakers, brass mills, and foundries in the United States. The five major classes are *coppers*, which contain greater than 99.3% copper; *high-copper* alloys, which contain at least 94% copper; *brasses*, which contain zinc as the dominant alloying agent; *bronzes*, which normally contain tin as the

dominant alloying agent, but also may contain such other metals as aluminum, lead, phosphorus, and silicon, but only small amounts of zinc; *copper-nickels*, which contain nickel as the principal alloy metal; *nickel silver*, which contains copper, nickel, and zinc as the principal metals; *leaded coppers*, which are cast alloys containing 20% or more of lead, but no zinc or tin; and *special alloys*, which are copper alloys with compositions not covered in the aforementioned groups. *Master alloys* and *hardeners* are copper-base alloys cast with a high alloying element content and are used in producing copper alloys. Hardeners and master alloys not only permit closer composition control than is possible by addition of pure metals, but also permit easier introduction of a deoxidizer, such as phosphorus. Beryllium copper master alloy, containing 7% to 10% beryllium, and phosphor copper, containing 10% to 14% phosphorus, are examples. The ASTM specifications for refined copper are designated in part 6, section B5-77 of the ASTM specifications and are under the jurisdiction of ASTM Committee B-5 on copper and copper alloys.

Industry Structure

Mine Production and Concentrate Trade.—Copper was mined in 53 countries, with the top 14 producing nations in the MEC accounting for almost 73% of world production. Almost 7 million tons was mined in the MEC with the largest contributors, Chile and the United States, comprising 54% of the top 14 producers. To the world's total mine production, the United States and Chile contribute 18.5% and 21%, respectively.

Most copper mine producers export some concentrates to other countries for processing, but the amount available for export varies considerably among producers. The largest concentrate exporters are, as shown in figure 1, Australia, Canada, Chile, Indonesia, Papua New Guinea, and the United States. (See figure 1.)

Only 20% of copper in concentrates produced was available for trade with other countries. The availability of concentrates for the world's smelting and refining countries has varied over time, owing to many factors such as transportation costs, the impact of the U.S. mine curtailment during the 1970's and 1980's, and the development of new smelting and refining capacity in mine-producing countries such as Chile, Peru, and the Philippines. The largest concentrate exporters in 1991 were Canada (17.8%), Chile (28.4%), the United States (14%), Indonesia (6.4%), and Portugal (9.8%). The United States has become a significant exporter of concentrates since the late 1980's, owing to its renewed position as a dominant mine producer as well as to its insufficient domestic smelter capacity. The African countries Zaire and Zambia did not export much in the form of concentrates largely because of their landlocked position, higher expense for bulk transport, and availability of cheap power for processing plants. These countries also consumed very little of their refined or blister copper, and so were large exporters of refined copper. The Republic of South Africa also exported crude copper, but consumed as much refined copper as it exported. The largest concentrate importers were Japan (61%), Germany (8.6%), South Korea (7.1%), Spain (7.6%), and Finland (5%).²

Refined Copper Production and Trade.—Historically, the largest smelters and refiners have been in or near the large refined copper-consuming industrialized countries to support their manufacturing industries. Figure 2 shows the dominance of the industrialized countries of North America and Europe as refined copper producers. Since 1971, as shown on figure 3, several Asian and South American countries have been increasing their refined production capacity. (See figures 2 and 3.)

In South America, the largest refined copper producer is Chile. In fact, CODELCO-Chile, the Government-owned copper producer, is the largest

refining company in the world. Australia also has been developing its refined copper industry in recent years. The largest refined copper producer in Asia was Japan, followed by a rapidly growing China. The copper industry of central Africa, because of its isolated location, size of the mine production, and energy availability, developed smelting and refining facilities early in its development. Elsewhere, with cheaper ocean transportation and lacking energy resources necessary for economic operation of a smelter and refinery, many mine-producing countries initially opted not to develop downstream processing. This was further promoted by industrialized countries with poor copper mine resources, which traditionally invested heavily in mine development in other countries to ensure long-term concentrate supplies. This resulted in significant Japanese and European ownership of the world's copper mines and smelters.

Refined copper, in its various forms, was an internationally traded commodity sold through producer contracts or spot market sales through the commodity exchanges of New York and London. Figure 4 compares the dominant refined-copper-producing areas with exports in 1991. It was significant that only 34% of the world's refined copper production was exported to the world's markets. Refined copper from South America comprised almost 33% of the world's refined copper exports, whereas Europe and North America made up more than 60% of the total production. Zambia (389,000 tons) was the second largest refined copper exporter after Chile (1.1 million tons). Copper rod was also a dominant form traded within countries such as the United States, where almost 60% of the copper mined and refined was used for rod. Trade in rod had been increasing in recent years, but long-distance transport of this product had been hampered by quality problems. New continuous-cast rod plants were constructed recently in many newly industrialized countries, largely for use in their economies. Following the need for expanded electrical facilities in these

countries, this was an area of significant growth for the future. The world's largest refined copper importers in 1991 were as follows:³ Japan (16.8%), Germany (15%), France (11.8%), Italy (11%), Taiwan (10.7%), the United States (8%), Belgium (6.4%), and the United Kingdom (6.5%). (See figure 4.)

Refined Copper Consumption.— Refined copper consumption statistics were measured at the first fabrication stage. That is, they represented refined copper consumption by rod mills, brass mills, foundries, chemical plants, and other miscellaneous manufacturers. Recognition of this fact is important largely because these statistics have been misrepresented in intensity of use studies. Consumption trends associated with comparative statistics, such as gross national product (GNP) and other economic dollar-valued indicators, have been misinterpreted as an indication of a society's consumption habits, rather than as a measure of the Nation's industrial consumption. Contrarily, a recent University of Arizona study indicated that in the United States, copper "embodied" in net imports of manufactures had increased from about 200,000 tons in 1970 to 577,000 tons in 1985, and this amount should be added to the modest growth in copper consumed by U.S. semifabricators for a more complete measure of U.S. societal consumption trends.⁴

The largest refined copper-consuming nations have long been the industrialized countries with large manufacturing bases. The final products, such as automobiles containing copper radiators, are not necessarily consumed in the country of manufacture. The major copper-consuming countries or areas of the world in 1991 were Western Europe (29.2%), the United States (19.7%), Japan (15%), the U.S.S.R. (6.5%), and China (5.4%). An estimated 10.7 million tons of primary and secondary refined copper was consumed in 1991. Figure 5 illustrates the proportion of copper consumed among MEC. Europe and the United States consume about 60% of

MEC copper consumption. (See figure 5.)

The United States has been historically the largest copper-consuming nation in the world, consuming more than 50% of the world's copper until 1949, when the Asian and European nations began to increase their manufacturing bases. After 1950, the U.S. share of world copper consumption began to decline, as shown in figure 6, until 1975, when it stabilized at about 20% of the total. At the same time, U.S. per capita consumption stabilized at about 20 pounds per person over the 1950-91 period, indicating that the U.S. manufacturing base was able to keep pace with the growth in population despite the heavy influence of finished copper good imports such as automobiles and refrigeration units. Trends in per capita consumption from 1875 to 1990, as shown in figure 7, indicate three periods of growth as (1) the rapid electrification that took place in the late 1800's and early 1900's, (2) the pre-World War II period, and (3) the much higher level of copper consumption (20 pounds per person) that followed World War II. The new technologies that followed World War II required higher levels of electrical and electronic material consumption. (See figures 6 and 7.)

Since the 1960's, the trend has been toward increased consumption by the Asian countries, particularly Japan, South Korea, and Taiwan. More recently, China has built new rod and brass mills for its increased domestic copper needs. China imported 114,000 tons of refined copper in 1991, compared with only 40,000 tons in 1990 and 75,500 tons in 1987, and was a significant importer of copper scrap. In 1991, the Taiwan Government approved an \$8.2 billion construction project that included a new powerplant, requiring a significant increase in copper consumption. Taiwan imported 397,900 tons of refined copper in 1991, compared with 253,100 tons in 1990 and only 161,400 tons in 1987. The significant growth of copper consumption in the Asian and Western European countries since 1964 is shown in figure 8. Japan began its significant growth in the late 1960's, whereas

Taiwan and Korea started in the 1980's. India's refined copper consumption also was growing, and this was expected to increase by 51% to about 204,000 tons per year by 1995. India's needs have grown much more rapidly than its mine production so that it has become increasingly dependent on imports. (See figure 8.)

These trends were expected to continue with increased consumption growth in Eastern Europe and South America. Growth in the United States, Japan, and Canada was seen as proceeding at a much slower rate. Growth in Japan has stabilized in recent years, as it has in the United States.

History of Latin American Mining.—Early Latin American (Andean) copper mining was prompted by the need to develop symbolic objects that served political power, the display of social status, and communication of religious belief. Goldplated and alloyed copper objects were common in the pre-Inca Chavin culture of about 1000 B.C.⁵ Electrochemical replacement and depletion silvering or gilding on copper surfaces were devised in pre-Columbian times to give a precious-metal appearance. The first known Andean example of copper-silver alloy is a Peruvian bead from the Lurin valley site of Malposo. Tumbaga, a gold-copper alloy, was first produced in the central Andes, but later became common to many parts of pre-Columbian South America and as far north as Mexico. In 1494, Columbus reportedly initiated gold mining with a copper byproduct in the Dominican Republic. The Spanish Conquistadores valued copper for use in armaments.

The first European copper mine in Latin America opened in 1522 at Taxco, Mexico. Mexico produced a cumulative total of 8,000 tons of copper by 1890, and averaged about 65,000 tons annually by 1905 and more than 200,000 tons per year by the early 1970's.⁶ The most important Mexican deposits were at Cananea and Nacozari (La Caridad) in Sonora and, formerly, at El Boleo in Baja California.

The 19th century was a time of political turmoil in Chile, and copper mining became increasingly important. The Pacific War, involving Chile, Bolivia, and Peru (1879-83), resulted in the incorporation of the copper-rich Regions I and II into northern Chile. For many years, only the high-grade carbonates and oxides were worked, and the ore was smelted locally in primitive charcoal furnaces. Copper mining expanded in Chile following the introduction of the first reverberatory furnace to Chile in 1842, which permitted smelting of copper sulfide minerals. In 1857, the first blast furnace was installed. Chile became the foremost world producer until 1882, when the United States took the lead. From 1850 to about 1900, copper produced in Chile was practically all shipped to England under the influence of significant European investment. A new era for Chilean copper again evolved in the early 1900's through U.S. investment and mining technology. Using the U.S.-developed froth flotation for copper ore concentration and large-scale, open pit mining methods, low-grade Chilean copper porphyries could be exploited. The Chilean Cordillera possesses several great copper porphyry deposits, including early discoveries of Chuquicamata, El Salvador, Poterillos, Rio Blanco, and El Teniente and more recently, of La Escondida and La Candelaria. Chile's largest, the Chuquicamata Mine (600,000 tons per year), began large-scale production in 1912. La Escondida Mine (300,000 tons per year) started production in late 1990. The mostly U.S.-owned, large Chilean copper mines were nationalized on July 16, 1971. The Government-owned copper company, Corporacion Nacional del Cobre de Chile (CODELCO-Chile), into which the expropriated mines were incorporated, is the largest copper mining and refining company in the world. Chile once again became the world's largest copper mine producer in 1982, when it surpassed the United States. Chile's annual copper production in 1991 was more than 1.8 million tons of copper.

Peruvian production in recent years has been about 400,000 tons of copper per year, but its copper industry did not grow significantly until after the Pacific War, aided by the completion of the central railway, and again between 1940 and 1960, by the significant exploration and mining development efforts of U.S.-owned companies.⁷ Though significant reserves are known in the Carajas District of Brazil, mines of the Rio Grande do Sul area have been the most important, producing about 46,000 tons of copper per year. Copper also has been mined in Argentina, Bolivia, Colombia, Cuba, Ecuador, Guatemala, Haiti, Honduras, Nicaragua, Panama, and Venezuela, but although some countries have undeveloped resources, the amount mined has been small. Between 1800 and 1926, the copper mines in the Bolivian Province of Pacajes near the Chilean border had an annual production of about 20,000 tons per year of copper.⁸ Argentina, Bolivia, Ecuador, and Honduras currently produce less than 600 tons per year of copper each. Cuba has produced copper from the Pinar del Rio Province near Matahambre since the end of the 19th century. Copper has been mined near Caracas, Venezuela, and from deposits near the Port of Cabello, in the State of Yaracuy, since the early 16th century. Copper mining in Haiti began in 1728, and with development of the Meme Copper Deposit in the late 1950's, continued through 1971.

In 1991, the countries of Latin America contributed 28.9% of the world copper mine production of about 8.8 million tons and held 37% of the total world copper ore reserve base of 587 million tons of copper. Chile possessed 24%; Peru, 4%; and Mexico, 3% of the world's copper reserve base.

Geology

According to their mode of origin, copper deposits may be grouped in the following broad genetic classes: (1) porphyry copper deposits and their associated skarn, hydrothermal veins, and replacement breccia deposits; (2) deposits associated with ultramafic, mafic, and

alkaline ultrabasic and carbonatite rocks; (3) volcanogenic and metavolcanogenic deposits; (4) sedimentary and metasedimentary deposits; and (5) veins and replacement bodies associated with metamorphic sequences, not otherwise classified. As a percent of total world capacity, the predominant types mined were: the porphyry copper and associated deposits (59%), stratiform sedimentary replacement and metasedimentary deposits (24%), volcanogenic massive sulfide deposits (7%), veins and replacement bodies (7%), and ultrabasic massive sulfide and carbonatite deposits (4%). Though the massive sulfide and vein and replacement deposits were much more numerous than the porphyry and stratiform sedimentary deposits, they tended to be smaller in both capacity and reserves, but generally contain a wider variety of other mineral coproducts. In the United States, porphyry copper deposits comprised about 93% and stratiform sedimentary and metasedimentary deposits about 6% of established mine capacity.

In recent years, plate tectonic theory has been emphasized in defining copper deposits as they relate to the Earth's lithospheric plates, their edges, subduction zones, and spreading axes in space and time. For example, deposits of the porphyry copper type occur mainly in magmatic, volcanic arc, and back-arc regions of plates overlying subduction zones; hence, their predominant location along areas such as the continental edges of North and South America. Copper deposits found in ultramafic sequences are characteristic of oceanic plate settings and ophiolite rock groups. Alkaline ultrabasic rocks and carbonatites intrude stable continental cratons and are presumed to have come from mantle-derived magmas contaminated with crustal rocks. At Palabora, the Republic of South Africa, a carbonatite is host to a copper deposit; as a significant producer of copper, this is a unique occurrence. Sedimentary copper deposits generally occur in rocks typical of passive continental margin and interior environments, and intracontinental rift systems. In addition, these deposits may

have been redistributed by later diagenetic or metamorphic hydrothermal systems, but retain their stratiform identity. *Stratiform* applies to a layered mineral deposit of any origin. *Stratibound* refers to a deposit confined to a single stratigraphic horizon.

Copper occurs in about 250 minerals; however, only a few are commercially important. The most common are chalcopyrite (CuFeS_2), covellite (CuS), chalcocite (Cu_2S), bornite (Cu_5FeS_4), enargite (Cu_3AsS), and tetrahedrite ($3\text{Cu}_2\text{S}\text{-Sb}_2\text{S}_3$). Metals may be leached out of the rock above the water table by circulating ground water, oxidized, and enriched in the underlying supergene zone. The supergene capping of an ore body often contains the highest concentration of copper as chalcocite or as various copper oxide and silicate minerals. Native copper also occurs in the oxidized or supergene zones.

Technology

Exploration.—Exploration for copper deposits may take place in potential areas within which the anticipated copper deposit is masked by post-ore cover, such as alluvium, and volcanic or sedimentary rock. Following discovery of a potential deposit by geophysical and geochemical means, successive and increasingly intensive drilling campaigns to characterize and quantify the deposit are undertaken before a decision is made to bring a deposit into production. Continued drilling programs to extend identified reserves may continue throughout the production life of the deposit.

A mining company develops an inventory of exploration properties through ongoing exploration and acquisition programs. With further examination, these properties eventually become candidates for development. Economic conditions determine whether there is a hiatus at this stage or whether the property can move on to development. Taking a prospect through all stages to a producing mine is full of risks and requires complex analyses in

geology, metallurgy, engineering, and finance. Environmental considerations are also important in today's decision process.

Good geological concepts will lead an exploration team into a regional environment with the highest probability of economic discovery. In addition, before exploration or development occurs, political and economic factors also will be considered. These factors include the potential for expropriation, availability of land, ease of land acquisition, and local attitude of people toward mining, including environmental concerns. Economic factors include tax policy, transportation facilities, infrastructure power costs, availability of labor, development incentives, and environmental and reclamation requirements.

Copper exploration was seriously lacking through most of the 1970's and 1980's, not only owing to a lack of available funds, but also to an increasingly hostile public point of view about the need for mining. For at least two decades, the socioeconomic and political trends of the United States have been effective in preventing rapid exploration and development of new ore deposits. Creeping urbanism, a desire to preserve pristine wilderness areas, and prevention of environmental pollution have had effect on the success of companies in getting exploration and mining permits in the United States.

No old mining district is positively dead in a geologic sense; the next minor geologic revelation may bring it to life. Further elucidation of ore genesis theory could revolutionize exploration. Improved exploration techniques on the horizon include: improved spatial and spectral imagery resolution for penetration of foliage and surface cover; increased digital geophysical coverage of the United States (magnetically, gravitationally, radiometrically, and spectrally), and improved drilling, sampling, and analytical methods. Geosensing, with the ability to predict ore body variations, geological disturbances, and in situ ore grade variations, also can be improved.

Estimates have varied on the frequency of success for exploration programs. A rough ratio might be 1:100; i.e., that for every 1 ore body of any type, 100 raw prospects must be tested. Substantial ore bodies that are large enough to return exploration expenditures, and provide a profit, are much more scarce. The ratio for world-class deposits to all deposits has been estimated to be more like 1:1,000.⁹ World-class deposits have been defined as those that consistently returned a profit even in periods of low metal prices, that are of a significant magnitude to affect a medium-sized company's profit, and that are in the lower one-third of cost per unit of metal sold. Using this definition, it was estimated that in more than 30 years (720 combined corporate years) of effort only 69 world-class deposits were found. Using revised criteria relating to size and profitability; i.e., a deposit yielding more than \$500 million in revenue, the number of successful, large discoveries could be increased from 70 to 166 between 1950 and 1986.¹⁰ Though small in number, these world-class deposits currently provide almost 60% of the world's production of copper. There were only 32 mines with copper production capacity of greater than 100,000 tons per year in 1991.

Mining and Milling.—Since the turn of the century, the evolution of technology for large-scale mining, milling, and concentrating of low-grade ores has resulted in a continued shift away from mining small, high-grade, massive sulfide deposits by labor-intensive underground methods. Today, open pit mining accounts for 55% of world copper mine capacity and about 83% of domestic mine capacity. Open pit mining requires a shallow deposit with typical stripping, waste-to-ore, ratios between 1:1 and 2:1. A typical surface copper mine uses rotary blasthole drills and a shovel-truck combination for the loading and hauling operation. Underground mining methods vary with the physical nature of the ore and host rock, but typically have lower waste-to-ore ratios and higher grades and

employ some form of large-scale block-caving such as that employed at San Manuel in the United States and El Teniente in Chile. Following extraction, run-of-mine ore is crushed and ground to liberate the copper sulfide minerals and beneficiated or concentrated via froth flotation to produce a concentrate containing about 30% copper suitable for smelting.

Faced with higher energy costs, deeper mines with longer haul distances, high labor rates, and lower ore grades, the domestic industry has strived to maintain and/or lower production costs over the past few decades. Major improvements in energy use and labor management in mining and milling technology have been made in recent years through improved methods of materials transport, grinding, and concentration. Technological improvements include in-pit crushing and conveying systems to replace truck haulage to the mill; semiautogenous and autogenous grinding circuits; column and cyclone flotation cells; larger-scale equipment, including trucks and flotation cells; computer-controlled truck dispatch systems; and improved on-line sampling and automated reagent control in the mill. A microwave system for communications was being used by Phelps Dodge at the Morenci Mine. Microwave was chosen over cable because of the changing mining contour, the distances to be covered, and potential for equipment damage by lightning to the older systems. In mining, further improvements were anticipated in automated mining, nonexplosive rock fragmentation, and process and extraction technologies that result in minimal hazardous conditions. The clean plant concept (hazard free) should be built into design criteria.

An important factor in domestic mine cost savings has been the development and rapid expansion of solvent extraction-electrowinning (SX-EW) technology for the treatment of acid-soluble oxide or chalcocite ores. In this process, dilute sulfuric acid is percolated through the ore, either in dumps, pads, or in situ. The copper-bearing solution (leachate) is collected and processed by solvent extraction methods to concentrate the

copper, which then is recovered by electrowinning, plating copper directly from solution onto a starter cathode. The resultant pure copper cathode thus bypasses the traditional smelting and refining steps. Recent advances in the organic extractants and in electrowinning have improved the economics of this process. Mines have realized tremendous cost savings by processing oxidized ores, leaching existing waste and ore dumps and lower grade mined ore, and by adjusting cutoff grades to the concentrator upward. Growth in SX-EW capacity has been rapid since the mid-1970's. SX-EW capacity for the world, which was estimated to be about 1.1 million tons of copper per year in 1991, was expected to exceed 2 million tons by the year 2000. SX-EW capacity has been particularly significant in Chile, the United States, Zaire, and Zambia, where favorable oxides and leachable sulfide deposits are more common. In Chile, an ammonia leach (Arbiter) process is to be tried on La Escondida sulfide concentrates in a mine expansion project under consideration there.¹¹

History of SX-EW Production in the United States.—In the United States, SX-EW capacity increased from only 37,000 tons in 1974 to 460,000 tons of copper in 1991. Copper electrowon production at U.S. mines and refineries for the years 1968-91 is shown in table 2. In 1968, U.S. electrowinning production amounted to 10,123 tons and by 1991 had increased to 441,241 tons as companies moved to cut costs through what had become a low-cost alternative for producing copper from certain ores. U.S. electrowinning capacity was expected to peak at about 690,000 tons in 1998. Average production costs were said to be 20 to 45 cents per pound depending on whether mining costs were partially written off against normal mining or were a factor at all. This compared with an average mining, milling, smelting, and refining cost of 60 cents per pound of refined copper extracted through the normal process, as estimated for 1990. (See table 2.)

Electrowinning began in the United States at two mines in 1968, the Inspiration and Bluebird, and a third, the Ray Mine, in 1969. The Cyprus Minerals Co. Bagdad plant began in 1970, while other Arizona plants started later in the 1970's, including Anamax Co.'s Twin Buttes plant (1975), Cyprus Minerals' Johnson plant (1975), Hecla Mining Co.'s Casa Grande plant (1976), Duval Corp.'s Sierrita CLEAR-process plant (1979), and City Service Co.'s Miami plant (1978). The Anaconda Minerals Co.'s Arbiter, MT, plant began in 1974. Duval Corp.'s Battle Mountain, NV, plant began copper production in 1979. In the 1980's, several new plants were put in place beginning with Magma's Pinto Valley plant (1981), the Burro Chief plant at the Tyrone Mine (1984), Magma's San Manuel oxide (1986) and in situ operations (1988), the new Cyprus Minerals' Sierrita plant (1987), the Phelps Dodge Morenci plant (1987), and the Chino Mines Co. plant (1988) at the Santa Rita Mine in New Mexico. While expansions and renovations continued at several operating plants during the 1980's, some were shut permanently, including the Ranchers' Bluebird plant (1982), the Arbiter plant (1977), the Sierrita CLEAR-process plant (1982), and the Battle Mountain plant (1984). The Cyprus Johnson plant was closed in 1986 with plant and equipment sold, but Arimetco renewed production in 1990 with a new plant. Kennecott's Ray plant was to undergo several renovations as it moved to improve the quality of its output. Shut down in 1982, the Ray plant was renovated and reactivated by ASARCO Incorporated after it purchased the plant in 1984. The Duval Corp. CLEAR-process plant at Sierrita, which produced a high-grade precipitate, was never economical to operate, and a new SX-EW plant was constructed at the Sierrita Mine in 1987 to recover copper from heap-leached oxide ores. In the 1990's, expansions were made at all Phelps Dodge plants, Cyprus Minerals increased production at Bagdad and Lakeshore and renewed production at Twin Buttes, and Arizona Metals Co. (Arimetco) began production at its

Yerington, NV, and Johnson Camp, AZ, plants. Morenci was the largest SX-EW producer in the United States with more than 150,000 tons per year of capacity.

Most SX-EW solutions were derived from leaching processes that were applied to oxide or soluble chalcocite dump, waste, or in situ ores. A notable exception was the Lakeshore or Casa Grande operation, which utilized a roast-leach process that was successful in processing concentrates from sulfide ore. Only when sulfide ore mining at the Lakeshore Mine became uneconomical did this operation close in 1984. However, the roast-leach process was renewed in 1988 after the plant was acquired by Cyprus Minerals, who planned to import sulfide concentrates from its own mines for use in the roasting, vat-leaching process. In situ leaching was started in 1984 at the Lakeshore Mine.

By 1977, the SX-EW process had been improved to the extent that most production resulted in a very high-quality cathode that could be used directly by wire rod plants, requiring no further refining. In addition to the mine-derived, domestic electrowinning production, a plant operated by Amax Nickel Inc. in Braithewaite, LA, also produced electrowon copper from a process that utilized imported copper matte from Botswana until 1985. This production, however, does not appear in the U.S. electrowon production statistics of table 2.

Smelting-Refining.—Most copper concentrates are processed through three-stage smelting to produce anode suitable for electrolytic refining. Concentrate first is processed in the primary smelting reactor to produce a copper sulfide-iron sulfide matte containing up to 60% copper. The matte is passed to a converter where it is oxidized. Sulfur is removed from the matte as sulfur dioxide in the gas stream, and iron is removed in the converter slag. Blister copper from the converter is fire refined in an anode furnace to remove oxygen and other impurities. The anode shapes are interspersed with either

copper, stainless steel, or titanium cathode starter sheets in an electrolytic cell or tank, and copper is plated from the anode to the cathode. Valuable impurities, including the precious-metal values, collect as sludge in the bottom of the electrolytic cell.

In the 1970's, environmental constraints and energy costs became a prime concern for the domestic smelting industry. Through the late 1970's and mid-1980's, smelters used interim methods such as tall stacks and intermittent operation to meet sulfur dioxide emissions standards. However, by 1987, most remaining smelters had abandoned traditional batch reverberatory smelting and had adopted one of the various continuous, flash and oxygen-enriched methods (Outokumpu flash, Noranda, Inco flash, Mitsubishi continuous). These furnaces require lower energy input and provide a more concentrated sulfur dioxide gas stream, which allows for sulfuric acid production for sulfur dioxide capture. In some instances, the byproduct sulfuric acid not only became an inexpensive source of acid, but also contributed to the expansion of the SX-EW capacity. However, its economic value to a smelter has varied.

Flash smelting involves the blowing of concentrate, flux, and oxygen into a hot furnace. The concentrate reacts rapidly with oxygen, releasing a tremendous amount of heat. As a result, flash processes are generally autogenous, requiring no external fuel input after firing-up. In 1988, Magma Copper commissioned the world's largest single furnace Outokumpu flash smelter with a 272,000-ton-per-year blister capacity. The majority of new smelters constructed worldwide since 1970 have been Outokumpu flash smelters. However, in the United States, two new Inco furnaces, Hayden and Hurley, have been commissioned since 1980. The Noranda process smelter, installed by Kennecott, was not autogenous, but had the advantage of processing larger size material, including scrap, and producing a higher grade copper matte.

Many copper smelters have found that the limit on environmental improvement at an acceptable cost rested with upgrading the converter process. Most plants have operated Pierce-Smith converters adapted for high sulfur capture, but generally at high cost. A switch from the present batch mode of matte processing to one of continuous operation without converters is expected to be a major improvement for the future.

Canada pioneered the use of oxygen in smelting during the 1960's, and some forecast that this is the trend of the future. The use of oxygen in copper smelting was borrowed from steelmaking technology. If the smelter complex (smelting furnace, converters, and anode furnace) are considered one operation, the smelting process would use a typical ratio of total oxygen tonnage to concentrate of about 0.25 tons. A 100,000-ton-per-year smelter, treating typical southwestern U.S. concentrates, would require about 300 tons of oxygen per day. The trend is toward higher levels of oxygen enrichment in smelting; this ratio is expected to increase through the next decade to more than 0.35 tons of oxygen per ton of concentrate. In the future, most smelters are likely to process all of their primary copper sulfides by oxygen enrichment processes, whether by flash or bath smelting, by the end of the decade.¹²

The continuous top-blowing process (Contop) smelter is an autogenous process in which concentrate is continuously melted in a cyclone furnace on top of a large settling chamber. The high temperature of the flash smelting, combined with top blowing of the slag in the settling chamber, volatilizes most of the impurities such as lead, arsenic, etc., and is well suited to ores having high impurity levels. It also provides for a low-copper slag that can be dumped without further treatment. Because of its low capital requirement and compact size, it was reportedly well suited for retrofit installation at reverberatory furnaces.

Cyprus Minerals Co. was building the first Isasmelt-process smelter in the United States, which was to be operational by mid-1992. Developed by Mount Isa Mines (MIM) Co. and the

Commonwealth Scientific and Industrial Research Organization (CSIRO) of Australia, this process used a single cylindrical reactor and a submerged Siros melt smelting lance in an oxygen-enriched, high-intensity smelting process that is easily controlled and has considerably lower energy needs than Cyprus' existing Miami, AZ, electric plant. The system offered capital and operating cost advantages and resolved some environmental problems. Associated with a 500-ton-per-day oxygen plant, the process also will allow a significant increase in concentrate capacity at the Cyprus plant. Slag from the new smelter will be cleaned in the existing electric furnace, and the existing acid plant will handle all sulfur dioxide process streams. The Cyprus smelter is the only remaining electric primary copper smelter in the United States.

The foam smelting process developed in the U.S.S.R. was being used on an industrial scale at three Soviet plants; enriched air was injected into the slag melt, and smelting occurs in the resulting slag foam. This process was used only in the U.S.S.R.

Technical improvements at the refinery level have included the use of permanent stainless steel or titanium starter sheets, improved solution chemistry, and automated system control leading to greater current efficiency and reduced impurity levels. As a result of reagent and production refinements, almost all domestic SX-EW production is high-quality cathode that does not require further refining. Continuous cast rod technology, in particular, requires high-quality refined copper.

The rapid increase in continuous cast technology for rod since the middle 1970's has rendered the wirebar, an intermediate cast shape for wire rod, almost obsolete and has effectively shifted intermediary casting from the refinery to the wire mill. Though it has not replaced deep well casting of intermediate cake, slab, and billet at brass mills, continuous casting technology also has been developed for some aspects of the sheet and tube sectors.

Economic Factors

Copper is an internationally traded commodity. The copper prices established in the terminal markets of the two major metals exchanges, the Commodity Exchange Inc. (COMEX) in New York and the London Metal Exchange (LME), broadly reflect the worldwide balance of copper supply and demand. Copper prices have historically fluctuated widely annually and from month to month. Prices are affected by numerous factors, including international economic and political conditions, levels of supply and demand, the availability and cost of copper substitutes, inventory levels maintained by the exchanges, consumers and copper producers, and, to a lesser degree, inventory carrying costs (primarily interest charges) and international exchange rates. Historically, there has been a consistently inverse relationship between refined inventories held by the exchanges and the copper price, as illustrated by figure 9. (See figure 9.)

Each copper product, including scrap, from mine through refinery has a distinct pricing procedure linked, for the most part, to its copper content and the market price for copper. For example, copper concentrates, which contain between 20% and 40% copper, are purchased based on recoverable copper content and anticipated smelter and refinery charges for processing.

Copper concentrates were sold predominantly under long-term contracts, which included provisions for the delivery of specified quantities and a formula by which the price paid was to be calculated. Contracts tended to be for periods as long as 10 years, though various terms were renegotiated at shorter intervals, and thus provided smelters with secure sources of feed material. Without such contracts, new mines would find development financing difficult. Contracts provided for two types of charges. A treatment charge was made for every ton of concentrate by the smelter, and a refining charge was made for every pound of recoverable copper contained. There was generally a provision for the participants

to benefit from copper price rises. There also may be penalties for undesirable impurities, such as antimony, arsenic, and bismuth. The basis for additional payment for precious metals in the concentrates was generally slightly less than the amount contained.

Refined copper prices vary according to form and purity. Historically, the price for refined wirebar was the "bellwether" price for refined copper, because this was the dominant form traded. With the advent of continuous casting for wire rod, however, high-grade cathode became the dominant form traded. Copper wire rod prices are based on the refined copper cathode price plus a processing premium. The price spread between copper scrap and refined copper must be sufficient to allow for processing costs. Refined prices not only relate to the refined shape and its quality, but also to the manner in which it was priced, i.e., through producers' annually negotiated contracts or through the commodity exchanges of the LME, COMEX, and Mid-America Commodity Exchange (MACE). Trading in copper began on the LME, January 1, 1877, and on the COMEX, May 15, 1929. A futures exchange, such as COMEX, is a centralized market where contracts for the future delivery of the commodity are bought and sold by competitive auction. Each contract for a particular commodity is identical, representing a specific amount and grade of a commodity designated for delivery at a specified date, which may be as far as 2 years in the future. Because all futures contracts are standardized, the only negotiable aspect of a contract is price. Futures contracts changed gradually over the years to correspond to the most active markets. The LME dropped its wirebar and standard cathode contracts and, since January 1989, traded only the Grade A (high-grade) cathode contract. Similarly, COMEX converted to the High Grade cathode contract on January 1, 1990. The spot, or first position, price was most often quoted for the exchanges. To this price, however, various premiums and other charges were added to determine the actual price paid by the buyer.

Historically, the U.S. copper producers' price series was related to annually negotiated contract sales with price changes occurring at frequent intervals. When quoted, this price normally included a charge for delivery and insurance. Most U.S. producers abandoned classic producer pricing during the 1970's and 1980's, as inventories accumulated on the exchanges and the COMEX price became more influential. Producers adopted the custom of using the first position COMEX price as a basis for contract pricing. During tight markets, however, such as has existed since late 1987, the speculative influence of a COMEX-based pricing system has proved to be less than satisfactory for the consumer, owing to price volatility. The conventional producer pricing system tended to provide more stability to the market. Periods of speculative interest have usually been brief. The long period of stock surpluses since 1982 dampened speculative interest until the end of 1987. Since that time, both producers and consumers have increasingly used futures contracts and the newly introduced copper options to hedge their sales and purchases.

Speculation in copper markets has been active since 1987 and has achieved a sophisticated level as trading advisors and fund managers devise ever more complicated schemes with futures and options. Their goals have become more obscure and less obtainable with prices that can be distorted briefly with wild price fluctuations. Some believe that the quiet, orderly markets enjoyed in the past are gone forever. Contangos can bring certainty and stability to markets, and backwardations can bring excitement and opportunity to make money. When and whether or not to intervene in a market is always a problem faced by the commodity exchanges. The U.S. authorities are quick to do this through raised margins and other mechanisms, but there always is a danger of losing speculators. Although the LME allows for price fluctuations, the planned use of "Asian" options might considerably lessen their frequency. Application of the average rate, or Asian options, is

designed to prevent too much activity happening on one day, usually the third Wednesday of the month, which is the exercise date for all maturing options. This is done by averaging the settlement dates of the first 3 weeks to provide an acceptable exercise price for the option, providing greater protection for the hedger. An added advantage is the spreading of speculative activity and dampening of inflammatory effects from sophisticated investment fund manipulation of the market. Many physical trading deals rely on averaging for pricing, and this approach reportedly is already widely used on the over-the-counter trade. On the LME it increases price transparency, lowers costs, and provides better financial and regulatory protection for users. Singapore is currently the only non-European country to have an approved LME warehouse for copper.¹³

Based on constant dollars, one must look to the depression era of the 1930's to find prices as low as those occurring between 1981 and 1988. Since that time, prices have been within the range of the constant dollar average for all prices, 1901-90. Copper prices not only responded to changes in the world economy, but also to the effects of large copper inventory accumulation, to copper cartel actions to restrict production, which were most effective prior to World War II, and from time to time to speculative influences on the commodity exchanges.

A word of explanation must be given about the relationship between the cost to produce and the market price for copper, which can be obscured by the many factors that affect both. It is certain, however, that the cost to produce has less influence on the market price for copper than does the marketplace, as set by the balance between supply and demand. Copper prices often have sunk below the average cost to produce during times of surplus, causing most world producers financial difficulty and providing considerable incentive to implement new cost-cutting technology. Contrarily, when markets are balanced, prices can be considerably above the average cost to

produce, owing to the effects of speculation. Adding confusion to the understanding of cost versus price is the fact that mines cannot be moved to an area of cheaper labor or energy when these are required as a result of international monetary manipulations. Devaluing a currency can cause temporary lower domestic costs at the mine, thus changing a nation's competitive stance. Contrarily, overvaluation of a currency can cause local costs such as labor and energy to be excessive and possibly even cause temporary closure of a mine if occurring during a period of world surplus. The latter situation was the case for U.S. producers during the early 1980's. Because of the strong dollar, the relative cost to produce for U.S. producers was higher in dollar terms than those of the rest of the world. In dollar terms, the world's producers outside of the United States were being paid extremely high for an equivalent pound of copper, while their domestic costs were covered by a devalued currency. When excess stocks were depleted and market balance finally was achieved in 1987, the "high-cost" U.S. mines were again operating and increasing production as world leaders in cost-cutting technology. Mines could not be moved or relocated to other countries in response to market demand and changing cost structures. There was no lower cost mine capacity elsewhere in the world to replace the significant U.S. copper contribution to world supply.

Refined copper inventories are kept on hand by consumers and producers as a means to meet demand. A just-in-time inventory philosophy in recent years has been assisted by the advent of the computer, allowing a more accurate analysis and timing of production and shipments. Normally, about 4 weeks of supply is considered adequate to meet market needs and prevent excessive speculation. Whenever inventories exceed this mark, prices tend to be lackluster, and conversely, whenever inventories are below this mark, speculation can drive up market prices. Surplus inventories may find their way to the commodity exchanges where their high visibility can

depress prices. The exchanges also provide a mechanism for hedging production and consumption, providing liquidity to the market. The primary economic purpose of futures trading is to provide a marketplace for hedging against the financial risk associated with volatile fluctuations in prices by transferring that risk to speculators.

Surplus refined copper inventories not only have accumulated periodically in response to periods of economic recession, but also as a result of U.S. Government purchases for the National Defense Stockpile. There is an inverse relationship between the amount of commercial stocks on hand and the market price for copper. High inventories levels have had a depressing effect on prices when these surplus supplies were released onto the market to compete with newly mined copper. Trends in U.S. copper inventories since 1955 are shown in table 3. (See table 3.)

The U.S. Government has been historically a large holder of refined copper inventories, but since the final large release of 1974 has not attempted to refill the National Defense Stockpile, which was released for the most part in response to the shortages of the Vietnam War years. From time to time, other nations such as Japan also have held refined copper stocks for strategic reasons. Materials shortages created during World War II prompted the creation of the National Defense Stockpile late in the 1940's. Beginning in the 1950's, the National Defense Stockpile became a vehicle for controlling the flow of mineral supplies during an emergency, buying copper in times of surplus (524,000 tons was purchased between 1953 and 1958; very little has been purchased since) and selling copper in times of shortage (808,000 tons was sold between 1965 and 1969 and 229,000 tons in 1974). The stockpile currently holds 26,352 tons of copper materials, including 20,000 tons of refined copper, 6,124 tons of copper in brass scrap, and 548 tons of nonstockpile-grade copper.

Operating Factors

Production Costs.—In recent years all domestic and most world producers endeavored to cut production costs in an effort to remain competitive through prolonged periods of depressed prices, such as that experienced during the mid-1980's. Domestic producers adjusted mine plans, reduced stripping ratios, and raised cutoff grades. Large capital investments were made in new in-pit crushing and conveying systems and on mill and concentrator expansions or replacements. Lower cost SX-EW capacity was expanded to process both oxidized ores and the higher grade waste dumps resulting from higher cutoff grades. Consolidation of assets through ownership changes improved operating efficiencies. Labor costs were reduced through improved employee productivity and wage and work-rule concessions by union and nonunion miners. Productivity at mines, in terms of hours of work per ton of copper produced, declined from more than 40 hours in 1980 to 28 hours in 1983 to an average 18.2 hours over the 1985-91 period. Similar cost savings were realized through smelter renovations and renegotiation of smelter contracts.

Byproduct values and the combined effects of inflation, government monetary policy, and exchange rates also affected operating costs. In the United States, technological improvements overcame the competitive disadvantage caused by shifting byproduct credits and the effects of inflation and exchange rate (I/ER). Conversely, devaluation of the kwacha and improved byproduct prices allowed Zambia to remain competitive despite deteriorating technical factors.¹⁴

Capital Costs.—An analysis of 71 planned and constructed new mine projects for which total development costs had been estimated for construction over the years 1991-2000, in Argentina, Australia, Brazil, Botswana, Burma, Canada, Chile, the Commonwealth of Independent States (C.I.S.), Indonesia, Malaysia, Pakistan, Panama, Papua New Guinea, Peru, Philippines, Turkey, and

the United States, indicated that an average of \$7,400 per ton of annual copper capacity, or about 8 cents per pound of recoverable copper must be invested to bring a new mine on-stream. Mine expansions at established mines, on the other hand, averaged \$2,500 per ton of copper capacity. A new SX-EW plant in the United States would cost an average of \$1,500 per ton. Kennecott's new smelting and refining complex was estimated to cost about \$3,000 per ton of capacity. New mine costs varied widely with location, size, and type of mine. For example, the 300,000-ton-per-year Escondida open pit mine in Chile was estimated to cost about \$2,600 per ton of copper, or only 3 cents per pound of recoverable copper over the life of the mine. In contrast, the Windy Craggy Mine in British Columbia might cost \$8,000 per ton of installed capacity and 5 cents per pound of recoverable copper and the Tambo Grande Mine in Peru about \$15,000 per ton of installed capacity and 11 cents per pound of recoverable copper, according to currently published estimates.

Total project financing also varied with location, size, and type of mine. Financing required for expansion at an existing mine ranged between \$66 million for the Olympic Dam, Australia, expansion to \$500 million for the Chuquicamata, Chile, expansion. The average new mine would cost \$242 million to develop. Of eight new open pit projects in Chile, the average cost was \$381 million for an average capacity of 122,000 tons of copper per year; in Peru, the average cost for two open pit projects, currently in exploration stages, was \$216 million for an average capacity of 35,000 tons of copper per year; and, in the United States, the average cost to construct a new open pit mine with an average capacity of 44,000 tons per year was estimated to be \$137 million. Some individual projects, such as the La Escondida Mine, cost as much as \$800 million to bring into production. The average of five SX-EW projects was \$207 million in Chile, or \$3,700 per capacity-ton. The average for four SX-EW

projects in the United States was \$15.7 million and \$1,800 per capacity-ton.

Environmental Requirements.—The many environmental protection laws and regulations that have been promulgated in the United States since the late 1960's have affected the copper industry in many ways. Most of the cost of compliance with environmental regulation was incurred at the smelter level. Although some regulations have resulted in offsetting costs through production of an additional salable product, such as sulfuric acid, and reduced operating costs in modernized smelters, the net effect has been to increase total operating costs.

Laws and regulations in force that affect U.S. copper operations include those promulgated under the Federal Clean Water Act; the Clean Air Act of 1970; the National Environmental Policy Act of 1969; the Solid Waste Disposal Act (including the Resource Conservation and Recovery Act (RCRA) of 1976); the Federal Surface Mining Control and Reclamation Act; the Toxic Substances Control Act; the Comprehensive Environmental Response, Compensation and Liability Act (CERCLA); and numerous State laws concerned with mining techniques, reclamation of mined lands, air and water pollution, and solid waste disposal. Transportation of mineral and hazardous substances also was regulated. Ground water regulations in Arizona were being developed and could have a greater impact on the copper industry than surface water quality. In 1990, the Arizona Aquifer Protection Permit (AAPP) program became an important factor. Arizona's Groundwater Protection Permit Program was expanded and refined into the AAPP. To obtain a permit, mining facilities must meet two tests: the Best Available Demonstrated Control Technology (BADCT) must be installed and the facility must show how it will protect ground water standards, above and beyond installation of BADCT.³⁰

Under the 1980 Bevill Amendment to RCRA, solid wastes from the extraction, beneficiation, and processing of ores and minerals were temporarily exempted from

regulation as hazardous wastes under subtitle C, pending a comprehensive study to determine potential hazard and feasibility of treatment. EPA published an interim interpretation that placed wastes from exploration, mining, milling, smelting, and refining within the exclusion pending completion of a Report to Congress. Acting under a court-ordered deadline, in 1986 EPA issued its regulatory determination in which it concluded that subtitle C regulation was not warranted for mining and beneficiation wastes. However, EPA proposed to narrow the scope of the Bevill exclusion, by implicitly applying a high volume, low hazard standard to these special wastes that would generally remove most mining and smelting wastes from the exclusion. This concept had been introduced by regulations proposed in 1978 for a universe of special wastes that were less amenable to RCRA control techniques. EPA subsequently withdrew its proposal to reinterpret the exclusion boundary.

The withdrawal of EPA's proposal to reinterpret was challenged in court, and in October 1988, the court found that the intent of the Bevill exclusion was to include only those wastes from processing ores that met a special waste criteria of high volume and low hazard. In compliance with the court, on October 20, 1988 (see 53 FR 41288), EPA published a proposal to define the scope of the exclusion and listed 15 wastes that met the necessary criteria. On April 17, 1989 (see 54 FR 15316), the agency published a revised list containing 6 wastes that it believed met all the necessary criteria and an additional 33 wastes that they conditionally proposed to retain until further study. EPA felt that these 33 wastes met the high volume criteria, but there were insufficient data to determine if they met a low hazard criterion, established, for the first time, in the April proposal.

On September 1, 1989 (see 54 FR 36592), EPA published a Final Rule for Bevill exclusion criteria and proposed a final list of 5 wastes to be temporarily retained within Bevill, including slag from primary copper processing, as well

as a reduced list of only 20 mineral processing wastes for conditional retention. Four wastes, including acid plant and scrubber blowdown from primary copper processing, were permanently removed from the Bevill exclusion. Two other copper associated wastes, bleed electrolyte from primary copper refining and wastewater from primary selenium production, were omitted for further consideration of exclusion. This final rule contained a modified definition of "processing of ores and minerals" that incorporated leaching operations and roast leaching operations, and a modified definition of "large volume." On September 25 (see FR 39298), EPA narrowed the list of conditionally retained wastes to only 13.

On January 23, 1990, EPA issued a final rule that retained 15 wastes, in addition to the 5 retained in the September 1 notice, within the exclusion pending preparation of a final Report to Congress and subsequent Regulatory Determination. The copper processing wastes retained were calcium sulfate wastewater treatment plant sludge from primary copper processing, copper slag, and slag tailings from primary copper processing.¹⁵

The major thrust of the Clean Water Act (an amalgam of numerous acts and amendments, including the Federal Water Pollution Control Act of 1972 and Clean Water Act of 1977 and some 23 amendments) and its legal interpretation is through its elimination of pollutant discharge into navigable waterways through the National Pollutant Discharge Elimination System (NPDES), which provides for a permitting system to clean up discharge of process wastewater, mine drainage water, stormwater runoff, and nonpoint sources. In U.S. copper mills, processing plants, and semifabricating plants, most process water is reclaimed and reused, particularly in the Southwest where there is a chronic water deficit. Mine water discharge problems usually occur when a mine and mill shut down, largely because there is no place, such as a mill, to use the continuously discharging mine water.¹⁶

Energy Requirements.—Open pit mining may extend to as much as 1,500 feet below the rim, and the energy required for hauling rock from such depths becomes an important cost factor. Hauling by truck was estimated to consume as much as 54% of the total energy consumed by all processes in the pit, including drilling, blasting, loading, hauling, and ancillary processes. Grinding and concentration consume about 45% of the energy used in the milling. The lower the ore grade, the more ore that must be processed, the finer the grinding required and thus, more energy consumed.

Major improvements in energy use in mining and milling have been made in recent years through improved strategies in grinding, concentration, and ore transportation. The use of large flotation cells has improved process efficiency and has lessened energy usage. Hydrometallurgical processes for copper recovery, such as the SX-EW recovery of copper, require more energy than pyrometallurgical processes. Electrowinning consumes 21 to 24 million British thermal units (Btu) per ton of cathode, or almost 20% of the total required from mine through refining stages. The in situ extraction of copper is the least energy consuming process, despite the low (50%) recovery. Energy consumption in dump leaching was higher because it is required for leachate circulation and cementation. The combined total energy required for dump leaching, cementation, and refining is about 94 million Btu per ton of cathode copper.¹⁷

Flash furnace technology and the Noranda and Mitsubishi continuous smelting technologies have resulted in energy savings. Energy consumption in millions of Btu per ton of refined copper recovered was reported¹⁸ as follows: Outokumpu flash smelting (18.92 million Btu), Inco flash smelting (21.25 million Btu), Noranda continuous smelting (24 million Btu), Mitsubishi continuous smelting (19.16 million Btu), and Oxy Fuel Reverberatory smelting (26.62 million Btu).

Transportation.—Seaborne cost for shipping copper concentrates from the United States to Japan or Europe ranged between \$22 to \$30 per metric ton of concentrates.

ANNUAL REVIEW

Legislation and Government Programs

Copper Study Group.—Preparations were initiated during 1991 for the final meeting to determine the existence of the International Copper Study Group (ICSG). First proposed in 1985 by the United States, at the request of several domestic companies, the ICSG was to be formally established on January 23, 1992, in a meeting held in Geneva, Switzerland. Countries representing 59.25% of the world trade in copper voted to accept the Terms of Reference (TOR), including the imminent acceptance by Zambia. Japan also intended to join as soon as certain technical amendments to the TOR can be made. By the January meeting, the following Governments had deposited their acceptance of the terms of reference with the United Nations: Belgium-Luxembourg, Chile, China, Finland, France, Germany, Greece, Italy, Netherlands, Norway, Peru, Philippines, Poland, Portugal, Spain, the United States, and the European Community (EC). Canada was to join just prior to the inaugural meeting, which was to be held in Geneva on June 22 to 26.

The ICSG made its appearance as an answer to some past and some current concerns about the world copper industry. Some of the concerns mentioned are a slow or erratic increase in copper demand and uncertainties associated with unstable prices and the future course of copper markets. Problems arising from these issues lead Governments to intervene in the market, and further, to adopt policies that may be harmful to the interests of other countries or to the copper industry as a whole. This group is to provide a forum for all market participants, both producers and consumers, to examine their common problems and to provide for an open dialogue and free exchange

of information. Greater transparency of the market is an important goal of this group through more complete, reliable, and up-to-date statistics, as well as through special investigations. Greater market transparency should reduce the chance of companies making incorrect market strategies, or of government error, when conceiving and applying basic production and trade policies.

The ICSG mandate stated the group's objective as intensifying international cooperation on issues related to copper, improving available information on the international copper economy, and serving as an adequate setting in which governmental consultations on copper may be discussed. The ICSG was to have the following functions: (1) to organize proposals and information exchanges on the international copper economy; (2) to improve copper statistics; (3) to evaluate periodically the market conditions and the prospects of the copper industry; (4) to perform investigations on issues of interest to the Group; (5) to hold discussions on ways and means of increasing copper demand and suggest market development projects that would be directed to, and undertaken by, established market development organizations; and (6) to research the problems and special difficulties that exist or could arise in the international copper economy.

Environmental Actions.—The EPA issued its final regulatory determination required by section 3001(b)(3)(C) of RCRA for 20 special wastes from the processing of ores and minerals. EPA planned to address 18 of the wastes under subtitle D, possibly in the program being developed for mining wastes. The 20 wastes covered included slag, slag tailings, and calcium sulfate wastewater treatment plant sludge from primary copper processing. Copper slag from primary copper processing was included among the four wastes that did not exhibit a hazardous characteristic, but for some of which, adverse environmental impact cases that affected surface water had been documented. EPA found that copper slag rarely, if ever, exhibited a hazardous

waste characteristic. Only 1 sample out of 70 exceeded EPA-toxicity regulatory levels for cadmium and lead. An examination of the slag management practices and environmental conditions for 10 active primary facilities indicated that slag currently generated posed a low risk to human health and the environment. As a result, regulation under subtitle C was not deemed appropriate. On the other hand, the Agency recommended subtitle C regulation for calcium sulfate wastewater treatment plant sludge, focusing only on the remaining active generator, located in Garfield, UT. The sludge at the Garfield facility was EP-toxic for arsenic. Even so, EPA found that current practices at the Garfield facility were adequate to limit contaminant releases and associated risks.¹⁹

EPA also issued a correction to the final rule on drinking water regulations for lead and copper on July 15. The national primary drinking water regulation for lead and copper was issued on June 7, but a provision for sampling techniques for measuring these metals was omitted and appeared in the correction. The maximum contaminant level for lead set by this rule was to remain effective until December 7, 1992. Each first draw tap sample for lead and copper testing was to be 1 liter in volume and was to have stood motionless in the plumbing system of each sampling site for at least 6 hours.²⁰

Trade Actions.—The United States stepped up its fight in the multilateral trade negotiations under GATT over the Japanese copper tariff in an effort to have Japan lessen or abolish its almost 5% tariff on refined copper imports. U.S. imports of refined copper to Japan have increased significantly in recent years. The EC also joined the United States during the Uruguay round, and although Japan's Ministry of International Trade and Industry (MITI) had resisted efforts to abolish the duty, it indicated a willingness to reduce it. The EC and the United States would like refined copper to be included in a list of zero options or materials on which duties have been

completely eliminated between the countries concerned. Japan imposed an import duty of 15 yen/kilo (\$0.052 per pound), or 5% ad valorem, for refined copper cathode. MITI offered a 33% reduction in its ceiling rate to \$0.049 per pound.

Congress took action to extend China's most-favored-nation (MFN) status until July 1992, but the country would be required to meet stringent standards set to improve its record on both human rights and arms sales.

Issues

Industry Investments, Earnings, and Ownership Changes.—The impact of copper on Arizona's economy in 1991 was \$5.65 billion, according to a report prepared by the Western Economic Analysis Center in Marana, AZ. Direct contributions to the economy were more than \$1.51 billion, which was down slightly from \$1.54 billion in 1990. Several categories, including numbers employed, earnings, and property tax payments, were reported as increasing. Arizona's mines annually produce more than 60% of the Nation's copper. Industry payments to State and local governments were almost \$101 million last year, down about 5% from that of 1990. By comparison, property taxes paid, at \$41.4 million, were almost 23% higher than the \$33.7 million paid in 1990. Lower copper prices caused the State income taxes to be lower.

ASARCO Incorporated's net earnings for the year were \$46 million, compared with \$149.1 million in 1990. Lower prices for metals were the major factors in the lower earnings. Earnings were also reduced by a deduction of \$6.6 million that was used to establish a reserve for a copper customer that had filed for bankruptcy. The company discontinued equity accounting for its investment in Mexico Desarrollo Industrial Minero, S.A. de C.V. (MEDIMSA), after considering the sale of this investment. The company spent \$282.9 million for property additions in 1991, including \$207.5 million for the copper expansion and modernization

program at the Mission and Ray copper mines and the El Paso copper smelter and \$12.3 million for payments on previously acquired properties. The company set aside a \$75.5 million charge to earnings for closed plant and environmental liability reserves. At yearend, these environmental reserves totaled \$104.2 million. Cash expenditures from these reserves were \$32 million in 1991, \$13 million in 1990, and \$13 million in 1989.²¹

Cyprus Minerals Co. reported income from its copper segment as \$132 million for 1991, down from \$166 million reported in 1990. Total revenues from copper and molybdenum operations was \$905.7 million. Lower copper prices and higher production costs were blamed for the fall in earnings in 1991. Profits were reduced by after-tax asset write-downs and accruals of \$31.8 million, primarily in talc and coal. The worldwide economic slowdown also had an adverse impact, primarily due to copper prices, down one-third from a 1988 high, depressed molybdenum prices, and declines in coal prices.²²

Despite improvements in Magma Copper Co.'s operating performance, total sales decreased to \$724.8 million in 1991 from \$754.2 million in 1990, primarily as a result of copper price decline. In addition, the company recorded a net loss for 1991 of \$120.5 million, compared with a net income of \$82.7 million for 1990. The net loss was attributable to various accounting adjustments that had no effect on its cash-flow. The noncash accounting adjustments reflected studies concerned with reorganization of the company into profit centers, a new collective bargaining agreement, and feasibility studies for the lower Kalamazoo ore body. An after tax restructuring charge was taken of about \$141 million, which included a \$92 million after tax write-down of the company's investment in its Kalamazoo ore body. Magma's copper operations also produce gold and other byproducts. Revenue from gold sales in 1991, including gold purchased from others, was \$18.2 million for 48,338 ounces. Silver revenue was \$11.3 million on sales

of 2.9 million ounces. Molybdenum disulfide sales were \$10.8 million for 5.4 million pounds.²³

In 1991, Phelps Dodge Mining Co. had earnings from operations of \$367.5 million on revenues of \$1.3 billion and invested \$262.6 million in capital programs. Phelps Dodge had invested more than \$110 million to keep the Hidalgo smelter in Playas, NM, at the leading edge in technology. Construction continued on the \$112 million Northwest Extension project at Morenci, AZ, which when completed in 1992 will add 70,000 tons per year of SX-EW cathode. Two other substantial capital programs continued: reentry into the Metcalf pit and extension of the ore crushing and conveying systems. Both projects will allow the Morenci operation to maintain low-cost production. Phelps Dodge owned a 16.25% interest in Southern Peru Copper Corp. (SPCC), which operated copper facilities in Peru and received an after-tax dividend payment of \$8.8 million from these operations in 1991. Lower company earnings in 1991 were the result of lower copper prices, higher production costs at Tyrone, and increased mining costs associated with moving into the Metcalf area of the Morenci Mine.²⁴

Colonial Metals Co., of Columbia, PA, bought out the 60-year-old former Bay State Refining Co. Inc. in February. Renamed Chicopee Alloys Inc., the brass and bronze ingotmaker, was looking into newer markets.

Mine and Plant Labor.—Productivity at all mines from which copper was produced as a principal product was 17.7 worker-hours per ton of recoverable copper produced by open pit, underground, and leach methods, a considerable improvement compared with 46.1 worker-hours per ton in 1973. Average productivity, including mine and mill operations, was 26 worker-hours per ton for 3,657 workers at 12 underground operating mines and 17 worker-hours per ton of recoverable copper for 10,028 workers at 17 open pit mines. The number of workers at U.S. copper mines and mills averaged 13,706 in 1991.

Arizona led in average number of mine and mill workers (9,524), followed by New Mexico (1,549 workers), Utah (1,211 workers), and Michigan (918 workers), according to Mine, Safety, and Health and Administration (MSHA) reports. (See table 4.)

In 1991, the average number of copper workers was up by 9.3% in Arizona, and copper workers continued to lead other Arizona industry workers in average weekly earnings. A copper miner's average weekly salary in 1991 was \$684. That was above the second highest, manufacturing, which was \$586. Industrywide employee earnings totaled \$430 million, up 4.9% from \$410 million paid in 1990.²⁴

Cyprus Minerals' copper operations in Arizona employed about 3,000 people. Its Arizona facilities included a mine and mill at Bagdad, a smelter and mine at Globe-Miami, and mines and mills near Tucson and in Pinal and Mojave Counties.

Magma Copper negotiated a 15-year collective bargaining agreement in October 1991, more than 8 months prior to the expiration of their existing contract. The agreement prohibits strikes and lockouts for at least 7 years. Hourly rated employees will receive annual wage increases of \$0.25 to \$0.35 per hour in each of the next 5 years, some of which are dependent on Magma's quarterly earning performance during such period. After the initial 5-year period, the agreement will continue in effect for an additional 10 years on the same terms, unless a modification is proposed by either party. If they are unable to agree on modifications, an arbitration panel will establish economic terms for 1 year. If during any 5-year period after the initial term there are two such arbitrations, the agreement will terminate upon the date of the arbitration award. At the end of 1991, Magma had 4,487 employees, of whom 3,176 were hourly wage employees. The United Steelworkers of America (USWA) represented the largest number of employees. At Pinto Valley, four individual unions were jointly certified; of these, USWA was the largest.

Phelps Dodge employed almost 2,000 people at the Morenci Mine in Arizona. Almost 1,150 people were employed at the company's Chino, NM, operations in 1991, according to the Phelps Dodge Annual Report.

Production Costs.—Most U.S. companies reported increases in costs for 1991, owing to higher labor, energy, and processing costs. Higher costs and lower metal prices affected most company earnings. Even so, cost containment continued to be a major focus of most companies with many continuing to implement cost saving changes.

Operating problems at Asarco's Ray mine and smelter complex adversely affected the company's earnings in 1991, according to the annual report. Selling and administrative costs increased to \$107.9 million in 1991 from \$95.5 million in 1990, principally to resolve a bad debt reserve for a copper customer. Depreciation and depletion costs were about the same as those in 1990, as increases arising from the capital spending program were offset by changes in production and ore reserves. Research and exploration costs were also unchanged from those of 1990.

Copper Range was implementing major cost-cutting changes to improve productivity. These included changes in communications, blasting patterns, jumbo machinery, mobility, and improved maintenance procedures. In an effort to improve communications, a consultant firm, Universal Schedule Corp. (USC), was employed. USC analyzed delays and advised of the consequences. USC also sought to improve communications between shifts, as well as between miners. New techniques for more efficient operation of new machinery were also introduced. The result was a 15% to 20% increase in productivity. Copper Range was reactivating the fourth grinding circuit, which had been purchased back from Echo Bay Ltd. The fourth circuit was about 90% complete at yearend. The company was also experimenting with column flotation. Four Diester columns were in operation, replacing a bank of 50 older flotation

cells. Mill capacity was about 30% greater than mine capacity with all four sections in working order.

Cyprus Minerals reported that it did not achieve anticipated reductions in copper costs in 1991. According to the company annual report, Cyprus Minerals sold 291,206 tons of copper in 1991, up from 276,691 tons in 1990, but its production costs climbed to 80 cents per pound, while the price received was 14 cents per pound lower than that in 1990. The company had been trying to streamline costs and unload underperforming assets. Cyprus Minerals made a decision to move its copper operations from Englewood, CO, to Phoenix, AZ, as part of an austerity program to trim its headquarters staff 43% and refocus on its core copper and coal production.

Factors affecting improvements at Cyprus Minerals included operations hampered by heavy rains in the first quarter, lower ore grades at several mine locations, and reduced revenues from molybdenum byproducts. The worldwide shortage in smelting capacity caused toll conversion costs to increase from less than 20 cents per pound to more than 25 cents per pound during 1991. As a result of this cost increase, Cyprus Minerals decided to toll smelt only small quantities of concentrates, while most would be processed through its Lakeshore roast/leach facility and/or stockpiled. Sales of copper were expected to drop to 249,476 tons in 1992. The biggest impact in cost improvement was expected to result from the Miami, AZ, smelter expansion and modernization. Productivity was expected to increase through the addition of 240-ton haul trucks at all Cyprus Minerals' Arizona copper mines. Costs were cut at the Miami Mine through an innovative gauge that made it possible to fill a mine truck fuel tank only once per day, reducing spills and saving \$200,000 per year.²⁶ Employees at Cyprus Minerals' Sierrita and Twin Buttes Mines in Arizona developed a mobile filtration/recycle system to reclaim oil during repair procedures, allowing the oil to be screened, cleansed, and returned to the

vehicle on-site, creating both cost savings and environmental benefits.

Magma Copper's net cash costs for copper sold have decreased from \$0.78 per pound in 1988 to \$0.71 per pound in 1991. Net cash costs per pound represent (1) costs of Magma source copper sold (excluding depreciation, depletion, and amortization) reduced by credits for byproducts and profits from custom processing divided by (2) total pounds sold from Magma sources.²⁷ The company attributed its reduced operating costs primarily to productivity increases, improved labor relations, full operation of its retrofitted smelter, and to a lesser extent, the increased use of the lower cost SX-EW method.

Production costs at Phelps Dodge's operations in 1991 were higher than in 1990, principally because of increased mining rates, lower ore grades, and higher costs for certain operating supplies, according to the Annual Report. However, the costs generally continued to reflect the high levels of production, the cost containment programs that were put into place, and increased copper production from SX-EW. SX-EW recovery of copper from low-grade ore stockpiles was a low-cost process. Substantial capital programs, completed in 1991 or now under way, were expected to contain further escalation of production costs. During the past 3 years, inflation impacted production costs, especially on energy and supply costs.

Production

Mine Production and Reserves.—Copper was mined in 13 States during 1992, with Arizona maintaining its lead with 63% of the total, followed by New Mexico and Utah. There were 65 copper-producing mines, up from 62 mines in 1990. Of these, 33 were copper mines and 32 were mines from which copper was produced as a byproduct or coproduct of gold, lead, silver, or zinc. Total U.S. operating mine capacity, in terms of recoverable copper, was estimated to be 1.96 million tons in 1991 compared with 1.86 million

tons in 1990. The growth was mostly the result of further increases from SX-EW production. Reserves at the major producing companies were reevaluated with some significant increases, as shown in table 5. (See table 5.) The number of unpatented mining claims held on Federal land fell about 13% during 1991 in Arizona, as exploration was cut back.

Arizona Metals Co. (Arimetco) completed a 27.2-ton-per-day SX-EW plant at Yerington for slightly more than \$5 million, including the cost of leach-pad construction. The company finalized an agreement with Billiton Metals to buy all of Arimetco's copper production for 5 years. The agreement included financing that allowed Arimetco to expand SX-EW capacity to more than double that of the existing facilities, raising Yerington's total capacity to 36.3 tons per day of cathode copper. About \$3 million was to be spent to renovate the original Yerington plant to produce 13.6 tons per day of cathode. Arimetco intended to develop the Yerington project in three stages: the first stage, already completed, included the installation of a crusher-conveyor system and leach treatment system with an 11.3-ton-per-day SX-EW plant. That system was completed in late 1989. The second stage included SX-EW plant expansion and another leach pad area. The low-grade Yerington ore is leached in two stages, each for 30 days. A feasibility study was ongoing for the third stage, which calls for open pit mining of the sulfide reserves, milling and concentration, roasting, leaching, and SX-EW processing.

Arimetco purchased the Ann Mason copper deposit, originally owned and explored by Anaconda Co. in the mid-1970's. Less than 3 miles from the Yerington pit, the Ann Mason contains indicated ore of 999 million tons of ore grading 0.51% copper. With this ore is a higher grade core of 7 million tons grading more than 1.0% copper that lies beneath several hundred feet of overburden. Lower grade, but economic ore may be accessible by stripping 150 feet of overburden. The Ann Mason deposit may be used to replace Yerington

pit ore on its depletion. Estimated project life would be about 30 years.

The 5,700-ton-per-year SX-EW plant at Arimetco's Johnson Mine cost \$3.3 million to build. The plant was constructed in about 4 months so that production began in late 1990. Arimetco planned to operate on stockpiled ore while preparation of the new pit outline was undertaken. The Johnson pit contained an estimated 3.6 million tons of ore grading 0.7% copper. Much of the ore lay beneath an existing truck haulage ramp used in earlier mining by Cyprus Mines Corp. When the pit is completed, the mining rate will increase gradually to 13.6 tons per day. In addition to the pit area being mined, the Johnson Mine had potential reserves of 21.9 million tons grading 0.27% copper that could be used to produce about 4,800 tons of copper per year. These reserves were located in 13.6 million tons near the mine and 9.6 million tons of reserves in the Copper Chief deposit.

Arimetco sold the Emerald Isle property to Holcorp Gold Mines for \$3.75 million. Arimetco was to build a 3.6-ton-per-day SX-EW plant for Holcorp. The sale was to be finalized in early 1992.

Arimetco purchased a 50% interest in the MacArthur deposit, 4 miles from the Yerington facilities. Holcorp Mines owned the remaining 50% interest in MacArthur and intended to finance construction of the two leach pads that will be used for MacArthur ore. The MacArthur deposit contained proven reserves of 36.3 million tons of 0.22% ore, including an open pit area with 8.3 million tons of 0.43% copper. Arimetco and Holcorp purchased the property from Timberline Minerals of Reno, NV, for \$3.8 million. The MacArthur plant will be placed adjacent to the new SX-EW plant that Arimetco recently completed at Yerington.

Arimetco acquired the Van Dyke property lease in 1990, and in 1991, completed a private placement of \$8.75 million to finance development. The reserves, under the town of Miami, AZ, are 226,800 tons of leachable copper. Arimetco was conducting feasibility

studies of the Van Dyke property, which contains a large amount of deep copper reserves exploitable by in situ leaching. Both Occidental Minerals Co. and Kocide Mining Co. explored and drilled this property before suspending operations due to various technical reasons. Arimetco acquired Van Dyke in 1990. Initial operations at Van Dyke were to focus on a 9.1-million-ton block of ore in and around the old workings and grading about 0.50% copper. Later, hydrofracturing and star-pattern injection and collection methods were to be used to extract copper from south of the old workings. A 13.6-ton-per-day SX-EW plant was to be constructed by Arimetco, although initial production was to be lower in the early stages.

Asarco launched a 3-year, \$260 million campaign to modernize and expand copper production facilities in 1989. Included were a \$130 million equipment upgrade at Ray Mine and a \$30 million program at its El Paso, TX, smelter. Expansion of mining at the Mission complex and renovation of the idle Pima concentrator were budgeted at \$94 million. Asarco acquired the Pima mill from Cyprus Minerals Co. for \$12.5 million. The Pima property included two mills and contained almost 35.4 million tons of copper ore grading 0.61% copper. The No. 1 mill was originally built by Fluor Utah in December 1971. The No. 2 mill was the one renovated. Cyprus Minerals Pima Mine stopped production in 1977 and remained inactive until April 1979. The No. 2 mill operated until October 1982, when it was shut. The property has been renamed Mission South. Asarco's mill renovation started in July 1990 and was completed by October 1991. Major modifications included addition of a SAG recycle crushing circuit. Flotation circuits were replaced with 1,500-cubic-foot cells. The main control room was also remodeled and reequipped with state-of-the-art process control systems.

Asarco was waiting for permits to allow production from a new SX-EW plant at the Silver Bell Mine. The new plant would produce 16,330 tons per year of copper cathode. Silver Bell was

producing precipitates from dumps remaining from ore mined in 1984. Precipitate production would cease by yearend 1993.

Azco Mining continued development on the Sanchez deposit in Graham Co. Reserves were 152 million tons grading 0.34% copper. Initial public hearings and a draft environmental impact statement were completed. Funding was being sought.

Cambior USA acquired control of the Carlota and Cactus deposits in Gila County, AZ, by purchasing Westmont Mining from Costain Minerals. Drilling indicated resources of 49 million tons, containing 0.45% copper. A prefeasibility study indicated an open pit, SX-EW operation producing 17,320 tons per year over an 11-year mine life.

Budge Mining had been drilling at the Korn Kob copper skarn deposit, Pima County, AZ, since 1989. After proving reserves of about 16.3 million tons of 0.40% copper, the property was released to the owner, Keystone Minerals.

Copper Range Co., a Metall Mining Corp. subsidiary, invested an additional \$7 million in new equipment, supplementing the \$9 million invested in 1990 at its White Pine Mine, MI. Ore milled at the White Pine Mine for 1991 was about 52.6 million tons and the refinery produced 52,617 tons of cathode in 1991, according to the company annual report. The underground operation consisted of two different producing sections, the northeast (NE) and southwest (SW) sections, which are interconnected. The NE had lower grade than the SW, but its geology was more uniform, predictable, and practically fault-free. The SW dipped 16% to 18% and suffered from heavy faulting. Previously, the SW was the mainstay, but during 1991, a program was started to reduce SW production so that it comprised only 45% of the effort. The mine plan called for five mining units in the SW and nine mining units in the NE next year.

Starting in 1989, Copper Range made several changes in its mining operations. Truck haulage was eliminated and ore was transported directly from the face to

Stamler feeder-breakers using load, haul, and dump (LHD) equipment. The average haul distance was also reduced by 200 feet, improving feeder-breaker move times. The feeder-breakers feed 36-inch conveyors, which dump onto larger belts.

The Pebble Beach porphyry copper-gold deposit was discovered in 1990 by Cominco Resources in Alaska. Preliminary reserves were estimated at 454 million tons grading 0.35% copper and 0.011 ounce per ton of gold. Pebble Beach is in south-central Alaska, 200 miles southwest of Anchorage and 60 miles from water.

Cyprus Minerals produced a total of 291,207 tons of copper in 1991, according to the company annual report. The fire that shut down the Cyprus Minerals Miami smelter stalled plans to resume mining at the company's mine near Pinos Altos, NM. Copper concentrates were stockpiled following the November 9 shutdown. A decline in zinc prices and the need to develop underground access to the copper ore body 300 feet lower were reasons given to shut down the Pinos Altos Mine in mid-July. Although the mine was shut, development continued on the new high-grade copper deposit, which was expected to provide at least 3 or 4 years of ore.

Cyprus Minerals spent about \$20 million on exploration during 1991, primarily in Australia, Canada, Chile, Mexico, Panama, the United States, and Venezuela. The company's long-term strategy was to enlarge its copper business and to go down the cost curve by developing a world class ore body. The company expected its exploration efforts to identify opportunities to develop economic ore bodies worldwide.

Formosa Resources Corp. started production from its Silver Butte Mine in Oregon, producing some zinc in addition to copper. The company was planning an expansion down dip in the deposit, expanding the lowermost drift.

Great Lakes Minerals had acquired five known chalcocite deposits along favorable stratigraphy in the Keweenaw district of northern Michigan. The company controlled about 200,000 acres of ground, including that previously

explored by Inco and Homestake in the 1970's. The largest deposit was the 543-S, which had reserves of 1.2 million tons of 4.41% copper and the G-2, which had 39,371 tons of 3.49% copper. Wheaton River Minerals of Toronto was to take an option for further exploration of the G-2. A feasibility study conducted in 1990 indicated the 543-S could be developed for about \$3 million. Noranda also took an option, agreeing to spend \$4 million in exploration over 4 years to earn 60% of 41,840 acres in Michigan from Great Lakes Minerals, which did not include the 543-S deposit. Since exploration was last done in this area in 1975, this was good news for copper exploration on the Keweenaw Peninsula.

The fourth mill line at Kennecott's Bingham Canyon copper mine was to start up in January 1992 and was expected to reach design capacity by mid-1992. During its first 5 years of operation, the new line was expected to add 32,000 tons of copper and 84,000 ounces of gold annually to the Bingham Canyon production. A total of \$219 million was invested in the new mill line.

Magma Copper was evaluating two major mine deposits, its lower Kalamazoo ore body, near the San Manuel underground mine, and its recently acquired Robinson Mining District. Although the company wrote off costs incurred by its former parent company in the Kalamazoo ore body, it has undertaken further studies to assess the economic viability of this property under current conditions. Extraction of sulfide ore from the San Manuel underground mine began in 1956, and about 99,790 tons of copper was produced in 1991, from 47,174 tons of ore per day averaging 0.67% copper.²⁸ The Upper Kalamazoo ore body consists of about 15.4 million tons grading 0.72% copper that can be economically exploited during the period covered by the current mine plan, based on 80-cents-per-pound mining costs. Although Kalamazoo development was suspended in 1984 owing to poor market conditions, it was restarted in 1986 only to be suspended again in October 1988; limited development resumed during the fourth quarter of

1989, reaching a production rate of 9,980 tons per day in December 1991.

Magma Copper's currently operating mining divisions are in southeastern Arizona and are the San Manuel Mining Div., Pinto Valley Mining Div., and Superior Mining Div. At San Manuel, copper is mined from an underground mine, an open pit, and an in situ operation. The Pinto Valley Mining Div. leaches mill tailings and conducts in situ leaching above an underground mine that is no longer in operation. The Superior Mining Div. mines and concentrates ore from its recently reopened underground mine.

The lower Kalamazoo ore body contains 273.1 million tons, but is not considered proven or probable reserves, and the company is currently evaluating whether any of these mineralized areas can be reclassified as proven reserves. This study is expected to be concluded by 1992. Subject to further feasibility studies, the company believes that the lower Kalamazoo ore body could produce about 77,110 tons of copper per year for 11 years. Sulfide ore from the underground mine is rail transported to the concentrator, which produces a 30% copper concentrate along with molybdenum disulfide as a byproduct. The concentrator has a rated capacity of 56,700 tons of ore per day, but during 1991, the concentrator processed an average of about 49,714 tons of ore per day, including reprocessed smelter slag and purchased ore. During 1991, about 11.8 million tons of copper oxide ore, averaging 0.373% acid soluble copper, was mined and separated from waste materials. The stripping ratio at the open pit mine was 2:1, waste to ore mined. The oxide ore was arranged on lined leach pads, and a water and sulfuric acid leach solution was sprayed over the ore.

Based on a recently completed reserve audit and resulting changes to Pinto Valley's Mine Plan and after giving effect to 1991 production, the open pit sulfide proven/probable reserves were lowered to 160.5 million tons from the estimate of 322 million tons of a year ago, according to Magma reports. Increases in productivity and cost improvements over

the next several years could result in reclaiming of all or a portion of these lost or reclassified reserves. During 1991, Pinto Valley produced about 20.9 million tons of ore with an average grade of about 0.386% copper. The stripping ratio was about 1.5:1 and will remain near that level until the late 1990's, after which the stripping ratio will fall sharply when mining sulfide ore at the open pit mine will be in its last phases. According to the company annual report, the Pinto Valley concentrator produced about 239,497 tons of concentrate. Low-grade copper-bearing waste is transported to large dumps that are then sprayed with water and sulfuric acid for leaching and treatment through an SX-EW plant. Pinto Valley produced about 6,804 tons of copper cathode in 1991.

Magma Copper continued its reclamation project started in 1988 for leaching of mill tailings at the old Miami underground mine. The tailings were reclaimed using hydraulic mining methods to produce a slurry of tailings and water. Sulfuric acid is added to the slurry to dissolve the copper and the leach solution is processed through the Miami Unit's SX-EW plant. The tailings are disposed of by pipeline to an abandoned Miami Unit pit. During 1991, about 3.5 million tons of tailings was mined, producing almost 4,082 tons of copper, according to the company annual report. Production was expected to continue until 1998 from this project.

According to the company annual report, about 10,886 tons of copper was produced from ore mined at the Superior Mine. In November, a fire occurred at the mine that curtailed production for most of November and all of December and resulted in a charge to cost of sales of \$2.2 million for 1991. At a production rate of 908 tons of ore per day, the Superior Mine had an estimated mine life through early 1997. Magma was evaluating an expansion of the mine to 1,360 tons per day. The evaluation was expected to be complete by mid-1992.

Magma completed a series of transactions for the acquisition of the Robinson Mining District near Ely, NV.

Development of the Robinson Mining District was to be conducted through the Robinson Mining Ltd. Partnership. The two owners of the Robinson Mining Ltd. Partnership were wholly owned subsidiaries of Magma; i.e., Magma Nevada Mining Co. was the general partner and Magma Ltd. Partner Co. was the limited partner. Based on a feasibility study, reserves were reported to be 182.3 million tons with average 0.61% copper and 0.010 ounce per ton gold. The mine could produce for 16 years at a rate of 56,700 tons of copper annually, at an estimated cost of about 57 cents per pound. Another feasibility study is under way to determine potential use of SX-EW methods, expected to be complete in 1992. Magma expected full production to start by the end of 1994, subject to necessary permits, financing commitments, and other factors.

According to the company annual report, Phelps Dodge's U.S. mines and related facilities produced 564,100 tons of copper, including 212,372 tons of copper from SX-EW operations. Eventually, the company expected SX-EW production to account for about 50%, or about 226,796 tons, of company production annually. This production is a major factor in lowering production costs. In 1991, ore and rock mined at Phelps Dodge facilities was as follows, in thousand tons: Morenci, 179,631; Tyrone, 83,953; and Chino, 93,620. A total of 357.3 million tons of material was mined at Phelps Dodge's domestic properties; total ore milled amounted to 69.3 million tons with an average grade for Morenci of 0.74% copper; for Tyrone, 0.79% copper; and for Chino, 0.67% copper. Chino produced 92,714 tons of copper in concentrate and precipitate and 50,077 tons of SX-EW cathode. In addition, precipitate production at Bisbee was about 91 tons.

The Morenci Mine, AZ, is the largest copper producer in North America and the second largest in the world, after Chuquicamata, Chile. The mine consists of two open pits, two concentrators, and an SX-EW plant. The two pits, the Morenci and Metcalf, are on two sections of the same deposit. Phelps Dodge owns

85% and Sumitomo Metals of Japan owns 15% interest in this mine. During 1991, Morenci produced a record 310,439 tons of copper. The company continued to study feasibility for mining the recently discovered Coronado deposit at Morenci. The Coronado deposit contains 163.3 million tons of sulfide ore at a grade of 0.71% copper and 272.2 million tons of leachable ore containing 0.29% copper.

Construction continued on the Northwest Extension project, which will add 63,500 tons of SX-EW copper cathode production annually. With this addition, the Morenci SX-EW plant would be the largest in the world with an annual production capacity of 154,200 tons per year of high-grade cathode copper. The Tyrone SX-EW plant was to be expanded in early 1992, with annual production capacity increasing from 49,900 tons to 63,500 tons annually. The Tyrone plant was expected to operate for at least 10 more years.

Chino Mines Co., a subsidiary of Phelps Dodge (two-thirds owner) and of Mitsubishi Corp. (one-third owner), operated an open pit, concentrator, and SX-EW plant in Santa Rita, NM. Chino produced a record 140,977 tons of copper, of which 50,077 tons was SX-EW cathode, according to the company annual report. A two-stage SAG mill discharge, pebble-recycle crushing was installed to increase throughput.

In early 1992, Phelps Dodge suspended indefinitely concentrator operations at the Tyrone Mine, NM, because the sulfide copper ore reserves had been substantially depleted. The company will continue to mine only material needed for leaching and for keeping the SX-EW plant at capacity. SX-EW capacity was to be expanded to 63,500 tons annually by 1992. Low-grade oxide and sulfide ore will be mined for its SX-EW facilities for about 10 years.

Phelps Dodge's 1991 exploration program targeted copper as well as other base and platinum-group metals. The company spent \$36.3 million, compared with \$33.1 million in 1990. About two-thirds of these expenditures was spent in the United States, but also

included were exploration efforts in Botswana, Canada, Chile, Costa Rica, Mexico, and the Republic of South Africa. Drilling at the Tyrone Mine in New Mexico resulted in identification of 91 million tons of leachable copper ore with an average grade of 0.35% copper. This will enable extension of the SX-EW operations at Tyrone for several years. The exploration group also continued to evaluate copper resources in the Safford District of Arizona. The Lone Star Deposit, which contains 1.45 billion tons of leachable material at a grade of 0.38% copper, and the Dos Pobres deposit, containing about 208.7 million tons of leachable ore with 0.48% copper, was further drilled for potential. Bulk sampling and testing of the Cochise project near Bisbee continued. If brought into production, Cochise could produce 36,300 tons of copper annually for about 10 years.

Phelps Dodge completed several major projects of a 3-year program to extend mining operations into new areas near its Morenci open pit in Greenlee County, AZ. Expansion into the Northwest Extension and reentry into the dormant Metcalf pit north of Morenci will provide ore after ore reserves in the 54-year-old Morenci pit are depleted sometime in the mid-1990's. Mining in the Northwest Extension started in 1989 and will provide about 907,200 tons of copper during the mines life, mostly as cathode from the SX-EW plant. The ore body is an oxide cap over sulfide reserves, with the oxides accounting for two-thirds of the reserves. State Highway 666 had to be relocated, which was completed in August 1991, allowing stripping of overburden. Sulfide mining will follow at a later date. Once the area is mined out, it will be used as a storage area for stockpiling low-grade ore from Metcalf, reducing overall mine operating costs during the latter stages of Metcalf pit mining. The Metcalf Mine was started in 1974, but shut in 1980 owing to weak copper prices. The 3-year expansion at Morenci increased production by 142%.

The Metcalf pit was originally estimated to contain 377 million tons of ore grading 0.77% copper, and while

comparable to Morenci, will require twice the stripping before it can be mined. Production from the Metcalf operation will be gradually increased as reserves are depleted in the Morenci pit during the next 4 to 5 years. The mining rate will eventually be 158,757 tons per day. The combined operations will produce about 521,631 tons per day. Several large construction projects were undertaken to mine the Metcalf ore. This included a two-phase expansion of the Morenci in-pit crushing and conveyor system (IPCC) to link the new ore source with the mills, a new truck shop for larger equipment, and improved water and electrical distribution systems. The IPCC system incorporates crushing, conveying, and reclaiming. The crushing plant includes two semiportable crushing stations and several conveyor belts that transport the minus 8-inch crushed ore from the pit to storage areas. In the second phase, scheduled for completion in 1992, conveyors will be installed to deliver ore from Metcalf to storage southeast of the Morenci pit.

Plexus Resources Corp. (51% Total Energold) filed a production plan with the Forest Service and engaged a contractor to do an environmental impact study (EIS) for the Bornite deposit, Oregon. The EIS was expected to be complete by yearend 1992. Plexus budgeted 1992 funds to complete the predevelopment work required for mine permitting at its Silver Star property in Washington. The 1983 feasibility study conducted by the former owner, Silver Star, was being updated. The deposit had 2.6 million tons of 1.81% copper and 0.035% molybdenum. An open pit mine was planned.

The Absaroka Mountains of Wyoming were discovered to have two porphyry copper-silver deposits that lie outside the wilderness area. These are the Kirwin and Sunlight Basin porphyries south of Cooke City, MT, and were receiving interest by some companies. The area is a deeply dissected Tertiary volcanic plateau.

Smelter Production.—Primary smelter production was at about the same level as

that in 1990. Eight primary smelters and a smelter-level SX-EW plant had a combined capacity of 1.37 million tons during the year. Included with primary smelter capacity was the Lakeshore roast/leach plant that processes concentrates from Cyprus Minerals' mines. In addition, five secondary smelters and a small 450-ton-per-year secondary electrowinning plant had a combined capacity of 441,450 tons. U.S. smelter capacity was expected to begin an upward trend over the next several years as a result of expansions planned for the El Paso, TX, Miami, AZ, San Manuel, AZ, and Garfield, UT, smelters. A total of 171,000 tons of new primary capacity was expected to be on-stream by 1995. The new smelter project for Texas City, TX, was expected to be canceled in 1992 because of stringent environmental requirements. Cerro Copper Products declared a force majeure for 2 months while it repaired a floor collapse in its secondary furnace.

The growing world shortage of copper smelter capacity presented an opportunity for Copper Range, which had extra smelter capacity. Copper Range planned to use this extra smelter and refinery capacity and, as of late 1991, the company was negotiating for toll concentrates.

Expansion and modernization of the Miami, AZ, copper smelter was slated for midyear 1992 completion by Cyprus Minerals. The project was to cost \$106 million and was to increase Cyprus Minerals smelting capacity by 50%. The smelter was shut down in November 1991 for repairs following a breakout of molten copper and the resulting fire. Production was to resume in March 1992 using the rebuilt electric furnace. By July 1992, the new Isasmelt furnace was expected to begin operation, gradually increasing until the full 589,670 tons per year of concentrate would be reached in 1993. Cyprus Minerals planned to stockpile concentrates while its smelter capacity was down with about 145,150 tons of concentrates treated through its roast/leach facilities at Lakeshore, AZ. Magma Copper was planning a 49,895-ton-per-year copper expansion at its San

Manuel smelter. The \$60 million expansion would involve removing the flue dust from the smelter and treating it at the SX-EW plant, increasing electrowinning output by about 11,793 tons per year, adding a third converter, and constructing a third acid plant. The project would be complete by early 1993.

Magma Copper Co. operated the largest and most modern copper smelting and refining complex in the United States. The smelter had a rated production capacity of 900,000 tons of copper concentrate per year, representing about 25% of U.S. smelting capacity, according to the company annual report. The company smelted and refined concentrates on a custom basis in addition to that generated from its own mines. Magma's total smelting production increased by 38% between 1988 and 1991. Magma was further evaluating another expansion of its smelting and refining complex to take advantage of a worldwide shortage of processing capacity. As a result of this apparent shortage, combined smelting and refining charges increased by more than 100% over the past year. Magma planned to expand its existing smelting and refining complex by 20% for a significantly lower cost and shorter construction period than that required for a new facility with the same capacity. Magma smelted and refined about 251,290 tons of concentrates on a custom basis. In 1991, the smelter processed about 913,535 tons of new sulfide concentrate, according to the company annual report.

Phelps Dodge smelted a total of 277,327 tons of copper in 1991 from its two smelters at Chino Mines Co. and at Hidalgo in New Mexico, according to the annual report.

Refinery Production.—Ten electrolytic, 6 fire refineries, and 14 electrowinning plants operated during the year. Total U.S. refinery capacity was 2.55 million tons of copper. Refinery production from primary sources increased markedly as a result of a 20% increase in SX-EW sources, but production from primary blister was down owing to temporary smelter

closures. Refined copper from scrap was also lower. Refined imports were higher, but exports were still markedly higher than those in 1990.

Cyprus Minerals continued to increase its copper leaching operations with expansions at Bagdad, Mineral Park, and Sierrita. A copper leach project was also under study at Tonopah, NV. Cyprus Minerals produced the first SX-EW cathode from its Bagdad Mine to meet the stringent specifications for trading on the LME and COMEX. Cyprus Minerals produced 95,255 tons or 33% of its annual production from SX-EW production technology.

Over the past few years, Magma Copper has increased the amount of copper sold in the form of cathode and decreased that sold as rod from 65% of total in 1989 to 32% of total copper sold in 1991. The company planned to increase the percentage rod sales for 1992. Magma has also increased its exports in recent years to fabricators in expanding Asian markets. Export sales, as a percentage of total revenues, were 50% in 1991, compared with only 28% in 1989. The company formed a new subsidiary, Magma Metals Co., to operate its smelting and refining complex and its rod plant and to conduct its sales and marketing activities. In 1991, Magma refined 259,909 tons of copper anode. Precious-metal-bearing residues were recovered and sold to third parties for recovery. The refinery was expanded to 272,000 tons per year from 227,000 tons per year of capacity as part of the company's expansion and modernization program.

At San Manuel, the in situ program was adversely affected by ground movement attributed to underground mining. Open pit mining activities also limit the areas available for in situ operations. Haulage roads and waste stripping activities will occasionally require that in situ activities be terminated until open pit mining activities have progressed through a specific area. Despite these constraints, in situ production during 1991 and 1990 at San Manuel totaled almost 11,340 tons of copper, as compared with about 4,082

tons in 1989. The in situ leaching is done through injection of acid leach solutions into holes 700 to 1,200 feet deep. The solution is percolated through rubblized oxide ore where the copper is dissolved and pumped to the surface for SX-EW processing. In the SX-EW plant, the pregnant leach solution is processed into copper cathode. In the solvent extraction process the leach solution is mixed with an organic reagent to extract the copper and then with an acid electrolyte to transfer the copper to the electrowinning solution. Stainless steel plates are used for starter sheets. The plant produced 43,545 tons of copper in 1991.

According to the company annual report, about 15,876 tons of copper was produced by the two Pinto Valley SX-EW facilities. In 1991, copper ores milled by the Pinto Valley Div. accounted for about 65,771 tons of copper cathode refined by the company.

Phelps Dodge Corp. produced 350,173 tons of refined copper in 1991 at its refinery in El Paso, according to the company's annual report.

Cerro Copper Products Co. declared a force majeure in April on all shipments of copper cathode from its electrolytic copper refinery in Sauget, IL, while it repaired damage to its casting facilities. Production was disrupted for about 2 months.

Copper Powder.—Copper powder production at U.S. ingotmakers, foundries, and miscellaneous manufacturers reached 17,400 tons in 1979, but has declined sharply since that time by more than one-half. Copper powder production in 1991, at 7,794 tons, also was down by 8.6% from that of 1990. At the same time, copper powder imports have increased since 1983 to about a 1,400-ton-per-year level. Nonetheless, exports, which were also lower by one-third in 1987 and were lowest in 1983 and 1984 compared with those of 1979, have continued to be relatively high and were nearly double the amount imported. Continued high exports, coupled with a decreased domestic production, have led to a

decrease in U.S. apparent consumption of copper powder from 16,692 tons in 1979 to about 7,500 tons in 1991. Powder metal sales, including copper powder, in North America were heavily dependent on the automotive industry, which decreased the number of vehicles shipped over the same period.

Copper powder consumption was reported from 18 companies in 1991, 35 companies in 1987, and down from 42 companies in 1986. Among the companies reporting to the U.S. Bureau of Mines, the largest consumers were General Electric Co., St. Mary's Carbon Co., Allied Signal Co., Atlantic Sintered Metals, Stack Pole Corp., Presmet Corp., and Precision Metal Products.

Copper powder usage, including bearings, comprised about 48% of major copper and copper-base powder markets, the total shipments for which amounted to about 16,239 tons in 1991, according to Metal Powder Industries Federation data. Probably the best known use for copper powder was the self-lubricating bearing that was the first major application, which still counted for about 70% of the granular copper powder used. Copper and copper alloy powder was used in the automotive and aerospace industry for brake linings and bands, bushings, instruments, and filters. Pure copper powder was also used in the electrical and electronic industries. Ultrafine powder has been developed to meet requirements of thick film electronic circuit applications. Copper powder in flake form was used for antifouling paints, decorative and protective coatings, and printing inks. Nonstructural applications included brazing; cold soldering; mechanical plating; metals and medallions; metal-plastic decorative products, such as floor tile and epoxy resins; fungicides; soil conditioning; and various chemical and medical purposes.

The top four copper and copper alloy powder producers were Alcan Metal Powders, Greenback Industries, Inc., U.S. Bronze Powders, and SCM Metal Products. SCM closed its Hammond, IN, plant in 1986, but continued to operate its Indianapolis, IN, Durham, NC, and Johnstown, PA, plants. The value of

U.S. copper powder production comprised only about 2% of the total metal powder sales in the United States, which amounted to almost \$1 billion. Commercial-grade copper metal powder prices were \$1.49 to \$1.61 per pound on June 5, 1991, down from prices of \$1.60 to \$1.70 per pound at yearend 1990, reflecting adjustments for the cost of copper.²⁹

Granular copper powder can be produced by a number of methods, including atomization, electrolysis, hydrometallurgy, and solid-state reduction. Each method yields a powder having certain inherent characteristics. Atomization was the preferred commercial production technique used because the powder chemistry, cleanliness, size, and shape can be better controlled with this method than with other methods.

Copper Sulfate.—Copper sulfate was produced from copper scrap, blister copper, copper precipitates, electrolytic refinery solutions, and spent electroplating solutions. Imports of copper sulfate, which have more than doubled since 1987, were accounting for an increased share of U.S. consumption. Exports were also marginally higher. The major copper sulfate producers of Europe were France, Germany, Italy, and Poland. Japan and the Republic of Korea were the leading Asian producers. Copper sulfate was used as an algicide and fungicide and as a source of copper for plant and animal feed. Industrially, copper sulfate was used to activate zinc and other sulfides in froth flotation; as a print toner in photography; as a stabilizer and in blue and green pigments; in copper plating baths for electronics, metal finishing, and in pickling baths; and numerous other chemical applications. Large crystal copper sulfate had special application in water treatment where it was used as a water purifier in municipal water supplies and other treatments. Domestic demand for copper sulfate had risen steadily since 1987 owing to increased use in agriculture.

Sulfuric Acid.—Byproduct sulfuric acid (100% basis) produced in the United States was up significantly to about 4.4 million tons, an increase of 42% since that in 1987. Even so, Phelps Dodge reported lower sulfuric acid production (1,180,883 tons) in 1991, compared with 1990 (1,205,467 tons), according to the company annual report.

Prices

When spot copper prices closed at \$0.98 per pound on the COMEX on July 1, in the middle of a weak U.S. and global economy, some analysts predicted that the bull market that has existed since 1987 was over. Some traders were predicting prices lower than \$0.80 per pound, but 3 months later, the COMEX price settled at \$1.07 per pound and the 3-month spread on the LME was in backwardation. Despite supply problems, U.S. refined copper stocks were 30.4% higher by yearend. December ended with an average \$0.98 per pound on the COMEX, but supply problems seemed to be persistent as Zaire's production, in particular, took a strong drop. Smelter constraints were also responsible for restraining an even flow of metal to the market, and as the U.S. economy began its recovery at yearend, copper prices above \$1.00 per pound seemed to be inevitable.

Smelter charges were high all year. The treatment and refining charges (TC/RC's) were driven up to the equivalent of \$0.26 to \$0.29 per pound of copper.

Consumption

U.S. consumption of copper was down by 4.3% compared with that of 1990, reflecting the economic recession until late in the year. In the United States, Western Europe, and Japan, the principal growth sectors were in construction, transportation, and engineering applications. The U.S. competitive position improved during the year with increased exports as a result of strong demand growth in Asia, creating a dramatic shift in the U.S. balance of

trade. U.S. exports of concentrates, refined copper, and semifabricates all improved during 1991. U.S. net imports of brass mill semifabricates decreased for the seventh consecutive year, having reached a peak in 1984.

Demand from nearly all of copper's end-use markets increased by yearend, but none experienced the kind of increase that occurred during the late 1980's. Sales of rod and wire to the automobile and construction markets increased substantially in September and October. Ammunition was Outokumpu American Brass's biggest growth market because of the Persian Gulf war. According to copper and brass distributors, demand for some copper used for military hardware jumped up fourfold as a direct result of the Persian Gulf war. Substantial increases were indicated in nickel-aluminum bronze used in landing wheel bushings, as well as for electrical connectors used in computer circuitry, copper rounds, naval brass, and 660 bronze alloy for use in general rebuilding of military vehicles and equipment.³⁰

Chrysler Corp. announced that its next generation of small cars due out in 1994-95 would use copper radiators. The radiators were to be supplied by a Japanese contractor rather than by the Chrysler plant in Dayton, OH, which had been the automaker's principal supplier of copper radiators for years. The supplier was to be the Japanese-owned Nippondenso Manufacturing, USA Inc., at Battle Creek, MI, which purchased most of its copper from subsidiaries of Outokumpu Oy in Sweden. The new radiators were thought to weigh 10 to 11 pounds each.

According to the National Association of Home Builders, more housing starts were seen as underlying an expected copper consumption increase of 27% for the construction sector in 1992. After reaching a peak in 1986, housing starts have been in decline every year, but 1992 was expected to reverse this trend.³⁰ As shown in figure 10, copper consumption by tube manufacturers has generally followed the index for housing starts since 1983. An important departure from housing started in 1986 with copper

consumption at copper tube mills increasing despite the dropoff in the number of housing starts. This was in large part caused by the increase in copper plumbing tube per unit, as houses increased in size and required more bathrooms and ancillary features, as well as of increased use in industrial buildings for sprinklers and other systems. This trend also reflects the increased exports of copper tube and pipe since 1986, which have increased by almost 280% to 20,240 tons in 1991. Net imports of copper tube have steadily declined since 1986 and, in 1991, the United States became a net exporter, as shown in figure 11. Canada (8,000 tons), Mexico (2,000 tons), and Saudi Arabia and Spain (each with 1,000 tons) were principal recipients of U.S. tube among 57 countries. (See figures 10 and 11.)

According to recent reports by the Copper Development Association (CDA), modest growth was occurring from both recaptured markets, most notably building wire, magnet wire, air conditioner tube, transformer winding strip, and bus systems, and from new market growth in electrical and electronic markets, plumbing, heating, and cooling applications. Since the rapid aluminum substitution of the 1960's and early 1970's, because of its efficiency and reliability, copper had reestablished its position in electrical wire applications. Aluminum, while retained for overhead power cable, was soundly rejected for building wire. The electrical end use sector had been the fastest growing sector in the United States and, in 1991, comprised 75% of copper consumption.

Changes in copper consumption trends included a significant drop in the end-use category "other uses," from 6% to the current 3% of the total, which followed the capture of the penny by zinc in 1981. Despite heavy substitution by other materials such as plastics and aluminum, copper consumed for the nonelectrical construction sector decreased little compared with higher losses in other sectors such as the nonelectrical transportation and machinery sectors in the United States. With failure of plastics in some water pipes and increased use of

copper for sprinkler systems, copper was making a comeback in some sectors of the country. Homes were increasing in size, and CDA data indicated that there was a concurrent increase of copper usage to 279 pounds of copper wire per average new house. This was about a 20% increase in copper consumption per average house over the past 10 years.

AT&T Network Cable Systems, in reviewing fiber-optics substitution for copper from a telecommunication company's perspective, concluded that as technology advances, better ways to use copper were being discovered and copper usage in the telecommunication industry was again on the rise. The company concluded that copper's demise in the telecommunication industry has been oversimplified, for while the process of fiber-optics replacement and the use of more efficient, smaller wires and multiplexing was undeniable, new networks were being installed for facsimile (FAX) machines, data systems, and cellular phones. These new growth areas, while less visible, have had a positive effect on the growth of copper in telecommunications in recent years. Insulated wire and cable shipments have increased since 1986, though the decline in copper telecommunications consumption between 1980 and the low point of 1986 was significant. This decline was anticipated to pick up speed in the late 1980's, but this trend never materialized. There reportedly was 3.5 million tons of copper in local U.S. telephone networks and replacing that copper will take time, because the copper infrastructure was reliable and cost efficient and it would be financially unwise to rip it out to replace it with fiber.³² (See table 7.)

World Review

Industry Structure.—Market Summary.—In recent years, supply has been running below demand levels, but in 1991, against a background of lower demand, world production of copper from mines and refineries was generally higher than demand. Excessive levels of world stocks were built up in the 1970's and

1980's, reaching as high as 6 months and 3 months of consumption in 1975 and 1983, respectively. However, by 1987, this excess had been eliminated, and stock levels retreated to less than 1 month's consumption. Since 1989, industry output has been constrained by an almost continuous string of major production disruptions because of civil unrest, strikes, and technical difficulties. Notable among the disruptions was the shutdown of the Bougainville Mine, regular strikes in Peru, production difficulties and strikes at two large Chilean mines, and a variety of problems in the African Copper Belt, particularly Zaire. The result has been, that by 1991, the significant increases in new mine production were nullified by production losses through reserve depletion, lower grades, industry deterioration, and disruptions.

The complete drawdown of refined stocks by 1987 resulted in a rapid increase in the copper price. U.S. producer copper prices have since fallen back from the high average of \$1.31 per pound for 1989 to an average \$1.09 per pound for 1991, in response to slower economic growth and a modest increase in inventories. As the world drew into a slower economy at yearend 1991, world refined stocks were 969,000 tons, a 42% increase compared with those at yearend 1990. Most of the stock increases took place on the exchanges. Refined inventories on the LME and COMEX totaled 330,000 tons and 30,000 tons, respectively, an increase of 84% compared with those at yearend 1990 for the two exchanges. An excessive backwardation tended to attract inventories to the LME at yearend; in contrast, the increase in COMEX stocks occurred earlier in the year, after which they remained fairly stable.

Fourteen mining companies joined to form the International Council on Metals and the Environment (ICME), headed by Noranda Minerals Inc. The organization was an effort to coordinate industry knowledge, experience, and resources to address international issues. The industry anticipated becoming more active in helping to develop and implement sound

environmental and health policies and practices.³³

Mine Production.—New Capacity.—World mine capacity totaled 10.7 million tons in 1991, including 363,000 tons of capacity from 10 new mines started in Australia, Canada, Chile, China, Colombia, and Portugal. The large La Escondida Mine (310,000 tons per year) in Chile had its first full year of production in 1991. In addition, several operating mines expanded capacity, resulting in a total world mine capacity increase of 4.7% compared with that of 1990. Even so, although U.S. copper mine production expanded by 2.7%, world mine production only increased by 1.5%, representing a capacity utilization of only 79.3%, an alltime low capacity utilization rate. Development was also started on several mines, accounting for about 89,000 tons expected to come on-stream in 1992 from 15 small mines in Australia, Botswana, Canada, Chile, China, the Republic of South Africa, Turkey, and the United Kingdom.

Australia.—Straits Engineers Contracting and Nord Pacific Ltd. (40%) formed a joint venture at yearend 1991 for the development of the Girilambone Deposit, New South Wales. The deposit has 4.3 million tons of 2.4% copper ore and some gold. A 16,000-ton-per-year copper mine was planned. Construction and engineering contracts were being negotiated. Mount Isa Mines Co. (MIM) planned to spend \$165 million on expansions and improvements to its Mount Isa copper facilities, including two semiautogenous (SAG) mills that were commissioned at the copper concentrator in 1991, reducing milling costs, and a fine-grinding project to boost recoveries for lead, zinc, and silver at the zinc concentrator.

Denehurst Ltd. began development of the Benambra copper mine in the State of Victoria, Australia. Output would be about 70,000 tons per year of concentrates with an average grade of 27% copper. Production was scheduled for November 1992. Furukawa Corp. owns 11.66% of Denehurst. Most of the

mine's output would be processed at Southern Copper's Port Kembla smelter refinery, owned 30% by Furukawa, 10% by Nissho Iwai, and 60% by CRA Ltd. The balance would be exported to Japan.

Canada.—The Goldstream open pit and underground mine at Revelstoke, BC, reopened in May 1991. Nippon Mining and Sumitomo provided \$7 million to allow the owners, Bethlehem Resources and Goldstar, to reopen the mine. The mine, closed since April 1984, was rehabilitated to produce 16,000 tons of copper. Reserves were 1.86 million tons of 4.81% copper and 3.06% zinc, sufficient until 1996.

Near the BHP-Utah Island Copper open pit, Moraga Resources and Crew Natural Resources identified two copper deposits, Expo and Red Dog, containing 143 million tons of 0.32% copper and 47 million tons of 0.32% copper, respectively. These deposits could provide ore for the concentrator beyond 1996. The open pit at Island Copper was deepened by a further 145 meters to extend the life of the reserves that were scheduled for exhaustion in 1991. The pit was 2.3 kilometers long and 1 kilometer wide with present bottom at 245 meters below sea level.

The Gibraltar Mine was owned 8.1% by Placer Dome Ltd. and was at Williams Lake, BC. The open pit produced 28,755 tons of copper in concentrate in 1991 and 3,331 tons of SX-EW cathode. Although output was slightly below that of 1990, it was expected to increase in future years as higher grade ore is mined from the new Gibraltar East ore body. Development of the Gibraltar East began in 1991. Costing about \$17 million, the mine will last for about 5 years and will offset loss of ore from the Pollyanna pit that is scheduled to close in early 1993. The mine has reserves of 150.4 million tons of 0.312% copper, enough for about 12 years. Placer was drilling on the adjacent Gibraltar North Zone, following an agreement with New Coast Silver Mines to amend a royalty agreement.

In 1991, the Trout Lake and Calinan underground mines produced 83,000 tons of concentrate grading 20.5% copper, in

addition to zinc. At the Trout Lake mine a shaft development was completed in mid-1990 that enabled mining rates to be increased to more than 800,000 tons per year of ore by 1995.

In October 1991, Inco completed the consolidation of its milling and concentrating operations in the Sudbury, Ontario, area at a cost of \$57 million. The Clarabelle mill was modernized and expanded to 40,000 tons per day of ore by the addition of a SAG mill and large flotation cells. The older Frost-Strobie mill was closed in 1991, and the Copper Cliff mill is scheduled to be closed in 1993. Inco's Lower Coleman Mine was started up in 1991 and will reach full capacity of 3,000 tons per day of ore in 1993. Development on the McCreehy East Mine will resume in late 1992 with production scheduled for early 1994. Inco's Birchtree Mine, which has been on standby since 1977, was to be expanded by 50% and the new Thompson I-D Mine started by 1994; both of these were primarily nickel.

Minnova was to start development of its new Izok Lake zinc-copper deposit in the Northwest Territories by 1993. Metall Mining also acquired a 40% stake in the project for \$15 million. The deposit had reserves of 13.5 million tons of ore grading 14.4% zinc and 3.2% copper. Production might start as early as 1996.

Westmin's Myra Falls operation on Vancouver Island, BC, produced about 20,000 tons per year of copper. The H-W and Lynx Mines feed the Myra Falls mill, with more than 90% from the H-W. Column flotation cells were installed in 1991. In exploring for new reserves, drilling intersected significant sections in the Cap Zone, and the company began development access in mid-1991. Grades of 2.3% copper and 20% zinc were intersected.

Prior to being purchased by Princeton Mining, the Similco Mine was scheduled for closure in 1990, but the company revised the mining plan. Production in 1991 was from the No. 1, No. 3, and Virginia pits. The Virginia pit was brought into production in 1991 and had reserves of 6.3 million tons of 0.38% copper. Additional reserves were being

evaluated as was the recently discovered Alabama deposit, an extension of the Virginia pit.

Bitterroot Resources acquired an option to earn a 50% interest in the Lac Minerals Copper Giant project of British Columbia. With reserves of 244.9 million tons containing 2.06% copper and 0.0045 ounce/ton gold, the deposit was being further evaluated for an open pit.

Aur Resources Inc. announced in October that the final feasibility study for its 55%-owned Louvicourt deposit in northern Quebec confirmed its viability. Costing \$326 million, production could start in 1994 and produce about 55,000 tons per year of copper, 17,000 tons per year of zinc, as well as gold and silver. Reserves were estimated at 39 million tons of 3.3% copper, 1.8% zinc, 21.6 grams per ton of silver, and 0.7 gram per ton of gold.

Chile.—Compania Mineral Ojos del Salado, S.A., a wholly owned Chilean subsidiary of Phelps Dodge Corp., operated two underground copper-gold mines and a concentrator near Copiapo in northern Chile. With the completion of an \$18 million expansion project in November 1991, Ojos del Salado produced a record 18,144 tons of copper in concentrate. This was the second expansion at the mill, doubling processing capacity from 1,724 tons of ore per day to 3,493 tons per day.

La Candelaria, a major copper-gold deposit, was 3 miles southwest of Ojos del Salado near Copiapo in the Atacama desert. Ore reserves were about 362.9 million tons containing an average of 1.1% copper and 3 million ounces of gold. In June 1991, Sumitomo Metal Mining Co., Ltd., and Sumitomo Corp. agreed to invest a 20% interest in La Candelaria. Phelps Dodge expected the project to produce about 91,000 tons of copper and 80,000 ounces of gold annually by the mid-1990's. This deposit was discovered in 1987 by Phelps Dodge. Phelps Dodge anticipated spending \$90 million on the Candelaria project in 1992, having spent \$20 million in 1991. The corporation expected to fund La Candelaria expenditures with borrowing

by the subsidiary that owned the project, which was to be guaranteed by the corporation only until the project was completed.

CODELCO-Chile planned to develop Quebrada Teniente, a 56-million-ton deposit with an average ore grade of 1.4% copper to offset uncertain production from El Teniente's sublevel 6. Quebrada Teniente was expected to take 3 years to develop and cost about \$42 million, but to produce about 55,000 tons per year of copper. Exploitation of the Inca level of the El Salvador Mine was to begin in 1992. This level has reserves of 161 million tons of 0.6% copper.

Antofagasta Holdings (60%) and Outokumpu (40%) began production from their El Lince SX-EW project in Chile. The deposit contained 16 million tons of ore with 1.54% copper. Operating capacity was anticipated to be 19,958 tons per year of copper. The project cost \$63 million and began production in December. Ownership in 1991 was Chemical Bank (60%), Mineral Carolina de Michilla (25%), and Outokumpu Chile (15%). Chemical Bank's share was to be bought out in 1992.

North Lilly Mining began operations at its Tuina copper mine in Chile. The operation was a joint venture between North Lilly and International Mahogany, a Canadian subsidiary. Production was to be 6,260 tons of copper by 1992. The mine was an open pit, followed by heap leach. An SX-EW plant was being considered.

Outokumpu Oy of Finland planned for its Zaldivar Mine in Chile to start up in 1995 with a capacity of 100,000 tons per year of copper. The planned open pit mine has reserves of 560 million tons containing 0.62% copper, including a zone with 140 million tons grading 1.2% copper. Negotiations continued between CODELCO-Chile and Mineral Valle Central to option rights for processing the Cauguenes Tailings, which originated from the El Teniente Mine until 1977. A feasibility study was expected to be complete by June 1992.

At Chuquicamata, main pit reserves are in excess of 2.9 billion tons, sufficient for a minimum of 50 years of

production. In addition, Chuqui Norte, or Radomiro Tomic, 4 kilometers north of the main pit, was the subject of a feasibility study in 1991. CODELCO-Chile planned an open pit, heap-leach, and SX-EW operation. Total reserves there were about 2.5 billion tons of 0.625% copper, about 80% of which was oxide and leachable. Plans were for a 150,000-ton-per-year mine, with no timetable as yet for development. Mansa Mine, a deposit discovered in 1990 south of the Mina Sur open pit was also under investigation, as was El Abra, 40 kilometers north of Chuquicamata. An early feasibility study on El Abra indicated the potential for a 155,000-ton-per-year SX-EW operation. Reserves were estimated at 400 million tons of 0.7% copper.

CODELCO-Chile planned to spend \$264 million for developing the Mansa Mine. Projected to start up in 1998, at the rate of 60,000 tons per year of copper, Mansa Mine will be an open pit mine that will utilize Chuquicamata's concentrator. Total reserves were 990 million tons grading 1.1% copper, with a central body of 324 million tons of 1.15% copper. CODELCO-Chile's largest project, costing \$450 million, was the Radomiro Tomic. CODELCO-Chile hoped to begin mining the 691-million-ton copper oxide reserves, which grade 0.73% copper, by 1996 at the rate of 150,000 tons per year of copper. The third large item is expansion of the Andina Mine to 90,000 tons of new capacity by 1996, costing \$218 million. Four projects planned for El Teniente would provide a total of 234,000 tons of new copper capacity by 1998 and would cost \$248 million.

Cominco Ltd. announced that the Quebrada Blanca joint venture with Teck Corp. (32.5%), Cominco Resources (10%), ENAMI (10%), and Sociedad Mineral Pudahuel (5%) was to start construction of its \$300 million bacteria leaching, SX-EW project. Cominco Ltd. (42.5%) had completed metallurgical testing and detailed mine plans at yearend. Construction of the mine was to take almost 3 years.

Placer Dome (70%) and Equatorial Gold N.L. (30%) were close to financing the Leonor Mine development in Chile at yearend. The open pit mine was expected to produce almost 28,123 tons per year of copper in cathode, using heap leaching and electrowinning. Reserves were estimated to be 24 million tons of 1.6% copper.

Indonesia.—The Ertsberg, or Gunung Bijih deposit, was discovered in the Jayawijaya Range in 1936, but it was not until 1960, when Freeport Indonesia, Inc. reexamined the deposit, that serious consideration for development occurred. Freeport Indonesia became the first foreign mining company to arrange a mining contract with Indonesia after passage of the new Foreign Investment Law in January 1967. The mine underwent several expansions over the years, finally reaching 32,000 tons of ore per day. In 1989, it was decided to further expand facilities with the development of the nearby Grasburg deposit, and the 52,000-ton-per-day expansion was completed by November 1991. The Grasburg open pit is 2.2 kilometers to the northwest of the Gunung Bijih Timor pit. To date, about 675 million tons of ore has been identified. This reserve is expected to be expanded in the future by further drilling. The five Indonesian deposits, the Ertsberg, Intermediate Ore Zone (IOZ) and Deep Ore Zone (DOZ), DOM, and the Grasberg, were located along the southern edge of the highly deformed Papuan Fold Belt that runs east-west through much of New Guinea.

The Papuan Fold Belt is the result of northward-moving Australian Plate being subducted under a detached portion of the south-moving Pacific Plate. The composite reserve totals about 770 million tons of ore at 1.45% copper, 1.66 grams per ton of gold, and 3.86 grams per ton of silver. The Grasberg is the most significant of the five with an ore zone that is 500 to 600 meters in diameter. Two pipelines deliver the concentrate 113 kilometers to the port site for dewatering and shipping. The concentrate grades 34% copper, 15 grams per ton of gold,

and 55 grams per ton of silver. In 1991, 39 concentrate ships handled about 600,000 wet tons of copper concentrates.

Mexico.—In 1991, Mexican copper production dropped by 11%. A proposal to use heap-leaching techniques at the Cananea Mine was being evaluated as a way to lower costs from about 85 cents per pound to 40 cents per pound. Minera Maria, a new mine started last year, produced 40,285 tons of 12% copper ore.

South Africa, Republic of.—At Palabora, the feasibility of opening an underground mine once the open pit operations ceased was under study. Investments were also being made to improve environmental controls. The Palabora copper mine was considered to be one of the largest open pits in Africa and the world. The open pit measures 1.9 kilometers long and 1.6 kilometers wide at the surface. Open pit operations were expected to continue to 1999, when the mine will have been developed to a depth of 805 meters below the surface. A 4.8-meter-diameter shaft was sunk 560 meters to explore the possibility of underground mining. Construction could begin in 1994. Production would be phased in to maintain a stable level of ore to the crusher as open pit production declines.

United Kingdom.—Imperial Metals Corp.'s 30%-owned subsidiary, Anglesey Mining PLC of the United Kingdom, estimated its Parys Mountain Mine, North Wales, would have a mine life of about 15 years. Financing of the project was to be complete at yearend, with mine and mill construction starting in January 1992. Current reserves, at a net smelter return cut off of \$35 per ton, were estimated to be 6.45 million tons of ore grading 2.34% copper, 5.35% zinc, 2.6% lead, 39 grams per ton of silver, and 0.32 gram per ton of gold.

Zambia.—A number of mines and plants were closed in Zambia or put on care and maintenance, but still contain viable reserves. For example, reopening

the Chambishi Mine to selectively mine 2% copper ores was under consideration. In recent years, exploration has indicated that most of the steeply dipping ore bodies mined are flattening at depth, necessitating alternative mining methods. Use of fill mining methods was recommended for the Konkola Deep Mining Project, the Baluba Center Limb Project, and the Nkana Expansion Project. Columnar flotation cells have been installed or are planned for most Zambian concentrators. At Mufulira, the concentrate grade was raised by 3% to 48% copper through the use of columnar flotation. Columnar flotation for copper-cobalt separation was also planned to enhance depression of cobaltiferous pyrite. Recently completed hydrometallurgical projects included a circuit change at the Nchanga tailings leach plant that resulted in an extra 1,000 tons per month of copper.

The Konkola Mine, 25 kilometers from Chingola, has reserves of 47 million tons of 3.9% copper, but resources of about 380 million tons of 3.5% copper. Konkola (Bancroft) Mine is the wettest mine in the Copperbelt. In 1990, an average 348,146 cubic meters of water was pumped per day. Plans were to raise production from the No. 3 shaft to 100,000 tons of ore per month between now and 1993 for a total production of about 2 million tons per year. A \$400 million project was under study to raise Konkola production to 6 million tons per year. The project would take 7 years to develop and would involve sinking a new shaft to increase hoisting capacity.

Exploration.—In 1991, most industrialized countries were in a recession or a period of reduced growth. The U.S. economy, already in recession, suffered from mounting bank losses. However, U.S. and world mineral exploration did not collapse as it did during the mid-1980's. Even though base metal prices declined, prices were still above cash costs for most operations. This allowed the continuation of established exploration programs, but sharply limited new initiatives. Planned 1991 world exploration expenditures

declined by about 8% from 1990 levels, according to a survey of 153 companies by the Metals Economic Group (MEG). Canada was leading in the exploration area with 23%, the United States and Australia were 19% each; Republic of South Africa, 13%; Latin America, 11%; and southern Pacific, 7%, of the total exploration expenditures. The remaining 8% was split evenly between Europe and the rest of Africa. Mexico and Chile were reported as the most attractive in South America. Canadian Government estimates for 1991 Canadian expenditures were about 30% lower than those in 1990. The U.S. Bureau of Land Management (BLM) reported 1991 claims were 25% below the 1990 level.³⁴ Even though BLM claims were down, U.S. domestic exploration expenditures were higher compared with those of 1990. In the United States and elsewhere, the industry's renewed interest in base metals was reflected by the number of discoveries announced in 1991. Reported North American discoveries included: Mazama (copper-gold), Washington, by Centurian Mine; Lake Leo (polymetallic), Manitoba, by Granges; three new zones at Scott Lake (polymetallic) by Greenstone; Trout Lake (polymetallic) by Hudson Bay; Inco's Trout Lake, Victor; and McCreeley East polymetallic deposits and the Kemess South extension in British Columbia. Cominco reported success on the Cerrattepe copper deposit in Turkey.

Argentina.—American Resources Corp. was exploring the 298-square-kilometer property known as Campana Mahuida in the Neuquen Province of southern Argentina. Previous exploration by the Argentine Government had indicated copper and gold targets. American Resources, a Mill Valley, CA, company, was one of the first international mining companies to participate in privatization of Argentina's mining industry. Drilling had indicated 5 million tons of leachable copper grading 0.7% copper, occurring near the surface of a porphyry deposit. There was also 22 million tons of secondary-enriched sulfide mineralization that graded 0.63% copper. A joint venture was to be formed with

Campana Mahuida and American Resources for exploration and development. American Resources planned to spend \$1 million on exploration in the first year.

Also in Argentina, International Musto Explorations Ltd. completed its agreement with Yacimientos Mineros de Aguas de Dionisio, the optioner and 20% owner of the Bajo de La Alumbrera, Catamarca, deposit. Musto was to start an 18-month, \$4 million feasibility study in early 1992. The deposit contains 340 million tons of ore with 0.49% copper and 0.016 ounce per ton of gold. Production was planned for about 60,000 tons per year of copper.

Canada.—The South Kerness project was located in British Columbia and was being explored by El Condor Resources, a joint venture made up of Kennecott (40%) and St. Phillips Resources and Stork Resources (40%). The project was in the process of obtaining permits and a feasibility study. The date of startup for the 26,000-ton-per-year copper project was thought to be 1995. The porphyry deposit was reported to have reserves of 252 million tons grading 0.23% copper and 0.62 gram per ton of gold. The copper-gold mineralization was similar to Mount Milligan, a project that was canceled.

Located in northwest British Columbia, Windy Craggy was estimated to have total reserves of 297.4 million tons grading 1.38% copper and was clearly a world-class deposit. Open pit reserves would comprise about 118 million tons of 1.9% copper. In response to earlier concerns raised during the public review process, Geddes revised its original open pit mining plan to a combination of open pit and underground to reduce acid rock drainage and planned on pipeline concentrate transport. A feasibility study had been under way, but the environmental movement against the mine was considerable by groups seeking to stop development of the mine and to make the rugged and remote property part of a wilderness preserve where resource development would not be allowed. Land-use planning was

becoming an important aspect of the issue. The Windy Craggy Project was seen as an important first step in the development of the northwest corner of the Province. The fact that the mineral potential of the area for other base metals deposits was high was seen as particularly disturbing to those who would have no development in this area. Failure by Geddes Resources, 39% by Northgate Exploration Ltd. and 20% by Cominco Ltd., to win environmental approval would jeopardize other mining projects in British Columbia, particularly if opponents of the project succeed in having the area designated a wilderness preserve. Approval by the United States and the State of Alaska also was essential because concentrate would be shipped through Haines, AK, where a site also would have to be found for dewatering the concentrate. To succeed, this project not only will have to break new ground for sound environmental technology, but will also have to surmount diverse interests in land-use planning. The proposed project also was subject to the Canadian Federal assessment review process (EARP) because it affects several areas of Federal jurisdiction on fisheries and water quality. The project was becoming a highly emotional political issue. It was adjacent to national parks in both the United States (Glacier Bay National Park-St. Elias National Park) and in Canada, Kluane National Park Reserve. River-rafting companies using the Tatshenshini River opposed development in untouched wilderness. The environmental campaign was spearheaded by the Vancouver-based Western Canada Wilderness Committee. Even though the Tatshenshini River is miles from the mine site, the rafting expedition companies argued that a road and bridge would spoil the wilderness experience of the 200 tourists that go on rafting expeditions each year.

The Windy Craggy property was thought to be viable at \$0.80 per pound copper. Operating costs were expected to be about 25 to 30 cents per ton of ore mined, higher than Geddes had originally planned because of the special selection of explosives, reagents, tailings

impoundment, and effluent treatment. The operation would employ 600 to 650 persons and yield 140,000 tons per year of copper for at least 14 years with potential for another 15 years. The initial development would be an open pit, followed in 10 years by underground. The major environmental concern was the potential for acid drainage from waste rock. Other concerns included earthquake effects on tailings dams, the lifestyle change for Haines, Alaska, and impacts on the Chilkat Bald Eagle preserve. Trucking disturbances could be eliminated by buried concentrate slurry and fuel oil pipelines. Geddes estimates the total direct and indirect costs of the environmental review process to date were about \$5.5 million and that an additional \$10 million will be needed.

Inco Ltd. spent \$40 million on exploration in 1991 and made two major copper-nickel discoveries in its Sudbury, Ontario, district. Both new deposits also contained platinum, palladium, and gold, according to the company annual report. The Victor Deposit, north of Sudbury, contained between 18 and 36 million tons of ore. About 6.2 million tons was proven or probable reserves with copper values of between 5.11% and 7.37% copper and nickel values ranging between 1.49% to 2.61%. West of Inco's new McCreedy East Mine, another deposit was located that has 7.2 million tons of reserves, of which about 5.3 million tons was proven or probable ore that graded 8.83% copper and 0.63% nickel.

During 1991, Jordex Resources Inc. explored near Port Hardy, Vancouver Island, and acquired Moraga Resources Ltd. in August 1991. Work was done on the Hushamu deposit to earn a 45% interest from BHP-Utah Mines Ltd. and on the Red Dog property on which Jordex would earn a 50% interest from Crew Natural Resources Ltd. Open pit reserves at Hushamu were about 173 million tons of 0.25% copper, 0.3 gram per ton of gold, and 0.01% molybdenum, while the Red Dog had 45 million tons of ore grading 0.32% copper and 0.4% gram per ton of gold.

Exploration continued on the zinc-copper zones at Trout Lake Mine,

owned by Hudson Bay Mining and Smelting Co., Ltd. (HBMS), Granges Inc., and Manitoba Mineral Resources Ltd. Exploration uncovered a new lens and additional reserves that should be sufficient to extend the life of the mine by several years.

Chile.—CODELCO-Chile anticipated transferring the Altamira Deposit to ENAMI for public bidding and development. Altamira had ore reserves of 12 million tons grading 2% to 2.5% copper. A 4,000-ton-per-day ore processing operation was envisioned.

Papua New Guinea.—In the Papua New Guinea Highlands, work continued on testing the promising copper discovery at Wafi, 105 kilometers southwest of Lae. CRA Ltd. purchased Elders Resources' 45% equity in the project, thereby acquiring total ownership. CRA's major copper-gold mine on Bougainville remained closed, and Bougainville Copper Ltd. continued to monitor the situation closely. Until a political solution is reached and law and order reestablished, the mine will not reopen. The Wafi prospect, which was considered a major copper find, would be an open pit with byproduct gold. CRA spent \$17.6 million on exploration in 1991 and was still investigating landowner status.

U.S.S.R.—Considerable interest was generated by the potential development for a large, world-class U.S.S.R. deposit in the Chita District of Siberia. The Udokan copper deposit was reported to have reserves of 1.25 billion tons of ore, grading 1.3% copper. It was described as one of the world's largest undeveloped copper deposits. Foreign companies were being invited to bid on the development although all labor and equipment was expected to be drawn from within U.S.S.R.

Production Disruptions.—Mine closures have accounted for an estimated 563,000 tons of mine capacity lost over the period 1987-91 in Brazil, Bolivia,

Canada, Finland, Germany, Japan, Mexico, Morocco, Namibia, Norway, Peru, Papua New Guinea, Philippines, Poland, the Republic of South Africa, Spain, Sweden, the United States, Zaire, Zambia, and Zimbabwe. In addition, about 217,000 tons and almost 100,000 tons of production was lost from Zaire and Zambia, respectively, through industry deterioration. Another 187,000 tons of copper mine capacity was expected to close in 1992, including the large Tyrone Mine in the United States.

Canadian copper mine production was anticipated to decline over the near term as new capacity would be insufficient to match mine closures.³⁵ One of the main reasons is the lack of base metal exploration that prevailed during the 1970's and early 1980's. Copper production was anticipated to decline to 725,000 tons by 1997, from the current level of 800,000 tons. Although a number of new promising deposits had been discovered, lengthening lead times required were seen as delaying their entry onto the market. By the year 2000, it was forecast that Canadian production could reach current levels once again. In Quebec, copper output would decline despite the planned startup of the large Louivcourt deposit, the Ragland Mine, and Grevet Project development. By the year 2000, almost all of the Province's existing copper mines will have closed as a result of reserves exhaustion. The large Windy Craggy Project in British Columbia, because of significant environmental problems, will not begin until 1998 or later.

In Canada, several mines shut during 1991. The Afton Mine in Kamloops, BC, closed in August 1991 because of lower copper and gold prices and increased smelting and refining charges. The operation still had reserves of 18.4 million tons of 0.45% copper, enough for 7 more years. The mine was owned 73% by Teck and 23% by Metall Mining. The Opemiska underground mine in Quebec, operated by Minnova Inc., closed in June 1991 when reserves were exhausted. About 5,710 tons of copper was produced at Opemiska in 1991. Noranda's Lyon Lake Mine and the Mattabi Mine of

Ontario were both closed in early 1991 because of reserves exhaustion. In June, Breakwater Resources Ltd. suspended mining at its Estrades massive sulfide mine near Joutel owing to low metal prices. At the end of 1990, reserves at Estrades were 940,000 tons, grading 10.7% zinc, 0.94% copper, 0.92% lead, 182 grams per ton of silver, and 5.6 grams per ton of gold.

In British Columbia, closures were anticipated over the next few years at the Bell and Equity Silver Mines (1992), Samatosum Mine (1993), Island Copper Mine (1996), and Similco and Goldstream Mines (1997). The Bell copper mine was expected to shut down in mid-1992, as economic ore reserves will have been depleted by that time. Minnova's Ansil Mine was scheduled to close in early 1993 owing to reserve depletion. The Samatosum Mine, BC, owned 70% by Minnova and 30% by Rea Gold, which was started in 1989, was scheduled to close in late 1992 because of reserve depletion.

Several labor strikes, most of short duration, were to also impact production during the year. A 4 1/2-month strike severely affected copper production from Princeton Mining's properties in British Columbia, and only about 15,000 tons of copper was produced in 1991, compared with about 25,000 tons of copper in 1990. A wildcat strike by more than 500 workers at Mexicana de Cananea's mine in Mexico lasted 6 weeks in June and July. A 138-day strike at the 2,000-ton-per-year San Francisco del Oro Mine in Mexico ended with 600 workers losing jobs in cost reduction moves. The market took the 2-week strike in July at Chuquicamata, Chile, in stride. A 3-week strike at El Teniente followed in August.

In Chile, both the El Teniente and El Salvador Mines had production problems. The rockburst problem at El Teniente was restricting production and at El Salvador, reserves were limited. CODELCO-Chile was developing a new production area, El Inca, which will allow El Salvador to continue in operation for a further 15 years, but with a 10% drop in output because the new area was in harder,

primary ore. An extensive exploration program was planned between Copiapo and Taltal in hope of finding a new big deposit. CODELCO-Chile was exporting El Salvador's clean concentrates and smelting Chuquicamata's high arsenic material at Potrerillos to avoid penalties. The El Salvador mill treated ore from Quebrada M open pit and El Salvador underground mine, but because of ore shortage it also treated slag from the Chuquicamata smelter, producing about 30,000 to 35,000 tons per year of copper from this source. Oxides from Quebrada M were stockpiled for leaching, which was to begin in 1994, producing 10,000 tons per year of SX-EW cathode.

At Chuquicamata, mined ore grades had fallen from 1.64% copper in 1987 to 1.29% in 1991 and were forecast to fall to 1.00% copper by 1995. As a result of major mill expansions completed in 1989, output levels were maintained in 1990, but by 1991, output fell by about 6% to 541,600 tons of recoverable copper, partly in response to the drop in ore grades, but also because of the 2-week strike.

It was becoming apparent that the production problems in Zaire would be long term and persistent. Analysts were projecting mine production for 1992 at about 160,000 tons, less than one-half the industry's potential. Gecamines was in need of investments for modernization and repairs, and the political unrest would probably dissuade any financial interest there.

Smelting and Refining.—New Smelter Capacity.—Plans for several new greenfield smelters continued to be announced during the year, but some were not as favored as others. The list of planned new smelters or new capacity at established smelters was long and included projects in Australia, Brazil, Canada, Chile, China, Indonesia, Japan, Thailand, Pakistan, Poland, the Republic of South Africa, and the United States. World smelter capacity was estimated to total 12.5 million tons in 1991, including scrap and low-grade SX-EW capacity, but was anticipated to increase to 14.2 million tons by 1995, if the planned

projects were completed. If all were instituted as planned, about 1.7 million tons of additional capacity would be available by 1995. However, by yearend, it already was apparent that two of the planned smelters, one in Texas City, TX, and one in Portugal, were to be canceled.

The smelter constraints felt around the world were being met with creative marketing skills and partly solved by shipping to many parts of the world where there was excess capacity or negotiable smelter charges. Indonesian concentrates were going to the United States, South African concentrates to Poland, Canadian concentrates to Mexico, and some concentrates to the excess capacity in the Commonwealth of Independent States (C.I.S.), and so forth. Combined TC/RC had escalated and by yearend, were 47% higher than at yearend 1990. The higher smelter charges were a major factor in causing some smaller mines to close. The combination of higher processing charges and good copper prices was promoting some concentrates to be transported to remote smelters around the world such as to the C.I.S., Poland, and Zambia.

The Southern Copper Co. refinery and smelter at Port Kembla, New South Wales, was established as a separate business unit in 1991. The major renovation to the smelter was completed by March 1991 with commissioning of the Noranda flash furnace, the acid plant, and new converters. The new anode furnaces and rotary anode casting wheel were completed in September. About 25% of the smelter's feed is scrap, and up to 50% of the smelter needs will be imported. Requirements were for 250,000 tons per year of concentrates. The smelter was treating Woodlawn Mine, Australia, and Burma and Turkey concentrates. The tankhouse equipment was also modified, solving some problems, but production at the tankhouse was lagging during its rebuilding program.

Australia's MIM planned to install a new Isasmelt furnace at Mount Isa that will increase smelting capacity from the current 180,000 tons per year to about

210,000 tons per year. The plant would be commissioned in the second half of 1992. The plant would have potential for 250,000 tons per year depending on availability of concentrates for feed. Some concentrate would have to be purchased from overseas. The refinery at Townsville had raised capacity to 200,000 tons per year.

In August 1991, Minorco bought Hudson Bay Mining and Smelting from its 56.2% subsidiary Inspiration Resources for \$85 million. Hudson Bay planned a \$156 million modernization program of the 70,000-ton-per-year Flin Flon smelter to modify it to meet emission regulations. The existing smelter had no acid plant and had until 1994 to comply. The new smelter, which will use Noranda reactor technology, was scheduled for startup in mid-1993 and will run along with the old plant until 1994. Smelter capacity will increase to 80,000 tons per year of copper, an increase of about 10,000 tons.

Inco planned to invest \$357 million in a new 600,000-ton-per-year sulfuric acid plant at its Copper Cliff smelter. At the same time, the smelter would be modified to treat concentrate in two new Inco flash furnaces, with the original reverberatory and flash furnaces being shut down. The first of the new furnaces was commissioned in October 1991, and the second was to be completed by 1993. The smelter capacity would remain at 130,000 tons per year. There is also an electrowinning circuit to recover 10,000 tons per year of copper from nickel refinery liquors. In 1991, Copper Cliff began processing matte from the new Radio Hill smelter in Australia.

In 1992, PRM Resources Ltd. planned to undertake a full feasibility study for its copper smelter/refinery project at Kitimat, BC. The \$500 million facility, which would have a 200,000-ton-per-year copper capacity, would process both Canadian and imported concentrates. Most British Columbia concentrates were exported to Japan.

An expansion at the Ventanas smelter in Chile was to increase throughput by 300,000 tons per year to 800,000 tons per year of concentrates, replace the

reverberatory furnaces with flash smelting technology, and add an acid plant. The renovations were estimated to cost about \$250 million. The smelter's current capacity is about 500,000 tons per year of concentrates. The Ventanas expansion was linked with CODELCO-Chile's plans to increase Andina Mine's production from about 115,000 tons per year to almost 200,000 tons per year of copper at a cost of about \$240 million. Andina's concentrates were exported, but would be treated at Las Ventanas following the expansion.

Exxon Corp.'s Chilean unit, Cia. Minera Disputada Las Condes, was trebling its smelting capacity at Chagres to almost 125,000 tons of blister copper per year. Cia. Minera Disputada will replace the 44,000-ton-per-year reverberatory furnace at Chagres with a new Outokumpu flash furnace, increasing capacity to 120,000 tons by 1993 and 160,000 tons by 1997. The expansion will allow the Chagres plant to be the first smelter in Chile to cogenerate electric power. The older smelter was closing 30 days per year to cut back on pollution. Disputada also was considering investing in a refinery to match smelter capacity at its expanded Chagres smelter.

At Caletones, Chile, smelter expansion plans included a new furnace and at the Potrerillos smelter, a reverberatory furnace would be replaced by an El Teniente modified converter. Acid plants were to be built at each. The smelters serve the El Teniente and Salvador Mines. Each project would increase capacity by 200,000 tons per year of concentrates. However,

CODELCO-Chile reportedly could not afford to go forward with these renovations simultaneously with others planned, so no firm schedule was given for completion of these projects. Among CODELCO-Chile project priorities was the projected investment of \$66 million to add smelting capacity at Chuquicamata by 1994. Modifications to the El Teniente converter and a new oxygen plant were planned to increase capacity to 525,000 tons per year of blister by mid-1992. Chuquicamata's two remaining

reverberatory furnaces may also be replaced with a flash furnace, but these plans were not firm.

Davy McKee was conducting a \$580,000 feasibility study for a new greenfield smelting and refining complex in Chile. The Refineria del Pacifico smelter would treat about 800,000 tons per year of concentrates, producing about 220,000 tons per year of copper in blister. The investment required was anticipated to be about \$450 million. The study was commissioned by ENAMI along with Lac Mineral Inc., ACEC-Union Miniere, ARBI Participacoes-Caraiba Metais, and Sudamericana de Metales. If successful, Lac Minerals planned to supply the new smelter with about 70,000 tons per year of concentrates from the El Indio Mine.

China National Nonferrous Metals Import and Export Corp. (CNIEC) expanded the Bayin smelter and refinery in early 1991 from 40,000 tons to 110,000 tons per year of copper. CNIEC was planning an expansion to the copper smelter at Daye in southwest China. Currently operating with a capacity of 220,000 tons per year of concentrates (30,000 tons per year copper), a new Noranda reactor will be installed (410,000 tons per year concentrates) by Noranda Copper Smelting and Refining. The new smelter would be operational in late 1994. The new capacity would be about 110,000 tons per year copper in blister. China also announced the construction of a \$120 million, 60,000-ton-per-year copper smelter in Tianjin, 200 kilometers southeast of Beijing. The plant was expected to start in 1995.

Hindustan Copper's Khetri, Rajasthan, smelter was being expanded from 31,000 tons per year of copper to 45,000 tons per year over the next 2 years. The company hoped to supply about 70% of India's copper needs by mid-1990.

The Indonesian company PT Petrokimia Gresik and Freeport Indonesia Inc. announced plans for the construction of a \$580 million copper smelter in Gresik, East Java, Indonesia. A 150,000-ton-per-year copper smelter was planned.

Outokumpu was planning an upgrade of its Harjavalta smelter, Finland, to

about 200,000 tons per year. A feasibility study was under way, and the upgrade was expected to cost about \$180 million.

Mitsubishi Materials Corp. started operation of its continuous smelting and refining furnace in October 1991 at Naoshima Works, Kagawa Prefect. The smelting capacity was 20,000 tons of concentrate per month, including 3,000 tons of copper anode from scrap.

A furnace rebuild project was completed at Mexicana de Cobre's La Caridad smelter in 1991. Improved processing efficiencies were to allow greater smelter output from the 170,000-ton-per-year smelter. Imports of concentrates from Canada have also contributed to higher output at the La Caridad Smelter during the year.

In the Republic of South Africa, a \$23 million smelter upgrade project at Palabora was expected to increase the company's refined copper production by 5% when it was completed in 1992.

In Thailand, Rayong Copper Industry (RCI), a joint venture led by Padaeng Industry Co. (PDI), was hoping to start construction of a 150,000-ton-per-year copper smelter and refinery project by the end of 1992. RCI was composed of PDI (51%), Mitsubishi Materials (13%), MIM (12%), Marc Rich (9%), and Mitsubishi Corp. and Mitsui Corp. (7.5% each). Bechtel International was providing technical consultancy, and Citibank was reportedly securing funds for the \$345 million project. Production at the plant was planned for 1995.

At present, Thailand does not exploit its copper reserves, estimated at more than 97 million tons, found in the northeastern Provinces of Loei and Nong Khai. However, the PDI also planned to build a \$61 million copper smelter at Rayong on the coast east of Bangkok with a 15,000-ton-per-year capacity. The plant was planned for a startup at the end of 1992 at 60% of capacity, reaching full capacity by 1995.

In Zambia, major smelter modernization projects were underway at Nkana and Mufulira. At Nkana, one of the reverberatory furnaces was converted to oxy-fuel firing and an El Teniente

Modified Converter (TMC) was to be installed in 1992, together with new gas-handling equipment and revamping of the acid plants. At Mufulira, the electric furnace was being rebuilt. CODELCO-Chile was providing the engineering services and Techpro Mining and Metallurgy was to complete the detailed design. The gas-handling equipment was inadequate and needed major modification before full benefits of additional equipment can be gained. These conversions will permit a production rate of 240,000 tons per year of copper with only three reverberatory furnaces (one oxy-fuel and two conventional fuel-air burners) and three converters (the TMC and two Peirce-Smith). Energy consumption should also fall to about 4,200 megajoules per metric ton and decrease operating and maintenance costs. With higher sulfur dioxide in the off gases, production of sulfuric acid should increase, especially with acid plant repair.

Smelter Production Disruptions.—Smelter production was disrupted as a result of regular maintenance procedures, accidents, startup difficulties, or environmental considerations in Australia, Canada, Chile, Zambia, and the United States. The Miami, AZ, smelter in the United States was down for an extended period late in 1991 owing to a fire. In Australia, technical difficulties disrupted the Southern Copper smelter startup, and in August, an explosion inside the furnace caused significant damage. Repairs and restoration took 39 days, but furnace operations resumed normally thereafter by the first week in October. It was estimated that it might be up to 12 months before the smelter could reach rated capacity of 80,000 tons per year of copper, however.

Delays in the rebuilding of ZCCM's Mufulira smelter in Zambia resulted in a build up of 70,000 tons of copper concentrates by yearend 1991. Increased production at the Nkana smelter and the restart of the Luanshya plant were unable to cope with the concentrate stockpile.

Refinery Production.—World refinery production was almost 10 million tons in 1991, but represented a decrease of 5.5% over that of 1990, largely as a result of the smelter bottleneck, but also because of problems in Zairian blister delivery. Both the United States and Chile increased SX-EW capacity. SX-EW capacity was 1.074 million tons in 1991, about the same as that in 1990, but was expected to increase to 1.6 million tons by 1995. About 600,000 tons of new greenfield refinery capacity was planned by 1995 in projects announced for Brazil, Canada, Chile, China, Peru, Portugal, and Thailand.

Nearly three-quarters of Australia's mine output was refined domestically. Anode and blister was produced at Mount Isa and cathode copper refined at the company's Copper Refineries Ltd. (CRL) plant in Townsville, the largest refinery in Australia. Both the Southern Copper smelter at Port Kembla and the Roxby Downs smelter have associated refineries. A small amount of copper also was produced by Pasminco's BHAS smelter in Port Pirie as a byproduct. All three refineries were upgraded or were in the process of being upgraded. Southern Copper was planning to double refinery capacity to 80,000 tons per year of copper by the middle of 1992. Capacity also was anticipated to increase to 66,000 tons per year at the Olympic Dam Refinery. Currently, more than 80% of the Roxby Downs smelter output was exported. By the beginning of 1993, Australia's refinery production was planned for increase by an additional 90,000 tons per year from the current level of about 350,000 tons per year.

In Bulgaria, a new tankhouse was to be completed at the Georgi Damyanov refinery at Srednogorie by 1993. The capacity of the tankhouse would be raised to 120,000 tons per year of refined copper.

A new copper refinery, Cobre de Pasteje, started operation in Mexico during the year. In response to the environmental problems of Mexico City, the electrolytic refinery of Cobre de Mexico was transferring some of its

production to its new facility in Celaya, Guanajuato.

Southern Peru Copper Corp. (SPCC) and Minero Peru were considering joint operation of the Ilo refinery. The 175,000-ton-per-year copper plant was owned by Minero Peru. A 7,000-ton-per-year expansion at the Ilo refinery resulted from more efficient use of electricity and was completed by the end of the first quarter 1992.

Poland produced 376,800 tons of refined copper in 1991, up about 10% from that of 1990. Custom smelting of imported concentrates from the Republic of South Africa comprised about 35,500 tons. About 70% of production was exported by Kombinat Gorniczno-Hutniczy Miedzi (KGHM), the Government-owned copper company. Production cash costs for 1991 were reported to be about 67 cents per pound after a 13-cent-per-pound silver byproduct credit. Owing to increased power prices, however, production costs were expected to be higher in 1992, perhaps as high as 80 cents per pound. The main thrust for the future was to be the modernization of facilities and the reduction of costs. Both Western Mining Corp. and Asarco offered to help KGHM in a modernization program. One major social problem that may have to be faced would be the significant reduction in the 40,000-strong work force that could result in major unemployment. A proposal was under consideration to form four copper companies, one for mining, a semifabricating company, an engineering and construction company, and a company to handle transport of copper materials.

Capacity.—Compared with that of 1990, world mine capacity increased by 2.1%, smelter capacity by 1.1%, and refinery capacity by less than 1%. Copper mine, smelter, and refinery capacity for 1991 is shown in table 8. World capacity utilization (82%) at mines was very low in 1991 owing to continued production disruptions, discussed in the previous section. The capacity utilization rate would have been lower except for the significant reduction

in Zairian capacity to bring it more into line with current potential. Since 1974, average annual world mine production has ranged between 79% and 85% of available capacity, being highest during periods of peak demand and low available capacity, such as existed in 1987, a year of high capacity (85%) utilization. (See table 8.)

The data in table 8 are rated annual production capacity for mines, smelters, and refineries as of December 31, 1991. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable long-term operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgement of the author, can be brought into production within a short period of time with minimum capital expenditure.

Capacity at mines represents the potential copper production contained in concentrates for many producers, but for some major producers—such as Chile, the United States, and Zambia—it represents copper recoverable at the smelter level, based on known recovery factors. SX-EW capacity is counted as smelter-level capacity only when the material must be further refined. It is otherwise counted as mine and refinery capacity, bypassing the smelter level. Past and present production potential are taken into consideration when rating a mine, especially where an engineering estimation is not available or seems inappropriate in the case of decreased ore grades. Generally, the rated capacity is based on 360 days per year and 2 to 3 shifts per day. For new facilities, capacity is prorated for the year in which it started, but the full capacity is used for the year in which a facility closes. Mines and plants generally are not counted if they are not operating at any time during the year, except where it may be reasonably expected that a shutdown may be temporary; i.e., usually less than 2 years. The closed mine at Bougainville, Papua New Guinea, was not counted as

available capacity during the year because its closure has exceeded 2 years. The cost to reactivate this mine was considered almost that of a new mine, and so it clearly falls into the long-term closure category.

Reserves and Resources.—The definitions for reserves and reserve base are published in U.S. Geological Survey Circular 831, "Principles of a Resource/Reserve Classification for Minerals." In this system, the reserve base is the measured plus indicated (demonstrated) resource from which reserves are estimated. Reserves are that part of the reserve base thought to be economically recoverable with existing technology at operating or developing properties. Among individual countries, Chile (24%) has the largest share of the reserve base, followed by the United States (15%), the U.S.S.R. (9%), and Australia (7.3%). Indonesia, Peru, Zaire, and Zambia also have large copper reserves. (See table 9.)

More than 90% of U.S. copper reserves was in five States—Arizona, Michigan, Montana, New Mexico, and Utah. The U.S. Geological Survey estimated that total world land-based copper resources, composed of the reserve base and a larger body of less well-characterized resource, was about 1.6 billion tons.

Copper reserves reported at operating or developing properties were sufficient to meet a projected cumulative demand of almost 118 million tons of primary copper through the year 2000. In addition, some of the material already identified in the reserve base, which was presumed to be uneconomic to mine, may become economic with new technology and/or higher copper prices. However, the rate of increase in the reserve base has declined since 1976. The world reserve base, including measured and indicated ore, increased by about 140% from 1965 to 1976, corresponding to a 56% growth in world production and 48% growth in consumption over the same period. Since 1976, however, the reserve base has increased by only 28% and production by only 21%, while

consumption grew by an impressive 36%. Since the late 1970's, the preoccupation with gold exploration and general neglect of base metal exploration led to a significant decline of reserves in Canada, Peru, the Philippines, and other countries. U.S. reserves have remained more or less static. Unless substantial new discoveries are made immediately, some countries' output will decline by the late 1990's.

OUTLOOK

Trends in Consumption

While reported refined copper consumption in the United States was down by about 4.3%, MEC consumption increased by 1.42% in 1991. This was a result of continued strong growth in several Asian countries. The European countries also indicated a lackluster copper consumption growth. Taking a longer view between 1980 and 1990, international demand for copper has been very strong, with copper demand in the MEC rising at an annual average of 1.7%. Copper demand growth for the 1980-91 period was about the same as for those of other nonferrous metals, such as aluminum and zinc, each of which rose by 1.6% per year. Higher rates of economic and investment growth in the 1980's compared with the 1970's prompted increased metal usage. A slowdown in substitution rate also favored copper.

The information technology revolution in the past 10 years caused rapid computerization of U.S. industry, together with increased electrical requirements in homes and vehicles. There also was a move back to copper plumbing in both housing and industrial building. Building wire use in single family homes in the United States was up by 20% in the past 10 years. The key factor for copper consumption growth was the need for new metals-intensive industrial investment, plus the competitive strength of copper to other materials.

Historically, world demand has risen steadily with only an occasional setback owing to economic recession, a trend that

was expected to continue. The importance of copper demand growth as it relates to the modern society may be observed by comparing trends with the world's population growth. As shown in figure 12, U.S. per capita copper consumption since 1950, while irregular owing to recessions and other economic phenomena, has averaged 20 pounds per person per year. The flattening of the U.S. curve in the past 10 years was largely owing to decreased market share by domestic mills owing to increased competition from foreign imports. By contrast, global per capita use of copper, which includes copper consumption in all economic sectors, has exhibited a steady increase averaging 1.66% per year between 1950 and 1990. If this long-term growth trend in copper demand per person continues, population pressure alone could result in requirements for about 15.7 million tons of copper in the year of 2000, significantly above our current forecast. In recent years, the per capita demand growth has slowed and, thus, demand in the year 2000 might be expected to be somewhat lower than the long-term trend would indicate, should these lower economic growth rates prevail for the world. However, the noticeable gap between the average annual 4.7 pounds per person consumed for the world and 20 pounds per person in the United States illustrates the considerable growth potential needed for an equivalent living standard. (See figure 12.)

Copper consumption growth in the Asian countries continued to add to increased world consumption, despite the economic malaise in the United States and Europe. In 1991, the Chinese economy reportedly grew by an impressive 10% and was a significant importer of copper. Consumption spending may be expected to continue to increase as a result of rising incomes and the continued investment in infrastructure development. Some analysts were predicting that China's demand will rise to 810,000 tons in 1992, from the 650,000 tons of 1991. As a result, imports of copper to China will continue to be an important feature of its economy

because it will need in excess of 200,000 tons to cover the supply shortage. Development of China's infrastructure was crucial to its economic growth. Telecommunications and transportation were both priority areas in China's eighth 5-year plan. Chinese refined copper consumption may reach 780,000 tons in 1993, about 30% over that of 1991. Some C.I.S. copper mine production was slated to be shipped from the C.I.S. to smelters in China. Growth trends in other Asian countries, such as Taiwan, Korea, and Japan, were anticipated to be lower over the next 3 years, supported by a more modest economic growth. India's need for copper has grown much more rapidly than its production of the metal and the country was dependent on imports for about 70% of its needs. Consuming about 135,000 tons of copper in 1990, India's consumption was expected to grow to about 292,000 tons by the year 2000. Several new rod mills have been constructed within the past several years.³⁶

Trends in Supply

On the supply side, the inventory of base metal reserves developed in the early 1980's has been drawn down. Political unrest in Papua New Guinea, Zaire, and Zambia has sharply curtailed copper supplies in these areas. It is difficult to determine how much capacity in the former communist countries will survive the rigors of market-based economies. There may actually be a decline in production from inefficient and environmentally dangerous operations that are shut down.

The conflict continued between mining and environmental forces. In Wisconsin, new mining legislation and a stringent permitting process have caused development delays for new discoveries. The uncertain status of Windy Craggy and Eskay Creek and cancellation of the Mount Milligan deposit development may discourage new exploration in that area.

As environmental requirements become more stringent in the industrialized nations and the mine-producer nations strive to develop their manufacturing

industries, there will be an increased move toward building new smelters and refineries nearer to the mine source in these and other nations, where it is affordable, and the process of permitting is quicker and easier. An example of a failed attempt to establish a new greenfield smelter in the United States was the Mitsubishi Corp. Texas City, TX, smelter project, which finally was withdrawn because of stringent water permit requirements that demanded zero discharge. About \$10 million and almost 3 years was spent in the attempt to start the project.

Three major copper projects were stalled in British Columbia, Canada—Mount Milligan, Windy Craggy, and Mount Polley—waiting for Mine Development Certificates (MDC). The MDC was issued only after review of environmental and socio-economic studies completed by the applicant. Complicating the problem was the increased involvement of the Canadian Federal Government and the full-scale Federal environmental assessment. The Mining Association of British Columbia identified more than 40 Federal statutes that could trigger an environmental assessment. Companies must wait until the regulatory requirements are finished before proceeding with construction financing. Projects were becoming more and more expensive before this happened, meaning millions of dollars was spent without knowing whether the deposit would ever go into production.³⁷ By yearend, the Mount Milligan project was canceled by Placer Dome. The Windy Craggy debate had become more of a land-use issue than an environmental concern.

According to one report,³⁸ investment in new mining projects suffered a sharp decline in 1991, as lower metal prices limited access to capital. There was a 21% dropoff in new projects reported to the 1992 Engineering and Mining Journal Project Survey, and more than a 22% decrease in the total dollar value of those projects. South America once again attracted most of the investment capital, but most of the projects were reported in North America. The nature and perception of mine project risk has

changed significantly in the past 20 years as fears of nationalization or expropriation have receded. The destabilizing effects of high oil prices of 10 to 15 years ago have disappeared along with the retreat of the petroleum companies from the mining industry. The basic structural imbalances caused during this era have largely been corrected. However, the problems of unstable governments continue, as do the new concerns related to land-use planning, the environment, AIDS, and social responsibilities. Bank financing tightened in the wake of the U.S. Savings and Loan crisis and its strain on bank liquidity. The collapse of real estate markets in the United States was also putting a strain on other sources of funds, such as insurance companies. These traditional sources of funds were becoming increasingly conservative in their lending practices. The high less developed country (LDC) debts incurred during the 1970's and 1980's and their defaults were also having an effect on the ease of lending.

Forecast Supply and Demand Trends

The copper market will remain stable in 1992, with significant U.S. consumption improvements and strong demand from China. It is estimated that Western World consumption will grow by 3.35% per year, increasing to 14.1 million tons by the year 2005 (see table 10). World copper consumption may grow as much as 3.46% per year to about 14.6 million tons by the year 2000. U.S. consumption had grown at an average rate of 1.34% per year between 1950 and 1988, as indicated in figure 13, and though it has been below this rate since 1989, it was anticipated that this trend will be regained as recovery from the current recession proceeds. (See table 10 and figure 13.)

Supply and demand are projected to remain relatively balanced during the early 1990's as a result of stable copper consumption growth and continued smelter bottlenecks. Copper inventories may rise modestly because of increased mine production. The possibility of

continued supply disruptions remains a concern. Higher rates of domestic consumption in the Far East, Central and South America, and a unified Germany should continue over the near term. Another positive factor for higher consumption rates will be a higher intensity of use in building and automotive sectors. The potential for infrastructure improvements in Eastern Europe and the Far East later in the decade will also help to maintain a balance between supply and demand.

A fairly optimistic view of copper consumption for the MEC was based in large part on the anticipation that LDC's will enjoy a faster economic growth in the early 1990's than in the late 1980's as the Latin American countries join developing Far Eastern countries in industrialization and higher copper consumption. In addition to a buoyant LDC consumption, the robust performance of copper is anticipated as a result of the failure of optical fiber to attain the complete substitution in the telecommunications end-use sector that many had anticipated. While some applications, such as long-distance networks, for example, have demonstrated the usefulness of optical fibers, this accounted for only a very small proportion of the copper used in the telephone system. According to some sources, optical fiber networks have proven to be a net plus for copper because more was being consumed in devices at either end of the fiber link than is displaced by the cable itself. Aluminum's inroads into copper cable areas also was not growing as rapidly as was once the case, and copper was retaking some of the market for replacement automobile radiators. Demand for sophisticated new automotive systems will require additional wire manufactured from copper. In the United States, the resurgence of electric cars is being prompted by tough air quality regulations. Several U.S., European, and Japanese automakers are updating their electric-car technology.

Copper demand from new housing starts in the United States was expected to increase by 27% in 1992, compared with

that of 1991.³⁹ After reaching a peak in 1986, housing starts have been in decline every year, so 1992 would represent a reversal of the 5-year trend. The National Association of Home Builders' (NAHB) 1992-93 forecast called for total housing starts to reach 1.28 million in 1992, of which 1.08 million are single-family units. In 1991, housing starts totaled 1.01 million with 840,000 single-family units. This translated into 240,268 tons of copper for housing in 1992, up from 189,194 tons achieved in 1991. The additional 240,000 single-family units represent 47,809 tons of copper, based on CDA's average of 439 pounds per 2,100-square-foot dwelling. The 26,000 new multifamily units equate to 3,266 tons of copper, based on CDA's average of 278 pounds per 1,000-square-foot unit. Momentum was forecast to continue into 1993 with an 11.3% increase in total housing starts over 1992.

For the mid-1990's, expect growth in consumption, balance between supply and demand, and relatively stable prices. World economic activity will improve copper consumption by the second half of 1992 and continue into 1993. Western World consumption will increase about 4% in 1992. Production will be limited by smelter capacity, which will affect refined production. A modest surplus of about 200,000 tons is anticipated for the Western World in 1992. Consumption will grow in the range of 1.7% to 4.7% through the 1990's. Strongest growth will be in the Far East. Asia's share of market economy consumption will increase from 32% to 34% in the next 10 years. Korea, Malaysia, Singapore, Taiwan, and Thailand will equal that of Japan. By 1995, domestic demand for copper in Thailand is projected to increase from 75,000 tons to 100,000 tons per year. Latin America will also improve, as well as Eastern Europe and China.

The decline of communism changed political agendas of western democracies, and government expenditures shifted from defense to infrastructure rebuilding. The former communist countries also must increase capital spending to modernize

and improve infrastructure. Increased copper will be needed for infrastructure and industrialization. While production and consumption rates for the former U.S.S.R. were anticipated to be lower over the short term, these should be measurably higher by 1996 as western investments and market practices start to take hold. At the same time, some processing plants such as smelters and refineries may have to be closed because of environmental concerns and costs. Some reports anticipate refinery capacity to be reduced by as much as 500,000 tons by 1996. In Eastern Europe, the development and improvement of telecommunications, building construction, and electricity in these nations will require considerable copper. There was a desperate demand for housing in the C.I.S.

One factor that was expected to continue to hold down the increase in mine production over the next 5 to 10 years was the plight of the African nations Zaire and Zambia. Both countries were expected to be producing less copper, although some recovery might be anticipated by 1995. Zambia's new Government offered some hope for improvement, but only a major investment of foreign capital would reverse the downward trend. The same can be said for Zaire, but restoration to the previous 500,000-ton-per-year level was seen as unlikely because of the current political situation. Expatriates working on the mines left, aid donors suspended their programs, and there was an AIDS epidemic in this part of the world that was likely to take a long-term toll on the economies of these countries.

Forecast trends for mine capacity at mines currently operating, developing, or closed in 1991 are shown in table 11. Most operating mines will experience a drop in copper production by the year 2000. Capacity at operating mines was forecast to decrease by almost 6% in the United States by the year 2000. Mine capacity growth in Chile on the other hand can be expected to be robust with copper output rising by 36% over the 1991-96 period to a 2.7-million-ton-per-year level and to over 3 million

tons per year by the year 2000. The United States also has the potential to increase mine capacity to about 2.5 million tons per year by the year 2000, but the increases will have to come from projects currently in exploration and development phases. The projected increases were very speculative and subject to delays by environmental requirements. Indonesia and Australia also were seen as attaining major increases in their mine output over the forecast period. More than 34% of future copper mine capacity will have to come from mines currently closed or in exploration and development, as only 66% of capacity in the year 2005 will be available from mines currently operating, as shown in figure 14. If current demand forecasts are nearly correct, this capacity will be insufficient. Not only are there many doubts about the ability of the industry to develop these speculative new mines, but additional new projects will be needed, as yet undiscovered. (See table 11 and figure 14.)

Despite the money tightness, top-tier mining companies that meet all the financial criteria of a good balance sheet and a low-production-cost project should have little trouble finding outside capital. To obtain easy financing for a copper project, cash production costs of about 60 cents per pound were indicated.⁴⁰ There was considerable concern, however, that many of the world's mining projects may not find suitable financing in a timely manner, as easily as they have in the past. To attract new private-sector capital investments, Governments need to identify and implement measures to reduce risks for investors and lenders considering exploration and mine development. Exploration, mining, export, and employment rights were all areas of risk and concern, in addition to good taxation and foreign exchange provisions. Obtaining capital for new mining investments may be a problem not only for countries such as Zambia and Zaire, which were struggling with internal problems, but also for countries such as the United States and Canada, which were struggling with diverse

interests that were opposed to development.

Some analysts observed that there was a marked decrease in exploration interest in the United States and Canada as companies joined the rush to seek out opportunities in less hostile ground in Chile and Mexico. With the spirit and intent of the 1872 Mining Law of the United States under attack, and increased withdrawal of public lands for exploration, the existing legal, financial, and environmental climate was squeezing out prospectors and mining companies that had typically generated new projects of the past. Canadian and U.S. companies were paying considerably less attention than they did some years ago to acquiring reserves in North America. Other South American countries were offering projects, including Argentina, which was putting up about 15 projects for bidding. Although the geological potential was good in Africa, these were still considered risky because of continued political uncertainty, high costs, massive bureaucracy, and health concerns. Mining opportunities in the C.I.S. also were popular, but carried some risk while the people adapted to a changing political and economic climate. Exploration expenditures in British Columbia were down roughly 50% from those of 1990, according to some analysts.

A comparison of supply and demand balances over the 1974-2005 period may be illustrated by comparing actual and projected inventory trends, as shown in figure 15. The trend line for 4 weeks of MEC copper consumption highlights the potential shortage that is forecast for the mid-1990's. Previously forecast surpluses for the 1991-95 period do not seem to be materializing, owing to substantial supply disruptions over the past 3 years. The slowdown in copper consumption that coincided with these disruptions over the past 2 years has not been severe enough to compensate for the supply deficit. As a result, the balance between supply and demand has remained relatively tight. (See figure 15.)

¹Copper Development Association (CDA) categories have been redistributed on a copper content basis (the alloy component has been subtracted). The electrical component has been extracted from all end-use categories except electrical and ordinance. Adjustments were also made for the new scrap component, which was subtracted. Ordinance data reflect U.S. Department of Commerce ACM military shipments to 1983; estimated data, thereafter, reflect CDA data for 1989.

²Includes wire and other forms used in electrical, communications, and other special uses.

³Data may not add to totals shown because of independent rounding.

¹Data formerly presented in thousand metric tons.

²Includes copper in transit from smelters in the United States to refineries therein.

³Includes chemical plants, foundries, and miscellaneous plants; includes 20,000 tons in the National Defense Stockpile.

⁴Data may not add to totals shown because of independent rounding.

¹Revised.

¹Listed as "U.S. producer cathode."

²Listed as "Electrolytic wirebar (Warrenton Refining Co.)."

³Listed as "COMEX high-grade first position."

⁴Based on average monthly rates of exchange.

^aEstimated. ^aRevised.

¹Data represent copper content by analysis of concentrates produced except where otherwise noted. Table includes data available through June 30, 1992.

²Reported figure.

³Less than 50 tons.

⁴Copper content of pelletized nickel-copper matte produced in smelter.

⁵Reported by Comision Chilena del Cobre (COCHILCO). Includes recoverable copper content of nonduplicative mine and metal products produced from domestic ores and concentrates, and leach production for electrowinning. Mine production data reported by Servicio Nacional de Geologia y Minería (SERNAGEOMIN) were as follows, in thousand metric tons: 1987—1,412.9; 1988—1,472.0; 1989—1,628.3; 1990—1,616.3; and 1991—1,840.0 (estimated).

⁶Copper content of cement copper. Includes copper content of pyrite for 1989.

⁷Recoverable content.

⁸Recoverable copper content by analysis of concentrates for export plus nonduplicative total of copper content of all metal and metal products produced indigenously from domestic ores and concentrates; includes leach production for electrowinning in Portugal.

⁹Includes copper content of pyrite.

¹⁰Includes electrowon from concentrates roast-leached.

¹¹Copper content by analysis of ore mined.

¹²Data are for fiscal years beginning Apr. 1 of year stated. Zambian-mined copper reported recovered during smelting and electrowinning.

¹³Data may not add to totals shown because of independent rounding.

^aEstimated. ^bRevised.

¹This table includes total production of refined copper, whether produced by pyrometallurgical or electrolytic refining methods and whether derived from primary unrefined copper or from scrap. Copper cathode derived from electrowinning processing is also included. Table includes data available through June 30, 1992.

²Reported figure.

³Data may not add to totals shown because of independent rounding.

⁴Includes leach cathode from Zaire, which is processed.

⁵May include secondary.

⁶Excludes leach cathode exported for reprocessing in Belgium.

⁷Data are for fiscal year beginning Apr. 1 of that stated. Electrowon covers only presumably high-grade cathodes reported as "finished production leach cathodes." Other, in addition to electrorefined cathodes, includes a smaller amount of "finished product shapes" presumably cast from electrorefined cathodes, high-grade electrowon cathodes, or any blister-anodes and low-grade electrowon cathodes that were furnace- or fire-refined.

⁸May not include copper-nickel matte (copper content more than 6,000 tons per year) imported from Botswana for toll refining.

^aEstimated. ^bRevised. NA Not available.

¹This table includes total production of copper metal at the unrefined stage, including low-grade cathode produced by electrowinning methods. The smelter feed may be derived from ore, concentrates, copper precipitate or matte (primary), and/or scrap (secondary). To the extent possible, primary and secondary output of each country is shown separately. In some cases, total smelter production is officially reported, but the distribution between primary and secondary has been estimated. Table includes data available through June 30, 1992.

²Argentina presumably produces some smelter copper utilizing its own small mine output together with domestically produced cement copper, and possibly using other raw materials, including scrap, but the levels of such output cannot be reliably estimated.

³Reported figure.

⁴Data include electrowon production; estimated to be 35,000 to 45,000 tons per year that is fire-refined and cast into wirebars; detailed data are not available.

⁵Data may be for year beginning Mar. 21 of year stated. Only estimated production data are available. Secondary production is estimated to be about 5% of total.

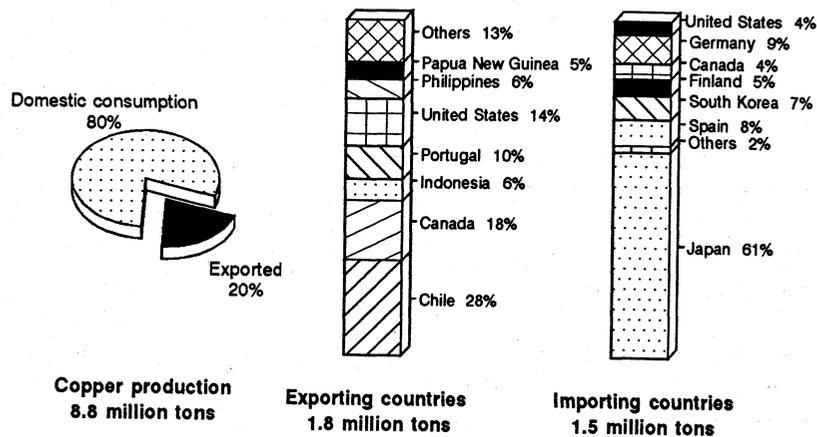

⁶Figures for U.S. primary smelter production may include a small amount of copper derived from precipitates shipped directly to the smelter for further processing; production derived from electrowinning and fire-refining is not included. Copper content of precipitates shipped directly to smelter are as follows, in metric tons: 1987—70,136; 1988—49,299; 1989—34,485; 1990—19,817; and 1991—24,954.

⁷For fiscal year beginning Apr. 1 of year stated. Electrowon is total electrowon production reported, less the quantity reported as "finished production, leach cathodes." (See table 38).

⁸Refined figure; unrefined data not available. Includes production from low-grade electrowon cathodes produced in nickel processing.

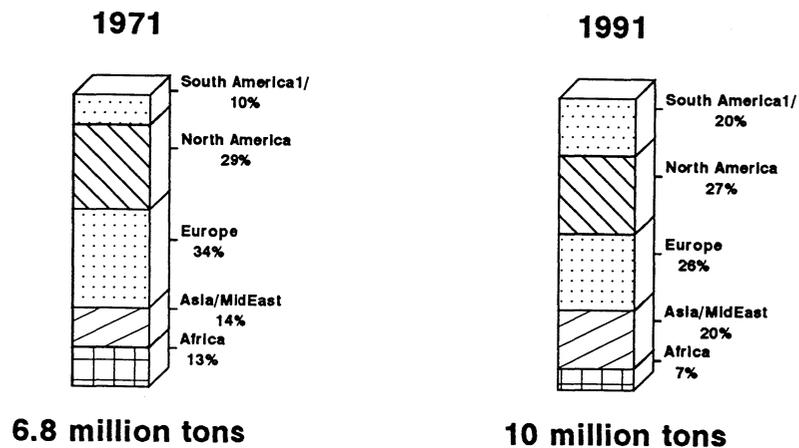

⁹Totals may not add to detail shown because of independent rounding.

DIATOMITE

By Lawrence L. Davis

Mr. Davis, a physical scientist with 36 years of industry and U.S. Bureau of Mines experience, has been the acting commodity specialist for diatomite since 1989. Domestic survey data were prepared by Tonya Hardin, statistical assistant; and international data tables were prepared by Audrey Wilkes, international data coordinator.

U.S. sales of processed diatomite decreased 3% to 610,000 metric tons, valued at \$140 million, according to the U.S. Bureau of Mines, U.S. Department of the Interior. The major use of diatomite was in filtration to separate suspended solids in liquids.

DOMESTIC DATA COVERAGE

Diatomite production data were collected from voluntary surveys of all 11 known operations. All responded, representing 100% of the production data shown in table 1.

ANNUAL REVIEW

Production

Five companies processed diatomite at 11 plants in 4 States. California continued to be the leading State, followed by Nevada, Oregon, and Washington. Major domestic producers were Celite Corp., with operations at Lompoc, CA, and Quincy, WA; Grefco Inc., Dicalite Div., at Lompoc and Burney, CA, and Mina, NV; and Eagle-Picher Minerals Inc. at Sparks and Lovelock, NV, and Vale, OR. Other producers were CR Minerals Corp., Fernley, NV; and Oil-Dri Production Co., Christmas Valley, OR. During 1991, Manville sold its Celite operation at Lompoc, CA, to Alleghany Corp. Celite also purchased the Inorganic Specialties Div. of Witco Corp., which

operates a diatomite mine and plant at Quincy, WA.

Consumption

Apparent domestic consumption of processed diatomite decreased 6% to 458,000 metric tons. In 1991, domestic and export sales of filter-grade diatomite were 441,000 metric tons, 2% less than that of 1990. Sales of diatomite as a filler, the second largest use, were about 83,000 metric tons, a decrease of 8% from that of 1990.

Markets and Prices

The average unit value of sales for processed diatomite was \$229 per metric ton, 5% above that in 1990. U.S. exports of processed diatomite were 152,000 metric tons, about 6% more than in 1990. The average unit value was \$297 per metric ton compared with \$293 per metric ton in 1990. Diatomite was exported to 72 countries. Canada, 21,900 metric tons; Japan, 17,700 metric tons; France, 14,300 metric tons; the Federal Republic of Germany, 13,800 metric tons; and Australia, 11,200 metric tons; combined received 52% of the total exported. U.S. exports represented 25% of domestic production. Imports of diatomite were 436 metric tons, of which 86% was supplied by Mexico.

World Review

World production was estimated to be 1.6 million metric tons in 1991. The

United States remained the world's leading producer, followed by France, the U.S.S.R., and Spain. These four countries accounted for 75% of world production.

OUTLOOK

Diatomite consumption is expected to increase slightly over the next few years. Filtration will continue to be the major end use.

FELDSPAR, NEPHELINE SYENITE, AND APLITE

By Michael J. Potter

Mr. Potter, a physical scientist, has been the commodity specialist for feldspar since 1976. Domestic survey data were prepared by Linder Roberts, statistical assistant; and the international data table was prepared by Virginia Woodson, international data coordinator.

Feldspars are major components in most igneous rocks and constitute a large part of at least the outer layers of the Earth and its moon. Feldspar, usually of the potash or soda type or in mixtures of the two, finds its principal end uses in the manufacture of glass and ceramics. In glass, feldspar is a source of alumina, which increases resistance to scratching and breaking and increases chemical stability. In ceramics, feldspar acts as a flux and lowers the melting temperature of a ceramic mixture.

Feldspar output decreased in 1991 compared with that of the previous year. Feldspar use in glass containers has been affected by competition from imported nepheline syenite, metal cans, plastic containers, and recycled glass cullet. A sluggish economy and fewer housing starts resulted in less feldspar demand in plumbing fixtures and tile. Imports of feldspar and nepheline syenite increased in 1991.

Studies were being made by the U.S. Department of Commerce and the U.S. International Trade Commission to determine whether imported nepheline syenite from Canada was being sold at less-than-fair value and if an industry in the United States was being materially injured or threatened with material injury.

DOMESTIC DATA COVERAGE

Domestic production data for feldspar are developed by the U.S. Bureau of Mines by means of a voluntary survey. Of the 12 active mill operations, 9 responded, representing 75% of the total

canvassed. These nine respondents reported a production of 475,000 metric tons or about 82% of the total domestic production shown in table 1. The estimated production of nonrespondents, 105,000 tons, was derived from past years' production levels and trends.

BACKGROUND

Definitions, Grades, and Specifications

Feldspar is the general term used to designate a group of closely related minerals, especially abundant in igneous rocks and consisting essentially of aluminum silicates in combination with varying proportions of potassium, sodium, and calcium. Principal feldspar types are orthoclase or microcline, both $K_2O \cdot Al_2O_3 \cdot 6SiO_2$, and anorthite, $CaO \cdot Al_2O_3 \cdot 2SiO_2$. Specimens of feldspar closely approaching these ideal compositions are seldom encountered in nature, however, and nearly all potash feldspars contain significant proportions of soda feldspar. Albite, or soda feldspar, and anorthite are the theoretical end members of a continuous compositional series known as the plagioclase feldspars, none of which is ordinarily without at least a minor admixture of potash. Commercially speaking, "potash spar" is feldspar containing 10% or more K_2O ; "soda spar" contains 7% or more Na_2O .

Perthite is the name given to material consisting of orthoclase or microcline and containing crystals that are intergrown

with crystals of albite. Most commercial feldspar can be classified most correctly as perthite.

In the feldspar industry, alaskite is a relatively coarse-grained, granitelike rock used as a feldspar ore from the Spruce Pine district of North Carolina. The principal mineral ingredients of this ore are approximately 45% plagioclase, 25% quartz, 20% microcline, and 10% muscovite mica. Minor amounts of other minerals are also present.¹ Beneficiated feldspar from alaskite is a major portion of total U.S. feldspar output.

Feldspar for glass manufacturing, ordinarily ground to 20 to 40 mesh, usually contains 4% to 6% K_2O , 5% to 7% Na_2O , and approximately 19% Al_2O_3 . Material for this purpose may be sold as a feldspar concentrate low in free quartz or in the form of a mixture containing feldspar and quartz with harmful impurities removed. In glass-grade feldspar, the iron content, expressed as Fe_2O_3 , should not exceed 0.10% for clear glass. Typically, 70 to 90 kilograms of ground feldspar is used to produce 1 ton of container glass.

Feldspar with a high potash-to-soda ratio is often preferred for pottery-making and is usually ground to minus 200 mesh. Potash spar ground to 120 or 140 mesh is usually specified for use in porcelain enamel, and even traces of such impurities as garnet, hornblende, tourmaline, and biotite mica ordinarily are not tolerated. Both potash and soda feldspars, ground to minus 200 mesh, are used in glazing.

Pottery-grade feldspar for whiteware and similar ceramic products may range from 5% to 14% in K_2O content and usually is ground to 200 mesh or finer. Limitations on iron content may be even more stringent than for glass grade; Fe_2O_3 content may not exceed 0.08% for many uses. Feldspar for use in filler applications, such as for foam rubber products, may be similar to pottery spar in fineness of grind and chemical composition, although more free quartz is often accepted; sometimes material for this purpose may be held to particle-size specifications expressed in micrometers.

Uses

The effects of feldspar on commercial glass batches include increased resistance to scratching and breaking and improved thermal endurance.² Processed feldspar is added to glassmaking formulas for its alumina and alkali contents. Alumina enhances the workability of molten glass and improves the finished product by giving it better chemical stability. The increased workability facilitates the operation of automatic machines for shaping jars and bottles. Greater chemical stability broadens the usefulness of the containers. Feldspar is used in ceramic mixtures, such as those for the making of vitreous china and porcelain enamels, principally as a flux. It fuses at a temperature below the melting point of most of the other ingredients. It also performs as a vitreous binder to cement particles of various crystalline substances present in ceramic mixtures. Feldspar serves advantageously in abrasives and scouring soaps. It forms a mild abrasive but is soft enough to avoid injury to the article being cleaned. Feldspar is also used as a filler in paint, foam rubber, and plastics.

Geology-Resources

Feldspar, one of the most abundant minerals in the Earth's crust, is found in significant amounts in some sedimentary strata and in nearly all igneous formations. Workable deposits of feldspar are probably widely distributed

throughout most of the world, and the total quantity of the mineral potentially available is very large.

It has been estimated that feldspar constitutes 60% of all crystalline igneous rocks. Granted sufficient demand and economic incentive, the mineral could be extracted from the world's granite, a source that is extremely large.

Data are not available on the quantity of feldspar in either domestic or foreign deposits. However, U.S. reserves are estimated to be quite large in the Spruce Pine district of North Carolina alone.

Feldspar concentrations of potential economic interest exist in many pegmatites, granites, and other granitic rocks and as accumulations of certain residual sands on ocean beaches or river banks.

Pegmatites are masses of coarsely crystalline rocks of igneous origin. Pegmatite bodies may range in size from small pods to extensive formations measuring hundreds or even thousands of meters. The principal feldspar ore bodies of pegmatitic type currently being exploited in the United States are in Connecticut, Georgia, North Carolina, and South Dakota. Potentially exploitable pegmatite bodies are known to exist in other areas.

The only feldspathic sand deposits being mined in the United States are in California, Idaho, and Oklahoma. Other accumulations of feldspathic sands in the United States offer possibilities as future sources of feldspar supply.

Granites are widely distributed igneous rocks of plutonic origin. Granites are present as major components of whole mountain ranges, and the dimensions of granite bodies can often be stated in kilometers. The important constituent minerals in granites are much the same as those in pegmatites, although there are likely to be significant differences in the respective proportions. Because of economic and technologic considerations, commercial utilization of granite in the United States as a source of feldspar is not presently taking place.

Technology

Most feldspathic rocks can be quarried by open pit procedures. High-grade, selectively mined feldspar from pegmatites may be dry processed, passing consecutively through jaw crushers, rolls, and pebble mills before being subjected to high-intensity magnetic or electrostatic treatment to bring the iron content down to an acceptable level.

The customary procedure applied to most massive deposits, such as alaskite, begins with drilling, blasting, and drop-ball breaking at the quarry, followed by primary and secondary crushing and fine grinding in jaw crushers, cone crushers, and rod mills, respectively. The sequence typically continues with acid-circuit flotation in three stages, each stage preceded by desliming and conditioning. The first flotation step typically depends on an amine collector to float off and remove mica, and the second uses sulfonated oils to separate iron-bearing minerals, most notably garnet. The third step, flotation with another amine collector, leaves behind a residue that consists chiefly of quartz. Sometimes the third step is bypassed, leaving a feldspar-silica mixture, which can be used in the manufacture of glass.

The flotation-cake feldspar or feldspar-silica mixture is dewatered in filters or drain bins and dried in rotary driers for use as glass-grade feldspar. Some material is further ground in pebble mills as pottery spar and for other uses.

Byproducts and Coproducts

Feldspar was obtained as a coproduct in 1991 from one company mining and processing lithium ore and one company treating weathered pegmatite ore containing mica and kaolin. Coproduct recovery of mica and silica sand was reported by some feldspar processors.

Economic Factors

Feldspar is largely sold in bulk and moved by rail hopper cars. Transportation can comprise 50% or more of the total delivered cost. Some

shipments are by truck. Most feldspar products are shipped no more than several hundred kilometers. An exception is premium-grade high-potash feldspar.

ANNUAL REVIEW

Feldspar

Legislation and Government Programs.—According to provisions of the Tax Reform Act of 1969, which continued in force throughout 1991, the depletion rate allowed on domestic and foreign feldspar production was 14%.

Production.—Feldspar or feldspar-silica sand was mined in seven States, led by North Carolina and followed, in descending order, by Oklahoma, Connecticut, California, Georgia, Idaho, and South Dakota. North Carolina accounted for 69% of the total. Nine U.S. companies operating 12 beneficiating plants and 1 grinding plant produced feldspar or feldspar-silica mixtures for shipment to more than 30 States and foreign countries, including Canada and Mexico. Of the nine companies, three produced potash feldspar, and the remainder produced soda or mixed (soda-potash) feldspar or feldspathic sand mixtures. North Carolina had five plants, California had two, and Connecticut, Georgia, Idaho, Oklahoma, and South Dakota each had one. The grinding plant was in South Carolina.

The U.S. Bureau of Mines uses a criterion of 8% minimum K_2O content in collecting data for potash feldspar.

In mid-1991, U.S. Silica Co. ceased operation at its Oceanside, CA, facility, which had been producing feldspar-silica sand. At yearend 1991, The Feldspar Corp. closed its Middletown, CT, plant. (See tables 1, 2, and 3.)

Consumption and Uses.—Fifty-five percent of feldspar sold or used in the United States went into glass, including glass containers and glass fiber. Feldspar going into pottery and other uses was

45% of the output. Lower feldspar consumption compared with that of 1990 followed the trend of the sluggish economy. Feldspar use in glass containers was also affected by competition from imported nepheline syenite. Reduced housing construction activity resulted in less feldspar demand in whiteware such as plumbing fixtures and tile.

In the rigid container market in 1990, market shares were metal cans, 62%; glass, 20%; and plastic, 18%.³ (See tables 4, 5, 6, 7, and 8.)

World Review.—Capacity.—The data in table 9 are rated capacity for mines and refineries as of December 31, 1991. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable long-term operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure. Because actual capacity data were not available, recent peak production during the past 5 years for the United States and foreign countries was considered to be equal to rated capacity. (See table 9.)

Costa Rica.—The most promising potential sources of feldspar appeared to be the feldspar quartz-phyric tuffs derived from volcanoes forming the Cordillera de Guanacaste. The tuffs were said to contain 30% to 40% feldspar. The relatively soft material would require only slight crushing and then froth flotation. Recovered quartz might be used for glassmaking. In Mexico, similar tuffs were being processed for glass-grade feldspar.⁴

Finland.—The two feldspar operations of Lohja Corp. Oy Ab were at Kimito (Kemio) in the extreme southwest of the country and at Alavus in western Finland.

Several pegmatites occurred within 4 to 5 kilometers of the Kimito plant and contained approximately 65% feldspar, 30% quartz, and 5% mica. About 100,000 tons per year of material was being mined, yielding about 40,000 tons per year of potash feldspar and 17,000 tons per year of quartz. Reserves were in excess of 20 years.

Both wet and dry processing was being employed, with the former including grinding, hydroclassification, magnetic separation, and flotation. The dry processing part of the plant included feed drying, screening, and magnetic separation. Additional high-intensity magnetic separators were installed in both wet and dry circuits. Two stages of hydroclassifiers were also incorporated. The new modifications were expected to be in operation by mid-1991 and were aimed at reducing impurity levels still further and ensuring product consistency. The glass and ceramic feldspar and quartz products were being exported to the Federal Republic of Germany, the Netherlands, Poland, and the United Kingdom.

At Alavus, the company's second feldspar operation, approximately 10,000 tons per year of pegmatite ore was being mined and subjected to dry magnetic separation. The potash feldspar product, with a low Fe_2O_3 content of 0.06%, was mostly being consumed in domestic glass and ceramics industries, especially sanitaryware.⁵

India.—Occurrences of feldspar have been reported in many parts of the country. Rajasthan has been the largest producing State with 61% of India's output in 1988. Total production has been in the range of 50,000 tons to 58,000 tons per year in recent years. In 1987, exports were approximately 13,900 tons of lump ore and 6,100 tons of powder. Exported material has gone to Bangladesh, China, Sri Lanka, Japan, Malaysia, the Philippines, Singapore, and Thailand. In India, major end uses of feldspar have been glass, ceramics, electrical porcelain, and vitreous enamels. In mid-1991, feldspar for export was \$32

to \$34 per ton, lump, f.o.b. Madras, and \$70 per ton, powdered, f.o.b. Madras.⁶

Spain.—The major feldspar producer, Industrias del Cuarzo SA, was mining a feldspathic deposit at Carrascal del Rio in Segovia. The company had proven reserves of 40 million tons and large probable reserves. The company's modern plant facilities included classification and washing, scrubbing and flotation, feldspar and sand separation, drying, grinding, micronizing, and iron removal. Capacities were 80,000 tons per year of potash feldspar, 140,000 tons per year of dry sand, and 60,000 tons per year of glass sand. About 54,000 tons per year of feldspar was being exported to France, Italy, Morocco, Portugal, and the United Kingdom.

Potash feldspar with 11.1% K₂O and 0.11% Fe₂O₃ was being sold for use in ceramics, frits, enamels, porcelain, china, sanitaryware, etc. Dry silica sand was sold for foundries, paint, fiber cement, reinforced concrete, mortars, etc.

A major expansion was planned for the next 5 years, which would raise feldspar production to 160,000 tons per year. Much of the increased output would be aimed at United Kingdom markets.

Llansa SA was obtaining mainly soda feldspar from massive pegmatites of granitic origin from quarries near Llanca in Gerona. Reserves were at least 5 million tons. Ore was crushed, washed to remove clays, hand sorted, secondary crushed, milled, and then passed through magnetic separation and air classification.

In 1990, Llansa produced 45,000 tons of soda-potash feldspar with 4.8% Na₂O and 4.3% K₂O, and 15,000 tons of soda feldspar with 6.8% Na₂O and 2% K₂O. End uses included sanitaryware, tableware, frits, enamels, pottery, electrical porcelain, glass, fillers, etc. Markets were mainly domestic.

Cia. Minera de Rio Piron SA emerged as a potash feldspar producer in 1989. The company operated a feldspathic sand deposit at Navas de Oro in Segovia. After flotation, drying, and magnetic separation, glass and ceramic grades of feldspar were produced. Ceramic grades were obtained by dry grinding to 150

mesh for enamels, 200 mesh for pottery, and 325 mesh for decorative and electrical porcelain. The company was selling about 30,000 tons per year to domestic markets, roughly equally divided between glass bottle and ceramics markets.

The fourth Spanish feldspar producer was Basazuri SL with a pegmatite deposit at Barreiros in Lugo. Output in 1988 was 79,000 tons of soda and potash feldspar. A fifth producer, Explotaciones Ceramicas Espanoles SA (Ecesa), may emerge at the end of 1992 with a low iron, potash feldspar deposit in Avila.

Imports of feldspar to Spain were approximately 42,800 tons in 1988, mainly from France. Exports were 4,000 tons in the same year, primarily to France and Morocco.⁷ (See table 10.)

Nepheline Syenite

Nepheline syenite was produced by Unimin Canada Ltd. from two operations at Blue Mountain and Nephon, Ontario, Canada. Shipments in 1989, the latest year for which information was available, were about 556,000 tons. A large portion was exported to the United States, with smaller quantities going to Europe and elsewhere. End uses included glass, whiteware, and as a filler and extender in paint, plastic, adhesives, and rubber.

In the latter part of 1991, preliminary reviews were made by the U.S. International Trade Commission (ITC) and the International Trade Administration to determine whether imported nepheline syenite from Canada was being sold at less-than-fair value. A final public hearing was to be held by the ITC in March 1992.

In Norway, nepheline syenite was produced at the Elkem Nefelin A/S, underground mining operation on the arctic island of Stjernøy. Output was 287,000 tons in 1988, the latest year for which data were available. Sales were largely to markets in Western Europe.

Prices for Canadian nepheline syenite listed in Industrial Minerals (London), December 1991, converted from Canadian dollars per short ton to U.S. dollars per ton, were approximately \$25

to \$32 per ton for glass grade, 30 mesh, bulk, carlots-trucklots, depending on iron content; \$75 per ton for ceramic grade, 200 mesh, bagged, 1-ton lots; and \$89 to \$102 per ton for filler-extender grade, bagged. (See table 11.)

Aplite

Aplite is a feldspar mineral that has more than one geological definition. However, apelite from the one active U.S. operation contains lime-soda feldspar. Aplite, usually unsuitable for use in ceramics, has been used in the manufacture of glass when it is sufficiently low in iron.

Aplite of glassmaking quality was produced in the United States by The Feldspar Corp. near Montpelier, Hanover County, VA. Domestic output decreased from that of 1990. The data are company proprietary and cannot be released for publication. Aplite traditionally has a somewhat lower price than feldspar. Industrial Minerals (London), December 1991, gave a value of about \$26 per ton for glass grade, bulk, 100% plus 200 mesh, f.o.b. Montpelier, VA.

With an annual production of 500,000 tons to 560,000 tons in recent years, Japan has been the world's largest producer of apelite. Italy is the world's largest producer of feldspathic materials, including feldspar and apelite; published figures did not give the relative breakdown of the two minerals products.

OUTLOOK

The glass container market, the largest outlet for feldspar, should remain stable in the near future. Competition will come especially from aluminum cans. To improve its standing, the glass container industry will want to work for improvements in the manufacturing process, lightweighting, strengthening the glass container, and labor productivity.⁸

Housing construction should improve at least modestly in 1992 after reaching a several-year low point of 1 million starts in 1991. Feldspar demand in plumbing fixtures and tile should likewise have at least a modest rebound.

¹Estimated. ²Revised.

³Table includes data available through Apr. 20, 1992.

⁴In addition to the countries listed, Czechoslovakia, Madagascar, and Namibia produce feldspar, but output is not officially reported, and available general information is inadequate for the formulation of reliable estimates of output levels.

⁵Series excludes production of leucite and sodalite; data consist only of that material reported by Brazil under the heading of "Feldspar." Data represent the sum of (1) run-of-mine production for direct sale and (2) salable beneficiated product; total run-of-mine feldspar production was as follows, in metric tons: 1987-98,828; 1988-140,041; 1989-140,651 (revised); 1990-104,000 (revised estimated); and 1991-100,000 (estimated).

⁶Data are for fiscal years beginning Apr. 1 of that stated.

⁷In addition, the following quantities of aplite ore were produced in metric tons: 1987-466,429; 1988-526,285; 1989-562,823; 1990-522,744 (revised); and 1991-500,327.

⁸Reported figure.

⁹Excludes nepheline syenite.

¹⁰Includes pegmatite.

FLUORSPAR

By M. Michael Miller

Mr. Miller, a physical scientist with 14 years of mineral experience with the Department of the Interior, has been the commodity specialist for fluorspar since 1989. Domestic survey data were prepared by Tonya Hardin, statistical assistant; and international data tables were prepared by Harold Willis, international data assistant. All units are in metric tons, unless otherwise noted.

In the United States, one major producer supplied about 12% of the Nation's fluorspar requirements, shipping primarily to the producer's parent chemical company. Supplementing fluorspar as a domestic source of fluorine was byproduct fluosilicic acid production from some phosphoric acid producers. According to the Bureau of the Census, imports of fluorspar decreased by about 27% compared with those of 1990. Hydrofluoric acid (HF) imports were about 19% lower than those reported in the previous year.

DOMESTIC DATA COVERAGE

Domestic production and consumption data for fluorspar were developed by the U.S. Bureau of Mines from voluntary surveys of U.S. operations. Surveys were conducted to obtain fluorspar mine production and shipments and fluosilicic acid production. Of the five fluorspar mining operations to which a survey request was sent, four responded, representing 100% of known domestic shipments. Production statistics in table 1 are withheld to protect company proprietary data. Of the 10 fluosilicic acid producers surveyed, 8 of 10 respondents reported production, representing 100% of the quantity reported. The consumption survey was sent to 91 operations quarterly and to 40 additional operations annually. Of the operations surveyed quarterly, 68% responded. Of the operations surveyed on an annual basis, 70% responded. Together, quarterly and annual responses

exceeded the apparent consumption data shown in table 1. This discrepancy between the reported and apparent consumption was caused by missing import data and a large quantity of reexports. These two factors made the apparent consumption lower than the reported consumption. (See table 1.)

BACKGROUND

Definitions, Grades, and Specifications

Technically, pure fluorspar, or the mineral fluorite, contains 51.1% calcium and 48.9% fluorine. Natural fluorite is commonly associated with other minerals such as quartz, barite, calcite, galena, siderite, celestite, sphalerite, chalcopyrite, other sulfides, and phosphates. It occurs in well-formed isometric crystals, in massive and earthy forms, and as crusts or globular aggregates with radial fibrous texture. In crystalline form, it can be colorless or may exhibit a wide range of colors, including yellow, blue, purple, green, rose, red, bluish and purplish black, and brown. It has a hardness of 4 on the Mohs' scale, a specific gravity ranging from 3.01 to 3.60, and a melting point of 1,378° C.

Three principal grades of fluorspar are available commercially: acid, ceramic, and metallurgical. Although the specifications for individual grades are generally well defined, some variation is permitted to satisfy the requirements of individual consumers.

In the United States, acid-grade fluorspar (acidspar) contains at least 97% CaF_2 . Some manufacturers of hydrofluoric acid in the United States and Europe can use 96% CaF_2 or slightly lower if the remaining impurities are acceptable. User specifications may impose limits on silica, calcium carbonate, sulfide or free sulfur, calcite, beryllium, arsenic, lead, phosphates, and other constituents. Moisture content of the dried material is preferably 0.1% or less. Particle size and distribution are sometimes specified for proper control of the rate of chemical reaction and stack losses. Very few reserves in the world can be used to produce acid-grade fluorspar without flotation processing.

Ceramic-grade fluorspar is generally marketed as No. 1 ceramic, containing 95% to 96% CaF_2 , and No. 2 ceramic, containing 85% to 90% CaF_2 . An intermediate grade of about 93% to 94% CaF_2 is also available. Specifications on impurities vary, but may allow a maximum of 2.5% to 3.0% silica, 1.0% to 1.5% calcite, 0.12% ferric oxide, and trace quantities of lead and zinc. Shipments of ceramic-spar are usually tailored to the specific need of individual consumers.

Metallurgical-grade fluorspar (metspar) contains a minimum of 60% effective CaF_2 . In the United States, metspar is usually quoted in terms of effective CaF_2 units, obtained by subtracting 2.5 times the silica content of the ore from its total CaF_2 content. The term "metspar" is usually used to refer to material with a maximum CaF_2 content of 85%, but

sometimes is used for material as high as 96%, which includes what is technically ceramic grade. Other countries may require a minimum of 80% CaF₂, which allows larger quantities of silica, usually a maximum of 15%, and other contaminants. Metspar is often traded as a lump or gravel that must pass a 25- to 37.5-millimeter screen (1 to 1 1/2 inch) and contain less than 15% of material passing a 1.6-millimeter screen (1/16 inch).

In the domestic steel industry, various shapes and sizes of briquets or pellets are being used. Generally made to consumer specifications, briquets contain varying quantities of fluorspar mixed with binders, fillers, and fluxing agents. Typically made on roll presses and ranging in size from that of a peach seed to a 5-centimeter square, briquets contain 25% to 90% CaF₂ and steel mill waste ingredients, such as mill scale, flue dust, shredded scrap, iron ore fines, and manganese ore fines. The most popular binders are molasses and lime, which do not require baking ovens. Imported briquets are often made from fines accumulated during metspar preparation and from flotation concentrates. Pellets have been made on balling machines using sodium silicate binder.

Geology-Resources¹

Fluorspar occurs in a wide variety of geological environments, which indicates that deposition takes place in a number of different ways. From an economic standpoint, seven of the most important modes of occurrence are as follows:

1. Fissure vein deposits commonly occur along faults or shear zones and are the most readily recognized form of fluorspar occurrence in the world. Although the vein structure may be persistent, the fluorspar mineralization commonly occurs as lenses or ore shoots separated by barren zones. Fissure veins occur in igneous, metamorphic, and sedimentary rocks.

2. Stratiform, manto, or bedded deposits occur as replacements in carbonate rocks. Some beds are replaced adjacent to structural features such as

joints and faults. Frequently, there is a capping of sandstone, shale, or clay.

3. Replacement deposits in carbonate rocks along the contact with acidic igneous intrusives are another common type of deposit. Deposits do not have to be the result of contact metamorphism, but may be introduced later, following the contact zone as a conduit and replacing the limestone.

4. Stockworks and fillings in shear and breccia zones are another form in which fluorspar occurs. The Buffalo deposit in the Transvaal consists of a network of fluorspar veinlets in sill-like bodies that are inclusions in the granite of the Bushveld complex.

5. Carbonatite and alkalic rock complexes may have fluorspar at their margins. Fluorspar grades are not usually sufficient to be economic, but the Okorusu deposit in Namibia is made up of a number of bodies of fluorspar in limestones, quartzites, and related rocks that have been intruded and metamorphosed by an alkaline igneous rock complex.

6. Residual deposits of fluorspar are formed in clayey and sandy residuum that results from surficial weathering of fluorspar veins and replacement deposits. These deposits may be the sources of metallurgical-grade fluorspar. They include detrital deposits blanketing the apex of veins and the upper portions of the veins themselves that have been weathered to depths of 30 meters or more.

7. Fluorspar may also occur as a major gangue mineral in lead and zinc vein deposits. Two operations in the Parral area of Mexico have treated the tailings of lead-zinc mines to recover fluorspar from previously discarded gangue minerals.

Identified world fluorspar resources are approximately 365 million tons of contained fluorspar. As might be expected, the countries with the highest production have the largest fluorspar reserves, although their production ranking does not necessarily mirror their reserve ranking. World resources of equivalent fluorspar from phosphate rock are approximately 325 million tons,

which includes about 32 million tons from domestic phosphate rock. (See table 2.)

Technology

Mining.²—Mining methods vary according to geologic conditions at individual deposits around the world. Deep deposits usually require underground techniques, while wide, shallow deposits employ open pit methods. If the ground is unable to support underground mining, open pit methods may be used even though overburden removal might be substantial. In some cases, open pit methods are used until the mining reaches a practical production limit because of excessive waste removal. Mining operations then move underground.

Narrow vein mining is often done by shrinkage stoping and open stoping where strong walls occur, while stratiform or bedded deposits use room-and-pillar patterns. Replacement and fissure vein deposits are mined with shrinkage stoping or cut-and-fill methods if they are deep, narrow occurrences. They may also be mined by open pit or strip-mining techniques when they occur near the surface and have competent sidewalls. The replacement and stockwork deposits in the Republic of South Africa, the carbonatite deposit in Namibia, and most of the fissure veins in Thailand are mined with open pit methods. However, replacement deposits in Mexico are extracted by stoping or cut-and-fill methods.

Beneficiation.—Most fluorspar must be upgraded for marketing. Metspar is often produced by hand sorting of high-grade lump crude ore, followed by crushing and screening to remove most of the fines. In the case of fluorspar ores of lower grade and/or ores with relatively coarse interlocking of minerals, gravity concentration processes are used based on the specific gravity above 3.0 for spar and below 2.8 for most gangue minerals.

Heavy-media cone and drum separators are particularly effective in the 37.5- by

4.75-millimeter (1 1/2- by 3/16-inch) size range, either for producing metallurgical gravel or for preconcentrating crude ore for flotation feed. For the finer sizes, the heavy-media cyclone process is frequently used. The high capacity and low operating cost of heavy-media methods give very satisfactory results. Ores as low as 14% CaF₂ can be preconcentrated to yield a flotation feed of 40% CaF₂ or more. In the process, lead and zinc sulfides and barite concentrate with the fluorspar, which enriches the flotation feed with these valuable minerals. In some cases, washing plants are also used prior to flotation to remove clay or manganese oxides (wad).

Ceramic and acid grades of fluorspar are produced by multistage froth flotation. Ore from the mine is crushed and ground to proper size; care is taken not to overgrind and cause fluorspar to be lost in the slimes. If lead and zinc sulfides are present, they are preferentially floated off with xanthate collector. After this process is completed, all the easy floating fluorspar is removed in a quick pass through a flotation circuit and sent on to the cleaner circuit. The tailings are discarded. The middling product is reground to separate the more finely interlocked grains of fluorspar and gangue and passed through one or more cleaner circuits. The final products generally comprise an acid-grade concentrate and, in some cases, one or more concentrates of lower grade, which are sold as ceramic grade, or pelletized and sold as metallurgical grade. Fatty acids are used as collectors for the fluorspar. Quebracho or tannin is used to depress calcite and dolomite; sodium silicate is used to depress iron oxides and silica; and chromates, starch, and dextrin are used to depress barite. Cyanide is used to depress any remaining sulfides. Lime, caustic, or soda ash can be used for acidity control. Flotation temperatures range from ambient to 80° C.

ANNUAL REVIEW

Legislation and Government Programs

The Defense Logistics Agency, Defense National Stockpile Center (DLA-DNSC), measures the fluorspar stockpile in standard dry tons (sdt). In 1991, it was authorized to sell 10,000 sdt (9,072 metric tons) of metallurgical-grade fluorspar during fiscal year 1991. The material offered is stockpiled near Gallup, NM. It is of nonstockpile grade and has an effective calcium fluoride content of 59%. There were no fluorspar stockpile sales during 1991. According to the revised fiscal year 1992 annual materials plan of DLA-DNSC, there is an existing authority for the disposal of 20,000 sdt (18,144 metric tons) of metallurgical-grade material.

Major changes in the fluorspar stockpile may occur. Based on revised national security needs required by new post-cold war planning assumptions, the Department of Defense has requested that Congress authorize disposal of significant portions of the National Defense Stockpile, including the entire fluorspar stockpile. The mechanism for this disposal would be the requested authorization for the Department of Defense to dispose of up to \$1 billion in excess stockpile inventories in any fiscal year.³

Depletion allowances against Federal taxes of 22% and 14%, respectively, remained in effect for domestic and foreign production by U.S. companies.

On November 15, 1990, the Clean Air Act Amendments of 1990 (CAAA) were enacted into law. Title VI covered stratospheric ozone protection and was directed primarily at chlorofluorocarbon (CFC) and hydrochlorofluorocarbon (HCFC) chemicals. Section 612 of title VI addressed a "Safe Alternatives Policy." Under this policy the U.S. Environmental Protection Agency (EPA) was required to promulgate, within 2 years of enactment of the CAAA, rules providing that it shall be unlawful to replace any class I (CFC's) or class II

(HCFC's) substance with any substitute substance that may present adverse effects to human health or the environment, where the EPA has identified an alternative to such replacement that reduces the overall risk to human health and the environment and is currently available. The EPA shall publish a list of the substitutes prohibited for specific uses and a list of the safe alternatives for specific uses.⁴

The risk assessment phase of this policy involves evaluation of ozone-depletion potential, global warming potential, toxicity, and flammability. This is followed by the risk management phase, where alternatives will be evaluated and compared by use.

Some CFC producers expressed opposition to this policy, because companies may be reluctant to invest in alternative chemicals that may have no value after the prohibition list is published.

Section 606 of title VI authorized the EPA to accelerate the phaseout schedules, if new scientific evidence warrants it, the availability of substitutes makes it practical, or the Montreal Protocol on Substances That Deplete the Ozone Layer is modified to include a phaseout schedule more accelerated than the one under this law. The latest scientific evidence, as reported by the National Aeronautics and Space Administration and the European Stratospheric Ozone Experiment, indicates a greater threat of ozone depletion than expected. In February 1992, the President announced that the United States would phaseout production of CFC's by the end of 1995, 4 years earlier than required by the Montreal Protocol. An accelerated international phaseout schedule will likely be adopted when signees of the Montreal Protocol meet in Copenhagen in November 1992.

Section 301(n)(6) of title III of the CAAA directed the EPA to complete a study of "the industrial and commercial applications of hydrofluoric acid in industrial and commercial applications to public health and the environment considering a range of events including worst-case accidental releases and shall make recommendations to the Congress

for the reduction of such hazards, if appropriate." During the course of the report preparation several questions were raised: (1) "Why should this study focus solely on hydrogen fluoride (HF) when it is only one of a number of toxic materials used industrially throughout the United States?" (2) "What is the difference between anhydrous HF and hydrofluoric acid, and do they pose the same hazards?" (3) "Is HF unique among hazardous chemicals in terms of its characteristics upon release or process safety management requirements?" (4) "There have been some serious incidents involving HF in the United States. What is the potential for a major disaster? What should be done to ensure that there is not a major disaster?" (5) Are the facilities handling HF aware of the potential hazards associated with a release of HF, and are they prepared to deal with a release?" (6) Is a community which has an HF facility located nearby aware of the hazards associated with a release of HF, and is the general public prepared to deal with a release?" (7) "Do other countries share our concerns, and if so, what is being done?" The EPA will attempt to address some of these questions while responding to the statutory requirements of the CAAA. A draft report was scheduled to be distributed for technical review in May 1992, while the final report was expected to be released in November 1992.⁵

Issues

As a result of the latest scientific evidence indicating that the rate of ozone depletion is greater than expected, there is pressure to speed up the phaseout of HCFC compounds and to move up the date for the outright ban to the year 2005 or earlier. This could have a pronounced effect on those consuming industries that are depending on HCFC's to replace CFC's. Commercial refrigeration and air conditioning systems depend on HCFC-22, while manufacturers of polystyrene, polyethylene, and polyurethane foams are expected to depend on blowing agents such as HCFC-142b, HCFC-141b, and HCFC-123.

Makers of refrigerators, air conditioners, and foam insulation oppose the accelerated phaseout of HCFC's. These industries have stated that they lack commercially viable alternatives necessary to eliminate the use of HCFC's. The air conditioning and refrigeration industry utilizes HCFC-22 in about 80% of its products, but no drop-in replacement will be available in the near future. These consuming industries argue that they need the HCFC's to bridge the gap between existing CFC-based technology and hydrofluorocarbon-based technologies. A major difficulty is that the consuming industries need to develop equipment design improvements to accommodate replacement compounds, while not knowing for sure which compounds will be available.

Production

Illinois was the only State reporting production in 1991 and accounted for 100% of all reported U.S. shipments. Data on shipments of fluorspar by State and grade are withheld to avoid disclosing company proprietary data.

Ozark-Mahoning Co., the Nation's largest fluorspar producer and a subsidiary of Elf Atochem North America Inc., operated three mines and a flotation plant in Pope and Hardin Counties, IL. Ozark-Mahoning also dried imported fluorspar to supplement its production. Seaforth Mineral & Ore Co. Inc. dried imported fluorspar at its facilities at Cave-In-Rock, IL, and East Liverpool, OH, for sale primarily to consumers in the ceramic industry. J. Irving Crowell, Jr., & Son shut down its Crowell-Daisy Mine in Nye County, NV. The Reynolds Mining Corp. mill in Eagle Pass, TX, was shut down in July of 1990 and was subsequently sold to Mexico's Sesa Fluorspar, Inc. The plant was dismantled and shipped to Mexico.

Ozark-Mahoning's Exploration Department operated five drills during 1991 and experienced a reasonable amount of success. At its Minerva No. 1 Mine, the company continued to mine on the new Cross Cut ore body. This trend is contrary to the normal trend direction

and was overlooked by the former mine owner Inverness Mining. To date, Ozark-Mahoning has mined more than 460 meters along the trend. It has completed test work on the column flotation of zinc ores and has purchased flotation columns for delivery in May 1992.

Eight plants processing phosphate rock for the production of phosphoric acid sold a reported 62,331 tons of byproduct fluosilicic acid at a value of about \$8.7 million. This was equal to 109,703 tons of 92% fluorspar equivalent.

Consumption and Uses

Acid-grade fluorspar, containing greater than 97% calcium fluoride (CaF_2), was used primarily as a feedstock in the manufacture of HF. Ceramic-grade fluorspar, containing 85% to 95% CaF_2 , was used for the production of glass and enamel, to make welding rod coatings, and as a flux in the steel industry. Metallurgical-grade fluorspar, containing 60% to 85% or more CaF_2 , was used primarily as a fluxing agent by the steel industry. Fluorspar is added to the slag to make it more reactive. It increases the fluidity of the slag (by reducing its melting point) and thus increases the chemical reactivity of the slag. Reducing the melting point of the slag brings lime and other fluxes into solution to allow the absorption of impurities.

Reported domestic consumption by the HF industry in 1991 remained essentially unchanged. Reported consumption by the steel industry decreased by about 52%, part of which was accounted for by a decrease in U.S. raw steel production of 13%.

In the ceramic industry, fluorspar was used as a flux and as an opacifier in the production of flint glass, white or opal glass, and enamels. Fluorspar was used in the manufacture of aluminum, brick, cement, and glass fibers, and was also used in the melt shop by the foundry industry.

Three companies reported fluorspar consumption for the production of HF. The U.S. Department of Commerce,

Bureau of the Census, reported that, based on its monthly survey, anhydrous, technical, and aqueous HF, 100% basis, "produced and withdrawn from the system," was 143,658 tons for 1991 compared with the 1990 quantity of 140,295 tons.

The largest use of HF was for the production of a wide range of fluorocarbon chemicals, including fluoropolymers and CFC's. CFC's were produced by five companies: Allied-Signal Corp., Ausimont USA Inc., E. I. du Pont de Nemours & Company Inc., Elf Atochem North America Inc., and La Roche Chemicals Inc. According to preliminary data from the U.S. International Trade Commission, production of trichlorofluoromethane (CFC-11) decreased by 27% to 44,815 tons and dichlorodifluoromethane (CFC-12) also decreased by 27% to 69,340 tons compared with 1990 figures. Data on production of chlorodifluoromethane (HCFC-22) were unavailable. No information is currently collected on production of the HCFC and HFC replacement compounds.

As a consequence of the announced accelerated schedule CFC-11 and CFC-12 production will be phased out by 1996. Because HCFC-22 is not a fully halogenated CFC and has a much lower ozone-depletion potential, it will be phased out at a later date, but earlier than had originally been proposed. The chemical industry continued to pursue research into replacement compounds for the CFC's and HCFC's that are to be phased out. Construction continued on commercial plants to manufacture some of the replacements. The CFC producers are developing HCFC substitutes that have ozone-depletion potentials of about 5% that of CFC-11, CFC-12, and CFC-113, which in total have accounted for more than 90% of CFC consumption. The most likely HCFC candidates to replace controlled CFC's are HCFC-22, for use in home air-conditioning (already in commercial use); HCFC-123, to replace CFC-11 as a blowing agent in polyurethane foams and refrigeration; HCFC-141b, to replace CFC-11 in blowing plastic foams; and HCFC-142b,

to replace CFC-11 as a blowing agent for polystyrene and polyethylene foams. Unfortunately, the viability of some of the HCFC compounds has been called into question owing to the likelihood that the phaseout schedule for HCFC's will be accelerated. In addition, HCFC-123 has run into toxicity and cost problems, and atmospheric measurements have indicated that the ozone depletion potential of HCFC-141b is much higher than originally calculated. The HFC substitutes have no ozone-depletion potential because they contain no chlorine atoms. The most promising HFC candidates are HFC-134a, to replace CFC-12 in refrigeration and auto air conditioners, and HFC's 32, 125, and 152. The latter three HFC's hold potential for use by themselves or as blends in mid- to low-temperature refrigeration and automobile air conditioners. In addition, some of the replacements may be mixtures of these compounds and HCFC's. Inhalation and toxicity tests continued on the various replacements.

The manufacture of synthetic cryolite and aluminum fluoride for use in aluminum reduction cells was a major use of HF. In the Hall-Héroult process, alumina is dissolved in a bath of molten cryolite, aluminum fluoride, and fluorspar to allow electrolytic recovery of aluminum. An estimated 20 to 30 kilograms of fluorine was consumed for each metric ton of aluminum produced. Aluminum fluoride was used by the ceramic industry for some body and glaze mixtures and in the production of specialty refractory products. It was used in the manufacture of aluminum silicates and in the glass industry as a filler.

HF was consumed in the manufacture of uranium tetrafluoride that was used in the process of concentrating uranium isotope 235 for use as nuclear fuel and in fission explosives. It was also used in stainless steel pickling, petroleum alkylation, glass etching, oil and gas well treatment, and as a cleaner and etcher in the electronics industry. It was used as the feedstock in the manufacture of a host of fluorine chemicals used in dielectrics, metallurgy, wood preservatives,

herbicides, mouthwashes, decay-preventing dentifrices, plastics, and water fluoridation.

Fluosilicic acid was used primarily to make aluminum fluoride for the aluminum industry and in water fluoridation, either directly or after processing to sodium silicofluoride. (See table 3.)

Stocks

Consumer stocks were 68,999 tons, a decrease of almost 8% from the level reported in 1990. At yearend, the National Defense Stockpile fluorspar inventory was unchanged from yearend 1990 and contained 892,000 sdt (809,000 metric tons) of acid-grade material, 310,000 sdt (281,000 metric tons) of metallurgical-grade material, 899 sdt (816 metric tons) of nonstockpile, acid-grade material, and 116,777 sdt (105,938 metric tons) of nonstockpile, metallurgical-grade material. The fluorspar stockpiles are at 22 sites across the country. The largest acid-grade stockpiles are in Wilmington, DE; Memphis, TN; and North Gate, CO. The largest metallurgical-grade stockpiles are in Marietta, PA; Large, PA; and Warren, OH.

Prices

According to prices published by Industrial Minerals (Metal Bulletin PLC), the price of domestic acid-grade fluorspar was unchanged compared with 1990 prices. Published yearend producer prices for Mexico and South Africa decreased compared with 1990 prices. Although not published in 1990, prices published in 1991 for Chinese fluorspar were significantly lower than those of other producers.

Yearend price quotations from the Chemical Marketing Reporter (CMR) were unchanged at \$0.6875 per pound for anhydrous HF and were unchanged at \$52.00 per 100 pounds for aqueous HF, 70%, in tanks. These quotations were equivalent to about \$1.52 per kilogram for anhydrous HF and \$114.64 per 100 kilograms for aqueous HF, 70%, in

tanks. The CMR yearend price quotation for fluosilicic acid, 100% basis, in tanks, was unchanged at \$340 per short ton (about \$375 per metric ton) and for synthetic cryolite ranged from \$510 to \$550 per short ton (about \$562 to \$606 per metric ton). (See table 4.)

Foreign Trade

According to the Bureau of the Census, U.S. exports of fluorspar increased by 395%. Almost 59,000 tons was exported to Mexico, which received 80% of U.S. fluorspar exports. The large export numbers reported by the Bureau of the Census reflect material classified as general imports, which is merchandise entered into customs bonded warehouses and U.S. foreign trade zones from foreign countries. This material, when transhipped to another country, appears in the trade statistics as U.S. exports. (See table 5.)

Imports for consumption of fluorspar decreased by about 27% compared with those of the previous year, according to Bureau of the Census data. However, based on reported consumption and domestic shipments, the decrease appeared to be about 18%. It is believed that there were some Chinese shipments unreported in the official trade data. The Bureau of the Census data do not indicate sufficient imports for consumption when compared to reported consumption data, consumer stocks, domestic shipments, and the Journal of Commerce Trade Information Service. Officially, the Republic of South Africa was the largest supplier of fluorspar to the United States, followed by, in descending order, China, Mexico, Spain, and Morocco. The average c.i.f. unit value, in dollars per metric ton, was \$144 for acid grade and about \$102 for subacid grade. If the missing shipments are added, China becomes the largest supplier, and the unit price for acid grade would be significantly lower. (See table 6.)

Imports for consumption of HF decreased 19% to a quantity equivalent to approximately 124,000 tons of fluorspar. Imports of synthetic and natural cryolite decreased 54% to a quantity equivalent to

approximately 4,030 tons of fluorspar. Imports of aluminum fluoride decreased by more than 6% to a quantity equivalent to approximately 50,000 tons of fluorspar. (See tables 7, 8 and 9.)

World Review

World fluorspar consumption and production decreased compared with 1990 levels. In order of rank, China, Mongolia, Mexico, the U.S.S.R., and the Republic of South Africa were the major producers. The international fluorspar industry experienced the continuing effects of major changes in traditional markets, such as fluorochemicals and steel. Many of the traditional producing countries saw significant decreases in fluorspar production in 1991, with Mexico being the hardest hit.

China.—Fluorspar exports from China continued at high levels, but decreased for the second straight year. Reported exports were 934 thousand tons in 1991, compared with 1.09 million tons in 1990 and 1.18 million tons in 1989. Based on reported export data and estimates of domestic consumption, it is estimated that China produced about 1.6 million tons in 1991. Although uncertainty exists concerning the level of domestic consumption in China, it is estimated that consumption levels have increased mainly for metallurgical grade. China's steel production has increased from 61 million tons to 71 million tons over the past 2 years.

Italy.—Fluorspar production in Italy continued to decline in 1991. Estimated 1991 production was 70,000 tons of acid grade and 30,000 tons of metallurgical grade. The largest producer was Mineraria Silius, S.p.A., which owns and operates an underground mining complex and a heavy-media plant adjacent to Cagliari, in southeastern Sardinia, and a flotation mill 17 kilometers west of Cagliari. In 1991, the Sardinian Regional Government increased its support of the company's operations, which include the mines, heavy-media plant and flotation

mill, and an aluminum fluoride-synthetic cryolite plant. Collectively, the mining complex has been renamed the Gerrei Mines, replacing the former Silius Mines designation.

Mexico.—Mexico's production dropped by more than 44% in 1990, as sales of both metallurgical grade and acid grade decreased. Process improvements and use of economical substitutes by the steel industry affected metspar sales. The CFC phaseout, U.S. recession, and price pressure from Chinese exports all adversely impacted Mexican production. These factors caused the shutdown of some mining units. Sesa Fluorspar, a new producer, operated the second half of 1990 and the first quarter of 1991. It shut down in 1991 primarily as a result of high freight costs. Fluorita de Rio Verde operated at full capacity in 1991 (7,500 tons per month), but their sales decreased, and they shut down "temporarily" at the end of 1991. The shutdown could be prolonged, but steps were taken to maintain operations to allow a restart if markets improve. Cia Minera La Valenciana SA planned to reopen its fluorspar mine in Torreón to supply feedstock for HF production. The company purchased the Essex-Dow HF plant from Paulsboro, NJ, and rebuilt it at Torreón. Plant output was scheduled to begin in the first quarter of 1992.

The Mexican fluorspar mining industry was hurt in 1991 by Chinese imports. As a result, the Mexican Chamber of Mines is preparing a countervailing duty investigation on Chinese fluorspar exports to Mexico. The investigation was initiated mainly at the request of the small producers.

Mongolia.⁶—Mongolia is the world's second largest producer of fluorspar. Table 10 shows revised production totals for 1987-90 and an estimate for 1991. Fluorspar is mined in east-central and southeast Mongolia, including the Chulut Cagan Del, Adag, Bor-Ondor, Hajuu-Ulaan, Zuun Cagan Del, Hamar-Uls, Orgon, Berh, Delgerhaan, and Har-Ayrag Mines.

Mongolia and the U.S.S.R. have had close ties since 1921 and have cooperated in mining ventures since after WWII. Soviet assistance provided mining technology, skilled labor, technicians, and substantial physical infrastructure. In return, the U.S.S.R. received relatively cheap raw materials. In the 1970's, the Soviet foreign trade association Tsvetmetpromexport promoted joint U.S.S.R.-Mongolian mining ventures, including the Mongolsovsvetmet Association, which operates a number of fluorspar and gold mines. A major fluorspar operation developed by Mongolsovsvetmet and the U.S.S.R. is the Bor-Ondor mine and mill complex in the extreme southwestern corner of Khentii Province. This complex consists of an underground mine and adjacent flotation mill, plus a 50-kilometer rail line connecting with the Trans-Mongolian railway at Tsagaandorolj. Mine production began in 1982, and mill production began in 1985. All of Mongolia's acid-grade fluorspar is produced at Bor-Ondor.

The changes in the U.S.S.R. and Eastern Europe have forced Mongolia to reform its economic, social, and political policies. The U.S.S.R. has accounted for 90% of Mongolia's foreign trade. The level of Soviet aid, both financial and technical, will be much reduced in the future. Mongolia needs to expand its trade and contact with the rest of the world to increase its return for exports, draw foreign investment, and replace the technical expertise lost when Soviet technicians depart.

To this end, the Mongolian President, Punsalmaagiyn Ochirbat, has initiated a policy promoting ties with nations outside the Soviet bloc. On January 23, 1991, the U.S. Trade Representative and the Mongolian Minister of Trade and Industry signed a trade agreement to improve economic and business ties between the two nations. The accord assigns each other most-favored-nation (MFN) status, with the corresponding MFN tariffs. Mongolia signed a similar agreement with Japan in 1990.

Namibia.—Okorusu Fluorspar Ltd. closed down its mine during November and December 1991 because production had been running ahead of contractual commitments and their storage facility in Walvis Bay was full. The time was used to perform maintenance work. Production was scheduled to start up again on schedule in January of 1992. Earlier technical problems have been overcome, and the mill was attaining the designed production rate of about 1,000 tons per week.

United Kingdom.—Fluorspar production is concentrated in Derbyshire, with production from Laporte Minerals, Weardale Minerals Ltd., Deepwood Mining Co. Ltd., Biwater Pipes Ltd., and Matlock Barytes Co. Ltd. Laporte Minerals is the largest acid-grade producer. Weardale Minerals Ltd. was part of the Minworth Group, which went into receivership in January 1991. It was sold to Sherburn Stone Co. Ltd. of Durham midyear 1991, which planned to continue operations at the Greenclough and Frazers Hush Mines. United Kingdom production was down 30,000 to 40,000 tons compared with that of 1990. (See table 10.)

Current Research

Sandia National Laboratories, Center for Solder Science and Technology, is developing "fluxless" soldering technologies. These technologies will not require the use of rosin-based fluxes, which traditionally have been removed after soldering through the use of CFC cleaning solvents. The research involves soldering technologies that use controlled atmospheres, protective coatings, and thermomechanical surface activation. Research has shown that in controlled atmosphere soldering, hydrogen plasma cleaning of heavily oxidized copper can produce oxide-free, solderable surfaces at temperatures below 250° C. Most electronic components cannot abide temperatures above 250° C. Additional research has been conducted on controlled atmosphere techniques, and the center is also investigating ultrasonic and laser

soldering processes.⁷ This research could result in lost markets for CFC solvents.

OUTLOOK

Consumption of metallurgical-grade fluorspar by the steel industry decreased dramatically in 1991. This was due in part to the overall drop in steel output, but it was mainly a reflection of the continuing change in technology, improvement in efficiencies, and tighter raw material specifications. Closure of open-hearth furnaces, which required significant quantities of fluorspar, reduces a traditional market for fluorspar. Other factors such as the introduction of bottom blown basic oxygen process furnaces, external desulfurization, and continuous casting have also aided the decline in fluorspar consumption. These technologies either do not need fluorspar, need greatly reduced quantities, or discourage its use to minimize refractory damage and downtime. The steel industry has been forced to modernize, increasing the efficiency of each stage of the steelmaking process and dictating tighter raw material specifications. The latter has led to lower impurity levels in the steel, and thus less need for fluorspar.

These factors indicate that U.S. consumption of metallurgical-grade fluorspar will continue to decrease through the 1990's. Major steel-producing countries are undergoing the same changes, and fluorspar consumption is also expected to decline in those countries. The U.S.S.R., China, and the Eastern bloc nations are farther behind on the modernization curve, but it is only a matter of time before modernization begins to lower fluorspar consumption to levels similar to those in Western Europe, North America, and Japan.

The aluminum industry consumes fluorine from different sources and in different forms. Although some acid-grade fluorspar is consumed directly, fluorine is also consumed in the form of aluminum fluoride and synthetic or natural cryolite. Aluminum fluoride is manufactured either directly from acid-grade fluorspar, from HF, or from

fluosilicic acid. A small amount of cryolite is imported for consumption, but most is recovered as a byproduct of waste fluorine recovery or, in the case of a new potline, by tapping an operating pot for molten electrolyte. This material, termed "molten crushed bath," is allowed to solidify and is then crushed for use in the startup of a new potline.

The domestic aluminum industry is expected to show slow steady growth over the next few years, but no expansion of capacity is anticipated. Although consumption of fluorspar by the aluminum industry decreased in 1991, as did imports of cryolite and aluminum fluoride, the consumption of fluorspar and fluorine chemicals by the aluminum industry is expected to remain at current levels or grow slowly.

Consumption of acid-grade fluorspar by the chemical industry for the production of HF is the largest market for fluorspar. The largest use of HF is in the manufacture of fluorocarbons (CFC's, HCFC's, and HFC's); the remainder is used in chemical intermediates, glass and metal processing, petroleum alkylation, stainless steel pickling, uranium chemical production, and other small uses. Consumption by the HF industry remained essentially unchanged in 1991. This was despite the continued decrease in CFC production. The loss in consumption for CFC production could have been taken up, at least in part, by production of HCFC and HFC replacement compounds. Growth in HF consumption for production of replacement HCFC's and HFC's could be slowed by increased recapture, purification, and recycling of CFC's. The EPA was required to publish regulations by July 1, 1992, establishing standards and requirements for the use and disposal of CFC's. These regulations will contain requirements that reduce the use and emission of CFC's and maximize the recapture and recycling of such substances. Although the regulations may contain requirements to use alternative substances, the requirement to recycle cannot help but boost the CFC recycling industry and thus possibly delay the conversion to replacement compounds

and technologies. In the short term, it appears that fluorspar consumption by the fluorocarbon industry will continue at much reduced levels from just a few years ago. Consumption should begin increasing by the mid-1990's, which is when the phase out of CFC production is to be complete and when domestic auto manufacturers will be switching over to the use of replacement compounds in auto air conditioners.

³Table includes data available through May 18, 1992.

⁴In addition to the countries listed, Bulgaria is believed to have produced fluor spar in the past, but production is not officially reported, and available information is inadequate for the formulation of reliable estimates of output levels.

⁵An effort has been made to subdivide production of all countries by grade (acid, ceramic, and metallurgical). Where this information is not available in official reports of the subject country, the data have been entered without qualifying notes.

⁶Reported figure.

⁷Year beginning Mar. 21 of that stated.

⁸Data for 1987 were provided by the Instituto Mexicano de la Fluorita (now disestablished). Data since 1988 are as reported by Consejo de Recursos Minerales.

⁹Principally submetallurgical-grade material.

GALLIUM

By Deborah A. Kramer

Ms. Kramer is a physical scientist with the Branch of Industrial Minerals and has covered gallium for 8 years. Domestic survey data were prepared by Susan Copeland, statistical assistant.

No domestic gallium production was reported in 1991. Imports continued to supply essentially the total U.S. demand. France and the Federal Republic of Germany were the principal import sources, accounting for 81% of the total.

Most of the U.S. gallium demand was for gallium arsenide (GaAs) semiconductors used in optoelectronic devices and integrated circuits. More than 70% of the gallium consumed in 1991 was used in optoelectronic devices—light-emitting diodes, laser diodes, photodetectors, and solar cells. Demand increased somewhat from that of 1990, mostly because of an increase in production of integrated circuits.

World production of gallium was estimated to be about the same as that in 1990, with most of the purified gallium produced in France and the Federal Republic of Germany. The largest gallium recovery plant in the world in Australia remained closed during the year; the operators were purifying gallium from material that was stockpiled earlier.

Gallium demand in the United States is expected to increase slowly as the country emerges from the recent recession. One of the most promising applications of gallium is in GaAs-base visible laser diodes in barcode scanners. If these replace helium-neon lasers in this application, gallium consumption could increase at a faster rate.

DOMESTIC DATA COVERAGE

Gallium data are collected from two voluntary surveys of U.S. operations. In 1991, there were 33 responses to the "Consumption of Gallium" survey, representing 92% of the total canvassed.

Significant quantities of gallium are used by universities and Government research facilities, which are not canvassed by the Bureau's survey. Data in tables 1, 2, and 3 representing gallium consumption were adjusted to reflect full industry coverage. (See table 1.)

ANNUAL REVIEW

Production

No production of primary gallium was reported in 1991. Hecla Mining Co.'s operation in St. George, UT, remained closed throughout the year.

Eagle-Picher Industries Inc. recovered and refined gallium from both domestic and imported sources at its plant in Quapaw, OK. Recapture Metals Inc., Blanding, UT, recovered gallium from scrap materials, predominantly scrap generated during the production of GaAs.

Consumption and Uses

An increase in gallium demand in the United States in 1991 primarily resulted from an increase in GaAs-base integrated circuit production, although optoelectronic devices still represent the largest sector of gallium use.

TriQuint Semiconductor Corp., Beaverton, OR, reportedly purchased GaAs manufacturer Gigabit Logic Inc., Newbury Park, CA, and GaAs-base device manufacturer Gazelle Microcircuits Inc., Santa Clara, CA. TriQuint, also a GaAs manufacturer, closed Gigabit's facility in Newbury Park and continued to operate out of its Oregon facilities.

Spire Corp. received a contract from the National Aeronautics and Space

Administration (NASA) to continue development of high-power, multiple-quantum-well aluminum gallium arsenide (AlGaAs)-GaAs laser diodes. These diodes, which operate in the 780-nanometer spectral range, are used for pumping other lasers that operate at 2.09 micrometers. This 2.09-micrometer emission is used in systems that are capable of detecting wind shear and microbursts near airports. Wind shears and microbursts were cited as the causes for at least one aircraft crash in recent years. Spire is developing low-cost fabrication and packaging methods that will make the diode-laser pumps widely available.

Spire also received a contract from the U.S. Army's Strategic Defense Command to develop low-defect-density GaAs on patterned silicon. This work was expected to permit integration of GaAs and silicon, combining the high-speed and/or optical communications properties of GaAs with very-large-scale integration technology that is available with silicon.

In a review of laser-diode technology, recent advances in various categories of laser diodes were discussed. AlGaAs laser diodes, which operate in the range from 750 to 860 nanometers, are the largest volume manufactured annually and are used primarily in compact-disk players and laser printers. Indium gallium arsenide phosphide (InGaAsP) diodes lase from 1,300 to 1,600 nanometers and are used principally in fiber-optic communications systems, with expected potential in fiber sensors. Indium gallium arsenide (InGaAs) lasers operate from 910 to 990 nanometers and are used in erbium-doped fiber amplifiers. The indium gallium aluminum phosphide (InGaAlP) laser

diode emits at 630 to 680 nanometers and is also known as the visible laser diode. Recently developed, the InGaAlP diode has the potential to replace helium-neon lasers in barcode scanners.¹

Manufacturing methods and development of new devices were highlighted in other reviews of the GaAs-based laser diode industry. Development of manufacturing techniques, such as metal-organic vapor deposition technology and molecular beam epitaxy (MBE), have enabled the development of multiple-quantum-well structures, strained superlattice structures, and surface-emitting laser diodes. These advances in laser diode technology have aided the emergence of visible laser diodes and improvements in InGaAsP lasers used in fiber-optic communications systems.² (See tables 2 and 3.)

Markets and Prices

Quoted prices, as published in American Metal Market, did not change during 1991. Beginning in January 1992, Eagle-Picher's quoted price for 99.99999%-pure gallium was expected to decrease from \$525 per kilogram to \$425 per kilogram. Prices for 99.9999%-pure gallium were scheduled to decrease to \$350 per kilogram. The average value of U.S. imports in 1991 was \$340 per kilogram, a slight increase from that in 1990; this value includes imports of both crude and high-purity gallium. (See table 4.)

Foreign Trade

Export data for gallium were not separately identified by the Bureau of the Census. According to the Journal of Commerce Port Import/Export Reporting Service (PIERS), 530 kilograms of gallium was exported, primarily to France. In addition, 292 kilograms (gross weight) of gallium arsenide scrap was exported to France. This source provides data only on materials that are transported by ship and may not reflect the total quantity of gallium exported.

Beginning in 1991, the Bureau of the Census began reporting data on imports

of GaAs wafers into the United States. In 1991, 2,186 undoped GaAs wafers, with a value of \$2.4 million, were imported. Japan (58%) and the Federal Republic of Germany (36%) were the primary source countries. The United States also imported 62,036 doped GaAs wafers at a value of \$39.1 million. Again, Japan (76%) and the Federal Republic of Germany (13%) were the main sources. (See table 5.)

World Review

Virgin gallium production was estimated to be about 40,000 kilograms in 1991. Although gallium demand did increase slightly in the United States, increased gallium recycling in Japan satisfied a significant portion of the country's demand. China has become a significant supplier of crude gallium in the past year, particularly to the Japanese market, but France and the Federal Republic of Germany remained the largest world suppliers of purified gallium. Rhône-Poulenc S.A.'s gallium recovery plant in Australia remained closed throughout the year, and the company continued to supply purified gallium from material stockpiled at the plant during its operation in 1989 and 1990. (See table 6.)

Germany, Federal Republic of.—In April, Wacker Chemitronic GmbH announced that the company planned to stop production of GaAs wafers and concentrate on silicon wafer technology. Wacker cited limited European demand and Japanese dumping as reasons for discontinuing production of GaAs wafers. The company was the Federal Republic of Germany's only commercial producer of GaAs wafers.

Japan.—Gallium imports into Japan were estimated at almost 30,000 kilograms, compared with 1990 imports of 20,314 kilograms. These imports supplied more than 40% of Japan's total gallium demand in 1991, estimated to be 70,000 kilograms, which includes recycled gallium scrap. The large

increase in imports from 1990-91 reflected an increase in imports of crude gallium, particularly from China. Japan's gallium demand was estimated to be concentrated in GaAs large-scale integrated circuits and optical devices, such as light-emitting diodes.³

Dowa Mining Co. Ltd., who developed gallium-base waxes for skis in 1990, planned to introduce new skis bonded with a sheet of gallium ethylene in early 1992. The sheet is formed by sintering a mixture of gallium powder and ethylene, and Dowa claimed that skis equipped with the sheet will be antistatic and would enable skiers to slide on any kind of snow. Alpine skis, marketed under the ULLR Racing name, will retail for about \$1,000, and cross-country skis will cost about \$554.

U.S.S.R.—Primary gallium production capacity was estimated to be 30,000 kilograms from four plants. In 1990, production was estimated at 16,000 kilograms. Demand in the U.S.S.R. was estimated to be 3,000 to 5,000 kilograms for defense applications and 2,000 to 3,000 kilograms for other applications. The U.S.S.R. reported that its product is from 99.99% to 99.99999% pure, but consumers in Japan rate the material at 99.99% purity. Because of the radical changes in the U.S.S.R., some of the gallium is appearing on the world market. Japan reportedly imported 1,300 kilograms in 1991, a significant increase from the 50 kilograms reported in 1990.⁴

Current Research

Scientists at Georgia Tech developed a small-scale process that could make the manufacturing of low-cost integrated optoelectronic circuits possible. The scientists grew GaAs devices on a GaAs substrate, peeled them off the substrate, then transferred them to a transparent polyimide sheet, which is used to align the GaAs devices on a silicon substrate. The peeling technique was originally developed at American Telegraph & Telephone Co.'s (AT&T) Bell Communications Research Center, but the Georgia Tech team modified the process

to address manufacturing and cost issues. Combining GaAs components and silicon components on a single integrated circuit allows the use of some GaAs properties that silicon does not have, such as light emission, while minimizing the cost. Integrated optoelectronics are important in the next generation of consumer electronics, such as videophones and high-definition television.

IBM Corp.'s European research laboratory developed a method to mass-produce and test as many as 20,000 semiconductor lasers on 1 GaAs wafer. IBM expects this new method of laser fabrication, which it calls full-wafer technology, to be faster, about 50% less expensive, and result in a higher percentage of working lasers per wafer. In the new technology, IBM used a process to etch small trenches in 2-inch-diameter wafers of laser material. Then it covered the trenches with a reflective material to turn them into mirrors. After testing the entire wafer, it was cut into 20,000 individual lasers. Current laser making methods form mirrors by breaking the wafer into tiny pieces first; the broken edges act as mirrors. Each device must then be tested one at a time. Semiconductor lasers are used in devices such as compact-disk players and laser printers.⁵

Toshiba Corp. demonstrated a visible laser diode made from indium gallium aluminum arsenide (InGaAlAs) that has the shortest wavelength of any diode currently available—650 nanometers. The company claimed that the InGaAlAs diode would produce light that is four times as bright as other commercially available laser diodes. Applications for the new laser diode include barcode scanners, which use primarily helium-neon lasers that emit light at 670 nanometers.

Using new metal-organic vapor deposition technology, Sanyo Corp. produced a bright red InGaAlP laser diode that operates at 635 nanometers for read-only applications. The emitting wavelength was shortened, and the brightness increased by misorienting the GaAs substrate. The shorter operating wavelength resulted in a smaller beam

contact, which should enable higher density in encoding optical disks. According to Sanyo, the density of write-to-disk data is 50% greater than currently available. This would allow 90 minutes of programming on a compact disk that normally contains 60 minutes and would increase the dot-per-inch output of laser printers from 300 to 370.⁶

Nissin Electric Co. Ltd. reportedly developed an MBE device that makes compound semiconductors using gaseous raw materials rather than the solid raw material used by conventional MBE systems.

In conventional MBE operations, solid raw materials must be supplied by opening doors in the equipment and requires batch operating processes. In Nissin's gaseous system, the material is drawn through a pipe, allowing for continuous operation. Nissin planned to sell the new equipment for slightly less than \$1 million.

Two separate studies on gallium demonstrated that gallium was a potential candidate in some superconducting materials. Researchers at Northwestern University formed a new family of superconducting compounds containing copper, gallium, and oxygen. The new material, which becomes superconducting at 73° K, is the first to conduct electricity along the planes formed by copper and oxygen atoms when they are separated by nonconducting chains of atoms. The use of copper and gallium reportedly forms a unique spacing structure between the copper-oxygen planes, which gives the superconductor better thermal and mechanical stability.

A team of scientists from Lawrence Berkeley Laboratory and the University of Warsaw in Poland demonstrated that GaAs that contains a little extra arsenic can conduct electricity with little or no resistance at 10° K. By adding additional quantities of arsenic during low-temperature growth of GaAs by MBE, scientists were able to create "islands" of pure arsenic in the compound. Earlier, scientists at the Massachusetts Institute of Technology had demonstrated that GaAs could be made insulating with the incorporation of additional arsenic. Although superconductivity research is in

its early stages, in the future, scientists hope to manipulate GaAs so that parts of the material are superconducting, parts are semiconducting, and parts are insulating.

Scientists were still pushing the limits of silicon technology, potentially allowing silicon to compete in areas that were thought to be better suited for GaAs. Two separate organizations reportedly developed methods to make silicon emit light—one of the properties that separates GaAs semiconductors from silicon semiconductors. Researchers at AT&T's Bell Laboratories duplicated efforts by British scientists in producing silicon that emits red light when green light from a laser is shone on it. The British researchers created what they called porous silicon, which was created by using acid to etch small holes in the silicon. This process created thin wirelike structures that have optical properties different from those of normal silicon. Although this represents an advance in silicon technology, it is still in the early stages of development. Porous silicon may be unstable in air, and scientists must find ways to use electrons rather than lasers to induce silicon to emit light before the material can be considered a serious candidate for light-emitting applications.⁷

At the University of Electro-Communications in Japan, professors reportedly generated orange light using grains of silicon. In an experiment, silicon powder with a diameter of about 1 micrometer was placed on a silicon substrate and heated to 2,000° C in an argon-oxygen atmosphere until silicon grains about 1 Angstrom formed, oxidized, and attached themselves to the substrate. Green laser light was focused on these grains, and orange light was created through photoluminescence.

Hitachi Manufacturing Co. Ltd. announced the development of a prototype silicon transistor that has the high speed of a GaAs transistor and operates at lower temperatures than conventional silicon transistors. Two of GaAs's advantages over silicon are its faster speed and ability to operate over a wider temperature range. The new

silicon device, if commercially feasible, could lessen the impact of GaAs components in some markets.

OUTLOOK

Nearly all the gallium consumed in the United States is used in manufacturing GaAs-base optoelectronic devices and integrated circuits. Much of the work in producing new devices and improving manufacturing techniques is funded, either directly or indirectly, by the U.S. Department of Defense. As Defense budgets undergo continued scrutiny and cuts in funding are made, it is possible that some of the GaAs integrated circuit research and development activities are scaled back or terminated. With slower advancements in technology, GaAs integrated circuits will be slow to enter the commercial market. At the same time, private industry and universities are funding some research and development activities on GaAs. If these efforts can offset some of the anticipated defense cutbacks, GaAs consumption for integrated circuits in the United States should grow, although slowly.

Advances in silicon technology may limit the penetration of GaAs into some applications, primarily because of the cost of GaAs components compared to the cost of silicon components. But GaAs optoelectronic components are competing with materials other than silicon. In particular, GaAs visible laser diodes are competing with helium-neon lasers in barcode scanning applications. To aid in getting a share of this market, GaAs manufacturing firms are developing new manufacturing technologies that improve performance characteristics while lowering the cost of GaAs visible laser diodes. This application for GaAs components has a significant potential for growth. Overall, it is likely that U.S. gallium consumption will grow slowly in the next few years.

World supply patterns for gallium may change in the next few years. With the breakup of the U.S.S.R. into independent States and the downplaying of the country's defense industry, it is likely that some of the gallium produced

in the independent States will be available on the world market. Even in 1991, Japan was seeing greater availability of Soviet gallium, although the material is not high purity. China and the independent States may provide a significant share of gallium demand in Japan at the expense of France and the Federal Republic of Germany. It is unlikely that Soviet material will have an immediate impact on the U.S. supply because of the high tariff rate on gallium; the U.S.S.R. still has non-most-favored-nation status. This may change if the independent States are granted most-favored-nation status.

GEMSTONES

By Gordon T. Austin

Mr. Austin, a physical scientist with more than 30 years industry and Government experience, has been the gemstones commodity specialist since 1986. Mr. William Field, statistical assistant, prepared the domestic production survey data.

Webster's defines a gem "as any jewel, whether stone, pearl or the like, having value and beauty that are intrinsic and not derived from its setting; a precious or, sometimes, a semiprecious stone cut and polished for ornament. A stone of value because it is carved or engraved, as a cameo or intaglio." Additionally, the dictionary states that gemstone or gem material is a stone or material from which a gem may be cut. In less formal or common terms a gem, gemstone, or gem material may be described as specimens of minerals or organic materials used for personal adornment, display, or to manufacture objects of art because they possess beauty, rarity, and durability.

In 1991, the value of natural gemstones from deposit in the United States was \$84.4 million, an increase of 60% compared with that of 1990. Production of gemstones included faceting rough, lapidary rough, carving material, specimen material, natural and cultured freshwater pearls, mother of pearl, fossil ivory, amber, agatized coral, and coral.

Synthetic gemstones are grown in the laboratory but have essentially the same appearance, and optical, physical, and chemical properties as the natural material that they represent. Synthetic gemstones produced in the United States include alexandrite, coral, diamond, emerald, garnet, lapis lazuli, quartz, ruby, sapphire, spinel, and turquoise. Simulants are laboratory grown gem materials that have an appearance similar to that of a natural gem material but have different optical, physical, and chemical properties. The gemstone simulants produced in the United States include coral, cubic zirconia, lapis lazuli,

malachite, and turquoise. Additionally, certain colors of synthetic sapphire and spinel, used to represent other gemstones, would be classed as simulants. Colored and colorless varieties of cubic zirconia are the major simulants produced. In 1991, the reported combined production value of U.S. synthetic and simulant materials was \$17.9 million, about a 17% decrease from that of 1990.

Wholesale and retail outlets, gem and mineral shops, gem and mineral shows dealers, cutting factories, and jewelry manufacturers were the major purchasers of domestic gem materials.

DOMESTIC DATA COVERAGE

The U.S. Bureau of Mines estimates U.S. production from the "Natural and Synthetic Gem Material Survey," a voluntary survey of U.S. operations, and from Bureau estimates of unreported production. Of the approximately 400 operations surveyed, 82% responded, accounting for about 95% of the total production, 92% of the natural production, and 100% of the synthetic and simulant production.

The number of operations surveyed in 1991 was essentially the same as the number surveyed in 1990. The response rate was essentially the same also. The Bureau estimated the production by nonresponding operations, by professional collectors, and by amateur or hobbyist collectors. The basis for these estimates were information from published data, conversations with gem and mineral dealers, analyses of gem and mineral shows and sales statistics, and from information informally supplied by collectors. In the formal voluntary

survey and the informal surveys, the Bureau is totally dependent upon the cooperation of the producers, brokers, dealers, and collectors. Individuals and companies have been very cooperative and forthcoming with information. The Bureau is very appreciative of this cooperation.

BACKGROUND

The history of production and preparation of gemstones begins with the wearing of items for personal adornment in prehistoric times; this preceded even the wearing of clothes. Amber was mined in the Baltic countries for use as a gem material before 25,000 B.C. Later, the Phoenicians in their writings described their trade routes to the Baltic for amber and to areas in Asia and Africa for other gemstones. The voyages of Columbus brought increased interest in gemstone deposits, especially emerald, in South America. The discovery of diamond in Africa in 1859 focused major interest on Africa. More recently, the discovery of diamond in Western Australia in 1967 resulted in the development of the largest known diamond deposit in the world.

Commercial mining of gemstones has never been extensive in the United States. Although more than 60 different gem materials have been produced commercially from domestic sources, most of the deposits are relatively small. In many instances, production rests in the hands of the numerous hobbyists and members of mineralogical and lapidary clubs. The Crater of Diamonds State Park near Murfreesboro, AR, is open to the public on a daily fee basis, as are

many other gemstone deposits throughout the United States. Many gem-quality stones are found at these locations each year.

Definitions, Grades, and Specifications

Select rocks, certain varieties of mineral specimens, and some organic materials, such as pearl, amber, jet, and coral, are included in gemstones data. Customarily, diamond, ruby, sapphire, and emerald are considered the major gems.

The most important qualities of gemstones are beauty, durability, uniqueness, and rarity. Beauty, indicated as splendor, purity, or attractiveness, is judged mainly according to the taste of the beholder, and includes such appearances as luster, transparency, brilliance, and color. Luster of a mineral or stone is independent of color and is the surface appearance in reflected light. Apart from materials that have a metallic luster, the chief contributors to luster are transparency and refractive index. In cut gems, the perfection of the polish enhances the luster. Visible imperfections impair the luster of transparent stones. However, defects, described as "jardens" or "inclusions," may enhance the beauty and value of natural rubies, sapphires, and other gemstones. In some cases these inclusions may be used to identify the country and even the mine from which the stone was recovered. Durability is measured by the resistance of a stone to abrasion, pitting, chipping, or splitting. Resistance to abrasion is correlated with relative hardness, but intrinsic brittleness and toughness indicate resistance to wear in other aspects. Rarity is an essential qualification and is more important for some stones in determining their value than their physical characteristics.

Of the approximate 2,700 mineral species, only about 100 possess all of the attributes required of a gem. It must be noted that collectors of gems may not require that a gem be durable because the stone is destined for display and is not to be worn. Therefore, the number of

species of gemstones may be greater than the 100 that meet all of the requirements. Silicates furnish the greatest number, including such minerals as beryl, topaz, tourmaline, and feldspar. Oxides such as corundum (ruby and sapphire) and quartz (amethyst, agate, etc.) comprise the second largest group. Sulfides, carbonates, and sulfates are of small importance; the phosphates yield only turquoise and variscite. An exception is pearl, essentially calcium carbonate, which is ranked high as a gem. Diamond, the best known gem, is an isometric crystalline form of the element carbon.

In general, gemstones are classified the same as minerals; that is, into group, species, and variety. Group refers to two or more gem materials that are similar in crystal structure and physical properties but have different chemical properties. Each individual member of the group is called a species. Varieties of species have similar crystal structure and chemical characteristics but differ in color. An example of this would be the hessonite variety of the grossular species of the garnet group.

Products for Trade and Industry

Cutting and polishing of gems from gemstones are done to obtain the most effective display of the material. No significant change is made in the fundamental properties, and the preparation is intended to enhance the desirable characteristics that are present initially. Gemstones are cut into gems in three main styles: cabochons, baroque, and faceted.

Cabochons are cut in four operations: sawing, grinding, sanding, and polishing. Sawing, the initial step in cutting, is customarily done with a diamond saw to obtain a slab or slice of the desired size and thickness from the rough gemstone. The cabochon outline is scribed onto a flat surface, most often using a template for making a standard size for jewelry mountings. Rough grinding of the stone may be by metal-bond diamond, electroplated diamond, silicon carbide, or aluminum oxide wheels or coated

abrasive disks. In grinding, the hardness of the gemstone determines the grit and hardness of the abrasive used. Multiple grinding steps starting with 80- to 100-mesh (grit) through 600-mesh abrasives are normally used. The scratches left by grinding are removed by progressively finer grinding and sanding. Disk or belt sanders use bonded to cloth abrasives, waterproof reinforced paper abrasives, or cloth charged with abrasive pastes. The final polish is obtained by using hard felt, wood, or leather laps, with various polishing agents such as fine diamond compound, tin oxide, tripoli, chromium oxide, cerium oxide, alumina, or rouge.

Polished irregular shapes are called baroque gems. An inexpensive method of polishing baroque gems is to tumble them in rubber-lined drums, using a grinding and polishing medium with or without water.
