Facet cutting usually is employed on transparent gemstones to increase brilliancy and appearance. It generally is confined to the harder materials. Softer materials may be faceted, but extreme care must be exercised in cutting and polishing the stones and in their use in jewelry. Often the softer gems are used only for display and not for making jewelry. The "round brilliant" cut, most commonly used in faceting, has 58 facets, 33 above the circle "girdle" and 25 below it, arranged in eightfold symmetry. The "round brilliant" and some other common cuts are illustrated in figure 1.

Industry Structure

The world market for rough diamonds is controlled to a degree by De Beers Centenary AG's marketing arm, the Central Sales Organization (CSO). It is by far the most controlled of the world's commodity markets. An estimated 80% to 85% of gem and natural industrial diamond is marketed by the CSO. The marketing is done through the CSO by the Diamond Trading Co. Ltd. and the Industrial Distributors Ltd. The CSO sells uncut gem diamonds on behalf of De Beers and most other major producers at sights (approved bidder viewings) in London, England, and Lucerne,

Switzerland. There are 10 such sights each year.

Diamonds reach the CSO sights through three channels. De Beers owned and operated mines, contracts sales by mine owner and operators, and open-market competitive sales. The distribution of rough diamonds in the Republic of South Africa is determined by the South Africa Diamond Board. All categories of rough diamonds that can be processed economically in South Africa must first be offered to local manufacturers. Rough can be exported duty free only if it has first been offered to the local market, otherwise a 15% duty is charged. Different systems of offering rough on the local market apply to the different mine producers, but they must offer the rough to local manufacturers in a manner determined by the board.

The CSO has been extremely successful at maintaining the rough diamond market for about 50 years. In modern times there has never been a decrease in CSO's price of rough diamonds. Table 1 illustrates the timing and the amounts of the average CSO price increases for rough gem diamonds from 1949 until the present, while table 2 indicates the value of CSO's annual sales for the past 10 years. The compounded effect over 43 years of these increases is a price increase of about 1,800%. Thus, a piece of rough that sold for \$100 in August 1949 would sell for about \$1,800 in April 1991. (See tables 1 and 2.)

For more than 30 years, the major diamond cutting and polishing centers of the world were in Belgium and Israel, with a certain amount of the larger stones being cut in the United States. However, in the early 1980's, the development of a large cottage industry in India—today there is estimated to be more than 500,000 cutters—made a major impact on world diamond trade. India consumes most of the world's small-gem, cheap-gem, and near-gem rough material in the manufacture of small stones, which resulted in annual cut-stone exports worth billions of dollars. These small stones averaged less than one-fifth of a carat (0.20 carat). The availability of small inexpensive stones resulted in substantial

changes in the design of jewelry. The utilization of small cut diamond stones (usually 0.07 to 0.14 carats each, called *melee*) to create a *pavé* effect (set close together to conceal the metal base) is but one example. Cutting and polishing of colored, synthetic, and simulant gemstones is centered in Thailand, India, Hong Kong, Korea, China, and Brazil, where cheap labor and favorable export laws ensure the lowest total costs for finished gems. It is estimated that the U.S.S.R.'s diamond cutting industry employs about 16,000 workers. The eight *Krystall* factories at Moscow, Smolensk, Kiev, Barnaul, Vinnitsa, Yerevan, Kusa, and Gomel employ fewer than 8,000, with the Moscow plant having about 900 workers. The workers at the various factories may be paid by different methods.

The workers at the Moscow plant are paid by the piece according to its size and difficulty of the cut. At Kiev, those workers whose work is not subject to inspection receive a 50% higher salary. Some of the *Krystall* factories have an incentive program for workers producing stones of 0.3 carats and larger. The incentive is a bonus of 5% of the added value that is paid to each 20-worker team that is shared by the team.

Annual cut diamond production is a function of the number of workers in the industry and their productivity. If it is assumed that the industry has a production rate of 20 carats of finished goods per month per worker and that polished yields are less than 40%, then the industry's consumption of rough and yield of finished goods can be estimated. It is estimated that during a year, the U.S.S.R.'s diamond cutting industry processes about 3.8 million carats of rough that yields about 1.6 million carats of polished goods. The polished goods would be worth between \$500 million and \$550 million on the world market.

During 1991, Leo and Schachter & Co. opened the United States' newest, largest, and most modern diamond polishing factory in New York. The factory is fully computerized to track every diamond from rough to finished stone. The computer predicts the cash return

from each piece of rough based on estimates of the rough's color, clarity, yield, and make, estimates are reported to be within 2% of actuals. The factory employs 40 polishers.

Geology-Resources

Gemstones are found in a large variety of igneous, metamorphic, and sedimentary rocks and mineral deposits, usually as a small fraction of the total deposit. The origins are as varied as the deposits. Gemstones form primarily by precipitation from watery solutions, by crystallization from molten rock, and by metamorphic processes. Approximately one-third of gemstones is composed of silicate minerals, about one-fifth of alumina-silicates, and almost one-seventh of oxides. The remaining compositional groups include the sulfides, phosphates, borosilicates, carbonates, and, in the single case of diamond, an element. The composition of selected gem materials is included as one of the items in table 3. (See table 3.)

There are no large resources of major gem materials defined in the United States. Emerald deposits are known in North Carolina, as are ruby and sapphire. Historically, sapphires have been mined in Montana, and significant commercial mining once again is underway. Numerous other domestic deposits of gemstones are known and have been mined for many years. However, no systematic evaluations of the magnitude of these deposits have been made, and no positive statements can be made about their reserve or the size of the resource.

Occasional finds of diamond have been made, but no great diamond pipes or alluvial deposits similar to those of Africa have been reported. Several companies are involved in diamond exploration in the Colorado-Wyoming State line area, in Michigan, Minnesota, Wisconsin, and Arkansas. Diamond-bearing kimberlites have been located and bulk samples have been processed for diamond recovery. Results have not been made public.

World resources of gemstones are nearly all unevaluated. However, world gem diamond reserve is estimated to be

about 300 million carats, including near-gem and cheap-gem qualities. Nearly all of the reserves are in Australia, Africa, and the U.S.S.R. (Siberia). The estimates for diamond reserves are of limited value because data needed for reliable estimates are not available from the producers. Reserve data on other gemstones are even less available than for diamond.

Technology

Synthetic Gems.—Synthetic gemstone production uses many different methods, but they can be grouped into one of three types of processes: melt growth, solution growth, or extremely high-temperature, high-pressure growth.

The year 1902 saw the first production of synthetic ruby using the Verneuil flame-fusion process. Later, sapphire, spinel, rutile, and strontium titanate were grown with this technique. In this process, a single crystal, called a boule, forms in the flame of a simple, downward-impinging oxygen-hydrogen blowtorch. Pure oxides of aluminum (in the cases of ruby, sapphire, and spinel) or titanium (rutile and strontium titanate) are poured into the top of a small furnace and melted. Other oxides are added as needed for process control and to obtain the specific color desired. The melted material solidifies as a boule on a rotating fire-clay peg as the peg is slowly withdrawn.

A boule has a very characteristic shape, with a rounded end; a long, cylindrical body; and a tapering end. It is usually about 13 to 25 millimeters in diameter, 50 to 100 millimeters long, and weighs 75 to 250 carats (a carat is 200 milligrams). Under controlled conditions, boules about 5 millimeters in diameter and more than 890 millimeters long can be produced for the manufacturing of jewel bearings.

Another melt technique is the Bridgman-Stockbargé solidification method, named for an American, P. W. Bridgman, and a German, D. C. Stockbargé, who, aided by three Russians, J. Obreimov, G. Tammann, and L. Shubnikov, discovered and

perfected the process between 1924 and 1936. Currently, the method is used primarily for growing nongem halide, sulfide, and various metallic oxide crystals, one of the metallic oxides being aluminum oxide or sapphire.

The Bridgman-Stockbargé process uses a specially shaped crucible, which is a cylindrical tube open at one end and capped at the other by a small, pointed cone. The crucible is filled with the powdered chemicals necessary to grow a specific crystal and is lowered slowly through a furnace. The small, pointed end of the cone cools first because it is the first part of the crucible that moves from the hottest part of the furnace into cooler regions and it is the first part to emerge from the furnace. As the crucible cools, the molten materials solidify, hopefully in the structure of a single crystal, in the point of the crucible. The crystal then acts as a seed around which the remainder of the molten material solidifies until the entire melt has frozen, filling the container with a single crystal.

This process is simple, and crystals of various sizes can be grown. The crystals are typically about 51 millimeters in diameter and 15 millimeters in length, but large ones exceeding 890 millimeters in diameter and weighing more than 1 metric ton have been grown. The crystals have the same shape as the crucible.

The Czochralski pulled-growth method is used for ruby, sapphire, spinel, yttrium-aluminum-garnet (YAG), gadolinium-gallium-garnet (GGG), and alexandrite. Czochralski developed his method about 1917 while working with crystals of metallic nutrients.

In the Czochralski method, ingredient powders—nutrients—are melted in a platinum, iridium, graphite, or ceramic crucible. A seed crystal is attached to one end of a rotating rod, then the rod is lowered into the crucible until the seed just touches the melt. Then the rod is slowly withdrawn. The crystal grows as the seed pulls materials from the melt, and the material cools and solidifies. Yet, because of surface tension of the melt, the growing crystal stays in contact with the molten material and continues to

grow until the melt is depleted of the desired material.

Typically, the seed is pulled from the melt at a rate of 1 to 100 millimeters per hour. Crystals grown using this method can be very large, more than 51 millimeters in diameter and 1 meter in length, and of very high purity. Each year this method grows millions of carats of crystals for use as gems, laser rods, windows for special scientific or technical applications, and for other industrial applications.

Certain gemstones pose unique problems with regard to attempts to grow them. The problems arise because certain materials are either so reactive that they cannot be melted even in unreactive platinum and iridium crucibles or they melt at much higher temperatures than the crucible materials can endure. Therefore, another melting system must be used, called the skull melting system. Cubic zirconia, because of its high melting point (2,700° C), must be grown using the skull melting method.

The "skull" is a hollow-walled copper cup. Water is circulated through the hollow walls to cool the inside wall of the skull. The cup is filled with powdered ingredients and heated by radio frequency induction until the powders melt. Because the water cools the walls of the skull, the powdered materials next to the walls do not melt, and the molten material is contained within a shell of unmelted material. Therefore, the reactive or high-temperature melt is contained within itself. When the heat source is removed and the system is allowed to cool, crystals form by nucleation and grow until the entire melt solidifies. Crystals grown using this system vary in size, depending on the number of nucleations. In growing cubic zirconia, a single skull yields about 1 kilogram of material per cycle.

Solution techniques for making synthetic gems include flux methods for emerald, ruby, sapphire, spinel, YAG, GGG, and alexandrite. The other solution method is the hydrothermal method, often used for growing beryl (emerald, aquamarine, and morganite) and quartz.

Quartz crystals are grown in a hydrothermal solution in large pressure vessels known as autoclaves. Careful control of temperature and pressure in the different areas of the autoclave result in the feed material, known as lascas, dissolving in the hotter portion. The material redeposits on seed crystals, located in the cooler portion, forming synthetic quartz crystals. The process usually takes 30 to 60 days for the crystals to reach the desired size. The process can also produce rock crystal, amethyst, or citrine.

The same system is used to grow beryl crystals. Beryl seed crystals are suspended in the cooler upper portion of an autoclave. Nutrient materials dissolve in the hotter, lower portion of the autoclave and, because of the temperature and pressure gradients, migrate to the cooler seeds and are deposited. Other techniques involve solid- or liquid-state reactions and phase transformations for jade and lapis lazuli; vapor phase deposition for ruby and sapphire; ceramics for turquoise, lapis lazuli, and coral; and others for opal, glass, and plastics.

The Verneuil, Czochralski, and scull melting processes are the melt techniques most often used for gem materials. The various synthetics and the method of production are shown in table 4. (See table 4.)

Enhancement of Gemstones.—Enhancement of all types of gemstones through chemical and physical means has become much more commonplace and in the past few years has included a wider variety of materials. Irradiation by electromagnetic spectrum (X-rays, gamma rays, etc.) and by energetic particles (neutrons, electrons, alphas, etc.) is being used to enhance or change the color of diamonds, topaz, tourmaline, quartz, beryl, sapphire, zircon, scapolite, and pearls. Blue topaz is normally irradiated, but this does not imply that all of these gem materials are regularly irradiated.¹

Many gemstones can be enhanced by chemical treatment or impregnations. The treatments may alter the bulk of the

gem material or only penetrate the surface. This includes bleaching, oiling, waxing, plastic impregnations, color impregnations, and dyeing. The treatments that alter only the surface of the material include surface coatings of various types, interference filters, foil backings, surface decoration, and inscribing. Chemical treatment is more widespread than just the common dyeing of quartz, treatment of turquoise, and oiling of emeralds. Chemical treatment and impregnations have been used to enhance amber, beryl, chalcedony, coral, diamonds, emerald, ivory, jade, lapis lazuli, opal, pearl, quartz, ruby, sapphire, tiger's eye, and turquoise.²

Since about 1987, fractures, cleavages, and other void-type imperfections that reach the surface in diamonds have been filled using a process developed by Mr. Zvi Yehuda, of Ramat Gan, Israel. This treatment can enhance that apparent clarity of treated faceted diamonds; examples are available that show SI stones enhanced to VS and I1 improved to SI2. Recently, it was announced that Yehuda also had developed a similar treatment for emeralds.

The oldest and most common method of gemstone enhancement is heat treating. Heat treatment of gem materials was used in Greece and Rome well before the Christian Era. Heat treatment can cause color change, structural change, and improve clarity. In the past, heat treatment was common for quartz and gem corundum. Today, materials that are heat treated to enhance their appearance include amber, beryl, diamond, quartz, ruby, sapphire, topaz, tourmaline, zircon, and zoisite.³

Recently, an additional type of treatment for sapphire has appeared—diffusion treatment, a chemical-heat treatment. In this process a thin layer of color is diffused into the surface of the gem. The color may be diffused as little as 0.1 millimeter or as much as 0.4 millimeter into the gem. The treatment is a long process of heat treatment in a bath of chemicals containing the proper proportions of titanium and iron. The American Gem Trade Association (AGTA) adopted a policy for the

disclosure of diffusion treated sapphires. The policy is "If the color of a gemstone is confined to an area near the surface so that the color of the stone would be visibly affected by recutting or repolishing then the following statement must also appear: Although the color induced in the diffusion treated sapphire is permanent, it remains confined to a shallow surface layer." Therefore, recutting or repolishing is not recommended.⁴

Mining.—Gemstone mining operations can range from the most primitive to the most sophisticated. In hard rock, at shallow depths, an operation by one, two, or three persons may be mined by prybar, pick, shovel, and buckets or baskets for carrying material; often drilling and blasting is employed. A larger operation includes drilling, blasting, and minimum timbering. Mechanized hauling and hoisting is done only at the larger mines.

Diamond mining in the kimberlite pipes of Africa and the U.S.S.R. and the lamproite pipes of Australia represent the ultimate in that huge quantities of ore must be mined to extract small quantities of diamond (20 to 30 carats per 100 tons of ore) produced at as low a cost as possible.

Placer mining for gemstones ranges from small-scale, simple procedures to huge, complicated operations. In some areas, digging is by hand, and sorting and recovery is by panning, screening, or sluicing. Diamond miners in the larger placer operations use bucket dredges and heavy-duty excavating equipment, as, for example, in Australia, Brazil, Namibia, the Republic of South Africa, and the U.S.S.R.

Processing.—Most gemstones are broken or crushed where necessary and concentrated by various combinations of hand picking, washing, screening, or jigging. In large-scale operations, mineral beneficiation methods are mechanized and employ the latest technology in each step from primary crushing and screening to the final recovery processes. Diamond recovery,

in particular, makes use of standard gravity methods, grease belts, electrostatic separation, skin-flotation, magnetic separation, separation by X-ray luminescence, and separation by optical sorting.

ANNUAL REVIEW

Production

In 1991, all 50 States produced at least \$1,000 worth of gem materials. Ten States accounted for 95% of the total value of production of natural gemstones. The States, in order of declining value of production, were Tennessee, California, Missouri, South Dakota, Arizona, Montana, Oregon, Texas, Arkansas, and Nevada. Certain States were known best for the production of a single gem material (i.e., Tennessee for freshwater pearls and Arkansas for quartz). Other States produced a variety of gemstones. Arizona produced the greatest variety. Production included agate, amethyst, antlerite, azurite, chrysocolla, fire agate, garnets, jade, malachite, obsidian, onyx, peridot, petrified wood, precious opal, shattuchite, smithsonite, and turquoise. California, Idaho, Montana, and North Carolina also produced a variety of gemstones. Historically, North Carolina is the only State to have produced all four of the major gems: diamond, emerald, ruby, and sapphire.

The average production value of natural gem materials for the past 10 years was \$28.4 million per year, with a high of \$84.4 million in 1991 and a low of \$7.2 million in 1982. The value of production for the past 10 years must be separated into two trends. The first trend was the period between 1981 through 1985, during which time approximately 24 operations reported production. Production averaged \$7.4 million per year and was generally level. In the second trend, 1986 to the present, production averaged \$424 million and was the result of an increase of 1,567% in the number of producers surveyed. The reported value of synthetic and simulant gemstone production was \$17.7 million in 1990. The reported value of

production decreased 17%. The average value of production of these gem materials for the past 6 years was \$16.5 million, with a high of \$20.5 million in 1990 and a low of \$10.3 million in 1986. Fifteen firms, five in California; four in Arizona; and one each in Massachusetts, Michigan, New Jersey, North Carolina, Ohio, and Washington, produce synthetic and simulant gem material. The eight States, in order of declining value of production, were Massachusetts, California, New Jersey, Michigan, Washington, North Carolina, Arizona, and Ohio.

Arizona is well known for the widest variety of gemstones produced by any State. In 1991, they included agate, amethyst, antlerite, azurite, chrysocolla, fire agate, fluorite, garnet, jade, jasper, malachite, obsidian (Apache tears), onyx, peridot, petrified wood, precious opal, shattuchite, smithsonite, and turquoise. Yet, turquoise, peridot, petrified wood, and azurite-malachite accounted for more than 90% of the total value of gem material produced. Production from Arizona of these gemstones was the largest in terms of dollar value in the United States and the world's largest for the first two. Additionally, four manufacturers of synthetic or simulant gem materials were in Arizona and produced about \$100,000 worth of material.

Arkansas is famous for the production of quartz crystals. Yet, Arkansas is second in value of production of freshwater pearls and shells and the only State in the United States that has had any sustained diamond production.

Since 1972 hobbyists have found from 300 to 1,500 diamonds per year at the Crater of Diamonds State Park. From 1906 to the present, it is estimated that production from the deposit is 100,000 to 150,000 carats; this amount of diamond production is insufficient to classify the United States as a diamond-producing country. Still, the potential to become a diamond producer may be there, and efforts were underway to evaluate this potential more fully. The program to evaluate the diamond deposit was halted by legal actions after completing three

exploratory drill holes. Although a Federal appellate court has cleared the way for the program to continue, the program is currently on hold.

Gemstone production from California includes a variety of materials. Tourmaline production from the State is the largest in the Nation, and California has the only producer of benitoite. Additionally, agate, alabaster, beryl, dumortierite, fire agate, freshwater mussel shell and pearls, garnet, gem feldspar, jade, jasper, kunzite, lepidolite, obsidian, quartz, rhodonite, topaz, and turquoise are produced from deposits in the State. Yet, even with this long list of gemstones, most people think of California in terms of its State gem benitoite, its high-quality tourmalines, and its fine orange spessartine garnets.

In May 1989, Pala International reported the discovery of the largest gem tourmaline pocket found in the Himalaya Mine during the past 13 years. The pocket yielded about 500 kilograms of tourmaline; 50% was carving or cabochon grade, less than 1% was faceting grade, and the remainder was specimen grade. The Himalaya continues to produce substantial quantities of fine-quality tourmaline.

As unusual as it may sound, the State also has a freshwater culture pearl farm at Marysville. The farm uses animals imported from Tennessee and other southeastern States. Productions includes pearls, shell, and finished nucleus for cultured pearl implants.

California also has four manufacturers of synthetic or simulant gemstones. The value of production from the State is the second largest for synthetics and simulants.

Colorado is not known as a gemstone-producing State, but it does hold some gemstone honors. For 4 or 5 years prior to 1988, Colorado had the only commercially operated amethyst mine in the United States. It has the only commercially mined deposit of lapis lazuli in the United States and one of the few fee-for-dig topaz deposits currently operating. Additionally, the State was the first to commercially produce turquoise and still has commercially operated

turquoise mines. The State also produced the United State's finest gem-quality rhodochrosite and a quantity of high-quality rhodonite.

Many different locations in the State produce aquamarine, the Colorado State gemstone. The best known locations and the locations with the longest history of continued production (since about 1884) are Mount Antero and White Mountain in Chaffee County. Mount Antero, at 4,349 meters, may be the highest gemstone location in the United States. White Mountain, separated from Antero by a small saddle, is only slightly lower at 4,237 meters.

Star garnet, the Idaho State gemstone, leads the list of gemstones produced in the State. Idaho is one of two places that produce significant amounts of star garnet; India is the other. These almandite garnets are translucent, purplish-red stones that show four- or six-ray stars when cabochon cut or are transparent deep red stones that can be faceted. The primary sources of Idaho star garnet are the placer deposits on the East Fork of Emerald Creek and its tributary gulches in Benewah County. Additionally, the placers of Purdue Creek in Latah County yield star garnets. Currently, garnets that do not cut stars also are commercially mined from areas in Clearwater County. These garnets range from purplish rose-red to a highly prized "special pink." Gem-quality garnets are found at several other locations in Idaho and are mined periodically by hobbyists or professional collectors for the gemstone market.

Opal is the second largest contributor to the total value of gemstone production in Idaho. The varieties produced include precious, yellow, blue, pink, and common. The Spencer opal mine is the largest producer. At the Spencer Mine, precious opal occurs as one or more thin layers within common opal that have partially filled gas cavities within a rhyolite-obsidian flow. About 10% of the material is thick enough to cut into solid gems; the remainder is suitable for making doublets and triplets. The Spencer Mine is also the source of the pink opal, which occurs as either pink

common opal or pink bodied precious opal.

In recent years, an increasing amount of gem material (smokey quartz, aquamarine, topaz, and garnets) was recovered from the Sawtooth batholith. A significant portion of the batholith lays within the Sawtooth National Recreation Area, administered by the Forest Service, U.S. Department of Agriculture. Herein lies a problem. The Forest Service prohibits the collection of gem and mineral specimens from the National Recreation Area under CFR Title 36, 269.9b, which prohibits the removal of "natural features of the land." Additionally, all mining is prohibited in a recreation area. It appears that material is still being collected from the area, but this may stop in the future.

In the U.S. gemstone industry, Maine and tourmaline are almost synonymous. In 1822, Maine's Mount Mica was the site of the first gemstone production in the United States. In 1991, Plumbago Mining Corp. was actively mining the Mount Mica pegmatite for gem material and mineral specimens. Over the years, production from Mount Mica has included hundreds of kilograms of fine-quality gem and mineral specimen tourmaline.

Mount Mica is not the only large producer of high-quality tourmalines. Dunton Mine of Newry Hill is the most prolific gem tourmaline producer in Maine. Since its discovery in 1898, the mine has produced tons of gem- and specimen-grade tourmaline. Other mines and quarries in a three county area produce gem- and mineral specimen-grade tourmalines. These include the Bennett, BB #7, Emmons, Harvard, Tomminen, Waisenen, Black Mountain and Red Hill Quarries, and Nevel Mine in Oxford County. It also includes the Mount Apatite Quarries in Androscoggin County and the Fisher and Porcupine Hill Quarries in Sagadahoc County.

Production from Maine deposits also includes fine-quality beryls—aquamarine, heliodor, and morganite. Pegmatites in Oxford, Androscoggin, and Sagadahoc Counties regularly produce fine-quality blue and blue-green aquamarine, rich

yellow- and gold-colored heliodor, and rose- and peach-colored morganite. In 1989, the largest rose colored morganite on record was found at the Bennett Quarry near Buckfield in Oxford County.

In 1989, Plumbago Mining Corp. opened the most significant commercial amethyst mine in the United States near the town of Sweden in Oxford County. Reported production in the first year of operation was about 2,300 kilograms of gem-quality and specimen-grade amethyst. The gem material has good deep purple color, but is mostly small pieces. An officer of the company did report the cutting of a 12-carat stone from the material and that some material recovered would yield stones as large as 20 carats. The mine did not produce during 1991.

Montana produces many different gemstones, some suited for faceting, while others are better suited for the cutting of cabochons, carvings, or objects-of-art. Montana is noted for the production of sapphires, Montana moss agate, and Dryhead agates. Yet, amethyst, amazonite, azurite, covellite, cuprite, garnet, onyx, opal, petrified wood, rhodochrosite, rhodonite, smokey quartz, sphalerite, and wonderstone (banded rhyolite) are also produced or have been produced from deposit in the State for use as gemstones.

Sapphires have been produced from Montana deposits since 1865. In recent years, Montana sapphire has gained in popularity, and because of the improved popularity, production has increased significantly. Currently, commercial sapphire production is from deposits on the Missouri River in Lewis and Clark County, the Rock Creek area in Granite County, and from the Yogo Gulch area in Judith Basin County. Additionally, there are fee-for-dig sapphire operations on the Missouri River and Rock Creek.

Until 1989, the value of Nevada's gemstone production was essentially dependent upon the production of turquoise and opal, and the production of turquoise was, and still is, declining. In 1989, Nevada reported the first major production of nephrite jade.

The Nevada jade is from a deposit near Tonopah. The material varies in color from different shades of green to black and some is mottled with off-white to tan markings. The reported quality is from fine gem to carving-grade. Mine run jade is available from fist-size pieces to individual boulders that weigh more than 1 ton. The jade is very similar to good to fine Wyoming jade.

Nevada has been a major producer of turquoise since the 1930's, and until the early 1980's, the State was the largest turquoise producer in the United States. Estimates indicate that over the years, 75 to 100 different mines and/or prospects have produced sizable quantities of turquoise. Production varied from a few thousand dollars worth of material at some properties to more than \$1 million at others. Estimates of total production to date are between \$40 to \$50 million.

Precious opal production from deposits in the Virgin Valley area began in about 1906. The opal from Virgin Valley is comparable to any in the world for its vivid play of color and is unsurpassed in terms of the size of material available. The material varies in color from deep pure black to brown to yellowish-white to white to colorless. The play of color includes all the colors common to precious opal—red, blue, green, yellow, orange, and so on. The opal is found primarily as replacement of wood, or sometimes, the replacement of cones of conifer trees. The use of the opal is greatly restricted because of a severe problem with crazing. Currently, two mines in Virgin Valley are open to individuals on a fee-for-dig basis during the summer months. The operators of these mines also mine the deposits for their own inventories.

North Carolina is the only State in the United States where all four major gem materials, diamond, ruby, sapphire and emerald, have been found. During 1988 was the last time all four major gemstones were found in the same year. The diamond was found in a gold placer mine, rubies and sapphires were recovered from the Cowee Valley, and emeralds were found near Hiddenite and Little Switzerland.

Production of ruby and sapphire from deposits along the Cowee Valley in Macon County began in 1895 when the American Prospecting and Mining Co. systematically mined and washed the gravels of Cowee Creek. Today ruby, sapphire, and fee-for-dig operations are in the Cowee Valley. Many people pay to dig or purchase buckets of gravel to wash to recover gem corundum, garnets, and other gemstones.

Every year there is publicity concerning the discovery of large and valuable rubies and sapphires at one or more of the mines in Cowee Valley. No doubt large corundum crystals and pieces of corundum are found each year. Similarly, valuable rubies and sapphires may be found, but the number of large and valuable gems and the values of these gems often are overstated. During the period when commercial mines operated in the area, gemstones were found that would cut fine-quality 3- to 4-carat stones. Today, the amount of quality gem material has greatly declined. Most of the rubies found are not of top color or clarity and on average are suitable for cutting stones of 1 carat or less. The sapphires tend to be larger than the rubies and high-quality sapphires are more abundant than high-quality rubies.

In 1875, emeralds were discovered near what is now Hiddenite, with the first attempts at commercial mining of emeralds in the Hiddenite area in 1881. Other attempts were made in the 1920's, the 1950's, the 1970's, and the latest attempt ended in 1990. At different times the emerald deposits in the Hiddenite area have produced large emerald crystals, and some significant stones have been cut from Hiddenite material. Yet, to date, it has not been possible to maintain an economically viable mine operation on any of the deposits. This includes the last attempt that would have mass mined the deposit and used a beryllometer to sort the emerald from the waste rock. The beryllometer worked well, but the amount of emerald present did not support the project.

Historically, Oregon has been known for the production of various picture and scenic jaspers, agates, thunderegg,

petrified wood, and to a certain degree, gem labradorite. Oregon's State rock, the "thunderegg," may be the best known gem material from Oregon. Graveyard Point, Priday, and Polka Dot are names that are uniquely associated with beautiful Oregon agates. The same is true for the relationships between the names Biggs, Deschutes, and Sucker Creek and picture or scenic jasper. Yet, gem labradorite (sunstone) is currently the largest single contributor to the value of annual gemstone production in Oregon. At least seven firms or individuals currently are producing sunstone from three different geographic areas.

The other gemstone to contribute significantly to the value of production from Oregon is opal. During 1988, the first significant commercial mining and marketing of a variety of very fine quality opals from Opal Butte began. The varieties include hyalite, rainbow, contra luz, hydrophane, crystal, fire, blue, and dendritic. Exquisite stones as large as 315 carats have been cut from contra luz rough from this deposit.

Tennessee has the largest U.S. production of freshwater mussel shells and pearls of the 11 producing States. The fishing and marketing of freshwater mussel shells and pearls are not new in the United States or in Tennessee. There has been an established U.S. freshwater mussel fishing industry since the mid-1850's. The mussels are from the family Unioidea, of which about 20 different species are commercially harvested. During 1991 the value of U.S. mussel shell exports was more than \$63 million.

To date, freshwater pearls from the United States have been a byproduct of the shell industry. Currently, the primary use of the shells is to make the bead nucleus used by the Japanese cultured pearl industry. Additionally, the shells are used in making cameos and as mother-of-pearl. With the coming of the freshwater cultured pearl farms in Tennessee and the increasing popularity of freshwater pearl jewelry with the U.S. consumer, this may change. In 1963, the first experimental U.S. freshwater cultured pearl farm was established. Since the technology for culturing

freshwater pearls was proven in the late 1970's, six freshwater pearl farms have been established. These farms are the beginning of the U.S. freshwater cultured pearl industry, and the cultured pearl is the heart and future of the U.S. pearl industry.

The gemstone that Utah is best known for, topaz, is not well suited for use as a gem, but it does make a fine mineral specimen. Topaz crystals have been collected from certain rhyolite flows in the Thomas Mountains for more than 100 years. Similar crystals also are found in select rhyolites in the Wah Wah Mountains. The crystals from the Thomas Mountains are predominately small, 10 to 20 millimeters long and 4 to 6 millimeters across, and crystals from the Wah Wah Mountains are even smaller. Occasionally, large gem-quality crystals are found. The color of the topaz varies from colorless to light yellow, sherry brown, rose or light pink. Unfortunately, the light yellow to sherry brown color fades to colorless if exposed to sunlight or heat and rose- or light pink-colored crystals are rare. Because of the size of the crystals and problem with color fading, the material yields only small to very small colorless stones.

Another Utah gemstone with nearly a 100-year production history is variscite, first produced in about 1893 near Fairfield. The latest recorded commercial production was from near Lucin during the summer of 1991. Variscite is found as fracture fillings or as nodules. The nodules may be solid, almost geode in nature, or fractured solid nodules that have undergone alteration. The color of the variscite varies from deposit to deposit and from location to location within the same deposit. It is a shade of light to dark yellow-green, but can be a dark, nearly jade green and so pale as to appear almost white. It also can have black and brown spiderwebbing.

Another material from Utah is snowflake obsidian. Snowflake obsidian (also known as flower obsidian) earns its name from the bluish-white or grayish-white patterns of cristobalite included into the normally black obsidian. During

1991, two different firms produced this material commercially.

Topaz, variscite, and obsidian from Utah are well known and are nice materials. But, in the author's opinion, the red beryl from the Wah Wah Mountains is the most remarkable and desirable of Utah's gemstones. Bixbite, the variety name for red beryl (called red emerald by some) is found in rhyolites at several locations in the Thomas and Wah Wah Ranges. The beryl varies in color from a pink to bright red, with the bright red being what could be called strong raspberry-red. The material from most of the locations is not as spectacular, either in crystal size or color, as the crystals from the Violet claims in the Wah Wah's.

The Violet claims in the Wah Wah's are the only known location for commercial production of red beryl. In recent years, the claims have furnished a small but steady supply of materials for both mineral specimens and a few fine-quality gems. The crystals average about 10 millimeters in length, and most are flawed. Because of the size of the crystals and flaws, finished stones only average about 0.40 carat with few more than 1 carat. The largest finished stone to date is only 4.46 carats. The material is expensive, but justifiably so, because of its beauty and rarity.

Certain other States produce a single gem material of note, they are: Alaska with its two jade mines; Florida's agatized coral; Hawaii's black coral; Minnesota's thomsonite; New York's herkimer quartz; Ohio's flint; and South Dakota's rose quartz.

The value of 1991 production by individual gemstone can be reported for those materials that have three or more producers and if one of the three does not account for more than 75% of the total or two of the producers account for 95% or more of the production. (See table 5.)

Consumption and Uses

Consumption of domestic gemstones was in the commercial and amateur manufacture of jewelry, for exhibit in gem and mineral collections, and for

decorative purposes in statuettes, vases, other art objects, and certain industrial applications.

Frequently, tourmaline is used as a standard for calibrating piezoelectric manometers and testing devices. It is also a control substance in boron experiments because it is itself an inert boron-containing compound. Tourmaline is the standard used in tests to check possible effects of water-soluble boron in fertilizers.

Many scientific and industrial instruments use tourmaline. One such use is tourmaline tongs, a simple laboratory instrument that shows the polarization of light. Because tourmaline is both pyroelectric and piezoelectric, meaning it generates electricity when heated or compressed, it is a component of instruments for measuring high pressures and fluid compressibility. Thermal dosimeters, which were early instruments that measured the intensity of radium emanations, depended upon tourmaline's pyroelectric properties.

Once the mark of a top-rated watch or timepiece was that it was Swissmade and had 18 or 21 ruby or sapphire jewel bearings. Originally, these jewel bearings were made from natural ruby and sapphire. Later, the availability of inexpensive synthetic gemstones allowed the natural materials to be replaced in the manufacture of jewel bearings.

Why are ruby and sapphire used as bearings? Because ruby and sapphire, color variations of the mineral corundum, are second only to diamond in hardness; they have no cleavage (cleavage being the tendency for a crystallized mineral to break in certain definite directions, indicates a minimum value of cohesion in the direction easy fracture) and thus they are very durable; they have a very low coefficient of friction when highly polished; they are chemically inert; and they can be cut and polished without great difficulty.

Watches were not the only instruments in which sapphire and ruby bearings were used. Most precision gauges in aircraft and boats depend upon jewel bearings, as do many gauges, meters, and other instruments in manufacturing and

chemical plants. The military is still highly dependent on jewel bearings for many of its high-tech weapons systems. Recently, another use for one type of jewel bearing appeared—as connectors for optical fibers.

In recent years, technological advances allowed the growth of large, high-quality synthetic ruby crystals, called laser ruby, for the manufacture of laser rods. Several other synthetic gemstones also are being produced for lasers, including chromium-doped chrysoberyl (dope being a element added to the crystal growing nutrients to achieve a particular color), synthetic alexandrite, and varieties of doped yttrium-aluminum-garnet (YAG).

Lasers require high-purity, optically perfect crystals. The crystal must be large enough so that a laser rod can be cut from the raw crystal, and the mineral or material must have the correct physical properties to allow light amplification without the necessity of excessive energy. Synthetic ruby, sapphire, and YAG have all these characteristics.

Over the years, both natural and synthetic corundum have been ground and graded as an abrasive. Corundum was the major compound used in the polishing of eyeglass lenses. While industrial diamond has replaced much of the corundum used in the lens-polishing industry, some polishers still use corundum for specialized lenses.

Other gem materials have enjoyed limited uses in nongem applications. The abrasive and ceramic industries use topaz as a raw material because of its hardness and chemical features. Once, lenses for eyeglasses were made from gem-quality beryl—if the morganite variety of beryl were used, one would truly be looking at the world through rose-colored glasses. Mortar and pestle sets, knife edges for balances, textile rollers, and spatulas are some nongem uses of agate.

Some industrial applications requiring clean homogeneous stones used low-quality gem diamond. The quantity of natural and synthetic industrial-grade diamonds used in the United States each year is 12 to 15 times greater than the amount of diamonds consumed by the jewelry industry.

The 1991 estimated value of U.S. apparent consumption was \$3,059 million, down about 18% for 1989's record high. The average annual estimated consumption for the past 10 years was \$2,871 million, with a high of \$3,711 in 1989 and a low of \$1,642 in 1982. The trend for estimated consumption for the past 10 years was one of continued growth, with about 68% total increase.

In 1991, the value of U.S. estimated apparent consumption of diamonds was essentially unchanged from that of 1990 at \$2.6 billion. The average annual value of apparent consumption of diamonds for the past 10 years was \$2,419 million, with a high of \$3,115 million in 1989 and a low of \$1,279 million in 1982. The trend for the value of apparent consumption for the past 10 years was one of significant increase. The value of apparent consumption of diamonds increased 100% over the period.

The 1990 estimated apparent consumption of colored stones, led by emerald, ruby, and sapphire, was valued at \$397.1 million, a decrease of 3%. The annual average value of consumption of colored stones for the past 9 years was \$325.0 million, with a high of \$406.9 million in 1989 and a low of \$252.4 million in 1982. The trend for apparent consumption of colored stones for the past 9 years was one of fluctuating increases and decreases, but the general trend was one of increased consumption.

The estimated apparent consumption of pearls—natural, cultured, and imitations—was \$19.5 million, an increase of about 18% from the 10-year low in 1990. The average annual consumption for the past 10 years was \$163.0 million, with a high of \$244.7 million in 1984 and a low of \$16.5 million in 1990.

Estimated apparent consumption of synthetic and imitation gemstones decreased about 78% to \$20.9 million. Average apparent consumption of these materials for the past 10 years was \$51.8 million per year, with a high of \$109.1 million in 1987 and a low of \$13.9 million in 1982. The trend for apparent

consumption for the past 10 years was one of generally strong growth except for the significant decrease in 1989 and 1991. Annual apparent consumption at the end of the period was 50% greater than at the beginning of the period. The U.S. Department of Commerce reported that jewelry store retail sales were \$13.8 billion, a 3.6% decrease compared with those of 1990.

Prices

Demand, beauty, durability, rarity, freedom from defects, and perfection of cutting determine the value of a gem. In establishing the price of gem diamond, the CSO's control over output and prices also is a major factor.

The average U.S. wholesale asking price of the top 25 grades (D through H color and IF through VS2 clarity) of a 1-carat diamond fluctuated between \$7,200 and \$7,300, and was \$7,300 at yearend. The average value per carat of all grades, sizes, and types of gem-quality diamond imports was \$517, a slight decrease compared with that of 1990. The average value of diamond imports for the past 10 years was \$405 per carat, with a high of \$525 in 1990 and a low of \$353 in 1984. The trend for the average annual value of diamonds imported for the past 10 years was one of general decline from the 10-year high in 1980 to stable prices in 1986, 1987, and 1988, followed by the 1989 and 1990 increases.

The average yearend wholesale purchase price of a fine-quality 1-carat ruby, paid by retail jewelers on a per stone or memo basis, was \$4,200, an increase of 20% from that of 1989. The average value of ruby imports decreased 39% to \$29.80 per carat. The average annual value of ruby imports for the past 10 years was \$37.12 per carat, with a high of \$48.71 in 1990 and a low of \$16.42 in 1984. The trend for the value of ruby imports for the past 10 years was one of rapid decline, 52% for the period from 1982 to 1984. This was followed by a steady, moderate increase until the 1991 decrease.

The average yearend wholesale purchase price of a fine-quality 1-carat

sapphire, paid by retail jewelers on a per stone or memo basis, was \$1,600, a 14% increase from that of 1989. The average value of sapphire imports increased 8% to \$23.31 per carat. The average annual value of sapphire imports for the past 10 years was \$23.23 per carat, with a high of \$27.97 in 1987 and a low of \$18.50 in 1984. The trend for the value of sapphire imports for the past 10 years was one of fluctuating increases and decreases. The 10-year period ended with the 1991 value 5% below the 1982 value.

The average yearend wholesale purchase price of a fine-quality 1-carat emerald, paid by retail jewelers on a per stone or memo basis, was \$2,750, the same as for 1989. The average value of emerald imports decreased 4% to \$42.01 per carat. The average annual value of emerald imports for the past 10 years was \$55.65 per carat, with a high of \$78.79 in 1988 and a low of \$35.06 in 1984. The trend for the value of emerald imports for the past 10 years was one of fluctuating increases and decreases from 1982 through 1984. A steady moderate growth followed until the 3 years of decline in 1989, 1990, and 1991. The average value in 1990 being about 76% of the 1981 value. (See tables 6 and 7.)

Foreign Trade

The value of exported exports plus reexports increased 9% to \$1,712 million, a record high. The quantity of cut diamonds exported and reexported increased slightly to 1,008,154 carats, and the value of diamond exported and reexported decreased slightly to \$1,351.2 million. The average annual quantity of cut diamonds exported and reexported for the past 10 years was 577,581 carats, with a high of 1,008,154 in 1991 and a low of 184,871 in 1982. The trend for the quantity of cut diamonds exported and reexported for the past 10 years was one of significant growth, 445%, from 1982 to 1991. The average annual value of cut diamonds exported and reexported for the past 10 years was \$734.6 million, with a high of \$1,398.8 in 1990 and a low of \$292.8 million in 1982. The trend for

the value for the past 10 years was one of fluctuating increase and decline over 3 years, followed by 6 years of growth, 32%, and then 1 year of slight decline. The period ended with value of exports and reexports 361% greater than at the start of the period.

The value of other precious stones, cut but unset and other than diamonds and pearls, exported and reexported increased to \$71.9 million. The 10-year trend for value of exports plus reexports of these types of gemstones was one of fluctuating increases and decreases, but one resulting in a significant overall total increase for the period. The value of exports and reexports of other precious stones not cut or set was \$113.6 million. An additional \$22.1 million worth of other gemstones was exported or reexported during 1991.

The value of synthetic gemstone exports plus reexports was \$21.9 million. The 10-year trend for the value of exports plus reexports was one of extreme decline during the period between 1982 to 1988, followed by significant growth, 608%, during 1989-90, and then a significant decline in 1991.

The value of natural, cultured, and imitation pearls, not set or strung, exports and reexports of pearls increased significantly to more than \$4.2 million.

The value of gems and gemstones imported increased slightly to \$4,640.6 million compared with those of 1990, but still below the 1989 record high of \$5,115 million. The value of imported gem diamonds accounted for about 86% of the total. The average annual value of gems and gemstones imports for the past 10 years was \$4,027 million, with a high of \$5,115 million in 1989 and a low of \$2,384 million in 1982.

The value of imported gem diamonds increased slightly to \$3992.0 million compared with that of 1990, but below the 1989 record high of \$4,358 million. The 10-year trend for the value of diamond imports was one of generally steady continuous growth until the decline in 1990 and the small growth in 1991 that resulted in current value still being less than that of 1988. Even with the downward adjustment, total increase for the period was 108%. During the period

the value of imported uncut diamonds increased 91%, while the value of cut stones imported increased 111%.

The imports of cut diamonds increased 6% in quantity and 2% in value to 6.7 million carats and \$3,464.6 million, respectively. The average annual quantity of cut diamonds imported was 6.9 million carats, with a high of 8.9 million in 1989 and a low of 1.6 million carats in 1982. The trend for the quantity of cut diamond imports for the past 10 years was one of continued increases until the 1990 decline; the period still ended with imports 79% greater than at the beginning of the period. The average annual value of cut diamond imports was \$2,929.2 million, with a high of \$3,805.5 in 1989 and a low of \$1,641.0 million in 1982. The trend for the value of cut diamond imports for the past 10 years was of strong growth and increases. The value at the end of the period was 111% greater than at the beginning.

The value of imports of other gem and gemstones, led by emerald, ruby, and sapphire, was \$531.1 million, a decrease of about 5% compared with that of 1990. Emerald imports increased slightly to \$165.5 million. The average annual value of emerald imports for the past 10 years was \$155.3 million, with a high of \$207.5 million in 1989 and a low of \$120.8 million in 1982. The 10-year trend for the value of emerald imports was one of fluctuating increases and decreases resulting in a 37% increase for the period.

The value of ruby imports decreased 28% to \$70.9 million from 1990's record-high value for the past 10 years of \$98.4 million. The average annual value of imports for the past 10 years was \$74.9 million, with a high of \$98.4 in 1990 and a low of \$58.7 in 1987. The 10-year trend for import values was one of extreme fluctuations. The period ended with values having increased 21% from the 10-year low for the period.

The value of sapphire imports was \$81.6, essentially unchanged from that of 1990. The average annual value of sapphire imports for the past 10 years was \$81.7 million, with a high of \$100.0

million in 1989 and a low of \$63.3 million in 1982. The 10-year trend for the value of imports was one of extremely fluctuating increases and decreases. The period ended with the value 29% greater than that at the beginning of the period.

The value of imported gem materials other than diamond, emerald, ruby, and sapphire increased slightly to \$213.1 million. The average annual value of imports was \$332.5 million, with a high of \$429.5 in 1988 and a low of \$210.3 in 1990. The 10-year trend for the value of imports was one of fluctuating increases and decreases resulting in the period ending essentially at the same level that the period started. (See tables 8, 9, 10, 11, and 12.)

World Review

Diamond sales by De Beers Centenary AG was \$3.93 billion in 1991, a decrease of 6% compared with 1990 sales of \$4.17 billion. Sales during the second half of 1991 were only \$1.84 billion, 11% less than the \$2.08 billion sales for the second half of 1990. A De Beers official stated that the reduction in sales was the result of the Persian Gulf war and the economic turndown in the United States. De Beers controls about 80% of the rough, uncut diamonds sold in the world. Sales of colored stones remained strong.

In May, De Beers unveiled the 273-carat Centenary diamond, reportedly the largest top-colored, flawless diamond outside of the British Crown Jewels. The Centenary was cut from a 599-carat piece of rough recovered at the Premier Mine in the Republic of South Africa in 1986. Three years were spent in preparing, cutting, and polishing the modified heart-shaped stone. The Centenary is insured for more than \$100 million.

Natural diamond production occurs in Africa, Asia, Australia, and South America. The principal producing localities are as follows: in Africa—Angola, Botswana, Namibia, the Republic of South Africa, and Zaire; in Asia—U.S.S.R. (northeastern Siberia and in the Yakut A.S.S.R.); in Australia;

and in South America—Venezuela and Brazil. (See table 13.)

Foreign countries in which major gemstone deposits (other than diamond) occur are Afghanistan (beryl, kunzite, ruby, tourmaline); Australia (beryl, opal, sapphire); Brazil (agate, amethyst, beryl, kunzite, ruby, sapphire, tourmaline, topaz); Burma (beryl, jade, ruby, sapphire, topaz); Colombia (beryl, sapphire); Kenya (beryl, garnet, sapphire); Madagascar (beryl, rose quartz, sapphire, tourmaline); Mexico (agate, opal, topaz); Sri Lanka (beryl, ruby, sapphire, topaz); Tanzania (tanzanite, garnet, ruby, sapphire, tourmaline); and Zambia (amethyst, beryl).

Angola.—The Government of Angola's diamonds company, Endiama, entered into a prospecting agreement with a Portuguese-Zairian consortium. The consortium is Sociedade Portuguesa de Investimentos and SAICAN; both firms are privately held. It is reported that the Zairian firm may have links with President Mobutu Sese Seko of Zaire. The prospecting rights are along the Cuango River near the Angola-Zaire border, the same area included in the April diamond sales agreement between Angola and De Beers Centenary.⁵

Australia.—Stirling Resources NL has entered into a joint venture with Sabminco NL on Stirling's Boab Creek exploration license in West Kimberleys of Western Australia. Stirling has identified what is interpreted to be a potential kimberlite pipe and buried alluvial channel. The license is adjacent to Sabminco's Diamond Mountain project area where Sabminco has recovered gem-quality diamonds from drill holes in a buried alluvial channel.

Brazil.—The Director of the Brazilian Gem and Precious Metal Institute announced that he expected that exports of cut gems and uncut gemstones would be about \$200 million for 1991. This would be an increase of 18% compared with 1990's \$170 million worth of

exports. He is hopeful that exports will increase to as much as \$500 million within 2 years. One reason for the increase in exports is that the domestic market is weak; in 1980 domestic purchases of gemstones was \$800 million, in 1990 they were \$360 million, and only \$300 million in 1991.

Canada.—Uranerz Exploration, operator of its joint venture with Cameco, announced the recovery of additional diamonds from drill samples from the Fort a la Corne property. The latest stones recovered averaged 0.04 carat with the largest at 0.6 carat. Some on the stones recovered were of gem quality.

Uranerz's exploration program has identified 70 potential kimberlite pipes in a corridor that is 50 kilometers by 20 kilometers from Price Albert to Nipawin in Saskatchewan. The first 15 sites tested proved to be kimberlites, and to date a total of 160 diamonds have been recovered from drill cores. Uranerz is playing down the exploration results, but experts are speculating on the possibility of a diamond mine in Saskatchewan by the end of the decade. Normally, geologists search for indicator minerals, minerals that form under the same conditions as diamonds, but at the Fort a la Corne property they found the actual diamonds in the drill samples.

Dia Met Minerals Ltd. announced the results of the analysis of one drill hole on the Dia Met and BHP-Utah Mines Point Lake prospect, a 800-square-kilometer joint venture in the Northwest Territories. Analysis of a 59-kilogram sample of core taken from between 140 and 180 meters yielded 81 diamonds each less than 2 millimeters in diameter. The drill hole was in a kimberlite pipe that is estimated to have a surface area of between 162,000 and 324,000 square meters and to have a depth of 1 kilometer. The Point Lake prospect is about 480 kilometers north of Yellowknife, the capital of Northwest Territories. The announcement has set off a rush to stake claims around the Point Lake prospect.

China.—A 60.5-carat diamond was unearthed from the Wafangdian Mine in

Dalian city in northeast Liaoning Province. Since the Wafangdian Mine went into production in 1990 many diamonds more than 10 carats have been found.⁶

Argyle Diamonds has opened a diamond cutting and polishing factory in China. The factory is a joint project between the Australian International Development Assistance Bureau and the China Pearl, Diamond, Gem, and Jewelry Import and Export Corp.

The factory, about 30 kilometers from the center of Beijing, is one of the most modern and best equipped training factories in the world. It is planned for the factory to train about 900 cutters by the end of 1992. The factory began training with five Australian trained Chinese cutters and nine skilled international trainers recruited by Argyle.⁷

Cook Islands.—In June, about two-thirds of the 39,000 black pearls offered in the first full auction by Cook Islands Pearls Ltd. was sold. A total of 54 lots, with a reserve price of \$2.7 million, was expected to bring more than \$4.5 million. The highest successful bid for a single lot was \$114,000 by Kikuchi Pearl Co. Ltd. of Japan.⁸

Ghana.—The Government of Ghana, Lazare Kaplan of the United States, and Inco Ltd. of Canada have entered into an agreement to mine and market Ghanaian diamonds. This is the first privatization of the diamond industry under the current Government. The agreement was 2 years in the making.

The agreement calls for a two-phased mining plan, the first of which will take 7 to 11 years to complete. The mine will be brought to a production level of about 0.5 million carats per year. The second phase will bring the mine to a production level of about 1 million carats per year. Currently, the mine production is between 0.1 and 0.2 million carats per year.

Murtob Mining Co. Ltd. of Akwatia purchased a diamond concentrating plant from Somerville Engineering Associates

of England. The plant is trommel and jig-grease tables style.

Guinea.—Bridge Oil Inc.'s Aredor Mine recovered another 100-plus carat stone. Since 1986 the Aredor Mine has produced more than five stones more than 100 carats. The latest stone was 192.9 carats and estimated to be worth more than \$2.0 million. The other large stones were; 100 carats sold in 1986 for \$1.56 million, 143 carats sold in 1987 for \$3.65 million, 181.77 carats sold in 1988 for \$8.62 million, and a 255.6 carat sold for more than \$10 million in 1989. The largest stone on record for the Aredor Mine was a nongem-quality 460-carat stone.⁹

India.—Total rough diamond imports for 1991 increased 57% in volume to 59,990,000 carats compared with those of 1990, while the value decreased 0.5% to \$1,990 million. The net polished diamond exports for 1991 totaled 8,817,000 carats valued at \$2,564 million, an increase of 0.2% and a decrease of 5%, respectively, compared with those of the previous year. This reflected the demand for cheaper goods for most of the year.

Ashton Mining, an Australian company, negotiated an agreement with the Indian National Mineral Development Corp. to assist in the modernization of the Panna Mine. The mine produced about 20,000 carats of diamonds in 1991, and the modernization is intended to increase production by increasing the amount of ore processed.

Indonesia.—Indonesian Diamond Corp. was delayed in the construction of its diamond plant in South East Kalimantan. The plant was ready for production in December 1991. The pilot plant, capable of running about 30 cubic meters per hour, processed material from the mine until the commercial plant was completed. The delay and cost overruns resulted in the plant costing about \$1.1 million more than the original estimate of \$2 million. The first diamonds from the commercial operation, 2,200 carats, were

sold for an average price of \$191 per carat. It is planned to operate both plants in the coming year to process about 54,000 cubic meters of ore per month and recover about 5,400 carats of diamonds each month.

Israel.—Israel has established a joint venture involving the U.S.S.R. and Panama to polish and market emeralds from the Ural area of the U.S.S.R. The joint venture will operate under the name Emural and have exclusive right on the U.S.S.R. emeralds for the next 50 years.

Two Israeli companies, Hargem and Izumrud, will supply the company with training as well as the polishing equipment and technology. Two factories were opened in the U.S.S.R. with about 200 workers and 4 Israeli experts. The joint venture is expected to eventually supply about 20% of the world emeralds.

The 1991 exports of polished diamonds from Israel were valued at \$2,472 million, an 11% decrease compared with those of 1990. During the year, 630 diamond cutting factories employed more than 9,500 workers.

Namibia.—Consolidated Diamond Mines (CDM) began production at the open pit Elizabeth Bay Mine in June. It is planned that the mine will produce about 4 million tons of ore per year that will result in the recovery of about 250,000 carats of diamonds. The production from the Elizabeth Bay Mine will increase CDM's annual production to about 1 million carats per year. During the expected 10-year life of the mine, the mine should produce about 2.5 million carats of diamonds.

Monarch Minerals and Mining, Inc., a U.S. firm, announced production began at its new diamond mine in southeastern Namibia in July. The mine is located on Monarch's 50-square-kilometer mining concession at the mouth of the Fish River.

Tahiti.—Sales of black pearls at the 14th International Pearls Sale in Papeete, Tahiti, were 48,771 pearls for \$4.97 million. These sales represented an

increase of 19% in the number of pearls sold, but the total value of sales decreased 17% and the average price per pearl decreased 30% compared with those of 1990. The pearls ranged in size from 8.5 to 18 millimeters in diameter and were of much better quality than in recent years. There were 40 overseas buyers at the auction representing companies from 6 different countries.

Tanzania.—Late in the year the Government of Tanzania urgently invited tenders from competent companies for mineral rights at the Merelani tanzanite area, Arusha region. The tender areas are nine 200-meter by 300-meter blocks. The applicants must be experienced gemstone miners, processors, and marketers. Additionally, they must indicate the prospecting methods they intend to use, the availability of equipment, the method of drilling, a detailed work program, security arrangement for the mine, and the financial commitment to the program. The successful applicants will be required to post a \$25,000 bond.

U.S.S.R.—Reports on Radio Moscow indicate the discovery of a major diamond field in Buryatskaya on the Soviet side of the Mongolian border. It is reported that more than 10 diamond-bearing sites in the eastern part of the Sayany Mountains were found. The discovery comes after 50 years of small-scale prospecting in the region, during which small quantities of diamonds were found.

The world's biggest new source of diamonds in this century may be the five kimberlite diamond pipes near the village of Pomorie at Lamonsov in the North Russian oblast of Archangelsk. Development plans for the pipes are for two shafts to a depth of about 1,000 meters, one on each side of the pipe. The cost to develop the five pipes, including the infrastructure and power station, is estimated to be \$4 billion. Funds of the project will have to come from foreign sources or joint ventures.

Tokyo Maruichi Shoji Co. (Maruichi) of Japan entered into a joint venture with the Yakut Autonomous Soviet Socialist

Republic for Maruichi to produce an unspecified amount of diamonds from the Republic for export to Japan. According to the agreement, approximately 10% of the diamonds will be cut and polished prior to export. This appears to be one step in the Yakut authorities taking control of the Republic's diamond production from the central U.S.S.R. Government.

Zimbabwe.—Auridium Consolidated NL of Australia has acquired the exploration license for the Ranch River diamond project that was forfeited by De Beers early in 1991. Kimberlitic Searches Ltd., a De Beers subsidiary, evaluated the project in the early 1980's and found the diamond project was uneconomical at that time. Auridium and its partner, Cornerstone Investments, Ltd., believe that given the current diamond market the project may be economical during the 1990's. Evaluations will be undertaken to determine if the deposit is economical at this time.

Delta Gold NL of Australia has applied for exploration rights in eight diamond-bearing areas totaling about 4,600 square kilometers. The company already has completed a great deal of fieldwork in the selected areas.

Current Research

An oval jade cabochon in a ring offered to Sotheby's Hong Kong Ltd. from its 1990 jadeite jewelry auction was found to have been treated with a new procedure to improve its appearance. Testing by the Hong Kong Gems Laboratory discovered a coating that is a highly adhesive, colorless organic resin mixed with a chemical compound that makes it resistant to high temperatures. The Gemological Association of All Japan found an oval jade cabochon that had exceptionally good color, luster, and transparency that was poor-quality, white jadeite treated with a green resinous coating. The coatings can be identified by immersing the piece in methylene iodide and shining a bright light on the stone to display the thin transparent layer of the coating.¹⁰

OUTLOOK

World demand for gem diamond can be expected to rise because of increasing effective personal incomes and the populations of the United States and other industrialized countries. Also, demand will increase because of highly effective promotional efforts. These promotions are changing social customs in many eastern countries, particularly the use of diamond engagement rings. The changes are resulting in significant growth in the diamond market. Demand for other precious gems will continue to grow as diamonds become more expensive and the popularity and acceptance of colored gemstones increase. Demand for synthetic and simulant gemstones for both personal and industrial consumption is expected to increase. The diversity of sizes, types, uses, and values of gems and gemstones precludes any meaningful forecasting of future demand.

^aEstimated. ²Revised. W Withheld to avoid disclosing company proprietary data.

¹Table includes data available through May 19, 1992. Total diamond output (gem plus industrial) for each country actually is reported, except where indicated by a footnote to be estimated. In contrast, the detailed separate production data for gem diamond and industrial diamond are U.S. Bureau of Mines estimates except for Australia (1987), Brazil (1987-90), and Central African Republic (1987-90), for which source publications give details on grade as well as totals. The estimated distribution of total output between gem and industrial diamond is conjectural, and for most countries, is based on the best available data at time of publication.

²Includes near-gem and cheap-gem qualities.

³Includes all synthetic diamond production.

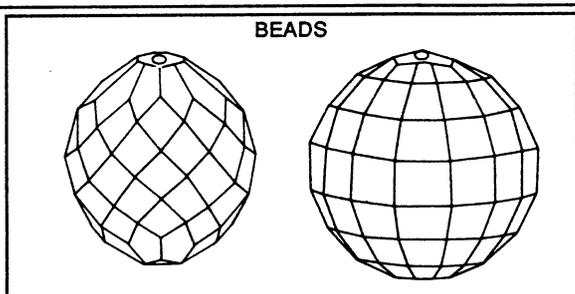

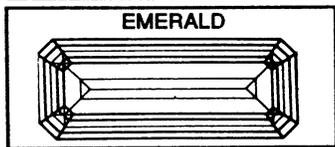

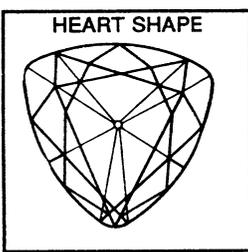

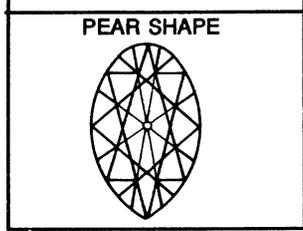

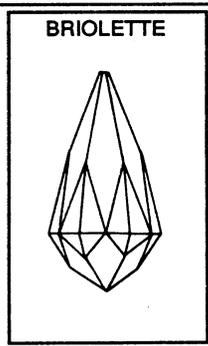

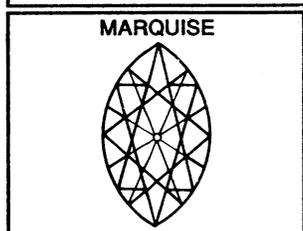

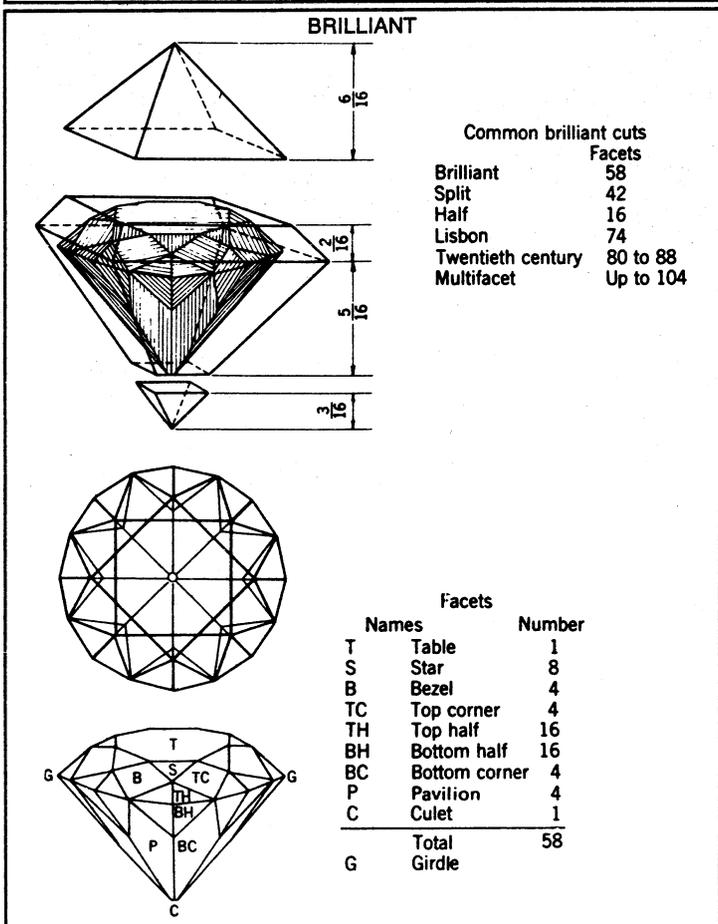

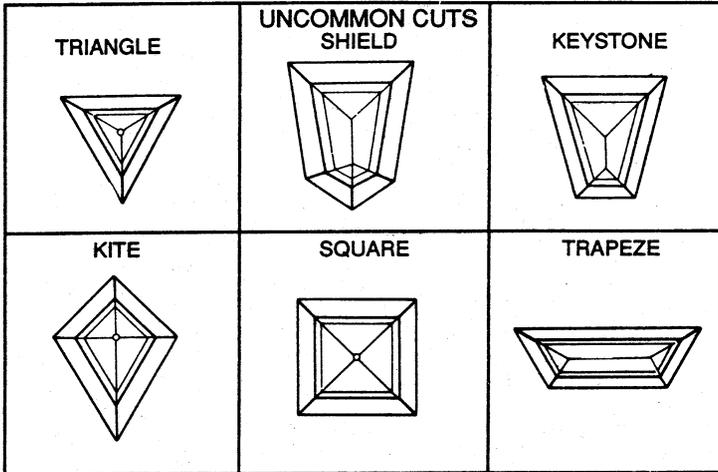

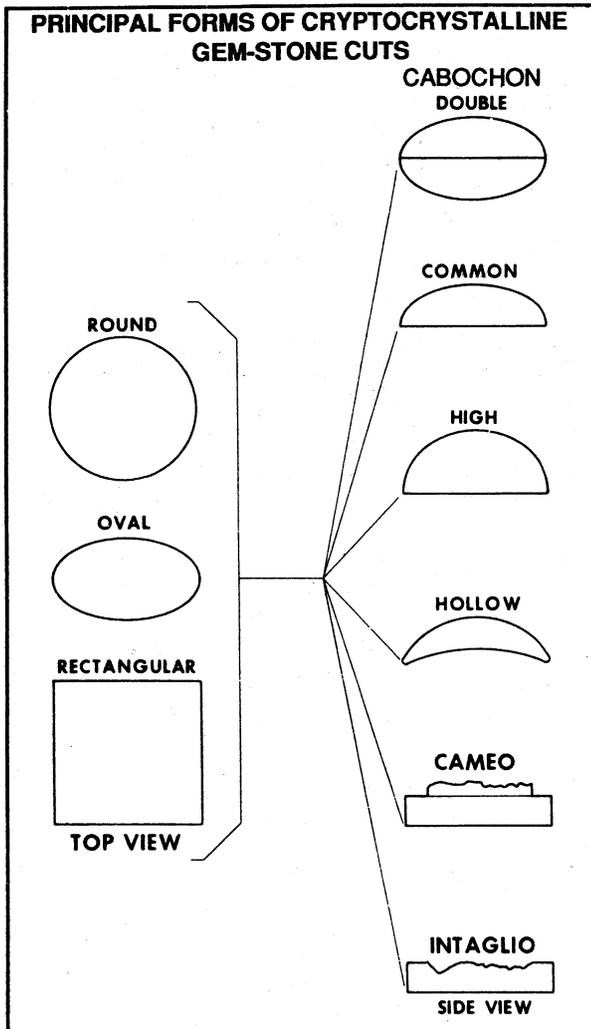

⁴Reported figure.

⁵Figures are estimates based on reported exports and do not include smuggled diamonds.

⁶Figures do not include smuggled artisanal production.

⁷Other De Beers' Group output from the Republic of South Africa includes Kimberley Pool, Koffiefontein Mine, Namaqualand mines, and Venetia mines.

 PRINCIPAL FORMS OF CRYPTOCRYSTALLINE AND CRYSTALLINE GEMSTONE CUTS

PRINCIPAL FORMS OF CRYSTALLINE GEMSTONE CUTS

GERMANIUM

By Thomas O. Llewellyn

Mr. Llewellyn, a physical scientist with more than 30 years of industry and U.S. Bureau of Mines experience, has been the commodity specialist for germanium since 1987. Domestic survey data were prepared by Tony E. Morris, statistical assistant.

The estimated domestic refinery production and consumption of germanium in 1991 were about 17% and 3%, respectively, below the levels of 1990. The lower production and consumption resulted mainly by a considerable reduction in defense infrared systems requirements.

DOMESTIC DATA COVERAGE

Domestic refinery production and consumption data for germanium are estimated by the U.S. Bureau of Mines based on discussions with domestic producers.

BACKGROUND

Germanium is recovered as a minor byproduct of the refining of base metal ores, and the potential supply of this metal, which is dependent on the level of zinc production, has historically exceeded demand.

Invention and development of the germanium transistor opened the path for the solid-state electronic field and, from 1950 through the early 1970's, provided an excellent market for germanium. Despite the continued growth of the electronics industry in the 1970's, germanium demand for transistors, diodes, and rectifiers declined because germanium was being replaced by electronic-grade silicon. However, the reduced demand for germanium in the electronics field was offset by a dramatic increase in demand for germanium in both infrared night vision systems and fiber-optic communication networks.

Definition, Grades, and Specifications

Germanium has a metallic appearance and is grayish white in color and lustrous, hard, and very brittle. It is a semiconductor, with electrical properties between those of a metal and an insulator. The National Stockpile Purchase Specification P-114-R, December 16, 1989, for intrinsic germanium metal specifies an electrical resistivity of 50 ohm-centimeter at 20°C (40 ohm-centimeter at 25°C) over the entire ingot length.

Germanium is available commercially as a tetrachloride and high-purity oxide and in the form of zone-refined ingots, single-crystal bars, castings, doped semiconductors, optical materials, optical blanks, and other specialty products.

Industry Structure

Most germanium occurs as a minor constituent of certain base metal ores and coal deposits. Those producers that currently recover primary germanium for the most part depend on germanium-rich residues, mainly from zinc derived from past or present base metal smelting operations.

In the United States, Eagle-Picher Industries Inc.'s Quapaw, OK, Specialty Materials Div. has the capability of recovering primary germanium from zinc smelter residues. Eagle-Picher also reprocessed scrap. Kawecki Berylco Industries Inc., a division of Cabot Corp. in Revere, PA, and Atomergic Chemetals Corp., Plainview, NY, produced germanium from reprocessed scrap and semirefined foreign material.

The Jersey Miniere Zinc Co. in Clarksville, TN, continued to produce germanium-rich residues as a byproduct of processing zinc ores from its Elmwood-Gordonville Mines. These residues were shipped to Metallurgie Hoboken-Overpelt S.A. (MHO) in Belgium for germanium recovery and refining.

Little information was available on the financial structure of U.S. and world germanium industries. Germanium refiners usually were involved in the production and sale of many different metals and specialty products.

Geology-Resources

Minerals in which germanium is concentrated are germanite, a sulfoarsenite of copper, germanium, and iron with an average content of 5% germanium; argyrodite, a double sulfide of germanium and silver containing 5% to 7% germanium; renierite, a complex sulfide of arsenic, copper, germanium, iron, tin, and zinc with 6% to 8% germanium; and several other minerals such as canfieldite, itoite, stottite, and ultrabasite. Primary germanium minerals are normally formed in sulfide mineralization processes at low-to-intermediate temperatures, and secondary varieties may result from supergene alteration of sulfide ore deposits.¹

Currently, there are two major reserves of germanium in the United States. The largest is the recoverable germanium that occurs as a minor constituent of zinc sulfide ores in the middle Tennessee zinc district. The other major reserve of germanium is in

southern Utah. Here the germanium is found in the iron oxide ore zone of a depleted copper mine.

There are no reliable germanium assay data available for many areas of the world. The U.S. and world resources could be expanded if germanium were to be recovered from ash and flue dusts resulting from burning of certain coals for power generation.

Technology

Germanium is obtained commercially as a byproduct of base metal refining. Improvements have been made, but the basic processes have remained virtually unchanged.

Regardless of the source, germanium raw materials are reacted with concentrated hydrochloric acid to form germanium tetrachloride, which is then purified by fractional distillation. The purified germanium tetrachloride is hydrolyzed with water to produce germanium dioxide, which is removed by filtration and dried. Dried germanium dioxide is reduced with hydrogen at about 760° C to a germanium metal powder, which is then melted and cast into metal bars. These bars are then zone-refined to produce intrinsic-grade metal. This high-purity metal is mainly used for electronic and infrared optics. Zone refining produces polycrystalline germanium.²

Certain applications of germanium, such as gamma-ray detectors, require single-crystal germanium. Single crystals are produced by two methods, the horizontal pulling process or the vertical pulling process, also known as the Czochralski method.

More than 50% of the metal used during the manufacture of most electronic and optical devices is recycled as new scrap. As a result of the low unit use of germanium in microelectronic devices, very little germanium returns as old scrap.

Substitutes

Less expensive silicon substitutes for germanium in certain electronic

applications. Certain bimetallic compounds of gallium, indium, selenium, and tellurium can also substitute for germanium. Germanium is more reliable in some high-frequency and high-power applications and more economical as a substrate for some light-emitting diode applications. In infrared guidance systems, zinc selenide or germanium glass substitutes for germanium metal, but at the expense of performance.

Economic Factors

Table 1 shows import duties for germanium products, which became effective on January 1, 1989, under the new Harmonized Tariff Schedule of the United States. Domestic producers are granted a depletion allowance of 14% on both domestic and foreign production of germanium. (See table 1.)

Operating Factors

Germanium has little or no effect upon the environment because it usually occurs only as a trace element in some ores and carbonaceous materials. The small quantities used in commercial applications also pose no threat to the environment. Germanium compounds generally have a low order of toxicity, except for germanium tetrahydride, which is considered toxic.

Based on a 1976 report, the energy requirements for the production of zone-refined germanium metal from zinc sulfide concentrates and scrap is 2,145 million British thermal units per net ton of germanium ingot.³

ANNUAL REVIEW

Strategic Considerations

The importance of germanium as a strategic and critical material was determined by the Federal Emergency Management Agency, and, on July 6, 1984, it was included in the National Defense Stockpile (NDS) with an initial goal of 30,000 kilograms of germanium metal. On July 24, 1987, a new NDS goal of 146,000 kilograms was

established, based on the Army's estimates for actual emergency conditions of mobilization.

Some of the metal inventory acquisitions made the previous year were delivered in 1991, and, as of December 31, the stockpile inventory was 68,913 kilograms of germanium metal.

Production

The U.S. Bureau of Mines estimated domestic refinery production from both primary and secondary materials to be 15,000 kilograms, a decrease of about 17% compared with that of 1990. Germanium producers were forced to scale down their output to meet falling demand for the metal by the Department of Defense.

On January 7, 1991, Eagle-Picher Industries Inc. announced that some of its affiliates had filed for reorganization under chapter 11 of the U.S. Bankruptcy Code in the U.S. Bankruptcy Court for the Southern District of Ohio, Cincinnati, OH. This action was taken by the company to cope with mounting personal injury claims against it as a result of an insulation product containing asbestos that it made more than 50 years ago. However, corporation officials assured the public that all operations, including production of the specialty materials (germanium and gallium), were not impaired by this action, and the company would be able to meet all of its commitments.⁴

Consumption and Uses

The U.S. Bureau of Mines estimated that consumption of germanium decreased about 3% compared with the level of 1990 as a result of decreasing demand for the metal. The estimated consumption pattern by end use of germanium in 1991 was as follows: infrared systems, 62%; fiber optics, 14%; gamma-ray, X-ray, and infrared detectors, 7%; semiconductors (including transistors, diodes, and rectifiers), 7%; and other applications (catalysts, phosphors, metallurgy, and chemotherapy), 10%.

Infrared systems and fiber optics continued to be the major end uses for germanium. Infrared optics were mainly used for military guidance and weapon-sighting systems. Germanium-containing lenses and windows transmit thermal radiation similarly to visible light transmission by optical glass. Germanium glass was also used for nonmilitary surveillance and monitoring systems in fields such as satellite systems and fire alarms. Germanium is used as a dopant in the core of many optical fibers employed in telecommunications.

The next-generation night navigation and targeting systems for the U.S. Army's new Light Helicopter will be provided by Martin Marietta Corp., Bethesda, MD. The company's new system is the latest version of the technology originally developed by the same corporation for the Army's Apache helicopter, but it incorporates advanced infrared focal plane arrays technology to produce higher resolution, TV-like images from greater distances than present systems. The value of the contract was expected to be about \$1 billion.⁵

Markets and Prices

Throughout 1991, domestic producer prices for germanium metal and dioxide, published by Metals Week, remained at the levels established in late 1981 (\$1,060 and \$660 per kilogram, respectively). However, discounting by producers was evident during 1991 because of competition from imported materials.

Free market prices, published by Metal Bulletin (London), which in June 1990 were in the range of \$500 to \$550 per kilogram, by May of 1991 reached a low range of \$340 to \$350 per kilogram; prices remained stagnant at that level for the remainder of the year. Plenty of germanium products were available on the market, and the world's oversupply was further aggravated by the U.S.S.R.'s entrance in the marketplace as an active supplier of germanium.

The Belgian producers' price for germanium metal, published by Metal

Bulletin (London), remained throughout the year at about \$860 per kilogram.⁶

Foreign Trade

In 1991, the estimated germanium content of imports was approximately 26,000 kilograms. Total imports of germanium materials decreased dramatically compared with those of 1990. The United Kingdom, Belgium, the Federal Republic of Germany, France, Hong Kong, and Canada, in descending order of shipments, accounted for approximately 88% of the total U.S. germanium imports for 1991. (See table 2.)

World Review

World refinery production was estimated at 80,000 kilograms, a decrease of about 2% compared with the 1990 level. The decline in world production was attributed to an oversupply and to a lower level of demand for the metal.

Capacity.—The data in table 3 represent rated annual production capacity for refineries on December 31, 1991. Rated capacity was defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable, long-term operating rate, based on the physical equipment of the plant and routine operating procedures for labor, energy, materials and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditures. (See table 3.)

Refineries' rated capacity of germanium was estimated based on discussions with some officials from private industry, past and present production rates, and published capacity data.

Japan.—Germanium metal production was 3,419 kilograms, an increase of more than 1% compared with 1990 metal production levels. However, germanium

dioxide production decreased from 12,350 kilograms in 1990 to 11,493 kilograms in 1991.

United Kingdom.—STC Submarine Systems, a subsidiary of Northern Telecom of London, United Kingdom, will supply a fiber-optic cable link between Copenhagen, Denmark, and Kingisepp, near St. Petersburg in the U.S.S.R. The 1,620-kilometer cable under the Baltic Sea will cost an estimated \$65 million.⁷

Current Research

The U.S. Bureau of Mines investigated germanium and gallium extraction from an ore sample obtained from the Apex Mine near St. George, UT. The sample contained about 0.09% germanium and 0.04% gallium. Research results showed that about 87% of the germanium and 97% of the gallium content in the sample were extracted, using a two-stage countercurrent sulfuric acid leach circuit. This study also determined that more than 10% of the germanium in the ore sample was in solid solution with silica, which would be unextractable with sulfuric acid.⁸

OUTLOOK

There were abundant supplies of germanium materials on the market in 1991. Germanium supplies are likely to remain high for the next 2 to 4 years owing to an increased availability of concentrates from Canada and also to a considerable amount of germanium metal emerging into the world market from the U.S.S.R. Producers for the second consecutive year were forced to lower prices to maintain their share of the market.

Market analysts agree that all primary germanium producers will probably face difficult times in the near future. This assessment is based on a continuing global oversupply of germanium materials together with a low market demand.

GOLD

By John M. Lucas

Mr. Lucas, a geologist with more than 30 years of experience in the mining industry, has been the U.S. Bureau of Mines commodity specialist for gold since 1980. While with private industry, Mr. Lucas was involved in exploring for a wide variety of commodities, including gold, in the United States as well as in Australia, Brazil, and Canada. Domestic survey data were prepared by Dwayne E. Penn, Lisa P. Conley, mineral data assistants, and Stephen L. Hays, supervisory mineral data technician. International data tables were prepared by Audrey D. Wilkes, international data coordinator.

Throughout history, gold has been treasured for its beauty and permanence. Most of the gold that is fabricated today goes into the manufacture of jewelry. However, because of its superior electrical conductivity and resistance to corrosion and other desirable combinations of physical and chemical properties, gold also emerged in the late 20th century as an essential industrial metal. Gold performs critical functions in computers, communication equipment, spacecraft, jet aircraft engines, and a host of other products. Although gold is important to industry and the arts, it also retains a unique status among all commodities as a long-term store of value. It was, until recent times, considered essentially a monetary metal, and most of the bullion produced each year went into the vaults of government treasuries or central banks.

Domestic and international gold mining operations continued to produce gold at a record level during 1991. The U.S. gold mining industry produced 289,885 kilograms (kg) (9,320,006 troy ounces¹) of gold, essentially the same as that of the previous year. The State of Nevada was once again the Nation's dominant gold-producing State. For the third consecutive year the total demand for gold used in fabricated products in the market economy countries exceeded the record demand level set in 1988. Jewelry continued to be the dominant end-use sector.

The U.S. Bureau of Mines, in an effort to provide statistical data on gold that are consistent with international

usage, reports gold data in kilograms and metric tons unless otherwise noted.

DOMESTIC DATA COVERAGE

Domestic mine production data for gold are developed by the U.S. Bureau of Mines from two separate, voluntary surveys of U.S. operations. One of these surveys is the lode-mine production survey of copper, gold, lead, silver, and zinc mines. Of the lode gold producers in operation to which a survey request was sent, 211 responded, representing 98% of the total lode-mine production of gold shown in tables 4 and 5. Production for the nonrespondents was estimated using reported prior-year production levels, adjusted by trends in employment, and other guidelines such as company annual reports, the news media, and State agency reports.

BACKGROUND

Gold lore and the use of gold predates written history. Gold has been considered a precious metal since ancient times, and the mystique and folklore associated with gold has been a part of the fabric of civilized society throughout history. Similarly, the search for gold has stimulated world exploration and trade for more than sixty centuries.

Gold mining in the United States began about 1800 in North Carolina, with Georgia joining in production in 1829 and Alabama in 1830; then Virginia, Tennessee, and later New Mexico became producers as prospectors moved west.

The most important gold discovery, because of its influence on development in the Western United States and the amount of gold produced, was at Sutter's Mill in California in 1848. Later discoveries were made in most other Western States and territories.

Gold mining in Australia began about 1849 as an offshoot of the California gold rush. Russian gold mining had been expanding since the mid-18th century, and by the eve of the California gold rush, Russia was producing about two-thirds of the world's gold. Gold mining in the Republic of South Africa started in the 1870's. The last major gold rush began just prior to 1900 in Canada's Yukon and in Alaska.

Early mining was largely by placer methods, with a multitude of miners working stream deposits (placers) by hand mining techniques, a practice that continues to this day in many areas of the world. In the 1860's, the more difficult underground mining of lode deposits—the sources of the placers—became important. Cyanidation, a chemical process for gold extraction, was introduced about 1890, and the concentration of finely ground ores by selective adherence of mineral particles to rising bubbles, the flotation process, was first used for gold ores about 1900 and came into general use in the 1930's. Heap leaching, essentially a form of cyanidation, has come into general practice for treatment of low-grade ores only during the past 2 decades.

Cumulative world production to date is estimated at more than 109,000 tons (3.5

billion ounces), about two-thirds of it mined in the past 60 years. The total is equivalent in volume to a cube roughly 18 meters (58 feet) on a side. The Republic of South Africa has been the source of about 41% of that gold, but nearly all countries have reported at least some production of gold.

U.S. gold production, from its beginning in the 18th century to date, totals about 11,600 tons (372 million ounces). The principal producing States, in declining order of cumulative production, are California, Nevada, Colorado, South Dakota, Alaska, Utah, and Montana; the remainder came from 11 other States. To date, lode gold mining has supplied about 50% of U.S. production; placer mining, 35%; and base metal mining, 15%. The Homestake Mine at Lead, SD, has accounted for about 10% of all U.S. gold production. Other major sources of past production include the Mother Lode and Grass Valley areas of California, the Comstock Lode and Goldfield areas in Nevada, Cripple Creek in Colorado, and the Fairbanks and Nome, AK, areas.

Most domestic gold mines were closed by Limitation Order L-208 in the early months of World War II (October 8, 1942) so that scarce equipment, supplies, and skilled workers could be focused on mining essential base metals. L-208 was revoked July 1, 1945. Because of increased cost and rehabilitation problems, only a few mines reopened after the war. During the resurgence of gold exploration and mining over the past decade, many deposits affected by L-208 have been reexamined or returned to productive status.

Definitions, Grades, and Specifications

Fineness refers to the weight proportion of pure gold in an alloy, expressed in parts per thousand; 1,000 fine gold is 100% pure gold. Commercially traded gold bullion is usually 995 fine or higher. The term "fine gold" may also be used to designate the particle size of gold in its native state; for example, a placer deposit with gold particles ranging from 0.38 millimeter

(mm) to 0.76 mm (0.015 to 0.3 inch) in diameter contains fine gold, whereas a similar deposit with particles more than 1.5 mm (0.06 inch) in diameter contains coarse gold.

The term "karat," like fineness, refers to purity, but is expressed in 24ths; thus 24-karat (24k) gold is 1,000 fine or pure gold, and 10k gold is 10/24, or 41.7% gold. Although there are many 10k alloys, each 10k alloy contains 41.7% gold. Various 10k alloys, for example, differ from each other in the number, identity, and proportions of their other constituent metals. Gold alloys used in jewelry and certain other end uses are referred to as karat golds, whereas alloys used in dentistry and electrical devices are designated more precisely. Yellow, red, and green karat golds are essentially ternary alloys of copper, gold, and silver, often with additions of zinc and sometimes a little nickel. White karat golds are usually composed of copper, gold, nickel, and zinc, although platinum and palladium have also been used as components.

Having assumed the functions previously performed by the London Gold Market, the London Bullion Market Association (LBMA), established in 1987, sets standards for its members that are widely used in world gold trade. Refined gold bullion bars are generally designated as "good delivery bars." A good delivery bar, as set forth by the requirements of the LBMA, must contain 350 to 430 troy ounces of gold with a minimum fineness of 995. The bar must bear the stamp of one of the world's 49 approved smelters or assayers, have a good appearance, and be easy to handle and stack. Smaller bars are also commonly available on the commercial gold market.

U.S. trade practice rules for the jewelry industry, set by the Federal Trade Commission, require that any article labeled gold must contain at least 10k gold, with a tolerance of three parts per thousand for most articles, or if soldered, seven parts per thousand. "Rolled gold plate" and "gold filled" are terms referring to articles made of base metal to which karat gold has been bonded by soldering, brazing, welding, or

mechanical means. A marking such as "1/10 10-karat gold filled" means that one or more surfaces are covered with 10-karat gold and the coating constitutes at least 10% of the weight of the entire article covered. No article may be marked "gold filled" if its karat gold surface constitutes less than 1/20 of the total weight. Thinner coatings are marked "rolled gold plate."

Gold has an atomic number of 79 and an atomic weight of 197, occurring naturally as a single stable isotope. The melting point of gold is 1,063° C. Gold's specific gravity is 19.3; it is about seven times heavier than an equal volume of metallic aluminum. In addition to being highly resistant to corrosion, gold is also extremely malleable and ductile; 31 grams (1 troy ounce) can be beaten into about 250 square feet of gold leaf about four-millionths of an inch thick, while a similar quantity can be drawn into more than 80 kilometers (km) (50 miles) of wire.

As an illustration of gold's high specific gravity or density, 1 cubic foot of pure metallic gold weighs a little more than 1,200 pounds; one cubic inch of pure gold weighs about 311 grams (10 troy ounces); a lump or nugget of gold the size of a navy bean weighs about 3 grams (0.1 troy ounce), and a flake of gold the size of a grain of rice weighs about 0.18 gram (0.006 troy ounce).

The troy system of weights is generally used in the United States for gold and other precious metals; however, to aid in harmonizing world data collection, Government practice now dictates the use of the metric system of measure. The troy weight system is based on the troy ounce of 480 grains or 20 pennyweight. One troy ounce is equivalent to 1.097 ounces avoirdupois. Many nations use the metric system; in this system, the weight of gold is designated in standard metric units: gram, kilogram, or metric ton. The metric ton is equivalent to 32,150.7 troy ounces. In addition to the metric or troy systems, other units of weight applicable to precious metals may also be encountered. On the Indian subcontinent, for example, the weight of gold may be expressed in terms of tolas;

one tola of 999 fine gold weighs 11.1 grams (0.375 troy ounce).

Uses and Products for Trade and Industry

In addition to its ages-old usage as a monetary metal as well as in jewelry, decorative applications, and dentistry, gold has a number of applications that are important to the functioning of domestic industry, modern high-technology, engineering, and defense systems. It is used extensively in a great variety of solid-state electronic devices, in industrial control and monitoring instruments, and in corrosion-resistant chemical process equipment.

Of the strategic and industrial uses of gold, the most important is its use in electronic devices, especially in printed circuit boards, connectors, keyboard contacts, miniaturized circuitry, and as a dopant in some semiconductors. Modern solid-state electronic devices such as computers employ very low voltages and currents, and thus require connectors, switch contacts, soldered joints, and certain other components that remain chemically and metallurgically stable for the life of the device. Increasingly complex civilian, military, and aerospace electronic systems use gold to ensure dependable operations under a wide range of operating conditions. For example, because of its ability to provide reliable electrical connections, gold is used extensively in spacecraft such as the *Hubble Space Telescope* that must function flawlessly in the harsh environment of outer space. A more down-to-earth example would be the common touchtone telephone that has up to 33 gold contact points; gold plating employed on the contact surfaces of the quick disconnect between the telephone and the line ensures static-free reception.

Gold alloys have long been used in certain electrical instruments; for example, as wipers and windings in slide-wire potentiometers, where long-term reproducibility is essential. Gold-palladium alloy wires are used in thermocouples, especially those used to measure high temperatures encountered in

some industrial processes and aircraft engines. Gold-containing brazing alloys such as gold-nickel alloy are important to the aerospace industry, especially in the assembly of some military jet turbine engines and high-performance rocket engines. Gold is used as a reflector of infrared radiation in radiant heating and drying devices and heat-insulating windows for large buildings. It is used in spacecraft such as the space shuttle, which relies upon gold to seal and protect its vital propulsion system from problems associated with hydrogen embrittlement. Gold-coated mirrors are the principal component of infrared jammers used on numerous military aircraft to confuse the guidance instruments of heat-seeking missiles.

Gold applied as organometallic liquids is used for the decoration of porcelain and glass dinnerware; gold leaf is used for the decoration of buildings, both inside and outside; and gold alloys are used in rupture discs in chemical process equipment and in the perforated "spinnerets" through which cellulose acetate fibers are extruded. Since 1975, when Americans could again hold gold without a license, a small amount of gold has been used in the United States each year for medallions, small bars, and other similar items having high gold content, purchased primarily as investments.

Although gold compounds are used in substantial quantities in electroplating, most of the gold sold in the international marketplace for industrial usage is in the form of metal or metal alloys. Many standard metallic forms are available, such as bars, rods, sheets, foils, wires, powder, granules, and shot. Conductive pastes and inks prepared with gold powder are widely employed in the electronics industry. Much jewelry gold is supplied as granules of specified karat content. Semimanufactured items for trade and industry may include gold jewelry findings or unassembled parts such as earring clamps, chain clasps, pins, etc.; dental findings; and inlaid, clad, and plated metals. Investment products such as bars, coins, and medallions are manufactured and sold by both industry and governments.

Industry Structure

In the United States during 1991, 90% of domestic gold production came from gold ore, and most of the remainder was a byproduct of copper and other base metal production. Placer gold production has declined to about 1% of the reported total production in recent years. Fifteen mines accounted for about 60% of domestic output in 1991; 83% came from mines in California, Montana, Nevada, and South Dakota. The leading producer in most recent years, Newmont Gold Co., provided about 17% of domestic output from its surface operations near Carlin, NV. The Homestake Mine, a deep underground mine in South Dakota, has been a major producer for many years. The Utah Copper Div. of Kennecott, a major copper producer, has been a significant gold producer in many years since 1979, a year when it was the Nation's largest gold producer. Kennecott's gold is a byproduct of its extensive copper mining operations at Bingham Canyon, UT.

Attracted by the favorable U.S. business climate, foreign investment in domestic firms that produce gold as a principal product or as a byproduct has increased since 1980. This is especially true for mining interests acquired by multinational companies, some of which in turn may be directly linked to foreign governments. The general attractiveness of the United States as a country in which to conduct business has been a principal motive behind these acquisitions. Canadian mining companies have, throughout the history of North American mining, operated mines in the United States, as to a lesser extent have United Kingdom and other European companies.

The South African gold mining industry, accounting for about 27% of current world output, consists of about 3 dozen large underground operations and several dozen smaller mines. In a typical year, the Republic of South Africa's gold industry reportedly mills enough ore to cover 60 city blocks to a height of 20 stories; from this volume is recovered enough gold to fill a small bathroom. These mines are owned or controlled by

six corporations that interlock through directorships and mutual shareholdings and have extensive mineral and industrial investments in many parts of the world. The corporations are Anglo American Corp. of South Africa, Ltd.; Anglovaal Ltd.; Gencor Ltd.; Gold Fields of South Africa, Ltd.; Johannesburg Consolidated Investment Co. Ltd.; and Rand Mines Ltd.

Geology-Resources

The Earth's crust has been estimated to have an average gold content of about 0.0034 gram per metric ton (0.0001 ounce per short ton), or 3.5 parts per billion (ppb). Sedimentary rocks, especially sandstones, tend toward higher-than-average gold content. In igneous rocks, the content averages slightly higher in darkly colored "mafic" rocks than in lighter colored "felsic" rocks. Seawater typically contains about 0.011 ppb gold; however, content varies widely with location and may range from 0.001 to 44 ppb. Numerous attempts have been made over the years to recover gold from seawater; however, none have been commercially sustainable. The gold content in surface and ground waters lies within the range of analyses for seawater, but varies widely depending on source. For instance, waters from gold mines in southern Yakut, U.S.S.R., contain an average of 0.7 to 0.9 ppb. In Colorado, waters draining from gold mining and other areas contain up to 0.15 ppb, but with no distinct differences between gold-enriched and gold-barren areas. Hot-spring waters generally contain more gold than other waters.

Gold deposits are found in many kinds of rock. Hydrothermal deposits appear to be somewhat more common in acidic and intermediate igneous rocks; in silty, laminated carbonate rocks; and in silicious or aluminous sedimentary or metamorphic rocks. The general deposit types include hydrothermal, hydrothermal-metamorphic, metamorphic, replacement (lode, massive, and disseminated), and cavity filling (fissures, stockworks, saddle, reefs, breccias, and conglomerates).

Gold occurs mainly as native metal, alloyed with silver and/or other metals, and as tellurides. A naturally occurring alloy of gold and silver is known as electrum. Other gold minerals are rare. Gold is commonly associated with the sulfides of antimony, arsenic, copper, iron, and silver.

Chemical and mechanical weathering and erosion cause gold in the free or metallic form to be released from lode or primary deposits and to accumulate as nuggets and grains in residual deposits or placer deposits. Although the richest lode gold deposits have been small fissure vein types with quartz gangue, the so-called bonanzas, much larger quantities of gold have been mined from large, medium-grade deposits. U.S. gold ores average about 3.5 grams per metric ton (0.1 ounce per short ton) or less; however, the advent of chemical heap leaching now makes it possible for rock with suitable properties containing considerably less than 3.5 grams per metric ton to be considered ore.

Technology

Exploration.—Although a number of new techniques have come into use in the exploration for gold, the gold pan remains one of the simplest and most efficient low-cost means of finding visible gold and tracing it to its source. Collecting, crushing, and panning quartz samples from geologically favorable areas is a common basic procedure employed in prospecting for bonanza-type lode deposits. Neutron activation analysis and atomic absorption spectroscopy, when properly applied, permit relatively fast and reliable gold analyses and have had an important bearing on the ability of field geologists to do geochemical surveys of areas formerly of little interest because of sampling costs and lack of outcrops. The long-established fire assaying technique, however, continues to be the most widely used method for determining the quantity of gold present in samples or market products where precision and accuracy of the results are important. The thoroughness of the fire assay method, however, usually results in overvaluation

when applied to placer samples. Even the most efficient placer gold recovery technique cannot always recover all of the gold values detected by fire assaying; recovery of the available free gold by panning and amalgamation generally yields more representative results. Newmont Gold Co. recently initiated an automatic assay system whereby more than 4,900 laser-read barcoded samples are directed daily through the various laboratory stages with the aid of computers. Geochemical studies have established relationships between gold and other elements, such as arsenic, copper, mercury, and tellurium, which can be useful trace elements in the search for gold. In recent years, computers have proven to be useful in determining the often subtle relationships between trace elements and gold mineralization. Metallogenic studies relating tectonic histories and regional and local geology have given better understanding of where important gold deposits may lie.

Wire-line core drilling and improved percussion drilling methods have reduced the costs and increased efficiencies of exploration and development. Research on sampling through statistical analysis techniques that take into account the distribution and size of gold particles in a sample has shown ways to effectively reduce sampling costs. Computer methods have been useful in defining the extent of pay zones in larger ore bodies, such as those in the Republic of South Africa, and have application to low-grade disseminated deposits. Improvements in mining machinery and procedures and the introduction of new gold leaching methods have combined to lower the economic cutoff limits for gold deposits, providing an impetus for extensive reevaluation of previously mined areas as well as the incentives necessary to encourage the exploration of new, heretofore unproductive, areas.

Mining.—The technology of gold mining is well established, having evolved largely over the past century. Much of the world's gold production has come from deep, narrow veins or from thin-bedded layers called reefs; these

have been difficult to mine (in the Republic South Africa, for example) because of high underground temperature and humidity and extreme rock pressure, which often cause dangerous rock bursts. Most domestic gold comes from surface lode mines.

Placer mining was once an important source of gold. Dredging offers the maximum efficiency in large alluvial or marine deposits; dragline, hydraulic, or bulldozing methods are commonly used in smaller, bouldery deposits such as those mined in some areas of Alaska. Most placer mining requires large quantities of water, but dry operation is also possible using bellows or other air-blowing equipment for separation. However, recovery efficiency may be lower in dry processing. To illustrate the effort entailed in small-scale manual placer mining, such as that which has been and continues to be practiced in many areas of the world, including the United States, two persons feeding a sluice box can shovel about 6 cubic yards of gravel per day. This is roughly equivalent to loading the beds of six 1-ton pickup trucks per day. Assuming that the gravel processed yields an average 0.49 gram per cubic meter (0.01 ounce per cubic yard) of gold, about 3 grams (0.06 ounce) of gold would be recovered per day. With a gold price between \$350 and \$400 per ounce, the gold recovered by two persons laboring all day would have an approximate value of \$21.00 to \$24.00, hardly an acceptable wage in the United States but a substantial sum in many areas of the world. Obviously, mechanization, even on a small scale, would vastly increase the amount of material that could be washed. Needless to say, mining a higher grade deposit would be even more productive. Should the gold recovered be in the form of coarse nuggets, valued also for their use in jewelry or as specimens, the value of the day's production would be increased. For large-scale, open pit lode gold mining, computer models have been developed to analyze various production factors and establish optimum pit configurations and extraction efficiencies.

The South African mining industry, a leader in deep mining technology for many years, has evolved new methods of controlling problems relating to rock stress, dust, and virgin rock temperature. Both large and small water-powered rock drills, large-diameter raiseboring machines, and new types of rubber-tired transporters have been developed in recent years to increase the efficiency of mining operations. Also, the South Africans have developed new techniques of shaft sinking, mineral processing, and extraction that are critical to the success of deep mining. At the Vaal Reefs Mine, for example, part of the gold ore is transported to the surface from a depth of more than 2,100 meters (7,000 feet) by hydraulic pumps. Much of the Republic of South Africa's current production is now coming from depths of 2,000 to 3,000 meters (6,600 to 9,800 feet) below surface, with some as deep as 3,600 meters (11,800 feet). The new generation of ultradeep mines are intended eventually to be mined to 4,500 meters (14,800 feet).²

Beneficiation.—Milling technology for gold is highly developed, and normal mill recovery rates range from 92% to 96%. Gold is recovered by cyanide leaching of gold ore contained in tanks or heaped on impervious leaching pads; by amalgamation, flotation, gravity concentration, and smelting; or by a combination of these processes. Increased exploitation of gold-bearing sulfide ores in recent years has led to the development and application of several technologies designed to render sulfide and refractory ores amenable to cyanide leaching; thus, process steps such as autoclaving, biological preoxidation, or fluid-bed roasting have recently been incorporated at a number of milling operations.

Smelting-Refining.—Many gold mining operations recover the gold from cyanide leach solutions by precipitation with zinc dust, though, in recent years, carbon-in-pulp (CIP) recovery technology has been adopted at a number of new mining operations. With CIP, activated

carbon made from coconut shells or other durable carbon sources collects gold from the cyanided pulp until it contains 10 to 12 kg (300 to 400 ounces) of gold per ton of carbon. Gold with accompanying silver is desorbed or stripped from the carbon with a strong alkaline cyanide-alcohol solution. The precious metals are recovered from the strip solutions by electrodeposition on a stainless steel wool cathode. The cathode deposit is then refined into bullion or doré, a mixture of mostly gold and silver. The carbon is reused after being screen-sized and reactivated through controlled roasting. Generally, gold recoveries range from 92% to 97% of the feed content. Gold leaching processes in use or under development that do not employ cyanide as the principal lixiviant or dissolution medium include the application of thiourea, iodine, malonitrile, or various bioextraction techniques. Some of these alternate techniques, unlike the long-established, well-understood cyanide process, may be accompanied by unacceptable cost or environmental burdens. When gold is associated with copper ores, it travels with the base metal through concentration and smelting to the refining stage. It is eventually separated from the anode slimes that accumulate in electrolytic copper refining cells and is recovered as gold bullion in the precious metals refinery. Gold losses in concentrating copper ores are about the same as for copper, but are negligible in smelting and refining.

Gold is refined by chlorination in the molten state (Miller process) and by electrolysis (Wohlwill process). Generally, gold bullion made by the Miller process is 996 to 997 fine, and bullion made by the Wohlwill process is 999.5 to 999.8 fine. (See figures 1 and 2.)

Recycling.—Because of its high intrinsic value, gold has been recycled throughout the ages. Thus, a modern article of jewelry containing recycled gold could conceivably contain atoms of gold from a golden earring worn by Helen of Troy or from a nugget of gold used in the year 4000 B.C. to barter for ingots of

crude copper or other goods at a Mediterranean seaport.

Precious-metals refiners throughout the world recover gold from scrap. In the United States, about 60% to 80% of the scrap comes from current manufacturing operations, and the remainder comes from old scrap in the form of items such as discarded jewelry and dental materials, used plating solutions, junked electronic equipment, etc. Gold is so valuable that even the gloves, aprons, and dust masks worn by gold workers and the dust or "sweeps" from their shops may be processed to yield payable quantities of metal. Similarly, a specialized field of secondary gold recovery focuses on gleaning gold from defunct gold-processing operations. Most domestic scrap processors are in the northeastern States.

The general flow of gold in the secondary industry is shown in figure 3. Refiners receive scrap in a variety of forms and determine processing steps according to batch size, average gold content, and the impurities to be separated. Scrap dealers and semirefiners may process the scrap and then ship the upgraded product elsewhere, including overseas, for further treatment and refining. Scrap is either purchased outright or treated on a toll basis.

A considerable quantity of scrap is generated in manufacturing operations, but because of tight security controls over waste materials in precious-metals plants, nearly all of this new scrap or "home-generated" scrap is recovered. Some old scrap, on the other hand, is lost because in practice gold cannot be economically recovered from all manufactured products; this is increasingly true as miniaturization of gold-bearing electronic products proceeds. The U.S. Department of Defense recovers a significant quantity of gold from military scrap; other Federal Government agencies either participate in the Defense recovery program or have their own. (See figure 3.)

Economic Factors

On January 31, 1934, following provisions of the Gold Reserve Act of that year, the official price of gold was raised by the U.S. Government from \$20.67 per ounce to \$35 per ounce. The value of \$1 was thus established at 28.57 thousandths of a troy ounce, and gold flowed into the United States. By 1949, gold stocks held by the U.S. Department of the Treasury had risen to a peak of 21,708 tons (698 million ounces).

During the 1950's and 1960's, foreign central banks vigorously exchanged their large dollar holdings for U.S. gold. Consequently, U.S. stocks declined, with much of the gold accumulating in stocks owned by foreign governments. When the outflow of gold was finally stemmed in August 1971 by a Presidential order closing the so-called "gold window" or ending the convertibility of U.S. dollars into gold, U.S. stocks stood at 9,069 tons (291.6 million ounces). Thereafter, U.S. stocks declined somewhat, reflecting gold auctioned by the Department of the Treasury in 1975, 1978, and 1979 and later minting of gold coins and medallions for public sale. At yearend 1991, U.S. Treasury stocks stood at 8,146 tons (262 million ounces).

Because of increasingly severe pressures on official gold reserves stemming from attempts by monetary agencies to hold the price of gold down to \$35 per ounce, a seven-nation International Gold Pool established a two-tier price system in March 1968. Under this system, there was an official price of \$35 on monetary transactions, thenceforth restricted to Government-owned gold, and an open market price for other transactions, which could fluctuate with supply and demand. Since then, the free market has flourished, and the price of gold has risen dramatically, while the monetary sector has evolved to the point where most nations conduct gold transactions and value their gold reserves at market-related prices. The United States is the only remaining holder of large gold reserves to value them at the low official price of \$42.22 per ounce. The U.S. dollar was devalued twice in

the 1970's, raising the dollar price of gold to \$38 per ounce on May 8, 1972, and then to \$42.22 on October 18, 1973, where it remains today. With the second devaluation, the President was empowered to eliminate regulations on the private ownership of gold, which had been in force since 1934, and these were eventually removed on December 31, 1974. January 2, 1975, was the first day that the general public was allowed to resume holding gold without a licence issued by the U.S. Treasury's Office of Domestic Gold and Silver Operations; the office was closed on July 31, 1975.

Trading in gold futures began in New York and Chicago upon restitution of the right to private ownership of gold. Trading volume has increased nearly sixteenfold since 1975, peaking at about 43,000 tons (1,380 million ounces) in 1982; the volume in subsequent years has ranged from about 25,000 to about 35,000 tons. However, only a small percentage of the gold traded enters the physical market.

Because of gold's monetary role and the fixed \$35-per-ounce price from 1934 to 1968, domestic producers had difficulty maintaining production in the face of rising costs. Gold was particularly attractive as a commercial metal because its price was stable, and a dependable domestic supply was provided to industrial users by the U.S. Treasury until March 17, 1968.

In March 1982, the U.S. Gold Commission, which had earlier convened to consider a renewed role for gold in the U.S. economy, concluded that reintroduction of gold into the current monetary system would probably not serve to alleviate potential economic problems such as inflation. The prospects for a return to a gold standard in other countries would also seem to be uncertain. However, as a so-called "hard currency," gold may come to enjoy a greater role in world economics than it has in the recent past. This is especially important as the world economic system adjusts to accommodate rapidly changing political, economic, and trade practices and to address the many issues associated with the rapid growth in world

population, dwindling resources, and slower growth in industrial productivity. Small-scale bartering arrangements involving gold continue as they have for centuries, especially in frontier mining areas such as those in South America, Africa, the western Pacific, and remote areas of North America where raw gold dust and nuggets may be used directly to purchase goods and services.

Prices.—The price of gold is a topic of continuing concern and interest to the producer and the consumer of gold alike; where it has been, where it will go, and the reasons behind its wild fluctuations over the past decade or so have been studied from every angle by numerous observers. Apparent causes for the price changes have been presented, and speculation on their future directions have been offered.

Unfortunately, many of these sophisticated econometric models, forecasting the price using combinations of economic, political, and social factors, that proliferated in the early 1980's had all but disappeared from the public domain by the end of the decade. The course of future events cannot, of course, be forecast with accuracy, nor can the price of gold. Forecasting gold's price is unusually complicated because gold occupies a unique position among the world's commodities. Gold is both an internationally traded commodity and, at the same time, a long-established, universally acceptable storehouse of value, considered by many people worldwide to be superior to fiat paper currencies with fleeting longevity or fluctuating, unpredictable value. Unlike many commodity prices that are more or less tied directly to supply and industrial demand, the price of gold cannot be viewed as one would view the price of other goods or services in a free market. Gold also cannot be viewed strictly from the standpoint of the U.S. market alone, for international, political, and economic events that may impose a positive or negative influence on gold the commodity may be overshadowed by developments perceived to favor gold the medium of exchange. For example, citizens of

nations that have been invaded by other countries during the course of their history tend to value the monetary and exchange aspects of gold more highly than countries such as the United States where this has not been the case. To them, gold is money or the preferred substance of wealth, and the ownership of even a small amount of physical metal ensures escape or a new beginning. Therefore, many individuals worldwide, as a matter of tradition or simple prudence, continue to hold small quantities of gold in the form of jewelry, coins, nuggets, etc., legally or illegally, as a portable form of universally accepted capital; for some, especially in developing countries, gold may constitute the only available and relatively risk-free form of old age or disaster insurance.

Although the average price of gold has declined from its record 1980 level of \$612 per ounce, it remains considerably higher than the prices of the early 1970's. This high price level, not generally enjoyed in recent years by many other commodities, continues, albeit to a lesser extent today than during the mid-1980's, to spark investor interest and lead to an overall sustained increase in the level of funding available to gold producers to invest in exploration and productive capacity. The heightened interest in gold has, as in the past, promoted exploration of those remote corners of the Earth where exploration for other less valuable minerals could not be justified but where their serendipitous discovery as a byproduct of exploration for gold will ultimately contribute to the needs of society.

In the fabrication of gold, particularly in the electronic and electrical industries, the cost of gold used per unit item is still such a small percentage of the total unit cost that the price of gold is often of small significance in pricing the product. Some industrial consumers of gold, however, confronted with unpredictable and potentially ruinous prices, have turned in recent years to the world futures markets to ensure that their future gold requirements will be available at preselected prices.

Costs.—Costs of mining gold in the United States range upward from costs typical of low-cost placer mining, where dredging or hydraulic operations are conducted profitably on gravels containing less than 0.49 gram per cubic meter (0.01 ounce of gold per cubic yard). Surface lode mining, although considerably more expensive than placer mining, is profitable with some ores containing as little as 0.2 gram or less of gold per metric ton (.006 ounce per ton), depending on the stripping ratio, size, and type of operation. Other important considerations include the characteristics of the ore processed and the mine's location with respect to the duration of the operational season and the infrastructural requirements. Underground mining for gold is the most expensive mining, but costs vary greatly from mine to mine; nevertheless, some underground mines are able to produce an ounce of gold at costs below those of some surface operations.

Costs for processing gold ores can vary widely, depending on the treatment required. Recent advances in heap leaching of gold and extraction with activated carbon may afford lower capital and operating costs than those associated with conventional cyanidation. One recent advance, for example, is particle agglomeration, a technique developed and patented by the U.S. Bureau of Mines to increase the flow rate of leaching solutions through crushed ore. Fine particles of ore that would otherwise impede solution flow by blocking the spaces between coarser fragments are bound together or agglomerated through the addition of a water-soluble binder such as portland cement or lime. Other innovative techniques developed in recent years to improve the efficiency of the heap-leaching process include the use of ore conveyors and stackers, solution heaters, and improved solution distribution and recovery and leak detection systems. Other advantages of heap leaching over conventional milling include shorter plant construction time and greater adaptability to lower grade ores. A disadvantage of conventional heap leaching is lowered recovery,

usually 60% to 80% of the gold present, compared with 88% to 92% or greater recovered by conventional mill treatment. The recovery efficiency of heap-leaching operations where agglomeration technology is employed approaches that of conventional methods.

Some producers, by forward selling of their future gold production, are able to maintain economic production even during periods when their production costs may exceed the existing market price of gold.

Taxes.—Taxes may be levied on mining operations for gold and other minerals at the Federal, State, and local levels. In addition to the usual business, occupation, and property taxes and licence fees required of all business enterprises, mining operations in many States are subject to severance or extraction taxes imposed on the yield or proceeds received from the sale of newly mined products. In 1989, the State of Nevada, for example, increased the net profits tax on State mineral production from about 2% to 5%. In 1986, a new Federal tax, the Customs User Fee, was adopted; it places a 0.22% levy on all imports, including gold and gold-bearing products. The fee was reduced to 0.17% on September 30, 1987. During 1990, the enabling legislation was extended to September 30, 1995, but in late 1991, the percentage levy was changed to a flat transaction fee of \$400 per shipment.

Most major gold-producing nations impose taxes on domestic mining operations; taxation of the gold mining industry in some countries may be specifically tailored to accommodate a nation's stated economic and political objectives. For example, in the Republic of South Africa, gold mines are taxed in accordance with two basic formulas: one taxes the profits of mines opened before 1966, while the other formula applies to newer mines. Many major gold-producing nations have also provided tax concessions, subsidies, and other assistance to gold mining. The former U.S.S.R. supported gold mining through administrative fiat. China encourages gold prospecting by both the civilian and

military population. Australian mining companies have for decades been exempted from paying taxes on profits derived from gold mining. However, effective January 1, 1991, the Government of Australia eliminated its 6-decade-old tax exemption of income derived from gold production, including byproduct production from those copper operations where gold represents more than 40% of the total income.

Operating Factors

Environmental Requirements.—The costs associated with meeting various Federal, State, and local environmental requirements can vary considerably from one mine site to another. At mines utilizing cyanide recovery techniques in their milling or heap-leaching plants, special precautions, monitoring and leak detection procedures, and site design features are employed to avoid contamination of the surrounding environment and to reduce the exposure of wildlife to cyanide-laden process streams. For example, at the Mesquite Mine in California, two solution ponds with about 4 hectares (9 acres) of exposed area have been completely covered with plastic to minimize wildlife exposure as well as water loss to evaporation. A variety of processes have been developed in recent years to detoxify or neutralize spent ore prior to disposal or final site reclamation. New regulations pertaining to cyanide use on Federal lands were issued during 1990 and further clarified during 1991 (See Legislation and Government Programs). In an emergency, chemical breakdown of cyanide can be induced quickly with chlorine gas.

Because of the danger of mercury pollution, the use of mercury amalgamation in domestic gold operations is now virtually nonexistent. Despite Government efforts to control the use of mercury, the amalgamation process continues to be used in an environmentally detrimental manner in some unregulated frontier mining operations in the Amazon Basin and in the Philippines. Mercury and arsenic can

be natural contaminants of gold ores, requiring troublesome or costly extraction processes. Other potential pollutants that may be byproducts from gold mining include antimony, bismuth, tellurium, and thallium. Two iron sulfides, pyrite and pyrrhotite, commonly occur in gold deposits and can be a source of stream pollution as they oxidize to sulfates and other soluble compounds. Pollution resulting from some placer operations may be reduced or eliminated through the use of properly designed settling ponds. Waste dumps, mill tailings, and excavations are increasingly subject to public scrutiny, and environment control costs must be taken into account along with other operating factors. Expanded mine safety requirements in recent years are another important cost factor.

Employment.—According to annual data prepared by the U.S. Department of Labor, employment in the Nation's gold mines and mills, exclusive of office employees, nearly tripled from about 7,000 in 1985 to almost 20,000 in 1990 and 1991. The number of jobs available in both surface and underground mines and associated processing plants is not always directly proportional to mine production, reflecting instead variations in development activity, the price of gold, weather, type of mining operation, etc. During 1989, citing employment studies for mining in Nevada and South Dakota, the Economics Institute of Boulder, CO,³ derived an employment multiplier of 19.4 jobs per \$1 million of gold production, giving an estimate for total direct, plus indirect employment attributable to domestic gold production, of about 51,000 persons. A companion study covering the period 1979-90⁴ showed employment multipliers and the industry's contribution to gross State products and State personal income for 11 gold-producing States. The report noted that induced employment from precious-metals production in Nevada, for example, accounted for between 14% and 20% of all new jobs created in Nevada from 1986 to 1989. An average employment multiplier of 20.3 jobs per

\$1 million in output was calculated for the 11-State area.

ANNUAL REVIEW

Legislation and Government Programs

On July 10, the President lifted economic sanctions against the Republic of South Africa, thereby allowing the resumption of imports and sales of gold Krugerrand coins and other products such as uranium, coal, and iron in the United States.

The director of the U.S. Bureau of Land Management (BLM) announced on August 14, 1990, that BLM had revised its existing bonding policies for surface mines and mines using cyanide and other leaching agents on Federal lands administered by the agency. According to the new bonding policies, mine operators had to post bonds to cover reclamation costs attributed to exploration and mining. The ceiling amounts for the bonds were about \$2,500 per hectare (\$1,000 per acre) for exploration and about \$4,900 per hectare (\$2,000 per acre) for mining operations. Operators having State bonds that met or exceeded the new reclamation requirements were not required to post a Federal bond. Mines using cyanide or other leaching agents were required to post a bond equal to 100% of BLM's estimate of reclamation costs required by Federal or State regulations. The affected areas included leach heaps, pads or dumps, or those parts of an operation discharging cyanide-bearing tailings and fluids to impoundments or ponds. Facilities not included were various forms of vat leaching, metal recovery, and refining. The new policy immediately affected new mining operations. Existing cyanide operations were to comply within 6 months and any other operations by January 1, 1992. On October 4, 1991, BLM modified its bonding policy to include previously excluded vat leaching facilities and to provide clarification of its 100% bonding requirement outlined above. Five days later, BLM issued clarification regarding the need to ensure adequate training for BLM personnel

involved in inspection of cyanide operations.

Regulations implementing the ban on the importation of gold coins minted or offered for sale in the U.S.S.R. were repealed by legislation enacted on December 4, 1991. The enabling legislation, Public Law 102-182, removed restrictions contained in the Comprehensive Anti-Apartheid Act of 1986. Prior to enactment, the regulations prevented U.S. collectors and others from acquiring or importing for exhibition numismatic gold coins of Soviet origin. (See table 1.)

Strategic Considerations

Gold is not a National Defense Stockpile item; however, the Treasury had stocks of bullion amounting to about 8,146 metric tons (262 million ounces) at yearend 1991. Large quantities of gold were also held as commercial and private bullion stocks. Therefore, the availability of gold in times of national emergency appears to be ensured.

One strategic aspect of the domestic gold mining industry that is infrequently considered is that the industry constitutes a valuable pool of experienced personnel, including chemists, geologists, engineers, and metallurgists as well as miners, machinists, and heavy equipment operators. In the event of a national emergency, these skills may be readily directed toward the discovery, development, and production of strategic materials.

Issues

An issue of continuing concern to domestic exploration companies, gold producers, and to producers of other minerals as well is that of mineral land availability. Because the geological forces that form mountains and unique physiographic features are commonly responsible for producing mineral deposits, exploration for gold and other minerals frequently focuses on these areas of disturbance. The same rugged features that make certain areas attractive to the minerals explorer may also make them

less accessible for mining because these areas may presently be more valued for their undisturbed or wilderness qualities than for their mineral potential. In recent years, the trend toward preserving increasingly greater areas of unevaluated wilderness land, on which exploration is prohibited or severely restricted, may lead to a decline in new discoveries as well as jeopardize national security.

Another issue of concern to the mining industry as well as law enforcement authorities has been the recent growth in telemarketing fraud and investment swindles involving sales of gold bullion and investment in questionable mining ventures. In late 1988, the North American Securities Administrators Association Inc. (NASAA) and the Council of Better Business Bureaus Inc. issued an Investor Alert entitled "Dirt Pile Gold Swindles." The alert was to educate the public regarding the organization, characteristics, and pitfalls of the classic "dirt pile" or "gold-in-the-ground" swindle. The NASAA is composed of representatives from the securities regulatory agencies of all 50 States plus Puerto Rico. Law enforcement authorities and various industry trade groups continue to police against other fraudulent practices, such as misrepresented gold quality marks on jewelry and bullion and faked collector coins.

Production

Of the 290 metric tons of gold (9.3 million ounces) produced in the Nation in 1991, 75% was attributable to the 25 leading producers. The average recoverable gold content of precious metals ores processed from lode mines was 0.84 gram per metric ton (0.02 ounce per short ton), while placer gravels yielded an average of 0.82 gram per cubic meter (0.02 ounce per cubic yard) of material washed.

The individual company production and performance data in this report were derived from published sources such as company annual reports.

Alaska.—Despite a 5% increase in gold production in Alaska during 1991, the value of that production declined 6% according to a survey of 1991 mineral activity prepared by the Alaska State Division of Geological and Geophysical Surveys (DGGS).⁵ Gold production of about 3,196 kg (102,754 ounces) was reported to the U.S. Bureau of Mines. However, the annual survey conducted informally by the DGGS suggests that a total of about 7,585 kg (243,900 ounces) of both lode and placer gold was produced; the comparable total for the previous year was 7,206 kg (231,700 ounces). The DGGS noted that placer production stabilized but fewer mines operated during the year; about 202 in 1991 compared with 216 in 1990. This decline reflects lower gold prices, exhaustion of resources in some areas, and increasing regulatory requirements. Placer mining, following a pattern established many decades ago, continued to be a small-business oriented industry providing many jobs to rural Alaska. Reported expenditures for exploration, 83% of which was for gold exploration, declined 40% overall in 1991. The one exception was exploration spending in south-central Alaska, which increased 17% over that of 1990. On October 15, 1991, the State's Reclamation Act, passed in 1990, came into effect. The new regulations require reclamation of all lands currently mined in Alaska, regardless of land ownership.

Greens Creek Mining Co.'s Greens Creek Mine, on Admiralty Island, was the State's largest gold-producing lode mine. Production during 1991 amounted to 1,150 kg (37,000 ounces) of gold plus major values in lead, silver, and zinc. Exploration of the site during 1991 resulted in the discovery of enough additional ore to effectively double the mine's proven and probable reserves. The company, held by Kennecott, Hecla Mining Co. CSX Corp., and Exalas Resources Corp., also made a number of operational improvements to the mine, including increasing mill capacity and implementing additional cost-cutting measures.

Near Cantwell, the Valdez Creek Placer Mine of Valdez Creek Mining Co., managed by Cambior Alaska, was reopened and produced almost 1,327 kg (42,680 ounces) during the year. Mining at the site had been suspended in October 1989 to allow diversion of Valdez Creek to gain access to gold-bearing gravels. The diversion was completed in March 1991 and, by the fall, the daily mining rate had reached almost 19,800 cubic meters (25,800 cubic yards). The company has set a production target of 3,110 kg (100,000 ounces) for 1992. Near Nome, Alaska Gold Co. continued to operate two Yuba class bucket-line stacker dredges onshore, processing thawed gold-bearing gravels. Large placer operations were also active near Fairbanks, Hogatza, Livengood, Ruby, Candle, and Manley Hot Springs.

Permitting difficulties at LaTeko Resources Ltd.'s Ryan Lode property led to the suspension in late 1990 of most of the mine's heap-leaching facilities at the mine site near Fairbanks. During 1991, the mine's new operator, Gateway Mining Co., concentrated on expanding the mine's ore reserves and initiating a program aimed at lengthening the productive operational season. Twenty-four km (15 miles) northeast of Fairbank, mine development work continued at the Fort Knox Joint Venture, which is 51% held by Fairbank Gold Ltd. and Gilmore Gold Inc. Feasibility work done during the year reportedly indicated that the property can be mined profitably as a large-scale open pit operation producing between 9,300 and 10,900 kg (300,000-350,000 ounces) of gold annually. Proven and probable reserves at Fort Knox amounted to 100 metric tons (3.2 million ounces) at yearend. Some of the work performed during the year included "condemnation" drilling to delineate barren sites for future mine infrastructure. In mid-September, Amax Gold Inc. announced its intention to purchase all the assets of the project and to proceed toward developing a producing mine by late 1984 or early 1995.

In southeastern Alaska, Echo Bay Mines Ltd. continued to perform environmental and permitting work at its

Alaska Juneau (AJ) Mine immediately behind the capital city of Juneau. A feasibility study updated to yearend by Echo Bay and its partner W.G.M. Inc. called for a large-volume underground mine and mill able to process 20,400 metric tons per day (22,500 short tons). At this rate, the property was expected to yield 11,660 kg (375,000 ounces) of gold per year for 13 years. The AJ produced more than 93 metric tons (3 million ounces) of gold between 1901 and 1944, when it was closed by increased taxes and labor shortages stemming from World War II. Echo Bay also owns the old Treadwell Mine on Douglas Island, 1.6 km (1 mile) west of Juneau, across the Gastineau Channel. Treadwell, also a former producer, yielded more than 93 metric tons (3 million ounces) of gold from underground between 1882 and 1917. One hundred and fifteen km (72 miles) north of Juneau, Echo Bay and its equal partner Coeur d'Alene Mines Corp. continued underground development work and exploration at their Kensington property, also a former gold producer. Nearby, Placer Dome U.S. Inc. continued to explore the Jualin Mine. Drilling on the property since exploration began in 1987 has amounted to more than 24,400 meters (80,000 feet). Although Placer withdrew from the project at yearend, other companies were expected to continue working there in 1992.

Early in 1991, Tri-Valley Corp., of Bakersfield, CA, formed a unique joint venture with TsNIGRI (Central Research Institute of Geologic Prospecting for Base and Precious Metals) of Moscow. Tri-Valley, which controls a large area of claims in the Richardson mining district 113 km (70 miles) southeast of Fairbanks, was approached by TsNIGRI in 1990. TsNIGRI was looking for a large, varied U.S. property like Tri-Valley's on which to demonstrate its expertise and unique exploration techniques applicable to the discovery of blind or hidden ore bodies. A Russian field crew spent the summer in the Richardson claims area. However, regulatory and political obstacles delayed the completion of crucial work until 1992.

A report⁶ was published summarizing a 1-year effort by Federal, State, and private interests to establish contacts with the neighboring Siberian mining industry. The report summarizes the results of visits by the U.S. team to Siberian gold fields and a reciprocal visit by Soviet mining personnel to Alaska. The report also reviews the history, geotechnical, and climatological settings of the eastern U.S.S.R., the mining industry in Magadan Oblast, Soviet surface and underground mining and processing techniques, and recent developments in these fields. The applicability of Soviet placer technology to Alaska is discussed. Pertinent Soviet technical references are included.

Arizona.—About one-quarter of the gold recovered in Arizona annually is recovered as a byproduct of copper mining; the remainder was recovered from several lode mining operations, the largest of which was Cyprus Gold Co.'s Copperstone Mine near Quartzite in LaPaz County. Copperstone, first opened in 1987 and operated by Cyprus Copperstone Gold Corp., is an open pit facility employing milling and heap leaching plus CIP recovery methods; operation of the heap-leaching facility was begun in 1991. Gold production during the year amounted to about 3,800 kg (112,000 ounces). In an effort to replace rapidly depleting reserves at the mine, the company was reportedly conducting exploration at its newly acquired Bronco Verdestone Oakland property in neighboring Yuma County.

Following construction delays during 1990, South Atlantic Ventures Ltd. began operation at its Oracle Ridge Mine in late February. Oracle Ridge, primarily a copper mine, also produces gold and silver as byproducts. During 1991, the property was expected to yield about 50 kg (1,540 ounces) of gold and 560 kg (18,000 ounces) of silver.

Underground mining was begun in early 1991 at the small but high-grade Mystic Mine. Milling of stockpiled ore began on-site at the end of the year. The owner, Fischer-Watt Gold Co. Inc., holds a 100% operating interest in the mine,

about 19 km (12 miles) north of Sun City in Maricopa County.

In October, Republic Goldfields Inc., formerly Mylartic Hygrade U.S. Inc., completed the first full year of production at its underground Congress Mine in Yavapai County. Also in Yavapai County, in the Big Bug District, gold-silver-copper concentrate shipments were begun in July from the newly reopened McCabe Mine. The initial 3-year mining plan at the underground operation reportedly called for the production of about 270,000 metric tons (300,000 short tons) of ore containing about 2,800 kg (90,000 ounces) of gold, 11,000 kg (350,000 ounces) of silver, and 725 metric tons (1.6 million pounds) of copper during the 3-year period. The mine is operated by Magma Gold Ltd., a newly organized gold mining subsidiary of Magma Copper Co. of San Manuel, AZ.

Gold exploration and mine development continued at a number of sites in Arizona during the year. Pima Mining, formerly Wounded Bull Resources NL, continued exploration and permitting activities at its Newsboy property near Wickenburg in Maricopa County. The company expects to bring the property into production in 1992.

In southeastern Cochise County, venture partners Placer Dome U.S. Inc. and Oneida Resources Inc. continued exploration work on their Mexican Hat project. However, ore reserves developed during an earlier drilling program were believed to be insufficient under existing market conditions. Work was continued on the Yarnell property in Yavapai County as the new owner, Bema Gold Corp., made plans to begin production in 1992 at a rate of about 1,000 kg (32,000 ounces) per year.

California.—The State of California was, for the fifth consecutive year, the Nation's second largest gold-producing State.

In Imperial County, Goldfields Mining Corp. celebrated the pouring of the millionth ounce (31.1 metric tons) of gold produced at its Mesquite Mine near Brawley. Mesquite began open pit and

heap-leaching recovery at the site in early 1986. The April celebration coincided with the opening of the company's "Mesquite Mine Overlook Trail," a self-guided, 1.3-km (0.8 mile) trail that introduces the public to the gold mine and its unique desert environment. The trail, a cooperative effort between Goldfields and the U.S. Bureau of Mines, is marked with numbered posts corresponding to printed information on plant life, environmental protection measures, the mining process, and surrounding geological features. To the east, and also in Imperial County, Glamis Gold Corp. continued its surface mining operations at the Picacho Mine, concentrating on expanding the capacity of its heap-leaching and gold recovery facilities. By late 1991, gold production at the mine had reportedly been increased by almost 60% over that of the previous year. The first full year of mining operations at the company's open pit Yellow Aster Mine in the Randsberg District of Kern County were completed in midyear. Glamis continued engineering and design activities at its nearby Baltic Project, where mining is scheduled to begin in mid-1992. In April, Glamis completed mining operations at its Alto Mine in Calaveras County. Leaching of the remaining ore and site reclamation were continuing at yearend. At Lac Minerals Ltd.'s wholly owned Colosseum Mine in San Bernardino County, 1991 gold production amounted to 1,907 kg (61,310 ounces). An active revegetation program was continued and included a new cactus reclamation project that involved thousands of yucca and agave cacti transplants and seed test plots.

Mining at Homestake's McLaughlin Mine yielded 8,172 kg (262,719 ounces) of gold during 1991, 2% less than that produced during the previous year. During the year, the mine received several commendations, including an award from the U.S. Bureau of Land Management, for innovative waste containment, reclamation, and environmental practices. The mine, near Lower Lake, about 113 km (70 miles) north of San Francisco, is the site of the first successful commercial application of

the autoclave process technology for the extraction of gold.

Two new gold mines reached the final development stages before entering the planned startup phase in early 1992; Viceroy Gold Corp.'s Castle Mountain Project in San Bernardino County and Amax Gold's Hayden Hill Mine in Lassen County were projected to produce annually about 3,100 kg (100,000 ounces) and 4,500 kg (145,000 ounces), respectively. At yearend, several other gold properties were in various stages of exploration or preproduction development.

A new California State law was signed in November eliminating the use of plastic pipes as mining claim markers. The new law specifies that only wood, stone, solid metal, or capped metal pipe markers can be used to mark claims on Federal lands in the State. The law also reduces the number of markers required for outlining a claim to five. Plastic or PVC pipe markers were determined to pose a potential wildlife entrapment hazard.

Colorado.—Gold mine production in Colorado declined for the fourth consecutive year, as lower metal prices and higher costs at Colorado's mostly underground mines led to closure or suspension at several operations producing during the previous year. Some projects under development were also delayed from opening. Among the mines affected by weaker gold prices were the Sunnyside Mine at Silverton, in San Juan County, closed in August by the owners, the San Juan County Mining Venture. Sunnyside production during the year amounted to 100 kg (3,228 ounces). The Alma London Venture near Fairplay, in Park County, was temporarily closed following the completion of an exploration drifting and surface drilling project by partners Alma American Mining Corp., Cobb Resources Corp., and American Boulder Gold Inc.

At Galactic Resources' Summitville Mine near Del Norte in Rio Grande County, all economic ore was mined out and placed on the leach pad by October. The company expected that leaching of

the ore would continue through the first half of 1992. Detoxification of the leach pad was expected to begin at the end of the first quarter of 1992 with reclamation of the heap to follow. Site reclamation had been an ongoing process with substantial reclamation activities occurring during 1990 and 1991. Gold production during 1991 amounted to 1,865 kg (59,978 ounces).

On the positive side of the ledger, Battle Mountain Gold Co. poured the first bar of production gold at its new open pit San Luis Mine, near the town of San Luis, in Costilla County. The new mining and milling operation recovered 684 kg (22,000 ounces) of gold and 435 kg (14,000 ounces) of silver during 1991. A series of startup problems continued to hamper operations for most of the year. Battle Mountain expected to recover almost kg (70,000 ounces) of gold and more than 1,200 kg (40,000 ounces) of silver during 1992. The mine employed 105 people with an annual payroll of \$3.5 million.

In Teller County, the Cripple Creek and Victor Gold Mining Co, a joint venture of Pikes Peak Mining Co., a wholly owned NERCO subsidiary, and Golden Cycle Gold Co. resumed mining of its Ironclad and Globe Hill properties in the Cripple Creek District and initiated crushing and leaching of newly mined ore near yearend. The joint venture continued evaluating its new Cresson Valley Project. Exploration drilling during 1990 and 1991 identified more than 62 metric tons (2 million ounces) of total gold reserves and deposits for the joint venture. In March, the partners marked the 100th anniversary of gold mining in the Cripple Creek District. All metal production during the year came from the Mine Dump Program and amounted to 483 kg (15,519 ounces) of gold and 326 kg (10,475 ounces) of silver. Under the mine Dump Program, dump material from old mines in the district, including the old Cresson Mine, is collected, crushed, and processed by heap leaching. Similarly, Solution Gold Inc. of Golden was also reportedly engaged in reclaiming and reprocessing

dumps in the Central City District in Gilpin County.

Legislation was enacted in Colorado during 1991 removing the ceiling on reclamation security bond requirements from small miners and giving local government and the public greater participation in the permitting process.

Gold occurrences of Colorado were detailed in a study published by the Colorado Geological Survey.⁷ The study discusses both Colorado's well-known deposits and more recently described occurrences, including hot-spring-and detachment-fault-related gold. Gold-bearing proterozoic massive sulfide deposits are discussed, and current theories on the tectonic setting and history of Laramide-Tertiary age gold deposits are presented. Production data for selected Colorado mining districts and an extensive bibliography are included.

Idaho.—Exploration activity in Idaho during 1991 declined about 50% from that of the previous year, according to a review of State activities prepared by the Idaho Geological Survey.⁸ The principal target of the 42 advanced exploration projects in Idaho was gold. Only two of six properties scheduled to begin production in 1991 actually reached maturity.

The two new gold mines beginning production during the year were Pegasus Gold's Black Pine Mine and U.S. Antimony Corp.'s (USAC) Yellow Jacket Mine. Changes in the mine plan and subsequent delays in regulatory approval put off startup at the Black Pine operation from midyear to late fall. Mining of ore began at the Black Pine, in Cassia County, with production from the Tallman pit crushed and loaded on the finished portions of the leach pad. Commercial metal production was not achieved until soon after the beginning of the new year. Black Pine was expected to yield about 1,900 kg (60,000 ounces) per year when fully operational. In Lemhi County, USAC opened its Yellow Jacket Mine in May following a period of operational fine-tuning at the new mill.

In Valley County, Hecla completed mining at its Yellow Pine Unit east of

Yellow Pine. The mine produced 546 kg (17,542 ounces) of gold during 1991. Leaching of the existing heaps was expected to be completed during 1992 for a projected 1992 yield of about 160 kg (5,000 ounces) of gold. During 1991, the Yellow Pine Unit was awarded the State of Idaho's "Excellence in Operation Award" for its environmental stewardship. Seasonal mining of ore at the nearby Stibnite Mine was begun in June by the mine's new owners, MinVen Gold Corp. Modification by MinVen to the plant facilities was expected to increase seasonal production to about 930 kg (30,000 ounces) per year. Idaho Gold Corp., an 85%-owned subsidiary of Bema Gold Corp., continued open pit mining and heap leaching at its Champagne Mine, 32 km (20 miles) west of Arco, in Butte County.

New gold mines that were earlier expected to begin production during 1991 but were delayed by low gold prices and permitting problems, included the following properties: FMC's Beartrack property near Salmon in Lemhi County; Grouse Creek Mining Corp.'s Grouse Creek Mine near Stanley in Custer County; Idaho Gold's Buffalo Gulch property near Elk City, Idaho County; and NERCO's Stone Cabin property in Owyhee County. NERCO's large open pit Delamar Mine, 8 km (5 miles) from the Stone Cabin property, produced 1,150 kg (37,000 ounces) of gold and almost 53 metric tons (1.7 million ounces) of silver during 1991.

Montana.—According to an annual review of mining development, prepared by the Montana Bureau of Mines and Geology,⁹ 207 exploration licenses were active in the State during 1991, up 14 from the previous year. As in recent years, the primary exploration target was gold but interest in other metals, such as copper, lead, and zinc, was increasing. The increase in exploration licenses apparently reflected a sharp increase in activity by private individuals in place of established corporate interests that dominated exploration in earlier years. All mineral activity in Montana, whether on private, State, or Federal land, is

regulated by the Montana Department of State Lands under three classes of permits—Small Miner Exclusion licenses, exploration licences, or operating permits. Despite a 42% increase in gold production, Montana retained its rank as the Nation's fourth largest gold-producing State.

Montana's leading gold-producing company, Pegasus Gold, began the year with four producing gold mines. During the last quarter, however, continuing weakness in the gold price forced Pegasus to suspend operations at its Basin Creek Mine in Lewis and Clark County. Mines remaining in operation were the Zortman-Landusky Mine in Phillips County; the Beal Mountain Mine south of Butte in Silver Bow County; and the Montana Tunnels gold, lead, silver, and zinc mine, 37 km (23 miles) south of Helena in Jefferson County. Production at the Zortman-Landusky operation, which consists of two separate surface mines several kilometers apart, established a new record for both gold and silver production at 3,617 kg (116,300 ounces) and 29,700 kg (954,000 ounces), respectively. The production increase was attributed to higher ore grades and an increase in tons mined from 11.8 million metric tons (13 million short tons) in 1990 to 12.9 million metric tons (14.2 million short tons) in 1991. Pegasus reduced its cash operating costs during 1991 to \$214 per ounce, from \$225 per ounce in the previous year. Gold grades of ore-in-process on the Landusky side of the dual mine operation were reported to be 0.51 gram per metric ton (0.015 ounce per ton), well below the cutoff grade at many similar operations elsewhere. Heap-leaching recovery methods are used at Zortman-Landusky. At the Beal Mountain Mine, Pegasus constructed 93,000 square meters (1 million square feet) of new leach pad area and doubled the capacity of its treatment plant. Production during the year amounted to 1,471 kg (47,300 ounces), down 5% from that of the previous year. Following last year's modification to the mining plan and treatment plant, gold production at the company's Montana Tunnels Mine rose 6% to 1,928 kg

(62,000 ounces), while operating costs were trimmed by 10%.

In Southern Jefferson County, production at Placer Dome's 100%-held Golden Sunlight Mine declined 18%, to 2,487 kg (79,963 ounces), primarily owing to mining of lower grade transitional ore. The complex metallurgical characteristics of the ore also led to lower recovery rates. The transition to higher grade ores was expected to result in an increase in production during 1992. In Fergus County, Canyon Resources Corp. completed its first full year as owner of the Kendall Mine. Improvements implemented under Canyon resulted in production of 1,775 kg (57,070 ounces) of gold, nearly double that of the previous year. Exploration during the year at Canyon's 27.6%-held Seven-up Pete Joint Venture in Lewis and Clark County led to the discovery on the partner's McDonald Meadows property of a sizable gold deposit with a geologic reserve estimated at yearend to contain about 168 million metric tons (185 million short tons) grading 0.96 gram per metric ton (0.028 ounce per short ton). Near Maiden, in Fergus County, Blue Range Mining Co. reportedly produced a small amount of high-grade ore from its McGinnis property adjacent to the now dormant Spotted Horse Mine. The company's Geis and Gilt Edge Mines did not produce during 1991. East of Jardine in south-central Park County, Homestake and TVX Mineral Hill Inc. produced about 1,330 kg (42,700 ounces) of gold at their jointly held Mineral Hill Mine. To minimize the environmental impact by mining on the environmentally sensitive area north of Yellowstone National Park, mining is conducted underground and a dry tailings system is employed to help maintain the zero discharge design of the surface milling and recovery facilities. Because the Mineral Hill project is within the historic town of Jardine, the company works closely with the State Historic Preservation Office to ensure preservation of the town's cultural resources. Precautions were also taken to minimize the impact on wildlife by the project. As part of a longer term exploration

program, drilling was continued on patented and U.S. Forest lands held by the joint venture in the Crevasse district east of Jardine.

Exploration and preproduction development work was continued during the year at a number of properties associated with or within the same districts as most of the aforementioned producers. Similarly, many generally small, intermittent placer mines were active, mostly on a seasonal basis, during 1991.

Nevada.—America's continuing position as one of the world's largest gold-producing nations depends on, to a certain extent, developments in the State of Nevada. Nevada, by far the Nation's dominant gold-producing State, produced 39% of the national total. Fourteen of the Nation's leading 25 gold mines in 1991 were in Nevada. Gold is the State's principal mineral commodity, accounting for 87% of the value of its nonfuel mineral output during 1991.

Newmont Gold Co. (NGC), the Nation's dominant gold-producing company, produced about 49,100 kg (1.58 million ounces) from its mining operations in Eureka and Elko Counties. NGC's total production during the year was derived from four surface mines feeding five nearby mills and three heap-leaching facilities. The company's total cash cost of production was reduced to \$203 per ounce during 1991 compared with the previous year's average of \$218 per ounce. Proven and probable ore reserves on NGC's Nevada properties increased by 6% to 625 metric tons (20.1 million ounces), the second largest ore reserve position on the continent. In December, the company's open pit Gold Quarry Mine became the first mine in North America to produce more than 1 million ounces of gold (31.1 metric tons) in a single year. The Gold Quarry Mine was commissioned by NGC in 1985, and during that year it produced 3,312 kg (106,500 ounces). It is the largest of the company's 16 deposits generally centered around the town of Carlin in northern Eureka County. During the year, NGC researched methods to treat its large

resource of refractory ores. A decision was made in midyear to build a roasting plant in conjunction with its existing mill facilities in the company's south area of operations at Carlin. The company's research into bioleaching of low-grade gold-bearing refractory materials advanced during the year to the stage where patent protection was sought.

During 1991, the Goldstrike Mine, of American Barrick Resources Corp. adjacent to NGC's Eureka County operations, set records for mining and gold production, exceeded design capacity for autoclave and mill throughput, and achieved greater-than-anticipated cost reductions. The mine moved 116 million metric tons (128 million short tons) of ore and waste during the year, recovering 16,927 kg (546,146 ounces) of gold. Goldstrike was expected to yield 28,000 kg (920,000 ounces) of gold during 1992. Of the total 1991 production, 59% was recovered using heap leaching, while the remainder came from milled oxide and sulfide ores. The company's Betze open pit was the principal source of ore. The company's new autoclave unit completed its first full year of operation, exceeding its design capacity by 32%. Barrick expected to have three additional autoclaves on-line by early 1993, thereby completing its 4-year Betze Development Plan, begun in 1989.

In Elko County, northeast of the Goldstrike-Carlin Operations, partners Independence Mining Co. Inc. and FMC Gold Co. achieved the highest level of gold output at their Jerritt Canyon Mine since production began in 1981; production for the year amounted to about 11,700 kg (376,700 ounces). Exploration during 1991, especially at the New Deep deposit, 11 km (7 miles) west of the mill site, led to a 33% increase in gold contained in proven and probable reserves.

Overall, 15 separate gold deposits have been discovered in the area comprising Jerritt Canyon operations; two deposits have been depleted since mining began in 1981. Independence continued open pit mining operations at its wholly owned Big Springs Mine, 16 km (10 miles) north of Jerritt Canyon. Other mines

operating in Elko County during 1991 included Dee Gold Mining Co.'s open pit Dee Mine, which produced 1,308 kg (42,046 ounces) of gold during the year, and Ivanhoe Gold Co.'s new Ivanhoe (Hollister) Mine, which completed its first full year of operation, producing 1,865 kg (59,978 ounces) of gold.

To the west, in Humboldt County, Santa Fe Pacific Gold Corp. poured its first bar of production gold at its new Lone Tree Mine southeast of Golconda. The company expected the new open pit facility to produce about 870 kg (28,000 ounces) of gold during 1991 and about 31,00 kg (100,000 ounces) of gold annually thereafter. In August, Santa Fe's nearby Rabbitt Creek Mine completed its first full year of production, producing about 3,600 kg (115,500 ounces) during the calendar year.

Twenty-two km (14 miles) southwest of the town of Battle Mountain, in Lander County, Battle Mountain Gold Co. (BMG) reported gold production of about 7,600 kg (244,000 ounces) from its open pit and milling and heap-leaching operations. Most of the gold produced during the year was derived from the company's Fortitude Mine and from satellite ore bodies. BMG's Copper Canyon heap-leaching facility completed its first full year of production, recovering about 310 kg (10,000 ounces) of gold. To the southeast, St. George Metals Inc. continued preparations to reopen its underground Dean Mine. Production at the Dean was expected to begin in mid-1992.

Twenty five km (16 miles) south of the BMG complex, Echo Bay set a new production record of more than 8,800 kg (284,327 ounces) at its McCoy and Cove gold and silver property. McCoy and Cove consists of large-scale surface and small-scale underground mines using milling and heap-leaching recovery methods. Mining was completed in the McCoy pit in early 1991, but subsequent exploration discovered additional ore that will be recovered when underground mining beneath the pit is completed. Echo Bay's cash costs per ounce of gold produced at McCoy-Cove during 1981 was \$253, compared with \$270 in 1990.

Echo Bay also owns a 50% interest in the open pit Round Mountain Mine at Round Mountain, about 190 km (120 miles) to the south of McCoy-Cove. The company's partners at Round Mountain are Homestake (25%) and Case Pomeroy (25%). During the year, gold production at the facility, all recovered by heap leaching, amounted to 10,543 kg (339,000 ounces), compared with 15,027 kg (483,192 ounces) in the previous year. The lower production was attributed to lower ore grade. The Round Mountain Mine is operated by Round Mountain Gold Corp.

West of Round Mountain near Gabbs, also in Nye County, FMC Gold Co.'s Paradise Peak gold and silver mine celebrated the February pouring of its millionth ounce of gold (31.1 metric tons) since beginning production in early 1986. The quantity of ore processed at Paradise Peak by milling and heap leaching rose sharply during the year; however, because ore grades continued to decline as the pit expanded, gold production declined 9% to 5,660 kg (182,000 ounces). Silver production declined sharply to 2.3 million ounces, reflecting the depletion in 1990 of the mine's high-grade silver ore. Near Beatty in southern Nye County, U.S. Nevada Gold Search Joint Venture completed mining at its Mother Lode Mine. Other gold and silver mines continuing operations in the Beatty area included the Bullfrog Mine, Gold Bar Mine, and the Sterling Mine.

North and west of Ely in White Pine County, U.S.M.X., Inc. continued to produce gold from its Alligator Ridge, Casino, and Green Springs Mines and began production at its Winrock Mine. Development of the company's Yankee Project began in September, and contract mining was begun in October. Metal production at Yankee was expected to begin by mid-1992.

Numerous other mines throughout the State continued to produce gold. Several mines were at various stages of preproduction, and several other properties were closed owing to depletion or unacceptable economic factors.

A paper published by the Bureau during 1991¹⁰ evaluated the factors

responsible for the tremendous resurgence of Nevada gold production over that of neighboring California. It was noted that the contrasting levels of success are not an effect of geologic favorability, but rather of differences in the political and regulatory climates between the two States.

Oregon.—According to a State report¹¹ on mining and exploration in Oregon, there were no primary lode gold mines producing in Oregon during the year. There were, however, several active placer mines, including Bonanza Mining Co.'s mine on Pine Creek in Baker County.

In early 1991, Formosa Exploration Inc. reportedly began mining gold- and silver-bearing zinc and copper ore at its underground Silver Butte Mine in Douglas County near Riddle. Owing to a forest fire hazard the mine was reportedly forced to close near yearend.

Though exploration was continued at a number of gold properties during the year, concern over the regulatory future affecting both exploration and future development reportedly contributed to a decline in exploration generally. More companies terminated Oregon projects in 1991 than initiated projects. Concern over regulations was heightened during the year when the State legislature passed a House bill referred to as the Chemical Process or Cyanide Heap Leaching bill. The measure overhauled the State's mining regulations by proposing a number of administrative changes, including a lengthy permit process and backfilling of open pits in special cases. At yearend, the State Environmental Quality Commission determined that objectionable aspects of the proposed ruling on chemical process mining will be subject to technical review by a third party.

Delays in permitting at Atlas Corp.'s Grassy Mountain project in Malheur County were reportedly related to the regulatory climate. Atlas had originally expected to begin mine construction at Grassy Mountain in 1992. The mine, as originally envisioned, was to produce more than 3,100 kg (100,000 ounces) of

gold per year and provide employment for almost 200 people from the largely agricultural area surrounding the site.

A 100-year-old ditch built by Chinese laborers in their search for gold near Myrtle Creek, in Douglas County, was listed on the National Register of Historic Places. The Bureau of Land Management announced in late July that 18 km (11 miles) of China Ditch had been listed on the register in recognition of the most ambitious and longest water diversion for gold placer mining in western Oregon.

South Carolina.—As in previous years, gold production data for South Carolina have been withheld in this publication to avoid disclosing company proprietary data. South Carolina's principal gold mines in operation during the year were the Ridgeway Mine in Fairfield County, the Haile Mine in Lancaster County, the Brewer Mine in Chesterfield County, and the Barite Hill Mine in McCormick County.

Brewer Gold Inc., a subsidiary of Westmont Mining Inc., temporarily ceased mining activities at the Brewer Mine in late 1990 following the failure of an earthen tailings dam at the mine site. Following construction of a new dam, mining operation were resumed in mid-1991.

South Carolina's largest gold mine, the Ridgeway Mine of Ridgeway Mining Co., a joint venture between RTZ and Galactic Resources Ltd., produced 4,406 kg (141,665 ounces) of gold during the year. The mine, comprising two open pits 1.6 km (1 mile) apart, recover gold by conventional milling and carbon-in-leach processing. Difficulties in compensating for harder ore from the north pit resulted in an 18% decline in production from that of the previous year. Ridgeway is the largest gold mine in the Eastern United States.

At the Haile Mine near Kershaw, Piedmont Mining Co. ceased mining and heap stacking activities in August to prepare for the resumption of mining on a much larger scale in 1992. Leaching and gold recovery operations were continued into 1992. Production for the

year was 327 kg (10,517 ounces), compared with 697 kg (22,402 ounces) in 1990. In March, Piedmont signed an agreement with Amax Gold Exploration Inc., a wholly owned subsidiary of Amax Gold. An exploration program begun in April resulted in a 130% increase in minable ounces of gold on the Haile property.

In March, the first bar of production gold was poured at the new Barite Hill Mine near McCormick, about 19 km (12 miles) north of Augusta, GA. The new open pit and heap-leaching facility, the State's fourth producing gold mine to be opened in recent years, is expected to yield about 640 kg (20,500 ounces) of gold and more than 1,900 kg (61,000 ounces) of silver per year. Barite Hill was developed by Gwalia (U.S.A.) Ltd., a subsidiary of Gwalia International Ltd. of Australia. The mine is surrounded by several long-abandoned gold mines, including the old Dorn Mine, which produced gold between the 1850's and 1930's.

Gold exploration was conducted on a moderate scale elsewhere in South Carolina as well as in several other southern States from Virginia through Alabama.

South Dakota.—Despite greater gold production in South Dakota during 1990 and 1991 when compared with that of 1989, lower gold prices and higher production costs severely impacted tax revenues for the State from gold mining. Combined tax revenues reportedly decreased 35% during the 1990 and 1991 period. Gold is the principal mineral commodity produced in South Dakota.

The State's principal gold-producing mine is the Homestake Mine at Lead. Except for a brief period during World War II, the mine has been operating continuously under the same ownership since 1877. Total cumulative production surpassed 1,135 metric tons (36.5 million ounces) in 1991, thus making the mine one of the most productive gold operations in the world. The operations at Lead include an underground mine; an open pit, known as the Open Cut, on-site of the original gold strike in 1876; a mill;

and a gold refinery. During the year, Homestake produced 9,924 kg (319,080 ounces) or 18% less than that in the previous year. The decline was attributed to a 17% drop in tons of ore mined underground together with an 11% decline in underground ore grade. A temporary shortage of experienced miners reduced the ability of the company to adjust operations to adequately compensate for the grade shortfall. To offset the tonnage loss during the year from the underground mine, lower grade Open Cut ore was supplied to the mill to maintain full milling rates. As a result, average grade processed through the mill dropped 15%, and the gold recovery rate was slightly lower. During the year, Homestake increased its total annual milling capacity by 8% to 2.54 million metric tons (2.8 million short tons). The \$11 million mill optimization effort was expected to increase future production by about 950 kg (30,000 ounces) annually. The company continued to work on its new North Homestake Project, and an exploration tunneling program that was begun in 1990 to explore deep gold mineralization discovered earlier about 5 km (3 miles) north of the existing workings. Tunneling was advanced about 1,500 meters (4,900 feet) during the year and, at yearend, stood at a total of more than 2,000 meters (6,600 feet).

South Dakota's second largest gold mine, Wharf Resources (USA) Inc.'s Annie Creek-Foley Ridge property, reportedly produced a record 2,910 kg (93,569 ounces) of gold during 1991. The open pit and heap-leaching operation is 5 km (3 miles) west of Lead. Cold weather conditions during February and March curtailed leaching operations at the Golden Reward Mine, 13 km (8 miles) southwest of Lead. The operator, Golden Reward Mining Co., is a joint venture between MinVen Gold and United Coin Mines Ltd. During 1991, the owners agreed in principle to merge United Coin into MinVen. The mine, a seasonal operation, is scheduled to produce 2,020 kg (65,000 ounces) during 1992 with production planned to increase to 2,490 kg (80,000 ounces) by 1994. At MinVen's 100%-held Gilt Edge Mine 8

km (5 miles) southwest of Lead, also an open pit and heap-leaching operation, production during the second quarter was adversely affected by unusually heavy rainfall, which damaged the solution containment system. Permanent repairs were completed by the end of the third quarter.

Bond Gold Richmond Hill Inc. reported recovering 1,300 kg (41,815 ounces) of gold during the year at its Richmond Hill property 8 km (5 miles) northwest of Lead. Exploration activities were concentrated around the open pit with an emphasis on the development of minable ore reserves. These efforts have been so far unsuccessful. The mine's existing reserves are expected to be mined out in 1992, but heap leaching will continue until the heaps are depleted of metal.

Following several years of test processing, production was resumed at the Red-Ex placer mine along Whitewood Creek near Deadwood. The mine, operated by Dakota Placers Inc., is expected to recover about 310 kg (10,000 ounces) of gold per year plus values in silver when fully operational. The Whitewood Creek Tailings Project in Butte, Lawrence, and Meade Counties was placed on hold by the owners, Goldstake Explorations (SD) Inc., pending an improvement in gold prices.

In mid-1991, the final draft of the Cumulative Environmental Evaluation (CEE) on mining in the Black Hills was submitted to the State Board of Minerals and Environment. The CEE, part of the State's Environmental Act, was conducted in conjunction with a 2-year moratorium on new mines beginning in February 1990. The CEE proposed a 2,430-hectare (6,000 acre) limitation on large-scale surface gold and silver mining in the Black Hills and a requirement that, by 1997, major mining companies reclaim 200 hectares (500 acres) of land disturbed by mining. Other recommendations call for reporting requirements, protection of critical resources, financial assurances for cyanide cleanup, and development of post-closure plans.

Utah.—Kennecott Corp.'s Bingham Canyon Mine continued to be one of the Nation's principal gold- and silver-producing mines, ranking third in the Nation in gold production during 1991. The mine, owned by RTZ and operated by Kennecott, produces gold and silver as byproducts of its copper mining activities. During the year, Kennecott studied the feasibility of expanding its on-site smelting capacity to handle all of its concentrate production, a part of which has been sold for processing elsewhere in recent years. A decision to build a new smelter was announced during the first quarter of 1992. Kennecott also operates the new Barney's Canyon gold mine about 6.4 km (4 miles) north of the Bingham pit.

The Mercur Mine of American Barrick in Tooele County achieved its fourth consecutive year of record production in 1991. The mine's new dump-leaching facilities registered a 58% increase in production from that of the previous year. Gold recovered from milled oxide and sulfide ores declined somewhat from that of the previous year. Total gold production from Mercur's two open pits amounted to 3,958 kg (127,280 ounces) during the year.

About 65 km (40 miles) northwest of St. George in southwestern Utah, Tenneco Minerals continued surface and heap-leaching operations at its Goldstrike Mine. Production at Goldstrike amounted to about 1,400 kg (45,000 ounces) during 1991.

Washington.—Although U.S. Bureau of Mines figures for Washington gold production have been largely withheld over the past decade to avoid disclosing company proprietary data, the Washington State Division of Geology and Earth Resources, in its annual review of the State's mineral industry,¹² noted that gold production increased again in 1991 as it has nearly every year since 1985. The report also noted that accompanying the increase in production, acquisition of mining properties in the State and expenditures for detailed evaluations of these properties during

1991 appeared to have increased relative to those of the previous year.

Gold production at the Cannon Mine, Washington's largest gold mine and the Nation's second largest underground gold mine, amounted to 4,726 kg (152,010 ounces) during 1991; silver production totaled 8,439 kg (271,352 ounces) during the same period. Cannon is a joint venture between Asamera Minerals (U.S.) Inc. and Breakwater Resources Ltd. During 1991, an exploration drift was being driven to intersect gold mineralization discovered by earlier drilling and to confirm drill-indicated reserves. Asamera also conducted exploration on properties that it holds in the Wenatchee area.

At Republic in Ferry County, Hecla's underground Republic Unit, or Knob Hill Mine, produced 2,418 kg (77,736 ounces) of gold and 9,686 kg (311,445 ounces) of silver in 1991, all from the Golden Promise area of the mine, which was discovered in 1984 just prior to the mine's closure owing to exhaustion of reserves. Gold production costs at Republic, among the lowest in the Nation, especially for an underground mine, amounted to \$140 per ounce in 1991. In August, Hecla completed a new decline-ramp connecting the Golden Promise area of the mine to the surface. The decline allows the use of diesel rubber-tired vehicles for loading and hauling ore directly to the surface. Hecla, using the new decline as an exploration base and recognizing the potential for the discovery of additional ore at Republic, embarked in 1991 on an extensive underground exploration program. In anticipation of further discoveries, preliminary engineering work was begun to nearly double the capacity of the mill, if and when new ore is located.

In February, Echo Bay completed its first full year of production at its new Kettle River project near Republic. Production for the full year 1991 amounted to 1,965 kg (63,191 ounces). The project has been developed as a joint venture between Echo Bay, the operator, and Crown Resources Corp. The project, scattered over 5,700 hectares (14,000 acres), has been developed

around five separate deposits. The fifth deposit, the Lamefoot property, was added in late 1991. The Kettle and the Overlook deposits provided mill feed during the year. Both deposits are mined from underground with access provided by decline ramps.

At the Crown Jewel deposit in Okanogan County, joint owners Battle Mountain Gold, the operator, and Crown Resources, conducted extensive drilling focused on delineating the extent of the deposit's gold mineralization. The partners also initiated the process of mine permitting in preparation for mining. Crown Jewel is part of a 3,240-hectare (8,000 acre) property package known as the Crown Jewel Exploration Project. Gold exploration in Washington generally was concentrated in Chelan, Ferry, Okanogan, and Stevens Counties. Of the 106 metallic mineral properties accounted for by the State in its 1991 review, gold was shown to be the primary or secondary target at 90 exploration or development sites. (See tables 3 through 7.)

Consumption and Uses

The use of gold in the domestic market shown in table 9 accounts for only part of the overall market for commercial products. An important segment of market demand is also satisfied by imported gold-bearing products in various forms ranging from unfinished jewelry products, such as gold chain and findings, to electronic equipment containing gold components.

The volume of gold futures traded on the Nation's gold futures exchanges during 1991 declined substantially from that of 1990, owing, in part, to apparent investor disinterest.

Contracts for gold futures traded during 1991 represented about 21,200 metric tons (680 million ounces) compared with those of the previous year, when the equivalent of more than 30,000 metric tons (973 million ounces) was traded. The New York-based Commodity Exchange Inc. (COMEX) was, as in the previous year, by far the dominant exchange.

Sales of newly minted gold coins by the U.S. Mint declined for the third consecutive year. On October 20, the fifth anniversary of the American Eagle gold bullion coin program, the U.S. Mint had sold 168 metric tons (5.4 million ounces) of contained gold, all sourced, as mandated in the enabling legislation, from contemporary domestic gold mines.

Although gold loan activity between commercial depository banks and gold producers generally seemed to have peaked in 1988, it continued to be an acceptable method of financing new mine development or expansion of existing facilities.

Stocks

Yearend stocks of refined bullion held by industrial users increased about 6% over those held at the end of 1990. On a quarterly basis, the greatest decline in industrial stocks was reported during the first quarter of the year and may reflect a withdrawal of material by manufacturers to meet anticipated demand, especially for jewelry products destined for sale later in the year.

Yearend stocks of gold certified for delivery by COMEX, the Nation's largest futures exchange, were essentially unchanged from those held at the end of the previous year.

Markets and Prices

The Engelhard industries/London daily final price of gold ranged from a high of \$404 per troy ounce at the beginning of the war in the Persian Gulf in mid-January to a low of \$345 per ounce in mid-September, its lowest level in more than 5 years. Uncertainty arising from the continuing turmoil in the U.S.S.R. and reports regarding the size of the U.S.S.R. bullion reserves led to a yearend rally that drove the price above \$370 per ounce.

Efforts by the European Commission to require all measurements to conform to the Commission's harmonization policy reportedly were defeated in 1991 by the Bank of England and the London Bullion Marketing Association. The opponents

successfully argued that the troy system of measurement does not easily translate into metric and should therefore be retained for use in the gold and other precious-metals markets.

Foreign Trade

Total U.S. exports of refined gold increased for the third consecutive year. Switzerland was again the principal recipient nation, receiving large quantities of both refined bullion and doré. In addition to Switzerland, Hong Kong and the United Kingdom were also principal destinations for refined bullion shipments.

The surge in late 1991 in total imports was due in part to late 1991 changes in the Customs User Fee as discussed earlier under "taxes." (See tables 8 through 11.)

Canada continued, as it has for more than a decade, to be the Nation's principal source of refined bullion. Imports of refined Canadian bullion during the year increased almost threefold, while similar imports from Uruguay and Brazil increased fivefold and twentyfold, respectively. (See tables 12 and 13.)

World Review

For the 12th consecutive year, world gold mine production has exceeded that of the previous year. In 1991, however, the growth rate slowed appreciably compared with the strong growth rates achieved during the mid-1980's.

In its 24th annual statistical review of world gold supply and demand, Gold Fields Mineral Services Ltd. (GFMS)¹³ observed that for the first time since 1983 the total supply of gold to Western World markets fell by more than 3% from supplies available during the previous year. GFMS' review, like reviews prepared by its predecessor, Consolidated Gold Fields PLC, has, for more than two decades, been as the most comprehensive source of world gold supply and demand data available on a comparable annual basis.

In addressing world gold mine production, the GFMS report noted that the slowdown in world production was

due to a variety of factors, including the increasing difficulty in attracting financing for marginal properties, plus the depletion, scaling-back, or closure of some older mines, thereby offsetting gains in new capacity elsewhere. Gold prices, having fallen to the lowest level in real terms since the early 1970's, impacted both investors and gold mines alike. Although many mines were able to adapt to the lower prices through production cost reductions, the savings gained were often accompanied by lower production. GFMS cautioned, however, that the formal gold mining sector's tenacity and its ability to adapt to lower prices has limitations, especially in high-cost underground mines. Without a price increase, the point at which higher cost operations cease to be economic is rapidly approaching, especially at a number of South African mines.

GFMS notes that the use of gold loaned to the market by producers in return for development capital has been a prominent addition to supplies in recent past years, especially 1988. In 1991, however, according to the GFMS report, lower prices, reduced mine development, and other factors reversed the popularity of gold loans and the net affect was, that for the first time, repayments of gold loans exceeded the demand for new loans by 11 metric tons (354,000 ounces). Forward sales added only 51 metric tons (1.6 million ounces) to the overall supply or about 200 metric tons (6.4 million ounces) less than that in the previous year.

Other components of supply assembled by GFMS in its annual report included net sales of gold from centrally planned economy countries, at 226 metric tons (7.3 million ounces), down 47% from those of 1990; official or central bank sales to the market at 105 metric tons (3.4 million ounces) contrasted sharply with those of the previous year when these institutions absorbed 66 metric tons (2.1 million ounces); supplies of old gold scrap added 410 metric tons (13.2 million ounces) to supplies, down 16% from that of 1990; and inferred disinvestment which, according to GFMS, showed the greatest turnaround during 1991, when

the private sector, which absorbed 173 metric tons (5.6 million ounces) in 1990, disposed of 241 metric tons (7.7 million ounces) during 1991. Most disinvestment was attributed to private investors in Europe and the United States.

GFMS reported that gold jewelry fabrication demand rose by 4% in 1991, the fifth consecutive year of rising demand in that sector. The 1991 increase was the result of inventory building by jewelry distributors and retail outlets, mainly in Europe and the Gulf countries. Also noted was a rapid increase in demand in China. For the first time in the annual GFMS series, estimates of fabrication demand for China and the U.S.S.R. were included.

According to the GFMS report, gold usage in electronics and industrial applications, at 147 metric tons (4.7 million ounces), was essentially unchanged from that of 1990. This was attributed to a sharp decline in computer sales and the first sign of weakening military equipment orders. Dental gold usage rose 5%, continuing a trend begun in 1988. Gold use in medals and invitation coins rose 20% to 23 metric tons (734,000 ounces) while gold used in striking official coins, 150 metric tons (4.8 million ounces), rose 32 metric tons (1 million ounces) over that of the previous year.

Although identified bar hoarding rose 12% during 1991, GFMS noted that when the masking effects of unusual events in Brazil during 1990 and 1991 are factored out, demand in this category actually reached its peak in 1989 and declined thereafter.

Capacity.—Rated annual production capacities for gold mines, as of December 31, 1991, are shown in table 14. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time at a normally sustainable, long-term operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes operating plants and plants temporarily closed that, in the

judgment of the author, can be brought into production within a short period of time with minimum capital expenditure.

Because of the size, diversity, and explosive growth of primary gold production over the past decade, comprehensive world capacity data that would include all operating units that contribute to national totals are generally not available. Therefore, in the absence of appropriate data, certain broad assumptions were employed to derive international capacity numbers that are compatible with production data shown in table 15.

Reserves.—Demonstrated U.S. reserves of gold in 1991 were about 4,770 metric tons (about 153 million ounces), and the reserve base was 5,250 metric tons (169 million ounces). Most of the U.S. gold reserve base shown in table 14 is confined to 18 States, with about 80% of the total in Alaska, California, Idaho, Montana, Nevada, and Washington. A dominant portion of the reserve base occurs in lode deposits.

Total world reserves shown in the table approximated 43,000 metric tons (1.38 billion ounces), of which nearly one-half was in the Republic of South Africa. The world reserve base for gold totaled about 49,500 metric tons (1.6 billion ounces). Reserves of gold in the U.S.S.R. were believed to be about 6,220 metric tons (200 million ounces).

Estimates of reserves become available only over an extended period of time. The reserves shown for Australia, Brazil, Canada, and the United States generally reflect post-1980 data and the success of exploration efforts frequently initiated years earlier in response to rising prices. (See table 14.)

Africa.—Despite the continuing burdens associated with weak gold prices, continued currency inflation, and escalating production costs, the Republic of South Africa's gold production fell less than 1% in 1971 to 601,013 kg (19.3 million ounces). Maintenance of this production level was achieved through the use of various cost containment efforts

including, when possible, the mining of higher grade materials, thereby reducing costs associated with mining, milling, and processing. Thus, the gold mining industry milled only 107 million metric tons (118 million short tons) with an average grade of 5.20 grams per metric ton (0.152 ounce per short ton) compared with the previous year's throughput of 111 million metric tons (122 million short tons) bearing 5.05 grams per metric ton (0.147 ounce per short ton). The success of various rationalization or cost containment programs was reflected in a 4.5% or \$14 per ounce decline in cash production costs from those of 1990. Over the past 20 years, however, South African gold mines have gone from being among the lowest cost gold producers in the world to the highest cost producers in 1991. The rate of increase in average production costs of the nearly three dozen mines representing the membership of the Chamber of Mines of South Africa slowed from 10% during 1990 to 4% during 1991.

Production costs for Chamber members ranged during 1991 from a low of \$208 per ounce at Gold Fields of South Africa Ltd.'s (GFSA) Driefontein Consolidated Mine to a high of \$512 per ounce at the 4-year-old H.J. Joel Mine owned by Johannesburg Consolidated Investment Co. Ltd. (JCI).

In terms of individual mine output, in metric tons, the largest South African gold mines during 1991 were the Anglo American Corp. of South Africa Ltd.'s (AAC) Freegold Mine with 113.8; the Vaal Reefs Mine, also owned by AAC, at 73.9; GFSA's Driefontein Mine with 56.8; AAC's Western Deep Levels Mine with 41.4; and GFSA's Kloof operations with 31.9.

The South African gold mining industry is dominated by six major corporate groups or "houses," including AAC, GFSA, JCI, Anglovaal Ltd., Gencor Ltd., and Rand Mines Ltd.

For a number of South African gold mines the past several years have been very difficult years. For many, severe cost cutting measures have resulted in a deferral of the large capital expenditures normally required on a regular basis for

the orderly development required to sustain full capacity in future years. Thus, should the fundamentals of the gold market improve substantially in the future, some operations will be unable to catch up with the rest of the industry without first investing major amounts of time and money. For example, on three different occasions Anglovaal's Lorain Mine in the Orange Free State (OFS) announced rationalization programs to reduce losses by lowering mill throughput and reducing employment. Similarly, Gencor announced plans to close one shaft at its St. Helena Mine also in the Orange Free State and, in June, curtailed operations at its new Wettvreden Mine in the Western Transvaal. The Republic of South Africa's gold mining industry is also very labor intensive, employing large numbers of mostly unskilled and semiskilled workers. With labor costs consuming an ever-increasing share of the working costs, reductions in the overall labor force continue to escalate. As a consequence, the number of people employed at the gold mines had fallen by the end of 1991 to less than 407,000, its lowest level since 1976. Gold Mine employment peaked in 1986 at 534,000.

Exploration for new gold deposits and extensions of existing deposits, reflecting the negative developments in the mining sector, was less active during 1991 than during recent past years when exploration activity delineated several potential new OFS mines such as Gencor's Poplar Mine in the Evander area and JCI's South Deep property adjacent to its Western Areas Mine in the Fochville area. During the year, Anglovaal continued exploration in the Sun and Oripi project areas in the Bothaville Gap area of the northern OFS.

In April, the European Community lifted its 1986 ban on imports of various South African products, including gold Krugerrand coins. Similar steps were taken by the United States in mid-July.

Gold production in Ghana rose 56% above the production reported during the previous year. This growth reflected increased production at Ashanti Goldfield Corp.'s Ashanti Mine at Obuasi as well as the first full year's contribution by three new mines opened in 1990. At the

Ashanti Mine, which has been operating since 1895, the company's new Sansu open pit facility reportedly contributed 4,980 kg (160,000 ounces) to Ashanti's total production of about 18 metric tons (580,000 ounces). The three new mines completing full year operations were Canadian Bogusu Resources Ltd.'s Bogusu Mine, the Pioneer Group and Ghanaian Government's Teberebie operations, and Sikamen Gold Resources Ltd.'s Goldenrae placer mine near Kiki. Several smaller gold mines operated in Ghana during the year while several others were in various stages of preproduction development.

A new gold mine was officially opened in the Republic of the Ivory Coast in November. The new open pit operation, near the village of Ity in the Man region of the country, is jointly owned by a Government subsidiary and Coframines, a subsidiary of France's BRGM. The Ity project, operated by Eden Roc Mineral Corp., of Toronto, Canada, reportedly contains a reserve of about 15 metric tons (500,000 ounces) of gold. Heap-leaching recovery methods are employed to recover the gold.

Australia.—Following 11 consecutive years of growth in gold production, Australian production declined 4% from that of the previous year. This slight decline reflected, in part, weak gold prices, rising production costs, and to some extent the effects of a new tax on gold mining that came into effect on January 1st. Over the long term, the new tax was expected to result in reduced production as the resultant disincentive to explore reduces the number of new discoveries being made.

The State of Western Australia was again the nation's dominant gold-producing State. Australia's two largest gold mines, Boddington and Telfer, were in Western Australia. Production at Boddington, the nation's largest gold mine, amounted to about 12,400 kg (400,000 ounces). During the year, a new \$15 million mill circuit to recover gold and copper from the mine's supergene ore reserves was completed. The new circuit raises the productive

capacity of the mine, 97 km (60 miles) southeast of Perth, by almost 10%. Boddington was managed by the Worsley joint venture, 40%-held by Reynolds Metals Co. Reynolds also retained a 50% interest in the Mount Gibson gold mine, 300 km (186 miles) north of Perth. Mount Gibson produces about 2,643 kg (85,000 ounces) of gold annually. During the year, Reynolds also acquired another gold mining company, Mawson Pacific Ltd., which has mining operations in Western Australia at Southern Cross and Marvel Loch.

With an annual gold production of about 8,080 kg (260,000 ounces), the nation and the State's second largest gold mine is the Telfer Mine near Nullagine, previously operated by Newmont Australia Ltd. During 1991, Newmont and BHP Gold Mines Ltd. merged their gold mining interests to form a new company, now among Australia's largest gold producers, called Newcrest Mining Ltd. BHP retained a 23% interest in Newcrest. The new company has interests in seven operating or developing Australian gold mines, including Boddington, Telfer, Browns Creek, London Victoria, Ore Banda, Tuckabianna, and New Celebration.

Western Mining Corp. (WMC) owned or managed gold mines in Australia that produced 27,956 kg (898,895 ounces) during the fiscal year ending in June 1991. WMC's largest gold operation, its wholly owned Kambalda Gold Operations with several mines in the Kambalda area, produced 9,145 kg (294,063 ounces), a 45% increase over that of the previous year. Other WMC gold interests in Western Australia included multiple mine operations near the towns of Mount Magnet, Leinster, Lancefield, Norseman, and Kagloorlie. In the Leinster area, WMC's Redeemer underground mine started full-scale production using two computer-controlled production drill rigs. WMC also has gold mining interests in the Australian States of Queensland, South Australia, the Northern Territory, and Victoria, as well as overseas.

Also in Western Australia, Placer Pacific Ltd. and its partner, AMC Gold Ltd., decided in early 1991 not to

proceed with a previously announced underground development plan at the Big Bell Mine near Cue. During 1991, Big Bell produced a record 4,223 kg (135,800 ounces). Production at Placer Pacific's 45.4%-held Granny Smith Mine, near Laverton, amounted to almost 6,282 kg (202,000 ounces). Granny Smith completed its first full year of production in May. Placer also held a 70% interest in the Kidston Mine west of Townsville in the State of Queensland. Kidston, Queensland's largest gold mine, produced 5,964 kg (191,753 ounces) during 1991. Along Kalgoorlie's famous Golden Mile, Homestake Gold of Australia Ltd. and its partner, Gold Mines of Kalgoorlie Ltd., produced 7,251 kg (233,160 ounces) at their gold operations, which consist of four mines (two open pit and two underground), five mills, and two roasters. The most important component of the Kalgoorlie operations was the Super Pit, one of the largest open pit mines in Australia. The partner's principal underground mine was the Mount Charlotte Mine near the city center.

In central New South Wales, CRA Ltd. moved closer to its planned mid-1992 startup at the Peak Mine, in the Cobar District. The new underground operation was expected to produce 3,110 kg (100,000 ounces) of gold together with copper, zinc, and lead. In the State of Victoria, a new mining act was reportedly passed into law in November. The new law reportedly was designed to foster and encourage the mining industry in Victoria, which has a long history of gold mining. In April, Brunswick NL poured the first bar of production gold at its New Fosterville Mine, 20 km (12 Miles) east of Bendigo, Victoria. Work was later halted at the mine but may resume in 1992. Other Australian gold mines reportedly beginning production during the year included the Tick Hill Mine of Carpentaria Gold in Queensland, the Tindals Mine of Tindals Gold Mines NL, Aquarius Exploration NL's Penny West Mine in Western Australia, and Dominion Mining Ltd.'s Woolwonga Mine in the Northern Territory.

The Government of Australia announced in June that mining would not be permitted at the Coronation Hill precious-metals deposit in the Northern Territory and that the deposit area will be incorporated within the Kakadu National Park. In 1989, responding to mounting opposition by conservationists following the 1985 discovery of the deposit, the Government stopped work on the project pending completion of a study commission report. The principal opposition to the project came from local aborigines who reportedly claimed that the Spirit Bula, which they believed resided in the hill, will bring sickness and destruction if disturbed. The Aborigines reportedly had not lived on the land for more than 60 years, and part of the area around Coronation Hill had previously hosted uranium mining and exploration activities. The three companies involved in discovering and evaluating the large gold, platinum, and palladium deposit at Coronation Hill had reportedly spent more than \$A15 million on exploration, engineering, and a feasibility study. Reserves of more than 31 metric tons (1 million ounces) of gold plus 5% platinum and palladium in the ores reportedly had been established prior to the stop-work order.

On March 7, GoldCorp Australia, operator of the Perth Mint in Western Australia, introduced three large gold bullion coins, one of which weighs 1 kg, or about 32 troy ounces, reportedly the world's largest legal tender coin of any type produced in this century. The largest gold coin ever minted was produced by the U.S. company Leach and Garner for the 1986 World Exposition in Vancouver, British Columbia, Canada. The 14-karat gold coin, valued at the time at \$1.2 million, weighed 165.3 kg.

Canada.—At the close of 1991 there were 60 primary gold mines operating in Canada, according to an annual review of Canadian gold developments prepared by the Canadian Department of Energy, Mines and Resources.¹⁴ Canada was again the world's fifth largest gold producer, following Australia.

With a total gold output of 77 metric tons (2.5 million ounces), Ontario remained the dominant gold-producing Province during 1991. Gold from the mines in the Hemlo area near Marathon, Ontario, accounted for more than 50% of Provincial production. The three Hemlo mines, all opened in 1985, were the Page-William Mine, the Golden Giant Mine, and the David Bell Mine. Only one mine was opened during 1991, the Cheminis Mine of Northfield Minerals Inc. and Towerland Properties, near Virginiatown, Ontario. The reopened underground operation was expected to produce at a rate of about 136,000 metric tons (150,000 short tons) of ore per year. In September, Corona Corp. and American Barrick closed their Renabie Mine near Wawa. Weak gold prices, declining reserves and grades at depth, and rising costs contributed to the closure. Several other Ontario mines, including the Bell Creek Mine, St. Andrew Goldfields' Mine, and one tailings reprocessing project, were also closed during the year.

Production in Canada's second largest gold-producing Province, Quebec, rose by 20% to 51.9 metric tons (1.67 million ounces) in 1991. The increase was attributed primarily to improved production at TVX Gold Inc.'s Casa Berardi Mine, 100 km (62 miles) north of LaSarre, and LAC Minerals' Bosquet No. 2 mine at Cadillac. Bosquet completed its first full year of production during 1991. In Bosquet Township, northwestern Quebec, Cambior Inc. entered commercial production on July 1 at its new wholly owned Mouska Mine. Production at the Mouska during the year amounted to 580 kg (18,647 ounces). Cambior held major interests in three other Quebec gold mines: the Doyon Mine, the new Silidor Mine, and the Pierre Beauchemin Mine. All are in the vicinity of Rouyn-Noranda, Quebec. Other mines beginning production in Quebec during 1991 included Agnico-Eagle Mines Ltd.'s Eagle West Mine near Joutel, the Norlartic Mine of Aur Resources Inc. and Nova-Cogesco Resources Inc., near Malartic, and the Simkar Mine of Renrico Explorations

Ltd. and Louvincourt Gold Mines Inc. east of Val d' Or. Several Quebec gold mines were closed owing to low metal prices.

Gold production from mines in the Yukon and Northwest Territories increased to 21.6 metric tons (696,774 ounces) in 1991. Low gold prices and higher operating costs forced Northgate Exploration Ltd. to place its Colomac Mine on care-and-maintenance status in June.

In November, Claude Resources, Inc. began gold production at its new Seabee Mine at Laonil Lake, 125 km (78 miles) northeast of La Ronge in the Province of Saskatchewan. The new underground mine was expected to produce about 1,500 kg (48,000 ounces) of gold per year from ore processed at an on-site, 400-ton-per-day carbon-in-pulp mill. Gold was first discovered at the Laonil Lake site in 1947, and the mine reportedly derives its name from the amphibious Seabee aircraft that serviced the property during subsequent summers of exploration. As at many other mining operations in northern Canada, two mining crews fly-in/fly-out on a 2-week rotational basis. Corona Corp. and International Mahogany Corp. depleted the ore reserves at their Jolu Mine 120 km (75 miles) northeast of La Ronge, Saskatchewan, then closed the mine.

British Columbia's gold production reached 18.7 metric tons (603,225 ounces) in 1991, a 16% increase over that of the previous year. Two new gold mines began production during the year: the Snip Mine of Cominco Ltd. and Prime Resources Group Inc. began in January, and Tenajon Resources Corp. and Westmin Resources Ltd.'s SB project northwest of Stewart in the Salmon River Valley began producing gold in June. Near yearend, Placer Dome Inc. terminated plans to jointly develop the rich Eskay Creek gold deposit with partner International Corona Corp. Exploration at Eskay Creek, in northern British Columbia, had outlined a gold reserve of more than 90 metric tons (2.9 million ounces).

Latin America.—Gold mine production in Latin America generally was little changed from that of the previous year.

In Brazil, gold production at 80 metric tons (2.6 million ounces) was 6% below that of 1990. Production by the nation's independent gold miners or "garimpeiros" was estimated to have declined about 15% during the year to about 47 metric tons (1.5 million ounces), while production from the regulated or formal sector increased from 30 metric tons (965,000 ounces) in 1990 to about 33 metric tons (1.1 million ounces) in 1991. Garimpeiros production had been declining for several years owing to weak gold prices, especially at the local level, declining ore grades, depletion of easily accessible alluvial deposits, and wet weather conditions. Increased Government enforcement of regulations pertaining to protection of the environment and the indigenous Indian populations, as well as illegal intrusions by garimpeiros on mineral land concessions held by companies in the formal sector, had also restricted activities in those areas affected. During 1991, there were an estimated 300,000 garimpeiros operating in Brazil. The Government of Brazil estimated that about one-half of the gold produced annually by the garimpeiros is smuggled out of Brazil from about 2,500 separate locations. In the State of Par , Brazil's State-owned mining company, Companhia Vale do Rio Doce (CVRD) reportedly began production in September at its new open pit Igarap  Bahia gold mine. The new mine, in the Carajas region, will treat 2,000 to 3,000 metric tons (2,200 to 3,300 short tons) of ore per day for an expected annual yield of 4 to 5 metric tons (130,000 to 160,000 ounces) of gold. The Igarap  Bahia Mine and the Fazenda Brasileiro Mine, which opened in 1985 in the State of Bahia, are CVRD's principal gold-producing operations. During the same month, CVRD's new open pit Maria Pr ta Mine in Bahia completed its first full year of operation. Near yearend, WMC Minera o Ltda. completed open pit mining at its 75%-held Jenipapo project west of Goi nia in the State of Goi s. About 270 km (165

miles) north of Goi nia, WMC continued open pit and heap-leaching operations at its Mara Rosa Mine. At Mara Rosa, the company expanded crushing capacity at the site to 200,000 metric tons (220,000 short tons) per year.

In Bolivia, the Kori Kollo Mine, near Oruro, Bolivia's largest gold mine, produced 1,555 kg (50,000 ounces) of gold using heap-leaching recovery methods. The mine also recovered 10.3 metric tons (331,000 ounces) of silver during 1991. Development work at the mine, owned and operated by Inti Raymi, an 85%-held affiliate of Battle Mountain Gold Co., was focused during 1991 on planning for the mining of a large mill-grade, gold-bearing sulfide deposit lying beneath the oxidized cap presently being mined. A number of overseas companies pursued gold in Bolivia during the year, including RTZ and Cominco Resources International Ltd. As in past years, suction dredging operations for placer gold by numerous small companies were active along the river channels of the Rio Beni, Rio Madre de Dios, and the Rio Madera in northern Bolivia and along the border with Brazil. In April, the Government of Bolivia revised its mining code. The new code has a number of provisions aimed at making Bolivia more attractive to foreign mining and exploration firms. New laws to encourage investment and mining were also enacted in several other Latin American nations, including Ecuador, Peru, and Venezuela.

Despite the recent heightened levels of gold mining and exploration activity in Chile, mine production was essentially the same as that of the previous year. Chile's leading gold-producing mine, El Indio, 83%-held by LAC Minerals, produced almost 600 kg (191,342 ounces) or 11% less than that in 1990. Production at the mine and the nearby Tambo Mine, high in the Andes near the Argentinian border, was affected by a number of factors during 1991, including lower ore grades and recoveries plus a 26-day labor strike. El Indio also produced 43.3 metric tons (1.4 million ounces) of silver and almost 30,000 metric tons of copper. In the Maricunga

District of central Chile, a prolonged startup of a new treatment plant resulted in lower-than-expected output at Placer Dome's 50%-held LaCoipa Mine. The new plant was fully operational by yearend, and gold production for the year amounted to 2,173 kg (70,000 ounces) or more than twice the previous year's output. North of LaCoipa in the same district, Homestake's wholly owned El Hueso Mine continued to be plagued by low metal prices, low ore grades, and the inability of the mine to expand proven ore reserves. Because of the low grades and slightly lower mining rate, gold production fell by 10% to 2,033 kg (65,356 ounces). Heap-leaching operations began during the first quarter at the San Cristobal Mine in the Atacama desert of northern Chile. The first gold was recovered in midyear. Battle Mountain Gold Co. owns a 56.52 interest in the mine through its affiliate, Niugini Mining Ltd. Startup problems at the mine resulted in 435 kg (14,000 ounces) less in production than the targeted 1,100 kg (35,000 ounces). San Cristobal was scheduled to produce more than 2,000 kg (65,000 ounces) in 1992. Following several years of high costs and operating difficulties at Anglo American's 56%-held Marte heap-leaching project, operations were suspended in September. Several Chilean gold projects were in an advanced stage of exploration during 1991, including Bema Gold Corp.'s Refugio Project and Dayton Mining Corp.'s Andocollo Project. Planned annual production rates for the two properties were 7,240 kg (233,000 ounces) and 3,400 kg (110,000 ounces), respectively.

In Colombia, Latin America's second largest gold-producing nation, Greenstone Resources Ltd., completed its first full year of production in November at its Oronorte Mine, in the Department of Antioquia, 250 km (155 miles) north of Bogotá. The newly reopened underground operation, discovered in 1939 and mined on a small-scale until 1946, has an annual production capacity of about 780 kg (25,000 ounces) of gold. Greenstone also had gold exploration interests in Costa Rica and at the Santa

Rosa project in Panama. Elsewhere in Antioquia, which produces 70% of the nation's gold, the drug war and guerrilla activity reportedly continued to pose security problems for mining and exploration companies.

Gold production at the Pueblo Viejo Mine in the Dominican Republic, that nation's sole gold producer, continued to decline. The lower production reflected the rapidly nearing depletion of the mine's oxide ore reserves. The Government of the Dominican Republic has established a commission consisting of the directors of the state-owned mining company, Rosario Dominicana S.A., and a group of advisors to determine ways to develop the mine's vast gold-bearing sulfide ores.

Near Magdalena, in Mexico's State of Sonora, Phelps Dodge Corp. and its partner, the Ariztequé Group, a private Mexican consortium, began production at the new Santa Gertrudis Mine. The open pit and heap-leaching facility, opened in late November, was designed to produce more than 1,560 kg (50,000 ounces) of gold per year. The most important development for gold in Mexico during 1991 was the interest shown by both Mexican and foreign mining companies in exploring for gold in Sonora, Baja California, and Sinaloa. Many of the companies with demonstrated interest in Mexico during 1991 were from the United States and Canada.

In Peru, a number of lode and placer mines continued operation during the year despite serious national economic and social difficulties and continuing terrorist activity that forced companies operating in the Central Mining District to make large investments in security measures. Following 6 years of exploration at the Yanacocha gold project, 20 km (12 miles) north of Cajamarca in northern Peru, Compañía Minera Yanacocha S.A. formed a mining consortium owned 40% by Newmont Mining and 60% by Peruvian and French interests. The company plans to start production by 1985 at a rate of 15.5 metric tons (500,000 ounces) per year. The investment required to develop the mine will reportedly be the first important

foreign investment in Peru's mineral sector in almost 20 years. The Yanacocha deposit is reportedly the first disseminated-type gold deposit discovered in Peru. In March, the Government of Peru authorized the purchase, sale, export, import, and private ownership of gold. The authorization included raw, refined, and semimanufactured gold. Previously, Banco Minero and the Central Reserve Bank were the only legal markets for domestic gold production.

Oceania.—Gold production in Papua New Guinea increased 96% over production achieved during the previous year. This large increase generally reflects the first full year of production at Placer Pacific Ltd.'s New Porgera Mine, in the highlands of Enga Province. The full year's production at Porgera was 37.8 metric tons (1,216,100 ounces), which was 43% more than initially projected owing to higher mill throughput and recoveries. Production was expected to increase further in 1992 with the mining of high-grade underground ore and the processing, by pressure oxidation, of stored residue material containing refractory gold. In the same Province, about 18 km (12 miles) southwest of Porgera, CRA completed its first full year of operation at its new Mount Kare alluvial project. Production during 1991 was reportedly a disappointing 282 kg (9,100 ounces). Operations were suspended following an armed attack on the mine in early 1991.

CRA also continued exploration and drilling at its Hidden Valley Project about 200 km (125 miles) southeast of Mount Kare. Misima Island Mines Pty. Ltd. produced about 10 metric tons (323,127 ounces) of gold during its second full year of production at the new Misima Mine in Milne Bay Province.

At Mount Fulbian in the far west of Enga Province, the OK Tedi copper-gold mine yielded 13.2 metric tons (426,034 ounces) of gold, down about 4% from that of 1990. Copper production, however, increased 24% during the same period. CRA's 53.6%-held Bougainville Mine remained closed during 1991. The

mine was closed in May 1989 owing to a political dispute.

The partners in the development of the giant Lihir Island gold deposit, RTZ Corp. and Niugini Mining Ltd., were under pressure from the Government of Papua New Guinea during the year to speed up development of the property. The property is on a small island off the east coast of the island of New Ireland.

In late 1991, Papua New Guinea's only precious-metals refiner, Metal Refining Operations, reportedly made its first shipment of refined 1-kg gold bullion bars directly to the international market in Hong Kong. The shipment, valued at about \$400,000, marked the first time in almost 100 years of gold mining in Papua New Guinea that gold has been sent directly to the international market in final refined form. Previously, gold from Papua New Guinea was refined elsewhere and entered the world market bearing the stamps and certification marks of overseas refineries.

Exploration for gold in the Southwest Pacific continued at a brisk pace. Law and order problems in Papua New Guinea, particularly in some highlands Provinces, continued to plague exploration, mining, and petroleum companies alike.

The only gold mine currently in operation in Fiji, the Emperor Mine in Vatukoula, first began gold and silver production in 1935. In January, Western Mining Corp. sold its interest in the property to Emperor Gold Mines Ltd. Gold was produced in 1991 from both surface and underground sources; however, a year-long labor dispute and low world gold prices resulted in a decline in production during the year.

A report was published describing the gold deposits and the excellent gold potential of the entire region of the Outer Melanesian arc system in the Southwest Pacific.¹⁵ The report covers northern Papua New Guinea, the Solomon Islands, Vanuatu, and Fiji, an area where 22 major gold deposits have so far been identified.

In January, Freeport Indonesia completed its first full year of mining copper-gold-silver ore at its recently

discovered Grasburg deposit in West Irian, on the Indonesian side of the island of New Guinea. Grasburg, adjacent to Freeport's older Ertsburg Mine, reportedly possesses the largest published gold reserves of any single operating mine in the world.

Grasburg's major contribution to Indonesia's total production was reflected in a 51% increase over that of the previous year. In the Province of East Kalimantan, CRA began commissioning work at its 90%-held Kelian gold mine. The first metal was poured in January 1992. In addition, one-half dozen or more State-owned and private companies were mining gold in Indonesia during 1991. Indonesia's Department of Mines and Energy reported that there were also as many as 30,000 illegal miners operating in Kalimantan, Sulawesi, Sumatra, and Java during 1991. The undocumented gold from these small operations has traditionally been refined and processed for local consumption by village jewelers or smuggled outside the country. Government officials speculated that gold production by illegal miners might average as much as 1 gram (0.03 ounce) per miner per day. If so, the total of illegally mined gold would be roughly 9,300 kg (300,000 ounces) per year. Small-scale gold mining has reportedly been conducted in Indonesia for thousands of years.

The 43% increase in New Zealand's 1991 production was mostly attributable to the first full year's contribution of gold from the new Macraes Mine, in the Otago region of New Zealand's South Island. In December, Cyprus Gold (NZ) Ltd. poured its first gold at its new Golden Cross Mine 8 km (5 miles) northwest of Waihi in the Hauraki Goldfield on the North Island. At full capacity, Golden Cross is expected to produce about 3,300 kg (106,000 ounces) annually for about 8 years. A report was published detailing the geology and mineral resources of New Zealand.¹⁶ New Zealand's gold-producing districts and the lode and placer mines and prospects are described.

U.S.S.R.—In late 1991, tentative statistical data on the performance of the Soviet gold industry began to emerge. Since 1926, all matters pertaining to gold had been classified as state secrets, even to the inner circles of the Government. In late November, the Russian Ministry of Finance released statistics on gold production, consumption, bullion reserves, and exports covering 1953 and 1984 through estimated 1991, thereby ending years of speculation by Western analysts, at least for the periods covered in the disclosure. The official mine production data for 1953, for example, demonstrated that actual 1953 mine production at 117 metric tons (3.8 million ounces) was substantially below estimates prepared by Western observers, including the U.S. Bureau of Mines. Estimates by the Bureau for gold mine production during the period 1984 through 1990 were essentially in line with the official data released by the Soviets.

The size of the Soviet bullion reserves had long been a source of speculation and controversy outside of the U.S.S.R. To many Western market analysts, the large quantity of marketable Soviet bullion generally thought to exist was seen to overshadow the world gold market. Despite the Russians' reputation as astute gold traders not inclined toward product dumping, sudden heavy Soviet sales to earn foreign exchange credits could, if improperly executed, seriously disrupt the world market. Prior to the release of official reserve data in November, there was a flurry of renewed speculation regarding the size of the reserves, their possible role in the Soviet monetary system, implications of a large reserve for the western market, world prices, etc. This speculation ceased when the official data were released, indicating that by 1991 only 240 metric tons (7.7 million ounces) remained in reserve compared with 2,050 metric tons (66 million ounces) held in 1953.

Information on the distribution of mine production in the U.S.S.R. was also released. About 60% of the U.S.S.R.'s gold production is reportedly derived from gold mines in Russia, with about 90% of that fraction deriving from placer

mines mostly in the Northeast region. The only other Republics of note are Uzbekistan, with almost 30% of the National total, and Armenia and Kazaksstan, with about 5% each.

At the end of 1991, Glavalmazoloto of the U.S.S.R., the State Ministry presiding over all mining, refining, and manufacturing operations relating to precious metals, was taken over by Russia and renamed Rosalmazoloto (the Russian word for gold is "zoloto"). Following long-established practice, raw gold is delivered from the mines to state offices in Moscow for distribution to refineries in Moscow, Priosky, and elsewhere. The refined production is then directed to manufacturers and reserve depositories.

Throughout the year there was considerable cautious interest on the part of U.S. and other companies regarding the apparent opportunities opening up for joint participation in Soviet gold mining. Some companies were able, by yearend, to establish tentative ties with emerging Russian businesses. By yearend, however, many questions remained to be answered before foreign companies could proceed to establish firm, workable relationships. There was uncertainty regarding the status of existing mining laws, permitting procedures and legitimate lines of authority, disposition and repatriation of profits, regulations regarding foreign participation and partnerships, etc. The answers to most of these problems were, like the Commonwealth of Independent States itself, evolving as the new year arrived. (See table 15.)

Current Research.—The U.S. Bureau of Mines maintains nine research centers throughout the Nation, and most conduct research into various aspects of mining and extractive metallurgy that may be directly or indirectly beneficial to the gold mining industry.¹⁷ Because gold mining is pursued in many nations, the results of this ongoing work may, like the Bureau's earlier work in heap leaching, ultimately benefit a broad segment of the industry worldwide. In 1991, the Bureau's research relating to gold mining

generally focused on the use of cyanide in the recovery process. The Bureau addressed several questions regarding the use of cyanide, including such topics as the mass balance of cyanide in the leaching process, the mobility of metals in the heap during heap leaching, the persistence of cyanide in the environment, alternatives to cyanide, and reclamation of mining sites where cyanide was employed. The Bureau was also investigating the leaching of metals from very low-grade ores using biotechnology. Bioleaching research for precious-metals focused on a preleach treatment of precious-metal-bearing sulfide ores.

OUTLOOK

Gold is an internationally traded commodity but, unlike most commodities bound by the traditional laws of market supply and demand, gold also serves as a substance of wealth, a storehouse of value, held by investors and Governments alike.

Preparation of an outlook for normal supply and demand may first require consideration of the outlook for prices. Although the price of gold generally defies forecasting, consideration of the forces at work in the marketplace may aid in establishing the direction that the price may take. GFMS as well as other market observers generally avoid forecasts for the gold price for more than the near term. In its annual review,¹⁸ GFMS emphasizes that future gold prices will be greatly influenced by two principal factors: future gold supply developments resulting from the breakup of the U.S.S.R. and the degree to which, in these uncertain times, gold will continue to be absorbed globally in jewelry, industrial, and investment applications. GFMS acknowledges that Western World mine production would probably decline sharply if the prices seen in early 1992 were to remain unchanged and that it has only been the miner's inherent optimism that has kept some marginal mines open under today's prices.

The demand for jewelry and to some extent consumer electronic products is greatly influenced by consumer

confidence in the economic future. A sustained economic recovery would instill confidence and lead to greater demand for gold-bearing products and higher gold prices. Similarly, the degree to which gold would be taken in or released from private or official investors' vaults is likewise dependent upon regional investor attitudes, Government policies, and markets.

The outlook for gold is aptly summarized by the GFMS¹⁸ review that concludes that robust world gold price recovery could occur under two very different scenarios. One involves a return to strong economic growth accompanied by a rapid increase in jewelry demand or, at the other extreme, a massive asset deflation that would cause a flight to gold. According to GFMS, "...Between these two extremes, however, it is possible to imagine that, with a relatively mundane rate of economic growth, the physical market will not tighten fast enough to give much encouragement to gold holders who could thus continue as net sellers and maintain a depressed gold price for some time to come."

¹Ounce refers to troy ounce. One kilogram of gold weighs 32.1507 troy ounces.

1991	19	20	5,511	2,888	33,729	6.118

¹Revised.

²Data are only for those mines that report annually on the U.S. Bureau of Mines voluntary survey; there are many more, usually smaller and less well-established operations, mainly in Alaska, that do not report.

³Excludes tonnage of material treated at commercial sand and gravel operations recovering byproduct gold.

⁴Includes gold recovered at commercial sand and gravel operations.

⁵Gold recovered as a byproduct at sand and gravel operations not used in calculating average value per cubic meter.

⁶May include hydraulicking.

⁷Data may not add to totals shown because of independent rounding.

^{*}Estimated. [†]Revised.

¹Table contains data available through June 22, 1992.

²Gold is also produced in Burma, Cuba, Czechoslovakia, the Eastern states of Germany, Norway, Senegal, Thailand, and several other countries. However, available data are insufficient to make reliable output estimates. Poland annually mines and processes copper ore estimated to contain about 31,000 kilograms of gold. Disposition of the gold byproduct is unknown.

³Reported figure.

⁴Only the combined total of gold and silver production is reported. For this table, based on the reported silver content of "about 2%" in 1987, gold content of the reported production figure is estimated to be 98% for 1987-91.

⁵Officially reported figures are as follows, in kilograms: Major mines: 1987—13,120; 1988—24,012; (estimated); 1989—24,900 (estimated); 1990—29,986 (revised); and 1991—33,584. Small mines (garimpos): 1987—22,660; 1988—55,053 (estimated); 1989—56,000 (estimated); 1990—72,110 (revised); and 1991—55,525.

⁶Gold purchases by Banco Central from placer deposits and mines; actual production estimated to be at least twice this amount.

⁷Year ending June 30 of year stated.

⁸Does not include undocumented production from small artisanal production.

⁹Revised to zero.

¹⁰Figures include reported mine production of 320 kilograms in 1988; 1,059 kilograms in 1989; 1,600 kilograms in 1990; and 1,450 kilograms in 1991 from the SAG mine. Remainder represents approximate reported sales to Government of artisanal production. Figures do not include artisanal production smuggled out of the country.

¹¹Refinery output.

¹²Excludes production from so-called people's mines, estimated at 15,000 kilograms per year during 1987-91, but includes gold recovered as byproduct of copper mining.

¹³These figures are based on gold taxed for export and include gold entering Liberia undocumented from Guinea and Sierra Leone.

¹⁴Includes production from Kalana Mine and artisanal production. 1990 includes Syama mine production.

¹⁵Data are based on official exports and do not reflect gold moved through undocumented channels.

¹⁶Year beginning Apr. 1 of year listed.

GRAPHITE

By Harold A. Taylor, Jr.

Mr. Taylor, a physical scientist with 25 years of industry, Federal Government, and U.S. Bureau of Mines experience, has been the commodity specialist for graphite since 1980. Domestic survey data were prepared by William Field, statistical assistant; and international data tables were prepared by Audrey Wilkes, international data coordinator.

Amorphous graphite was not mined domestically in 1991. Graphite supplies exceeded industrial demand to a major degree. Most prices of the major imported graphite increased from those of 1990, and one decreased. Prices did not reflect the severe oversupply. Production of manufactured graphite and graphite fibers decreased 10% and 14%, respectively. (See table 1.)

DOMESTIC DATA COVERAGE

Domestic production data for synthetic graphite are developed by the U.S. Bureau of Mines from a voluntary survey of domestic producers. Of the 32 operations polled, 100% responded. This represented 100% of the total production data shown in table 5.

BACKGROUND

Definitions, Grades, and Specifications

Graphite, a soft crystalline form of carbon, has been called plumbago and black lead. It crystallizes in a lamellar hexagonal system, has a gray to black metallic luster, and is greasy to the feel. It is anisotropic in its physical properties and has a weak plane of cleavage parallel to the lamellae.

The term "amorphous" when applied to graphite is a misnomer. The term "microcrystalline" is more descriptive. The definition of amorphous, as applied to graphite, has been further complicated by longstanding industrial application of the term to very fine particles of crystalline flake graphite that can be sold

only for low-value use such as foundry facings. Fine-grained varieties of lump graphite that are easily reduced to fine particle size by grinding are called amorphous lump to distinguish them from the tough, platy and acicular varieties, known as crystalline lump, that can be reduced in particle size only with extreme difficulty.

Crystalline flake graphite is well defined in paragraph 214 of the Tariff Act of 1930 as follows:

"The term crystalline flake means graphite, or plumbago, which occurs disseminated as a relatively thin flake throughout its containing rock, decomposed or not, and which may or has been separated therefrom by ordinary crushing, pulverizing, screening, or mechanical concentration process, such flake being made up of a number of parallel laminae, which may be separated by mechanical means."

Under the foregoing definition, finely divided particles of crystalline flake graphite would be classified as crystalline graphite. The Court of Customs Appeals, however, has held that commercial designations and not scientific terms must govern classification, and when a commercial meaning differs from the technical meaning, the commercial designation must govern. Therefore, quantities of fine crystalline flake graphite are imported under the amorphous classification.

Sri Lankan lump graphite is classified as amorphous or crystalline. Each type is divided into a number of grades, depending on the size (such as lump, ranging from the size of walnuts to that

of peas; chip, from that of peas to about that of wheat grains; and dust, finer than 60 mesh), graphitic carbon content, and degree of consolidation.

Amorphous graphite is graded primarily on graphitic carbon content. Commercial ore contains about 75% to 93% carbon, depending on the source.

Crystalline flake graphite from Madagascar is divided into two main grades, "flake" (coarse flake) and "fines" (fine flake). Madagascan crucible flake must have a minimum of 85% graphitic carbon and be essentially all minus 20 plus 80 mesh in particle size. Other crystalline flake graphites are also graded according to graphitic carbon content and particle size.

Natural graphite is marketed in the form of crystalline graphite as flake, lump, chip, and dust and in the form of amorphous graphite in sizes from fine powder to lumps up to the size of walnuts. It is common practice to blend different graphite to obtain a product having certain desired physical and chemical properties. In many instances, the composition of these blends is retained as a trade secret.

Geology-Resources

The three principal types of natural graphite—lump, amorphous, and crystalline flake—are based on physical characteristics that are the result of major differences in geologic origin and occurrence. A variety of silicate minerals are generally associated with graphite in the ore.

Lump graphite occurs as fissure-filled veins. It is typically massive, ranging in particle size from extremely fine grains (amorphous) to coarse, platy intergrowths of fibrous to acicular aggregates (crystalline). The origin of vein-type graphite deposits is believed to be hydrothermal.

Amorphous graphite is formed by metamorphism of coalbeds by nearby intrusives. Its purity depends on the purity of the original coalbeds. Amorphous graphite usually is associated with sandstones, shales, slates, and limestones.

Flake graphite commonly occurs disseminated in regionally metamorphosed sedimentary rocks, such as gneisses, schists, and marbles. It is believed that the graphite was formed under the same conditions that caused the metamorphism of the rocks—from carbon deposited with the sediments.

Although the flake graphite deposits of certain countries conform to this description, most of the commercial deposits that are exploited are the result of weathering of these metamorphic rocks, with the graphite being found in lateritic clays that have accumulated at the surface. Graphite, quartz, and other resistant minerals have been freed by weathering of the feldspars, thus lessening the amount of crushing necessary before beneficiation.

World graphite reserves totaled 21.0 million metric tons.¹ Detailed breakouts are given in the 1988 Minerals Yearbook chapter.

Technology

Mining.—In Sri Lanka, lump graphite is mined underground from narrow, steeply dipping veins. The ore is mined principally by overhand stoping and filling, using temporary stulls when necessary to support the walls. Hand drilling is used in most stoping to achieve selective mining and to avoid unwanted fines and product contamination. Drills are used in developing headings. The ore is hauled by truck to the sorting and classification yard.

Amorphous graphite beds are usually mined underground. However, the beds are much thicker than those of amorphous lump and crystalline lump. The ore is drilled, blasted, hand-loaded into cars, and hauled to the surface by conventional methods.

Flake graphite deposits have been mined by underground and surface methods. Underground deposits are usually unweathered and require drilling and blasting. Most surface mining is confined to the weathered part of the deposit, and normal excavating equipment such as power shovels, bulldozers, and rippers is used with a minimum of drilling and blasting. The ore is usually trucked to the mill.

Milling.—Sri Lankan amorphous and crystalline lump graphite are refined by hand cobbing and hand sorting and wiping lumps on wet burlap to remove fines. Light hand sorting and cleaning operations are done by women, while the heavier duties are performed by men.

Most amorphous graphite that requires beneficiation is not worth mining. Preparation for most uses requires grinding only, and coarse impurities are removed by screening or air separation methods.

Flake graphite from disseminated deposits must be concentrated to meet market requirements. Virtually every known concentrating device and combination of separating principles have been tried. The mineral has gained a reputation of being difficult to concentrate, and probably in no other industry has such a large proportion of the mills failed to make commercial recoveries. Graphite actually is one of the easiest minerals to segregate into a rough concentrate, but one of the most difficult to refine.

Because of the premium placed on the mesh size of flake graphite, the problem in milling is one of grinding to free the graphite without reducing the flake size excessively. This is difficult because, during grinding, the graphite flakes are cut by quartz and other angular gangue minerals, thus reducing flake size rapidly. However, if most of the quartz and other

angular minerals are removed, subsequent grinding will usually reduce the size of the remaining gangue, with little further reduction in the size of the flake.

Because graphite floats readily and does not require a collector froth, flotation has become the accepted method for beneficiating disseminated ores. The chief problem lies with depressing the gangue minerals. Relatively pure grains of quartz, mica, and other gangue minerals inadvertently become smeared with the soft, fine graphite, making them floatable and resulting in the necessity for repeated cleaning of the concentrates to attain high-grade products.

Substitutes

Some interchange of the various types and grades of natural graphite and between manufactured and natural graphite takes place, but the degree is difficult to determine. Manufactured graphite does not compete with natural graphite in most uses because of its greater cost. Manufactured graphite is not substitutable for natural flake graphite in clay-bonded graphite crucibles, although some crucibles are machined from manufactured graphite for special uses. Calcined coke and other carbons are satisfactory substitutes for graphite for certain foundry core and mold washes and are used when they can compete in terms of price and supply. Other carbons with high purity can be used in batteries.

Economic Factors

The price structure of graphite is quite complex because of the wide variety of products and the lack of standard market quotations. Prices quoted in trade journals are only a range negotiated between buyer and seller and sometimes do not reflect the real market. Quotations are available in Industrial Minerals, Chemical Marketing Reporter, and the U.S. Bureau of Mines Annual Report. However, average declared import values per ton for amorphous and crystalline graphite have been available for years from U.S. Bureau of the Census data.

The cost for domestically produced graphite from new mines would be much higher than that for graphite from the major foreign sources, for the same type and purity. The high cost of production results from high labor costs and the low graphite content of the ore.

Taxes.—Graphite producers are granted a 22% depletion allowance for tax purposes on domestic lump and amorphous and 14% on domestic flake and on foreign operations.

Tariffs.—Duties on graphite items imported from most favored nations (MFN) are minimal. Graphite from the U.S.S.R. and certain other nations is subject to a higher duty. (See table 2.)

Operating Factors

Environmental Requirements.—Natural graphite is an inert nontoxic substance, and environmental requirements are limited to dust control and certain organic vapors arising from ingredients blended with it to manufacture products.

Employment.—Production and marketable natural graphite requires little hand labor, except for the graphite mined in Sri Lanka. Even in areas of low-cost labor, mechanical methods are used to mine and concentrate flake graphite.

Because of the small size of the domestic natural graphite industry, no publishable employment data are available. Because there is only one small mine open intermittently and the product is beneficiated and processed to a minimal extent, employment probably does not exceed 50. Much of the imported graphite requires grinding, perhaps further refining, mixing with other grades to meet consumer specifications, bagging, and shipping. The total number of persons engaged in these operations, including marketing, probably does not exceed 500.

ANNUAL REVIEW

Legislation and Government Programs

No acquisitions of graphite from the strategic and critical materials stockpile occurred in 1991. Sales of Madagascar crystalline flake from the stockpile totaled 106 tons in 1991 compared with 453 tons in 1990. (See table 3.)

Production

United Minerals Co. continued its suspension of production of its amorphous graphitic material from its Montana mine in 1991. Output of manufactured graphite decreased 10% to about 229,000 tons, at 29 plants, with a likelihood of some unreported production for in-house use. Production of all kinds of graphite fiber and cloth decreased 14% to 3,243 tons.

The graphite fiber industry had some important changes in 1991, mostly caused by oversupply of high-modulus fiber in weak markets. Courtaulds Ltd. sold its Grafil operation in California at midyear and closed its plant at Coventry, United Kingdom. The firm cited a severe overbuilding of capacity that destroyed profitability. Mitsubishi Rayon Co. bought the Grafil operation, and Courtaulds will continue to supply its precursor. In the fall, Amoco Performance Products Inc. announced a downsizing of its composites operation and a 2-month suspension of high-modulus fiber production to cut inventories. The firm offered a voluntary severance program to shrink employment. It has been heavily dependent on defense-related business.

Hoechst AG and Horsehead Industries Inc. announced a merger of their subsidiaries, Sigri GmbH and Great Lakes Carbon Corp., effective yearend. Sigri will be the majority partner, and the new firm will be headquartered in Germany. (See tables 4, 5, and 6.)

Consumption and Uses

Reported consumption of natural graphite decreased 16% to about 35,610 tons, according to a survey of more than 230 users. The three major uses of natural graphite were refractories, brake linings, and in foundries, which together accounted for 58% of reported consumption. (See table 7.)

Nonclay refractories represent two important uses categories of graphite. Standard refractory products, particularly gunning and ramming mixes, accounted for a sizable part of the demand in the past 5 years, mainly as amorphous graphite. Crucibles, shrouds, nozzles, stopper heads, and retorts, used in hot-metal processing operations such as the continuous casting of steel, use significant amounts of crystalline flake. Coarse flake graphite is preferred for crucibles and refractory associated items, but generally it is mixed with some fine crystalline material of lower value. The newest important refractory use for graphite in steelmaking is in carbon magnesite brick, where large amounts of crystalline flake are now used.

Graphite is used in brake and clutch linings. More graphite is being used as the brake and clutch producers change over from asbestos. The graphite lubricates, transfers the heat of friction away from the part, and leads to a lower rate of wear. Graphite is more commonly used in heavier duty nonautomobile lining. Low-quality crystalline flake and amorphous graphite are suitable for foundry facing use. The graphite is mixed with a small amount of clay, suspended in an adhesive material, and applied as a thin coating to mold surfaces to provide for clean and easy mold release of the metal castings.

Graphite is important as a lubricant; when used as a lubricant, it can be a dry powder or mixed with oil or water. It is used with materials that must withstand extreme conditions, such as very high temperatures. Material for this use must be free of abrasive-type impurities.

Graphite used in packings, which includes expanded graphite and graphite foil, has been broken out this year for the

first time. While this new category includes uses in ammunition and seed coatings, in addition to packings, most of the tonnage was used to make expanded graphite and graphite foil and final products resulting from them.

Prices

Natural graphite prices are often negotiated between the buyer and seller and are based on purity and other criteria. Therefore, published price quotations such as those in Industrial Minerals are given as a range of prices. Another source of information for graphite prices is the average customs value per ton of the different imported classes. These mainly represent shipments of unprocessed graphite. A third source for natural graphite prices is the amount paid per ton at the point of consumption.

The price for crystalline graphite at the point of consumption—mostly crystalline flake, some crystalline dust, and a little lump graphite—dropped slightly to \$1,579 per ton from \$1,600 (revised). The price for amorphous graphite (including small amounts of amorphous-synthetic graphite mixtures) rose by 22% to \$819 per ton from \$671 per ton (revised). (See tables 8 and 9.)

Foreign Trade

The United States changed its tariff classification to the Harmonized Code on January 1, 1989. This has made the 1988 and 1990-91 import and export statistics somewhat noncomparable.

Total exports of natural graphite increased 68%. Exports of graphite electrodes totaled 105,204 tons valued at \$170.7 million, of which 54,309 tons (\$54.0 million) went to Canada, 6,940 tons (\$15.3 million) to Venezuela, 6,610 tons (\$23.5 million) to Japan, 6,113 tons (\$10.7 million) to Brazil, and the balance to other destinations.

Imports of natural graphite decreased 33% from those of 1990. Imports of natural graphite from all major sources except Mexico dropped drastically. (See tables 10, 11, and 12.)

World Review

This year was a disaster for graphite producers and traders. Customers were living off the graphite stockpiles they were frightened into building by the supposed onset of shortage last year. The economic downturn cutting sales of the customer's products and the prospect of sales from the GSA stockpile exacerbated the situation. The market in other major graphite-consuming nations was in a similar condition for the same reasons. Mercifully, no major new producers came on-stream during 1991; only one Canadian producer of any size operated this year. The Norwegian operation was closed for most of the year. In addition, imports of Chinese graphite into the United States were halved from those of the previous year. Interestingly enough, posted prices were seldom lowered, although market participants reported drastic discounts.

Australia.—Gwalia Consolidated Ltd. agreed in principle to proceed with the Munglinup crystalline flake graphite project, then put it on hold at yearend. The completed engineering study indicated that it would cost \$9 million and take 9 months to finish. The operation would have an initial capacity of 3,000 to 4,000 tons per year and an ultimate capacity of 10,000 tons. The Western Australian Mines Dept. has approved the project.

Canada.—A paper describing the Lades-Iles flake graphite deposit of Stratmin Inc. was presented at the Society for Mining Metallurgy and Exploration (SME) Annual Meeting. The firm began its geophysical work in 1987 using electromagnetic methods. The deposit is in a Precambrian Grenville sedimentary belt. The formation sequence in the pit begins with a biotite-garnet gneiss, overlain by a band of quartzite, superimposed by a marble body, followed by another quartzite band, itself overlain by a biotite-garnet gneiss. The graphite in the deposit itself is concentrated in the marble core with lesser amounts found in the quartzite.

The mill has a complex flowsheet with 11 flotation stages; nevertheless, the product obtained was better than expected, running 96% C and even sometimes more than 97.5% C. The firm is anticipating a production of 17,500 tons in 1992.²

Stratmin announced in November that it would resume operating its concentrator on a full-time basis. It had been operated only on a part-time basis since April because of large inventories and unexpectedly good performance of the concentrator.

Korea, North.—Kyowa Shoji Co. of Japan formed a joint venture, called Jisong Graphite Joint Venture, to produce 50,000 tons of graphite per year from the Fungsan Mine. This will represent more than a doubling of national production.

Mexico.—Minera Montemayor SA de CV has bought an amorphous graphite mine 100 km northeast of San Ignacio. The mine is presently producing at the 8,000-ton-per-year level. The new owners plan to increase this to about 18,000 tons per year by mid-1992. This would be a major increase in Mexican graphite production, if implemented. The mine's main markets have been domestic.

Namibia.—Rossing Uranium Ltd. engaged Van Eck & Lurie (Pty.) Ltd. to build a modular graphite processing pilot plant at Rossing's graphite deposit. The plant is part of Rossing's evaluation of its crystalline flake graphite deposit at Otjiwarongo, 300 km north of Windhoek. The plant has crushing, screening, milling, flotation, and filtration modules, plus a drying, screening, and bagging plant for completing the products. The 2 tons of ore per hour capacity plant will make a variety of products with different purities and flake sizes, as adjusted to customer's needs. The ore grade ranges from 3.6% to 12% graphite. Rossing had previously investigated a large low-grade deposit near Usakos.

Graphite also occurs in the south in the Namaqualand granites. The Aukam Mine produced from this source.

Norway.—Elkem A/S bought the Skaland crystalline flake graphite operation from Graphitwerk Kropfmuhl late in the year. The operation was closed for most of the year. Elkem is modifying and upgrading the operation.

South Africa, Republic of.—MINTEK and the South African Development Trust Corp. Ltd. have begun exploration of the Steamboat crystalline flake graphite deposit. It is 50 km southwest of Alldays in the far northern part of Transvaal Province. Reserves delineated to a depth of 100 m totaled 2.5 million tons with a content of 8.8% flake graphite. Additional reserves may extend for 3 km to the east. Beneficiation tests gave more than a 90% recovery of a product containing more than 90% carbon.

Current Research

A new U.S. Bureau of Mines-developed process for the recovery of crystalline flake graphite from kish moved a step closer to implementation. Kish is a graphitic waste produced in steelmaking when the excess carbon in the hot metal crystallizes out and associates with the slag or is collected in the bag house. In March 1991, the U.S. Bureau of Mines signed a Memorandum of Agreement with The Asbury Graphite Mills Inc. and Inland Steel Co. to assess the quality, quantity, and cost of using the new process. Inland Steel will construct and operate a bench-scale system and a 1-ton-per-day-capacity pilot plant at its Indiana Harbor steel plant. Asbury Graphite will evaluate and test the pilot plant product through the refractorymakers it serves. The U.S. Bureau of Mines will assist in the design and operation of the bench-scale system and the plant.

A number of new end uses for fullerenes were developed this year, some of them involving graphite. This was the result of a major breakthrough late in 1990, when a simple preparation method was discovered for fullerenes. It involves heating graphite rods in a vacuum chamber and collecting the fullerene-rich

soot deposited on the chamber surfaces. The fullerenes are related to graphite even though they are not graphite compounds but are a separate class of carbon materials. Fullerenes have complex configurations of approximately 60 or more carbon atoms, the best known of which are shaped like a soccer ball. A class of microtubular fullerenes arranged in spiraling scrolls of sheets of carbon atoms has been discovered. These are not true fullerenes since the carbon atoms are arranged in a hexagonal geometry like that of graphite. There will probably be additional classes of fullerenes discovered, such as the just-discovered helical and thin-film ones.

Buckminsterfullerene can be swiftly crushed to diamond at room temperature, much more simply than the current methods of producing synthetic diamonds. Rapid nonhydrostatic compression of this fullerene to about 20 gigapascals efficiently transforms this material instantaneously into bulk polycrystalline diamond at room temperature in a diamond anvil cell. The process probably works so efficiently because the fullerene crystal structure is sterically fairly close to the one of diamond; graphite's structure has much less resemblance. It is also possible to grow diamond crystals on top of ultrathin fullerene films.

Researchers suggested a number of other uses for fullerenes. MicroMet Technology Inc. of Charlotte, NC, has discovered a new type of steel made with fullerenes that it calls Rhondite. Its carbon molecules are linked in chains wrapped around iron atoms, and this cablelike structure in turn wraps around a larger core of iron. Rhondite is said to be 1.5 times as strong as conventional steel and 300% more durable than major high-performance metals. It can be made on existing steelmaking equipment at a realistic cost. Fullerenes might be usable to lubricate gears in micromotors, although they do oxidize and break down when heated. A strong, light material might be made from fused fullerenes, and fullerenes appear to superconduct and to change the wavelength of light. Because fullerenes can give up and immobilize

electrons, they should be good catalysts. (See table 13.)

OUTLOOK

Projected demand for crystalline flake graphite totaled 23,000 tons for 1995 and 25,000 tons for the year 2000. Demand for other graphite, mostly amorphous, totaled 15,000 tons for 1995 and 13,000 tons for the year 2000. This very slow growth rate reflects the maturity of the market, mostly in refractories, and particularly in carbon-magnesite brick.

¹All tonnages are reported in metric tons, unless otherwise noted.

^oEstimated. ^pPreliminary. ^rRevision. W Withheld to avoid disclosing company proprietary data.

¹Table includes data available through May 9, 1991.

²In addition to the countries listed, Canada produced graphite during the period covered by this table but output is unreported because of company confidentiality.

³Does not include the following quantities sold directly without beneficiation, in metric tons: 1985—16,425; 1986—19,074; 1987—10,505; 1988—18,269 (estimated); and 1989—20,000 (estimated).

⁴Data are for fiscal year beginning Apr. 1 of that stated.

⁵Indian marketable production is 10% to 20% of mine production.

⁶Reported figure.

GYPSUM

By Lawrence L. Davis

Mr. Davis, a physical scientist with 36 years of industry and U.S. Bureau of Mines experience, has been the commodity specialist for gypsum since 1985. Domestic survey data were prepared by Virginia Harper, statistical assistant; and international data tables were prepared by William L. Zajac, Chief, Section of International Data.

Demand for gypsum products decreased in 1991, a result of decreased construction activity, especially in new housing starts that decreased 15% to 1 million units. Crude gypsum mined, calcined gypsum produced, and shipments of wallboard products were all lower than in 1990.

Sales of gypsum products decreased 15% to 22 million short tons, and value decreased 21% to \$1.3 billion. Increased competition caused lower prices for gypsum products. Imports for consumption of crude gypsum decreased 14% to about 7.6 million tons. Total value of gypsum product exports increased slightly to \$86 million.

DOMESTIC DATA COVERAGE

Domestic production data for gypsum are developed by the U.S. Bureau of Mines from a survey of U.S. gypsum operations. Of the 117 operations to which the annual survey request was sent, 113 responded, representing 97% of the total crude gypsum production shown in tables 1 and 2. Nonrespondents were estimated from monthly and quarterly canvasses or from previous years' data. (See table 1.)

BACKGROUND

Definitions, Grades, and Specifications

Gypsum has a composition of 79% calcium sulfate and 21% water, $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$, and is used as a commercial and generic term for all calcium sulfate materials. The well-formed transparent crystalline variety is

called selenite. The massive variety is called alabaster and can be easily carved. The fibrous, silky variety is called satin spar. Gypsite is a mixture of clay and gypsum crystals.

Anhydrite is calcium sulfate, CaSO_4 , with no water of crystallization. It is a naturally occurring mineral commonly associated with gypsum. When gypsum is calcined at high temperatures, it is converted to anhydrite.

Commercially calcined gypsum, $\text{CaSO}_4 \cdot \frac{1}{2}\text{H}_2\text{O}$, is a manufactured hemihydrate product produced by partial calcination of gypsum. It is produced by heating gypsum at temperatures to 350° F. Commonly called plaster of paris, when water is added to form a paste, it quickly sets and hardens to form gypsum again.

Byproduct gypsum is a chemical product of manufacturing processes such as phosphoric acid, hydrofluoric acid, citric acid, and titanium dioxide from ilmenite, consisting essentially of $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$. The sludge produced from scrubbers in the desulfurization of stack gas in thermal powerplants is also byproduct gypsum.

Keene's cement is anhydrous gypsum plaster with certain accelerator additives. It is produced by special high-temperature calcining. All of these minerals and materials, including the articles molded from the plaster, are commonly called gypsum or plaster.

Industry Structure

The domestic gypsum industry is large and is dominated by a few large vertically integrated companies that mine and calcine gypsum and manufacture plaster

and wallboard products. These companies also sell crude gypsum for use in cement and agriculture. The large wallboard producers, through foreign subsidiaries, produce most of the crude gypsum that is imported to feed coastal wallboard plants. Plants on the east coast import mostly from Canada's Maritime Provinces, while plants on the west coast import gypsum from Mexico. Crude gypsum from Spain, the other major source of U.S. imports, is used mainly by cement plants.

Gypsum production is worldwide, with at least 80 countries known to produce. Because of its wide distribution and plentiful supply, most of the world's production is consumed domestically. Exceptions include Canada and Mexico, which export significant portions of their production to the United States; Thailand and Australia, which export to much of the Southeast Asia market; and Spain, which exports to the United States, Scandinavia, and other countries. In the United States and other industrialized nations, the major use of gypsum is in the manufacture of gypsum wallboard products. Most crude gypsum is mined in rural areas and shipped to urban areas for manufacture into wallboard and ultimate consumption. In developing countries, most gypsum is consumed by local cement plants.

Geology-Resources

Gypsum deposits may be found in any geologic era, but they are most common in the Permian. They are commonly found in association with the source rocks for petroleum. Most massive gypsum

and anhydrite deposits occur as large, lenticular, stratified bodies that were formed by evaporation of seawater in basins that have one or more restricted openings to the sea. The basins range in diameter from a few miles to many hundreds of miles.

Classic evaporite formation involves the deposition of anhydrite, with later hydration of the anhydrite by meteoric waters to gypsum at depths ranging from 0 to 1,000 feet. The depth of hydration is generally related to topography, structure, and climate because these factors affect the depth of ground water and surface water penetration.

Technology

Gypsum deposits are explored to determine their physical and chemical properties and to determine a minable thickness and the ratio of gypsum to anhydrite. The depth of hydration is important in mining because the presence of only a few percent anhydrite is sufficient to render gypsum unusable for making plaster. Adequate samples may be obtained from outcrops or drill cores.

Deposits near the surface are developed by stripping the overburden, developing either single- or multiple-bench open pits, and constructing access and transportation routes. Underground ore bodies are developed by sinking shafts or driving adits, with mining development and production by the room-and-pillar system.

Most domestic gypsum is produced from surface mines using standard open pit mining methods. In a typical domestic mine, the gypsum is drilled and blasted as needed, probably every week or two. Broken gypsum rock, loaded with hydraulic shovel or front-end loader, is hauled to the primary crusher by a fleet of three or four 35-ton haultrucks. All material removed from the mines is crude gypsum. All waste is left in the mine.

The processing of crude gypsum depends on the end use. Gypsum for use in cement is crushed to minus 1½ inch plus ¾ inch. For agricultural or filler use, the gypsum is pulverized to 100 mesh or finer.

To produce plaster and wallboard products, minus-100-mesh gypsum is heated in batch kettles to remove three-quarters of the water of crystallization, converting gypsum, $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$, to the hemihydrate product, $\text{CaSO}_4 \cdot \frac{1}{2}\text{H}_2\text{O}$. A few rotary kilns are also used, in which case a coarse feed with fines removed is calcined. During the commercial calcining process, gypsum is heated to 250° F for about 2 hours, then the temperature rapidly rises to 300° to 350° F, at which time the calcine, called stucco, is dumped into a hot pit. The calcine is then mixed with various additives, including a retarder or accelerator, and manufactured into prefabricated wallboard products and other plaster and cement products.

Plaster is generally reground calcine, modified with retarders or accelerators and containing various binders such as hair, sisal, fiberglass, aggregates, or colored pigments. Retarders, usually glue, starch, or slaughterhouse byproducts, can increase the setting time to as much as 6 hours. Accelerators, such as metal salts, set plaster, or anhydrite, can reduce the setting time to less than 5 minutes. The plaster is packed in bags and sold under various trade names.

Prefabricated products include lath, veneer base, sheathing, and wallboard. These board products are manufactured by continuous methods on automatic machines that can be adjusted to any of the standard products. A slurry of wet plaster with additives and an accelerator is spread between two moving sheets of paper. Moving through the shaping rolls, the edges are molded and sealed. The green board is run out on a traveling belt until the plaster has set. The board is then cut with a revolving knife into appropriate lengths and slowly passed through a drying kiln.

ANNUAL REVIEW

Production

The United States remained the world's leading producer of gypsum, accounting for 15% of the total world output. Crude gypsum was mined by 32 companies at 61 mines in 20 States. Production decreased 6%. Leading producing States, in descending order, were Oklahoma, Iowa, Michigan, Texas, California, Nevada, and Indiana. These seven States produced more than 1 million tons each and together accounted for 76% of total domestic production.

Leading companies were USG Corp., 11 mines; National Gypsum Co., 7 mines; Georgia-Pacific Corp., 7 mines; Harrison Gypsum Inc., 2 mines; and Briar Gypsum Co., 1 mine. These 5 companies, operating 28 mines, produced 69% of the total crude gypsum.

Leading individual mines, in descending order of production, were USG's Plaster City Mine, Imperial County, CA; USG's Sweetwater Mine, Nolan County, TX; Harrison's Cement Mine, Caddo County, OK; USG's Sperry Mine, Des Moines County, IA; USG's Shoals Mine, Martin County, IN; National's Tawas Mine, Iosco County, MI; USG's Alabaster Mine, Iosco County, MI; USG's Fort Dodge Mine, Webster County, IA; Briar's Briar Mine, Howard County, AR; and National's Sun City Mine, Barber County, KS. These 10 mines accounted for 43% of the national total. Average output for the 61 mines decreased 11% to 253,000 tons.

Gypsum was calcined by 13 companies at 71 plants in 28 States, principally for the manufacture of gypsum wallboard and plaster. Calcined output decreased 13% in tonnage and 14% in value. Leading States, in descending order, were California, Iowa, Florida, Texas, Nevada, and New York. These 6 States, with 28 plants, accounted for 47% of the national output.

Leading companies were USG, 20 plants; National Gypsum, 18 plants; Georgia-Pacific, 10 plants; Domtar, 8 plants; and Celotex, 4 plants. These 5

companies, operating 60 plants, accounted for 84% of the national output.

Leading individual plants were, in descending order of production, USG's Plaster City plant, Imperial County, CA; USG's Jacksonville plant, Duval County, FL; USG's Sweetwater plant, Nolan County, TX; USG's Sperry plant, Des Moines County, IA; USG's Shoals plant, Martin County, IN; Briar's Briar plant, Howard County, AR; USG's Baltimore plant, Baltimore County, MD; National's Tampa plant, Hillsborough County, FL; USG's Stony Point plant, Rockland County, NY; and USG's Fort Dodge plant, Webster County, IA. These 10 plants counted for 30% of the national production. Average calcine production for the 71 U.S. plants was 216,000 tons, a 13% decrease.

A total of 681,000 tons of byproduct gypsum, valued at \$3.1 million, was used, principally in agriculture but some for gypsum wallboard manufacturing. Approximately 78% was of nonphosphogypsum origin compared with 69% in 1990.

According to the Gypsum Association, yearend gypsum wallboard plant capacity for producing 1/2-inch regular wallboard decreased slightly to 24.11 billion square feet per year. Total wallboard shipments were 16.8 billion square feet, 70% of capacity. Continued weakness in the wallboard market caused many plants to operate well below capacity level. Domtar's plant at Florence, CO, remained closed throughout the year, and its plant at Sweetwater, TX, was idle during the second half of the year. Centex American's new plant in Bernalillo, NM, came into production. Its other plant in Albuquerque did not operate. (See tables 2 and 3 and figure 1.)

Consumption and Uses

Apparent consumption, defined as production plus net imports plus industry stock changes, of crude gypsum, including byproduct gypsum, decreased 13% to 23.3 million tons. Net imports provided 33% of the crude gypsum consumed. Apparent consumption of

calcined gypsum decreased to 13% to 15.3 million tons.

Yearend stocks of crude gypsum at mines and calcining plants were 2.4 million tons. Of this, 54% was at calcining plants in coastal States.

Of the total gypsum products sold or used, 5.2 million tons, about 24%, was uncalcined. Uncalcined gypsum, crushed and screened to specifications, is marketed for use in portland cement manufacture, agriculture, and fillers. The cement industry uses gypsum to retard the setting time of concrete.

Finely ground gypsum rock is used in agriculture to neutralize alkaline and saline soils, improve the permeability of argillaceous materials, and provide sulfur and catalytic support for maximum fertilizer utilization and leguminous productivity. Small amounts of very pure gypsum are used as fillers and in glassmaking, papermaking, and pharmaceutical applications. In 1991, 63% of the uncalcined gypsum was used in portland cement, and the remainder was used mainly for agricultural purposes.

Of the total calcined gypsum products, most went into prefabricated products. A small percentage was used in industrial and building plasters. Of the prefabricated products, based on surface square feet, 63% was regular wallboard; 26% was fire-resistant type X wallboard; 4% was 5/16-inch mobile home board; and 3% was water- and/or moisture-resistant board. Lath, veneer base, sheathing, predecorated, and other types made up the balance. Of the regular wallboard, 80% was 1/2 inch and 13% was 5/8 inch.

In descending order, the leading sales regions for prefabricated products were the South Atlantic, Pacific, East North-Central, and Middle Atlantic. Together they accounted for 65% of the total. (See tables 4 and 5, and figure 2.)

Markets and Prices

On an average value-per-ton basis, f.o.b. mine or plant, crude gypsum increased slightly to \$6.09, calcined gypsum decreased slightly to \$15.67, and

byproduct gypsum increased slightly to \$4.49. Prefabricated products were valued at \$76.80 per ton, plasters at \$95.36 per ton, and uncalcined products at \$12.87 per ton.

According to the Department of Commerce, the average producer price of regular 1/2-inch wallboard was 8% lower in 1991 than in 1990, and type X board was 6% lower.¹

Lower demand and lower prices, especially for gypsum wallboard products, continued to cause difficult times for much of the industry. Two companies, Celotex and National, remained under chapter 11 bankruptcy protection.

Foreign Trade

Imports for consumption of crude gypsum decreased 14% to 7.6 million tons. Net imports represented 33% of apparent consumption. Crude gypsum from Canada and Mexico was used mainly to feed wallboard plants in coastal cities. Imports from Spain, the other major source of imported gypsum, were used mostly for portland cement manufacture. Gypsum wallboard imports, principally from Canada, decreased 64% to 108 million square feet. The decrease is a reflection of fewer housing starts in the United States. (See tables 6 and 7.)

World Review

Estimated world production of crude gypsum decreased slightly to 104 million tons. Total world production figures are probably low because, in some countries, significant production was consumed captively and not reported. Also, production from small deposits in developing countries was intermittent and often unreported. The United States remained the world's largest producer of crude gypsum with 15% of the world total.

Canada.—Eastern Gypsum Inc. closed its new gypsum wallboard plant in McAdam, New Brunswick. The facility was still for sale at yearend.

The Gypsum Association in the United States, of which all Canadian wallboard producers were members, reported that yearend capacity of 1/2-inch regular wallboard in Canada was 3.32 billion square feet, a slight decrease compared with that of the previous year.

China.—Two new mines were being planned near Xuzhou in northern Jiangsu Province. The planned output of 600,000 tons per year was to be used to make plaster.²

Dominican Republic.—A U.S. firm was reported to have entered into a joint venture with the Government to mine gypsum in Baharona Province. Production was expected to reach 1 million tons per year.³

Hungary.—Navan Resources PLC, from Ireland, was negotiating a joint-venture agreement with Erc-es Asvanybanyak, the Government-owned minerals company. Navan will receive an equity position in exchange for technology and investment. The operation currently supplies 200,000 tons of crude gypsum for use in cement manufacture and 30,000 tons per year of plaster.⁴

Mexico.—Compania Minera Caopas, S.A. opened a gypsum quarry and plant at Santa Rosalia in California Baja Sur. It was reported to be the largest privately owned gypsum facility in Mexico. Design capacity is 2 million tons per year and current production is nearly one-half of that.⁵

OUTLOOK

More than 90% of the gypsum consumed annually in the United States is used in construction, mainly in gypsum wallboard products, building plasters, and in the manufacture of portland cement. The decline in construction activity that has depressed demand for gypsum products over the past several years appears to be slowing. Gypsum product demand decreased in 1991, but a slow

recovery is expected to take place over the next few years.

HELIUM

By William D. Leachman

Mr. Leachman, a chemical engineer with 38 years of U.S. Bureau of Mines experience, has been the commodity specialist for helium since 1983. He also prepared the domestic survey and international data tables.

Grade-A helium (99.995% or better) sales volume in the United States by private industry and the U.S. Bureau of Mines was 61 million cubic meters [2,198 million cubic feet (MMcf)] in 1991.¹ Grade-A helium exports by private producers were 27 million cubic meters (978 MMcf), for total sales of 88 million cubic meters (3,176 MMcf) of U.S. helium. The Bureau's price for Grade-A helium, f.o.b. plant, was \$1.352 per cubic meter [\$37.50 per thousand cubic feet (Mcf)] and bulk liquid helium was \$1.622 per cubic meter (\$45 per Mcf) on January 1, 1991, with additional costs for container services and rent. On March 1, 1991, the price of gaseous helium was increased to \$1.747 per cubic meter (\$48.45 per Mcf), and the bulk liquid helium price was raised to \$2.017 per cubic meter (\$55.95 per Mcf). The last price increase was made on October 1, 1991, when the price of Grade-A helium was raised to \$1.983 per cubic meter (\$55 per Mcf) and liquid helium prices were raised to \$2.253 per cubic meter (\$62.50 per Mcf). Private industry also increased their helium prices last year, but less than the Bureau's.

DOMESTIC DATA COVERAGE

Domestic production data for helium are developed by the U.S. Bureau of Mines from records of its own operations as well as the High Purity Helium Survey, a single, voluntary canvass of private U.S. operations. Of the eight operations to which a survey request was sent, 100% responded, and those data plus data from the Bureau's operations

represent 100% of the total helium sales and recovery shown in table 2.

BACKGROUND

The U.S. Bureau of Mines role in helium matters dates back to the First World War when the Army and Navy became interested in using helium as an inert lifting gas and contacted the Bureau for assistance because of its natural gas expertise. In 1925, the Government's Helium Program was officially placed under Bureau control by Congress (Helium Act of 1925). In 1929, the Bureau's Amarillo, TX, large-scale helium extraction and purification facility was built and began operation. During World War II, demand increased significantly, and four more small Government helium plants were built.

New technology increased helium demand in the 1950's and led to the construction of the Keyes, OK, plant in 1959. Dwindling Hugoton-Panhandle Field natural gas supplies aroused concerns that no economic source of helium would exist by the turn of the century.

In 1960, Congress replaced the 1925 act with new legislation (Helium Act Amendments of 1960). The purposes of the act were to provide for conservation of helium for essential Government activities and to supply the current and foreseeable future helium needs of the Federal agencies. The act directed the Secretary of the Interior to purchase and store helium for future Government use and to operate and maintain helium production and purification plants and

related helium storage, transmission, and shipping facilities.

Purchases for helium conservation were made under 22-year contracts with private natural gas companies, which added crude helium extraction capabilities to their existing gas processing facilities. Four companies built five crude helium plants. The Bureau constructed a high-pressure pipeline to transport the helium from Bushton, KS, and intermediate points to the Bureau-owned Cliffside Field for storage.

Helium needs of the Federal agencies, particularly the U.S. Department of Defense (DOD), the National Aeronautics and Space Administration (NASA), and the U.S. Department of Energy (DOE), have been met, and there is enough helium in storage to meet their foreseeable needs for up to 100 years, depending on future Government program needs. The entire present Federal helium demand is supplied solely by the Exell Helium Plant.

In the mid-1970's, the Bureau began accepting privately owned crude helium for storage in Cliffside under long-term contracts. Private industry currently has a 7-month supply of helium in Government storage, assuming all private market requirements would be supplied from storage.

Geology-Resources

Domestic measured and indicated helium resources as of January 1, 1991, the latest figures available, are estimated to be 12.8 billion cubic meters [463 billion cubic feet (Bcf)]. The total identified helium resources are about 2.2

billion cubic meters (78 Bcf) less than those reported in 1990. The decrease is attributed to the reevaluation of the undefined indicated helium resources, which are based on the Potential Gas Committee's estimation of potential natural gas resources in the United States. The resources include measured reserves and indicated resources estimated at 6.9 billion cubic meters (249 Bcf) and 0.9 billion cubic meters (32 Bcf), respectively, in natural gas with a minimum helium content of 0.3%. A slight decrease in the measured reserves of helium is reported due to ongoing evaluations of the Nation's depleting helium resources. The change of the pressure and temperature bases at which the resources are reported [14.7 pounds per square inch absolute (psia) and 70° F to 101.325 kilopascals absolute and 15° C] also account for a 2% decrease in the volumes reported. The measured reserves included 1 billion cubic meters (34 Bcf) stored by the Bureau in the helium conservation storage system. Measured helium resources in natural gas with a helium content of less than 0.3% are estimated to be 1.1 billion cubic meters (40 Bcf). Indicated helium resources in natural gas with a helium content of less than 0.3% are estimated to be 3.9 billion cubic meters (143 Bcf). Approximately 4.4 billion cubic meters (160 Bcf) or 92% of the domestic helium resources under Federal ownership are in the Riley Ridge area and the Church Buttes Field in Wyoming and in the Cliffside Field in Texas.

Most of the domestic helium resources are in the midcontinent and Rocky Mountain regions of the United States. The measured helium reserves are in approximately 98 gasfields in 11 States. About 89% of these reserves is contained in the Hugoton Field in Kansas, Oklahoma, and Texas; the Keyes Field in Oklahoma; the Panhandle and Cliffside Fields in Texas; and the Riley Ridge area in Wyoming. The U.S. Bureau of Mines analyzed a total of 223 natural gas samples from 19 States and 1 foreign country during 1991 in conjunction with its program to survey and identify possible new sources of helium.

Technology

Technology that uses liquid helium to produce superconducting temperatures continues to be developed and utilized. Liquid helium continues to be used at Fermi National Accelerator Laboratory for Tevatron/Tevatron 1, which was the world's first superconducting particle accelerator. The liquid helium-cooled superconducting magnets used in this accelerator provide an intense and extremely steady magnetic field using only a fraction of the energy required by conventional electromagnets. The Tevatron is presently the second highest energy particle accelerator in the world (1.6 trillion electron volts). In addition, the DOE has already selected the magnets it proposes to use in the Superconducting Supercollider (SSC). These SSC magnets will be similar to those liquid helium-cooled magnets used at Fermi because they have been proved and tested in operation. When completed, the SSC will have about 20 times the power of the Tevatron (40 trillion electron volts). The Texas site for the SSC was selected by DOE in January 1989.

Argonne National Laboratory is developing a marine magnetohydrodynamic (MHD) propulsion system for military and commercial use. This system has no moving parts, but uses magnetic fields and electricity to pump water through a tube. This method of propulsion was illustrated in the science fiction movie "Hunt for Red October." Researchers at Argonne will use the world's largest helium-cooled superconducting dipole magnet to study the propulsion system. Development of this technology could lead to a new generation of water transportation vessels that would travel more quickly, quietly, and efficiently than present ships.

Liquid helium use in magnetic resonance imaging (MRI) continues to increase as the medical profession accepts and develops new uses for this equipment. MRI equipment is providing accurate diagnosis of medical problems where exploratory surgery was previously required. Another medical application being developed uses MRI to determine

by blood analysis if a patient has any form of cancer. Most researchers seem to think it will be at least 5 to 10 years before the new high-temperature [about -184 °C (-300 °F)] superconducting materials affect liquid helium demand.

Lifting gas applications are increasing. The U.S. Navy and U.S. Air Force are investigating the use of airships to provide early warning systems to detect low-flying cruise missiles. The Drug Enforcement Administration has installed six tethered radar blimps along the southern border of the United States to detect drug smugglers. In addition, NASA is now using helium-filled balloons to sample the atmosphere in Antarctica to determine what is depleting the ozone layer that protects the Earth from harmful ultraviolet radiation. Similar work is also underway in the Arctic. A stealth blimp is being tested by the Army's Intelligence and Electronic Warfare Center in New Jersey. In the commercial market, several companies besides Goodyear are now using "blimps" for advertising.

The development of Strategic Defense Initiative (SDI) weapons such as the antisatellite (ASAT) rocket, chemical laser, and rail gun has slowed with the decline of the "cold war." The ASAT rocket uses liquid helium-cooled infrared sensors for target location and guidance. Gaseous helium is used in the lasing gas mixture of the chemical laser, and liquid helium is used to cool the tracking telescope used to locate the target and aim the laser beam. High-pressure gaseous helium provides the initial push that inserts the projectile into the bore of the rail gun at a velocity of about 1,770 kilometers per hour (1,100 miles per hour). Electromagnetic energy applied along the bore accelerates the projectile to a final velocity of about 14,500 kilometers per hour (9,000 miles per hour). Superconducting magnetic energy storage (SMES) is also being investigated to provide power for DOD laser systems and electric power peak shaving in commercial applications. SMES allows the accumulation and storage of electrical energy over the long term (hours) when excess capacity is available and

discharges it in minutes or as needed to provide for peak demands.

Other evolving technologies that require the unique properties of helium are (1) metastable helium for energy storage, which involves raising helium electrons to an excited energy state and then stabilizing the atom there; (2) fiberoptic production, where an ultrapure atmosphere is required; (3) helium-filled plastic pillows, where low density is required to simulate a precursor wave from a nuclear blast; (4) helium ion tumor treatment, where large inert particles are required; (5) liquid helium-cooled superconducting microswitches, called Josephson junctions, which are much faster than conventional semiconductors and use less power; (6) "aneutronic" nuclear fusion where nuclear energy is produced by fusion of deuterium and helium-3, which produces few or no neutrons; and (7) helium-hydrogen breathing mixtures that enable deep-sea divers to reach depths below 580 meters (1,700 feet).

ANNUAL REVIEW

Legislation and Government Programs

The Administration is proposing legislation to amend the Helium Act of 1960 to remove the requirement that all Federal agencies buy their major helium requirements exclusively from the Secretary of the Interior. This means they could buy helium from private industry helium vendors or the U.S. Bureau of Mines, whichever they choose.

The Federal Helium Program is designed to provide all Federal agencies with their current and foreseeable-future helium needs to carry out other Government programs authorized and funded by Congress. The Bureau's major helium customers are DOD, NASA, and DOE.

Production

In 1991, 14 privately owned domestic helium plants were operated by 10 companies. Eight of the privately owned

plants and the U.S. Bureau of Mines plant extracted helium from natural gas. All extraction plants except one use cryogenic extraction processes. The volume of helium recovered from natural gas increased 34%, while sales increased about 4% in 1991. A shortage of private helium production was prevented by purifying crude helium that had been stored in the Bureau's Cliffside Field. All natural gas processed for helium recovery came from gasfields in Colorado, Kansas, New Mexico, Oklahoma, Texas, and Wyoming. Eight private plants and the Bureau's plant purified helium this year. Pressure-swing adsorption is used for helium purification at seven of the private helium plants and at the Bureau's plant. Cryogenic purification is used by the other producer. The Bureau also uses cryogenic purification for backup. The Bureau and seven private plants that produce Grade-A helium also liquefy helium. The plant operators and locations are Air Products and Chemicals Inc., Hansford County, TX; and Liberal, KS; Navajo Refined Helium Co., Shiprock, NM; Kansas Refined Helium Co., Otis, KS; Exxon Co., U.S.A., Shute Creek, WY; and Union Carbide Corp., Linde Div., Bushton and Ulysses, KS. Nitrotec's helium plant near Burlington, CO, produces Grade-A helium but does not liquefy helium. Linde's helium plant at Elkhart, KS, was shut down in 1988. (See tables 1, 2, and 3, and figures 1 and 2.)

Consumption and Uses

The major domestic end uses of helium were cryogenics, welding, and pressurizing and purging. Minor uses included synthetic breathing mixtures, chromatography, leak detection, lifting gas, heat transfer, and controlled atmospheres. The Pacific and Gulf Coast States were the principal areas of helium consumption.

Bureau sales to Federal agencies and their contractors totaled 9.399 million cubic meters (339 MMcf) in 1991, a decrease of about 16% when compared with last year's sales. This decrease was due largely to the helium price increases

during the year and reduced SDI spending as the cold war declined. Sales to DOE also continue to decline.

The Federal agencies purchase their major helium requirements from the U.S. Bureau of Mines. Direct helium purchases by DOD, NASA, DOE, and the National Weather Service constituted most of the Bureau's Grade-A helium sales. Most remaining helium sales to Federal agencies were made through Bureau contract distributors, who purchased equivalent volumes of Bureau helium under contracts described in the Code of Federal Regulations (30 CFR 602). Some of the contract distributors also have General Services Administration helium supply contracts. These contracts make relatively small volumes of helium readily available to Federal installations at lower freight charges by using the contractors' existing distribution systems. (See figure 3.)

Stocks

The volume of helium stored in the U.S. Bureau of Mines helium conservation storage system, which includes the conservation pipeline network and the Cliffside Field near Amarillo, TX, for future use totaled 1 billion cubic meters (34.3 Bcf) at yearend. The conservation storage system contains crude helium purchased under contract by the Bureau and privately owned helium stored under contract. Excess helium production of private industry extracted from natural gas supplying fuel markets in the winter is stored by the U.S. Bureau of Mines under contract. This privately owned crude helium is returned as needed to the owners for purification to supply private industry demand. During 1991, 26.6 million cubic meters (958 MMcf) of private helium was delivered to the Bureau's helium conservation storage system and 18.7 million cubic meters (675 MMcf) was withdrawn for a net increase of 7.9 million cubic meters (283 MMcf) of private helium in storage. (See table 4.)

Transportation

All Grade-A gaseous helium sold by the Bureau was shipped in cylinders, modules (large gas cylinders), special railway tankcars, or highway tube semitrailers. Small gas cylinders are filled at the Amarillo plant, and railway tankcars are filled at the Exell plant. Other shipping containers for gaseous helium can be filled at either plant. Bureau liquid helium was shipped in dewars and semitrailers from the Exell plant. Private producers and/or distributors shipped helium predominantly as a liquid in semitrailers. These semitrailers delivered the liquid helium to distribution centers where some of it was gasified and compressed into trailers and small cylinders for delivery to the end user. The remaining liquid helium was sold as bulk liquid or repackaged in dewars of various sizes for delivery.

Prices

The U.S. Bureau of Mines price for Grade-A helium, f.o.b. plant, was \$1.352 per cubic meter (\$37.50 per Mcf) and bulk liquid helium was \$1.622 per cubic meter (\$45 per Mcf) on January 1, 1991, with additional costs for container services and rent. On March 1, 1991, the price of gaseous helium was increased to \$1.747 per cubic meter (\$48.45 per Mcf) and the bulk liquid helium price was raised to \$2.017 per cubic meter (\$55.95 per Mcf). The last price increase was made on October 1, 1991, when the price of Grade-A helium was raised to \$1.983 per cubic meter (\$55 per Mcf) and liquid helium prices were raised to \$2.253 per cubic meter (\$62.50 per Mcf). Private industry also increased their helium prices last year, but lagged behind the Bureau's.

Foreign Trade

Exports of Grade-A helium, all by private industry, increased by 10% in 1991 to 27.1 million cubic meters (928 MMcf) (table 3). About 49% of the exported helium was shipped to Europe. Belgium-Luxembourg, France, and the United Kingdom, collectively, received

about 85% of the European helium imports. About 35% of the U.S. helium exports went to Asia, with Japan receiving about 89%. Other exports were as follows: about 8% to North America; about 2% each to Australia-New Zealand, Middle East, and South America; and less than 1% each to Africa, the Caribbean, and Central America. The shipments of large volumes of helium to Western Europe were attributed to helium uses in cryogenic research and superconducting equipment. Significant volumes were also being used in breathing mixtures for diving, welding, and as a lifting gas. Although no helium was imported by the United States in 1991, import tariffs on helium remained at the 3.7% rate established on January 1, 1987. No further decreases in import tariffs are scheduled.

World Review

World production of helium, excluding the United States, was estimated to be 11 billion cubic meters (400 MMcf), most of which was extracted in Poland and the U.S.S.R. The remainder was produced in small plants in China and India. (See table 5.)

OUTLOOK

Until recently, all superconductors required liquid helium [-269° C (-452°F)] to reach superconducting temperatures. Current research on superconductors has resulted in the discovery of superconducting materials that operate above liquid nitrogen temperatures [-196° C (-320° F)]. These new superconductors have physical limitations, such as brittleness and poor current-carrying capacities, which have precluded their use in most superconducting applications. If these physical problems are solved, the new materials could replace liquid helium-cooled superconductors.

Since 1987, the market for U.S.-produced helium has grown at an average annual rate of 9%. Private industry's market has been growing at 10% per year, while the Federal market has grown

at 6%. At the present time, private industry is supplying about 85% of the domestic demand for U.S.-produced helium, while the Bureau is supplying the remaining 15%. Private industry supplies all of the U.S. helium exports. The foreign market made up about 31% of U.S. helium sales in 1991 and has grown at an average rate of almost 19% per year since 1987.

At the present time, the outlook for helium looks good with growth continuing in new technologies that use helium. An adverse impact from high-temperature superconductors, if any, is not expected for several years.

¹All helium volumes herein reported are at 101.325 kilopascals absolute (14.696 psia) and 15° C (59° F). One thousand cubic feet (1 Mcf) at 14.7 psia and 70° F = 27.737 cubic meters at 101.325 kilopascals absolute and 15° C. One cubic meter at 101.325 kilopascals and 15° C = 36.053 ft³ at 14.7 psia and 70° F.

INDIUM

By Stephen M. Jasinski

Mr. Jasinski, a physical scientist with 5 years of U.S. Bureau of Mines experience, has been the commodity specialist for indium since 1988. Domestic survey data were prepared by Susan Copeland, mineral data assistant.

In the past decade indium usage has been boosted by its increasing importance in high-technology electronics. Indium and its compounds are used in liquid crystal displays, infrared detectors, high-speed transistors, solar cells, and variety of other related applications.

In 1991, the Indium Corporation of America (ICA) and Falconbridge Ltd. joint venture firmly established itself as the leading producer of indium metal in North America and one of the largest in the world. The two companies joined in 1989 and constructed an indium refinery at Falconbridge's Kidd Creek Mine in Timmons, Ontario, Canada. The plant, which is operated by Falconbridge, produces standard-grade (99.97% purity) indium as a byproduct of copper and zinc processing. All indium ingots are shipped to ICA in Utica, NY, the exclusive marketed agent.

Increased refinery production of indium in Canada and France resulted in a slight oversupply situation in the world market in 1991, with world production increasing 20 metric tons over that of 1990. This caused prices to drop slightly throughout the year.

Domestic consumption remained level in 1991, with solders and alloys accounting for about 40% of total usage. The production of indium and indium-tin oxide sputtering targets for use in manufacturing thin film coatings for glass and semiconductors continued to be the most active area of research and development.

DOMESTIC DATA COVERAGE

The two domestic refiners of indium in 1991 chose not to respond to the voluntary survey of indium produced from primary sources. There was no domestic mine production of indium in 1991. Domestic consumption estimates were based upon discussions with the major refiners and consumers and analysis of trade data.

BACKGROUND

Definitions, Grades, and Specifications

Indium is silvery-white in color and has a brilliant metallic luster. It is softer than lead, is very ductile and malleable, and has a very low melting point; therefore, it is well suited for use in solders and low-melting alloys. It retains these plasticlike properties to temperatures near absolute zero. Indium can endure considerable deformation through compression and cold-welds easily.

Some physical constants of pure indium, chemical symbol In, are: atomic number, 49; atomic weight, 114.82; melting point, 156.61° C; boiling point, 2,080° C; and density, 7.31 grams per cubic centimeter at 20° C. Standard grade is 99.97% purity, and high grades are available from 99.99% (4N) to 99.999999% (8N) purity.

Uses and Products for Trade and Industry

Indium was available in various forms, such as ingot, foil, shot, ribbon, wire, and powder. Standard-grade indium was generally used in solders, chemical compounds, plating solutions, and fusible alloys. High-purity indium was used for semiconductors, coatings, and solar cells.

Thin-film coatings on glass, which included indium oxide and indium-tin oxide (ITO), constituted 35% of total domestic indium usage in 1991. Coatings have been the largest area of growth and research for indium in the past 5 years. Applications involving thin coatings on glass can be divided into two categories, electrically conductive and infrared reflecting.

Electrically conductive coatings, the largest group, were used primarily in liquid crystal displays (LCD) for watches, television screens, portable computer screens, video monitors, and other related display devices. Aircraft and locomotive windshields used a transparent, electrically conductive ITO film as a defroster or defogger. In this application, the electric current heats the film quickly to clear the glass. Indium coatings are more effective than other types of materials, but the use of indium was limited because of its higher cost and limited supply. Several automobile manufacturers have also experimented with indium, but because of the cost and availability factors, most have opted for a zinc-silver oxide coating for quick-defrosting windshields. In a similar use, glass doors on commercial refrigerators

and freezers are kept free of condensation and frost by a heated thin film of ITO.

Another group of films includes visually transparent infrared reflecting coatings on window glass, used to control energy losses by reflecting heat inward in winter and outward in summer. For residential windows, the coating is usually applied to a plastic sheet and encased between two panes of glass. This prevents erosion of the coating and reduces the cost of production. Because the expense of refitting a commercial building remains high, other less expensive metals, such as silver, were used instead of indium in coatings on commercial windows.

A major domestic use for indium has been as an addition to bismuth, cadmium, lead, or tin alloys to lower the melting point. These alloys can be used in such applications as electrical fuses, fusible links, or as holding material for the grinding of optical glass. Pure indium and several indium alloys will wet glass and were used for glass-to-metal and glass-to-glass seals.

Indium was used as a strengthening agent for lead solder and as the base material for a variety of low-melting-temperature solders. Many indium-base solders have a melting point below 183° C, the melting point of conventional 63% Sn-37% Pb solder used in electronic applications. This makes indium solder useful for components that would be damaged by a high soldering temperature. Indium-base alloys also remain flexible over a greater temperature range than tin-lead solder. Indium solders reduce the possibility of gold scavenging, a problem that occurs when tin-lead solder is used to join gold components. The solder will gradually leach gold from the contact surface, thus weakening or damaging the soldering joint.

Several manufacturers of pressurized water nuclear reactors used an alloy consisting of 80% silver, 15% indium, and 5% cadmium for nuclear control rods. The production of these rods declined in the United States in the early 1970's when orders for new nuclear powerplants began to drop. Following the Three Mile Island nuclear accident in

1979, all orders for new nuclear powerplants in the United States ceased and subsequent consumption has been only for replacement rods, which must be changed every 15 years.

The use of indium in batteries grew in 1991, as several proprietary indium alloys were used as a replacement for mercury in alkaline batteries. The indium compounds are used for the same purpose as mercury, to prevent the buildup of hydrogen gas in the sealed container, which can cause the battery to leak. Low-mercury batteries were available in AAA, AA, C, D, and 9-volt sizes and did not increase in price.

Minor uses of indium included indium-palladium and indium-gold alloys in dentistry, use as a surface lubricant for abrasive compounds, and as an additive to lubricating oil to prevent corrosion. Certain radiation-detection badges used indium foil because low-energy neutrons easily induce radioactivity in indium.

Industry Structure

ICA, Utica, NY, produces most of its standard-grade indium at the Kidd Creek plant in Timmons, Ontario, Canada, where it is recovered as a byproduct of Falconbridge's Kidd Creek copper-zinc operations. All indium is shipped to the ICA refinery in Utica where it is sold as standard-grade indium or upgraded to higher purity metal. Arconium Specialty Alloys, Providence, RI, refines indium from imported zinc residues, low-grade indium bullion, and indium scrap. Arconium; ICA; Johnson Matthey Electronics, Spokane, WA; and several other companies produce high-purity indium shapes, ingots, and foil. Metalspecialties Inc., Fairfield, CT, intermittently recovers indium from old scrap. New scrap is usually returned to the supplier for reprocessing.

Because indium is primarily recovered from residues, slags, flue dusts, and intermediate compounds resulting from zinc smelting, world mine production is inferred from the average indium content of zinc ore mined. Canada is the largest producer of zinc in the world; therefore,

its mine production is believed to contain the largest quantity of indium.

North America has the world's largest refinery capacity, more than 100 tons per year; however, production was about one-third of the capacity in 1991. Europe and Japan possessed the bulk of the world capacity.

Geology-Resources

Indium occurs predominantly in solid solution in sphalerite (ZnS), the principal mineral of zinc ore, but it often is found in ores of copper, lead, and tin. Indium does not occur in the native state. The average indium content of the Earth's crust is estimated at 0.1 part per million, about the same as that of silver.¹ The indium content of mined zinc deposits ranges from 0 to 100 parts per million. The highest known indium concentrations are in vein, replacement, and contact metasomatic sulfide deposits, especially those containing tin minerals. The indium contents of these tin deposits typically range from 100 to 21,000 parts per million. Deposits of this type include those in the Central City district in Colorado, the Argentine Andes, the Cornwall tin district in England, and the Mount Pleasant deposit in New Brunswick, Canada.

Because indium is usually recovered as a byproduct of zinc, world indium reserves for most countries are based on weighted estimates of the average indium contents of regional zinc ores. For some countries the reserve figure has been based on data provided by the individual country's geologic information agency. (See table 1.)

Technology

A variety of methods are employed to recover indium, depending on the source material and indium content. Indium is primarily recovered as a byproduct of zinc processing. Among the more common methods of recovery are leaching the indium-containing material with sulfuric or hydrochloric acid and extracting the crude indium from solution by cementation on aluminum or zinc

sheets. Solvent extraction with organic solutions is used to recover indium from dilute solutions. Another method involves the precipitation of indium phosphate selectively from slightly acidic solutions and conversion to oxide by leaching in a strong caustic soda solution, followed by reduction of the oxide to metal.

During the smelting of zinc, the indium concentrates in the zinc-lead bottom metal and is separated from that portion by chlorination under molten salt, forming an indium-rich slag. Indium is recovered from the slag by leaching and cementation on zinc or aluminum sheets. The indium deposits on the sheets as a low-density, sponge-like mass, which breaks away and floats to the surface of the solution. The indium sponge is washed, briquetted, melted, and cast into anodes for electrolytic refining.² (See figure 1.)

Recycling.—Spent sputtering targets are returned to the manufacturer for recovery of the indium. Usually the sputtering target consists of indium or indium-tin oxide placed on a copper substrate. After the usable indium surface has been eroded, the remaining material, 20% to 60% of the surface area, depending on the type of target, is returned to the producer to be recycled.

Most indium solder and plating solutions are not recycled. Spent nuclear control rods containing indium are radioactive; therefore, they are buried in nuclear waste disposal sites.

Fusible alloys that are used in applications such as lens blocking, where the alloy is remelted and reused, eventually have to be returned to be realloyed due to contamination and loss.

Byproducts and Coproducts

Indium is a minor byproduct of processing base metal ores or zinc residues. The value of recovered indium is negligible in relation to the value of zinc production. Coproducts include molybdenum, silver, tin, and tungsten.

Substitutes

In solder and fusible alloys, bismuth can substitute for indium, but only for certain applications, because some bismuth-base solders are prone to brittleness. Hafnium can replace silver-indium-cadmium in nuclear control rods. Silver-zinc oxide costs less than indium-tin oxide; therefore, it is preferred for use in automobile windshield coatings for quick defrosting applications.

Economic Factors

Indium, which is classified under Harmonized Code Tariff 8112.91.3000 as "unwrought, waste and scrap, and powders of indium," was imported free from most favored nations (MFN) and subject to a 25% ad valorem duty from non-MFN.

ANNUAL REVIEW

Legislation and Government Programs

The Defense Logistics Agency, which maintains the National Defense Stockpile, proposed reducing the goal for indium in the stockpile 41,990 kilograms to 7,740 kilograms. The inventory on December 31 was zero. Purchases were expected to begin in 1992 at the rate of 1,555 kilograms annually.

Consumption and Uses

Domestic consumption was estimated at 30 tons, and the estimated usage pattern was as follows: solders and alloys, 40%; coatings, 35%; electronic and semiconductor uses, 15%; and research and other, 10%.

Markets and Prices

The price for standard-grade indium began the year at \$225 per kilogram and dropped in July to \$210 per kilogram, where it remained until the end of the year. The price quoted for other producers was slightly higher. The oversupply of indium worldwide caused the price to drop slightly during the year.

Foreign Trade

U.S. imports for consumption from Canada increased from 11% of the total in 1990 to 60% in 1991. This was because of the opening of the Kidd Creek indium plant in Ontario by ICA and Falconbridge. All indium refined at the plant was sold through the ICA sales office in Utica, NY. (See table 2 and figure 2.)

World Review

World indium production in 1991 was estimated at 140 tons, an increase of 20 tons from 1990. The increase was attributed to the opening of the Kidd Creek facility in Canada and greater output from Metaleurope in France. World consumption was estimated at between 120 to 130 tons. The world indium market was in a slight oversupply situation as the leveling off of new uses for indium and the world economic recession slowed the quick growth the indium market had experienced in the late 1980's.

Capacity.—The data in table 3 are the rated annual capacity for refineries as of December 31, 1991. Rated capacity is defined as the maximum quantity of material that can be produced in a given period on a normally sustainable long-term operating rate. It is based on the physical equipment of the plant and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that in the judgment of the author can be brought into production within a short period with minimum capital expenditure.

Refinery capacities for indium are based on the combination of data on engineering capacity provided by some companies and estimates by the U.S. Bureau of Mines. (See table 3.)

Canada.—NovaGold Resources of Halifax, Nova Scotia, signed a letter of intent to purchase the Mount Pleasant tin-

tungsten mine in New Brunswick from Lac Minerals Ltd. The Mount Pleasant property was opened as a tungsten mine in 1983, but it was closed in 1985 due to the depressed tungsten market. The property has substantial reserves of tin, tungsten, and molybdenum. Mount Pleasant also has one of the largest reserves of indium in the world.

NovaGold intends to recover tin as the primary metal and bismuth and indium as coproducts. Because of the recent trend of low tin prices, NovaGold plans to use the value of indium production to enhance revenue. The sale was expected to be final in 1992.

The Falconbridge-ICA plant in Timmons, Ontario, completed its first full year of operation in 1991, and it was the largest producer in North America. The estimated output was about 25 tons. Refinery capacity was 30 tons per year, but the plant is expected to adjust output to demand patterns.

Cominco Ltd. produced indium at its Trail, British Columbia, refinery from domestic and imported materials. The plant operated at less than 50% capacity because of the slow market conditions. Cominco sold its indium primarily outside of North America.

Japan.—Japan consumed about 66 tons of indium in 1991, a slight increase from that of 1990. About 40% of that went into the production of thin-film coatings. Domestic refinery output was estimated at 30 tons, with imports supplying the balance of market requirements. The Geological Survey of Japan began a study of the world's indium deposits in 1991 and collected samples from the Mount Pleasant site in Canada, the Toshama deposit in India, and the Akenobe, Goka, and Toyoha Mines in Japan.

OUTLOOK

World reserves and increases in production capacity are sufficient to meet expected demand for indium through the year 2000. Consumption of indium is expected to increase gradually in this period, especially for LCD's semiconductor materials, batteries, and in

low-temperature solder for military and commercial electronics. Other uses such as nuclear control rods, which have a lifespan of 15 years, and fusible alloys should remain steady.

IODINE

By Phyllis A. Lyday

Mrs. Lyday, a physical scientist with the U.S. Bureau of Mines, has been the commodity specialist for iodine for 13 years. Domestic survey data were prepared by Blanche Hughes, statistical assistant; and international data tables were prepared by William L. Zajac, Chief, Section of International Data.

Three producers of crude iodine supplied approximately 62% of domestic demand; the remainder was imported. Because some exports and imports are in product categories rather than crude products, net imports are not clearly developed. The major world producer, Japan, produced iodine from brines associated with gas production. The second largest producer, Chile, produced iodine as a coproduct of sodium nitrate.

DOMESTIC DATA COVERAGE

Domestic production data for iodine are developed by the U.S. Bureau of Mines from a voluntary survey of U.S. operations. Of the four operations to which a survey request was sent, four responded, representing an estimated 100% of the total production shown in tables 1 and 8. (See tables 1 and 8.)

BACKGROUND

Definitions, Grades, and Specifications

Commercial crude iodine normally has a minimum purity of 99.5%. Resublimed iodine is usually 99.9% pure. Most iodine is converted for industrial use to potassium iodide, sodium iodide, and other inorganic compounds, as well as numerous organic compounds.

Geology-Resources

Iodine occurs in rocks and soils, surface and underground brines, and caliche ores. Michigan brines contain

about 30 parts per million (ppm) of iodine in the Sylvania Formation of Devonian age. California brines contain 30 to 70 ppm of iodine in brines associated with oilfields in the middle Miocene age, Monterey Formation, and the lower Pliocene age Repetto Formation. Louisiana brines contain about 35 ppm of iodine. In Oklahoma, iodine concentrations associated with oil and gas range between 150 and 1,200 ppm. In Woodward County, OK, iodine occurs in the Morrowan Formation of Pennsylvania age. The iodine concentration averages about 300 to 350 milligrams per liter; 22 barrels of brines are required for each kilogram of iodine.

Extensive iodine-bearing nitrate ores occur in caliche deposits in a belt several hundred kilometers long in the Atacama Desert of northern Chile. The ore layers are 1 to 3 meters thick, usually flat or gently dipping and near the surface. Evaporate minerals such as lautarite (CaI_2O_6) and dietzeite ($2\text{CaO}\cdot\text{I}_2\text{O}_5\cdot\text{CrO}_3$) occur as cementing material in unconsolidated surface material or as veins and impregnations in bedrock.

Japanese brines contain 50 to 135 ppm of iodine in the Kiwada, Otadai, and Umegase Formations of the Kazusa Group of Pliocene age. The major iodine-producing area was the southern Kanto Gasfield, which extends over Chiba, Tokyo, and Kanagawa Prefectures. Iodine was produced in the Niigata and Nakojo Gasfields in Niigata Prefecture, on the Sea of Japan side of central Japan, and the Sadowara Gasfield in Miyazaki Prefecture, southern Kyushu.

In Indonesia, iodine occurs with trace amounts of bromine in brines associated with oil. The most important iodine-producing area is the Gujangan anticline of sandstone and diatomaceous marls of the Upper Pliocene, Kailiberg Formation.

On Okinawa, iodine occurs in concentrations of about 85 ppm in the Tomigusuku Formation of the Shimajiri Group of late Miocene-early Pleistocene age.

Technology

Processing.—In Japan and the United States, iodine is removed from brines by processes that separate the brines from any associated hydrocarbons. In the blowing-out process, brine is acidified and iodine is liberated by reducing the pH to about 3. A countercurrent stream of air transports the liberated iodine to a second tower in which the iodine is absorbed by a solution of hydriodic acid. The iodine settles, is filtered, and melted under concentrated acid. Brine stripped of iodine is treated and then reinjected into its subsurface formation of origin.

In the absorption process, brine is passed through an absorber, and the waste brine is neutralized and sent to a disposal well. The absorbent laden with iodine is treated with an alkaline solution to regenerate the absorbent and eludes iodine as sodium iodide. Iodide is precipitated under acid.

Japanese plants also use an ion-exchange resin. Upon saturation, the iodine is eluted using a caustic solution that regenerates the resin. Iodine is then

processed with a sodium chloride solution and melted under acid.

Chilean caliche deposits are mined by open pit methods. The ore is leached with an alkaline solution to dissolve the iodine as sodium iodate, which is converted to sodium iodide. Iodine is precipitated by reacting with additional alkaline solution. The precipitated iodine is filtered in bag filters and the iodine free-leach solution is returned to the nitrate-leaching cycle.

Recycling.—The removal of ionic silver from photographic processing solutions, such as developer, fixer, bleach fixers, and washwaters, can be accomplished with halogens such as iodine and an adsorbent. Photographic silver is commonly recovered by electrolytic methods if the concentration is greater than 500 ppm. Adsorbents such as natural and synthetic zeolites, activated alumina, activated silica, Fuller's earth, and ion exchange resins are used to recover low concentrations of silver from a stream.

Economic Factors

Prices.—Changes in the official price of crude iodine have in the past been initiated during shortages. Because iodine cannot be substituted in radiopaque, animal feeds, catalysts, and stabilizers readily, shortages tend to cause the accumulation of inventories to ensure an adequate supply. An adequate supply tends to lower and stabilize the price. (See table 2.)

Costs.—One typical iodine brine well costs about \$2 million to complete and is between 1,800 and 3,000 meters deep. Electrical costs for maintaining the pumps to bring the brine to the surface, for air-blowing the iodine, and for reinjecting the brine are major components of maintenance costs. Capital costs have been estimated at \$20 per pound of annual iodine production. These costs include high-quality stainless steels because iodine is highly corrosive. In addition, the brine must be leased from

private landowners over large acreage for many years. The principal material cost is for chlorine because 1 pound is required for every 1.4 to 1.8 pounds of iodine produced.

Tariffs.—Crude and resublimed iodine enter the United States duty free. Calcium and cuprous iodine has a 25% ad valorem for non-most-favored-nation status. Potassium iodide has a 2.8% ad valorem for most-favored-nation status and 7.5% ad valorem for non-most-favored-nation status.

Depletion Provisions.—The domestic and foreign depletion allowances for mined iodine are 14% of gross income, and they may not exceed 50% of net income without the depletion deduction. The domestic and foreign depletion allowances for minerals from brine wells are 5%.

Operating Factors

Environmental Requirements.—The reinjection of waste brine is a limiting factor to the production of iodine. During 1982, the Environmental Protection Agency reclassified disposal wells for spent brine after halogen extraction as Class 5 wells. All of the reinjection wells for iodine in Oklahoma were drilled for the reinjection of waste associated with brine production or oil and gas effluent.

Toxicity.—Iodine is absorbed by the body and concentrated in the thyroid. Iodine is essential to higher animals and humans. A normal person requires about 75 milligrams of iodine per year, which is usually consumed as iodized salt that contains one part sodium or potassium iodide to 100,000 parts of sodium chloride. Iodine deficiency is a major cause of goiter.

The maximum safe concentration for short-term air environment exposure of up to 1 hour is 1.0 ppm. Exposure of the lungs and eyes can be irritating at concentrations of 0.1 ppm and should be avoided. Greater exposure can cause

severe irritations to the eyes and the respiratory tract and may lead to pulmonary edema.

In 1979 and 1986, nuclear accidents caused the release of radioactive iodine, I^{131} , into the atmosphere. A dosage of potassium iodide (KI) administered before or shortly after exposure of radioactive iodine can block the intake of radiation to the thyroid. The dosage must be repeated if exposure continues. Replenishing the thyroid with KI prevents the thyroid from using radioactive I^{131} for normal metabolic needs.

ANNUAL REVIEW

Legislation and Government Programs

The Food and Drug Administration (FDA) announced the expiration of the provisional listing for FDA Red Dye No. 3 containing 58% iodine by weight. Uncertified material is commonly called erythrosine or other names, including Color Index (C.I.) Acid Red 51 and C.I. Food Red 14. FDA Red No. 3 is a bluish red color of the xanthene class and is currently identified in Chemical Abstracts as CAS Reg. No. 16423-68-0. The common name established by industry is fluorescein. The effective date of the expiration was January 29, 1990, for the use of Red No. 3 in coloring cosmetics and externally applied drugs and for all uses of the lakes. Lakes are soluble dyes absorbed on or combined with an inorganic carrier. Red No. 3 continued to be used in food additives.

Strategic Considerations

The National Defense Stockpile contained 6.1 million pounds of crude iodine. The stockpile goal remained at 2.6 million kilograms (kg) (5.8 million pounds). The Defense Logistics Agency (DLA) of the U.S. Department of Defense disposed of 35,634 kg of excess material valued at \$124,772 during fiscal year 1991. The DLA sought to barter surplus metals and minerals, including iodine, but no exchanges were reported.

Production

IoChem Corp. began production in 1987, 2 miles east of Vici, Dewey County, OK, by the blowing-out process. The majority of production was shipped to Schering AG, Federal Republic of Germany, under a long-term contract. IoChem was reported to have nine production wells and four injection wells with a total production capacity of 1,400 kg.

North American Brine Resources began operation of a miniplant at Dover in Kingfisher County, OK, in 1983. The plant is at an oilfield reinjection disposal site that obtains brines from about 50 wells in the Oswego Formation. Iodine concentrations ranged up to 1,200 ppm. The company also operated a plant at the border of Woodward and Harper Counties, OK, that began operating in 1991.

Woodward Iodine Corp. began production in 1977 and was purchased by Asahi Glass Co. of Japan in 1984. Woodward operated a plant in Woodward County that produced iodine from 14 brine wells using the blowing-out process. Nameplate capacity was reported at 900,000 kg per year.

Consumption and Uses

Iodine was used primarily in animal feed supplements, catalysts, inks and colorants, pharmaceuticals, photographic equipment, sanitary and industrial disinfectants, stabilizers, and radiopaque medium. Other smaller uses included production of batteries, high-purity metals, motor fuels, iodized salt, and lubricants.

The lithium-iodine battery was the first commercially successful lithium battery and is unusual because of its in situ growth of electrolytes. Superior charge transfer is achieved using an iodine compound with powdered iodine. Layers of lithium iodide act as both electrolyte and separator and are self-sealing in the event of a crack. Thus, the batteries are intrinsically reliable and withstand abuse.

Mallinckrodt Medical Inc., a division of Mallinckrodt Inc., was restructured

into a separate corporation in July 1990. Mallinckrodt Medical ranks as one of the world's leading medical products companies, organized in five divisions: anesthesiology, cardiology, nuclear medicine, radiology, and sensor systems. The company pioneered many advances in the development of X-ray contrast media and later nuclear medicine products for use in diagnostic procedures. The company produces a range of X-ray contrast media and nuclear medicine pharmaceuticals using iodine to visualize the body's organs and blood vessels.¹ Optiray, a nonionic X-ray contrast medium, was introduced in 1989 and will be expanded to several European countries. The conventional ionic segment was distributed under the brand name of Conray and Hexabrix for marketing in several countries.² Aided by a \$75 million investment, output was being doubled at St. Louis, MO.

Sterling Drug, a unit of Eastman Kodak, announced a worldwide pharmaceutical and consumer health alliance with Sanofi of French Elf Aquitaine. Omnipaque was offered by a licensing arrangement from Norwegian patent holder Hafslund Nycomed to Winthrop Pharmaceutical.

Clinical trials reached phase 2 in the United States for Hafslund Nycomed's Iodixanol nonionic X-ray contrast medium. The medium, described as third generation, is the first of its kind approved for general use.³

Bristol-Myers Squibb offered Isovue, the U.S. market leader among nonionics, to the Italian Bracco Industria Chimica. United-Guardian Inc. granted Columbia Laboratories Inc. of Hollywood, FL, an exclusive option on an iodoform-based antiseptic stick. The stick is reported not to stain, sting, or burn and can be carried in a pocket or purse.⁴

Eastman Chemical Co. completed a \$200 million expansion of its chemicals from coal complex in Kingsport, TN. The expansion will increase the production of acetic anhydride made from coal by 560 million pounds to 1.2 billion pounds per year.⁵ Eastman is one of two companies that produce acetic anhydride, the other being Hoechst Celanese with

270,000 pounds of production per year at three plants in three States. About 80% of acetic anhydride is used to produce cellulose acetate.⁶

Tall oil capacity increased as capacity was expanded to 920,000 tons per year of fractionation capacity. Westvaco boosted capacity at Charleston Heights, SC, by 10,000 tons in 1990 and at De Ridder, LA, by 25,000 tons in 1991. Iodine is used to stabilize the tall oil for use in various tall oil fatty acids and tall oil rosin that compete against other types of oils for use in polymers. The supply of crude tall oil is increasing due to additional pine pulp production.⁷ (See table 3.)

Prices

The average declared c.i.f. value for imported crude iodine was \$10.16 per kg (\$4.61 per pound). The average declared c.i.f. value for imported crude iodine from Japan averaged \$9.89 per kg (\$4.49 per pound). The average declared c.i.f. value for iodine imported from Chile was \$10.38 per kg (\$4.71 per pound). Quoted yearend U.S. prices for iodine and its primary compounds are shown in table 4. (See table 4.)

Foreign Trade

The U.S. Government adopted the Harmonized Commodity Description and Coding System (Harmonized System) as the basis for its export and import tariff and statistical classification systems. The system is intended for multinational use as a basis for classifying commodities in international trade for tariff, statistical, and transportation purposes. The Harmonized System as proposed includes resublimed and crude iodine under the same code, and the duty rate is free. Values that differ significantly could be a result of items being placed in the wrong category. (See tables 5 and 6.)

World Review

Capacity.—The data in table 7 are rated capacity for plants as of December 31,

1991. Mine capacity for iodine is based on rated capacity as reported by the company, another government agency, or another published source.

Chile.—Sociedad Química y Minera de Chile (SQM, formerly known as SOQUIMICH) was the largest producer of iodine in Chile. Production capacity at the Maria Elena plant was raised from 230,000 to 430,000 metric tons per year. Investment of about \$2 million has involved the expansion of solar evaporation ponds and process modification. Installed capacity was reported at 6,000 tons per year, although current production was about 4,000 tons per year.⁸ SQM also announced plans to be certified under the International Organization for Standardization (ISO) 9000 program, which calls for third-party quality-assurance registration of a manufacturer's facility, process, and product lines. It places particular emphasis on documentation and uniformity of process.⁹

Cominac S.A., a subsidiary of Inversiones Errazuriz S.A. Enterprises, began production at two of three reserve areas of the Pozo Almonte project. The site is situated in a valley where the natural gravity flow is utilized to collect the iodine-rich solutions. A third reserve area was undergoing a third step in a civil process to determine ownership. The two areas under development are not involved in the civil processing and are under development by a subsidiary company, Compania de Salitre y Yodo de Chile (Cosayach). Cosayach has a plant to recover 600 metric tons of iodine per year by heap leaching. Plans to expand capacity were being developed.

ACF Minera Ltda., is a Chilean company with 50% joint venture with DSM of the Netherlands. The company maintains three production facilities that have a nameplate capacity of 1,200 metric tons and are located in the first region of Chile at La Granja, Lagunas, and Iris. The facilities are about 100 miles southeast of the port city of Iquique. The production capacity was reported to be 810 metric tons of 99.5% to 100.5% iodine, with mineral reserves

of 48,000 metric tons of iodine in situ. The company also owns mineral rights at other locations in the first and the second regions of Chile.¹⁰

Indonesia.—The only producer of crude iodine was the state-owned pharmaceutical firm, P. T. Kimia Farma, that operated a plant at Watudakon near Mojokerto, East Java.

Japan.—Production of iodine was from underground brines associated with natural gas. Japan was the world's leading producer of iodine in 1989. Six companies operated 17 plants with a total production capacity of 9 million kg per year.

Mallinckrodt announced a 10-year exclusive agreement with Yamanouchi Pharmaceutical for distribution of Optiray in Japan. (See table 8.)

Current Research

A radioiodine-labeled tracer for studying receptors in the brain may be particularly useful in studying disorders such as Parkinson's disease. Researchers describe the high affinity that the tracers have for dopamine sites involved with Parkinson's disease. Parkinson's is thought to be caused by the degeneration of a set of neurons in the brain that use dopamine as a neurotransmitter.¹¹

Researchers at Los Alamos National Laboratory are working on a semiconductor material that could convert sunlight into electrical or chemical energy. Semiconductor crystals of platinum linked with halogens such as iodine form the basis of the mixed-halide chains. The material has tremendous chemical flexibility. The unusual feature of the mixed-crystal is that the electron remains in the high-energy state after the light source is removed, thus providing a mechanism for storing electrical energy.¹²

An iodine compound was used to synthesize gilvocarcin M, a class of natural products. Gilvocarcin M is one of a growing class of compounds that has been isolated from bacteria. The compounds share a common aromatic

ring system to which various rare sugars are attached through a carbon bond. The compounds are being studied as potential anticancer, antiviral, and antibiotic drugs.¹³

OUTLOOK

Iodine production capacity in the United States and Chile has doubled during the past decade, ensuring an adequate world supply. Uses for iodine in specialty chemicals have remained stable. Recent developments in digital images using computers can produce electronic prints and overhead transparencies without using processing. Using a digital camera, or scanning and film and converting to digital, images are produced using pixels or numerical by position and color and stored on hard drives, disks, tape, or optical storage. Future use of iodine in films and processing could be limited to specialty imaging in the next decade.¹⁴

IRON ORE

By William S. Kirk

Mr. Kirk became the commodity specialist for iron ore in 1992, and was previously responsible for cobalt, depleted uranium, hafnium, nickel, radium, thorium, and zirconium. The domestic survey data were compiled by Robin C. Kaiser, statistical assistant, Branch of Data Collection, and Henry F. Sattlelight, management analyst. The world production table was prepared by William L. Zajac, Chief, International Data Section.

Domestic iron ore production and shipments changed less than 1% from 1990, with production increasing slightly and shipments decreasing. Total reported consumption, however, decreased by 16% and consumption of U.S. ores decreased by 12%. The fall in consumption was the result of decreased U.S. steel production, which dropped 11% from that of 1990. World production fell 3% to 900 million metric tons (Mmt).

DOMESTIC DATA COVERAGE

U.S. production data for iron ore are developed by the U.S. Bureau of Mines from two separate, voluntary surveys of domestic operations. The annual "Iron Ore" survey (1066-A) provides the basic data used in this report. Of 46 addressees to whom the 1066-A form was sent, 46 responded, representing 100% of total production shown in tables 1 through 4. In past years, production for nonrespondents to the annual survey was estimated from monthly surveys (1066-M), from railroad reports, or from reported production levels in prior years. This information may be supplemented by employment data, mine inspection reports, and information from consumers.

Data on consumption and stocks of iron ore and agglomerates at iron and steel plants were provided by the American Iron Ore Association (AIOA). AIOA also provided data on ore shipments from loading docks on the upper Great Lakes as well as receipts at transfer docks and furnace yards

nationwide. The dock and steel plant data were compiled jointly by AIOA and the American Iron and Steel Institute (AISI). Data on consumption of iron ore for nonsteel end uses were compiled from information gathered from other Bureau surveys.

BACKGROUND

Industry Structure

History.—The history of iron mining in early America has already been reviewed in several other publications of the U.S. Bureau of Mines and its predecessor.¹ For additional information on the economic history of the entire U.S. iron and steel sector, the reader should refer to the comprehensive works of Father Hogan of Fordham University.²

The history of the iron ore industry as it currently exists began in 1844 with the discovery of "hard" magnetite-hematite ores on the Marquette Range of Michigan and the subsequent founding of the Jackson Mining Co.³ At first, lack of transportation facilities prevented rapid development. However, completion of a shipping canal at Sault Ste. Marie in 1855 opened the way for further development of mining in the Lake Superior region. By 1885, ore had been discovered in the Gogebic and Menominee Ranges of Michigan and Wisconsin, and annual production of ore had climbed to more than 2 Mmt, 20 times the volume in 1860. The high grade of these ores, combined with the low cost of water transportation, made them increasingly

competitive at Eastern furnaces and forced many small mines in New York, Tennessee, and the Mid-Atlantic States to close. This trend was accelerated in the 1880's by production from the Vermilion Range and the discovery of the great Mesabi ore bodies in the 1890's. By the turn of the century, most of the Eastern mines had closed. In Alabama, production of iron ore increased nearly tenfold between 1880 and 1890, and Birmingham was established as a major ironmaking center. During this period, many steel companies acquired iron ore properties in the Lake Superior District, and the production of many smaller mines was consolidated by the formation of large mining companies. The mergers that took place in the steel industry between 1893 and 1905 basically organized the iron ore industry into the structure that exists today.

Hundreds of mines closed during the 1950's because of the depletion of higher grade ores, rapidly rising imports, and costs of underground mining. By 1981, 15 mines accounted for 90% of the Nation's production of iron ore. By 1986, the 15 mines had been reduced to 10 because of increasing imports of steel and 2 deep recessions from which the iron ore and steel industries have not yet fully recovered.

Size and Organization.—In 1991, iron ore was produced by 20 companies operating 24 mines, 16 concentration plants, and 10 pelletizing plants. The mines included 21 open pits and 1 underground operation. Seven mines

operated by four companies accounted for the majority of the output. Virtually all ore was concentrated before shipment, and about 97% was pelletized.

Since the mid-1950's, quasi-symbiotic relationships have existed between several iron ore operations in Canada and the United States because of ownership ties. In 1982, U.S. companies owned about 70% of Canadian production capacity for iron ore and held significant minority interests in iron ore mines in Australia, Brazil, Liberia, and New Zealand. Since then, Japanese interests have acquired part of the Canadian and overseas holdings previously owned by companies in the U.S. iron and steel sector.

The iron ore industry of Canada and the United States has been undergoing a major restructuring since 1985 aimed at lowering pellet costs and improving financial health. The bulk of this restructuring occurred in the summer of 1986, when the industry was experiencing one of its worst years since the Great Depression. Most of the pellet producers had already streamlined their operations by late 1987, when overall demand for steel began to grow. The modest recovery accelerated in 1988, only to level off in 1989.

The breadth and intensity of the restructuring is illustrated by USX Corp., the largest steel producer in the United States. The company was formed after U.S. Steel Corp. acquired the Texas Oil and Gas Corp. USX is now a more diversified company with interests in energy, steel, mineral resources, real estate, and engineering services. Its energy segment includes the Marathon Oil Co. in addition to Texas Oil and Gas Corp. U.S. Steel paid \$6.5 billion for Marathon in 1982. The former U.S. Steel Corp. had been a leader in domestic steelmaking and iron ore mining for about 85 years prior to the 1986 restructuring.

USX owns and operates the Minntac Mine at Mountain Iron, MN. Minntac is the largest iron mine in the United States and supplies fluxed pellets to USX's blast furnaces at Gary, IN, and Dravosburg, PA. At the end of 1988, USX and the Blackstone Group formed a joint venture

known as Transtar Inc., which manages a variety of bulk transportation subsidiaries. USX sold 56% of its extensive transportation holdings to Transtar for about \$600 million. A number of USX railroad lines were involved, including the Duluth, Missabe, and Iron Range Railway Co. (DM&IR). The new transportation company also acquired USX's lake shipping and river barging operations. In 1989, USX sold its 100% equity in the Quebec Cartier Mining Co. (QCM) to Dofasco Inc.

The giant Canadian iron ore operation is currently owned by Dofasco (50% equity), Mitsui & Co. Ltd. of Japan (25%), and Companhia Auxiliadora de Empresas de Mineracao (CAEMI) of Brazil (25%).

At the beginning of 1991, USX announced plans to divide its common stock into separate steel and energy issues. The company's U.S. Diversified Group (real estate, engineering services, timber, and certain coal interests) was to be included with the steel group. Stockholders approved the stock restructuring proposal at their annual meeting on May 6, 1991. Approval of the May stock proposal facilitates further restructuring of the corporation and requires the steel group to fund capital expenditures from its own internally generated cash-flow. It is not known at this time what effect the stock separation and accompanying corporate changes will have on the Minntac operation.

Recent technological advances have affected not only day-to-day operations, but also the structure of the industry. An increasing number of integrated steelworks in North America are using fluxed pellets. This newer, more easily reducible type of pellet is created by adding limestone (CaCO_3) and/or dolomite [$(\text{Ca},\text{Mg})\text{CO}_3$] to the iron ore concentrate during the balling stage. Sufficient fluxstone is added to raise the ratio of $(\text{CaO} + \text{MgO})/(\text{SiO}_2 + \text{Al}_2\text{O}_3)$ in the pellet to above 0.6. The most common ratio is about 1. Fluxed pellets comprised 39% of total U.S. production in 1990. Idle capacity was brought on-stream at three mining complexes on the Mesabi Range during 1989 to meet

increased pellet demand. The idled complex of Reserve Mining Co. at Silver Bay, MN, was renovated by Cyprus during the last quarter of 1989. Cyprus shipped a trial batch of fluxed pellets in April 1990.

Combined United States and Canadian production represented only about 11% of the world output of usable ore in 1989. At least 45 other countries mined crude ore during the year. The leading producer was the U.S.S.R., which accounted for about 25% of world output in terms of metal content, followed by Brazil with 19% and Australia with 12%. Trends in world mine production since 1986 are shown on a country basis in table 22. Major mines are listed individually in table 21.

In 1989, the U.S.S.R. produced 241.0 Mmt of direct-shipping ore and concentrate. A large part of the concentrate was consumed to make 68.7 Mmt of pellets. The bulk of the iron ore produced in Australia, Brazil, India, and the Republic of South Africa consisted of high-grade direct-shipping ore or products derived from much higher grade crude ores than those mined in the United States.

Geology-Resources

Iron is the fourth most abundant rock-forming element, comprising about 5% of the Earth's crust. Astrophysical and seismic evidence suggest that the element has also combined with nickel to make up the bulk of the Earth's core. A small part of the crustal iron has been concentrated by sedimentary, igneous, or metamorphic processes into deposits containing up to 70% of the element.

The largest concentrations of iron are found in banded sedimentary iron formations of Precambrian age. These formations currently supply most of the world's iron ore and constitute the bulk of the world's iron resources. Precambrian ores are mined extensively in Africa, Australia, Canada, China, India, South America, the United States, and the U.S.S.R. Individual banded iron formations (BIF's) can vary from less than 30 to 600 meters (m) in thickness.

Some are relatively flat-lying, while others are steeply dipping or have been complexly folded. Some BIF's are exposed almost continuously along the margins of geosynclines and commonly underlie basin areas of hundreds or thousands of square kilometers (km²). Most consist of fine-grained iron oxides and quartz, with accessory iron silicates and in some places iron-bearing carbonates, and contain 20% to 40% iron. These rocks comprise ores of the taconite type mined in Canada, China, Norway, the United States, and the U.S.S.R.

Locally, the BIF's have been concentrated by natural processes to form high-grade deposits of hematite or goethite by leaching of silica and oxidation of ferrous minerals. The high-grade ores are classed as residual or replacement deposits, depending on whether removal of silica was accompanied by introduction of additional iron oxide. The residual ores are usually earthy, porous, and contain 50% to 60% iron in their natural state. Examples are the soft ores of the Lake Superior District, the Schefferville District of Labrador, and the Krivoy Rog District of the Ukrainian S.S.R. Some soft ores appear to be merely decomposed bodies of BIF, containing 20% to 40% iron in the form of martite, hematite, or goethite. Examples of the latter are bodies of "wash ore" in the western Mesabi Range, which are highly siliceous but easily concentrated by gravity methods.

Replacement ores in the Precambrian BIF's are usually dense, massive, and contain 64% to 68% iron. Often, the ores retain banded structures of the original sedimentary rock. Examples are the hard ores of the Vermilion Range, MN; Steep Rock and Michipicoten Districts of Ontario; Minas Gerais, Brazil; Fort Gouraud, Mauritania; and Sishen, Republic of South Africa.

Another class of sedimentary iron deposits, of regional importance in the southeastern United States and Western Europe, is oolitic ironstone of Paleozoic to Cretaceous age. The formations are extensive laterally and contain 20% to 40% iron, but they differ from the

Precambrian BIF's in several important respects. They are usually less than 15 m thick, and minable layers are commonly less than 6 m thick. The deposits rarely contain more than 48% iron, and most contain only 25% to 35% iron. The ore consists of very fine-grained hematite, quartz, chamosite,⁴ and siderite in varying proportions; sometimes enough calcite is present to make self-fluxing ore. The ore is usually high in phosphorus and difficult to beneficiate. Oolitic ironstones were mined until recently in Alabama, Newfoundland, and the United Kingdom and are still mined extensively in France and to a lesser extent in central Europe. They are also mined in Egypt and comprise most of the iron resources of Pakistan.

A third type of sedimentary ore, consisting of siderite or limonite in flat-lying lenses up to 6 m thick, is mined in east Texas from the Weches Formation of Eocene age. The ore is associated with glauconitic sand and clay and contains up to 35% iron.

Massive deposits of magnetite, sometimes with hematite, thought to be of igneous origin, are important sources of iron ore in many parts of the world. These deposits can contain as much as 65% iron and are often rich in titanium and vanadium, as at Lake Sanford, NY. There are two principal types of these igneous deposits: magmatic segregations and pyrometamorphic replacements. The first type is represented by irregular or layered masses that appear to have formed by segregation of magnetite crystals in magma, or as tabular, sheetlike bodies formed by injection of an iron-rich fluid into surrounding rocks. The Precambrian Bushveld Igneous Complex of the Republic of South Africa with its layers of magnetite and chromite is frequently cited as an example of magmatic segregation and crystal settling. The sill-like ore bodies at Kiruna, Sweden, and Pea Ridge, MO, represent the injection version of the process. The magnetite ores in these last two deposits contain significant amounts of fluorapatite, which must be removed during beneficiation.

Pyrometamorphic deposits are concentrations of magnetite that have replaced portions of the limestone or igneous country rock at or near the contact of an igneous intrusion. These deposits may be partly altered to hematite and contain up to 65% iron, depending on the extent of replacement. Garnet, epidote, and wollastonite are commonly formed along with the magnetite during the thermal metamorphism of the country rock. Deposits of this type are commonly associated with Jurassic or younger intrusives in the Western United States, Mexico, and western South America; they are also found in Pennsylvania. Examples include Iron Springs, UT; Eagle Mountain, CA; Hanover, NM; Cornwall and Morgantown, PA; El Romeral, Chile; and Marcona, Peru.

Technology

A study entitled "An Updated Analysis of Mortality in a Cohort of Minnesota Taconite Miners and Millers" was published. The report, sponsored by the AIOA, is the second update of a study of 3,444 taconite miners and mill operators who were first exposed to taconite in the period 1947-58. Previous analyses of deaths through 1977 and again through 1983 showed no significant excess deaths from any specific causes. The first study, initiated in 1979, was performed because of reports in the early 1970's that some taconite ore contained amphibole minerals that had characteristics similar but not identical to those of asbestos, which could be a health hazard. In addition, this study examined the potential for adverse health effects from exposure to crystalline silica, a constituent of the host rock and ore. The updated study extended the observation period for an additional 5 years, through 1988, which means that from 30 to 41 years elapsed from the workers' first exposure. This was an important step because of the long latency periods between exposure and disease that are characteristic of asbestos and crystalline silica-related diseases. The results of the study supported the conclusions of the two earlier studies that

there is no evidence of asbestos-related disease associated with the mining and milling of taconite in northeastern Minnesota. Also, there is no evidence that silica in the taconite ore bodies increased the risk of silicosis or lung cancer.

Column flotation in recent years gained acceptance by the mineral industry because of the advantages it offers over that of conventional flotation equipment such as its capability of producing a higher grade concentrate. Other benefits include lower capital and operating costs and improved control and stability. In the iron ore industry columns have been found to be effective in treating fine-grained concentrates in the final stages of cleaning.⁵ Columns provide greater selectivity than conventional equipment in removing silica and iron middlings. Iron middlings are grains that contain both iron and silica.

Economic Factors

The United States has exhausted the reserves of high-grade direct-shipping ore it once had in Michigan and Minnesota. Almost all of the ore being mined now is low-grade taconite, which requires costly beneficiation and pelletizing. Moreover, the taconite mining and pelletizing complexes are deep in the interior of the country, far from any saltwater harbor. Because of the advantages of Great Lakes shipping, U.S. pellets are currently competitive at Gary, Cleveland, and Detroit. However, high rail costs put U.S. pellets at a disadvantage in the Mid-Atlantic States and Alabama. Imported ores and agglomerates from Brazil, Canada, and Venezuela constitute the bulk of the iron units consumed at these coastal steelworks.

The St. Lawrence Seaway is a mixed blessing for the mining industry, being a bottleneck for ore carriers as well as an inexpensive means of transport in the Great Lakes region. The eight locks in the Welland Canal and the seven locks in the St. Lawrence River are all similar in size and have a gate-to-gate length of 262 m. The relatively short length of each lock prevents oceangoing ore carriers

longer than 222 m from entering the Great Lakes. At the same time, domestic 1,000 footers cannot leave the Lakes. Foreign ore bound for Indiana or Ohio either has to be offloaded onto smaller vessels in the gulf of the St. Lawrence or transferred to rail cars at Baltimore or Philadelphia. In some cases, ore is barged from the Port of New Orleans up the Mississippi River to steelworks in the Ohio River Valley and western Pennsylvania. The high rail costs that keep domestic ores from going to the coastal steelworks also keep foreign ores out of the inland steelmaking regions.

Operating Factors

Employment.—Statistics on employment and productivity in the U.S. iron ore industry in 1991, shown in table 2, were derived from quarterly employment data supplied by the Mine Safety and Health Administration (MSHA) and from production data derived from U.S. Bureau of Mines surveys. Both sets of data were obtained from producers' reports.

The statistics include production workers employed at mines, concentrators, pelletizing plants, and in repair and maintenance shops, but do not include 830 persons engaged in management, research, or officework at mines and plants. Employees engaged in ore preparation, such as sintering, at blast furnace sites are not included.

Because employment data reported to MSHA are primarily for safety analysis, hours spent by salaried employees in mines or plants may be included by operators in the total number of hours worked at individual mines or plants. This has resulted in understatement of calculated productivity by 10% to 25% for some operations, but its effect on others is not known. If company reporting practice is consistent, however, comparison of productivity from one year to the next should be reasonably valid. Average quarterly employment was 2.9% higher than that of 1990.

Transportation.—Transportation of iron ore on the U.S. Great Lakes has changed considerably since 1971, when the first self-unloading "super-carrier," capable of carrying 45,000 metric tons (mt) of iron ore, was placed in service. Since then, 12 similar vessels have been built, each about 300 m (1,000 feet) long and capable of carrying about 60,000 mt of iron ore pellets. Each of these carriers replaced about four older vessels and can deliver about 2.5 Mmt of ore to lower lake ports during an 8-month shipping season. The last of this group of ships was completed in 1981.⁶ While these vessels were being built, a similar number of older ships were lengthened to increase their carrying capacity and were also fitted with self-unloading equipment. By the spring of 1991, all but 2 of the 58 bulk carriers in the U.S.-flag fleet were self-unloaders. The average cargo capacity of the lake vessels has thus increased since 1971, while the total number of vessels has been reduced by more than 60%.

To accommodate the "1,000 footers," new loading facilities and materials handling systems were built at four of the seven upper lake ports, the last of which was completed in 1983, and three new receiving terminals were completed on Lake Erie. The self-unloading vessels have all but eliminated the use of Hulett clamshell unloaders at lower lake ports. The "1,000 footers" have unloading capacities of up to 10,000 metric tons per hour (mt/hr), while loading capacities at upper lake ports are of similar capacity. Details on individual port facilities are given in Greenwood's Guide to Great Lakes Shipping.⁷

Cargo capacities of vessels traveling the St. Lawrence Seaway between Montreal and Lake Erie are still limited to about 26,000 mt. On the north shore of Lake Erie, Stelco Inc., which has equity in several U.S. taconite mines, completed an unloading facility in 1979 that can accommodate 1,000-foot carriers. The Nanticoke facility can handle up to 6,000 mt of pellets per hour and has a stockpiling capacity of 860,000 mt of pellets and 1.06 Mmt of coal.⁸

U.S. coastal ports are still limited to incoming cargoes of 65,000 mt or less. Hunterston, Rotterdam, Taranto, and several other ports in Western Europe can now accommodate iron ore cargoes of 150,000 to 300,000 mt. The Ertsoverslagbedrijf Europoort terminal west of Rotterdam currently holds the world record for the largest single cargo of iron ore ever unloaded. On August 22, 1989, 356,541 mt of Carajas sinter feed and natural pellet ore was delivered to the terminal by the world's largest ore carrier, the 365,000-deadweight-ton (dwt) *Berge Stahl*. The *Berge Stahl* and the *Docefford*, another vessel capable of carrying more than 300,000 mt of ore, were built in 1986, primarily for trade between Brazil and Japan. In Japan, cargoes of 200,000 to 260,000 mt can be accommodated at Fukuyama, Kakogawa, Keihin, and Oita. Similar size cargoes are also routinely delivered to the island of Mindanao in the Philippines for sintering. The 351-m-long main berth of the Philippine Sinter Corp. has a depth of 23 m and can handle all but the very largest vessels that load at Ponta da Madeira. The three major loading ports in Western Australia (Dampier, Port Hedland, and Port Walcott) have all been modernized and had their berths deepened to permit loading of ore carriers of the 250,000-dwt class.

Two major pipelines for transport of iron ore slurries were completed in northern Mexico in 1983, connecting the La Perla and Hercules Mines with a pelletizing plant in Monclova. An 8-inch, 87-km line from La Perla is connected to a 14-inch, 295-km line that runs from the Hercules Mine to Monclova. The pipeline system can transport up to 4.5 Mmt of iron ore concentrates per year. A second system is operating in the Pacific Cordillera of Mexico. Two parallel lines transport concentrates 45 km from the Pena Colorada Mine in the mountains of northwestern Colima down to a pelletizing plant on the coast near Manzanillo. The 900-m drop in elevation permits the lines to be gravity operated. Major pipelines have also been built in Brazil and India since 1977, and others

are operating in Argentina, Australia, New Zealand, and Peru.

ANNUAL REVIEW

Production

Domestic iron ore production showed a modest increase in 1991, rising from 56.4 Mmt in 1990 to 56.7 Mmt. The iron ore industry increased its output of usable ore by 0.6%. Productivity for usable ore in the Lake Superior District was unchanged from that of 1990.

Iron ore was produced by 21 open pit mines and 1 underground mine. Twenty-two mines produced ore for the iron and steel industry, while the remainder shipped ore mainly to cement plants. Installed domestic production capacity for usable ore on December 31, 1991, was estimated at 83 million metric tons per year (Mmt/yr), of which 81 Mmt was pellets. Total output of usable ore was equivalent to about 70% of installed production capacity, up from 68% in 1990. An average of 3.2 mt of crude ore was mined in 1991 for each mt of usable ore produced. This ratio does not take into account the tonnage of waste rock or overburden removed. The ratio of total materials mined to usable ore produced was probably greater than 5:1. Low-grade ores of the taconite type mined in Michigan and Minnesota accounted for 99% of total crude ore production. U.S. production of pellets totaled 54.78 Mmt, 97% of usable ore output. The average iron content of usable ore produced was 62.6%. Shipments from U.S. loading docks on the upper Great Lakes totaled 51.10 Mmt in 1991.

Michigan.—Michigan accounted for 22% of the national output of usable ore in 1991. Ninety-nine percent of the State's production consisted of pellets produced at the Empire and Tilden Mines near Ishpeming in Marquette County. Both mining ventures are managed by Cleveland Cliffs Inc.'s (CCI) Cleveland-Cliffs Iron subsidiary. Empire shipped 7.5 Mmt of pellets produced from magnetite concentrate. Tilden shipped

3.8 Mmt of magnetite pellets and 1.2 Mmt of hematite pellets, for a total of 5.0 Mmt.

Production of usable ore was up 34% from the 1990 figure of 9.5 Mmt. Production of pellets totaled 12.6 Mmt, of which 7.8 Mmt was made at the Empire plant and 4.8 Mmt was made at Tilden.

On March 19, the Marquette Range produced its 300 millionth long ton of iron ore pellets. Five mines contributed to the overall total since pellets were first produced in 1956.

Minnesota.—Minnesota produced 76% of the national output of usable ore in 1991. All of the State's production came from open pit mines on the Mesabi Range. Production of pellets totaled 42.2 Mmt, equivalent to about 87% of installed production capacity of the State's seven taconite plants.

In mid-August, CCI restructured its Pickands-Mather subsidiary. Pickands Mather was renamed the Cliffs Mining Co., but the total number of employees in the organization was unchanged. The restructuring was part of an ongoing integration process begun in 1986 when CCI acquired all of the outstanding stock in Pickands Mather & Co. from Moore McCormack Resources. At the time of the acquisition, Pickands Mather was managing four large iron ore properties: the Hoyt Lakes complex, the neighboring Hibbing Taconite Co., Wabush Mines of Quebec, and Savage River Mines of Tasmania.

The restructured subsidiary was to retain its ownership interests in both the Hibbing Taconite joint venture and Wabush Mines. It would also continue to manage both Hibbing and Wabush, as well as the LTV Steel Mining Co. The Cleveland-Cliffs Iron Co., CCI's other principal subsidiary, will continue to hold ownership interests in the Empire and Tilden Mines of Michigan and manage both operations. All of CCI's salaried personnel in the Lake Superior District who have been providing central services to the mines are now part of another newly formed subsidiary, Cliffs Mining Services Co.

On August 1, 1991, Eveleth Mines launched a \$7.5 million project to expand crushing capacity at its taconite operations on the Mesabi Range. The taconite came from two pits, which straddle the western edge of the City of Eveleth. Each of the pits had its own crushing plant and could be operated independently. After crushing, the ore was railed 14 km south to the company's 6.2 Mmt/yr pelletizing plant near Forbes. Most of the project money was used to upgrade the existing crusher building at the Thunderbird North Mine and replace the primary crusher. The crusher dump bays were enlarged, and a third secondary crusher was added to the middle level of the building. The modifications were to increase the output of the crusher from 38,000 mt to 60,000 mt of crude taconite per day. The 60% increase in capacity was to allow Eveleth to begin developing new reserves near the old Auburn Mine northwest of Midway. At the same time, the company would be able to idle operations at its Thunderbird South Mine. According to company officials, the South Mine had only about 1 year of stripped ore left and was more costly to mine because of its higher stripping ratio.

On September 6, LTV Steel Co. halted mining at its McKinley Extension Mine near Aurora. The McKinley Extension was the last active natural ore mine not only on the Mesabi Range, but in the entire Lake Superior District. The closure brought an end to an era in Minnesota mining, which began in 1884 when the Minnesota Iron Co. began shipping natural ore from its Soudan underground mine near Lake Vermilion. Natural ores were the mainstay of the U.S. iron ore industry prior to the development of the taconite pelletizing process. The old Lake Superior ores averaged 50% to 60% Fe and could be shipped directly to the steelworks without prior beneficiation. In 1944, at the peak of World War II, 103 natural ore mines were operating in Minnesota and another 43 in Michigan. That year, the two States shipped 65.5 Mmt of crude ore directly to consumers and another 23.9 Mmt to beneficiation plants. The ore was

essentially all hematite and averaged 51.9% Fe. By the end of the Vietnam Conflict, most of the natural ore had been mined out. The McKinley Extension Mine is in White Township, about 8 km southwest of LTV's Hoyt Lakes pelletizing plant. The Northwest Ore Div. of LTV has been operating the mine under a lease from the USS Minnesota Ore Operations of USX Corp. since 1983. The lease was obtained from the United States Steel Corp. by Jones & Laughlin Steel Corp., one of LTV's predecessors. The mine consists of two pits: the Donora and the Stephens. LTV was forced to halt operations after exhausting the remaining pockets of ore in the Donora. The last 15,000 mt of ore in the Stephens pit was removed in 1990. LTV was considering reactivating the Connie Mine near Virginia, MN, to meet part of the demand for natural ore. The Connie Mine is in Wuori Township, on the western edge of the Minorca taconite operations of Inland Steel Mining Co.

CCI became the principal supplier of pellets to the Weirton Steel Corp. of West Virginia. Under an agreement concluded on October 2, pellet shipments were to begin in 1992 and run for 12 years. The Cleveland-based iron ore merchant expected to supply Weirton with at least 1.0 Mmt of pellets annually. As part of a parallel agreement, CCI invested \$25 million in a special nonmarketable issue of Weirton preferred stock. The preferred stock pays a cash dividend of 12.5% per year, payable quarterly. Weirton had four blast furnaces, with working volumes ranging from 1,300 to 1,530 cubic meters.

In 1990, Inland Steel Mining Co. began construction of its new Laurentian Taconite Mine, the first new mine to be constructed on the Mesabi Range in Minnesota in more than a decade. Inland Steel Mining is a wholly owned subsidiary of the Inland Steel Co. The new open pit operation will provide iron units for the parent company's integrated steelworks at Indiana Harbor, IN. The mine entered service in 1991, when crude taconite from the first benches was being trucked 10 km to Inland's existing Minorca mining and pelletizing complex

on the northeastern edge of Virginia, MN. The Laurentian taconite was replacing ore from the Minorca pit, where reserves are almost exhausted. The new mine was to enable the 2.5-Mmt/yr pelletizing plant to continue operating until the year 2031. The initial stage of the project cost more than \$10 million. Inland expected to spend at least another \$10 million to fully develop the Laurentian Mine site.

The Laurentian ore body provides the plant with more than 15 years of reserves. Inland also hoped to negotiate leases on adjoining properties that could supply another 25 years of reserves. Inland has additional ore at two other sites—the Ordean Reserve west of Minorca and the East Rouchleau pit on the outskirts of Virginia.

In June 1991, Inland began blending the Laurentian ore with ore from Minorca. The blending may be able to extend the life of the Minorca pit until 1994, when mining would be shifted entirely to the new ore body. A dedicated haul road was constructed from the pelletizing plant through the Pike River Basin to the mine site. The use of a conveyor system in place of the haul road was not considered economically feasible.

Missouri.—The Pea Ridge Iron Ore Co. produced iron oxide powder at its mining complex near Sullivan, MO. The company has the only active underground iron mine in the country. The mine is on the northeast flank of the Ozark uplift and has proven reserves of 160 Mmt of ore grading 55% magnetic iron. The mining and pelletizing complex was developed jointly by St. Joe Minerals Corp. and Bethlehem Steel Corp. between 1957 and 1964 at a cost of about \$52 million. At that time, Pea Ridge was known as the Meramec Mining Co.

In December 1990, Pea Ridge's contract with National Steel expired, leaving Pea Ridge without a blast furnace customer. In January 1991, the company ceased pellet production and began concentrating on specialty iron oxide products, which had formerly been coproducts.

Utah.—Geneva Steel of Utah operated two open pit mines in the Pinto District of Iron County. Reserves were depleted at the Excelsior Mine during the year, leaving the Comstock and Mountain Lion as the only operational mines. The district, 32 km west of Cedar City, has provided magnetite and hematite ores for blast furnaces in the Rocky Mountain region on an intermittent basis since 1923. Coarse ore and fines were shipped 370 km on the Union Pacific Railroad to Geneva's integrated steelworks at Provo. The ore was hauled twice a week in train units of 72 cars, each with a capacity of 100 short tons. The actual mining was contracted out to the Gilbert Development Corp.

Other States.—Three California mines produced iron ore during the year—the Baxter, the Beck, and the Soledad Canyon. The bulk of the shipments went to cement plants in the Los Angeles basin. The Baxter and Beck Mines are both in San Bernardino County in the eastern half of the Mohave Desert. The Baxter Mine is operated by the California Portland Cement Co.; the Beck Mine, by Standard Industrial Minerals Inc. The P.W. Gillibrand Co. produced a magnetite concentrate as a byproduct of its Soledad Canyon sand and gravel operations in Los Angeles County. The Soledad Canyon District is at the northwestern end of the San Gabriel Mountains and encompasses parts of the environmentally sensitive Angeles National Forest. The district has several promising alluvial and lode deposits of titaniferous magnetite and ilmenite.

In South Dakota, Pete Lien & Sons Inc. mined low-grade hematite at the CF&I pit near Nemo in Lawrence County. The mine was reopened in 1988 after a hiatus of 9 years, but operated only during part of 1991. The company produced ore averaging 29.1% Fe. Production was limited by the relative remoteness of the Black Hills mine site from consumers. The bulk of the ore was shipped to the Dakota cement plant operated at Rapid City by the State Cement Commission. The ore comes

from a 30- to 90-m-thick Precambrian iron formation that forms a ridge along the east side of Boxelder Valley.

Consumption and Uses

The U.S. steel industry accounts for 98% of domestic iron ore consumption. The steel industry experienced a poor year as production and shipments of steel products declined along with the recessionary economy. Production of raw steel in the United States fell more than 11%.

Another factor affecting the consumption of iron ore is that electric arc furnaces, used in steelmaking primarily by minimills, do not use iron ore. Electric arc furnace steelmaking accounted for 38.4% of total steelmaking in 1991. This was the largest share for electric arc furnace steelmaking in the United States.

Consumption of iron ore was 13.7% lower than the figure for 1990. Consumption for ironmaking and steelmaking totaled 63.662 Mmt. Monthly consumption of pellets, direct-shipment ore, and merchant sinter by the industry averaged 5.31 Mmt compared with 6.14 Mmt in 1990. Reported consumption of iron ore for manufacture of cement, heavy-medium materials, animal feed, ballast, ferrites, pigments, and other nonsteel products was 691,000 mt.

At the end of 1991, the U.S. economy was struggling to overcome recessionary problems. U.S. production of hot metal and pig iron totaled 64.9 Mmt, an 11% drop from that of 1990. During 1991, the number of blast furnaces in operation ranged from 40 to 45.

Consumption of iron ore and all types of agglomerates reported to the AISI by integrated producers of iron and steel totaled 63.59 Mmt. This included 51.33 Mmt of pellets; 10.30 Mmt of sinter, briquettes, etc.; and 1.95 Mmt of natural coarse ore. Of the primary ore consumed, 76% was of domestic origin, 11% came from Canada, and 12% came from other countries. Other materials consumed in sintering plants included mill scale, flue dust, limestone and dolomite,

slag and slag scrap, and coke breeze. Other iron-bearing materials charged to blast furnaces included steel-furnace slag, mill scale, and slag scrap. According to AISI, 2.54 Mmt of ferrous scrap was consumed in blast furnaces in 1991.

In January, LTV Corp. idled one of two operable blast furnaces at its Cleveland Works in Ohio. Then, in February, Inland Steel Co. mothballed its "B" blast furnace at Plant No. 3 in East Chicago, IN. Plant No. 3's "A" furnace has been shut down since July 1990. The bulk of Inland's production will continue to come from the giant No. 7 furnace, which currently produces about 8,700 mt of metal per day at Plant No. 2. Inland does not plan to restart Plant No. 3 until 1994 when No. 7 will have to be shut down for relining.

Both Bethlehem Steel Corp. and USX Corp. have made plans to close some of their older hot-metal operations on the East Coast. The Bethlehem closures were linked to a proposed joint venture with British Steel PLC. Under the plan, obsolete ironmaking and steelmaking operations at Bethlehem, PA, would be permanently closed.

In February, USX Corp. announced plans to halt ironmaking and steelmaking at its Fairless Hills works near Philadelphia. The works had two operable blast furnaces. The shutdown of the hot-metal part of the Fairless operations would allow the USS steelmaking division to reach its 100% continuous casting goal by late 1992. In 1990, Fairless operated three of eight open-hearth furnaces built in the early 1950's.

Stocks

Stocks of iron ore and agglomerates reported at U.S. mines, docks, and consuming plants have been gradually dropping for more than 30 years. This trend temporarily reversed itself in 1988, but has since continued downward. At yearend, total industry stocks were 24.0 Mmt. Furnace yard stocks stood at 17.6 Mmt and included 12.7 Mmt of domestic ores, 2.5 Mmt of Canadian ores, and 2.4 Mmt of foreign ores. Mine stocks at

yearend were 11.3% higher than those of 1990.

Stocks of unagglomerated concentrates reported at pelletizing plants totaled 1.8 Mmt at yearend, an increase of 100% from that of 1990, and ranged in Fe content from 47% to 68%. This material is not included in mine stocks of usable ore reported in the accompanying tables because it is considered an intermediate product. Stocks of byproduct ore also have been excluded since 1983 from the mine stock data to avoid disclosing company proprietary information.

Transportation

In 1991, seaborne iron ore trade was the greatest generator of dry bulk shipping demand in the world. About 375 Mmt was shipped more than 1.96 trillion ton-miles.

Great Lakes shipping continued to play a key role in the competitiveness of the U.S. iron ore industry. Relatively mild weather allowed the Corps of Engineers to keep the Soo locks open until January 15, 1991. Ore shipments from Escanaba on Lake Michigan continued until January 31. The 1990-91 navigation season lasted 335 days (March 3 to February 1) and was the longest in more than a decade. The U.S. Great Lakes fleet hauled 49.9 Mmt of ore, agglomerates, and related products during the 1990-91 season.

The fleet operated 57 of its 65 serviceable vessels, with the 57 vessels accounting for 93% of carrying capacity. Since 1980, the number of U.S.-flag vessels on the Great Lakes has dropped from about 140 to 65. At the same time, the average carrying capacity has risen from 20,900 mt to 26,000 mt. Of the 65 vessels, 6 were cement carriers and 3 were self-propelled tankers.

Prices

Foreign iron ore producers won price hikes in Japan and Western Europe for the third consecutive year. In Japan, prices for lump ore were up about 6%; fines, about 8%. Very few published prices for domestically produced pellets changed in 1991. Oglebay Norton was

still quoting a price of 72.45 cents per long ton unit of iron, natural, for its standard grades of Lake Superior pellets. A long ton unit (ltu) is equivalent to 0.01 long ton or 22.4 pounds. The quotation included delivery to rail-of-vessel at lower lake ports. The Pickands Mather quotation of 59.40 for pellets was still in effect at the end of 1991. The price for Minntac acid pellets was left at 37.344 cents per dry ltu of iron, delivered into railcars at the Minnesota mine.

Published f.o.b. prices for direct-reduced iron (DRI) were also unchanged from those quoted in 1990 and were as follows, per mt: at Georgetown, SC, \$125.00 to \$135.00; at Contrecoeur, Quebec, \$115.00; and at Point Lisas, Trinidad and Tobago, \$120.00.

Price negotiations opened in Europe in December 1990, but quickly bogged down. Brazil's Cia. Vale do Rio Doce (CVRD) asked for increases on the order of 18% so that it could (1) begin upgrading its older operations in the Iron Quadrangle, and (2) continue to properly service the enormous debt incurred in developing the giant Carajas Mine. At the end of January, Rohstoffhandel GmbH and Erzkontor Ruhr GmbH, the principal buyers for the German steel industry, finally agreed to price increases of 7.95% for Itabira fines and 6.95% for Carajas fines. In the settlements that followed, CVRD's competitors obtained increases that ranged from 0.56% for Hamersley lump to 8.89% for Carol Lake concentrates. The suppliers' positions were supported by three arguments. First, producers in Western Australia may have to develop several new mines to meet the growing demand for iron ore in the Far East. This would require a heavy financial investment on the producers' part. Second, iron ore shipments from Liberia were completely disrupted by the recent civil war and ensuing political uncertainty. Last, Canadian producers closed two pelletizing operations in Ontario and were temporarily cutting back production in the Quebec-Labrador Trough.

Foreign Trade

U.S. exports of iron ore were 27% higher than those of 1990. Virtually all exports consisted of pellets and concentrates shipped via the Great Lakes to Canadian steel companies that are partners in U.S. taconite projects in Michigan and Minnesota. U.S. imports of iron ore dropped 26% to 13.3 Mmt.

Net imports for 1991 were one-third lower than the average of the previous 4 years and were equivalent to 22% of U.S. ore consumption. Canada's share of net imports was 79%; Brazil's was 29%.

World Review

At least 48 countries mined iron ore during the year, producing a total of 901 Mmt. The U.S.S.R. was the largest producer, with an output of 200 Mmt of concentrate or direct-shipping ore plus 68 Mmt of pellets. Soviet production accounted for about 21% of the world's marketable output in terms of metal content. World production of pig iron, which directly reflects ore consumption, decreased by 4.5% to 509 Mmt. World DRI production rose by 7.6% to 19,755 mt.

For the first time since 1984, Australia surpassed Brazil as the leading exporter of iron ore, shipping 116 Mmt to world markets, considerably more than that in 1990. Australia's top customer, Japan, accounted for more than one-half of its exports. Brazil's primary customers were the European Community (EC) and Japan.

World production of pellets was estimated at 213.2 Mmt, about 84% of rated capacity.

Integrated iron ore operations have become extremely complex and resemble medium-sized towns in some cases. The production capacity of an operation of this magnitude is determined by equipment limitations at several stages of recovery. To simplify analysis and make comparisons of individual mines easier, data were collected that represent the rated or design capacity at three key points in the recovery process: crusher-screen output, concentrator output, and

pelletizing furnace output. These three points were chosen because they serve to readily separate the mining, beneficiating, and agglomerating stages of the operation. At the first two points, the iron ore is already in a marketable form and can be diverted for sale or tolling if bottlenecks occur either downstream at the operation or upstream at competitors' facilities.

Changes in the economics of the process could also make diversion feasible. Table 24 shows world pelletizing capability at the close of 1991. The data represent the rated capacities of 82 plants in 26 countries. A significant part of the data was collected by the International Iron and Steel Institute in 1987. The table excludes plants that have not produced since 1982. Four of these idled plants are identified in the table footnotes because they could be reactivated in some realistic scenarios. Table 24 also excludes sintering plants.

Australia.—In 1991, the three major producers, BHP Iron Ore Ltd., Hamersley Iron Pty. Ltd., and Robe River Iron Associates, were implementing long-term expansion plans, primarily infrastructure improvements.

BHP Iron Ore Ltd. made a series of moves aimed at making the company a larger producer, perhaps surpassing Hamersley as the country's largest producer. BHP's primary mine, Mount Whaleback, was made more productive by widening the pit floor, thereby facilitating equipment movement. It was expected that production at the mine would reach 26 to 28 Mmt/yr in the near future. Railway and mine construction work at BHP's Yandi deposit, 90 km west of Newman, proceeded well. The Yandi (previously known as the Yandicoogina) was expected to begin production early in 1992 at 5 Mmt/yr. The mine design, however, was based on a yearly capacity of more than 7 Mmt and could be expanded to 10 Mmt/yr with minimum capital costs, as most of the infrastructure would already be in place. In 1990, BHP, already part owner of Mount Goldsworthy Mining Associates, purchased the balance. Subsequently,

BHP sold 15% of the operation to its Japanese partners, CI Minerals and Mitsui C. Itoh Iron Ore Corp. In 1991, the company began replacing the mine's 120-mt truck fleet with 200-mt trucks. Production at the mine, which was 7 Mmt/yr, was expected to increase to 8.5 Mmt/yr. The 1991 combined capacity at ore bodies No. 25 and No. 29, adjacent to Yandi, was more than 5 Mmt/yr, and the concentrator at Whaleback was capable of producing 3 Mmt/yr from stockpiled low-grade ore. Korean steelmaker, Pohang Iron & Steel (Posco), became BHP's largest single customer following contract negotiations in 1991. Much of the ore resulting from BHP's expansions was expected to go to Posco. BHP shipped 54,811 Mmt of ore during the year.

Hamersley Iron Pty. Ltd., the largest Australian iron ore producer, became the first Australian iron ore producer to produce and ship more than 50 million long tons in 1 year. Production increased from 43.9 Mmt in 1990 to 50.2, while shipments for the same period rose from 40.9 to 50.6 Mmt. The commissioning of a new haul truck fleet at the Mount Tom Price Mine helped increase productivity to record levels. At the Paraburdoo Mine, upgrading of the processing plant resulted in increased throughput and record production. Production of ore from the Channar Mine increased during the year while development work continued with the opening of new mining areas. Development of the Marandoo project was significantly delayed during the year. The Marandoo deposit, which was reported to contain 400 Mmt of high-grade ore, was slated to come on-stream in mid-1994. Located 40 km east of the Mount Tom Price Mine, the Marandoo deposit is near the surface and varies in thickness from 27 to 40 m. The Mount Tom Price Mine was considered the jewel in the company's operation as it supplied high-quality ore, of which 55% was lump and the remainder fines. However, reserves at Tom Price were being depleted, and to maintain a highly marketable product mix, Hamersley needed to supplement the output of Tom

Price with Marandoo ore. As Australia's largest iron ore producer, Hamersley produced about 50 Mmt/yr. Because Marandoo would extend the life of the Tom Price by 4 years by adding 10 Mmt/yr of production, its development was considered essential to Hamersley's future. Development was delayed by claims by an Aboriginal community, who rejected anthropological and archeological studies stating that there were no significant Aboriginal sites in the Marandoo region. The Aboriginal community claimed to have two significant sites there and was concerned about them being disturbed by the introduction of mining and the resulting infrastructure. The Western Australian government decided to conduct another anthropological study. The issue was unresolved at yearend.

In 1991, Robe River was the world's fastest growing major iron ore producer, the result of a long-term expansion program. Under the program, the company was making considerable improvements in the five following areas: (1) in the area of mining, the company purchased larger capacity trucks, (2) a major exploration and development program was completed, reportedly providing sufficient ore reserves to last the company for 20 years, (3) expansion of the ore processing plant was under way, (4) in upgrading the transportation facilities, Robe River was purchasing new locomotives and rehabilitating and extending the rail beds and (5) at the Port of Cape Lambert, changes in the stockpiling system resulted in an increase in shiploading rates and almost doubled the stockpiling capacity. In addition, two new tugs were purchased. The expansion was expected to be completed in 1993, raising production capacity from 24 Mmt to 32 Mmt. Robe River shipped 60,000 mt of sinter fines to Bethlehem Steel Corp.'s Sparrow Point steelworks near Baltimore, its first such delivery to the United States. Robe River's 1991 ore shipments were 24,754 Mmt.

A proposal to abolish export controls on iron ore sales was rejected by the Australian Government. The legislation gave the Federal Government the power

to reject exports of most minerals on any grounds. That power had not been used in the case of iron ore for many years. However, iron ore producers would have liked to see the restriction lifted.

Joint-venture partners CRA Ltd. of Australia and Midrex Corp. of the United States announced plans to further develop the HIs melt direct-iron ore smelting technology. The partners formed Hismelt Corp. Ltd., of Perth, Western Australia, to manage the project. Plans call for the construction of an advanced research and development facility on the site of an old blast furnace in Kwinana, 40 km south of Perth, to be commissioned in early 1993. The pilot plant is expected to cost \$77.5 million. The HIs melt process is a single-stage process that involves the direct smelting of iron ore in a closed, molten-bath reactor. Iron ore fines and coal are injected directly into the molten bath to produce a pig iron equivalent. If the process can be successfully commercialized, it would serve as an alternative to the traditional blast furnace route and would compete against the Corex process owned by Vöest-Alpine Industrieanlagenbau AG of Austria. Like the Corex process, it would eliminate the need for coke ovens, blast furnaces, and sinter plants, thereby bypassing many of the environmental problems associated with cokemaking and sintering. It also uses relatively cheap energy coal rather than higher quality coking coal.

Brazil.—CVRD planned to increase production at its Carajas iron mine to 50 Mmt/yr over a 5-year period, depending on market acceptability. The mine, in northern Brazil, produced 35 Mmt of ore in 1990. Because nearly all of the output from Carajas is exported, CVRD planned to expand its port facilities at Ponta de Madeira. The company invited bids for the construction of a second pier. CVRD ore shipments in 1991 amounted to 112,700 Mmt.

Canada.—CCI closed its Wabush Mine, mill, and pellet plant for 71 days over the summer to reduce both inventory

levels and production. The Wabush complex was in Labrador, Newfoundland.

Mitsubishi Corp., Japan, bought 20% of the Iron Ore Co. of Canada (IOC) from M.A. Hanna Co. of Cleveland. Hanna retained an 8.14% interest in IOC. IOC's other shareholders included Bethlehem Steel (34.5%), National Steel (20%), Dofasco (6.4%), and Labrador Mining and Exploration Co. (11%).

On October 3, Wabush Mines announced plans to downsize its mining and pelletizing operations in eastern Canada by 25%. The downsizing, which took effect at the end of 1991, lowered the production capacity of the joint venture from 6.1 Mmt/yr to 4.6 Mmt/yr. In 1991, the venture shipped 4.79 Mmt of iron ore products from its terminal on the lower St. Lawrence River. All of the material shipped was pellets, with the exception of about 100,000 mt of concentrate that was used as sinter feed. Wabush makes four types of pellets—both standard and fluxed grades, containing either 1% or 2% manganese.

The pelletizing plant is at Pointe Noire, Quebec, on the south shore of Sept-Iles Bay. Feed for the pelletizing plant is railed from the company's Scully Mine at Wabush Lake in Newfoundland. A dedicated 61-km rail line connects the mine to the Quebec North Shore and Labrador Railway at Ross Bay Junction. From Ross Bay Junction, the iron ore concentrate is hauled an additional 385 km via Sept-Iles to Pointe Noire. Wabush is owned by Stelco Inc. (34.50%), Dofasco Inc. (22.10%), Acme Steel Co. (13.75%), Inland Steel Co. (13.75%), Finsider International S.A. (8.89%), and CCI (7.01%). CCI is responsible for the management of the operation.

According to company officials, management's decision to downsize was based on three factors. First, most of the partners in the joint venture needed fewer pellets because of the recession. Second, production costs had risen to an unacceptable level, lowering the competitiveness of the operation. Third, the complex was left with excess capacity in the wake of the bankruptcies of LTV Steel Corp. and Wheeling-Pittsburgh Steel

Corp., two former partners in the venture. Approximately 200 of Wabush's 940 employees were affected by the downsizing.

France.—Usinor Sacilor closed its pig iron operation in December and planned to close its iron mine in 1992.

India.—As part of India's push to expand its ironmaking capacity, a pig iron and a DRI plant began operations, and plans to build others were announced. Indian Iron & Steel Co. commissioned a new pig casting plant at its Burnpur works in West Bengal. The plant had a capacity of 600 mt per day. Lakshmi, an Indian textile machinery manufacturer, formed a joint-venture with the Tamil Nadu Industrial Development Corp. to set up a foundry pig iron plant. The plant, to be either at Salem or Arakonam near Madras, was expected to have an initial production capacity of 150,000 mt/yr, which was to be doubled subsequently. The plant was expected to be fed with iron ore from Belary-Hospet. Tata Iron & Steel Co. planned to build a new pig iron plant in Tamil Nadu in partnership with the Kothari group. The initial capacity of 120,000 mt/yr was to be doubled later. Like the Lakshmi-Tamil Nadu plant, the plant was expected to be supplied by the Belary-Hospet mines in Karnataka. TAMILNADU Sponge Iron Ltd. began production of the first 30,000-mt/yr module at the company's new DRI plant. Work on a second module was to start shortly. The plant was the first to use lignite (brown coal) as the reducing agent. Goldstar Steel & Alloy Ltd. was constructing the country's largest coal-based direct-reduced iron plant at Visakhapatnam in Andhra Pradesh. The plant was to have a production capacity of 220,000 mt/yr from two modules. Goldstar was planning to start commercial production by the end of 1991 and to reach 90% of capacity within 3 years. Thereafter the company planned to build two more modules of 110,000 mt/yr to reach a capacity of 440,000 mt/yr by 1994. Goldstar was licensed to produce 800,000 mt/yr. The Kalyani Group, a

steel producer, planned to set up an 80,000-mt/yr gas-based DRI project at Dharamtar, in the Raigad region of Maharashtra. Construction work on the Kalyani project was scheduled to begin in September with commissioning to take place in 1993. In the same district, Nippon Denro Ispat was constructing a 1-Mmt/yr Midrex DRI plant. Hindustan Electro-Graphites planned to build a 60,000-mt/yr DRI plant in the Borai district of Madhya Pradesh. The plant was expected to use coal-based DR technology and was expected to begin production by the end of the year. Plans called for a second phase of the project to expand to 200,000 mt/yr. Midrex was to construct a DRI plant for Usha Rectifier of New Delhi. The plant was expected to begin production in late 1993 at the rate of 800,000 mt/yr. The plant, to be built at Jagdishpur in the Sultanpur district of Uttar Pradesh, was to be capable of using as much as 100% Indian lump ore as well as a combination of lump and pellets. Usha planned to use India's Bailadila and Banspani Mines and pellets from Kudremukh's operation in Karnataka as sources. The industrial group Prakash Industries of Delhi planned to build a 150,000-mt/yr DRI plant at Champa in Madhya Pradesh. The majority (13 of 18) of the DRI plants under construction around the world as of November 15 were being built in India.

Sail, the state-owned steelmaker, requested approval to construct a 5-Mmt/yr iron ore mine in the Rowghat area of Madhya Pradesh. If completed, the mine would replace the Dalli-Rajhara Mines that were supplying Sail's Bhali steelworks.

Iran.—The National Iranian Steel Co. awarded a \$400 million contract to Kobe Steel for the development of a new mine. The mine, at Chador Nalu in central Iran, was expected to begin production in 1995. Annual output was expected to be 5 Mmt.

Liberia.—Iron mining at the Nimba deposits restarted after being shut down for 1 year by the civil war. Damage to

the mining areas of Yekepa and Todakeh was found to be minimal.

U.S.S.R.—An Australian company, Hancock Resources Ltd., formed a joint venture named Amurstal-Hancock to build a metals complex that would use Australian iron ore. Hancock's joint-venture partner is a number of Russian ferrous enterprises known collectively as Metalurgprom and the Amurstal plant at Komsomlsk-Na-Amurye in the Russian Far East.

Venezuela.—Siderurgica Venezolana S/A (SIVENSA), the largest private Venezuelan steelmaker, inaugurated its 600,000-mt/yr hot-briquetted DRI plant in February. The plant was operated by Siderurgica del Caroni S/A (SIDECAR), a member of SIVENSA'S steelmaking division. Near Peurto Ordaz, the plant was intended to supply hot-briquetted iron (HBI) principally to the adjacent SIVENSA steelworks. The SIDECAR plant was engineered and supplied by an international consortium consisting of Midrex Corp. and Voest-Alpine Industrieanlagenbau.

OUTLOOK

The U.S. iron ore industry is totally dependent on the domestic steel industry for sales. This dependence is not expected to change in the near future. Because of this relationship, the reader is referred to the outlook sections in the "Iron and Steel" and "Iron and Steel Scrap" chapters. Only 7% of the iron ore shipped in 1991 was exported, with virtually all of it being pellets going to steelworks in Ontario. It is difficult for the United States to compete in the world iron ore market because of the country's declining ore grades, the inland location of its mines, and high labor and fuel costs.

For the near term, growth of the U.S. iron ore industry is tied to the growth of the integrated steelworks along the Great Lakes. This growth is expected to average less than 2% per year over the next decade and could very easily be

negative if the recessionary conditions of 1991 are prolonged. The U.S. steel industry is concentrating on making high-value, quality steels, not increasing tonnage. Domestic blast furnace production in the year 2000 is expected to be no more than 60 Mmt. The U.S. iron ore industry has no choice but to focus on making higher quality agglomerates, such as fluxed pellets, that meet much tighter chemical and physical specifications than have been required in the past.

Electric arc furnaces currently account for more than one-third of total crude steel production. Because of advances in steelmaking, steel products now require lower residual alloy content than can be readily achieved with scrap. This indicates a role for imported DRI in the coastal regions of the United States. The growth of gas-based DRI production capacity outside North America has been spectacular in recent years. Although a large part of this growth has occurred in Venezuela, the bulk of the construction has been spread evenly through a myriad of countries that have surplus natural gas. It is too early to tell whether coal-based DRI production will be economically feasible in the United States. No matter how spectacular DRI growth is over the next decade, it will not be able to replace more than a fraction of the world's blast furnace production because of technological restrictions. The blast furnace is expected to remain the mainstay of the iron and steel industries in most developed countries over the next 25 years.

In contrast to the United States, demand for iron ore in other parts of the world is expected to escalate. Some of the greatest growth is being experienced in the Far East. China is currently producing more hot metal than the United States and is modernizing and expanding blast furnace operations throughout the country. Smaller but no less spectacular growth is occurring in the Republic of Korea and in Taiwan. Pohang Iron & Steel Co. Ltd. of Korea now has seven blast furnaces—four at Pohang and three at Kwangyang, with a fourth planned for Kwangyang. Steelworks in the EC have become more competitive in recent years

and should benefit from the growth in steel consumption that is forecasted to occur in Western Europe after the single market takes effect and internal trade barriers are removed. Production of pig iron in Brazil, and to a lesser extent, Argentina and Mexico, consumes much of the Latin American iron ore production. Brazilian pig iron production more than doubled between 1981 and 1989. Price controls reportedly were responsible for the dropoff. Mexican pig iron production has been relatively constant since 1981, ranging from 3.2 Mmt to 3.9 Mmt. Japanese imports of iron ore are not expected to increase dramatically, in spite of the country's dynamic construction and automotive industries, because Japanese companies are moving to higher value products.

⁴Chamosite is a yellow-green to greenish-gray iron-rich alumino-silicate that forms oolites in sedimentary ironstones. Fine-grained varieties of the alumino-silicate are also found in the groundmass of the ironstone, together with siderite and kaolinite. The mineral, which contains about 30% Fe, is closely related chemically to the chlorites, but has a layered structure more akin to serpentine [$Mg_3Si_4O_{10}(OH)_2$]. Chamosite is a major constituent of the Jurassic ironstones of the English Midlands.

NA Not available.

¹Includes only those mines, complexes, or mining groups that had shipments of at least 4.0 million metric tons in 1989, 1990, or 1991.

²The mixed ore is considered to be the result of "hematite enrichment."

³Other Goan shippers include Damodar Mangalji & Co. (Pvt.) Ltd., V.S. Dempo & Co. (Pvt.) Ltd., Sociada de Fomento Industrial (Pvt.) Ltd., Minerals & Metals Trading Corp. of India Ltd., Orient Goa (Pvt.) Ltd., V.M. Salgaocar & Brother Ltd., A.V. Sarmalkar, and Sesa Goa Ltd.

⁴Liberian Mining Corp. (LIMINCO) assumed full control of the LAMCO Joint Ventura in late 1989. The Mining complex was being operated for LIMINCO by a subsidiary of the African Mining Consortium Ltd. Mining operations and shipments were interrupted by the civil war, but resumed at a reduced rate in Apr. 1991.

¹Estimated. ²Revised.

³Table includes data available through July 9, 1992.

⁴In addition to the countries listed, Cuba and Vietnam may produce iron ore, but definitive information on output levels, if any, is not available.

⁵Insofar as availability of sources permits, gross weight data in this table represent the nonduplicative sum of marketable direct-shipping iron ores, iron ore concentrates, and iron ore agglomerates produced by each of the listed countries. Concentrates and agglomerates produced from imported iron ores have been excluded under the assumption that the ore from which such materials are produced has been credited as marketable ore in the country where it was mined.

⁶Data represent actual reported weight of contained metal or are calculated from reported metal content. Estimated figures are based on latest available iron content reported, except for the following countries for which grades are U.S. Bureau of Mines estimates: Albania, Hungary, and North Korea.

⁷Nickeliferous iron ore.

⁸Dry weight.

⁹Reported figure.

¹⁰Series represent gross weight and metal content of usable iron ore (including byproduct ore) actually produced, natural weight.

¹¹U.S. Bureau of Mines estimate of China's usable iron ore production. The ore grade of the series is equivalent to 50% Fe content to provide data approximately comparable with world market production. Bureau estimates, run-of-mine ore in China averages only about 35% Fe. Production of crude ore, as reported by The Year Book of Iron and Steel Industry of China was as follows, in thousand metric tons: 1987—161,430 (revised); 1988—167,700 (revised); 1989—171,850 (revised); 1990—168,300 (revised, estimated); 1991—170,000 (estimated).

¹²Includes magnetite concentrate, pelletized iron oxide (from roasted pyrite), and roasted pyrite (purple ore).

¹³Data are for year beginning Mar. 21 of that stated.

¹⁴Gross weight calculated from reported iron content based on grade of 66% Fe.

¹⁵Concentrates from titaniferous magnetite beach sands.

¹⁶Includes manganese iron ore.

¹⁷Includes magnetite ore as follows, in thousand metric tons: 1987—4,979; 1988—5,492; 1989—6,594; 1990—5,613; 1991—5,658.

¹⁸Includes byproduct ore.

¹⁹Less than 1/2 unit.

NA Not available.

¹Staged additions are treated at some mining complexes as if they were separate plants. Site data excludes plants that have had no production since 1982. Plants that produced after 1979, but have been continuously idle since 1982, are cited in the footnotes because they could be reactivated at some reasonable cost.

²The total for the United States includes the newer part of the E. W. Davis Works at Silver Bay, MN, but not the idled plant owned by Cleveland-Cliffs Inc. at Republic, MI. Cyprus Minerals Co. acquired the cannibalized Silver Bay facility in Aug. 1989 and resumed production in Jan. 1990. Cleveland-Cliffs has been considering reopening its 1 Mmt/yr Republic plant, which has been on care and maintenance since 1981.

³Pellets produced from imported direct-shipping ores and/or concentrates.

⁴The older of the two plants, operated by A/S Sydvaranger at Kirkenes, has been idle since 1986. In addition, the 0.50 Mmt/yr plant operated by Norsk Jernverk at Mo-i-Rana was shut down in Jan. 1987 for an indefinite period, leaving only one plant in Norway on-line.

⁵In early 1988, the capacity of the Svappavaara plant was upgraded from 2.8 to 3.5 Mmt/yr. The 0.3 Mmt/yr steel belt plant at Malmberget is used for both research and development purposes as well as ordinary production.

⁶Based on incomplete information.

The Skopje plant operated by Rudnici i Zelezara was recently idled.

⁷Excludes the No. 1 pelletizing plant (capacity of 2.4 Mmt/yr) of the Bong Mining Co. The No. 1 plant has been idle since 1980.

⁸The Nador plant operated by Societe d'Exploitation des Mines du Rif (SEFERIF) has been idle for several years.

⁹There is an additional plant with a capacity of 1.8 Mmt/yr at Mandovi in Goa, but it has been closed since 1982. The owner was planning to reopen the facility using high-grade blue dust from the Bellary Hospet area of Karnataka as feed.

¹⁰There is an additional plant with a capacity of 3.0 Mmt/yr at Dampier in Western Australia, but it has been closed since 1980.

 COMPARISON OF U.S. IRON ORE PRODUCTION WITH TOTAL PRODUCTION FOR THE WORLD

IRON OXIDE PIGMENTS

By David A. Templeton

Mr. Templeton, a physical scientist with 4 years U.S. Bureau of Mines experience, has been the commodity specialist for iron oxide pigments for 1 year. Domestic survey data were prepared by Gloria Peebles, statistical data assistant; and international data tables were prepared by Audrey Wilkes.

DOMESTIC PRODUCTION

According to the U.S. Bureau of Mines, mine production and sales of crude iron oxide pigments (IOP) in 1991 edged upward to 34,083 and 40,220 metric tons, respectively. Sales of synthetic iron oxide pigments dropped to 117,224 tons, a level not seen since the period between 1984-86. Imports for consumption held steady at the 34,000-ton level, and exports returned to the 1987-88 level of 20,000 tons after a 2-year dip to the 10,000-ton level.

Data in table 2 regarding sales of finished synthetic pigments have been rearranged to show the three primary pigments. Hitherto, only the red pigments stood alone in the published figures, and black and yellow were each published as combinations with other categories (brown and mixtures/specialties, respectively). The extraneous data have been combined into one number (see under brown), and black and yellow now stand alone along with red. (See table 2.)

Industry Structure

The many changes affecting the pigment and iron oxide industries in 1991 included acquisitions, plant closings, and bankruptcy. Harcros Pigments, Inc. purchased Northern Pigment of Toronto, Canada, for \$C17 million, thus bringing its total number of pigment-producing plants to four. Conversely, Columbian Chemicals Co. shuttered its predominantly red-producing plant in Monmouth Junction, NJ, at midyear,

thereby leaving it with a sole plant in St. Louis, MO.

Changes in the regenerator oxide industry included the exit of two companies and the entrance of a third. Perox, which had previously produced iron oxide at two separate plants via regenerating pickle liquor, filed for chapter 7 bankruptcy in February. The Fairfield, AL, plant is now owned and operated by U.S. Steel, and Sharon Steel retains ownership of its plant in Sharon, PA, but contracted its operation to International Steel Services, Inc., of Pittsburgh. Lehi, UT-based Peteco Inc. folded in September when Geneva Steel switched to a new finishing method that produces a lime-white powder rather than the red precipitator dust formerly used as pigment for cinder blocks. Magnetics International, Inc., a division of Inland Steel Industries, Inc., began treating spent pickle liquors at a new plant in Burns Harbor, IN. The state-of-the-art facility, which houses two spray roasters, was designed specifically to produce high-quality ferrite powders while regenerating acid in the process, as opposed to typical plants that focus on the latter.

The magnetic iron oxide business introduced a new domestic player as well. Three of the four plants that Harcros purchased from Pfizer Inc. produce this material, one solely (Valparaiso, IN) and two ancillary to pigment production (Easton, PA, and East St. Louis, IL). Ishihara Sangyo Kaisha (ISK) purchased the Valparaiso plant outright and reportedly will take all production from the Easton and East St. Louis plants on a toll basis. ISK joins U.S. producers 3M Co. and Magnox, Inc., in supplying the

magnetic media markets with the raw material for audiotapes and videotapes, computer disks, etc.

Effective January 1, 1992, Bayer AG, the German parent of Mobay Corp. et al., grouped all of its U.S. business concerns under the name Miles Inc. (As this is a 1991 report, table 3 does not reflect this change.) Pigment-related business will be handled by the Miles Industrial Chemicals Div.

World Review

Savage Resources Ltd. continued exploration of a promising deposit in northwest Tasmania near Savage River Township. The deposit, discovered in 1987, has been extensively drilled, and three distinct ore bodies have been identified. Portions of each deposit comprise the HT Ocher Site, which has been assessed to contain 350,000 tons of brown, yellow, and red iron oxide pigments (175-, 130-, and 45-thousand tons, respectively). Having delineated sufficient resources to satisfy the original goal of 10,000 tons annual production for 10 years, efforts to produce a refined pigment continue.

Oakville, Ontario-based Stewart Lake Resources Inc. neared completion of a feasibility study addressing the production of IOP from a worked deposit near Sofia, Bulgaria. The Kremikovtsi deposit was reported to contain black, brown, ocher, and red pigments, but a wider selection will probably be produced via blending.

²Includes pyrite cinder.

³Included with synthetic black iron oxide to avoid disclosing company proprietary data.

⁴Includes other specialty oxides and mixtures of natural and synthetic iron oxides.

⁵Included with synthetic brown iron oxide to avoid disclosing company proprietary data.

⁶Data may not add to totals shown because of independent rounding.

TABLE 3
PRODUCERS OF IRON OXIDE PIGMENTS, REGENERATOR IRON OXIDES,
AND STEEL-PLANT WASTE IRON OXIDES IN THE UNITED STATES IN 1991

Producers	Plant location
Finished pigments:	
AST Co.	Granite City, IL.
American Minerals	Camden, NJ.
Blue Ridge Talc Co., Inc.	Henry, VA.
Columbian Chemicals Co.	St. Louis, MO, and Monmouth Junction, NJ.
DCS Color & Supply Co., Inc.	Milwaukee, WI.
George B. Smith Color Co.	Kirkland, IL.
Harcros Pigments Inc.	Emeryville, CA, East St. Louis, IL, Easton, PA.
Hilton-Davis Co.	Cincinnati, OH.
Hoover Color Corp.	Hiwassee, VA.
Mineral Pigments Corp.	Beltsville, MD.
Mobay Corp. Inorganic Chemicals Div.	New Martinsville, WV.
New Riverside Ochre Co., Inc.	Cartersville, GA.
Pea Ridge Iron Ore Co.	Sullivan, MO.
Prince Manufacturing Co.	Quincy, IL, and Bowmanstown, PA.
Solomon Grind-Chem Services Inc.	Springfield, IL.
Swansea Minerals Inc.	Tempe, AZ.
Crude pigments:	
Cleveland-Cliffs Iron Co., Mather Mine and Pioneer plant (closed July 31, 1979; shipping from stockpile.)	Negaunee, MI.
Hoover Color Corp.	Hiwassee, VA.
New Riverside Ochre Co., Inc.	Cartersville, GA.
Pea Ridge Iron Ore Co.	Sullivan, MO.
Swansea Minerals Inc.	Tempe, AZ.
Virginia Earth Pigments Co.	Hillsville, VA.
Regenerator and steel plant waste iron oxides:	
Armco Inc.	Ashland, KY.
Chesapeake Specialty Products	Baltimore, MD.
Gulf States Steel, Inc.	Gadsden, AL.
Perox ¹	Birmingham, AL, and Sharon, PA.
Petco Inc. ²	Lehi, UT.
Shance Chemical Corp.	Philadelphia, PA.
Weirton Steel Corp.	Weirton, WV.

¹Out of business; plants continued to produce under new owners and/or operators.

²Out of business; Geneva Steel adopted a new process.

¹Estimated. ²Revised.

³Table includes data available through Apr. 28, 1992.

⁴In addition to the countries listed, a considerable number of others undoubtedly produce iron oxide pigments, but output is not reported, and no basis is available for formulating estimates of output levels. Such countries include, but are not limited to, China and the U.S.S.R. Because unreported output is probably substantial, this table is not summed to provide a world total.

⁵Revised to zero. Production of crude iron oxide pigments in Canada cannot be verified. Production of iron oxides in Canada is limited to synthetic pigments and regenerator oxide.

⁶Includes Vandyke brown.

⁷Reported figure.

IRON AND STEEL

By Gerald W. Houck

Mr. Houck, a physical scientist with 35 years of industry and U.S. Bureau of Mines experience, is the commodity specialist for iron and steel. International data tables were prepared by Harold Willis, international data coordinator, and Ted Spittal, Orkand Corp. Ferroalloys survey data were prepared by Jo-Ann Sterling and Robin Johnson, mineral data assistants.

Iron and steel are vital to the United States for both national security and economic well-being. They are the basic metals of an industrial society. Although there are many acceptable substitutes for many of their uses, in the short term, there are no practical substitutes on a large scale because of the cost and lack of availability of alternative materials. Ferroalloys are alloys of iron that contain a sufficient amount of one or more other chemical elements to be useful as an agent to introduce these other elements into a molten metal, usually steel.

In prior years, the U.S. Bureau of Mines has published a separate annual Minerals Yearbook chapter covering ferroalloys. This year, data tables on ferroalloys production and consumption are contained in this chapter. The reader is referred to the Yearbook chapters dealing with specific elements, especially those for chromium, manganese, and silicon, for analysis and detail with respect to the ferroalloys industry.

This was a poor year for the U.S. steel industry, as production and shipments of steel products declined along with the recessionary economy. Production of raw steel in the United States dropped more than 11% to 79.7 million metric tons, from 89.7 million produced in 1990. Net shipments of steel mill products by U.S. companies dropped about 7%, to 71.5 million tons, from 77.1 million tons in 1990.

Imports of steel mill products declined about 8%, to 14.3 million tons, from 15.6 million tons in 1990. Imports captured 17.8% of the apparent consumption of mill products, up from

17.5% in 1990. Imports of fabricated steel products, such as fasteners, wire, and fabricated structural steel, totaled 1.7 million tons, representing another 2% of the U.S. steel market. (See tables 1 and 2.)

Exports of steel mill products increased to 5.8 million tons, from 3.9 million tons in 1990. This was the fifth consecutive year of increased steel mill product exports by U.S. companies and was the second highest year for steel mill product exports since World War II.

Prices of steel mill products declined in 1991. The Bureau of Labor Statistics' Producer Price Index for steel mill products declined 2.3% to 109.5 (1982 base=100.0).

The combination of lower volume and lower selling prices resulted in continued financial losses for the U.S. steel industry. The American Iron and Steel Institute, reporting on the aggregated financial results of companies that produced about 64% of the Nation's raw steel in 1991, announced that 1991 losses were \$2,072 million on steel sales of \$27,270 million. These companies have reported cumulative losses of \$11,540 million over the 10-year period 1982-91.

Worldwide production of raw steel in 1991 was 733.7 million tons, down 5% from that of 1990. Production in Eastern Europe and the former U.S.S.R. fell dramatically--more than 18% in 1991 alone. In China and other developing nations of Asia, Africa, and the Middle East, however, growth continued at a vigorous pace, partially offsetting the declines in the United States and the Eastern bloc. Production in Western

Europe and Japan was about the same as that in 1990.

Consistent with international usage, the U.S. Bureau of Mines is reporting all data on iron and steel in metric units, unless otherwise noted.

DOMESTIC DATA COVERAGE

Data regarding U.S. production of iron and steel and shipments of steel mill products are those reported by the American Iron and Steel Institute. These data can be regarded as representing 100% of the raw steel producers in the United States.

BACKGROUND

Definitions, Grades, and Specifications

Iron is the most useful and most abundant, as well as the cheapest of the metallic elements. It is also the most versatile and most widely studied and understood. Its many uses are based on the properties of its alloys; iron is never used by itself. Some of its useful alloys include the word "iron"; viz, pig iron, wrought iron, gray iron, malleable iron, ductile iron; others are known as "steel." The term "steel" was originally applied to an alloy of iron that would become very hard if cooled rapidly from a high temperature. Early steelmakers did not know that a carbon content from about 0.3% to about 1% is required for producing these properties, but by trial and error they developed empirical methods to produce metals of the proper carbon content.

Today, "iron" refers to alloys that contain too much carbon to be formable by forging or rolling. "Pig iron" contains about 4.5% carbon and is useful only for steelmaking or for remelting into cast-iron products. Gray iron, malleable iron, and ductile iron are categories of cast iron and are produced by the foundry industry.

In modern terminology, "steel" refers to an alloy of iron that is malleable at some temperature containing manganese, carbon, and often other alloying elements. Steel containing only carbon and manganese is called "carbon steel"; steel containing metallic elements such as nickel, chromium, or molybdenum is termed "alloy steel"; and steel containing sufficient chromium to confer a superior corrosion resistance is called "stainless steel." Hundreds of individual alloy specifications have been developed to produce combinations of strength, ductility, hardness, toughness, magnetic permeability, and corrosion resistance to meet the needs of modern consumers. These alloy specifications are called "grades."

The malleability property of steel allows it to be produced by rolling or forging into a variety of product forms. Examples of forms include structural shapes (such as beams and angles), rails (such as railroad rails), round bars, wire, various types of pipe and tubular products, and flat-rolled products. In every case, the product is produced on specialized equipment in a range of sizes to suit intended applications.

For some products, metallic or nonmetallic coatings are applied to the product by the steel producer. Additionally, various thermal treatments may be used to provide the customer's required properties.

"Steel mill products" refers to products produced by a steel mill, either by forging or rolling, in the form normally delivered for fabrication or use. Some companies purchase semifinished steel mill products from other steel companies and use these semifinished products to produce steel mill products. To avoid double counting of steel mill product shipments under these circumstances,

steel mills identify any shipments of steel mill products to other companies that are reporters of steel mill product shipments. The accumulated shipments of all companies, less the shipments to other reporting companies, are identified as "net" shipments.

Regarding the reporting of imports and exports, "fabricated steel products" are products produced from steel mill products, but not including products that incorporate steel products along with other materials. Examples of fabricated steel products are fabricated structural steel and steel fasteners. "Other iron and steel products" refers to products that are not produced from steel mill products. Examples of other iron and steel products include iron or steel castings and direct-reduced iron.

Industry Structure

Integrated Steel Producers.—Integrated steel producers are those that smelt iron ores to crude liquid iron in blast furnaces and refine the iron, with some scrap, in basic oxygen furnaces, producing liquid steel. The liquid steel is mostly cast into semifinished products in continuous casting machines, although 24% of U.S. production in 1991 was cast in ingot form and subsequently rolled into semifinished form. The integrated steel industry in the United States in 1991 consisted of 16 companies, operating ironmaking and steelmaking facilities at 24 locations. Several of these companies also operated nonintegrated plants and/or other steelmaking facilities at the same locations.

The product mix of the integrated producers consists predominantly of flat products: sheet and strip, some of which is galvanized or tinplated. Some integrated producers made structural shapes and bar products as well, but, for the most part, these products are produced by nonintegrated mills.

Nonintegrated Steel Producers.—Nonintegrated steel producers melt raw materials, primarily scrap, in electric furnaces. Broadly

speaking, there are two subcategories of nonintegrated mills: minimills and specialty mills. "Minimills" is a term used to describe steel producers that utilize modern technology in a plant built to produce a limited product line with maximum efficiency. These plants always incorporate electric melting of low-cost raw materials, continuous casting, and a hot-rolling mill, often closely coupled to the casting operation. It was once accepted that minimills produced only simple bar products such as reinforcing bars, wire rods, and small structural shapes. Today, however, minimills have become dominant in all long products, including special quality bars and large structural shapes. One company has successfully applied the minimill concept to the production of flat-rolled steel with the successful operation of a thin-slab (50-millimeter) casting machine, closely coupled to a hot-strip mill, producing commercial quality hot bands. This plant produced 1 million tons and operated at a profit during 1991, according to the company. Several companies operate multiple minimills with cumulative steelmaking capability greater than that of the smaller integrated mills.

The second category of nonintegrated mills, specialty mills, is less well defined. Specialty mills definitely include the producers of stainless steel, alloy electrical steel, tool steel, and high-temperature alloys. In addition, this category includes producers of forging ingots and a variety of steel plants that, while not producing a large quantity of steel, are a significant part of what is called "the steel industry."

Overall, the nonintegrated sector of the industry consisted of 68 companies, with 96 raw steelmaking locations.

Substitutes

Iron, as steel or cast iron, is the most widely used metal in the world because of its high strength-to-cost ratio. In applications where strength is not the major requirement, iron competes with less expensive nonmetallic materials or more expensive materials having some

property advantage. Where weight reduction is required, aluminum, plastics, and occasionally magnesium or titanium may be substituted; motor vehicles and airplanes are obvious examples. In construction, concrete, usually reinforced with steel, and wood are frequently substituted for steel. In packaging, steel cans, pails, and household goods were largely replaced with aluminum, glass, plastics, and paper, but drums and other containers used for more severe applications are almost invariably made of steel.

ANNUAL REVIEW

Legislation and Government Programs

Since October 1, 1984, the import of steel products into the U.S. has been limited by a program of "Voluntary Restraint Agreements (VRA's)," which were negotiated following an investigation conducted by the U.S. International Trade Commission in which imports of certain steel products were found to be a substantial cause of serious injury, or threat thereof, to certain domestic industries. The President determined that imposing countervailing duties under the Trade Act of 1974 was not in the national economic interest and directed the U.S. Trade Representative to negotiate VRA's with countries whose exports to the United States had increased significantly in previous years due to an unfair surge in imports.

Agreements were negotiated with the European Community and 16 individual nations. Although the structure of the agreements varied from one country to another, each involved an agreement by the foreign Government to limit exports of certain steel products to the United States. To bring the agreements into effect, U.S. steel producers withdrew pending unfair trade petitions, and the U.S. Government suspended antidumping and countervailing duties that were in effect on the products covered by the agreements. The VRA's covered a 5-year period ending September 30, 1989.

In July 1989, the President announced a "Steel Trade Liberalization Program"

extending the VRA program for 2 1/2 years, to terminate March 31, 1992. Negotiations resulted in new agreements with the European Community and the 16 other countries.

During 1991, negotiations were conducted in an effort to reach a "Multilateral Steel Agreement" among the major steel trading nations. The proposed agreement would have established international disciplines on government subsidies. It would have defined some forms of government support, such as research and development grants or assistance for environmental protection purposes, as permissible, and accordingly, not subject to national countervailing duty laws. The agreement also would have phased out tariffs and prohibited a number of measures, such as quotas, VRA's, and special licensing provisions, that are designed to restrict or regulate trade in steel products. Agreement on the Multilateral Steel Agreement was not reached before the expiration of the VRA's on March 31, 1992.

As a result of the expiration of the VRA's and the failure to reach agreement on the Multilateral Steel Agreement as of mid-1992, there are no special trade provisions now in effect for steel; it is subject to the same agreements, including the General Agreement on Tariffs and Trade, as are other products.

Production

This was a poor year for the U.S. steel industry, as production and shipments of steel products declined along with the recessionary economy. Production of raw steel in the United States dropped more than 11% to 79.7 million tons from 89.7 million tons produced in 1990. Net shipments of steel mill products by U.S. companies dropped about 7% to 71.5 million tons from 77.1 million tons in 1990. The drop in production was greater than the drop in shipments because the steel companies trimmed inventories that had accumulated during the prior year. (See tables 3, 4, and 5.)

Electric arc furnace steelmaking was utilized for 38.4% of total steelmaking in 1991. This is the highest share ever for production for electric arc furnace steelmaking in the United States.

Open-hearth steelmaking dropped to 1.6% of the total. During 1991, both of the only operating open-hearth steelmaking shops in the United States were permanently shut down. One of the two, at Geneva Steel Co., Provo, UT, was replaced by a basic oxygen steelmaking plant. The other open-hearth shop, at the U.S. Steel Group (USX Corp.) plant near Philadelphia, PA, was shut down, along with the blast furnace iron-producing facility at the same site, as U.S. Steel Group apparently plans to supply steel produced at other locations to the finishing facilities located there.

The trend toward the use of continuous casting continued. The share of raw steel produced by continuous casting was 75.8%, up from its previous high of 67.4% in 1990. New continuous casting equipment was under construction at yearend at several locations, ensuring that the continuous casting ratio will continue to increase.

Consumption and Uses

Shipments of steel products by U.S. companies were down 7.2% to 71.5 million tons, but export shipments were up 80%. Shipments to domestic customers were down 11%. Shipments for some applications were down much more than that, as the recession hit hard in the industrial sectors of the economy; shipments for oil and gas drilling, mining, quarrying, and lumbering were down 26% from the 1990 level, and shipments for industrial and agricultural machinery, equipment, and tools were down 22%. Uses that were less severely impacted were automotive, which was down 10%, and containers, packaging, and shipping materials, which was down only 5%. (See table 6.)

Markets and Prices

Prices for steel mill products were under severe pressure during the entire

year. The Bureau of Labor Statistics' Producer Price Index for steel mill products was down by 2.4% at 109.5 (1982 base=100.0.) Numerous efforts by steel companies to increase their prices were reported, but vigorous competition prevented prices from being increased.

Foreign Trade

The U.S. steel companies increased their foreign sales of steel mill products. Exports of steel mill products increased to 5.8 million tons. This is the highest annual level of exports since 1970 and the second highest level since World War II. Canada was the nation receiving the largest amount of exported steel, 1.5 million tons, with Mexico in second place, receiving 1.2 million tons. Increases in exports to Mexico, Korea, and Japan represented most of the year-to-year increase in exports over 1990. (See tables 7 and 8.)

Imports of steel mill products declined about 8% from those of 1990. VRA'S were in effect during the entire year, but imports were, in the main, less than the restraint levels would have allowed. The combination of a weak dollar, slack demand, and vigorous competition apparently kept import allowances from being filled. The European Community, Canada, and Japan were major sources for steel mill product imports. Brazil and Korea were also major importers, with much of the steel from these countries being imported in semifinished form for conversion in the United States into other steel mill products. (See tables 9, 10, and 11.)

World Review

World production of pig iron and direct-reduced iron in 1991 totaled 528.5 million tons, down 4% from that of 1990. The collapse of economies in Eastern Europe and the former U.S.S.R., along with the recession in the United States, accounted for the decrease.

Direct-Reduced Iron.—Direct-reduced iron has become a significant part of world production. While pig iron production dropped, production of direct-reduced iron soared to almost 20 million tons in 1991, with an 8% increase in 1991 and 58% over the past 5 years. Direct reduction of iron ore has proved to be a cost effective way for developing countries, especially those with an abundance of natural gas, to encourage economic growth. As a result, in the Middle East, Southeast Asia, Mexico, and Venezuela, production of direct-reduced iron is on the increase.

As of November 1991, world capacity for direct-reduced-iron production was estimated to be 28 million tons, with an additional 11.5 million tons under construction. Developments in India and Iran deserve special mention. The Government of India is encouraging the development of direct-reduced-iron facilities to slow the high rate of scrap imports. Since 1989, four direct-reduced iron plants, with a combined capacity of 1.4 million tons, have been started up, bringing India's total annual capacity to 1.7 million tons. An additional 4 million tons of capacity is under construction, with completion planned from 1992 through 1994.

Iran's program to develop direct-reduced-iron facilities was interrupted by its war with Iraq. With that conflict over, construction of these facilities has been resumed. About 0.8 million tons of capacity was started up in 1990 and 1991; an additional 4.3 million tons is scheduled for 1992-94, which would bring Iran's total capacity for direct-reduced iron to 5.8 million tons.

Other nations where direct reduction facilities are under construction are Saudi Arabia (0.65 million tons scheduled for 1992), Malaysia (1.2 million tons, 1993) and Indonesia (1.35 million tons, 1993.) (See tables 12 and 13.)

Steel.—World production of steel was 733.7 million tons, down 5% from that of 1990. Declines in the United States, Eastern Europe, and the former U.S.S.R. were partially offset by continued strong

growth in China, Korea, and in the other nations of Southeast Asia and the Middle East. (See tables 14 and 15.)

OUTLOOK

The outlook for 1992 is for further declines in pig iron and steel production in the Eastern European nations and the former Soviet Republics. Strong growth will continue in China and the Far East.

In the United States, recovery from the depressed operations of 1991 is apparent, but the growth is not robust. Vigorous world competition will limit the ability of U.S. companies to maintain their record-breaking level of export sales.

The expiration of the VRA's on March 31, 1992, has increased the uncertainty about the future of imported steel. On June 30, 1992, a group of 12 domestic steel companies filed complaints alleging dumping and/or illegal subsidization against importers of flat-rolled sheet and strip products from 20 nations, including all the major steel importing nations. These pending petitions are currently causing even greater uncertainty in the steel marketplace. If the U.S. International Trade Commission finds that imports are a cause of "injury" to the domestic steel industry and if the Department of Commerce supports the allegations of dumping and subsidization, countervailing duties will be applied. (See tables 16 through 25.)

Of which:					
Pig iron	'508,895	'539,602	'546,306	'532,607	508,730
Direct reduced iron	'13,825	'14,286	'16,641	'18,366	19,755

⁴Estimated. Revised. NA Not available.

¹Production is pig iron unless otherwise specified.

²Direct-reduced iron is obtained from ore by reduction of oxides to metal without melting.

³Table excludes ferroalloy production except where otherwise noted. Table includes data available through July 2, 1992.

⁴In addition to the countries listed, Vietnam and Zaire have facilities to produce pig iron and may have produced limited quantities during 1987-91, but output is not reported and available information is inadequate to make reliable estimates of output levels.

⁵Reported figure.

⁶Less than 500 tons.

⁷Includes blast furnace ferroalloys.

⁸Previously listed as estimated pig iron production.

⁵Estimated. ⁶Revised. NA Not available.

¹Steel formed in first solid state after melting, suitable for further processing or sale; for some countries, includes material reported as "liquid steel," presumably measured in the molten state prior to cooling in any specific form.

²Table includes data available through June 29, 1992.

³In addition to the countries listed, Burma, Ghana, Libya, and Mozambique are known to have steelmaking plants, but available information is inadequate to make reliable estimates of output levels.

⁴Reported figure.

⁵Data are for year ending June 30 of that stated.

⁶Includes steel castings.

TABLE 16
GOVERNMENT INVENTORY OF FERROALLOYS,
DECEMBER 31, 1991

(Metric tons of alloy, unless otherwise stated)

Alloy	Stock- pile grade	Non- stock- pile grade	Total
Ferrochromium:			
High-carbon	670,865	629	671,494
Low-carbon	272,373	15,357	287,730
Ferrochromium-silicon	51,699	1,242	52,941
Ferrocolumbium (kilograms contained columbium)	271,435	150,820	422,255
Ferromanganese:			
High-carbon	942,813	—	942,813
Medium-carbon	26,374	—	26,374
Ferrotungsten (kilograms contained tungsten)	381,359	536,778	918,137
Silicomanganese	21,386	—	21,386

TABLE 17
HISTORICAL FERROALLOY
PRICE TRENDS

(Weighted annual averages)

Year	FeMn ¹	FeCr ²	FeSi ³
1977	327.20	36.25	28.55
1978	334.11	33.11	29.96
1979	440.14	43.03	41.70
1980	428.37	45.85	41.77
1981	410.97	46.37	40.01
1982	396.23	46.01	37.93
1983	328.21	36.71	36.67
1984	331.60	43.21	41.89
1985	330.21	43.71	35.71
1986	319.22	39.94	33.65
1987	341.80	43.89	36.78
1988	510.23	85.08	56.82
1989	619.64	75.67	48.96
1990	644.27	47.51	39.94
1991	602.92	47.32	36.98

¹Imported standard-grade ferromanganese—prices in dollars per long ton of alloy.

²Imported charge-grade ferrochromium—prices in cents per pound of contained chromium.

³Imported 75%-grade ferrosilicon—prices in cents per pound of contained silicon.

TABLE 18
PRODUCERS OF FERROALLOYS IN THE UNITED STATES IN 1991

Producer	Plant location	Products ¹	Type of furnace
FERROALLOYS (except ferrophosphorus)			
Alabama Silicon Inc.	Bessemer, AL	FeSi	Electric.
AMAX Inc., Climax Molybdenum Co. Div.	Langeloth, PA	FeMo	Metallothermic.
American Alloys, Inc.	New Haven, WV	FeSi, Si	Electric.
Applied Industrial Minerals Corp. (AIMCOR)	Bridgeport, Al, Kimball, TN	FeSi, other ²	Do.

^{*}Estimated. [†]Revised. NA Not available. W Withheld to avoid disclosing company proprietary data; included with "Other."

¹Table includes data available through May 29, 1992.

²To the extent possible, ferroalloy production of each country has been separated according to the furnace type from which production is obtained; production derived from metallothermic operations is included with electric furnace production.

³To the extent possible, ferroalloy production of each country has been separated so as to show individually the following major types of ferroalloys: Spiegeleisen, ferromanganese, silicomanganese, ferrosilicon, silicon metal, ferromanganese, ferromanganese-silicon, and ferronickel. Ferroalloys other than those listed that have been identified specifically in sources, as well as ferroalloys not identified specifically have been reported as "Other." For countries for which one or more of the individual ferroalloys listed separately in this footnote have been inseparable from some other ferroalloys owing to the nation's reporting system, such deviations are indicated by individual footnotes.

⁴Reported figure.

⁵Includes silicomanganese.

⁶Included with other.

⁷Includes ferromanganese-silicon and ferronickel, if any was produced.

⁸Includes silicospiegeleisen.

⁹Includes ferronickel, if any was produced.

¹⁰Series excludes calcium silicide.

¹¹Includes calcium-silicon, ferrotungsten, ferromolybdenum, ferromanganese, ferrocolumbium, and other ferroalloys.

¹²Estimated figures based on reported exports and an allowance for domestic use.

¹³Includes production from Bophuthatswana. Includes net production of ferromanganese-silicon, if there was any.

¹⁴Soviet production of electric furnace ferroalloys is not reported; estimates provided are based on crude source material production and availability for consumption (including estimates) and upon reported ferroalloy trade, including data from trading partner countries.

¹⁵U.S. output of ferromanganese includes silicomanganese and manganese metal.

¹⁶U.S. output of ferromanganese includes high- and low-carbon ferromanganese, ferromanganese-silicon, chromium metal, and other chromium materials.

¹⁷Spiegeleisen for the Western states of Germany is included with blast furnace ferromanganese.

¹⁸Includes silicospiegeleisen for France.

¹⁹Ferromanganese includes silicomanganese (if any was produced) for countries carrying footnote 5 on "Ferromanganese" data line.

²⁰U.S. production under "Other" for 1988-91.

²¹Ferromanganese includes ferromanganese-silicon (if any was produced) for Republic of South Africa and United States.

IRON AND STEEL SCRAP

By Raymond E. Brown

Mr. Brown, a physical scientist with 36 years of industry and U.S. Bureau of Mines experience, has been the commodity specialist for iron and steel scrap since 1986. Domestic survey data were prepared by Robert W. Thompson and Henry F. Sattlighthigh, Ferrous Data Section. International data tables were prepared by William L. Zajac, Chief, International Data Section.

Use of iron and steel scrap to produce new steel and ferrous castings, vital to the United States for both national security and economic well-being, represented significant energy, environmental, economic, and resource conservation benefits. Direct-reduced iron, pig iron, and iron carbide could be substituted for iron and steel scrap but were usually considered more expensive than scrap. Also, availability of these substitutes on a large scale was limited, and there were certain technical problems associated with the use of some of these substitute materials. However, these scrap alternatives had certain advantages, which included providing iron free of residual elements, such as copper, for use in producing higher quality steel and ferrous castings products.

The metric system is the official system of measurement of most countries. The U.S. Bureau of Mines, in an effort to provide statistical data on iron and steel scrap that are consistent with international usage, has reported data in kilograms and metric tons unless otherwise noted. To convert from: short tons (st) to metric tons (mt) multiply by 0.907185; long tons (lt) to metric tons multiply by 1.016047; metric tons to short tons multiply by 1.102312; metric tons to long tons multiply by 0.984207; metric tons to kilograms (kg) multiply by 1,000; and kilograms to metric tons multiply by 0.001. The number of pounds (lb), avoirdupois, in a: short ton or net ton (nt) = 2,000; long ton or gross ton (gt) = 2,240; metric ton =

2,204.623; and kilogram = 2.204623. All tables, except for table 16, which reported the selling price of No. 1 heavy melting steel scrap in dollars per long ton as well as dollars per metric ton, and the text of this publication employed the metric system.

Brokers, dealers, and other outside sources supplied domestic consumers in 1991 with 40.7 million metric tons¹ of all types of ferrous scrap at a delivered value of approximately \$4.15 billion, while exporting 9.3 million tons (excluding used rails for rerolling and other uses; and ships, boats, and other vessels for scrapping) valued at \$1.23 billion. In 1990, domestic consumers received 45.6 million tons at a delivered value of approximately \$5.32 billion; exports totaled 11.6 million tons valued at \$1.64 billion. This represented tonnage decreases of 11% for received quantities and 19% for exported quantities.

DOMESTIC DATA COVERAGE

Domestic production data for ferrous scrap were developed by the U.S. Bureau of Mines from voluntary monthly or annual surveys of U.S. operations. Of the operations to which a survey request was sent, 58% responded, representing an estimated 73% of the total consumption shown in table 2 for three types of scrap consumers. Consumption for the nonrespondents was estimated using prior reports adjusted by industry trends. An estimation error was also contained in the difference between the reported total

consumption of purchased and home scrap and the sum of scrap receipts plus home scrap production, less scrap shipments and adjustments for stock changes. For scrap consumption data shown in table 2, this difference amounted to 0.2% for manufacturers of pig iron and raw steel and castings, 3% for manufacturers of steel castings, 5% for iron foundries and miscellaneous users, and 1% average for all types of manufacturers combined. (See table 1.)

ANNUAL REVIEW

Legislation and Government Programs

The Environmental Protection Agency (EPA) conducted a pilot study to investigate the presence of polychlorinated biphenyls (PCB's) and other hazardous substances in waste products produced at metal salvage and recycling facilities. Input materials were segregated by type to allow separate shredding of three distinct material categories: automobiles only, white goods (appliances) only, and mixed input. PCB's were found in all sampled materials. However, 98% of the PCB's was associated with the shredder residue waste product, which is better known as fluff. Lead and cadmium were also found in most of the fluff samples.²

The EPA proposed treatment standards under the land disposal restrictions program for electric arc furnace (EAF) dust (wastes identified as K061 dust) that were nonwastewaters and contained 15%

or more total zinc.³ The Institute of Scrap Recycling Industries, Inc. (ISRI) had asked the EPA to remove metal shredders and recyclers from the list of categories potentially subject to emission standards under section 112 of the Clean Air Act.⁴ The EPA would target metal-related toxics and their producers among "strategic initiatives" under the President's \$6.2 billion EPA budget proposal for 1992.⁵

Bethlehem Steel Corp. and the U.S. Department of Energy signed an agreement for the engineering, construction, and operation of a blast furnace coal injection demonstration project at Bethlehem's Burns Harbor, IN, plant. Total cost of the project was \$144 million. Its aim was to inject granulated coal directly into the blast furnace combustion zone.⁶

Environmental and other legislation that the U.S. Congress was considering action on included the following: the Resource Conservation and Recovery Act (RCRA), the Nation's primary recycling and disposal statute, which defined what was waste and determined which wastes were hazardous; the Comprehensive Environmental Response and Cleanup Liability Act (CERCLA or Superfund), which held scrap processors and recyclers liable for environmental cleanup; limiting trade of "wastes" across State and international boundaries; the Toxic Substances Control Act (TSCA), which governed the use of toxic materials in manufactured articles, restricting their use when danger to the environment could be demonstrated; encouraging increased recycling; promoting markets for recycled goods; and increasing the duty on imported products containing U.S. processed scrap.

Available Supply, Consumption, and Stocks

Overall domestic demand for ferrous scrap in 1991 by the iron and steel and the ferrous castings industries, the major consumers of this raw material, was down about 12% compared with that of 1990. Because of weaker demand worldwide for ferrous scrap in 1991,

average annual prices for most scrap grades declined.

According to the Steel Can Recycling Institute (SCRI), Pittsburgh, PA, new and expanded steel can recycling programs throughout the United States pushed the 1991 overall recycling rate for certain types of steel cans to a record high of 34%. The 1991 figure represented a 38% increase compared with the 1990 overall recycling rate of 24.6% for food and beverage cans. In addition to food and beverage cans, SCRI included in its 1991 calculations paint and aerosol cans plus lids and closures found on other containers. About 880,000 metric tons of used steel cans was recycled into new steel and iron products or used in the copper precipitation industry in 1991.

Proler International Corp., a major processor of ferrous and nonferrous scrap, shut down its year-old detinning plant in Houston, TX, after losing \$3 million on its operations in 1990. The detinning plant, which came on-stream in May 1990 and was the largest in the United States, suffered from competition from its main customers, domestic steel mills, and the lack of future business from a proposed but unsuccessful new minimill plant called Buffalo Steel.⁷

Three communities in Indianapolis, IN, Lawrenceville, GA, and San Antonio, TX, were selected as winners in the 1991 Steel Recycling Award. The award, jointly sponsored by Keep America Beautiful, Inc., Stamford, CT, the Steel Can Recycling Institute, Pittsburgh, PA, and the American Iron and Steel Institute, Washington, DC, was open to more than 460 certified and precertified Keep America Beautiful Inc. affiliate communities. The three winners, selected for their efforts in helping communities develop innovative educational programs and sustaining the recycling of steel, aluminum, glass and plastic containers and paper, each received cash awards.

Nucor Corp., headquartered in Charlotte, NC, was building a new flat-rolled steel facility in Hickman, AR. This \$300 million mill, with an annual capacity of more than 1 million tons, would be in operation by early 1993.

This was the second minimill facility to be built in the United States to employ thin-slab casting technology. Nucor's first flat-rolled steel plant, in Crawfordsville, IN, with an annual capacity of about 1 million tons per year, began production in June 1989. The Crawfordsville plant maintained total residual levels of less than 0.25% in furnace charges.⁸

The Erman-Howell division of Luria Steel and Trading Corp., a 66-year-old scrap brokerage firm headquartered in Bannockburn, IL, went to bankruptcy court in May to seek protection from its creditors. Erman-Howell intended to wind down its business and liquidate its assets under the voluntary chapter 11 petition filed in U.S. Bankruptcy Court in Chicago, IL.

A recycling consortium would be formed by the big three U.S. automakers, General Motors Corp., Ford Motor Co., and Chrysler Corp., to develop technology for recycling the 20% to 25% of a vehicle's weight that was not recovered and reused. The consortium also would be expected to try to develop improvements of existing techniques for handling recyclable materials and to develop or encourage component designs that expedite disassembly. Additionally, the group would be expected to work on improved, more acceptable methods of material disposal. German automaker BMW had also launched a pilot program in North America with a view of building a national recycling capacity for all BMW models once they had reached the end of their natural lives.⁹

Maytag Corp. would begin using plastic tubs in place of porcelain-enameled steel units in its dishwashers by the middle of 1992. This switch would cost the steel industry 5,000 tons or more of cold-rolled sheet annually. Executives and engineers at Whirlpool Corp. were considering the use of laminated steel in the drums of electric and gas dryers for the home laundry market in this country. Each drum was made from 12- to 13-pound blanks of cold-rolled steel, and appliance industry sources estimated Whirlpool used close to 14,000 tons of the metal each year for the drums.

Laminated metal could lower dryer operation noise levels. Laminated metallic materials, composed of two sheets of steel or aluminum with a layer of viscoelastic plastic placed between, formed a sandwich composed of metal-plastic-metal.

Geneva Steel, Provo, UT, shut down the last operating open-hearth furnace used for steelmaking in the United States in December 1991. The eight open-hearth furnaces that had been used by Geneva were replaced by two revamped basic oxygen process (Q-BOP) furnaces. Open-hearth steel production in the United States began in 1868. The open-hearth process reached its peak in 1955 when 90% of this country's steel was produced by this method. Since 1955, steel production by the open-hearth process had been replaced by the basic oxygen and the electric furnace processes.

Florida Steel Corp. began operating a new 60-ton direct current arc furnace at its steel mill in Tampa, FL. The furnace was built by Deutsche Voest-Alpine Industrieanlagenbau GmbH, Dusseldorf, Federal Republic of Germany, and is based on a concept jointly developed with Florida Steel.¹⁰

North Star Steel Co., headquartered in Minneapolis, MN, had shuttered indefinitely its Milton, PA, minimill facility, citing slow orders for rebar and an unexpected transformer failure. The company planned to conduct a study of east coast construction markets before restarting the plant. North Star was also studying the idea of building its first minimill plant west of the Rockies.

USX Corp. permanently closed the iron and steel-producing operations and a pipe mill at its Fairless Works in Fairless Hills, PA, in March 1991. U.S. steel broke ground for this massive open-hearth steelmaking plant, the largest steel mill ever built, in 1951. The plant, which opened in 1952, was a major consumer of ferrous scrap.

A U.S. Congressman, versed on environmental issues that impact the scrap processing industry, addressed the keynote breakfast at the ISRI convention in Las Vegas, NV, in March.¹¹ In

addition to traditional "spotlight" sessions on metals, the ISRI Convention provided an expanded consideration of nonmetallic commodities that included plastics recycling.

U.S. steelmakers continued their quest for higher quality flat-rolled products by investing hundreds of millions of dollars in modernization programs designed to lift product quality, enhance mill productivity, and satisfy the demands of increasingly finicky customers.¹²

Imports of metallurgical-grade coke increased 44% in 1991 to 997,000 tons compared with that of 1990. Metallurgical coke imports represented 5% of domestic apparent consumption in 1991 compared with 3% in 1990. The United States continued as a net importer of metallurgical coke. Domestic coal consumption in coke plants decreased 13% in 1991 to 30.7 million tons. Domestic metallurgical coal exports increased 2% in 1991 to 58.6 million tons compared with those of 1990.

Raw steel production was 79.7 million tons in 1991 compared with 89.7 million tons in 1990. The shares of raw steel produced by electric, basic oxygen, and open-hearth furnaces were, respectively, 38%, 60%, and 2% in 1991 and 37%, 59%, and 4% in 1990. Continuous cast steel production represented 76% of total raw steel production in 1991 compared with 67% in 1990. Raw steel capacity utilization was 75% in 1991 and 85% in 1990. Raw steel production capability was 106.7 million tons in 1991 compared with 105.9 million tons in 1990.

Net shipments of all grades of steel mill products were 71.5 million tons in 1991 and 77.1 million tons in 1990. Imports of steel mill products decreased from 15.6 million tons in 1990 to 14.4 million tons in 1991. Exports of steel mill products increased from 3.90 million tons in 1990 to 5.76 million tons in 1991. The apparent supply of steel mill products decreased from 88.8 million tons in 1990 to 80.1 million tons in 1991. Imports of steel mill products, as a share of the U.S. market, were 18% in both 1990 and 1991. Estimated steel mill processing yields [(total net shipments of steel mill products/total raw steel production)(100)]

increased from 86% in 1990 to 90% in 1991. Pig iron production decreased from 49.7 million tons in 1990 to 44.1 million tons in 1991.

Iron castings shipments totaled 6.74 million tons in 1991 compared with 7.76 million tons (revised) in 1990. Steel castings shipments (including investment castings) totaled 0.94 million tons in 1991 compared with 1.06 million tons (revised) in 1990.

Steel mills accounted for 76% of all scrap received from brokers, dealers, and other outside sources; steel foundries received 5%; and iron castings producers and miscellaneous users received 19%. The apparent total domestic consumption of ferrous scrap in 1991, in million tons, was composed of 39.8 net receipts (total receipts minus shipments), 21.5 home scrap, and 0.2 withdrawals from stocks. The 1991 total was 61.5 million tons; the apparent total domestic consumption was 69.5 million tons in 1990. The total market for U.S. scrap (net receipts plus exports minus imports) was 48.2 million tons in 1991 compared with 54.7 million tons (revised) in 1990. Stocks of ferrous scrap held by both steel mills and ferrous foundries decreased in 1991. (See figure 1.)

Prices

Based on average composite delivered prices per long ton quoted weekly and monthly by the American Metal Market (AMM), converted to metric tons, No. 1 heavy melting steel scrap cost \$91.79 in 1991, ranging from a low of \$84.32 in December to a high of \$103.38 in January. Based on Iron Age data, also converted to metric tons, No. 1 heavy melting steel scrap cost \$91.74 in 1991, ranging from \$83.88 in December to \$101.62 in January. The average composite price for No. 1 heavy melting steel scrap in 1991 was lower compared with that of 1990, by 13% based on both AMM and Iron Age data. Based on prices quoted weekly by Iron Age for tonnages of 18-8-grade stainless steel scrap (bundles and solids) delivered to consumers in the Pittsburgh, PA, area, the average price of nickel-bearing

stainless steel scrap decreased 6%, from \$911.62 per ton in 1990 to \$861.28 per ton in 1991.

In 1991, the average price for total ferrous scrap exports (excluding used rails for rerolling and other uses and ships, boats, and other vessels for scrapping) decreased 7% to \$131.92 per ton compared with that of 1990, while that of total imports increased 1% to \$132.81 per ton.

Foreign Trade

Foreign trade tables were based on the Harmonized Tariff Schedule (HTS), which became effective January 1, 1989. Additionally, valuation continued to be reported on an f.a.s. basis for exports and on a customs value basis for imports.

The trade surplus in 1991 for all classes of ferrous scrap (including used rails for rerolling and other uses and ships, boats, and other vessels for scrapping) was \$1.09 billion in value and 8.3 million tons in quantity. This represented a decrease of 25% in value and 18% in quantity compared with the 1990 surplus of \$1.46 billion (revised) in value and 10.2 million tons (revised) in quantity. The balance of trade for all U.S. merchandise [exports (f.a.s.) less imports (customs value)] showed a deficit of \$65.4 billion in 1991, down from a deficit of \$101.7 billion in 1990.

The quantity and value of total exports and imports in 1991 declined from the record highs of 1990. In 1991, the quantity of total imports decreased by a slightly larger percentage compared with the quantity of total exports. In contrast, the value in 1991 of total exports decreased by a larger percentage compared with that of imports.

Total U.S. exports of ferrous scrap (excluding used rails for rerolling and other uses; ships, boats, and other vessels for scrapping; stainless steel; and alloy steel) in 1991 went to 54 countries and totaled 8,851,187 tons valued at \$978,368,820 for an average of \$110.54 per ton. Six countries received 78% of the total quantity. The largest tonnages went to the Republic of Korea, 2,609,651 tons; Turkey, 1,776,487 tons; Taiwan,

778,184 tons; Canada, 714,783 tons; India, 591,664 tons; and Mexico, 492,502 tons. The value of scrap exports to these six countries was \$911,363,875, 69% of the total value.

Total U.S. exports of stainless steel scrap in 1991 went to 32 countries and consisted of 232,089 tons valued at \$196,379,504 averaging \$846.14 per ton. Six countries received 94% of the total quantity. The largest tonnages went to the Republic of Korea, 94,333 tons; Japan, 67,954 tons; Canada, 20,739 tons; Italy, 16,076 tons; Spain, 13,022 tons; and Taiwan, 4,979 tons. The value of stainless steel scrap exports to these six countries was \$182,899,411, 93% of the total value.

U.S. exports of alloy steel scrap (excluding stainless steel) in 1991 were shipped to 42 countries. The total comprised 261,868 tons valued at \$58,096,797, for an average of \$221.86 per ton. Six countries received 85% of the total quantity; the largest tonnages went to the Republic of Korea, 79,930 tons; Canada, 70,682 tons; Mexico, 23,219 tons; China, 19,125 tons; Taiwan, 16,976 tons; and Hong Kong, 12,794 tons. The value of alloy steel scrap to these six countries was \$46,056,605, 79% of the total value.

In 1991, based on tonnage of iron and steel scrap by customs district, New York, NY, was the leading customs district for exports, accounting for 18% of the total exports, followed by Los Angeles, CA, with 15%, and Philadelphia, PA, with 10%. Pembina, ND, was the leading customs district for reexports, accounting for 48% of the total reexports, followed by Detroit, MI, with 30%, and New York, NY, with 7%. Detroit, MI, was the leading customs district for imports, accounting for 36% of the total imports, followed by Seattle, WA, with 29%, and Buffalo, NY, with 8%. In 1990, again based on tonnage of ferrous scrap by customs district, New York, NY, was the leading customs district for exports, accounting for 17% of the total exports, followed by Los Angeles, CA, with 13%, and Philadelphia, PA, with 9%. San Juan, PR, was the leading customs district for

reexports, accounting for 42% of the total reexports, followed by Detroit, MI, with 36%, and Providence, RI, with 17%. Detroit, MI, was the leading customs district for imports, accounting for 43% of the total imports, followed by Seattle, WA, with 25%, and Buffalo, NY, with 8%. For more details, including tonnages and values, refer to published data in U.S. Bureau of Mines Mineral Industry Surveys on iron and steel scrap.¹³

Total U.S. imports for consumption of iron and steel scrap were supplied by 38 countries in 1991. They contained 10,109 tons of tinplate waste or scrap valued at \$2,240,032.

World Review

World demand for iron and steel scrap in 1991 was estimated to have decreased 4% compared with that of 1990. However, demand for ferrous scrap in 1991 increased in certain countries. These included industrialized countries such as Canada, the Federal Republic of Germany, and the Republic of South Africa; Asian countries such as China, India, Indonesia, the Republic of Korea, and Taiwan; Latin American countries such as Brazil and Venezuela; Middle Eastern countries such as Iran; and African countries such as Egypt.

The United States continued to be the leading exporting country of iron and steel scrap. France, the Federal Republic of Germany, the Netherlands, the U.S.S.R., and the United Kingdom were also major exporters of ferrous scrap.

In October 1991, the 7 nations of the European Free Trade Association (EFTA) and the 12 members of the European Community (EC) reached an agreement to link together Western Europe's 380 million people into a powerful new economic bloc. The agreement would create a European Economic Area, the world's largest and wealthiest single market, when it takes effect on January 1, 1993. The arrangement was reached among foreign ministers and trade ministers that met in Luxembourg after more than 1 year of often difficult negotiations and must be approved by the

Governments of all 19 countries. The deal would effectively expand the EC's single market. However, the sensitive sector of agriculture would be excluded.

Trade barriers at State and local levels emerged as a significant new problem for foreign companies seeking business in the United States, according to a new EC report. In addition, the report contended that while most countries were pushing vigorously toward a global trade system, the United States continued to rely heavily on unilateral actions to solve trade problems.¹⁴

Automotive recycling programs were active in Europe as well as in the United States. A joint venture on automobile recycling by Mercedes-Benz AG, Federal Republic of Germany, and Voest-Alpine AG, Austria, allowed car recycling with minimal environmental impact and without the need for removing plastics from the vehicles.¹⁵ An association of German companies, led by automaker Adam Opel AG, was working to produce cars that are 100% recyclable. Other group participants, including Hoesch AG, Thyssen AG, and Bayer AG, would provide expertise in steel, glass, and plastics. Draft laws that threaten to make automakers dispose of scrap vehicles prompted the search for an all-recyclable car.¹⁶ Mercedes-Benz AG and other German carmakers, including Volkswagen AG, had agreed to take back the autos they manufactured for recycling. Peugeot SA, a French automaker, had joined with two other organizations to launch a junk car recycling program that would process more than 7,000 vehicles over a 2-year period. In the Federal Republic of Germany, BMW AG and Volkswagen AG had started auto disassembly plants to recover metals, plastics, glass, and other materials from old vehicles.¹⁷

Governments in Belgium and Denmark had agreed to refund to scrap processors part of the cost of disposal of fluff generated from their shredder operations.¹⁸ The Federal Republic of Germany recently enacted tough laws aimed at reducing waste.¹⁹ SIDERINSA, the association of independent iron and steel producers in Madrid, Spain, signed

a contract with Tecnicas Reunidas (Madrid) for a project that would treat dust generated from Spanish steelworks.

Canadian scrap metal processors faced an ever-rising tide of Government regulations that were driving up the cost of business, according to the leader of the Canadian Association of Recycling Industries (CARI). According to a Canadian Federal environmental official, Canada's scrap processing industry was essential to that nation's goal of a 50% waste reduction by the end of this century.

Japan, which was importing ferrous scrap at an annual rate of more than 300,000 tons for the past 15 years, began turning into a ferrous scrap exporting country in 1991. Ferrous scrap exports from that country in December 1991 exceeded 200,000 tons. It was highly probable that total exports of ferrous scrap from Japan in 1991 would exceed 1 million tons. Two dramatic changes had occurred in the structure of the Japanese ferrous scrap market in the past 4 years. Namely, scrap imports declined sharply and pig iron imports rose significantly. Japan's next generation effort to streamline steelmaking, known as the direct iron ore smelting reduction process (DIOS), was said to be making good progress. A pilot plant was scheduled to open in 1993. Japan passed a new law that emphasized the recycling of natural resources. A new program to increase recycling of aluminum and steel cans was implemented.

Korean steelmaker Han Kook Steel and Mill Co. Ltd., Haman, Republic of Korea, had placed an order with ABB Metallurgy for the supply of a 50-ton direct current electric arc furnace. The furnace would feature a 35-megavolt-ampere transformer and was scheduled to go on-stream in the second quarter of 1992.

Thousands of pieces of excess U.S. military equipment and scrap metal left over from Operation Desert Storm would be auctioned off in Saudi Arabia. Items ranging from chairs and vehicles to ferrous and nonferrous scrap would be sold.

Independent steelmakers had expressed concern over falling quality standards in the United Kingdom's ferrous scrap supplies. In its annual report, the British Independent Steel Producers' Association (BISPA) stated that over the past year "most steel plants encountered an increasing incidence of scrap quality problems," including downgrading of material and scrap contamination.²⁰

Current Research

Florida Steel Corp. installed the Constee process at its Charlotte, NC, steel minimill in 1989. A feature of the process is the continuous charging of preheated ferrous scrap to an electric arc furnace. The Center for Materials Production, Pittsburgh, PA, completed an industry and utility-sponsored study of the process. The results of the analysis showed that Florida Steel had achieved productivity and electrode usage improvements, but energy usage had remained constant during the test period.²¹ Subsequent information indicated that Florida Steel had been able to achieve lower levels of energy consumption with further experience.

A technology to upgrade galvanized steel scrap into clean scrap for steelmaking had been unveiled by Metal Recovery Industries, Inc., U.S. (MRIUS), East Chicago, IN, and the U.S. Department of Energy's (DOE) Argonne National Laboratory, Argonne, IL. The technology uses an electrochemical process to dissolve the zinc coating off of galvanized steel surfaces. MRIUS planned to open a pilot facility in East Chicago, IN, by mid-1992. Metal Recovery Industries, Inc., Hamilton, Ontario, Canada, was the parent company of MRIUS.²²

OUTLOOK

The total market for U.S. ferrous scrap is affected by many factors. For example, major factors that impact the demand for domestic scrap include the quantities of domestic raw steel and ferrous castings produced, the level of scrap exports, and Government laws and

regulations. To a lesser extent, other factors affecting the overall market for U.S. scrap include the production levels of U.S. industries that make ferroalloys, cement copper, and certain chemicals; the use of scrap substitutes; technological changes in steel mills and ferrous foundries; and the value of the U.S. dollar in relation to other world currencies. The health of the world's steel mills and ferrous foundries is of the utmost importance to the domestic scrap industry. The United States, the world's leading exporter of ferrous scrap, relies heavily on exports as a safety valve for the release of excess scrap when domestic demand slips.

Although demand for ferrous scrap was down in 1991, the overall outlook for the total market for U.S. ferrous scrap through 1995 is expected to be one of continued growth. The total market for U.S. scrap is forecast to reach 64 million tons in 1995, which represents an average annual growth rate of about 2%. This optimistic forecast is based on a combination of favorable factors affecting the market, which include continued world growth in the quantity of steel produced in scrap-based electric arc furnaces; an increase in the percentage of steel that is continuously cast; and an absence of excessive Government rules or restrictions on U.S. exports of scrap.

¹All quantities are in metric tons unless otherwise specified.

TABLE 1
SALIENT U.S. IRON AND STEEL SCRAP AND PIG IRON STATISTICS

(Thousand metric tons and thousand U.S. dollars)

Stocks, Dec. 31:	1987	1988	1989	1990	1991
Scrap at consumer plants	4,394	4,131	4,213	4,433	4,257
Pig iron at consumer and supplier plants	255	188	276	169	214
Total	4,649	4,319	4,489	4,602	4,472
Consumption:					
Scrap ²	61,963	69,692	65,507	70,451	62,020
Pig iron ³	45,386	53,567	52,968	51,100	45,810
Exports:					
Scrap	9,405	9,161	11,149	11,580	9,345
Value	967,018	1,351,955	1,748,643	1,635,218	1,232,845
Imports for consumption:					
Scrap (includes tinplate and terneplate) ⁴	765	942	1,016	1,309	1,073
Value	82,016	133,577	149,109	171,510	142,552

¹Revised.

²Data do not add to total shown because of independent rounding.

³Internal evaluation indicates that scrap consumption by manufacturers of pig iron and raw steel and castings is understated by the following approximated quantities: 4.1 million metric tons in electric furnaces in 1987; 4.7 million metric tons in electric furnaces and 0.2 million metric tons in open-hearth furnaces in 1988; 6.6 million metric tons in electric furnaces and 0.9 million metric tons in open-hearth furnaces in 1989; 2.9 million metric tons in electric furnaces in 1990; and 3.1 million metric tons in electric furnaces in 1991.

⁴Internal evaluation indicates that pig iron consumption (for open-hearth furnaces) is understated by approximately 1.5 million metric tons in 1988 and 0.8 million metric tons in 1989.

⁵Excludes used rails for rerolling and other uses and ships, boats, and other vessels for scrapping.

Grand total²	45,784	44,908	2,871	20	13,364	883	62,020	45,810

¹Includes molten pig iron used for ingot molds and direct castings.

²Data may not add to totals shown because of independent rounding.

³Less than 1/2 unit.

⁴Internal evaluation indicates that scrap consumption in electric furnaces operated by manufacturers of pig iron and raw steel and castings is understated by approximately 3.1 million metric tons.

Total	314,580	321,164	339,603	330,964	326,365

^aEstimated. ^bRevised.

¹Unless otherwise noted, figures represent reported consumption of iron and steel scrap utilized in the production of pig iron, ferroalloys, crude steel, foundry products, and rerolled steel, as well as other unspecified uses in the steel industry and by other unspecified industries as reported by the United Nations Economic Commission for Europe in its Annual Bulletin of Steel Statistics for Europe, 1989, v. 17, New York, 1990, 28 pp., which is the source of all reported data unless otherwise noted. All estimates are by the U.S. Bureau of Mines.

²Source: Canadian Foundry Association as reported by Energy, Mines, and Resources Canada.

³Excludes used rails for rerolling and other uses and ships, boats, and other vessels for scrapping.

⁴Source: U.S. Bureau of Mines.

⁵Reported data are from Instituto Latino Americano del Fierro y el Acero. Statistical Yearbook of Steel Making and Iron Ore Mining in Latin America, 1989, Santiago, 1990, 231 pp. Source does not provide details on what is included; presumably figures include total steel industry ferrous scrap consumption but exclude scrap used outside the steel industry.

⁶Source: Eurostat. Iron and Steel, Luxembourg, monthly and annual issues. Data include consumption in blast furnaces, melting shops, rolling mills, and independent steel foundries.

⁷Excludes scrap consumed in iron foundries.

⁸Excludes scrap consumed within the steel industry for purposes other than the manufacture of pig iron, ferroalloys, crude steel, foundry products, and rerolled steel (details on use not available).

⁹Excludes scrap consumed outside the steel industry.

¹⁰Source: Industrija. Belgrade, 1986-90 editions.

¹¹Source: Organization for Economic Cooperation and Development. The Iron and Steel Industry in 1985, Paris, 1987, 52 pp.; The Iron and Steel Industry in 1986, Paris, 1988, 52 pp.; The Iron and Steel Industry in 1987, Paris, 1988, 52 pp.; and The Iron and Steel Industry in 1988, Paris, 1989, 52 pp.

¹²Excludes a substantial tonnage derived from shipbreaking, possibly in the order of several million tons annually, for electric-furnace-equipped steel mills.

RAW STEEL PRODUCTION (AISI), FOR ALL TYPES OF MFR'S COMBINED: TOTAL IRON AND STEEL SCRAP CONSUMPTION, PIG IRON CONSUMPTION, HOME SCRAP PRODUCTION, AND NET SCRAP RECEIPTS

KYANITE AND RELATED MATERIALS

By Michael J. Potter

Mr. Potter, a physical scientist, has been the commodity specialist for kyanite since 1975. Domestic survey data were prepared by Joe Daniels, statistical assistant; and the international data table was prepared by Virginia Woodson, international data coordinator.

Kyanite, andalusite, and sillimanite are anhydrous aluminum silicate minerals of the same composition represented by the chemical formula $\text{Al}_2\text{O}_3 \cdot \text{SiO}_2$. Related materials include synthetic mullite, dumortierite, and topaz, also classified as aluminum silicates, although the last two additionally contain substantial proportions of boron and fluorine, respectively. The largest end use of kyanite group minerals and mullite is in the manufacture of high-alumina, high-performance refractories, including brick and shapes and monolithic refractory applications such as for high-temperature mortars or cements, ramming mixes, and castable refractories.

U.S. production of kyanite was estimated to have decreased slightly compared with that of 1990 because of a generally sluggish economy and reduced activity in the iron and steel industry. Domestic synthetic mullite output decreased compared with that of the previous year. Imports of andalusite in 1991 were approximately 5,100 metric tons compared with 17,700 metric tons in 1990.

DOMESTIC DATA COVERAGE

There are two known domestic kyanite mine-and-mill operations, but data are not known and would not be publishable because of company proprietary data. Of the three known synthetic mullite producers, all responded to the voluntary domestic survey. However, data cannot be published because of possible revealing of company proprietary data.

BACKGROUND

Definitions, Grades, and Specifications

Kyanite, andalusite, and sillimanite are a closely related trio of aluminum silicate minerals, differing slightly in physical properties and crystallographic characteristics, but sharing the same chemical composition, which can be represented as $\text{Al}_2\text{O}_3 \cdot \text{SiO}_2$. When heated, kyanite begins to break down to a noticeable extent at 1,315° C (andalusite at 1,382° C and sillimanite at 1,549° C) to form a mixture of mullite, $3\text{Al}_2\text{O}_3 \cdot 2\text{SiO}_2$, and vitreous silica, SiO_2 . The mullite so produced usually consists of an aggregation of interlocking, acicular crystals and remains dimensionally and chemically stable until the temperature is raised to at least 1,810° C. These properties enable mullite to serve as a component in refractory shapes and furnace linings for a wide range of industrial applications. Above 1,810° C, mullite dissociates slowly with little change in volume into corundum (Al_2O_3) and silica, which recombine to form mullite at a lower temperature.

Topaz, $\text{Al}_2\text{SiO}_4(\text{F}, \text{OH})_2$, and dumortierite, $\text{Al}_7(\text{BO}_3)(\text{SiO}_4)_3\text{O}_3$, are also often classed as members of the kyanite group of minerals. Upon firing, topaz loses fluorine and dumortierite loses boron, yielding refractory residues consisting essentially of mullite. A number of other substances—fire clay, siliceous bauxite, and kaolin, for example—owe their ability to perform satisfactorily in some refractory applications to the fact that, when heated, at least part of the aluminum silicate they contain is converted to mullite.

There are three types of synthetic mullite. Low-temperature sintered synthetic mullite is made by sintering siliceous bauxite or mixtures of bauxite and kaolin above 1,549° C. High-temperature sintered synthetic mullite is prepared by sintering mixtures of alumina and kaolin, bauxite and kaolin, or alumina, kaolin, and kyanite above 1,749° C. Fused synthetic mullite is made by melting Bayer-process alumina and silica or bauxite and kaolin in an electric furnace at about 1,900° C.

All domestic kyanite ore is ground to permit separation and recovery by froth flotation of the mineral particles from accompanying gangue. The flotation concentrate product is graded for sale to consumers in five particle-size ratings: 35, 48, 100, 200, and 325 mesh. Kyanite concentrates may contain from 56% to 60% alumina, from 38% to 44% silica, and from 0.2% to 0.9% iron oxide. Lump kyanite from India, ranging in size from pea to boulders, was formerly imported into the United States. Indian reserves are limited, however, and material is no longer being exported.

Products for Trade and Industry

Kyanite and related materials are consumed in the manufacture of high-alumina or mullite-class refractories and in lesser quantities as ingredients in ceramic compositions. U.S. kyanite is marketed either in raw form or after heat treatment as mullite. In the 35- to 48-mesh range, kyanite is used in monolithic refractory applications such as high-temperature mortars or cements, ramming mixes, and castable refractories or with clays and other ingredients in refractory

compositions for making kiln furniture, insulating brick, firebrick, and a wide variety of other articles. More finely ground material, minus 200 mesh, is used in body mixes for sanitary porcelains, wall tile, investment-casting molds, and miscellaneous special purpose ceramics.

Data on the properties of finished refractory products are available from the producing firms. However, selection of the best refractory available for a specific application can sometimes be made only by testing under actual operating conditions. Load-bearing capacity, slag resistance, spalling characteristics, and other factors are often of prime importance.

Zircon sand containing some kyanite, sillimanite, and/or staurolite is used for foundry and refractory sand.

Technology

Both mines of the one U.S. kyanite producer are open pit, hard-rock quarrying operations. Blasted material is reduced to manageable size by drop-ball breaking and trucked to the processing plants where it is crushed to minus 1-inch size in jaw and cone crushers and then ground in rod mills to minus 35 mesh or finer. Two stages of flotation with alkaline-fatty acid or acid-petroleum sulfonate collectors produce an intermediate kyanite concentrate, which after being freed from iron by high-intensity magnetic treatment, becomes a salable product. Some kyanite is calcined at about 1,593° C and sold as mullite.

Byproducts and Coproducts

Quartzitic waste tailings from kyanite concentrators may be marketed locally as construction sand, but transportation costs limit the shipping radius of this byproduct.

Andalusite occurs in pyrophyllite ores that are mined by a company for ceramic and refractory purposes in North Carolina. A zircon-refractory heavy-mineral sand produced in Florida contains a small amount of aluminum silicates (kyanite, sillimanite, and staurolite) and is used for foundry and refractory sand.

Substitutes

Substitute and alternative materials for kyanite-group and mullite products in refractories include fire clay, calcined bauxite, and alumina. Other materials such as magnesite, chromite, silicon carbide, and zircon are interchangeable for specific end uses and conditions. Local availability of refractory raw materials is an important factor in choosing refractory products because transportation costs may prohibit use of alternative, technically superior materials.

ANNUAL REVIEW

Legislation

The allowable depletion rates for kyanite, established by the Tax Reform Act of 1969 and unchanged through 1991, were 22% for domestic production and 14% for foreign operations.

Production

Kyanite was produced at two open pit mines by Kyanite Mining Corp.: the Willis Mountain and East Ridge Mines in Buckingham County, VA. The company also operated beneficiation plants and calcining facilities for conversion of kyanite to mullite.

High-temperature sintered mullite was produced by C-E Minerals at Americus, GA, and North American Refractories Co. at Greenup, KY. (North American was previously known as Didier Taylor Refractories Corp. until mid-1991).¹ Electric-furnace-fused mullite was produced by Washington Mills Electro Minerals Corp. at Niagara Falls, NY.

Consumption and Uses

The U.S. Bureau of Mines does not collect data on end uses of kyanite and synthetic mullite. However, refractories for the iron and steel industries were probably the major end use of kyanite-mullite, consuming an estimated 55% of the quantity produced. Nonferrous metallurgical operations were believed to be the next largest use, estimated at 20%.

A third category, estimated at 15%, consisted of glassmaking furnaces, ceramic kilns, boilers, petroleum-processing equipment, etc. Nonrefractory uses were estimated to make up the remaining 10%.

In the iron and steel industries, mullite is important in critical areas of blast furnace stoves and stacks, reheat furnaces, steel degassing chambers and soaking pits, and many types of auxiliary pouring and handling equipment. In the nonferrous metal industry, an end-use example is in refractory linings of alumina reduction cells.

In glassmaking, fused mullite refractories can be used in the ports, which are at the side or end of a glass furnace. The port comes under attack from gases from the furnaces, as well as alkalis, lime, and silica particles carried through by the gases. Fuel oil ash and sulfur dioxide can also be carried through. The fused mullite is very slow wearing and able to withstand the high velocity and dust-laden gases.²

Uses for the andalusite-pyrophyllite products marketed by Piedmont Minerals, Hillsborough, NC, included soaking pit refractories in the form of plastics, gunning mixes, and castables; other uses were kiln car blocks, mortars, foundry washes, and other uses.³

Other miscellaneous uses include kiln furniture, blown aluminum silicate high-temperature insulation, brake linings, foundry mold facings, glass additions for alumina contents, ceramic tile, pyrometer tubes, high-tension insulators, spinnable mullite fibers, shell castings, ceramic honeycomb, mortars, grinding media, whitewares, extrusion dies, and welding rod coatings.

Prices

Prices at yearend 1991, in British pounds, from Industrial Minerals (London) were unchanged from those of the previous year. The apparent price decreases for 1991 in table 1 are the result of a stronger U.S. dollar against the British pound than that in 1990. (See table 1.)

Foreign Trade

Shipments of U.S. kyanite, mullite, and synthetic mullite were believed to have been made to foreign destinations, including Europe and Asia. Imports of andalusite, mostly from the Republic of South Africa, were approximately 5,100 metric tons with a customs value of \$933,000, according to the U.S. Department of Commerce. (See tables 2 and 3.)

World Review

Capacity.—Rated capacity is defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable long-term operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure.

The data in table 3 are rated capacity for mines and refineries as of December 31, 1991. Some capacity data for Japan, the Republic of South Africa, and Sweden were obtained from literature sources. For other countries, recent peak production or estimated production was considered to be equal to rated capacity.

Australia.—Ramsgate Resources Ltd. was conducting exploration and development work on an andalusite deposit in the mining center of Spargoville, west of Kambalda in Western Australia's Eastern Goldfield. The property was reported to contain several occurrences of outcropping andalusite-bearing chlorite-biotite schist. Analyses of a small number of samples of the Spargoville andalusite indicated a high-quality material.⁴

Bolivia.—Andalusite-bearing deposits were identified in the northern part of the Cordillera Real (Andes Mountains) in Larecaja Province, La Paz. Andalusite

content was estimated to be 10%, outcropping in a continuous belt 12 kilometers long and at least 400 meters wide. Andalusite was also found in the fluvial sand deposits of the Mapiri region, associated with rutile, tourmaline, and zircon.⁵

China.—Andalusite occurs in the Provinces of Henan and Liaoning. Outside testwork indicated material with 55% to 60% Al₂O₃ and 1% to 2% Fe₂O₃, which is higher than the 1.0% maximum iron content of andalusite shipped from the Republic of South Africa. There were preliminary indications that the iron in some Chinese andalusite may be locked up within the large andalusite crystals. This situation could make it difficult to obtain an acceptable material by beneficiation.⁶ (See tables 4 and 5.)

Current Research

A magnetic separator recently developed by International Process Systems, Inc., of Golden, CO, was said to have solved the problem of limited operating life of the very thin belts used in rare-earth magnetic roll separators. The new separator was developed for dry applications, with five basic magnetic strength levels being offered. Possible applications were said to include coarse particles (greater than 2 millimeters) such as kyanite-group minerals and other ores and materials.⁷

OUTLOOK

The sluggish economy and reduced activity in the iron and steel industry were believed to be contributing factors affecting kyanite-mullite demand in 1991. New technology, such as continuous casting, has reduced demand for refractories in, for example, soaking pits. However, kyanite-mullite demand in the near future should remain stable because of continued improvement in product quality, handling, transportation, shipping, etc. Also, new uses and applications are being found.⁸

³Owing to incomplete reporting, this table has not been totaled. Table includes data available through Apr. 10, 1992.

⁴In addition to the countries listed, a number of other nations produce kyanite and related materials, but output is not reported quantitatively, and no reliable basis is available for estimation of output levels.

⁵Reported figure.

⁶In addition, about 7,000 metric tons of sillimanite clay (also called kaolinized sillimanite) is produced annually containing 40% to 48% Al₂O₃.

LEAD

By William D. Woodbury

Mr. Woodbury, a physical scientist with the U.S. Bureau of Mines, Branch of Metals, had 25 years of mining and civil works geotechnical experience upon becoming the Bureau's lead specialist in 1982. Domestic survey data were prepared by Eraina Dixon and Lisa Conley, mineral data assistants; international data were prepared by Theodore Spittal and Virginia Woodson, international data coordinators.

Lead is a soft, heavy metal, the most corrosion resistant of the common metals, and one of the oldest metals used by man. Among the nonferrous metals, in terms of tonnage, demand for lead is surpassed only by demand for aluminum, copper, and zinc. Some historians have theorized that the downfall of the Roman Empire was expedited by the debilitating effects on its citizens of drinking water carried in lead pipes. Buildings built in Europe four centuries ago still stand under their original lead roofs. Today's major use of lead is in lead-acid storage batteries. The electrical systems of vehicles, ships, and aircraft depend on such batteries for startup, and in some cases, batteries provide the actual motive power. Other batteries provide standby electrical power for emergencies, and very large lead-acid systems are designed to provide "peaking" power in such applications as commercial power networks and subway systems. An increasing use is in the uninterruptible power supply systems necessary for voltage control and emergency power in critical computer storage systems. Lead in gasoline, once the second largest use of lead in the United States, has been virtually phased out to eliminate the health hazard it was found to present. Some nontransportation uses of lead include increasing use for soundproofing in office buildings, schools, and hotels and earthquake shock dampening in building foundations. It is widely used in hospitals to block X-ray and gamma radiation and is employed to shield against nuclear radiation both in

permanent installations and when radioactive source material is being stored and/or transported.

After 7 consecutive years of significant growth, world demand for lead peaked at more than 6 million metric tons in 1989, but dropped by almost 450,000 tons during 1990 and 1991 as the world economy entered recession. World lead refinery production declined by almost 200,000 tons in 1991, in spite of continuing near-record secondary production in some countries, including the United States. For many years prior to 1983, primary metal demand represented about 60% of the total but gradually declined to about 55% in recent years. This trend is expected to continue with the continuously evolving worldwide environmental consciousness and less dissipation in the end-use pattern. World mine production of lead in 1991 leveled off or declined slightly in most countries, including the United States, with only Australia, China, and Peru reporting marginal increases. Total domestic refinery production in 1991 declined by about 100,000 tons from that of 1990, demand was off by about 30,000 tons, and stocks were rationalized precipitously. World and North American average prices at yearend were about 4 cents per pound below yearend 1990, after slight yearend recoveries. In the United States, prices bottomed in June, but on the London Metal Exchange (LME) the decline was gradual through November. The average spread between the two was 8.2 cents per pound compared with about 9 cents per pound in

1990, still attractive for domestic importation in spite of the decreased demand.

DOMESTIC DATA COVERAGE

Domestic data for lead are developed by the U.S. Bureau of Mines from five voluntary surveys. Typical of these are the combined secondary producer and consumer surveys, both monthly and annual. Of the 208 consuming companies to which a survey request was sent, 184 responded, representing 97% of the total U.S. lead consumption shown in tables 1, 9, 10, 11, 12, and 13. Of the 42 companies and/or plants producing secondary lead, exclusive of copper base, to which a survey request was sent, 33 responded, representing 87% of the total refinery production of secondary lead, not including that from copper base scrap, shown in tables 1, 6, 7, and 8. Production and consumption for the nonrespondents were estimated using prior-year levels adjusted for general industry trends.

BACKGROUND

Geology

Besides being a major user of lead, the United States is a major mine producer and by far the world's leading metal producer. Missouri is by far the main producing State. The leading foreign mine producers, with output similar to that of the United States, are Australia, China, and the U.S.S.R. The leading

metal producers behind the United States are the U.S.S.R., the United Kingdom, the Federal Republic of Germany, and Japan. These five account for about one-half of the world's refined lead production, including secondary.

The minerals in lead ores are relatively simple, with the sulfide galena (PbS) being the major mineral. Most lead deposits contain galena associated with sphalerite (ZnS), pyrite (FeS₂), chalcopyrite (CuFeS₂), and other base metal sulfides or sulfosalts, some of which are recovered to yield byproducts or coproducts, most commonly zinc and silver. Galena usually contains variable amounts of silver also (argentiferous galena). Most sphalerite has associated cadmium, in quantities from traces to 2%, and small quantities of germanium, gallium, indium, and thallium. Lead deposits are of four types: massive sulfide, replacement, contact metamorphic, and vein.

Massive sulfide deposits of lead and zinc have two basic forms of ore body control: sedimentary-structural and volcanogenic-stratabound. The former, known also as Mississippi Valley Type (MVT) deposits, include presently producing areas such as Missouri's Viburnum Trend, Canada's Pine Point District and the Polaris Mine, both in the Northwest Territory, and the Laisvall District of Sweden. The Polaris Mine, well north of the Arctic Circle near the Magnetic North Pole, is the world's most northerly producing mine. MVT deposits are hosted in limestone-dolomite sequences, karst controlled, and often have considerable associated collapse brecciation and/or reef control resulting from ancient drainage patterns and/or facies changes. Volcanogenic-stratabound deposits are commonly interlayered with sedimentary rocks and are usually found in older folded and metamorphosed belts. Examples in Canada are the Bathurst Mine in New Brunswick, the Kidd Creek Mine near Timmons, Ontario, and the Sullivan Mine at Kimberley, British Columbia; examples elsewhere are the Broken Hill and Mount Isa Mines of New South Wales and Queensland, respectively, in Australia; and the Kuroko

District of Japan. These deposits are commonly finer grained and more difficult to win the metals from than the pure sedimentary types. The complex strataform volcanogenic deposits of Alaska, such as the rich producing Red Dog and Greens Creek Mines, exhibit some characteristics of both of the above-described massive sulfide types. The actual concentration of the minerals and/or ore body control, however, relate more to the degree of metamorphism associated with folding and thrusting.

Replacement-type deposits of lead and zinc are commonly irregular hydrothermal deposits in carbonate rocks, but some also occur in quartzites or metamorphic rocks. The form and extent of the ore bodies are determined by the structural and stratigraphic elements that localize the replacement activity of the ore-bearing solutions. They include tabular or cylindrical flat-lying bodies called mantos, pipelike structures that cross the bedding, and irregular-branching bedded deposits associated with veins. Typical examples are the Cerro de Pasco Mine in Peru, the Tsumeb Mine in Namibia, the silver-lead district of Central Mexico, and the Leadville and Gilman districts in Colorado.

Veins are the best known type of ore deposits. They are the most obvious and therefore were the first to be exploited by ancient miners. The vein deposits are commonly situated in faults, joints, or formational contacts. They contain an irregular mixture of barren, or gangue, minerals and are generally arranged in pod-shaped deposits or "shoots," 3 to 30 feet long horizontally and extending hundreds of feet vertically or down the dip. Only a small part of U.S. lead production comes from veins, but there are many highly productive vein-type deposits in Europe, Central America, and South America. The silver-lead deposits of the Coeur d' Alene ("Silver Valley") district in Idaho occur in an extensive vein system. Some other productive examples are the Santa Barbara (Chihuahua), Fresnillo (Zacatecas), and Taxco (Guerrero) Mines in Mexico and the German Harz Mountains, Clausthal, and Freiberg deposits.

Contact metamorphic-type deposits are found near igneous intrusions, which have either provided the solutions or emanations creating the deposits, or have altered and rearranged a mineral deposit already present prior to the intrusion. Deposits range in size from small vein systems to massive pods hundreds of feet long. Although many deposits of this type are mined for other metals in the United States, none have produced significant amounts of lead by today's standard and then only as a byproduct. The Kamioka, Obori, Chichibu, and Nakatatsu deposits of Japan are excellent examples of this type. However, only the two Kamioka Mines at Gifu are presently producing.

Toxicity

A major problem with lead in some uses is its toxicity, since accumulation of even minute quantities in the aqueous system of the body can cause permanent brain damage and/or central nervous system disability, liver and kidney damage, and even death. Even the use of lead shot for hunting geese, ducks, and other migratory waterfowl is declining because of lead's toxic effect on the marine-life chain. Lead's toxicity presents problems in producing it as well as in using it, and emissions from lead smelters and refineries are closely regulated, as are worker blood-lead levels and inplant permissible exposure limits in all lead and lead oxide producing, lead-acid battery manufacturing, and other lead products plants. This adds to the cost of producing lead but is necessary to protect both the general public health and the health of lead industry workers.

Most potential adverse health effects resulting from lead overexposure have been known to some degree for many years. However, in recent years, a major issue and controversy has arisen with respect to the determination of an absolute "threshold" level below which no effects occur. The position of the U.S. Environmental Protection Agency (EPA) to date is that none has been clearly demonstrated. This has especially sparked considerable scientific debate in

the case of average blood lead levels (PbB's) and long-term, low-level exposure to lead primarily stored in the nonaqueous body system. Whereas research on lead effects on blood pressure, kidneys, and red blood cells goes back many years, research on physical development, reproductive effects, and carcinogenicity has primarily emerged in the past decade.

Average PbB's in the United States have fallen dramatically in recent years as the use of lead in gasoline has been eliminated and the dangers of exposure to and ingestion and/or inhalation of old slaking paint and dust have been heavily publicized. Adverse health effects clearly associated with lead apparently begin to occur only at levels well above the current national average. The EPA's current average PbB estimate is 4 to 6 micrograms of lead per deciliter ($\mu\text{g}/\text{dl}$) of blood compared with 12.8 in 1980 for the most sensitive population group, pre-school children. New Center for Disease Control (CDC) guidelines published in 1991 call for individual nutritional and educational intervention for children at 15 to 19 $\mu\text{g}/\text{dl}$ levels, although results of several recent studies of lead effects on infant and mental development in this general range are somewhat inconsistent, or at least not universally definitive when including foreign studies. A 10-year followup study completed in 1989 of 104 children who had suffered clinical lead poisoning found no significant association between blood lead and stature development using their nonpoisoned siblings as controls. In addition, a study completed in 1991 measuring the possible adverse effects of low-level lead exposure on growth in pre-school children found no significant adverse effects on size or growth.

Research has shown that long-term lead exposure can cause adverse effects upon male human reproductive functions at high blood lead levels greater than 40 to 50 $\mu\text{g}/\text{dl}$, but comparable data relative to human females is virtually nonexistent. However, concerns have recently arisen over the implications of lead's apparent ability to cross the placenta and affect the fetus. Six studies between 1986 and 1991

were unable to definitively confirm an association between blood lead and decreased birth weight of children born to occupationally exposed workers, but in an earlier study by Dr. Needleman in 1984 there was a suggestion of minor congenital abnormalities, not subsequently confirmed. It has been known for many years that the human skeleton ultimately retains 90% to 95% of the lead in a person. This raises the possibility that such bone lead could be released to the blood as a function of aging or during times of calcium stress such as pregnancy. A 1988 study of almost 3,000 women showed a significant increase in PbB's after menopause, but no osteoporosis data were obtained. Clearly, more research is needed here.

Experimental animal studies have provided convincing evidence for the carcinogenicity of some lead compounds, specifically lead acetates and phosphates, but the massive doses required to produce tumors demonstrates that the carcinogenic potency is weak. Human epidemiological studies on lead and cancer to date are characteristically inconsistent, and none has corrected for smoking, a significant confounding variable. At this time, EPA considers the potency factor of lead sufficiently low enough as not to consider its carcinogenicity potential in establishing risk-based policies.¹

ANNUAL REVIEW

Legislation and Government Programs

In January, a partnership was formed among Chrysler Corp., Ford Motor Co., and General Motors Corp. called The United States Advanced Battery Consortium (USABC). With participation from the Electric Power Research Institute, its purpose is to develop advanced batteries capable of providing future generations of electric vehicles with significantly increased range and performance. In October, USABC signed an agreement with the U.S. Department of Energy (DOE) to jointly research and equally fund a 4-year, \$260 million program to this effect. This substantial commitment of resources, which also

includes facilities, technology, and personnel, by government and industry jointly in a commercial effort is unparalleled, and a first of any kind involving domestic automakers. If successful, the project could become the model for future public-private cooperation to resolve issues affecting energy resources, the environment, and international competitiveness. The International Lead-Zinc Research Organization (ILZRO) is cooperating in the program with respect to possible roles for advanced lead and zinc battery systems.

In April, lead producers and battery manufacturers were approached by the EPA to voluntarily participate in the "33-50 program," a national effort to reduce industrial emissions of toxic substances one-third by 1992 and one-half by 1995. In a related development of good faith by EPA, in May, an administrative stay was placed on the hazardous waste listing for lead slurries generated from control devices on acid gases that are not dedicated to control particulate air emissions. EPA intends in the future to amend and clarify the scope of listing for all nondedicated (to airborne particulates) controls of sludges generated from air pollution devices. Also in May, EPA made the final determination not to regulate primary lead smelter slags as hazardous waste and tentatively proposed to handle them in conjunction with mining wastes in a later ruling pending reauthorization of the Resource Conservation and Recovery Act (RCRA) in 1992. This was the most significant rulemaking affecting the lead industry in 1991. Other legislative amendments to RCRA pending at yearend with respect to lead involved a uniform Federal lead-acid battery recycling bill, and/or mandatory secondary lead content, along with other lead process waste issues. Source reduction bills on both sides of Congress (some reintroduced from 1990 as Toxic Substances Control Act, TSCA, amendments) affecting minor uses of lead in such diverse "markets" as plumbing, solder (except in electronics), food packaging, inks, dyes, cosmetics, paints, pesticides, and toys were still pending at

yearend. During the year, EPA also undertook comprehensive reviews of the National Ambient Air Quality Standard (NAAQS) for lead, primarily to affect smelters, and New Source Performance Standards (NSPS) for secondary lead plants. Both rules were expected to be promulgated in late 1992. At yearend, 37 States had passed battery disposal or mandatory recycling laws, with action initiated in 6 others. In December, a New York State Court judge disallowed negligence and product liability claims filed against paint manufacturers by New York City, ruling that the city had known for years of the dangers of lead-base paint and had filed suit too late.

Issues

Two significant issues involving lead arose in 1991, one coming to a head and being at least partially resolved, the other promising continuing future bitter debates. Firstly, from January through September, a Regulatory Negotiating procedure, initiated by EPA's Office of Pesticides and Toxic Substances (OPTS), was chartered by law to write a uniform Federal battery recycling rule under TSCA. The chartered committee, comprising government at all levels, business (producer and consumer, small and large), labor, retail trade associations, and environmental and/or legal interests worked diligently for 9 months and were close to an agreeable rule, notwithstanding RCRA problems beyond its chartered jurisdiction. However, TSCA requires risk analysis and cost-benefit studies, performed simultaneously in this case, which can demonstrate positive risk benefits. Unable to satisfy this requirement, especially with respect to lead-acid batteries in landfills--the major issue, the procedure was terminated in September as unacceptable for Federal rulemaking. Apparently, illegally disposed of lead-acid batteries are not a provable significant environmental hazard at this time sufficient to justify further Federal controls. Recycling rates determined by Battery Council International (BCI) reached 97.8% in 1990.

The second issue of major significance that emerged in 1991, and that could prove disastrous to the domestic lead industry if consummated, was that of employing a 150% to 250% excise-pollution tax on lead metal to pay for lead-base paint damage mitigation and cleanup. Legislation to this effect was introduced in the House of Representatives in July, the Lead Paint Hazard Abatement Act, as a purely revenue act, the cost of which would wind up being directly passed on to the ultimate consumers. No action had been taken at yearend. However, no one can question the seriousness of the "old lead" problem, and it must be dealt with somehow, being essentially a city problem potentially affecting significant numbers of persons as older houses continue to decay and/or are demolished, creating additional disposal problems. The paradox is that even if the domestic lead system is "sealed and leveled" (imported metal and product content would be equally taxed), there is the danger that the battery industry could be driven offshore because, even with import duties, source metal discounts would eventually be greater along with lower production margins owing to less environmental sensitivity, cheaper labor, etc. Along with exporting jobs, however, the United States would also most likely wind up exporting environmental control as domestic secondary capacity would dry up because most spent batteries would flow out of the country also. In this case, solving one dilemma could create two more, possibly a third because the cheaper batteries would become expensive enough to eventually lead to mostly uncontrolled battery "chop-shop" rebuilders, which would circumvent excise taxes completely, as well as create a potential environmental disaster.

Production

Primary.—The decrease in domestic mine production of lead in 1991 resulted from the announced significant cutback by The Doe Run Co. for the last three quarters in order to bring overall market supply and anticipated demand in better

balance to avoid stock buildups. However, in spite of this decision and the closure of the Bunker Hill Mine in Idaho in January, along with several other temporary shutdowns, significant production increases at other mines, notably Red Dog and Sweetwater, resulted in an overall lesser decrease of about 18,000 tons. As a result, production from Missouri was reduced to about three-quarters of the national total compared with 79% in 1990. Alaska, Idaho, Colorado, and Montana, in order of priority, produced all but 2,600 tons of the balance. The top 10 mines listed in table 4 produced 95% of the total, and the top 15 all but 2,800 tons. In terms of corporate ownership, three entities, The Doe Run Co., ASARCO Incorporated, and the Cominco American-Dresser Inc. partnership, accounted for about 90% of domestic lead mine production.

During 1990 in southeastern Missouri, The Doe Run Co. of St. Louis, the Nation's largest integrated lead producer, operated three mine and mill divisions, Buick, Fletcher, and Viburnum, which consisted of six mines and four mills. The aggregate capacity, including that from the Brushy Creek Mine which remained on care and maintenance in 1991, was 26,300 tons of ore per day according to parent company Fluor Corp.'s annual SEC Form 10-K. On a fiscal year basis ending October 31, 1991, Doe Run mined and milled 3.56 million tons of ore grading 6.08% lead, which was a decline of about 40,000 tons in contained metal from that of 1990. This resulted in metal production at Doe Run's integrated smelter-refinery in Herculaneum, MO, of about 157,000 tons of refined lead for calendar year 1991 compared with about 231,00 tons in 1990. In addition, Doe Run produced and sold 39,000 tons of copper concentrate and 42,000 tons of zinc concentrate in its fiscal year 1991 from its mines. As of October 31, 1991, these mines had proven ore reserves of approximately 71.1 million tons with an average grade of approximately 4.75% lead, according to Fluor's SEC Form 10-K. Approximately 65% of Doe Run's ore is on properties under Federal mineral leases for terms of 10 to 20

years, renewable for 10 years, for which the company pays the Bureau of Land Management a royalty of 5% of the gross value of concentrates produced. Under the State implementation plan for Herculaneum required by the Federal Clean Air Act, as amended, Doe Run in 1991, completed \$17 million of the \$18 million in control projects agreed to. This was expected to contribute to lowered future production costs, as was the 25% cut in employment in April in conjunction with the production cutback. Significant startup costs were also incurred at Doe Run's new secondary plant discussed below. As a result, the company earnings dropped from \$36 million in 1990 to an operating loss of \$4 million in 1991, according to parent company Fluor Corp.'s annual report to stockholders.

Asarco operated two mine and mill complexes in southern Missouri that together produced 94,700 tons of lead in concentrates, compared with 82,500 tons in both 1989 and 1990, according to the company's annual report to the stockholders. This represented 77% of the production of its "integrated" smelter-refinery at Glover, MO, compared with 72% in 1990, a further step toward Asarco's stated goal of full integration for Glover. Another contribution to the company's newly designated Missouri Lead Circuit in 1991 was a 35% expansion of the Sweetwater Mine's "capacity" reflected by a 45% production increase from 31,300 tons of lead in 1990 to 45,300 tons in 1991, according to Asarco. The West Fork Mine continued a production level, as in 1989 and 1990, of about 50,000 tons, about 20% below envisioned "capacity." The Glover facility produced 118,000 tons of lead in 1991 compared with 112,000 tons in 1990 and 108,000 tons in 1989, according to the report. Asarco purchased about one-half of Cominco American Inc.'s half share of the Magmont Mine to supplement Glover's feed. Asarco's refinery at Omaha, NE, which receives the bullion output from its East Helena, MT, smelter, produced 71,000 tons of lead in 1991, compared with 61,000 tons in 1990 and 65,000 tons in 1989. Asarco also received, as

operator, 50% and 37.5% shares, respectively, of the production from the Leadville (CO) and Galena (ID) Mines. At yearend, Asarco reported reserves in Missouri of 20 million tons grading 4.9% lead at Sweetwater and 6.8 million tons grading 5.7% lead at West Fork.

The Magmont Mine at Bixby, MO, a 50-50 joint venture of Cominco American Inc., the operator, and Dresser Industries Inc., was the Nation's second largest lead-producing mine in 1991, in spite of being only 2 to 3 years from exhaustion. According to parent company Cominco Ltd.'s (Canada) annual report to stockholders, continued exploration yielded no new ore body extensions and added very little additional reserves. However, about 454,000 tons was added to total reserves through block adjustments after mining exceeded original reserve estimates, and sophisticated engineering continued to increase the number of pillars, an increasing share of production, available for recovery. Magmont continued to plan for eventual near-term shutdown. In 1991, Magmont milled 1,019,000 tons of ore grading 6.5% lead compared with 984,000 tons at 7.1% and 962,000 tons at 6.8% in 1990 and 1989, respectively. This yielded 83,000 tons of concentrate grading a record 78.3% lead compared with 87,000 tons at 78.0% and 81,000 tons at 77.9% concentration in 1990 and 1989, respectively. The mine also produced 8,500 tons of zinc in concentrate from 1.0% ore and 1,260 tons of copper from 0.2% ore (1,460 tons from 0.3% ore in 1990--revised). Cominco Alaska's Red Dog Mine, about 90 miles north of Kotzebue in northwest Alaska, had a difficult first full year of production, achieving only slightly more than 75% of anticipated capacity for lead. Some ore from the mine proved difficult to treat and experienced lower than estimated recoveries, but modifications to the mill circuits improved performance toward yearend. Lead concentrate production was 69,500 tons grading 57.2% compared with 372,600 tons of zinc concentrate grading 57.1%. The mill also produced a bulk concentrate of 31,000 tons grading 20.9% lead and

32.8% zinc. Ultimate average annual production levels are projected to be 70,000 tons for lead and 325,000 tons for zinc contained from measured and indicated reserves of 59.7 million tons at yearend of ore averaging 5.5% lead and 18.4% zinc (60.8 million tons end of 1990--revised). (See tables 2 through 5.)

Secondary.—Domestic secondary production in 1991 decreased after 5 consecutive years of growth, as capacity utilization was only about 80%. However, this was primarily the result of a significant net capacity increase for the year (largely to be offset by a major closing early in 1992). In the last quarter of the year, Doe Run's 54,000-ton-per-year state-of-the-art Resource Recycling plant, known as the Buick facility, came on-stream at Boss, MO, and produced successfully at near capacity. At midyear, Tejas Resources, a subsidiary of Powerlab Inc., a major lead oxide manufacturer, came on-stream with a 27,000-ton-per-year capacity, "just-in-time" secondary lead smelter-refinery; i.e., batteries broken elsewhere with no on-site storage. Also at midyear, Roth Brothers Smelting Corp., a nonbattery processor, closed its 10,000-ton-per-year-capacity plant at East Syracuse, NY. During the year, several smaller but similar type producers also closed, primarily a result of being overcome by too low margins (low metal prices versus high scrap prices) combined with continuously tightening emission and workplace standards. At yearend, the secondary lead industry was composed of 16 companies that operated 23 battery breakers-smelters with capacities of 10,000 to 120,000 tons per year. Also operating were five smaller operations, including Asarco's Omaha, NE, refinery, with furnace and kettle capacities from 6,000 to 10,000 tons per year, that did not process batteries. In addition, 14 small companies with 15 plants of less than 1,000 tons per year each of capacity were producing mainly specialty alloys for such uses as solders, brass or bronze ingots, and bearing metals, etc. The combined capacity, including Roth Bros., for the latter two sectors; i.e., "non-

battery smelters," was 56,000 tons, and production was about 44,000 tons, including that of Roth Bros. Total domestic secondary lead production capacity at yearend was estimated to be 1.10 per year compared with 1.03 (revised) million tons at yearend 1990, when that sector produced at about 90% of capacity. In February, Asarco and MIM Holdings Ltd. of Australia announced jointly that they were considering entering the secondary smelting business in the United States, possibly utilizing MIM's "Isasmelt" process. Reportedly, they were looking at locations in the southeast. Later in the year, MIM successfully brought on-stream a similar plant at its subsidiary, Britannia Refined Metals, in Northfleet, the United Kingdom. A decision was expected in 1992. (See tables 6 through 8.)

Consumption

Reported consumption of lead declined by almost 30,000 tons in 1991 compared with that of 1990, mostly in battery offtake and the cessation of lead gasoline additive production in midyear. Lead used in construction remained about level for the sixth consecutive year, but lead oxides used for glass, paint, ceramics, and other chemicals increased after declining for 6 consecutive years, primarily owing to the continuing high demand for video tubes. Most other uses increased or decreased marginally, although lead for bearing metals declined by 30%, a reflection of the continuing recession, but also probably owing to some new alloy substitutions because of lead recycling problems. The latter conditions also prevailed in the case of the 2,000-ton decline for lead used in solder in 1991. Although apparent consumption indicated a decline of 70,000 tons in 1991 compared with that of 1990, the 2-year total is about the same as that for reported consumption. This is explained by the significant production decrease in 1991, forcing the consumer to draw down stocks, in concert with high last quarter 1990 metal imports not reaching the consumer until the first

quarter in 1991. (See tables 9 through 14.)

The Battery Council International (BCI) reported starting-lighting-ignition (SLI) battery production of 77.81 million units in 1991 compared with 79.61 million units in 1990. At an estimated average lead content for all the several classes of about 23 pounds per unit, that sector's offtake was about 812,000 tons. Extrapolated from partial reported data to the U.S. Bureau of Mines, the industrial (stationary)-traction(motive) power sector was estimated to have consumed 185,000 tons of lead, an increase of 13,000 tons over 1990's estimate. Consumer batteries; i.e., small, sealed lead-acid (SLA) cells for flashlights, toys, powertools, lawn mowers, floor polishers, etc., were estimated to have consumed the balance, about 10,000 tons. According to BCI, inventories of SLI batteries at yearend stood at 8.49 million units compared with 9.49 million units at yearend 1990, still well over a 30-day supply. The more than 18% offtake of total battery lead by the industrial and traction sector was the highest since 1986 when it was just less than 20%. The industrial and traction battery sector includes uninterruptible power supply (UPS) designed to ensure constant voltage for large computer systems at hospitals, banks, communication networks, etc., and standby power supply (SBS) for emergency lighting and some telephone systems. About one-third of the lead total in this category applies to electric vehicles and submarines, including some surface boats and some in-plant and mine equipment. The whole industrial-traction sector exhibits great potential for continued future growth as networking of computers of all capacities continues to grow, probably the most significant factor in 1991, and general purpose electric vehicles and customer load-leveling loom ever closer to universal application. As evidence of this growth to date, in 1982 this sector consumed only 67,900 tons of lead, which represented less than 10% of the total lead consumed for batteries.

World Review

According to the International Lead and Zinc Study Group (ILZSG) statistics, consumption of soft and antimonial lead in the market economy countries (MEC) declined slightly in 1991 to 4.46 million tons, compared with 4.48 million tons in 1990 and 1989's record of 4.58 million tons.² Comparable world total apparent consumption of lead in all forms for those years was 5.60, 5.79, and 6.05 (record) million tons, respectively. The significant disparity between the dropoffs in the two data sets obviously reflects the serious economic disruptions resulting primarily from Eastern European geopolitical restructuring during the period. This also resulted in revising downward the estimated world refinery production and consumption data totals for 1990 by over 100,000 tons each. According to ILZSG, exports of refined lead from the former "Soviet bloc," including China and North Korea, to the MEC's declined from more than 100,000 tons in 1990 to about 60,000 tons in 1991, about one-half from the former U.S.S.R. in both years. Refinery production in the former "Soviet bloc" European States, excluding Poland, declined from 950,000 tons in 1989 to an estimated 760,000 tons in 1991, also a reflection in general of the worldwide recession. Although world total refinery production declined 330,000 tons during this period, the secondary sector declined only 100,000 tons and continued to increase its "market share" as end uses of lead continued to become less dissipative along with a growing environmental sensitivity to encourage recycling everywhere. At yearend, world stocks of lead metal had increased marginally from yearend 1990, representing a normal 30-day supply, as supply and demand were in good balance owing to the aforementioned rationalizations. The world price (LME average cash) for 1991 was 3 cents per pound lower than that for December 1990, but for the year was 11.8 cents per pound lower than 1990's average. Compared to the December 1990 average price of 28.3 cents per pound, the price at the low point of 1991

after continual decline was 23 cents for November, rising only to an average of 24.1 cents in December. (See tables 15, 16, and 19.)

Mine Capacity.—There was a net loss of world mine capacity in 1991 of about 75,000 tons, mostly in Europe, as several small mine closings occurred in Bulgaria, Finland, France, Italy, and Sweden, and three major closings in Spain, only slightly offset by a small mine opening in Portugal. In the major producing countries there was a large-scale opening, the Hajar Mine in Morocco; a major reopening, the Sa Dena Hes Mine (formerly Mount Hundere) in the Canadian Yukon Territory; and major capacity reductions at Broken Hill and Elura, New South Wales, Australia.

Mine closures in Ontario (Lyon Lake) and Nova Scotia (Gays River) in Canada mostly offset the new capacity there; a capacity increase at the Thalanga Mine in Queensland along with the opening of the Currawong open pit mine in New South Wales mostly offset the capacity decrease in Australia. In Asia, the long awaited opening of the major Rampura-Agucha open pit mine in Rajasthan, India, was offset slightly by a small mine closing in Japan. In the United States, the Bunker Hill Mine in Idaho closed as the new Van Stone Mine in Washington came on-stream. However, production at the latter was temporarily suspended for economic reasons along with the Ward Mine in Nevada, the Butte Hill Mine in Montana, the Star Mine in Idaho, and the Sunnyside Mine in Colorado, all shut down by yearend. World lead-producing mines operated at 84% of capacity in 1991, the same as in that of 1990, although estimated production decreased by 68,000 tons. Production decreases occurred in Bulgaria, Mexico, the former U.S.S.R., the United States, and Yugoslavia, totaling about 84,000 tons for those major producing countries. Increases estimated to total about 30,000 tons occurred in the major producing countries of China and Peru. (See tables 17 and 18.)

Metal Capacity.—World smelter and refinery capacities during 1991 were somewhat rationalized relative to mine capacity, mostly "environmental retrofitting" and subsequent reratings resulting in increased efficiencies at many plants. Only in Bulgaria were there major closings, that of two smelter-refineries at yearend. At Boss, MO, the Buick facility started operations as a secondary plant, although part of the capacity is theoretically available for primary throughput if needed. In the Federal Republic of Germany, the Imperial Smelting Furnace (ISF) at Duisburg increased capacity by 8,000 tons, and at Binsfeldhammer a new 100,000-ton-per-year QSL smelter came on-stream to replace the existing conventional smelter rated at 80,000 tons. A new ISF plant and refinery also opened at Chanderya in India. In Australia, a new Isasmelt plant, rated at 60,000 tons per year, came on-stream at Mount Isa, Queensland, adding 30,000 tons after partial derating of the existing plant. Secondary capacity worldwide continued to increase as new plants totaling 162,000 tons came on-stream in France, the Federal Republic of Germany, India, the United Kingdom (world's first Isasmelt secondary), and the United States. However, there was a major closing of a 50,000-ton-per-year rated capacity smelter at Elswick, Newcastle, in the United Kingdom. The refinery continued in operation as an alloy-remelter similar to the Alco Pacific plant in Carson, CA. (See table 17.)

Reserves.—Worldwide reserves of lead contained in demonstrated resources from both producing and nonproducing deposits estimated to be economically viable at yearend realized commodity prices were estimated at 68 million metric tons (Mmt) by the U.S. Bureau of Mines. For the largest producers among the MEC's, Australia and the United States contained about 10 Mmt each and Canada 7 Mmt, compared to about 15 Mmt for the countries of the former U.S.S.R. and China combined. Estimated average grades among major MEC producers

ranged from about 6% in Australia to about 1% in Mexico and Spain, compared with a little under 3% in the United States and about 2.5% for demonstrated resources of all of the MEC's, including the United States. No definitive average grade data are available for the former U.S.S.R. or the Asian centrally planned economies. At current production levels and extraction efficiency, these data would indicate a recoverable metal supply of 16 to 17 years. However, marginal economic deposits, measured and indicated, would extend the "reserve base" to 125 million metric tons at somewhat less extraction efficiency on average. In this category, Australia would clearly dominate at an estimated total of 35 Mmt, followed by the United States at 22 Mmt.

In a significant exploration development during 1991, BHP Minerals announced at yearend the discovery of a new polymetallic deposit in Queensland, Australia, called Cannington, with identified reserves to date exceeding 20 million tons of ore grading 10.2% lead. BHP, operator of the Cadjebut Mine in Western Australia, owns a 58% share of the deposit. At the start of the year, CRA Ltd. announced the results of 1990 drilling at the Century deposit, also in Queensland. Reserves were estimated in two zones of 70 million tons each grading 2% lead-7% zinc and 1% lead-13% zinc. Another future, potentially significant addition to reserves was a large lead-zinc discovery announced in the first quarter by Enterprise Nationale de Recherche Minière in Algeria of about 200 million tons of ore at Azrou N' Bechar in the Amizour region. In a potential resource development for the late 1990's, Ivernia West Corp. increased inferred reserves at the Lisheen deposit in County Tipperary, Ireland, from 9.3 million tons to 13.5 million tons grading 2.1% lead and 12.4% zinc. The project is a joint venture with Chevron Mineral Corp. of Ireland. (See table 17.)

Current Research

The U.S. Bureau of Mines is assisting the EPA in the development of treatment

methods to decontaminate lead wastes at several Superfund sites. Interagency agreements have been signed for the cleanup of two former scrap battery processing sites in Ohio, and the characterization and treatment studies on the battery casings and soils from these were completed in 1991. An alternate soil treatment process is being developed that will also meet the criteria that cleaned materials; i.e., soils to be disposed of on-site, qualify for nonhazardous disposal at significantly lower cost than hazardous offsite disposal of the uncleaned mixed materials. By EPA criteria, the material must contain less than 210 ppm lead and meet its Toxic Characteristic Leaching Procedure (TCLP) or Extraction Procedure (EP "Tox") tests. Late in the year a meeting was held to review the conceptual flowchart design for the U.S. Army Corps of Engineers' contractor for final design of the on-site plant system.

The typical lead wastes from such older abandoned battery-breaker sites are ebonite casings and soil and some contaminated polypropylene (less than 10% of modern domestic battery casings are ebonite). The contaminants are lead sulfate, lead oxides, and lead metal, the processing of which involves five steps: water wash, separation, size reduction, carbonation, and acid wash. Step one employs any device supplying tumbling action while washing so that adhering sulfate sludge does not become subsequently embedded in size reduction of the screened minus 4-inch casing wastes. The sludge then passes through an 18-mesh screen for smelting or leach-electrowinning. The separation step involves screening (3 to 4 sizes) of the minus 4-inch casing wastes and air or water elutriation with final separation into plus and minus 3/8-inch fractions. In step three, the plus 3/8-inch casing waste is reduced to minus 3/8-inch by granulator, hammer mill, or shredder, and combined with that from step two for carbonation (step four); sodium and ammonium carbonates work equally well. After rinsing, the minus 3/8-inch carbonated casing wastes are washed in a dilute acid solution. Nitric, acetic, and

fluosilicic acids were all tested successfully (step five). Dissolution of the lead carbonate generates carbon dioxide, resulting in a scrubbing action that removes the remaining lead from any fissures. The leachate can then be processed by electrowinning to recover metallic lead.³ An alternative method of direct slurry electrolysis combining washing and electrowinning in one step for soil treatment showed great promise experimentally. As metallic lead was removed at the cathode, the fluosilicic acid employed was regenerated without loss by adsorption on the soils processed. The U.S. Bureau of Mines future efforts are being directed to adopting the process to remove and recover lead from other sites, such as mine wastes, mill tails, foundry sands, and flue dusts.

A comprehensive coverage of lead-related investigations and an extensive review of current world literature on the extraction and uses of lead and its products were published in quarterly issues of Leadscan, published by the Lead Development Association, London, United Kingdom.

OUTLOOK

Although domestic demand for lead grew on average about 4% per year from 1985 to 1989 (table 10), this rate cannot be sustained in the future because some end uses of lead will be curtailed or eliminated entirely by legislation and/or source reduction, one of the current pollution prevention regulatory strategies. Use of lead in nongrowth markets such as solders, paints, and coatings (already eliminated in interior house paints), ceramics, gasoline additives, containers or other packaging (including inks or dyes, especially where food is concerned), and cosmetics will certainly be affected. Some reduction of lead per battery unit can also be anticipated as the technology continues to advance. As a result, U.S. annual growth in lead demand will probably fall within a range of 0.5% to 1.5% per year in the decade of the nineties, averaging about 1%, as the storage battery sector becomes even more dominant. The lower growth rate

can certainly be expected if source reduction is applied to the ammunition sector, currently the third largest end use. The higher growth rate could be attained if the use of lead-acid batteries for peak-power, load-leveling applications becomes widely accepted for households and commercial facilities and/or there is a moderate demand for private, general purpose electric cars. The latter two conditions will probably not prevail until the end of the century or early in the 21st century.

World demand for lead grew at an average rate of more than 2% through 1989 from the low recession year of 1982 (table 16). Lower growth in U.S. demand, which is currently 22% of the total, will undoubtedly lower the overall world growth rate somewhat in the future. However, storage battery use in all applications will certainly grow faster in the rest of the world than in the United States as some poorer nations increase their living standards while they grow with the world economy. It is estimated that currently about 60% of world demand is for batteries, compared with about 80% in the United States, and is forecast to reach about 70% by the end of the decade as the rest of the world's supply-demand pattern is rationalized by environmental concerns. Therefore, the most probable world growth in lead use until the end of the century is forecast to average about 1.5% per year once the world's economy recovers from the evident recession of 1991-92.

The attendant worldwide production outlook is interrelated with anticipated structural changes. Because of large capital demand and high costs associated with environmental concerns, large production surpluses in the near term are not likely. High realized producer prices are critical to profitably amortizing the large improvement expenditures anticipated over the next 10 years. However, this will continue to be partially subjected to developing situations in zinc and silver markets because of the geologic relationships of the three metals in the primary production sector. The trend of increasing secondary share of production and consumption exhibited in

tables 19 and 16, respectively, is expected to continue until optimum recycling is achieved. Complex multinational, multifaceted realignments and restructuring, including divestitures, among world lead producers and product manufacturers are expected to continue through the rest of the century. Most noticeable will be investments of primary producers, in many cases through acquisitions and mergers, in secondary lead production to protect existing market share.⁴

^aEstimated. ^bRevised.

¹Table includes data available through June 16, 1992. Data included represent the total output of refined lead by each country, whether derived from ores and concentrates (primary) or scrap (secondary), and include the lead content of antimonial lead, but exclude, to the extent possible, simple remelting of scrap.

²Reported figure.

³Data may not add to totals shown because of independent rounding.

⁴Less than 50 tons.

⁵Revised to zero.

⁶Data are for fiscal year beginning Apr. 1 of that stated.

TABLE 20

LIME

By M. Michael Miller

Mr. Miller, a physical scientist with 14 years of minerals experience with the Department of the Interior, has been the commodity specialist for lime since 1989. Domestic survey data were prepared by Blanche S. Hughes, statistical assistant; and the world production table was prepared by Harold D. Willis, international data assistant.

Lime is an important chemical with hundreds of chemical, industrial, and environmental uses in the United States. It is a basic chemical that ranked sixth in total production in the United States in 1991. Its major uses are in steelmaking; pulp and paper manufacturing; construction; and the treatment of water, sewage, and smokestack emissions.

Total lime sold or used by domestic producers, including that from Puerto Rico, decreased by about 178,000 short tons to 17.3 million short tons in 1991. Production included the commercial sale or captive consumption of quicklime, hydrated lime, and dead-burned refractory dolomite. These products were valued at more than \$895 million. Commercial sales decreased for the first time in 5 years, while captive consumption remained essentially unchanged from 1990 levels.

DOMESTIC DATA COVERAGE

Domestic production data for lime are developed by the U.S. Bureau of Mines from two separate, voluntary surveys of U.S. operations. The survey used to prepare this report is the annual "Lime" survey. Of the 116 operations to which the annual survey request was sent, 101 responded, representing 85% of the total sold or used by producers shown in table 4. Production for seven nonrespondents was provided based on the monthly survey. Production for five nonrespondents was estimated using reported prior-year production figures. There were three plants idle or shut down. (See table 1.)

BACKGROUND

Definitions and Specifications¹

Lime is a manufactured product made by calcining limestone (calcium carbonate or a combination of calcium and magnesium carbonate) or other calcium carbonate materials at temperatures ranging from 1,800° F to 2,400° F. It is never found in a natural state. The calcination process drives off the carbon dioxide, forming calcium oxide (quicklime). The subsequent addition of water creates calcium hydroxide (hydrated or slaked lime). The term "lime" is a general term that includes the various chemical and physical forms of quicklime and hydrated lime. It may be high calcium, magnesian, or dolomitic. Quicklime is calcium oxide (CaO) with no water of crystallization. Hydrate is hydrated calcium oxide, or calcium hydroxide [Ca(OH)₂], and contains 24% combined water. Dead-burned refractory dolomite is dolomite that has been calcined at 2,800° F to 3,150° F. All of these products are called lime.

Quicklime is commercially available by the carload, in bulk, or in paper bags, in the following standard sizes:

1. Lump lime—the product exceeds 2.5 inches in diameter. Although sizes can vary, the typical size is 5 by 8 inches. This largest size of quicklime is strictly a product of vertical kilns.

2. Crushed or pebble lime—the product ranges in size from 0.25 inch to 2.25 inches, but the specific product size is more precise. This size has traditionally been a product of rotary kilns, but is now available from vertical kilns as either a

primary product or as a result of crushing lump lime.

3. Ground lime—the product is generally ground from larger size material. A typical product size passes nearly 100% through a No. 8 sieve and 40% to 60% through a No. 100 sieve.

4. Pulverized lime—the product is the result of further grinding. A typical product size passes nearly 100% through a No. 20 sieve and 85% to 95% through a No. 100 sieve. This is usually a secondary product and is produced by intense grinding and classification.

5. Pelletized lime—the almond-shaped pellets or briquets are of uniform 1-inch size, molded from quicklime fines.

Hydrated lime is shipped in bulk tank trucks, rail cars, and in 50-pound paper bags. As a result of the hydration process, it is of fine particle size. A typical product size passes 85% or more through a No. 200 sieve, and a few special applications may require a product passing 95% to 98% through a No. 325 sieve.

Because of the differences in limestones, a rigid standardization of lime material specifications is impossible. Few plants manufacture lime with exactly the same properties; as a result, lime specifications are by necessity quite general in their provisions. (See table 2.)

Technology²

Lime manufacture involves three main processes: stone preparation, calcination, and hydration. Stone preparation involves quarrying or mining (including drilling, blasting, and conveying broken stone), crushing, and screening to provide the proper size kiln feed. Care is taken

to avoid contamination with undesirable impurities, such as iron oxide, silica, and alumina. Although most lime manufacturers produce their own stone, some purchase the stone for kiln feed from commercial limestone producers.

Calcination is a simple chemical reaction. It is the addition of heat to limestone to cause thermal decomposition, in which the coproducts of CaO (quicklime) and CO₂ (carbon dioxide) are formed. This process is performed in a kiln, of which there are a wide variety of systems in use. The two basic kiln designs are rotary and vertical (or shaft). There are a few other miscellaneous designs, but the majority of commercial kilns are of rotary or vertical design.

A rotary kiln is a long cylindrical kiln with a refractory lining, inclined at a slight angle, rotated at a slow speed, and fired by fuel at the lower end. The calcareous raw material (kiln feed) is fed into the upper end and calcined at about 2,000° F during its travel through the kiln to form quicklime, which is discharged at the lower end. The calcination temperature depends on size and composition of kiln feed and the type of desired product. The carbon dioxide is driven off as a gas and normally exits the system with the stack gas.

Vertical kilns are short, wide, vertical cylinders lined with refractory materials. They are usually circular in cross section, typically with a diameter of 9 to 14 feet and a height of 50 to 70 feet. They are the most widely employed type in the world, especially in Europe. A vertical kiln is divided into four distinct zones where specific parts of the manufacturing process take place. They are, from top to bottom, (1) stone storage zone, (2) preheating zone, (3) calcining zone, and (4) cooling and discharge zone.

Examples of other kiln designs are the rotary hearth kiln and the fluosolids kiln. The rotary hearth design consists of a preheater, circular hearth, and cooler, all refractory lined. Stone is placed on the hearth and rotated through a heating chamber. In the fluosolids kiln, fine-sized stone is densely suspended by air and hot gases in the preheating and

calcining zone of a vertical heated chamber. It can be operated at lower temperatures because of the fine stone size. The quicklime product is the most highly reactive of any commercial lime.

Byproducts and Coproducts

Most lime companies mine their own limestone or dolomite for kiln feed. Some companies also produce a separate coproduct crushed and pulverized stone production. If practical and if markets exist, byproduct fines from the kiln feed preparation process and kiln dust from the calcination process are also marketed. Precipitated calcium carbonate (PCC) is produced as a coproduct at three commercial lime plants by combining quicklime with byproduct carbon dioxide recovered from the kiln. Byproduct carbon dioxide is also recovered for use in the carbonation step of sugar refining.

Substitutes

Limestone is a low-cost substitute for lime for many uses such as agriculture, fluxing, and flue gas desulfurization (FGD). Limestone contains less reactive material, is slower to react, and may have other disadvantages compared to lime, depending on the use. Calcined gypsum is an alternative material in industrial plasters and mortars. Cement, lime kiln dust, and fly ash are potential resources as substitutes for some construction uses of lime. Alkalis such as caustic soda, soda ash, sodium bicarbonate, sodium sulfate, and magnesium hydroxide are substitutes used in the neutralization stage of water treatment.

Economic Factors

Prices.—Traditionally, lime has been a low-priced commodity. Its average value, as reported to the U.S. Bureau of Mines on an f.o.b. plant basis, ranged from \$4 to \$15 per ton from 1910 to 1970. It was only in the 1970's, when energy prices escalated, that lime prices showed a progressive and dramatic increase. This steady increase continued into the 1980's, although at a slower

pace. In 1987, lime decreased in value for the first time since 1968. When comparing prices over the past 20 years, based on constant 1991 dollars, two trends become evident. From 1972 to 1978, prices fluctuated, but finished the period up 41%. From 1979 to 1991, prices decreased steadily, finishing the period down almost 30%. (See table 3.)

Costs.—Production costs in lime manufacture can be divided, in descending order, into the following categories: energy (mainly fuel costs), kiln feed, dust collection, depreciation, direct labor, and miscellaneous. The ranking may differ from plant to plant, and most of the categories display a great range in costs from one plant to another. The difference in ranking and the range in costs are accounted for by such variables as distance from fuel sources; thermal efficiency of individual kilns; whether kiln feed is quarried, mined underground, or purchased; electrical energy rates; and age of the plant.³

Tariffs.—In the Harmonized Tariff Schedule of the United States, quicklime, slaked lime (hydrate), and hydraulic lime are listed under 2522.10, 2522.20, and 2522.30, respectively. Imports are free from countries with most-favored-nation (MFN) status and Canada. Non-MFN countries have tariffs of 0.2¢ per kilogram (about \$2.20 per short ton) for quicklime, 0.3¢ per kilogram (about \$3.31 per short ton) for slaked lime, and 0.2¢ per kilogram (about \$2.20 per short ton) for hydraulic lime. Mexican imports of lime are assessed a countervailing duty of 1.21%. This applies only to Mexican lime producers included in the scope of a countervailing duty investigation completed in 1984 and a changed circumstances administrative review completed in 1989.

ANNUAL REVIEW

Legislation and Government Programs

Title IV of the Clean Air Act Amendments of 1990 authorized the U.S.

Environmental Protection Agency (EPA) to establish an acid rain program to reduce the adverse effects of acidic deposition. As part of the implementation of this statutory mandate, four proposed rulemakings were issued on December 3, 1991. The proposed rules included: the permits regulation, the allowance system regulation, the continuous emissions monitoring regulation, and the excess emissions penalties regulation. These rulemakings regulate the four core components of the acid rain program: the permit, which includes a source's emissions control plans and requirements; the allowance system, which provides a source the flexibility to meet its sulfur dioxide emissions limitation requirements economically; the continuous emissions monitoring system, which ensures source compliance; and the excess emissions program, which defines the consequences for failing to comply with the sulfur dioxide and nitrogen oxides emissions requirements.⁴

Production

The term "lime," as used throughout this chapter, refers primarily to six chemicals produced by the calcination of high-purity calcitic or dolomitic limestone followed by hydration where necessary. They are (1) quicklime, calcium oxide (CaO); (2) hydrated lime, calcium hydroxide [Ca(OH)₂]; (3) dolomitic quicklime (CaO•MgO); two types of dolomitic hydrate, (4) type N [Ca(OH)₂•MgO] and (5) type S [Ca(OH)₂•Mg(OH)₂]; and (6) dead-burned dolomite. Nondolomitic quicklime and hydrated lime are also called high-calcium lime. Lime can also be produced from a variety of calcareous materials such as aragonite, chalk, coral, marble, and shell. Lime is also regenerated; that is, produced as a byproduct, by paper mills, carbide plants, and water treatment plants; however, regenerated lime is beyond the scope of this report.

Total U.S. lime production from limestone, including that of Puerto Rico, was essentially unchanged. Commercial

lime sold by producers decreased by 178,000 tons from that of the previous year. Captive lime used by producers remained essentially unchanged.

In 1991, 70 companies produced lime. Leading producing companies, in descending order, were Dravo Lime Co., with two plants in Kentucky and one plant in Alabama; Mississippi Lime Co. in Missouri; Marblehead Lime Co., with two plants in Illinois and one each in Indiana and Michigan; Chemstar Inc., with two plants each in Arizona, California, and Nevada and one in Utah; Allied Lime Co., with two plants in Alabama; Continental Lime Inc., with one plant each in Montana, Nevada, Utah, and Washington; Martin Marietta Corp. in Ohio; Chemical Lime Inc., with two plants in Texas; APG Lime Co., with one plant each in Texas and Virginia; and Wimpey Minerals PA Inc., with two plants in Pennsylvania. These 10 companies operated 28 plants and accounted for 57% of total lime production.

Domestic lime plant capacity is based on 365 days minus the average number of days for maintenance times the average 24-hour capacity of quicklime production, including quicklime converted to hydrated lime, and reported in short tons per year. Specific plant capacity data were available for 50 commercial lime plants. Based on the data available, the commercial lime industry operated at 74% of capacity in 1991. (See tables 4 and 5.)

The industry completed a number of plant expansions and started construction of a new plant. Dravo Lime Co. completed installation of an 800-ton-per-day preheater rotary kiln of Kennedy Van Saun design at its plant in Saginaw, AL. It went on-line in late March 1991. It replaced a 200-ton-per-day rotary, which was placed in inactive status. Dravo Lime Co. and Tenn Lutrell Co. announced a joint-venture agreement to market Dravo's patented Thiosorbic lime (magnesium enhanced lime) for FGD in Tennessee and the mid-Atlantic region. Tenn Lutrell will produce Thiosorbic lime at its lime plant near Knoxville, TN. Thiosorbic lime is the registered trademark of Dravo's magnesium-

enhanced lime. Cheney Lime and Cement Co. completed installation of a preheater rotary kiln of Kennedy Van Saun design at its plant near Alabaster, AL. It went on-line in the first quarter of 1991. Continental Lime Inc. completed installation of a second kiln at its plant at Townsend, MT. The kiln was a used Allis Chalmers with a preheater of Continental design and went on-line January 1991. The company began installation of a third rotary kiln at its plant at Delta, UT. The kiln was a used F. L. Smidth with a preheater of Continental design and is scheduled to go on-line in September 1992. Chemstar Inc. began construction of a 600-ton-per-day Maerz vertical shaft kiln at its Ten-Mile Plant near Soda Springs, ID. Startup was planned for early August 1992. Work on zoning and permitting approvals continued for a new plant planned for Cosgrave, NV. Construction is expected to begin in the third quarter of 1992. (See table 6.)

Consumption and Uses

Lime was consumed in every State. The breakdown of consumption by major end uses was as follows: 66% for chemical and industrial uses, 24% for environmental uses, 8% for construction uses, and 2% for refractory dolomite. Captive lime was used mainly in sugar refining and in the production of steel in basic oxygen furnaces.

In steel refining, quicklime was used as a flux to remove impurities such as phosphorus, silica, and sulfur. Dolomitic lime was often substituted for a fraction of the high-calcium lime to extend refractory life. Dead-burned dolomite, also called refractory lime, was used to line the bottom of open-hearth steel furnaces to extend the life of the brick lining until the last open-hearth furnaces operated by the U.S. steel industry closed down in 1991. Dead-burned dolomite was a component in tar-bonded refractory brick used in basic oxygen furnaces. Lime consumption for raw steel production remained essentially unchanged at 5.1 million tons and

accounted for about 30% of all lime consumed in the United States.

In nonferrous metallurgy, lime was used in the beneficiation of copper ores to neutralize the acidic effects of pyrite and other iron sulfides and maintain the proper pH in the flotation process. It was used to process alumina and magnesia, to extract uranium from gold slimes, and in the recovery of nickel by precipitation. It was used in gold and silver recovery operations to control the pH of the sodium cyanide solution used to leach the gold and silver from the ore. Such leaching processes are called dump leaching when large pieces of ore are involved, heap leaching when small pieces of ore are involved, and carbon-in-pulp cyanidation when the ore is leached in agitated tanks. Dump and heap leaching involve crushing the ore, mixing it with lime for pH control and agglomeration, and stacking the ore in heaps for treatment with cyanide solution. Lime is used to maintain the pH of the cyanide solution at a pH level between 10 and 11 to maximize precious-metals recovery and to prevent the creation of dangerous hydrogen cyanide gas.

In the environmental sector, lime was used in the softening and clarification of municipal potable water. In sewage treatment, lime was used to control pH in the sludge digester, which removes dissolved and suspended solids that contain phosphates and nitrogen compounds. It also aided clarification and killing of bacteria. Lime was used to neutralize acid mine and industrial discharges. In FGD systems serving utility and industrial plants, lime was used to react with sulfur oxides in the flue gas. Lime was used to stabilize sludges from sewage and desulfurization plants before disposal.

The paper industry used lime as a coagulant aid in the clarification of plant process water. It was used, generally in conjunction with soda ash, for softening plant process water. This is a precipitation process to remove bivalent soluble calcium and magnesium cations (and to a lesser extent manganese, ferrous iron, zinc, and strontium), which contribute to the hardness of water. This

process also reduces carbonate alkalinity and dissolved solids content.

In the basic Kraft pulping process, wood chips and an aqueous solution (called liquor) of sodium hydroxide and sodium sulfide are heated in a digester. The cooked wood chips (pulp) are discharged under pressure along with the spent liquor. The pulp is screened, washed, and sent directly to the paper machine or for bleaching. Lime is sometimes used to produce calcium hypochlorite bleach for bleaching the paper pulp. The spent liquor is processed through a recovery furnace where dissolved organics are burned to recover waste heat and where sodium sulfide and sodium carbonate are recovered. The recovered sodium sulfide and sodium carbonate are diluted with water and then treated with slaked lime to recausticize the sodium carbonate into sodium hydroxide (caustic soda) for reuse.

Lime was used to make PCC, a specialty pigment used in premium-quality coated and uncoated papers. The most common PCC production process used in the United States is the carbonation process. Carbon dioxide is bubbled through milk-of-lime to form a precipitate of calcium carbonate and water. The reaction conditions determine the size and shape of the resulting PCC crystals.

The chemical industry used lime in the manufacture of alkalis. Quicklime was combined with coke to produce calcium carbide, which was used to make acetylene and calcium cyanide. Lime was used to make calcium hypochlorite, citric acid, petrochemicals, and other chemicals.

In sugar refining, milk of lime, a suspension of hydrated lime in water, was used to raise the pH of the product stream, precipitating colloidal impurities. The lime itself was then removed by reaction with carbon dioxide to precipitate calcium carbonate. The carbon dioxide was obtained as a byproduct of lime production.

Dolomitic quicklime was used as a flux in the manufacture of glass. Quicklime was used to make calcium silicate building products such as sand-lime brick;

hydrated lime was used to produce silica refractory brick.

In construction, lime was used for soil stabilization to upgrade clay soils into satisfactory base and subbase materials. Common applications included the construction of roads, airfields, building foundations, earthen dams, and parking areas. Hydrated lime was used with fly ash to make a base material, in asphalt mixes to act as an antistripping agent, and in plaster, stucco, and mortar to improve durability. Other applications of lime included agricultural uses, leather tanning, plastics manufacture, and pigments. (See figure 1 and table 7.)

Prices

The average value of lime sold or used by producers, as reported to the U.S. Bureau of Mines on an f.o.b. plant basis, was essentially unchanged from that of the previous year at \$51.73 per short ton. Average values were \$49.80 per ton for chemical and industrial lime, \$61.80 for construction lime, \$71.16 for lime used in agriculture, and \$75.86 for refractory dolomite.

The average value of quicklime sold decreased to \$49.93 per ton. Average values per ton were \$48.27 for chemical lime, \$42.07 for construction lime, \$59.53 for lime used in agriculture, and \$74.17 for refractory dead-burned dolomite.

The average value of hydrated lime sold increased to \$63.30 per ton. Average values were \$60.69 for chemical lime, \$68.39 for lime used in construction, and \$76.95 for lime used in agriculture.

Foreign Trade

According to the Bureau of the Census, exports of lime decreased by 5% to 42,000 tons. Imports of lime remained essentially unchanged at 174,000 tons. Most U.S. trade was with Canada and Mexico, which together accounted for more than 99% of the U.S. imports and exports of lime. Canada was the major trading partner, receiving 90% of U.S.

exports and shipping 85% of U.S. imports. (See tables 8 and 9.)

World Review

Canada.—Shipments of lime were essentially unchanged from 1990 levels, but shipments in both 1990 and 1991 were 8% lower than those in 1989. In 1990, shipments were down owing to a 3-month strike in the steel industry. In 1991, shipments were down owing to the economic recession. Preliminary figures for 1991 indicate that Canada producers shipped about 2.12 million tons valued at \$186 million.

Germany, Federal Republic of.—German Group Preussag AG purchased Harz Kalk GmbH of Saxony-Anhalt. Harz Kalk GmbH was the largest producer of lime and limestone in the former German Democratic Republic. It operated six limestone and lime facilities: Werk Rbeland, Werk Kaltes Tal, Werk Hornberg, Werk Bad Ksen, Werk Oberrohn, and Werk Schraplau. Preussag AG, which has interests in energy, ship building, steel and nonferrous metal production, and trading, plans to invest about \$120 million to construct new lime production facilities and mortar plants. Harz Kalk will be operated as an independent group member company as a subsidiary of Fels-Werke GmbH.⁵

United Kingdom.—ICI announced the sale of its lime business to Luxembourg-based Minorco. ICI's lime business is in Derbyshire near Buxton and includes three quarries and two processing and calcining facilities. The largest lime plant is at Tunstead, with the capacity to produce 695,000 tons of quicklime per year and 330,000 tons of hydrate. The second plant is at Hindlow, with the capacity to produce 240,000 tons of quicklime per year. The company's major markets are steel, chemicals, sugar processing, and water treatment. The company is to be renamed Buxton Lime Industries.⁶

Tilcon Ltd., a subsidiary of BTR PLC, formed a 50-50 joint-venture company with Belgian lime and industrial minerals producer Calcitherm-Carmeuse Group. The new company, called Tilcon Carmeuse Ltd., will produce and market quicklime and hydrated lime in the United Kingdom. Feasibility and marketing studies were undertaken in 1991 to decide the number and location of new lime plants to be built at Tilcon's existing quarries. New plant construction is expected to be complete by mid-1993. The new plants will supply Tilcon's traditional markets: steel, construction, chemicals, water treatment, and sewage treatment.⁷

The 1st International Seminar on Lime and Other Alternative Cements was held on December 9-11, 1991, at Stoneleigh, Warwickshire, United Kingdom. About 60 participants attended from Europe, the United States, and other parts of the world. The seminar addressed the production of lime and lime pozzolana cements and their uses and applications. (See table 10.)

Current Research

The EPA at Research Triangle Park, NC, has conducted research into the use of hydrated lime to destroy dioxins in the vapor phase at medium temperatures (350° C). The results suggest that the reaction technology may be transferable to polychlorinated biphenyl (PCB's) vapor destruction and to chlorinated hydrocarbons such as pesticides. At present, destruction of these materials can only be accomplished at high temperatures (2,500° C). If the research proves out and the process can be scaled up, it could result in substantial cost savings over the high-temperature process.⁸

The Argonne National Laboratory, Department of Energy (DOE), has been test burning pelletized refuse-derived fuel that utilizes hydrated lime as a binder. Three test burns are currently funded, and DOE has tentatively accepted a proposal for a 5-year commercial development program. The new test program would examine the long-term

effects on boilers and boiler tube corrosion, mass-burn garbage plant retrofits, 100% refuse-derived fuel burns, and dolomitic lime use. Utilizing hydrated lime as a binder solves a problem that has vexed refuse-fuel researchers. Fuel pellets frequently broke up during transport and tended to fall apart during prolonged storage. Positive results of this program could create a new market for lime.⁹

Research was conducted to study combining industrial wastes with lime for soil stabilization. Experiments utilizing scanning electron microscope observations and X-ray diffraction analysis investigated chemical compounds of an anhydrous stabilizer and reaction products produced in hydrated stabilizer and stabilized soil. Results of the laboratory research were compared to the effectiveness of ordinary portland cement. The results indicated that a new stabilizer produced from the combination of lime and incinerated industrial wastes had self-cementing characteristics similar to portland cement. It would be suitable for addition to high-moisture loam soil and organic matter for subgrade stabilization purposes.¹⁰

Chemists, in the Department of Chemistry, University of Hannover, Federal Republic of Germany, have conducted research on the treatment of soil contaminated with PCB's using hydrophobic (water repellent) lime and other reagents. Their tests involved the in situ treatment of PCB-contaminated soil using a Dispersion by Chemical Reaction Process. This process uses quicklime treated with fatty acids as the carrier and dispersing agent for the additional reagents needed for the solid-phase treatment and dehalogenation of the PCB's. The specially prepared lime, when mixed with PCB-contaminated soil, preferentially absorbs the PCB's. The quicklime then undergoes a delayed exothermic reaction forming hydrated lime, which is broken into submicron-sized particles. These particles contain the dehalogenation reagents and absorb the PCB's. The hydrated lime slowly reacts with natural carbon dioxide to generate insoluble calcium carbonate.

This immobilizes the PCB's and provides an environment where the chemical reactivity of the compounds is increased, allowing detoxification and dehalogenation reactions to occur. The time required for these reactions to occur depends to a large extent on the temperature at which the process is run. Thus, the remediation process can be run in situ, where reaction times could take several months, or externally at elevated temperatures of about 400° C, where the reactions would take a matter of minutes.

Neither quicklime nor hydrated lime alone appears to be a successful treatment of PCB's. The key to the Dispersion by Chemical Reaction Process is the proprietary dehalogenation reagents. Using the described process and the reagents, the researchers achieved a dehalogenation reduction rate of 70% over a period of 7 days at ambient conditions.¹¹

OUTLOOK

Lime has dozens of end uses in the chemical, industrial, and construction industries. Steelmaking is still the largest single end use for lime, and although raw steel production in the United States decreased by 13% in 1991, the steel industry's consumption of lime remained essentially unchanged from 1990 levels. Consumption by the steel industry has been flat over the past 3 years. Steel output is expected to increase modestly in the short term, but should receive a boost from the passage of the Intermodal Surface Transportation Efficiency Act (ISTEA), which includes \$121 billion for highways and \$31.5 billion for transit. This should maintain this traditional lime market near or slightly above current consumption levels.

Other sectors of the lime market are more difficult to analyze. No other single end use consumes more than 10% of total consumption, although environmental uses when grouped together account for 24%. FGD consumption has the greatest growth potential, having increased steadily since the U.S. Bureau of Mines began collecting consumption data for it in the

early 1970's. With passage of the Clean Air Act Amendments of 1990, consumption of lime for FGD use is expected to show continued growth during the 1990's, although it appears that the FGD market may not grow as dramatically as originally anticipated. The majority of utility powerplants intending to install FGD scrubbers are leaning toward the use of limestone scrubbers instead of lime scrubbers. In addition, now that the desulfurization market has been recognized as a major market, more companies and Federal research laboratories have become involved in researching alternative desulfurization technologies.

Other environmental markets should be solid, with the greatest potential for growth in sewage sludge stabilization. Research continues into the use of lime combined with other reagents for the destruction of PCB's and dioxins. This potential coupled with its ability to neutralize acid wastes and to precipitate and immobilize heavy metals may lead to wider usage in environmental markets.

In the short term, major construction projects such as construction of the Denver International Airport will boost consumption of lime for soil stabilization. From 1993 through 1997, the highways allotment in ISTEA should provide a boost to the asphalt antistripping and soil stabilization markets. ISTEA has allotted in excess of \$20 billion per year for highway construction projects during that period.

Consumption by the pulp and paper industry was flat in 1990. According to experts in the chlor-alkali industry, consumption of caustic soda for pulp and paper is slowing and is expected to grow by 1% or less over the next 5 years. Because lime is used to recausticize sodium carbonate into caustic soda, consumption of lime by the pulp and paper industry is also expected to be flat. Lime consumption for PCC production will continue to increase as the push to build satellite PCC plants near paper mills continues.

Consumption of raw materials for glass manufacture is expected to grow at a rate of 1% per year through the mid-1990's.

Lime and limestone compete in the glass market with the choice depending on established manufacturing practice, regional availability, and prices. Lime consumption for glass manufacture is expected to outgrow limestone consumption owing to the lime's lower energy costs to the user.

Regionally, the continued expansion of gold production will provide a growing market in the West for lime consumed in cyanide-based gold recovery processes. Two producers of soda ash in Wyoming have constructed facilities for the lime-soda production of caustic soda, and a third is in the construction stage. This could develop into a significant regional market for lime.

In the south-central United States, a major regional market could develop in the middle to late 1990's. A major manufacturer of propylene oxide is considering switching from the use of caustic soda to hydrated lime for the dehydrochlorination stage of the manufacturing process. If the manufacturer proceeds with the substitution, the company would consume about 500,000 tons of hydrated lime per year.

A number of promising markets that are in the research or demonstration stage are lime used as a binder in refuse-derived fuel, PCB and dioxin treatment, and autoclaved cellular concrete. The latter is a construction material manufactured by mixing portland cement, lime, aluminum powder, water, and a large proportion (up to 75%) of sand or fly ash. The material has outstanding dimensional stability, is thermally efficient, fire resistant, easily worked, and is cost effective in terms of construction time and energy use. It has been in wide use in Europe for 25 years. An 18-month demonstration tour is scheduled in the United States for mid-1992.

^{*}Estimated. ¹Revised. NA Not available.

²Table includes data available through June 12, 1992.

³Lime is produced in many other countries besides those listed. Argentina, Iraq, Pakistan, and Syria are among the more important countries for which official data are not available.

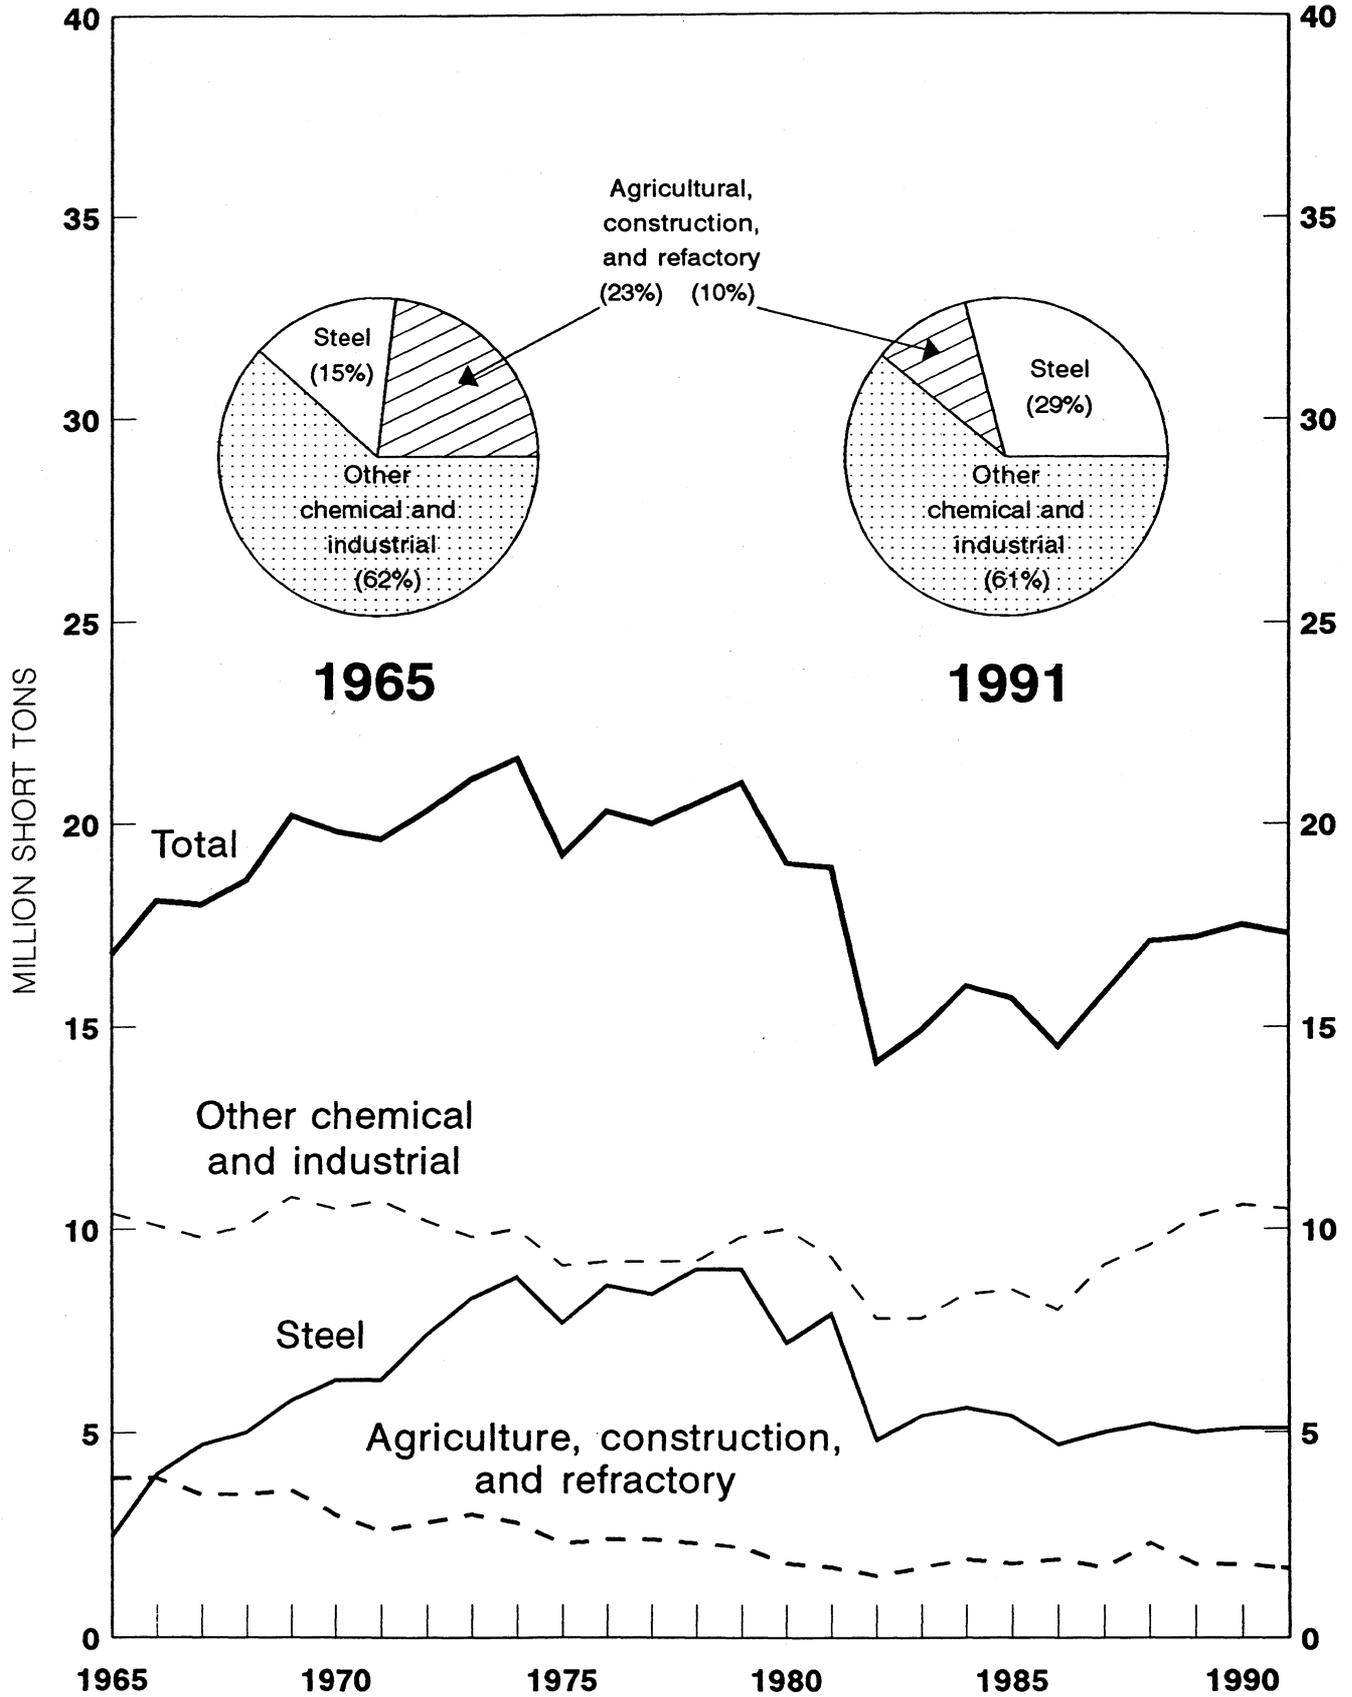

⁴Less than 1/2 unit.

⁵Revised to zero.

⁶Reported figure.

⁷Includes hydraulic lime.

FIGURE 1
TRENDS IN MAJOR USES OF LIME

LITHIUM

By Joyce A. Ober

Mrs. Ober, a physical scientist with 14 years industry and U.S. Bureau of Mines experience, has been the commodity specialist for lithium since 1986. Domestic survey data were prepared by Carleen Militello, statistical assistant; and international data tables were prepared by staff, Branch of Data Collection and Coordination.

The United States led the world in lithium mineral and compound production and consumption. Domestic estimated consumption decreased slightly for the first time in 4 years; world production has risen steadily. Domestic producers announced modest price increases for the fifth consecutive year.

Because lithium is electrochemically reactive and has other unique properties, there are many commercial lithium products. Producers sold lithium as mineral concentrate, brine, compound, or metal depending on the end use. Most lithium compounds were consumed in the production of ceramics, glass, and primary aluminum.

DOMESTIC DATA COVERAGE

The U.S. Bureau of Mines collects domestic production data for lithium from a voluntary survey of U.S. operations. The two U.S. companies responded to the survey, representing 100% of total production. Production and stock data were withheld from publication to avoid disclosing company proprietary data. (See table 1.)

ANNUAL REVIEW

Legislation and Government Programs

The Department of Energy (DOE) planned to offer portions of its 36-million-kilogram stock of lithium hydroxide monohydrate for sale. The DOE stocks were excess from a weapons program that used the lithium to make tritium, a compound necessary for

nuclear fission reactions. The stockpile originally contained about 42,000 metric tons of material, from which about 75% of the lithium 6 isotope had been removed. This material possibly contained 8 to 9 parts per million of mercury, which could present an environmental hazard. DOE had planned to offer the lithium hydroxide for sale since 1989, but delayed the disposal until an environmental impact study was complete. A final decision about disposal had not been made at yearend, and no material was offered for sale in 1991.

Production

The two companies that produced lithium in the United States in 1991 did so from two different types of deposits. Both firms mined spodumene, (a lithium-aluminum-silicate mineral) from large hard-rock deposits in North Carolina using open pit methods. One company recovered lithium from geothermal brine deposits in Nevada.

Lithium carbonate is the most important lithium compound produced from both types of deposits. Spodumene was a major raw material for the production of lithium carbonate in North Carolina, and small amounts of spodumene concentrate were produced for sale. Extracting lithium from spodumene entails an energy-intensive chemical recovery process.

After mining, spodumene is crushed and undergoes a flotation beneficiation process to produce concentrate. Concentrate is heated to 1,075° C to 1,100° C, changing the molecular structure of the mineral, making it more

reactive to sulfuric acid. A mixture of finely ground, converted spodumene and sulfuric acid is heated to 250° C, forming lithium sulfate. Water is added to the mixture to dissolve the lithium sulfate. Insoluble portions of ore are then removed by filtration. The purified lithium sulfate solution is treated with soda ash, forming insoluble lithium carbonate that precipitates from solution. The carbonate is separated and dried for sale or use by the producer as feedstock in the production of other lithium compounds.

Production of lithium carbonate from brine in Nevada is much less energy intensive than production from spodumene. Brines enriched in lithium chloride—averaging about 300 parts per million when operation began in 1966—are pumped from the ground and progress through a series of evaporation ponds. Over the course of a year to 18 months, concentration of the brine increases to 6,000-parts-per-million lithium through solar evaporation. When the lithium chloride reaches optimum concentration, the liquid is pumped to a recovery plant and treated with soda ash, precipitating lithium carbonate. The carbonate is then removed through filtration, dried, and shipped.

FMC Corp., Lithium Div., formerly Lithium Corp. of America (Lithco), mined spodumene from pegmatite dikes near Bessemer City, NC. The company produced lithium carbonate and a full range of downstream compounds, including lithium metal and some organic lithium compounds, at a chemical plant near the mine. The company completed

Cyprus Foote Mineral Co. produced about 6,400 tons of lithium carbonate from its brine deposit in Silver Peak, NV, and about 8,300 tons of spodumene concentrate at its mine in Kings Mountain, NC.¹ It operated processing facilities for downstream lithium products and metal in Kings Mountain, Exton, PA, Sunbright, VA, and New Johnsonville, TN. The company continued to maintain its lithium carbonate plant at Kings Mountain on a care-and-maintenance status as it had since mid-1986.

Consumption and Uses

The aluminum, ceramics and glass, lubricating grease, and synthetic rubber industries consumed most of the lithium minerals and chemicals. These markets were primarily related to transportation; i.e., the aircraft and automotive industries. Industrial and consumer applications also used ceramics and glass. Estimated domestic consumption decreased about 4% in 1991. Ceramics and glass production and aluminum smelters were the largest consumers of lithium carbonate and lithium concentrates in the United States. In other countries, aluminum producers consume little lithium carbonate.

Lithium carbonate and mineral concentrate additions in ceramics and glass manufacturing processes lower process melting points, reduce the coefficient of thermal expansion and the viscosity, and eliminate the use of more toxic chemicals. The manufacture of thermal-shock-resistant cookware (pyroceramics) consumed the majority of lithium used in the ceramics and glass industry domestically. The manufacture of black and white television picture tubes consumed significant amounts of lithium concentrates overseas. Low-iron spodumene and petalite (another lithium mineral) were a source of lithium used to improve the physical properties of container and bottle glass and as a source of alumina, another important component of the glass. Glass manufacturers used lithium in container and bottle glass, enabling them to produce lighter weight, thinner walled products.

Aluminum producers added lithium carbonate to cryolite baths in aluminum potlines. The chemistry of the potline converts it to lithium fluoride, lowering the melting point of the bath, allowing a lower operating temperature for the potline, and increasing the electrical conductivity of the bath. Operators used these factors to increase production or reduce power consumption.

The multipurpose grease industry was the third largest end use for lithium in 1991. Lithium hydroxide monohydrate was the compound used for the production of lithium lubricants. Lithium-base greases are favored for their retention of lubricating properties over a wide temperature range; good resistance to water, oxidation, and hardening; and formation of a stable grease on cooling after melting. These greases continued to be utilized in military, industrial, automotive, aircraft, and marine applications.

Almost all major battery manufacturers marketed some type of lithium batteries, and research and development continued for further substitution in applications that implement more conventional alkaline batteries. These batteries represent a growth area for lithium consumption, but sales have not increased as rapidly as originally expected. Eastman Kodak Co., the first company to offer a lithium battery to the U.S. consumer market, chose to discontinue production owing to low sales. Kodak's 9-volt lithium battery had at least twice the life of a comparable alkaline battery, but consumers were not willing to pay the higher price.

Lithium batteries offer improved performance over alkaline batteries at a slightly higher cost. They were used in watches, microcomputers, and cameras, and, more recently, in small appliances, electronic games, and toys. The military purchased large and small lithium batteries for a variety of military applications. The Galileo spacecraft, launched in October of 1989 for its 6-year trip to explore the atmosphere of Jupiter, contained lithium-sulfur dioxide batteries to power its scientific instruments when it reaches its destination. Recent modifications to the

lithium-sulfur dioxide battery have extended the life of the batteries to at least 10 years with little or no reduction of performance.

Aircraft manufacturers in several countries have designed new aircraft using aluminum-lithium alloys for wing and fuselage skin or structural members. Use of aluminum-lithium alloys can reduce the weight of the aircraft by more than 10%, allowing significant fuel savings during the life of the aircraft. The alloys, which are 2% to 3% lithium by weight, are attractive to the aircraft and aerospace industry because of their reduced density and superior corrosion resistance compared to those of conventional aluminum alloys. These alloys face direct competition, however, from composite materials consisting of boron, graphite, or aramid fibers imbedded in polymers.

Butyllithium, a catalyst in synthetic rubber production and the most important organic lithium compound, was one market area that was growing. Both domestic companies recently increased capacity for production of this compound. Small quantities of other lithium compounds were important to many industries. Lithium chloride and lithium bromide were used in industrial air-conditioning systems, commercial dehumidification systems, and in the production of sophisticated textiles. Sanitizers for swimming pools, commercial glassware, and public restrooms contained lithium hypochlorite, as did dry bleach for commercial laundries. Patients diagnosed as suffering from manic-depressive mental disorders may take medication containing a pharmaceutical grade of lithium carbonate. Lithium metal was used as a scavenger to remove impurities from copper and bronze, and anhydrous lithium chloride was used as a component in fluxes for hard-to-weld metals such as steel alloys and aluminum.

Prices

Both domestic companies increased prices for almost all lithium products for the fifth consecutive year. Prices

Both domestic companies increased prices for almost all lithium products for the fifth consecutive year. Prices averaged about 5% higher in 1991 than in the previous year. The close balance between supply and demand worldwide kept prices in step with inflation. Although installed production capacity remained in excess of demand, Cyprus Foote's chemical plant at Kings Mountain remained inactive, helping to keep supply and demand balanced sufficiently to maintain the trend. (See table 2.)

Foreign Trade

Total U.S. exports of lithium compounds were about 8% lower in 1991 than they were in 1990. Exports of lithium carbonate increased slightly, but lithium hydroxide and lithium metal exports decreased. The majority of U.S. exports of lithium compounds were to the Federal Republic of Germany, Japan, and the United Kingdom. Imports of lithium compounds reported by the U.S. Bureau of the Census decreased 25%. Cyprus Foote Mineral Co. owns a lithium brine operation in Chile; 99% of all lithium imports was from this source. Lithium ore concentrates from Canada and Zimbabwe were consumed in the United States, but no import statistics were available. (See tables 3 and 4.)

World Review

A small number of countries throughout the world produced lithium ore and brine. The United States produced the most lithium; significant quantities also were produced in Australia, Canada, Chile, China, Portugal, the U.S.S.R., and Zimbabwe. Argentina, Brazil, and Namibia produced smaller quantities; production primarily consisted of concentrates. Rwanda, the Republic of South Africa, and Zaire are past producers of concentrates. Pegmatites containing lithium minerals have been identified in Austria, France, India, Ireland, Mozambique, Spain, and Sweden, but economic conditions have not favored development of the deposits. Lithium has been identified in subsurface

brines in Argentina, Bolivia, China, and Israel. Companies in France, the Federal Republic of Germany, Japan, and the United Kingdom produced downstream lithium compounds from imported lithium carbonate.

Capacity.—The data in table 5 are rated capacity for mines and refineries as of December 31, 1991. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable long-term operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgement of the author, can be brought into production within a short period of time with minimum capital expenditure. Any restrictions to capacity utilization related to legal, political, or environmental restraints have been footnoted.

Lithium presented special problems during compilation of production capacities for different operations. Ore concentrate products are not comparable to lithium carbonate. Lithium carbonate was the primary compound produced at lithium chemical plants and the compound from which all other lithium chemicals were produced. Because even high-grade ore products usually contained less than 4% lithium and lithium carbonate contains almost 20% lithium, production capacities reported in tons per year represent large differences in the actual lithium content of the product. For that reason, capacities were reported based on the lithium content of the products also known as contained lithium.

Capacity from the Cyprus Foote's Kings Mountain plant is still listed in the table, but this capacity has been idle since mid-1986 and is not expected to reopen in the near future. (See table 5.)

Argentina.—Small annual production occurred from pegmatite deposits in the Catamarca and San Luis Provinces.

Spodumene reserves are estimated at 140,000 tons of 0.7% lithium.

Brine deposits have also been identified. FMC signed an agreement with the Argentine Government in 1986 to explore the Salar del Hombre Muerto in Catamarca Province. Estimates of geologic resources have been reported at 130,000 tons of lithium contained in brine ranging from 0.22 to 1.08 grams per liter. The Salar del Rincon also was identified as a lithium resource in the Salta Province.²

Australia.—Lithium Australia Ltd. (LAL), subsidiary of the Gwalia Group, mined high-grade, low-iron spodumene at its mine in Greenbushes, Western Australia. LAL produced two spodumene concentrate products through a flotation process for sale to the ceramics and glass industry. The majority of the company's spodumene concentrate was used in the manufacture of black and white television picture tube glass and pyroceramics in the Pacific rim countries and Europe. Glass-grade concentrate with lower lithium content was marketed in the same countries for consumption in container glass.

LAL was awarded the Outstanding Export Achievement Award in 1990 by the Western Australia Department of Trade Development for its growth in export sales and success in establishing a new export industry for Australia.

Bolivia.—The Government of Bolivia and FMC reached an agreement for a joint-venture operation in the Salar de Uyuni, a lithium brine deposit considered to be a national asset. FMC's plans included an exploration program and a plant for recovery of lithium carbonate from the evaporated brines. Extreme political pressures in 1990 prompted the Government of Bolivia to cancel the accord and issue a call for international bids. FMC was ultimately awarded the contract.

FMC will produce 10,000 tons per year of lithium carbonate over 40 years under the terms of the contract. A feasibility study should begin in mid-1992 and be

completed within 2 years. FMC is expected to invest \$92 million for the feasibility study and construction of the lithium carbonate plant.³

Preliminary studies of the Salar de Uyuni, which is more than 3,600 meters above sea level, indicated resources of 5.5 million tons of lithium, 110 million tons of potassium, and 3.2 million tons of boron. The salar may be the world's largest salt flat.⁴

Brazil.—Brazil has produced small quantities of lithium minerals for almost 30 years. Companhia Brasileira de Lítio built a plant in Aquas Verhelhas, Minas Gerais, to produce 1,000 tons of lithium hydroxide and 200 tons of lithium carbonate.

Canada.—Tantalum Mining Corp. (Tanco) mined spodumene concentrate at its mine near Bernic Lake in southeastern Manitoba. Since mining began in 1984, Tanco has grown to become the largest supplier of lithium concentrates to the U.S. ceramics and glass industry. The Canadian spodumene was similar to the material mined in Australia (high-grade spodumene with very low iron content), making the concentrates ideal for direct application in the ceramics and glass industry.

A number of other lithium deposits have been identified throughout Canada. A pegmatite deposit was operated in Quebec for about 10 years starting in 1955, but there has been no production since then. The largest demonstrated resources occur in the Yellowknife deposits in the Northwest Territories.⁵ Although these are large deposits, the location is too remote for production to be feasible in the foreseeable future.

Chile.—Cyprus Foote Mineral Co. is the sole owner of its lithium brine operation at the Salar de Atacama, Sociedad Chilena de Lítio Ltda., having bought the remaining interest from the Chilean Government in 1989. Cyprus Foote produced lithium carbonate from the brines from this Salar, which has been worked since 1984. The project

originated as a joint venture between Foote and Corporación de Fomento de la Producción (CORFO), a Chilean Government agency. Production capacity for lithium carbonate increased steadily from a 6,300-ton-per-year capacity to reach the current level of almost 12,000 tons per year.

The possibility of a second lithium operation at the Salar de Atacama had been under investigation. Minera Salar de Atacama Ltda. (MINSAL), the consortium formed by AMAX Exploration Inc. (United States), CORFO, and Molibdenos y Metales S.A. (Chile), completed studying the feasibility of developing another lithium operation on the Salar in 1988. Evaluations of the results were analyzed, and AMAX announced its decision to sell its portion of the project in 1990.⁶

China.—Lithium pegmatite and brine deposits are worked in China, but specific information about any of the deposits is not available. Lithium carbonate and hydroxide from China has been marketed in the Federal Republic of Germany, Japan, and the Netherlands.

France.—Lithium metal is produced by Metaux Speciaux SA in Plombières St. Marcel, Savoie. The plant has the capacity to produce 25 tons per year of very high-purity metal for use in aluminum-lithium alloys. The company is a subsidiary of Pechiney.⁷

Germany, Federal Republic of.—The Federal Republic of Germany has been a major producer of lithium compounds, although no lithium ore is mined there. Chemetall GmbH, a member of the Metallgesellschaft Group AG, produced downstream lithium compounds and metal from lithium carbonate imported from the United States and other countries. The company's lithium operations are in Langelshelm.

Japan.—Japan is a major consumer of lithium compounds, some of which it produces from imported lithium carbonate. FMC and the Honjo Chemical

Co. have a joint venture, Asia Lithium Corp., to market FMC's lithium products in Japan. Asia Lithium was constructing a 100-ton-per-year battery-grade lithium metal operation in Kagawa. Yahagi Iron Co. also produced lithium metal in Nagoya.

Namibia.—Southwest Africa (SWA) Lithium Mines produced petalite concentrate at its Rubicon Mine near Karibib. Low-grade ores were beneficiated through a flotation process, while high-grade ores were handpicked. Small amounts of two other lithium minerals, lepidolite (lithia mica) and amblygonite (lithia alumina phosphate), were other products. The Federal Republic of Germany imported most of these concentrates. High-grade lepidolite was handpicked at the company's Helicon Mine for export to Western Europe and Japan.⁸

Portugal.—Lithium has been produced inconsistently in Portugal. Recent reports indicate that production has gone up significantly in recent years, but details on the operations and markets are not available. Past lithium production has been lepidolite.

United Kingdom.—Lithium Corp. of Europe operates a facility in Bromborough, Mersyside, for the production of lithium metal and butyllithium. Lithium carbonate and lithium chloride are imported from its parent company, FMC.

U.S.S.R.—Lithium ores, compounds, and metal were produced in the U.S.S.R., but no details were available.

Zimbabwe.—Bikita Minerals Ltd. mined petalite, another lithium mineral, near Masvingos. Although the ore reserves were becoming depleted, installation of a dense-media separator made it possible to recover lithium in the form of petalite averaging about 4.4% lithium oxide from a stockpile of previously rejected material. This extended the estimated mine life 30 years.

Hand sorting, the method used since the mining began in 1916, amassed a stockpile of more than 1 million tons that could be recovered with a significant savings in mining costs after installation of the new device. Hand sorting continued to be used only for special small orders of minerals other than petalite.⁹ (See table 6.)

OUTLOOK

The aluminum industry experienced a slowdown in 1984, and, as a result, domestic lithium consumption decreased dramatically that year. Lithium consumption has increased slightly since that time. This increase was primarily due to the economic recovery of the aluminum industry as well as increased demand for lithium compounds and minerals in the ceramics and glass and synthetic rubber industries. Similar increases are expected for the future.

Demand for butyllithium is expected to continue to increase, and both domestic producers have increased production capacity to meet that demand. Demand for lithium metal for batteries and alloys should increase, but total consumption of the metal will remain small in comparison to the demand for lithium chemicals. Markets should remain relatively stable with slight growth, although new applications for mineral concentrates could increase demand for those materials significantly in the next few years. Lithium demand could increase dramatically if any of the new technology areas such as nuclear fusion were perfected. This is not expected to occur within the remainder of this century and probably not within the next 25 years.

¹Table includes data available through Apr. 4, 1992.

²In addition to the countries listed, other nations may produce small quantities of lithium minerals, but output is not reported, and no valid basis is available for estimating production levels.

³Estimates based on imports by the United States.

⁴These estimates denote only an approximate order of magnitude; no basis for more exact estimates is available. Output by China and the U.S.S.R. has never been reported.

MAGNESIUM AND MAGNESIUM COMPOUNDS

By Deborah A. Kramer

Ms. Kramer is a physical scientist with the Branch of Industrial Minerals. She has covered magnesium and magnesium compounds for 8 years. Domestic survey data were prepared by Lillian M. Wood, statistical assistant; international data tables were prepared by Ron Hatch, international data assistant, and William Zajac, Chief, Section of International Data.

U.S. magnesium production declined for the second year in a row, primarily because of depressed economic conditions and competition from imports from Canada. In a reaction to the increased imports from Canada, one U.S. producer filed an antidumping and countervailing duty suit charging the Canadian producers with material injury to U.S. industry.

The world magnesium industry in 1991 was marked with capacity shutdowns to mitigate the effects of inventory buildup that occurred during the year. Plants in Canada, Norway, the United States, and Yugoslavia announced temporary capacity shutdowns citing reasons such as deteriorating market conditions and availability of less costly material from the former U.S.S.R. One plant in Canada that had opened in 1990 was closed permanently because of technical difficulties. In conjunction with these closures, market prices throughout the world dropped significantly during the year.

U.S. production of magnesium compounds declined for the third year in a row. Seawater and brines were the source materials for 72% of the total production of magnesium compounds. Refractories were the principal end use for most of the magnesia produced, but represented a smaller-than-usual share of total consumption. Caustic-calcined magnesia was used in the agricultural, chemical, construction, and manufacturing industries.

One new magnesia plant opened in Australia during 1991, and expansions in capacity were planned in Canada, India,

and Israel. In addition to new plant construction, many magnesia producers were developing new products to increase the use of magnesia in applications such as environmental uses and flame retardants. Refractories manufacturers continued to upgrade their facilities to produce improved products to satisfy the needs of the iron and steel, nonferrous metals, glass, and cement industries.

DOMESTIC DATA COVERAGE

Data for magnesium metal are collected from two voluntary surveys of U.S. operations. Of the 118 companies canvassed for magnesium consumption data, 96% responded, representing 53% of the primary magnesium consumption shown in tables 4 and 6. Data for the five nonrespondents were estimated based on prior year consumption levels and other factors.

Data for magnesium compounds was collected from one voluntary survey of U.S. operations. Of the 19 operations canvassed, 84% responded, representing 72% of the magnesium compounds shipped and used shown in table 14. Data for the three nonrespondents were estimated based on prior year consumption levels and other factors.

BACKGROUND

Definitions, Grades, and Specifications

Primary magnesium metal contains a minimum of 99.8% magnesium. Magnesium-base alloys are named by the

composition of the two chief alloying elements, each designated by a letter, and the approximate percentage of each alloying element. For example, AZ91 contains about 9% aluminum (A) and 1% zinc (Z), and HK31 contains about 3% thorium (H) and 1% zirconium (K). Other letters used in specifying magnesium alloys are E for rare-earth metals and M for manganese.

Magnesite, or magnesium carbonate ($MgCO_3$), has a theoretical magnesium content of 47.6%. Dolomite is a calcium carbonate-magnesium carbonate mineral ($CaCO_3 \cdot MgCO_3$) that has a theoretical magnesium content of 22%. Brucite, magnesium hydroxide [$Mg(OH)_2$], contains up to 69% magnesium, and olivine ($Mg_2Fe_2SiO_4$) contains up to 19% magnesium. Of these minerals, magnesite and dolomite are the largest sources of magnesium and magnesium compounds.

Seawater, brines, and bitterns represent vast sources of magnesium and magnesium compounds. In the United States, more than 60% of the magnesium compounds produced annually is recovered from seawater and brines, and 80% of the magnesium metal production capacity uses seawater or brines as a raw material.

Various magnesia products are made by calcining magnesium carbonate or magnesium hydroxide at different temperatures. Caustic-calcined magnesia, which is readily reactive with water, is calcined at temperatures up to 890° C. Dead-burned magnesia, also called refractory or sintered magnesia, is

calcined at temperatures up to 1,450° C and is unreactive with water. Fused magnesia is produced at temperatures greater than 3,000° C. Magnesia produced from magnesite is generally called natural magnesia, and magnesia produced from seawater or brines is called synthetic magnesia.

Standards for magnesia, including chemical composition, bulk density, and particle size, generally are set by the consumer for a specific application. Refractory magnesia composition depends on the area of the furnace in which the material is to be used. Magnesia produced from magnesite can contain between 88% and 98% magnesia, with varying quantities of silica, iron, calcium, and alumina impurities. Synthetic magnesia normally is purer than natural magnesia, containing between 92% and 99.5% magnesia, with smaller quantities of the same impurities found in natural magnesia. Most fused magnesia contains greater than 94% magnesia.

Products for Trade and Industry

The principal use for magnesium metal, averaging greater than 50% of U.S. consumption annually, is as an alloying addition to aluminum. Magnesium improves the hardness and corrosion resistance of pure aluminum. Aluminum-magnesium alloys are used in a variety of applications, including automobiles, trucks, aircraft, appliances, and home siding. Two-piece beverage cans, containing about 2% magnesium, are the largest single use for these aluminum-magnesium alloys.

Magnesium and its alloys are used as structural components on automobiles, trucks, aircraft, computers, and power tools. Many of these applications use magnesium because of its light weight and ease of machinability. Magnesium is used in the iron and steel industry for external hot-metal desulfurization and in the production of nodular iron. Production of the nonferrous metals, beryllium, hafnium, titanium, uranium, and zirconium, involves the use of magnesium as a reducing agent. Anodes of magnesium are used for cathodic

protection of underground pipe and water tanks. Small quantities of magnesium are used as a catalyst in producing organic compounds, as photoengraving plates, and in alloys other than aluminum.

Refractory magnesia represents the largest use of magnesium in compounds. Refractory magnesia is manufactured into bricks and other shapes principally for linings in furnaces and auxiliary equipment used to produce iron and steel. Magnesia-base refractories also are used in furnaces in the cement, glass, and nonferrous metals industries.

Caustic-calcined magnesia is used in a variety of applications in the agricultural, chemical, construction, and manufacturing industries. Caustic-calcined magnesia is an important component of animal feed and fertilizer, providing essential nutrients for livestock and plant growth. In construction, caustic-calcined magnesia is used in special cements for industrial flooring and in lightweight insulating wallboard. In the chemical industry, it is used as a starting point for the manufacture of other magnesium salts. Special grades of caustic-calcined magnesia are used for pharmaceuticals, including antacids, toothpaste, milk of magnesia, and cosmetics. Magnesia is used to remove sulfur from flue gases and boiler fuels and is used for acid neutralization in process wastewater and in lubricating oils. Caustic-calcined magnesia is also important in manufacturing paper, rayon, and rubber.¹

Other magnesium compounds are used in place of, or in addition to, caustic-calcined magnesia in many of the above applications. Magnesium hydroxide is used in the pulp and paper industry; magnesium sulfate is used for pharmaceuticals, animal feed, and fertilizers; and magnesium carbonate is used in the chemical, pharmaceutical, and rubber industries. Fused magnesia is used primarily for electrical insulation.

The principal use for olivine is as a foundry sand used in casting iron and steel components and some nonferrous metals. Olivine is used in smaller quantities for refractories, slag control in blast furnaces, and soil conditioning. In

Europe, olivine is used instead of silica sand for blasting debris from bridges and buildings and in incinerators.²

Industry Structure

U.S. producers of magnesium and magnesium compounds are shown in tables 1 and 2. Olivine is produced by two companies in the United States—Applied Industrial Minerals Corp. (AIMCOR) and Olivine Corp. AIMCOR operates two mines in North Carolina and Washington and processing plants in Indiana, North Carolina, and Washington, and Olivine operates one mine and one processing plant in Washington.

Electrolytic plants in Canada, Norway, the U.S.S.R., and the United States represent 85% of the world magnesium metal production capacity. Smaller thermal plants are in Brazil, Canada, China, France, India, Italy, Japan, and Yugoslavia.

The largest magnesite production facilities in the world are in China, North Korea, and the U.S.S.R. Together, these three countries account for 53% of the world magnesite production capacity. Japan and the United States account for 59% of the world's magnesium compounds production capacity from seawater or brines. Fused magnesia is produced in Canada, France, Israel, Japan, the United Kingdom, and the United States.

Norway is the world's principal producer of olivine, and in addition to supplying its domestic needs, Norway is a major world supplier of olivine. Countries with smaller output are Austria, Italy, Japan, Mexico, Spain, Sweden, and the United States. (See tables 1 and 2.)

Geology

Magnesium is the eighth most abundant element and constitutes about 2% of the Earth's crust. It is the third most plentiful element dissolved in seawater, with a concentration averaging 0.13%. Although many minerals contain magnesium, magnesite, dolomite, brucite, and olivine are the only minerals from

which magnesium compounds are recovered commercially.

Dolomite is a sedimentary rock commonly interbedded with limestone, which extends over large areas of the United States. Most dolomite occurrences are likely the result of replacement of calcium by magnesium in preexisting limestone beds. Magnesite primarily is found in four types of deposits—sedimentary beds, alterations of serpentine, vein fillings, and replacements of limestone and dolomite. Brucite is found in crystalline limestone and as a decomposition product of magnesium silicates associated with serpentine, dolomite, magnesite, and chromite. Olivine generally occurs as granular masses or disseminated grains or crystals and is a common constituent of basic igneous rocks such as basalt and gabbro. Dunite is an olivine-rich rock.³

Technology

Processing—Metal.—Two thermal processes currently are in use to recover magnesium metal from dolomite—the Pidgeon process and the Magnetherm process. Both use the same basic chemistry, but the Pidgeon process uses an external heat source, and the Magnetherm process uses heat generated by the electrical resistance of the reactants. In the Pidgeon process, dolomite and ferrosilicon are formed into briquettes and heated in a retort under a vacuum. Magnesium oxide in the dolomite reacts with the ferrosilicon to produce magnesium vapor, which is cooled and condensed in a separate section of the retort. Plants in Canada, Italy, and Japan use this process to recover magnesium.

In the Magnetherm process, calcined dolomite, ferrosilicon, and alumina are heated under a vacuum. Alumina reduces the melting point of the slag produced by the dolomite-ferrosilicon reaction to make resistance heating practical. Magnesium vapor is cooled and condensed in a condensing chamber. The Magnetherm process is used in plants in Brazil, France, Japan, the United States, and Yugoslavia.

Electrolytic recovery of magnesium requires a magnesium chloride feedstock that normally is prepared from seawater or brines. Two types of magnesium chloride can be made—hydrous and anhydrous. In the preparation of hydrous magnesium chloride, used by Dow Chemical Co., magnesium hydroxide is precipitated from seawater by the addition of dolomitic limestone. Adding hydrochloric acid to the magnesium hydroxide produces a neutralized magnesium chloride solution. This solution is dehydrated until it contains about 25% water and then is fed directly to electrolytic cells.

Magnesium Corp. of America (MagCorp) and Norsk Hydro A/S of Norway use an anhydrous magnesium chloride feed for their electrolytic cells. MagCorp uses solar evaporation initially to concentrate magnesium chloride brines from the Great Salt Lake. After adding calcium chloride to precipitate sulfate impurities and removing boron by solvent extraction, the brine is concentrated further and dehydrated in a spray dryer. The resulting powder is purified, concentrated, prilled, and dehydrated to produce anhydrous magnesium chloride.⁴ Norsk Hydro starts with concentrated magnesium chloride brine. The brine is purified, concentrated, prilled, and dehydrated to produce anhydrous magnesium chloride.

Electrolytic cells used to recover magnesium from either hydrous or anhydrous magnesium chloride differ from company to company, and most information about cell design and operating conditions usually are not disclosed. Essentially, magnesium chloride fed to an electrolytic cell is broken down into magnesium metal and chlorine gas by direct current at 700° C. Magnesium is removed from the cell and cast into ingots, and the chlorine gas is recycled or sold.

Magnesium International Corp. developed a one-step process for producing anhydrous magnesium chloride that was demonstrated at Magnesium Co. of Canada Ltd.'s (MagCan) new plant that opened in 1990 and closed in 1991. Reacting magnesite with chlorine gas in

the presence of carbon monoxide in a packed-bed reactor at 900° C produces magnesium chloride and carbon dioxide. Liquid magnesium chloride collects at the bottom of the reactor and is tapped periodically for transfer to electrolytic cells.⁵

Processing—Nonmetal.—Preparing either caustic-calcined or dead-burned magnesia from magnesite involves crushing the magnesite to various sizes, depending on the type of material to be produced. After crushing, magnesite is beneficiated; the degree of beneficiation depends on the quality of the ore and its ultimate end use. Lower quality ore often requires heavy-media separation, magnetic separation, and flotation to remove impurities. High-quality ore may require only screening and hand sorting to produce a material of acceptable quality. Caustic-calcined magnesia is produced in shaft kilns, multiple-hearth furnaces, or rotary kilns. Dead-burned magnesia is produced in rotary or shaft kilns.

In producing synthetic magnesia, seawater or brines are treated either with a small quantity of lime or sulfuric acid to remove dissolved carbon dioxide. Then calcium hydroxide, in the form of lime or dolime, is added to precipitate the dissolved magnesium as magnesium hydroxide. The resulting slurry is thickened and vacuum-filtered to yield a filter cake containing about 50% magnesium hydroxide. The filter cake can be directly calcined to produce caustic-calcined or dead-burned magnesia, or it can be calcined and pelletized before dead-burning to give specific size and density characteristics.

Fused magnesia is produced by fusion of high-grade magnesite or caustic-calcined synthetic magnesia in an electric arc furnace. After fusion, the material is crushed, inspected to remove any unfused magnesia, and crushed further in a ball mill.

Recycling.—Magnesium scrap is in forms similar to those of other nonferrous metals. New scrap comes in forms such as castings, drippings, drosses, gates,

runners, and turnings. Old scrap primarily comes from old aircraft parts and discarded consumer products, such as lawnmower decks, chainsaw housings, and hand tools. The diecasting industry traditionally is the largest source of scrap magnesium.

Sorted scrap is charged into a steel crucible, which is heated to 675° C. As the scrap at the bottom begins to melt, more scrap is added. The liquid magnesium on the bottom is covered with a flux to inhibit surface burning. After any alloying elements are added and melting is complete, molten magnesium is transferred to ingot molds by either hand ladling, pumping, or tilt pouring.⁶

Economic Factors

Costs to produce magnesium metal vary greatly, depending upon the feed material and the process used. Operating costs for magnesium production range from \$309 to \$2,283 per metric ton, with energy costs as the largest component of the total operating cost. Total production costs from seawater sources were lower than from brines or dolomite sources. Magnesium compound operating costs also vary depending upon source material and processing techniques. Operating costs range from \$24 to \$425 per ton for magnesium compound production, with seawater as the most costly source. Energy costs also represent the largest component of total operating costs.⁷

Tariffs for magnesium and magnesium compounds are shown in table 3. The depletion allowance for magnesium chloride from domestic or foreign sources is 5%. Magnesium carbonate and dolomite have depletion allowances of 14% from domestic and foreign ores. Depletion allowances for other ores are brucite, 10% (domestic and foreign); and olivine, 22% domestic and 14% foreign. (See table 3.)

ANNUAL REVIEW

Magnesium

Legislation and Government Programs.—On September 5, MagCorp initiated an antidumping and countervailing duty investigation into imports of magnesium from Canada and Norway. In its petition filed with the International Trade Commission (ITC), MagCorp claimed that imports of pure and alloy magnesium were being sold in the United States for less-than-fair value. MagCorp also claimed that these imports threaten material injury to the U.S. magnesium producers.⁸ On September 25, ITC dismissed the countervailing duty investigation concerning imports of primary magnesium from Norway.⁹

On December 2, the International Trade Administration (ITA) announced a preliminary determination that magnesium imports from Canada were subject to a countervailing duty of 32.85% ad valorem. This determination applies only to Norsk Hydro; Timminco Ltd.'s countervailing margins were assessed at 0.04%, less than the amount for which duties are collected. ITA cited five programs that benefited Norsk Hydro—preferential electric rates, grants from the Quebec Industrial Development Corp., exemptions from water bills, Institute of Magnesium Technology research, and the Canadian-Quebec Subsidy Agreement.¹⁰ Final countervailing duties and preliminary antidumping duties were scheduled to be announced in 1992.

On May 20, the Environmental Protection Agency made a final determination that none of the 20 waste streams excluded from the Resource Conservation and Recovery Act (RCRA) under the Bevill amendment will be regulated as hazardous. Included in this determination is wastewater from magnesium processing generated at MagCorp's plant in Rowley, UT. The 20 waste streams may be regulated under a special subtitle D of RCRA being developed for nonhazardous mining extraction and beneficiation wastes.¹¹

Production.—U.S. primary magnesium producers operated at about 73% of their rated capacity in 1991, and total production dropped by about 6% from that of 1990.

Northwest Alloys Inc., a wholly owned subsidiary of the Aluminum Co. of America (Alcoa), announced in late December that it would reduce the operating rate at its Addy, WA, magnesium production plant by 50% by March 31, 1992. About one-half of the plant's work force of 500 was expected to be laid off. Northwest Alloys had been supplying outside contracts in addition to Alcoa's internal needs, but after the shutdown, outside contracts will not be renewed after they expire. The plant, which uses the Magnetherm process, has nine furnaces, but has been running only seven or eight for most of the year. The shutdown will reduce the number of active furnaces to four or five. (See table 4.)

Consumption and Uses.—U.S. automakers continued to replace some aluminum and steel components with magnesium. General Motors Corp. planned to incorporate 6.8 kilograms of magnesium parts into its V-8 engines for limited use in its Cadillac models beginning in mid-1992. Ford Motor Co. approved 1.1-kilogram magnesium seat supports for its 1994 model Aerostar minivans. Ford also announced that it would use magnesium steering columns in the 1992 models of its light-duty trucks. By 1993, Ford estimates that the steering columns, which are already incorporated in some of its passenger cars, will consume about 6,700 tons of magnesium annually. Suppliers for the steering columns will be Diemakers Inc., Monroe City, MO, and the Contech Div. of SPX Corp., Kalamazoo, MI.

Chrysler Corp. planned to use almost 2.7 kilograms of magnesium in engine components in its low-volume Viper sports cars, due out in 1992. Chrysler also expected to use 1.4-kilogram magnesium steering column brackets in its 1993 models of a new midsize car. In addition, Chrysler announced that it

would incorporate 2 kilograms of magnesium accessory drive brackets in its 1993 Jeep sports utility wagons.

Diemakers was chosen as the supplier for magnesium valve covers for the 1994 models of Chrysler's T-300 truck V-10 engines and its 1992 Dodge Viper 10-cylinder engines. The truck valve covers were expected to require more than 70 tons of magnesium annually, and the Viper valve covers were expected to use more than 11 tons annually. As a result, Diemakers broke ground for an additional 3,600-ton-per-year expansion that would double the company's total diecasting capacity.

Toyota Motor Corp. reportedly began purchasing magnesium cam covers from U.S.-based Tennessee Diecasting Div. of Harvard Industries Inc. for some of its in-line 6-cylinder engines. Each cam cover uses about 1.8 kilograms of magnesium.

As a result of the increased interest in magnesium automotive components, Spectrulite Consortium Inc. and Latrobe Industries Inc. formed a joint venture to produce magnesium castings primarily for this market. Initial plans were to convert existing aluminum casting equipment at Latrobe's plant in Pennsylvania to magnesium casting. Latrobe Spectrulite scheduled its first production for the second quarter of 1991 and planned to install additional casting equipment as sales volume requires. (See tables 5 and 6.)

Stocks.—Consumer stocks of primary magnesium ingot decreased to 4,876 tons at yearend 1991 from 5,428 tons at yearend 1990. Consumer stocks of magnesium alloy ingot also decreased to 739 tons at yearend 1991 from 879 tons at yearend 1990. Producers' stocks of primary magnesium were 21,294 tons at yearend 1991, a 9% increase from 1990 yearend stocks of 19,535 tons. (See table 7.)

Markets and Prices.—At the beginning of the year, MagCorp announced that it lowered its price for primary magnesium by 20 cents to \$1.43 per pound in order

to match Dow's price, which had been decreased to \$1.43 per pound in December 1990. Although both companies maintained these price quotes throughout the rest of 1991, press sources reported that actual selling prices for primary magnesium were about \$1.10 to \$1.25 per pound by yearend.

At the end of January, Dow announced that it would reduce its prices for diecasting alloy AZ91D from \$1.43 to \$1.34 per pound. As an incentive for automobile manufacturers to use magnesium, alloy prices traditionally have been lower than primary magnesium prices. By reducing the quoted price, Dow reinforced this tradition. Reductions in both primary metal and diecasting alloy prices were attributed to increases in inventories and surplus capacity.

Foreign Trade.—Exports of magnesium increased by 6% from those of 1990. The Netherlands (28%), Japan (24%), and Canada (15%) were the primary destinations for U.S. exports. The United States continued as a net exporter of magnesium.

For the second year in a row, Canada was the principal source of magnesium imports, accounting for 89% of the total in 1991. Total imports were 19% greater than those in 1990; most of this increase was the result of increased imports of primary metal from Canada. (See tables 8 and 9.)

World Review.—World production of primary magnesium dropped by about 4% in 1991, with most of the decline in Europe and the United States. According to the International Magnesium Association, world inventories were 55,100 tons at yearend 1991, which was a 26% increase from inventories at yearend 1990.

By the second quarter of 1991, Dow and Norsk Hydro increased price quotes for primary magnesium marketed in Europe by 5%, but neither company would say how much the increase was or what the new prices were. According to the companies, the new price quotes more accurately reflected supply-demand

conditions. Press sources indicated that magnesium was selling at approximately \$1.10 to \$1.20 per pound in Europe.

By yearend, however, significant quantities of magnesium reportedly were entering the European market from the U.S.S.R., which led to an oversupply situation, and reports of prices for this material were about 80 cents per pound. To correct what the company felt was erroneously low free market price quotes stemming from the Soviet material, Norsk Hydro announced that they would establish a European producer price beginning in 1992. Norsk Hydro planned to report this price on a quarterly basis and stated that the new price quote would reflect actual transaction prices. In December, Norsk Hydro announced that the first quarter 1992 price would be 3.85 Deutchemarks per kilogram, equivalent to about \$1.09 per pound. (See table 10.)

Australia.—Queensland Metals Corp. (QMC) reportedly accelerated the development of its planned 60,000-ton-per-year magnesium production plant in Australia. Design studies for a pilot plant were scheduled to be completed by yearend, and research continued on producing high-purity magnesium chloride from QMC's magnesite deposit to feed the proposed plant. QMC's accelerated development of the project was prompted by the projected increase in the use of magnesium in automotive applications. The Australian Government announced that it would help fund a research project to construct a 1,600-ton-per-year pilot plant to produce magnesium from QMC's magnesite deposit. The planned completion date for the pilot plant is 1994.

Brazil.—In July, Cia. Brasileira de Magnesio (Brasmag) filed a petition with the Brazilian Economy Ministry Department claiming that U.S. and Canadian magnesium producers dumped magnesium and magnesium alloys in Brazil. According to Brasmag, Norsk Hydro in particular was able to sell its magnesium at a low cost because of Government subsidies. Brasmag reportedly reduced its annual production

rate from 12,000 tons to 8,000 tons because of the alleged dumping. Brasmag also indicated that the dumping occurred when the Brazilian Government decided to open its economy by reducing import duties. According to Norsk Hydro, however, its sales to Brazil were small; the company exported 57 tons of magnesium to Brazil in 1990 and planned to increase that to 200 to 300 tons in 1991. Decisions on the antidumping charges were expected to be completed in 1992.

Canada.—In April, Alberta Natural Gas Co. Ltd. (ANG) announced that it would no longer fund the 12,500-ton-per-year primary magnesium plant operated by MagCan. ANG, the project's primary financial backer, cited high operating costs and high interest rates as factors in its decision. MagCan's plant in Alberta was closed at the end of April. The plant had not operated at full capacity since its startup in early 1990 because of technical problems at the facility. At yearend, the Province of Alberta was seeking a buyer for the closed plant; the Province had issued loan guarantees for the plant.

Timminco reportedly began a reorganization of its metals division in April, which included a reduction in production at its Haley, Ontario, primary magnesium plant. The reorganization was expected to result in adjusted inventories and production levels in line with current demand.

Norsk Hydro planned to cut back production at its Becancour, Quebec, primary magnesium plant by 40% to about 20,000 tons per year, beginning in November. Although the rated annual capacity of the plant was 45,000 tons, the plant reportedly had been operating at a rate of 35,000 tons per year. With the reduction in capacity at Becancour, coupled with an earlier cutback at the company's Porsgrunn, Norway, plant, Norsk Hydro expected the company's total production in 1992 to drop by 25,000 to 35,000 tons from 1991 levels.

Development of the Magnola project in Quebec suffered a setback because of the bankruptcy of the Lavalin group, owner of one of the joint-venture partners.

Although Lavalin has been purchased, Noranda, the second joint-venture partner, did not know what the corporation that purchased 52% of Lavalin intends to do with the Magnola project. Any startup of a planned 50,000-ton-per-year plant designed to recover magnesium from asbestos tailings has been delayed until 1997. A third joint-venture partner is being sought for the project, and the next stage, which involves an engineering and feasibility study, has been delayed until the end of 1992.

Hydro Magnesium announced that it signed an agreement with Meridian Technologies of Canada to develop magnesium wheels for the North American automobile industry. The development programs will consist of two stages. First, the market prospects will be analyzed, and a process to produce high-pressure magnesium wheel diecastings will be developed. A decision on the second stage, construction of a wheel plant, was expected to be made early in 1992.

Japan.—Magnesium demand exceeded 27,000 tons in 1990, according to the Japan Light Metals Association, which was an alltime record. Aluminum alloys, primarily for use in beverage cans and in construction, accounted for about 74% of Japan's magnesium demand. Castings accounted for about 5%, nodular cast iron production accounted for 11%, and the remaining 10% of demand was consumed for cathodic protection and other uses. Demand for magnesium in 1991 was projected to be 30,000 tons, with aluminum alloying continuing as the largest end-use sector.¹²

Norway.—Norsk Hydro announced that it would cut back production at its Porsgrunn plant to 35,000 tons per year by closing one of the plant's two production lines. The plant reportedly was operating at an annualized rate of 45,000 tons until the shutdown in the autumn. During the closure, Norsk Hydro planned to modernize the facilities to improve flexibility. The shutdown was scheduled to last for 2 years.

Beginning in 1992, Norsk Hydro will need to find a new raw material source for magnesium production. Kali und Salz GmbH, a German potash producer, was supplying the Porsgrunn facility with byproduct magnesium chloride brines from its Salzdetfurth facility. Kali und Salz planned to close this facility during 1991 and would be able to supply Norsk Hydro through yearend 1991 from stocks. Billiton Refractories BV of the Netherlands was cited as a potential supplier of magnesium chloride raw materials from its solution mining operation in Veendam.¹³

Yugoslavia.—In February, Magnohrom reportedly cut back production at its 7,000-ton-per-year primary magnesium plant in Bela Stena by 15% to 20%, citing deteriorating market conditions and availability of less costly material from the U.S.S.R. During the cutback, which may extend into 1992, Magnohrom planned to overhaul production equipment in order to reduce production costs. (See tables 11 and 12.)

Magnesium Compounds

Production.—Production of caustic-calcined magnesia increased significantly in 1991 at the expense of dead-burned magnesia production, which declined by almost the same quantity. Seawater and brines were the source material for about 72% of the total U.S. production of magnesium compounds. U.S. production of olivine in 1991 declined by 7% from that of 1990, but the average value of production increased by 30%. (See table 13.)

Consumption and Uses.—Dead-burned magnesia refractories for use in metal, cement, and glass production furnaces continued to be the primary application for magnesium compounds in the United States. In 1991, agricultural applications (animal feed and fertilizer) were the dominant use for caustic-calcined magnesia, accounting for 26% of U.S. shipments. Chemical processing was the next largest segment, with 22% of total

shipments. The following categories, with the individual components in parentheses in declining order, were the other end-use sectors for caustic-calcined magnesia: Metallurgical (refractories, water treatment, electrical, foundry, and stack-gas scrubbing), 21%; manufacturing (rayon, fuel additives, rubber, and pulp and paper), 17%; construction (oxychloride and oxysulfate cements, general construction, and insulation), 6%; pharmaceuticals and nutrition (medicinal and pharmaceutical, sugar, and candy), 3%; and unspecified uses, 5%.

Magnesium carbonate was used principally in medicines and pharmaceuticals, with additional applications in chemical processing and fertilizers. Magnesium hydroxide was used mainly in the pulp and paper and chemical industries, with smaller usage in water treatment and medicines. Magnesium sulfate was used mostly in pharmaceuticals and animal feed. Other applications for magnesium sulfate included chemical processing, insulation, and oxysulfate cements. Magnesium chloride was used in chemical processing and in oxychloride cements. Magnesium chloride brines were used for road dust control and chemical processing.

Foundry uses continued to be the largest application for olivine in the United States, accounting for 66% of consumption of domestically produced material. Refractory applications accounted for 16%, sand blasting and other abrasive applications accounted for 11%, and slag control accounted for the remaining 7% of U.S. olivine consumption.

Martin Marietta Magnesia Specialties Div. announced the development of a new product for water treatment applications. The new product, called FlowMag, was designed to remove heavy metals and neutralize acids from industrial wastewater processing streams. The new product reportedly produces less than 30% of the sludge volume normally produced when the wastewater is treated in a clarifier system. Disposal costs, therefore, were lower, and the company claimed that FlowMag was 40% to 100% more efficient on a weight basis.

In a review article on flame retardants, the properties of magnesium hydroxide were discussed. Magnesium hydroxide has a flame retardant effect by releasing its water of hydration to delay combustion, and when combustion does occur, the combustion products are nontoxic. Magnesium hydroxide competes with aluminum trihydrate in flame retardant applications. It is slightly less effective, but it also is less costly. The main application for magnesium hydroxide is in polymers such as polypropylene and nylon, which have to be processed at high temperatures.¹⁴

The glass industry used a variety of magnesia-base refractories in its production furnaces; magnesia, magnesia-chrome, and magnesia-spinel bricks were the most commonly used. Magnesia-chrome bricks were becoming less frequently installed in newer furnaces because of environmental concerns about the hexavalent chrome ion. Hexavalent chrome is considered carcinogenic and is water soluble. Problems arise when the refractories are removed from the furnace and discarded. New furnaces tended to install magnesium-aluminum-spinel, high-alumina, and fused-cast refractories to alleviate the environmental risks.¹⁵ (See table 14.)

Markets and Prices.—Yearend prices for magnesium compounds, as quoted in the Chemical Marketing Reporter, remained the same as those at yearend 1990. Beginning in 1991, the U.S. Bureau of Mines began including prices for dead-burned and synthetic magnesia in table 15. (See table 15.)

Foreign Trade.—Olivine trade data were not reported separately by the Bureau of the Census. The Journal of Commerce Port Import/Export Reporting Service (PIERS) provided some information on U.S. trade in olivine; this source, however, reports only those materials that are transported by ship. According to PIERS, 2,424 tons of olivine was exported in 1991. Peru, 44%, and Chile, 40%, were the primary recipients. Imports of olivine, all from

Norway, totaled 93,755 tons. (See tables 16, 17, 18, and 19.)

World Review.—Australia.—Production at QMC's open pit magnesite mine at Kunwarara, Queensland, began in early April. By June, the first ore from the mine was run through the preconcentration and beneficiation plants in Parkhurst. During the first year of production, QMC expected to produce 67,000 tons of dead-burned magnesia and 12,000 tons of fused magnesia. Total annual production at the plant was expected to reach 150,000 tons of dead-burned magnesia and 25,000 tons of fused magnesia by 1995.

In addition to dead-burned and fused magnesia, QMC was developing other magnesia products through joint-venture operations. QMC was working with CSIRO on three projects, called Environmag, Cemag, and Flamemag. The Environmag project was investigating the market potential and technical requirements for magnesia and magnesium hydroxide in environmental applications. Cemag was a research and development project for the production of magnesia-base cements. Flamemag was also a research and development project to develop low-cost, high-purity magnesia and magnesium hydroxide for use as flame retardants.¹⁶

Austria.—Radex Heraclith AG announced that it purchased a majority stake in Austria's other magnesite producer, Veitscher Magnesitwerke AG in April. Radex planned to combine its refractories operations with the newly purchased shares of Veitscher Magnesitwerke into a holding company, Osterreichische Magnesit AG. Radex operated a magnesite mine and 120,000-ton-per-year magnesia plant, and Veitscher Magnesitwerke operated a mine and 375,000-ton-per-year magnesia plant.

Canada.—By early 1991, Baymag's fused magnesia plant in Exshaw, Alberta, reportedly was operating at 20% more than its rated annual capacity of 14,000 tons. In response to the demand for fused magnesia, the plant was scheduled

to undergo an expansion to double capacity by the addition of two furnaces.

Czechoslovakia.—The Government-owned magnesite mining operation, Slovenske Magnezitove Zaovdy (SMZ), announced plans to decrease magnesite extraction by 25% by the year 2000. Adverse ecological effects of the mining operations were cited as the reason for the decrease in production. Instead of increasing production to generate more revenue, SMZ planned to focus on improving the quality of its products.

Greece.—Grecian Magnesite S.A. and Lafarge Refractaires Monolithiques of France reportedly formed a joint venture to produce basic monolithic refractories at a new plant in Greece. The joint-venture company, Ellamag Monolithic Refractories S.A., will be owned 51% by Lafarge and 49% by Grecian Magnesite. Grecian Magnesite will provide the raw materials from its nearby mines, and Lafarge will provide its expertise in refractories. Ellamag's initial capacity was expected to be 18,000 tons per year, and production was scheduled to begin in the spring of 1992.

India.—In an article reviewing the country's industrial minerals, changes in India's magnesite industry were highlighted. More than 80% of India's magnesite reserves were high in calcium oxide and iron oxide, and consequently were not suitable as refractory materials for India's iron and steel industry. Magnesite producers were considering further beneficiation of the magnesite or producing magnesia from seawater to satisfy the iron and steel industry's needs. Demand for dead-burned magnesia in the iron and steel industry is declining with the decrease in the use of open-hearth furnaces in steelmaking. Also affecting India's magnesite industry is the policy that prohibits exports of Indian magnesite and allows imports of dead-burned magnesia with less than 6% silica content. Refractories manufacturers are allowed to import dead-burned magnesia at concessional duties on the grounds that domestically produced material is

unsuitable for their needs. Consequently, India's magnesite producers were facing competition from imported material from Brazil, China, North Korea, and Turkey.¹⁷

Tamilnadu Magnesite Ltd. and Khaitan Supermag Ltd. reportedly formed a joint venture to construct a 30,000-ton-per-year high-quality, dead-burned magnesia plant. The joint-venture partnership was called India Magnesia Products Ltd., and initial production was expected to begin in the first quarter of 1993.

Israel.—Dead Sea Periclase Ltd. and Japan's Tateho Chemical Industries Co. Ltd. reportedly formed a partnership to produce fused magnesia in Israel. The new company, called Tateho Dead Sea Fused Magnesia Co., was expected to begin construction of a \$28 million, 13,000-ton-per-year plant at Dead Sea Periclase's existing location in Mishor Rotem in early 1992. Initial product shipments were scheduled to begin at the end of 1993. Tateho Chemical operates fused magnesia plants in Japan and the United States, and Dead Sea Periclase operates a synthetic magnesia plant in Israel. (See tables 20 and 21.)

OUTLOOK

The International Magnesium Association's annual forecast of world magnesium supply and demand for 1991 estimated an annual average growth rate of 3.0% in magnesium consumption from 1990 to 1996. Most of the growth was expected to occur in diecasting, wrought products, and desulfurization applications. In diecasting uses, Japan, North American, and Western European automotive industries were expected to be the largest growth areas. Wrought products, traditionally an area of stable consumption, was the second largest expected growth application. Magnesium's success in automotive applications was expected to translate into wrought product applications in Western Europe and North America. In desulfurization, expected growth in Latin American use of magnesium was responsible for the overall increase in

world demand. The International Magnesium Association also projected capacity utilization rates for the same period. World capacity (not including that of the U.S.S.R. and China) is expected to increase by about 10% from 1991 to 1996, and capacity utilization was expected to be 89% by 1996, compared with 84% in 1991.

Production and demand for magnesium compounds in the United States was expected to remain relatively stable over the new few years, but the proportion of magnesia used as refractories was expected to decrease. As refractories producers improve the quality of their products, furnace linings will not need to be replaced as frequently, thus lowering the demand for magnesia in refractory applications. But other magnesium compounds were gaining applications in new industries, particularly environmentally related applications. The increase in demand for other magnesium compounds, coupled with the decline in refractories demand, was expected to lead to a stagnant demand for magnesia in the United States.

Recent political changes in the former U.S.S.R. may have a significant effect on the supplies of both magnesium metal and magnesite. Normally, most of the magnesium produced in the U.S.S.R. was used in the production of titanium for defense applications. With the shift of emphasis away from defense applications and the country's need for hard currency, much of this magnesium may appear on the world market at greatly reduced prices; this has already occurred in Europe in 1991. In the United States, high tariff rates for countries with non-most-favored-nation status have minimized the effects of Soviet material, but if the independent States are given most-favored-nation status, material imported from the former U.S.S.R. may have a significant impact on U.S. supply of magnesium metal.

For magnesite, the U.S.S.R. was one of the world's largest producers. But non-most-favored-nation tariff rates also affect the importation of caustic-calcined and dead-burned magnesia into the United States. Changes in tariff rates also may

affect the U.S. supply of magnesia, although purity considerations in the products may limit their usefulness in domestic applications. (See table 22.)

TABLE 10
WORLD ANNUAL PRIMARY MAGNESIUM PRODUCTION CAPACITY,¹
DECEMBER 31, 1991,
BY CONTINENT AND COUNTRY

(Metric tons)

Continent and country	Capacity
North America:	
United States	179,000
Canada	54,000
Total	233,000
South America: Brazil	
	10,600
Europe:	
France	15,000
Italy	10,000
Norway	41,000
U.S.S.R.	² 214,000
Yugoslavia	7,000
Total	287,000
Asia:	
China	9,000
India	600
Japan	13,000
Total	22,600
World total	553,200

¹Includes capacity at operating plants as well as at plants on standby basis.

²Includes 90,000 tons of annual magnesium production that is used exclusively for titanium production.

¹Figures represent crude salable magnesite. In addition to the countries listed, Bulgaria produced magnesite, but output is not reported quantitatively, and available general information is inadequate for formulation of reliable estimates of output levels. Table includes data available through May 5, 1992.

²Series reflects output of marketable concentrates. Production of crude ore was as follows, in metric tons: 1987—860,163; 1988—810,837; 1989—1,385,565; 1990—1,432,741 (revised); and 1991—1,500,000 (estimated).

³Magnesian dolomite and brucite. Figures are estimated on the basis of reported tonnage dollar value.

⁴Year beginning Mar. 21 of that stated.

⁵Revised to zero.

MANGANESE

By Thomas S. Jones

Dr. Jones, a physical scientist with more than 30 years industry and U.S. Bureau of Mines experience, has been the commodity specialist for manganese since 1982. Domestic survey data were prepared by Glenn Wallace, statistical assistant; and the international data table was prepared under the direction of William Zajac, Chief, Section of International Data.

Manganese is essential to iron and steel production by virtue of its sulfur-fixing, deoxidizing, and alloying properties. Currently, no practical approaches exist for replacing it by other materials or for obtaining the bulk of U.S. requirements from domestic sources. The steel industries and economies of Japan and Western Europe are in much the same position relative to manganese as are those of the United States.

Ironmaking and steelmaking continued to account for about 90% of domestic manganese demand in 1991. For ore, rate and quantity of use in pig iron production were significantly lower than those in 1990. The quantity of U.S. imports of ore listed in table 1 was the least since 1982, whereas that of silicomanganese rose to a new record. Government inventories of manganese, all forms, were only minimally diminished and still represented more than 2 years of apparent consumption. U.S. strategic concerns about manganese were lessened by political developments relating to the Republic of South Africa and the former U.S.S.R.

In metallurgical applications, the main component of manganese demand, market conditions were generally subdued worldwide in 1991. The actual price of metallurgical-grade manganese ore declined slightly after 3 successive years of substantial advances. The price remained sufficiently high to support consideration of reactivating various former mining operations and development of known but previously unutilized resources. Prominent producers of ore and ferroalloys cut back on output.

World ore production was estimated to have decreased more than one-tenth. The Minerals Bureau of the Republic of South Africa revised its previously published data on ore production. The new figures for the 1980's generally were higher, significantly so in some instances.

The level and nature of manganese use by the United States is not expected to change much in the near future. The manner and extent of effects on global manganese supply and demand were not yet clear from transition of the former U.S.S.R. from Soviet states to republics. In 1990, traditionally large ore exports by the U.S.S.R. were almost insignificant.

DOMESTIC DATA COVERAGE

Data on domestic consumption of manganese ore, exclusive of that consumed within the steel industry, are collected by means of the "Manganese Ore and Products" survey. The approximately 20 firms canvassed by means of this survey process ore by such methods as grinding and roasting or consume it in the manufacture of manganese ferroalloys, metal, and chemicals. In 1991, responses were obtained from all firms canvassed, whose collective consumption is believed to represent that of the United States except for negligible quantities consumed by other firms, if any. The aggregated consumption data so obtained were incorporated into table 5 but only displayed within totals to avoid disclosing proprietary data.

BACKGROUND

Definitions, Grades, and Specifications

Ore.—The U.S. Bureau of Mines has compiled statistics on manganese-bearing ores, concentrates, nodules, and sinter, all referred to simply as "ore," by manganese content as follows: manganese ore, 35% or more manganese; manganiferous ore, less than 35% but not less than 5% manganese; and within the latter ferruginous manganese ore, 10% to 35% manganese; and manganiferous iron ore, 5% to 10% manganese.

Manganese ore may be considered as metallurgical, chemical, or battery grade. Metallurgical-grade material has an approximate manganese content range of 38% to 55% and may differ from chemical-grade ore only in physical form. Chemical- and battery-grade ores are often categorized by manganese dioxide (MnO_2) content, which typically is in the range of 70% to 85% (44% to 54% Mn). The U.S. Government maintains specifications for metallurgical, chemical, and battery grades of ore for stockpile purposes; industry has no corresponding standards.

Ferroalloys and Metal.—Ferromanganese is a manganese-iron-carbon alloy classified according to decreasing carbon content into standard or high-carbon grades, medium-carbon grades, and low-carbon grades. Silicon is also specified in silicomanganese (such as 18%) and ferromanganese-silicon (about 30%). For U.S. tariff purposes,

ferroalloys are required to have an iron content of 4% or greater; a manganese material with less iron would be treated as manganese metal. The specifications the U.S. industry generally follows for manganese ferroalloys and metal are those of the American Society for Testing and Materials.

Products for Trade and Industry

Metallurgical-grade ore is used primarily in making ferroalloys, pig iron, and steel. In making ferroalloys, ore with a relatively high manganese and low phosphorus content is particularly desirable.

The sulfur-fixing, deoxidizing, and alloying attributes of manganese, whose atomic weight is 54.94, are obtained mostly through use of intermediate forms such as ferromanganese. Manganese ferroalloys for use in steelmaking are selected on the basis of cost per manganese unit, allowable steel carbon and silicon specifications, and steelmaking practice. For 1991, with the cost of manganese in metallurgical ore taken as 1.0, the corresponding approximate costs per manganese unit were 2.0 for high-carbon ferromanganese, 1.8 for silicomanganese, 3.2 for medium-carbon ferromanganese, and 6.2 for manganese metal. Metallic manganese is little used per se because it is typically brittle and unworkable.

Manganese is added to aluminum principally by use of briquets of compacted aluminum and manganese powders that typically contain 75% Mn. Electrolytic manganese metal and aluminum-manganese master alloys that typically contain 25% Mn are also used for this purpose.

Various manganese dioxide-types of material, possibly ground, are used for batteries and other applications. These include natural mineral product (NMD) and synthetic dioxide produced either electrolytically (EMD) or chemically (CMD). If pure, these dioxides would contain 63.2% Mn.

Other manganese materials and some of their uses include manganese sulfate ($MnSO_4$) and manganous oxide (MnO)

for animal feed and soil conditioners, ground manganese ore for brick coloring, and potassium permanganate ($KMnO_4$) for water treatment.

Industry Structure

Makeup of the world's manganese ore producers has been chiefly as follows: Australia, Groote Eylandt Mining Co. Pty. Ltd. (GEMCO) plus recently Portman Mining Ltd.; Brazil, Cia. Vale do Rio Doce (CVRD) (including Urucum Mineração S.A.) and Indústria e Comércio de Minérios S.A. (ICOMI), plus a number of relatively small mines; China, apparently mostly small- to moderate-size operations in the eastern Provinces; Gabon, Compagnie Minière de l'Ogooué S.A. (COMILOG); Ghana, Ghana National Manganese Corp.; India, more than 200 mines, with Manganese Ore India Ltd. the most prominent company; Mexico, Cía. Minera Autlán de C.V. (Autlán); Republic of South Africa, The Associated Manganese Mines of South Africa Ltd. (AMMOSAL) and Samancor Ltd.; and the U.S.S.R., two large complexes, mining the Chiatura Basin in Georgia and the Nikopol' Basin in the Ukraine. Most ore produced goes into metallurgical applications.¹ Ore for nonmetallurgical uses generally is supplied by the large-scale producers mentioned plus smaller ones elsewhere.²

In recent years, the U.S.S.R. had been supplying more than 1 million tons³ of ore annually to Eastern Europe. However, such exports were only about 800,000 tons in 1987 and dropped precipitously to 141,000 tons in 1990. Radical political changes in Eastern Europe and the U.S.S.R. cast considerable uncertainty on the future of exports from the new republics of Georgia and Ukraine that formerly were the source of the U.S.S.R.'s exports. Otherwise, the supply of ore to the international market has been from an oligopolistic-like group of countries consisting of Australia (GEMCO), Brazil (ICOMI and CVRD), Gabon (COMILOG), and the Republic of South Africa (AMMOSAL and Samancor).

Smelting of ore into manganese ferroalloys is much more diversified than ore production. Leading ferroalloy producers are as follows: Brazil, Cia. Paulista de Ferro-Ligas (a number of plants); China, many plants; France, Société du Ferromanganèse de Paris-Outreau (SFPO); Federal Republic of Germany, Thyssen Stahl AG; Japan, Japan Metals & Chemicals Co. Ltd. and Mizushima Ferroalloy Co. Ltd.; Mexico, Autlán; Norway, Elkem A/S; Republic of South Africa, Metalloys Ltd., a subsidiary of Samancor; and the U.S.S.R., a number of plants. The U.S.S.R. has been by far the largest producer.

Four market economy countries (MEC's) currently produce metal, all electrolytically, in decreasing order of capacity: the Republic of South Africa, the United States, Japan, and, beginning in 1989, Brazil. China and the U.S.S.R. produced metal, including that obtained metallothermally in the U.S.S.R. World productive capacity for metal was given as 84,000 tons annually as of 1985⁴ and would be approximately the same in 1991.

Annual world capacity for EMD was assessed as 218,000 tons in 1989, including capacities of 78,000 tons for Japan and 39,000 tons for the United States.⁵ The main change since has been the establishment of a new plant in Australia with an annual capacity of about 20,000 tons. The principal producer of CMD is Belgium's Sedema S.A., with annual capacity of about 40,000 tons.

Geology-Resources

The world's major land-based economic resources of manganese are of two principal types: marine chemical sediments and secondary enrichment deposits.⁶ Marine chemical deposits represent a majority of known resources. In 1985, the Manganese Centre (name changed in 1989 to International Manganese Institute) estimated that known relatively high-grade deposits (those with a manganese content of at least 44%) contained about 360 million tons of manganese.⁷ As given in the

"World Review" section of this chapter, the reserve base for manganese can be considered more than 10 times this size. The world's potential supply of manganese also includes extensive marine accumulations, such as oxide nodules on deep ocean floors and oxide crusts on midocean ridges, whose commercial future is indeterminate.

Among the more common minerals occurring in manganese ores are oxides, including pyrolusite, a mineral form of manganese dioxide; the oxysilicate braunite; and rhodochrosite, a mineral manganese carbonate. Many of the minerals occurring in South Africa's Kalahari Field have been described in a recent article.⁸

Technology

Exploration.—Highly selective methods of locating land manganese deposits do not exist, but interpretation of geologic environments can assist prospecting.⁹

Mining.—Most manganese ore is produced by mechanized operations. Standard earth-moving equipment is used in surface mining. Underground mining generally is by room-and-pillar techniques. Selective mining may be practiced in producing battery- and chemical-grade ores from a deposit being worked principally for metallurgical-grade ore.

Beneficiation.—Crushing, screening, washing, jigging, and tabling as well as flotation, heavy-medium, and high-intensity magnetic separation are being or have been used to upgrade raw manganese ore into usable concentrates. Carbonate ore may be calcined. Ore fines are sintered into bulkier shapes at some ferroalloy plants, a practice being adopted increasingly by ore producers as well.

Processing.—Electrothermy is the predominant method of manufacturing manganese ferroalloys, as by the submerged-arc-furnace process.¹⁰ Blast furnace-type operations are still used in a few foreign countries to make important

quantities of high-carbon ferromanganese. Recovery of metallics other than iron from manganese-bearing ore is rare.

Manganese metal and EMD commonly are produced by electrolyzing a solution of manganese sulfate prepared from ore that has been reduction roasted. Production of the dioxide is especially sensitive to minor ore impurities.¹¹ CMD can be prepared by precipitating manganese carbonate from a sulfate solution and decomposing the carbonate to oxide.¹²

Recycling.—Scrap recovery specifically for manganese is insignificant. Considerable manganese reenters processing as a minor component of steel scrap, steel slag, and nonferrous scrap. Such recycling of manganese tends not to lead to a progressive buildup in steelmaking but it does in aluminum processing.

Economic Factors

As noted in a study by the Minerals Availability Program (MAP) of the U.S. Bureau of Mines, transportation is the most significant cost element in the production of manganese concentrates.¹³ In a recent MAP assessment of costs for most major mines in MEC's, transportation accounted for about two-thirds of concentrate cost. Transportation costs were about equally divided between transportation to the port and transportation to the market. Also according to this assessment, the major mines for metallurgical-grade ore of the MEC's are quite competitive as to ore production cost. Of the considerable resources evaluated, about 80% had estimated production costs within 20% of the lowest cost.

Operating Factors

Environmental Requirements.—In 1988, the Environmental Protection Agency (EPA) imposed an annual requirement of reporting releases to the environment of manganese chemical compounds and metal (40 CFR 372). This initially applied to operations

classifiable within Standard Industrial Classification codes 20 to 39 that annually manufacture or process at least 75,000 pounds of these materials, subject to a minimum concentration limitation. This threshold decreased to 25,000 pounds for 1989 and beyond. Also, a reporting threshold of 10,000 pounds was established for annual use of these materials other than in their manufacturing and processing.

Toxicity.—Manganese is an essential element for people, animals, and plants. For adults, a daily dietary intake in the range of 2 to 5 milligrams of manganese has been recommended, and it seems that normal diets satisfactorily meet human requirements.¹⁴ In excess, manganese can be harmful to the respiratory and nervous systems.¹⁵ Thus, manganese can be an industrial poison, but normally is not a hazard.

ANNUAL REVIEW

Legislation and Government Programs

Sanctions against the Republic of South Africa established under the Comprehensive Anti-Apartheid Act of 1986 were terminated on July 10 in accordance with Presidential Executive Order 12769 (56 FR 31855). U.S. imports of manganese materials produced in the Republic of South Africa had not been directly affected by the sanctions program throughout its duration because of the certification of manganese as an essential mineral that was unavailable from reliable and secure suppliers.

In accordance with the Deep Seabed Hard Mineral Resources Act, the National Oceanic and Atmospheric Administration of the U.S. Department of Commerce approved 5-year extensions of the licenses and 1994-99 exploration plans for three ocean mining consortia, on July 31 for Ocean Management Inc. and Ocean Mining Associates (56 FR 37344) and on November 5 for Ocean Minerals Co. (56 FR 63716).

Strategic Considerations

Security of Supply.—Manganese, for which there is no economical substitute, is essential to steelmaking. Steel producers in the MEC's of the United States, Japan, and Western Europe have shared a common concern about lack of economically minable domestic manganese deposits. Also, MEC ore supply has been from relatively few sources, chiefly Australia, Brazil, Gabon, India, Mexico, and the Republic of South Africa, and from just one or two major ore mining companies in each of these countries. The United States has been additionally concerned about supply of manganese ferroalloys because its domestic ferroalloy industry has declined well below self-sufficiency in manganese.

Stockpile.—The status of goals and inventories of manganese materials in the National Defense Stockpile at the end of 1991 is given in table 2. The goals were unchanged from those in effect at yearend 1990. Changes in yearend inventories and sales during 1991 are summarized in table 3. The decrease in the inventory of metallurgical ore and increase in the inventory of high-carbon ferromanganese were mainly because of the stockpile upgrading program. Most of the change for high-carbon ferromanganese occurred in July when the Defense Logistics Agency accepted into inventory 74,143 tons produced under that program. Sales were only of nonstockpile grade ore, of which the largest amount, about 138,000 tons, was material being held at Butte, MT, that needed to be removed to permit Superfund cleanup activities at that site. On an overall basis, these changes only minimally reduced the reserve of contained manganese being held by the Government, which still exceeded 1.9 million tons at yearend.

Issues

The United States has been lacking in reserves and significant production of manganese almost since the start of domestic steel production. Extensive efforts to discover worthwhile ore

deposits or effective methods of using low-grade resources, including steel slags, have resulted in little commercial promise. In a 1985 report, the U.S. Congressional Office of Technology Assessment (OTA) concluded that improvements in steel production technology offered the best prospect for reducing U.S. manganese import vulnerability.¹⁶ In so doing, OTA discounted ocean mining for the present, a view shared by most participants at a December 1989 conference on marine mining.¹⁷

The setting up and maintenance of a large stockpile has been the most tangible aspect of Government manganese programs. Management of the makeup, size, and disposition of this stockpile has been a key part of Government policy. Current law limits use of the stockpile to emergency situations, but its mere presence has had economic implications. Political developments during 1991 related to two foreign countries may lead to a reevaluation from the U.S. perspective of the strategic aspects of manganese, which could have a major impact on stockpile policy. The ending of U.S. sanctions against the Republic of South Africa diminished the possibility of a sanctions-related supply disruption. The lessening of international tensions accompanying transformation of the U.S.S.R. into a commonwealth of independent republics also seemed to favor lowered concern about potential deficiencies in the U.S.'s manganese supply.

Production

Ore and Concentrate.—U.S. production and shipments consisted only of a small amount of manganiferous material for use in coloring brick. This material was mined in Cherokee County, SC, and had a natural manganese content in the range of 5% to 15%. Shipment data were not published to avoid disclosing proprietary data.

Ferroalloys, Metal, and Synthetic Dioxide.—Production statistics for these materials were not published to avoid

disclosing proprietary data. Plant sites and products are given in table 4. The only production of manganese ferroalloys, including that of high-carbon ferromanganese for the Government stockpile, was by Elkem Metals Co. at its Marietta, OH, plant. In June, Elkem Metals opened a research and development center near Pittsburgh, PA, as a replacement for a research center that was in operation for many years at Niagara Falls, NY. Programs at the new center were to include improvement of existing alloys, development of new ones, and process control technology for ferroalloys production.

Rayovac Corp. ended manufacturing operations at its plant at Covington, TN, in July. Activities there have included production of EMD and grinding of manganese ore, mostly for consumption in dry cell battery manufacture elsewhere within Rayovac. The plant had an annual capacity for EMD of about 5,500 tons, the smallest of the four domestic plants then operating. Factors cited as leading to closure of the plant were the ready availability of manganese-based materials at lower cost than as produced at Covington and the need for large capital and research investments at Covington.

Consumption, Uses, and Stocks

Metallurgical applications accounted for most manganese consumption, about 90% for steelmaking. This can be deduced from the data relating to manganese end use that form the basis of tables 5 and 6 plus certain other information. Table 7 presents industry averages for pounds of manganese used in ironmaking and steelmaking (including for castings) per ton of raw steel produced. For 1991, these consumption rates, derived from the reported data in tables 5 and 6, were lower than those in 1990. The substantial drop in manganese ore usage in ironmaking reflected the trend toward lower manganese contents in hot metal. The data for ferroalloy consumption implied some shifting from ferromanganese to silicomanganese.

Relatively small quantities of manganese were used for alloying with

nonferrous metals, chiefly aluminum. For alloying with aluminum, compared to immediately prior years, the proportion of manganese added as metal was in 1991 again significantly less than for that added as manganese-aluminum briquets and other forms.

Nonmetallurgical applications for manganese included animal feed, brick coloring, dry cell batteries, manganese chemicals, and plant fertilizers.¹⁸ Chemetals Inc., directly or indirectly a supplier of manganese for all of these applications, underwent a change in ownership carried out between January and June, from Belgium's Société Générale de Belgique to COMILOG, headquartered in Paris. Chemetals' plants involved in the acquisition included those at Baltimore, MD, where manganese chemicals and other manganese products are produced, and New Johnsonville, TN, where EMD is produced.

According to the National Electrical Manufacturers Association, the year-to-year increase in value of domestic shipments of dry batteries declined to slightly more than 1% in 1991, as compared with increases of 5% to 6% in recent prior years. Within the dry battery industry, manufacturers of cells containing manganese continued striving to completely eliminate the use of mercury. To go from mercury levels of 0.025% or less to zero in alkaline cells, Rayovac in December signed an agreement with Japan's Matsushita Battery Industrial Co. that would permit Rayovac to use technology developed by Matsushita for producing alkaline cells free from mercury. The Eveready Battery Co.'s technology group in Ohio developed a mercury-and-cadmium-free alkaline battery that was being manufactured in Switzerland and marketed in Europe.

Among ownership changes in the battery industry, Duracell International Inc., a leading manufacturer of alkaline cells and headquartered in Bethel, CT, made a stock offering in May and went from private to public ownership. Not quite 3 years prior, Kohlberg Kravis Roberts & Co. had led the privatization of Duracell's businesses in acquiring

them from Kraft Inc. In March, Eastman Kodak Co. sold its battery operations in Newark, NY, that had included manufacture of lithium-manganese dioxide cells. The sale was to a small group of investors who formed Ultralife Batteries Inc. with the stated intentions of continuing and diversifying lithium battery operations at Newark.

Markets and Prices

Manganese Ore.—The price of metallurgical manganese ore receded slightly after having increased significantly for 3 years in succession. Factors helping arrest the upward trend included cutbacks in ferromanganese production, as in Canada, Germany, and Norway; halting of shipments of ore to the U.S.S.R. because of nonpayment; and downward pressure on price from ore being supplied from Western Australia. Settlement of contracts between Japanese customers and their suppliers again set the trend. F.o.b. prices for ore from Australia's GEMCO agreed upon around June 1 were a mix, with no change for high-grade lump, a decrease of about 3% for sinter containing about 54% manganese, and a decrease of about 6% for premium fines. Prices for high-grade lumpy ore from South Africa's AMMOSAL and Samancor were settled in July at a markdown of about 2% from the 1990 f.o.b. price.

The average price, c.i.f. U.S. ports, for metallurgical ore containing 48% manganese declined similarly and was assessed as \$3.72 per metric ton unit. The metric ton unit is 1% of a metric ton; i.e., 10 kilograms or alternatively 22.05 pounds of contained manganese. The price of manganese in ore in 1991 and 1990 thus can be expressed in cents per kilogram as 37.2 and 37.8, respectively, or in cents per pound as 16.9 and 17.1, respectively. The price of a metric ton of ore is obtained by multiplying the metric ton unit price by the percentage manganese content of the ore.

The ore market consists of a number of submarkets because of differences between ores according to the various end

uses such as ferroalloy production, blast furnace ironmaking, and battery manufacture. Table 8 gives the price trend for metallurgical ore during the past two decades.

Manganese Ferroalloys.—Price trends for manganese ferroalloys, as given by quotations for imports, were negative, both for average price relative to that for the prior year and for change during the year. For ferromanganese, this was attributed at least in part to lowered demand and for silicomanganese to cheap imports into Western Europe from China and Eastern Europe. In the United States, the decline in year-average price exceeded 6% for high-carbon ferromanganese and, at more than 3%, was about one-half as great for silicomanganese.

For high-carbon ferromanganese containing 78% manganese, the price range of imported material, f.o.b. Pittsburgh or Chicago warehouse, started 1991 at \$630-\$650 per long ton of alloy and declined throughout the year, to end at \$555-\$560, a decrease for the year of about 13%.

The price range for imported silicomanganese with 2% carbon, in cents per pound of alloy, f.o.b. Pittsburgh or Chicago warehouse, began 1991 at 25.75-26.5 and advanced to 27-28 as of late March. A decline began in May and lasted the rest of the year. The yearend range of 23.6-24.15 was almost 9% below that at the beginning of the year.

Domestic producer prices (Elkem Metals) given by Metals Week for high-carbon ferromanganese and silicomanganese were unchanged from those previously listed in 1989. These prices, f.o.b. plant or warehouse, were \$695 for high-carbon ferromanganese and 35 cents for silicomanganese.

Manganese Metal.—For bulk shipments of domestic material, f.o.b. shipping point, trade journal listings were the same throughout the year as already published effective mid-November 1990. Metals Week gave a price range of \$1.04-\$1.05 per pound, whereas American Metal Market gave \$1.05 per pound.

Foreign Trade

Unit values indicated that all ore exported in 1991 was metallurgical grade except for about 200 tons. No ore was reported to have been reexported. The data for ore exports listed in table 9 show a slight decrease for quantities in 1991 compared with those in 1990. On the other hand, deduction from these data of apparent transshipments of Gabonese ore to Mexico indicates exports substantially increased in 1991. Exports of ferromanganese overall and silicomanganese also were much greater in 1991 than those in the previous year. Those of ferromanganese were the greatest since 1979, among which those to Canada were more than twice the amount exported in 1990. Exports of ferromanganese containing less than 2% carbon were 11,025 tons in 1991 or almost 3 times as great as the 3,945 tons exported in 1990.

In terms of the manganese content of imports, the ratio of the sum of ferroalloy plus metal to the sum of ore plus dioxide was again larger at 3.4 than that in the previous year and the greatest since 1982. The data on imports for 1990-91 listed in table 10 signified for ore a decrease in amount of about one-fifth, with or without adjustment of the data for apparent transshipments of Gabonese ore to Mexico. The decline in 1991 was principally because of reduced receipts of ore containing less than 47% manganese, for which category no receipts were reported from Brazil or the Republic of South Africa. The overall quantity of ore imported in 1991 was the least since 1982. Manganese content averaged 50.1%, the highest since the same percentage was attained in 1987.

Imports of ferromanganese were about 16% less overall in 1991 than those in 1990, and had an average manganese content of 78.3%. Receipts of high-carbon ferromanganese from France declined about 25% and those from the Republic of South Africa about 41% to give for the Republic of South Africa the smallest quantity since 1983. Unusual items among ferromanganese imports were, for the high-carbon grade, receipts

from the Philippines and a quintupling of receipts from the United Kingdom, and, among the lower carbon grades, receipts of 412 tons from the U.S.S.R. For spiegeleisen, imports were reported as 149 tons, mostly material of high unit value from the Federal Republic of Germany; no exports were reported.

Increases in imports were registered for silicomanganese, metal, and dioxide compared with those for 1990. Silicomanganese imports increased 15% to surpass the previous record for quantity set in 1989. This advance included record receipts from Brazil and Canada. For metal, imports of unwrought material from China were almost 4 times as great as those in 1990, while those from the Republic of South Africa in the category of "metal, other" were 1.8 times as great. The amount of manganese dioxide imported was the greatest since 1988 and was nearly triple the 1990 amount. Australia, a new source, accounted for more than 40% of the total, and receipts from Ireland were more than five times as great as those in 1990. All dioxide imports were apparently synthetic material.

Among other manganese chemicals, imports of potassium permanganate in 1991 totaled about one-half as much as in 1990 and were the least since 1982. For the principal recent sources, declines were particularly pronounced for China and Spain. Under imports classified as "Other sulfates," which includes manganese sulfate, the entries for Mexico totaled 11,012 tons valued at \$5.0 million.

Tariffs.—The schedule of tariffs that applied during 1991 to U.S. imports of selected manganese materials is given in table 11.

Duty-free treatment under the Generalized System of Preferences (GSP) program was indefinitely suspended for imports from Yugoslavia effective December 24. This action, under Presidential Proclamation 6389 (56 FR 64467), imposed duties at the most-favored-nation rate. Among imports of manganese materials, the item principally affected was silicomanganese.

A ruling of the Office of the U.S. Trade Representative in June continued to deny duty-free status to imports of medium-carbon ferromanganese from Mexico. Mexico had petitioned that the import ceiling limit for medium-carbon ferromanganese be waived within the 1990 GSP product review.

Antidumping duties on potassium permanganate from China and Spain were changed in accordance with administrative reviews of 1989 imports by the International Trade Administration (ITA) of the U.S. Department of Commerce. For material from China, the margin of 39.63% that had applied since January 1984 was effectively raised to 128.94% in April (56 FR 19640). For material from Spain, the margin was lowered from 16.16% to 3.96% in November (56 FR 58361).

The ITA also determined that high-grade chemical manganese dioxide (CMD-U) from Japan was a later developed product within the scope of the already existing antidumping duty order on EMD from Japan, and therefore subject to an antidumping duty at the "All others" 73.3% rate. This decision was published in preliminary fashion in November (56 FR 56977) and affirmed in January 1992 (57 FR 395).

World Review

Capacity.—The rated capacity data in table 12 are as of December 31, 1991, and are the same as in the previous year except for Australia and the Republic of South Africa. The figure for Australia was increased to include operations in Western Australia, and that for the Republic of South Africa was increased to compensate for upward revision of data for production in past years. The data correspond to the manganese contents of ore and/or concentrates capable of being utilized, as in feed to a smelter. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable, long-term operating rate.

Reserves.—Only a few of the world's many manganese concentrations have

enough economic significance to be classed as reserves;¹⁹ no domestic deposits qualify.²⁰ World reserves of manganese, generally on the same basis as capacity, are given in table 13 with no distinction between ore type or application. The data in this table are the same as given in the 1990 Minerals Yearbook except for Australia and the Republic of South Africa. The estimates for Australia have been revised on the basis of resource data provided by Australia's Bureau of Mineral Resources. The reserve base figure for the Republic of South Africa has been changed to conform with that of the South African Minerals Bureau, which includes material with less than 30% manganese content. The data in table 13 are exclusive of perhaps 1% to 2% of total known reserves. These are in nonlisted countries having a similar proportion of world production, as can be seen from table 15.

Argentina.—Carbometal S.A.I.C., with plants at El Níhuil and Carrodilla in Mendoza Province, initiated production of manganese ferroalloys. The company's annual capacities were 5,500 tons for high-carbon ferromanganese, 1,100 tons for medium-carbon ferromanganese, and 6,600 tons for silicomanganese.

Australia.—Broken Hill Pty. Co. Ltd. (BHP) reported that manganese ore shipments to foreign and domestic destinations by its GEMCO subsidiary totaled about 1.3 million tons.²¹ This was a drastic decrease from a similar total of about 2.0 million tons in 1990. Production operations at the company's Groote Eylandt Mine in the Northern Territory likewise were significantly reduced. In November, effective from January 1, 1992, organizational changes were announced that placed all of the manganese-related operations of BHP into a BHP Manganese Division. This division became one of seven components within BHP Minerals, which itself early in 1991 had shortened its name from BHP Minerals Utah International.

Australian Manganese Co. Ltd. (AMCL), the newest operation within BHP Manganese, began exports in

February from its EMD plant near Newcastle, New South Wales, which had been brought up to full operational capacity of about 20,000 tons per year. This export-oriented plant was built in 1987-89 and was being fed with ore from GEMCO.²²

Production of manganese ore in Western Australia continued on the scale of 300,000 tons annually. This was from operations such as those in which Portman Mining Ltd. was participating in the east Pilbara region at Woodie Woodie.²³ A former manganese resource also being reactivated was that at Horseshoe, Mount Fraser, to the west center of Western Australia, by Sabminco NL.

Belgium.—The Sadacem Group within Gechem, the chemical subsidiary of Société Générale de Belgique, was acquired by COMILOG in the first part of the year. Facilities sold included those at Tertre for the manufacture of CMD, manganese sulfate, and other manganese chemicals, and at Langerbrugge (Ghent), where manganese ferroalloys have been produced. COMILOG has been involved commercially with the facilities it acquired for many years.

Brazil.—ICOMI, the manganese mining subsidiary of Cia. Auxiliar de Empresas de Mineração S.A. (Caemi), no longer was shipping high-grade lump ore containing 48% manganese from operations at Serra do Navio, Amapá Territory. Its highest grade lump product had a nominal manganese content of 46%. To better position itself as a long-term supplier, the company planned to move to Porto de Santana sizable stocks of intermediate-grade and lower grade products that had accumulated during mining. Infrastructure at the mine, for which the present concession expires in the year 2003, was expected to be shared with the University of São Paulo for studies of Amazon ecology.

Relocation of ore stocks was part of Caemi's overall program of consolidating its manganese activities at the port area, where ore sintering and ferroalloy smelting were progressing. Capacity of

the plant producing a sinter containing about 52% manganese had been raised to in excess of 100,000 tons per year. Depending on demand, the potential existed for doubling that capability. Ferromanganese output at Cia. Ferroligas do Amapá, Caemi's ferroalloy subsidiary, was reported to have been near its annual capacity of 25,000 tons.

In the Carajás region, total manganese ore shipments from the Azul Mine of CVRD through the coastal port of Ponta da Madeira decreased by about one-seventh to 414,000 tons. Although exports advanced about 13% to 291,000 tons, shipments to Brazilian consumers fell by almost one-half to 123,000 tons.²⁴

Production of manganese ferroalloys increased about 14% to set a record of 486,000 tons. Compared with outputs in 1990, only that for high-carbon ferromanganese declined, by about 2% to 165,000 tons. Production of medium- and low-carbon ferromanganese recovered by 10% to total 21,000 tons while that of silicomanganese gained about one-fourth to reach almost 300,000 tons, also a record.

In 1990, manganese ore sales by Urucum Mineração S.A., CVRD's 47%-owned subsidiary in the State of Mato Grosso do Sul, had risen more than 60% to 321,000 tons, of which 181,000 tons was exported and 140,000 tons went to domestic customers.

Burkina Faso.—InterStar Mining Group Inc., a Canadian firm, signed an agreement with the Government of Burkina Faso to develop the Tambao deposit near the northern borders with Mali and Niger. The deposit was projected to yield high-grade ore. Tambao has been known for more than 30 years, but its development has been impeded by lack of rail transport. Plans announced suggested beginning with ore production on the scale of about 80,000 tons per year using trucks where no railroad exists, followed by quadrupling of output once shipment can be made entirely by rail. Ownership of InterStar was about one-third each by two Canadian companies (Phoenix Canada Oil Co. Ltd.

and Starrex Mining Corp. Ltd.) and the public.

Canada.—The manganese smelter of Elkem Metal Canada at Beauharnois, Quebec Province, was shut down indefinitely as of the end of May. This smelter produced high-carbon ferromanganese and silicomanganese. One of the larger such smelters in the world and Canada's only producer of manganese ferroalloys, it was closed as part of a rationalization of the manganese ferroalloy operations of Elkem, the Norwegian parent. A proposal made in 1989 to form a joint venture between the Beauharnois smelter and the predominantly manganese smelter of BHP's Tasmanian Electro Metallurgical Co. Pty. Ltd. in Tasmania had not yet been consummated.

France.—Near the end of the year, Usinor-Sacilor S.A. completed an electric furnace plant for manganese ferroalloys on the coast at Dunkirk, where the company already has a steel plant. The plant's annual capacity was about 100,000 tons combined for ferromanganese and silicomanganese. Most of the output was expected to be consumed internally for steelmaking. One of the principal feed materials contracted for was ore from CVRD's Azul Mine in Brazil. Use of ore from this mine was facilitated by equipping the smelter with a unit for sintering fines.

Symptomatic of the slow market for manganese ferroalloys, SFPO was reported in the latter part of the year to be operating its blast furnace plant for high-carbon ferromanganese at Boulogne at only about two-thirds of capacity.

Gabon.—Exports of manganese ore from COMILOG's Moanda Mine decreased about one-sixth, compared with those in 1990, to 2,021,000 tons. Ocean shipments in 1991 consisted of 80 cargoes, of which 53 were via the Owendo terminal in Gabon and 27 were via the Pointe-Noire terminal in the Congo.²⁵ Like other major manganese ore producers, COMILOG cut back its

mining operations. In 1990, production of 2,671,000 tons of ore had included 69,000 tons of battery-grade ore.

Germany, Federal Republic of.—Both in the early and latter parts of the year, Thyssen Stahl shut down temporarily the production of ferromanganese from its plants in the Duisburg area. The company continued to be a significant producer of medium-carbon ferromanganese. This alloy was obtained at Thyssen's Ruhrort plant by refining in an oxygen converter high-carbon ferromanganese that had been produced in a blast furnace at its Hamborn plant.

India.—Effective April 1 at the beginning of the 1991 fiscal year, the Government broadened its ban on the export of manganese ore, previously directed at high-grade ore, to include medium-grade ore containing more than 38% manganese and less than 0.2% phosphorus.

Developments in the manganese ferroalloy industry included commercialization at midyear of a so-called high-pressure sintering process for manganese ore fines. This technology was put into operation in a 100-ton-per-day unit at the Chandrapur plant of Maharashtra Elektrosmet Ltd.²⁶ Khandelwal Ferro Alloys Ltd., with a plant also in Maharashtra State at Kanhan, installed equipment giving it the capability to produce low- and medium-carbon ferromanganese on a small scale to augment its existing output of high-carbon ferromanganese. In June, conversion was completed from production of ferromanganese to ferrochromium for one of two 9-megavolt-ampere ferromanganese furnaces at the Joda plant, Orissa State, of Tata Iron and Steel Co. That plant had had an annual ferromanganese capacity of about 40,000 tons. At Balasore, southwest of Calcutta, Ispat Alloys Ltd. started trial production in the latter part of the year from a ferromanganese-silicomanganese furnace having an annual capacity of about 20,000 tons.

Japan.—Roughly one-fifth of the manganese ore purchases contracted for in the 1991 fiscal year represented a supply diversification. The majority of material from new sources was relatively high-grade ore from the operations of Portman Mining in Western Australia. Material from Brazil's ICOMI also being tried included sinter containing about 52% manganese and low-grade fines containing about 36% manganese.

Production of manganese ferroalloys increased 4% to a total of 607,000 tons. The total consisted of 419,000 tons of high-carbon ferromanganese, the largest such quantity since 1984; 92,000 tons of low-carbon ferromanganese; and 96,000 tons of silicomanganese. In the latter part of the year, Pacific Metals discontinued its small production of ferromanganese from its plant at Hachinohe in Aomori Prefecture.

Imports of silicomanganese remained the most significant item of foreign trade in manganese ferroalloys. The 1991 import total for silicomanganese was 266,000 tons, of which more than 50% was from China. The continuing high level of imports of silicomanganese led the domestic ferroalloy producers to file an antidumping petition with the Government on October 8, which was directed against producers in China, Norway, and the Republic of South Africa. The Government began its formal investigation on November 29. Other trade data for manganese ferroalloys in 1991 included imports of ferromanganese totaling 35,900 tons, a 25% decrease from the 1990 total; exports of ferromanganese totaling 5,500 tons, a decrease of 11%; and negligible exports of silicomanganese amounting to only 72 tons.

The downward trends in 1989-90 for production and exports of EMD were reversed. Output rose about one-seventh to 64,500 tons, and exports increased almost 4% to 34,400 tons.

Production of electrolytic manganese metal decreased 11% to 4,470 tons. Imports of unwrought manganese metal, including scrap, increased by almost one-third to 19,800 tons. The Republic of South Africa and China were the most

important sources with 52% and 42%, respectively, of the total.

Mexico.—Outputs by Autlán, the principal producer of manganese ore and ferroalloys, were reduced for all such materials except battery ore. The reduction overall was roughly two-fifths for ore products and one-seventh for ferromanganese plus silicomanganese. Production from the Molango District in Hidalgo State in 1991 and 1990, respectively, consisted of 460,000 and 737,000 tons of carbonate ore, of which 73,000 and 106,000 tons were sold without nodulizing, 181,000 and 368,000 tons of oxide nodules produced by calcining carbonate ore, and 25,200 and 23,900 tons of battery ore from the Nonoalco Mine. Combined production of manganese ferroalloys from Autlán's plants at Tamós in Veracruz State and Teziutlán in Puebla State in 1991 and 1990, respectively, came to 139,000 and 170,000 tons for all types of ferromanganese and 54,100 and 58,600 tons for silicomanganese.

Norway.—The two Norwegian manufacturers of manganese ferroalloys reported production cutbacks. Both of Elkem's plants were affected, Elkem PEA at Porsgrunn and Elkem Sauda at Sauda, which together were producing all the chief manganese ferroalloys. At its Kvinesdal facility where principally silicomanganese was being produced, Tinfos Jernverk A/S shut down one of the two furnaces for maintenance for 2 months in the first half of the year.

The Government granted Elkem and Tinfos another 2-year exemption from sanctions against importing manganese ore from the Republic of South Africa. Previously, the exemption had been extended until July 20, 1991.

South Africa, Republic of.—The Minerals Bureau, which had been reviewing South African data on manganese ore production for several years, made revisions to many of its previous figures, a number of which were increased substantially. Information

furnished by the Minerals Bureau to the U.S. Bureau of Mines in February 1992 was the basis of the ore production data for the Republic of South Africa by category for 1991 in table 14 and in total for 1987-91 in table 15. Of the data listed in table 15, that for 1989 underwent one of the most pronounced revisions, as total production was increased by more than one-third.

In response to slack demand on the international ore market, Samancor stated in July that it would reduce output significantly from its Mamatwan and Wessels Mines in northern Cape Province. Manganese ore shipments by AMMOSAL from the Kalahari Field in Cape Province were 1,114,000 tons, the lowest quantity since 1987 and a further decline of more than 20% from shipments in 1990.

South African manganese ferroalloys were also produced at a reduced rate. In July, the Transalloys Div. of Highveld Steel and Vanadium Corp. Ltd. lowered the operating level for silicomanganese at its Witbank plant, Transvaal Province, to less than one-half of its annual capacity of about 200,000 tons. At about the same time and for about one-third of the year, Transalloys also took out of service its annual capacity for medium-carbon ferromanganese of about 50,000 tons. In late summer, a strike halted ferromanganese production for a time at the plant of Ferroalloys Ltd., a subsidiary of AMMOSAL. The company said shipments were unaffected from its plant at Cato Ridge, Natal Province, with an annual capacity of about 200,000 tons.

U.S.S.R.—Silicomanganese exported to Western Europe was reported to be influencing ferroalloy markets there. Quantities shipped to the European Community (EC) were several times those in 1990.

Early in the year, the Commission of the European Community allowed the provisional antidumping duty to expire on imports of potassium permanganate from the U.S.S.R. The Commission was unable to identify any direct exports of this compound from the U.S.S.R. to the EC since 1988.

Exports of ore reported for 1990 were only 141,000 tons, the smallest such quantity since at least World War II. Statistics as to destinations were not available.

Current Research

The U.S. Bureau of Mines reported on additional studies of hydrometallurgical processes for extracting manganese from low-grade domestic sources. In one investigation, countercurrent fluoride-enhanced acid leaching (hydrochloric acid plus calcium fluoride) was used to attain manganese extractions of 98% from manganese silicate-type ore. Samples were from the Silverton district, San Juan County, CO and contained 35% manganese.²⁷ Another investigation dealt with the use of fluosilicic acid (H_2SiF_6), a fertilizer industry byproduct, to leach slags generated in making steel by the basic oxygen process. Two-stage countercurrent leaching yielded manganese extractions of 73% to 83% from slags containing about 1% to 3% manganese. Based on the test results, a process was proposed by which 75% of the manganese could be recovered from such slags in the form of manganese-iron hydroxy carbonates containing 4% manganese and 32% iron.²⁸

Conditions within submerged arc furnaces being used to smelt manganese ore into ferromanganese have been studied and modeled over many years to develop ways of avoiding eruptions to which such furnaces tend to be subject. A thermochemical analysis of ferromanganese smelting was carried out on the basis of a method proposed for calculating the electrical resistance of the mix of ore, coke, and flux. From this it was concluded that a sudden decrease in carbon dioxide content of the top gas should be regarded as a sign of imminent trouble.²⁹

Current emphasis on producing steel with a low residual phosphorus content led a German steelmaker to investigate the effects of phosphorus, silicon, and manganese contents of pig iron on final phosphorus content when making pig iron into steel in an oxygen converter.

Conditions at that particular plant included use of scrap with a relatively high manganese content. It was found that higher manganese inputs did not necessarily preclude achieving a low phosphorus level, as the results also depended on iron content of the slag.³⁰

In recent years, certain Japanese steelmakers have introduced manganese as manganese ore during oxygen converting rather than as a ladle addition of ferromanganese after injection is complete. The potential of this practice, as well as use of manganese ore in blast furnaces and electric arc furnaces, was assessed by means of a thermochemical analysis. Use of manganese ore in oxygen converting was found to be favored by slag conditions of low volume, low iron oxide content, and high basicity. It was noted that the economics of using ore in place of ferromanganese were complex and site specific.³¹

Japan's Nippon Steel Corp. reported on development of improved technology for control of oxygen converting that included an on-line sensor for manganese content of the steel. Operation of the sensor was based on spectrographic analysis of the light emitted from the steel bath, which was picked up by an optical fiber system. Manganese concentration was evaluated from determination of the emission intensity of manganese relative to that of iron.³²

Carbon pickup from the mold flux can be a problem in the continuous casting of ultra-low-carbon steels, such as those with a carbon content of 0.003% or less. Tests by Japanese workers in which manganese dioxide was added to the flux as an oxidant at concentrations of up to 20% indicated this to be one of the more successful methods of dealing with this problem.³³

Egyptian workers investigated the use of native ore as a pigment for surface coatings and found such ore could economically replace iron oxide pigments in anticorrosive primers. Their tests were based on two types of samples from the Sinai Manganese Co., high-grade ore nominally containing about 44% manganese and medium-grade ore containing 18% to 28% manganese. The

samples tested had manganese contents of 58.1% and 23.4%, respectively, in both of which the dominant manganese mineral was pyrolusite.³⁴

MnBi, the intermetallic compound having equal atomic concentrations of manganese and bismuth, is potentially useful as a permanent magnet material and for other purposes. Practical application of MnBi has been impeded by the severe macrosegregation of manganese and resultant nonhomogeneity that occurs during attempts to prepare the compound using conventional casting procedures. A survey was made of alternative preparation techniques and the magnetic properties of the compositions obtained.³⁵

Information pertaining to phase equilibria in the manganese-nickel system at temperatures up to the melting point of nickel was reviewed by the U.S. Bureau of Mines. From this, a manganese-nickel phase diagram was put forth, and various aspects of phases within it were discussed.³⁶

The possibility that the chemical behavior of manganese in the oceans may have had a significant influence on the timing of the Earth's periods of glaciation was indicated by a model relating oceanic release of carbon dioxide to solar radiation. The model embodied a cycle between dissolved manganese carbonate and deposition of manganese dioxide. Data supporting the model's assumptions were obtained from manganese crusts and from manganese profiles in deep-sea sediments.³⁷

OUTLOOK

The trend of manganese demand, domestically and globally, will continue to closely follow that of steel production. Nonmetallurgical components of manganese demand, especially batteries, may experience higher growth rates than for steel production, but will have only a minor effect on overall manganese demand.

As given in table 16, U.S. apparent consumption of manganese has ranged within approximately plus or minus 10% of 700,000 tons of contained manganese

for nearly a decade. This has largely been a consequence of similar variability in domestic steel production. Manganese demand as calculated in table 16 generally has corresponded to but not traced precisely the level of activity in the steel industry. Differences in the respective year-to-year variations are believed to show the influence of unmeasured changes in stocks of manganese materials, such as those of importers, the effect of which may outweigh changes in demand by steelmakers.

The outlook for domestic steel production, as discussed in the annual report for "Iron and Steel," includes a modest improvement for 1992 over that of 1991, from which a slight pickup in manganese demand can be inferred. Forecasts of the International Iron and Steel Institute (IISI) continue to project little growth in U.S. steel output through 1995. This suggests that U.S. apparent consumption of manganese in 1992-95 is unlikely to range far from 700,000 tons of contained manganese, on the continued assumption of insignificant change in manganese unit consumption in steelmaking. The majority of U.S. demand will be met by imports.

Global forecasts of IISI and others suggest that world manganese demand during the balance of the 1990's should increase only marginally. The IISI foresees for steel consumption a static condition for industrialized countries and an increase for developing countries and China that slightly exceeds a decrease expected for the former U.S.S.R. and Eastern Europe. Some realignment of overall supply-demand relationships for ore and ferroalloy is expected from change in operating philosophy of the manganese mines and smelters and steel sector of the former U.S.S.R. Depending on the future course of ore prices, resurgence of ore production from localities such as Western Australia can add to future supply for at least a limited number of years.

TABLE 1
SALIENT MANGANESE STATISTICS

(Thousand short tons, gross weight)

	1987	1988	1989	1990	1991
United States:					
Manganese ore (35% or more Mn):					
Exports	63	68	57	77	73
Imports for consumption	341	512	639	338	258
Consumption	*533	*554	616	548	521
Stocks, Dec. 31: Consumers	*456	*458	518	418	303
Ferromanganese:					
Exports	3	3	9	8	16
Imports for consumption	368	531	476	419	352
Consumption	409	468	440	455	381
Stocks, Dec. 31: Consumers and producers	48	91	75	62	55
World:					
Production of manganese ore	*26,404	*27,542	*29,323	*28,036	*24,666

*Estimated. Revised.

TABLE 2
U.S. GOVERNMENT STOCKPILE GOALS AND YEAREND INVENTORIES
FOR MANGANESE MATERIALS IN 1991

(Short tons, gross weight)

Material	Stockpile goals	Physical inventory, Dec. 31			Sold, pending shipment	Grand total ¹
		Stockpile grade	Nonstockpile grade	Total		
Natural battery ore	25,000	169,511	19,425	188,936	14,787	203,723
Synthetic manganese dioxide	25,000	3,011	—	3,011	—	3,011
Chemical ore	170,000	172,655	89	172,744	417	173,161
Metallurgical ore	2,700,000	1,626,720	745,584	2,372,304	155,825	2,528,128
High-carbon ferromanganese	439,000	942,813	—	942,813	—	942,813
Medium-carbon ferromanganese	—	29,072	—	29,072	—	29,072
Silicomanganese	—	23,574	—	23,574	—	23,574
Electrolytic metal	—	14,172	—	14,172	—	14,172

¹Data may not add to totals shown because of independent rounding.

TABLE 3
SALES AND INVENTORY CHANGES FOR MANGANESE MATERIALS
IN U.S. GOVERNMENT STOCKPILE, 1991

(Short tons, gross weight)

Material	Sales		Change in yearend inventory
	Stockpile grade	Nonstockpile grade	
Natural battery ore	—	14,000	—
Metallurgical ore	—	145,959	(190,468)
High-carbon ferromanganese	—	—	74,273

TABLE 4
DOMESTIC PRODUCERS OF MANGANESE PRODUCTS IN 1991

Company	Plant location	Products ¹				Type of process
		FeMn	SiMn	Mn	MnO ₂	
Chemetals Inc.	Baltimore, MD	—	—	—	X	Chemical.
Do.	New Johnsonville, TN	—	—	—	X	Electrolytic.
Elkem Metals Co.	Marietta, OH	X	X	X	—	Electric furnace and electrolytic.
Kerr-McGee Chemical Corp.	Hamilton, MS	—	—	X	—	Electrolytic.
Do.	Henderson, NV	—	—	—	X	Do.
Ralston Purina Co.:						
Eveready Battery Co.	Marietta, OH	—	—	—	X	Do.
Rayovac Corp.: Materials Div.	Covington, TN	—	—	—	X	Do.

¹FeMn, ferromanganese; SiMn, silicomanganese; Mn, electrolytic manganese metal; MnO₂, synthetic manganese dioxide.

TABLE 5
U.S. CONSUMPTION AND INDUSTRY STOCKS
OF MANGANESE ORE,¹ BY USE

(Short tons, gross weight)

Use	Consumption		Stocks, Dec. 31	
	1990	1991	1990	1991
Manganese alloys and metal	W	W	W	W
Pig iron and steel	90,000	52,000	101,000	30,000
Dry cells, chemicals, miscellaneous ²	W	W	W	W
Total	548,000	521,000	418,000	303,000

W Withheld to avoid disclosing company proprietary data; included in "Total."

¹Containing 35% or more manganese (natural).

²Natural ore, including that consumed in making synthetic manganese dioxide.

TABLE 6
**U.S. CONSUMPTION, BY END USE, AND INDUSTRY STOCKS OF
 MANGANESE FERROALLOYS AND METAL IN 1991**

(Short tons, gross weight)

End use	Ferromanganese			Silico- manganese	Manganese metal
	High carbon	Medium and low carbon	Total		
Steel:					
Carbon	214,855	77,281	292,136	78,493	2,004
Stainless and heat-resisting	13,247	(¹)	13,247	6,142	2,808
Full alloy	28,835	6,359	35,194	17,250	460
High-strength, low-alloy	22,775	2,841	25,616	5,750	(¹)
Electric	(¹)	(¹)	(¹)	(¹)	(¹)
Tool	106	(¹)	106	(¹)	44
Unspecified	123	608	731	390	420
Total steel	279,941	87,089	367,030	108,025	5,736
Cast irons	10,353	767	11,120	1,686	—
Superalloys	W	—	W	—	130
Alloys (excluding alloy steels and superalloys)	1,048	328	1,376	W	² 18,676
Miscellaneous and unspecified	1,892	—	1,892	3,095	499
Total consumption³	293,234	88,184	381,418	⁴112,806	25,041
Total manganese content⁵	229,000	71,000	300,000	74,000	25,000
Stocks, Dec. 31:					
Consumers and producers	42,041	13,249	55,290	9,359	5,670

W Withheld to avoid disclosing company proprietary data; included with "Miscellaneous and unspecified."

¹Withheld to avoid disclosing company proprietary data; included with "Steel: Unspecified."

²Approximately 85% of this usage was for consumption in aluminum alloys.

³Includes estimates.

⁴Internal evaluation indicates that silicomanganese consumption is considerably understated.

⁵Estimated based on typical percent manganese content (rounded).

TABLE 7
U.S. UNIT CONSUMPTION OF MANGANESE IN
IRONMAKING AND STEELMAKING

(Pounds per ton of raw steel unless otherwise specified)

Form used	1990	1991
IRONMAKING		
Basis:		
Production of raw steel million tons ¹	98.9	87.9
Ore ²	.8	.5
STEELMAKING		
Basis:		
Production of raw steel and steel castings million tons	100.0	*89.1
Ore ²	(?)	(?)
Ferromanganese	6.8	6.5
Silicomanganese	1.4	1.6
Manganese metal	.1	.1
Total, steelmaking	8.3	8.2

*Estimated.

¹As ingots, continuous- or pressure-cast blooms, billets, slabs, etc.

²Containing 35% or more manganese.

³None reported.

TABLE 8
TIME-PRICE RELATIONSHIPS
FOR MANGANESE IN
METALLURGICAL ORE

Year	Average annual U.S. price, dollars per metric ton unit	
	Actual price	Based on constant 1987 dollars
1971	0.59	1.56
1972	.59	1.49
1973	.64	1.52
1974	.89	1.93
1975	1.36	2.69
1976	1.43	2.65
1977	1.46	2.54
1978	1.38	2.24
1979	1.38	2.06
1980	1.67	2.29
1981	1.69	2.11
1982	1.56	1.83
1983	1.36	1.53

¹Estimated. ²Revised. XX Not applicable.

³Table includes data available through May 11, 1992. Data pertain to concentrates or comparable shipping product, except that in a few instances the best data available appear to be for crude ore, possibly after some upgrading.

⁴In addition to the countries listed, Colombia, Cuba, Panama, Peru, and Sudan may have produced manganese ore and/or manganiferous ore, but available information is inadequate to make reliable estimates of output levels. Low-grade ore not included in this table has been reported as follows, in thousand short tons, gross weight: Argentina (19% to 30% Mn) 1987-7, 1988-10, 1989-6, 1990-6 (estimated), and 1991-6 (estimated); and Czechoslovakia (about 17% Mn), an estimated 1 in each year.

⁵May be for average content of each year's production rather than for content of typical products.

⁶Metallurgical ore.

⁷Reported figure.

⁸Gross weight reported; metal content estimated.

⁹Reported gross-weight figures are the sum of (1) sales of direct-shipping manganese ore and (2) production of beneficiated ore, both as reported in Anuário Mineral Brasileiro.

¹⁰Includes manganiferous ore.

¹¹Calculated metal content includes allowance for assumed moisture content.

¹²Concentrate.

¹³Much of India's production grades below 35% Mn; average content was reported as 38% Mn in 1985.

¹⁴Estimated product total, mostly oxide nodules; may include smaller quantities of direct-shipping carbonate and oxide ores for metallurgical and battery applications.

¹⁵Category represents the combined totals of Greece, Indonesia, Italy (from wastes), Japan, the Republic of Korea, Pakistan, the Philippines, Thailand, Turkey, and Zambia.

¹Where available, data for manganese dioxide included beginning in 1984.

²Including manganiferous ore.

³New series for steel-related end uses beginning in 1989.

⁴Includes miscellaneous nonmetallurgical uses of ore beginning in 1987.

⁵Not specifically based on reported data; includes processing losses. Through 1988, the distribution within this category is approximately the same as for end uses above. Beginning in 1989, includes nonidentified uses of steel corresponding to about one-third of total steel shipments.

MERCURY

By Robert G. Reese, Jr.

Mr. Reese, a physical scientist with the Branch of Metals, has been the commodity specialist for mercury for 4 years. Domestic survey data were prepared by Kevin Bacon, mineral data assistant; and the international data table was prepared by William Zajac, Chief, International Data Section.

The mercury market continued to shrink in 1991. Major factors in the lower consumption included the availability and development of substitutes and mercury's potential to be a health hazard and environmental pollutant. In 1991, the United States produced mercury only as a byproduct of gold mining. Worldwide, mine production declined in response to lower prices and demand.

ANNUAL REVIEW

Production

The primary mine production data contained in the accompanying tables were the quantity of mercury produced at the McDermitt Mine as reported in Placer Dome Inc.'s annual and 10K reports. The McDermitt Mine, closed in late 1990, remained idle through yearend 1991. Reportedly though, the company continued to sell mercury from the mine's stocks.

According to the Bureau's voluntary survey, eight gold mines in California, Nevada, and Utah recovered byproduct mercury. The mines in Nevada accounted for almost all of the byproduct production shown in table 1. The Paradise Peak Mine in Nevada was the largest byproduct mercury producer.

Consumption and Uses

Industrial consumption of refined mercury metal plummeted for the third consecutive year. Product evolution and environmental concern continued to depress mercury consumption by the battery industry. Changing technology

has reduced the mercury content of some batteries by as much as 98%. Also, mercury-free batteries such as the zinc-air cell continued to replace mercury-bearing batteries in some applications. The drop in consumption by the chlorine and caustic soda industry was attributable to the closure of several mercury-cell plants. In other applications, the most significant factor affecting demand was probably the general economic recession, although the mercury content of the final product was a concern to many manufacturers.

Stocks

Stocks of refined mercury held by consumers and dealers declined by almost 22% in 1991 and, at yearend, were equivalent to about 3 months industrial consumption. Data on stocks held at mines were withheld to avoid disclosing company proprietary data. The Department of Energy (DOE) held an inventory of used (scrap) mercury at Oak Ridge, TN. The Government classified all this material as excess to its needs. The Defense Logistics Agency (DLA), acting as DOE's agent, offered limited quantities of the material for sale at monthly auctions. DLA shipped 215 metric tons during the year, leaving yearend stocks at 224 tons.

At yearend 1990, the National Defense Stockpile contained 5,459 tons of mercury. During 1991, the goal for the stockpile was 362 tons. The remaining 5,097 tons was regarded as excess to Government needs. DLA, acting as the Government's sales agent, sold 129 tons of the excess mercury, leaving 5,330 tons in the stockpile at yearend.

Markets and Prices

The New York dealer price for delivered primary mercury, reported in Metals Week as a range, declined throughout most of the year. The price at the low end of the range began the year at \$180 per flask. From this peak, the low-end price declined steadily until the beginning of September when it reached \$85 per flask, its low for the year. The price remained at \$85 per flask until the end of October. During the final 2 months of 1991, the price increased, reaching \$155 by yearend. The price at the high end of the range tracked the movement of the low end price closely, but was \$5 to \$15 per flask higher.

Analysts attributed the price movement to supply-demand fundamentals. Globally, declining demand combined with abundant supplies resulted in falling prices during most of the year. As the prices dropped, some suppliers reportedly reduced their operations. As supplies tightened toward yearend, consumers and dealers bid up the mercury price to obtain the mercury needed to meet their commitments. The annual average of the weekly low end price was \$122.42 compared with \$249.22 in 1990.

World Review

World mercury demand, especially in industrialized countries, probably declined. Although there were no supporting data, media articles continued to show other countries' concern about potential mercury contamination.

At least 11 countries produced mercury in 1991. Several mercury mines curtailed

operations in response to the perceived drop in demand. According to media reports, a Chinese mine closed, and the Almaden Mine in Spain reduced its production significantly.

OUTLOOK

The outlook for the mercury market remains as it has for the past several years. Enactment of additional regulations restricting the use of mercury is likely. When combined with the lack of new major uses for the metal, mercury demand should continue to decline. With reduced operations at many producers, the U.S. Government may have an opportunity to further reduce its large mercury holdings.

MICA

By Lawrence L. Davis

Mr. Davis, a physical scientist with 36 years of industry and U.S. Bureau of Mines experience, has been the commodity specialist for mica since 1983. Domestic survey data were prepared by Linder Roberts, statistical assistant; and international data tables were prepared by Audrey Wilkes, international data coordinator.

Public Law 100-418 requires that U.S. Government agencies implement the use of metric units in their business activities by the end of fiscal year 1992. Consequently, all numbers in the text and tables are shown in metric units.

In 1991, about 103,000 metric tons of scrap and flake mica was produced in the United States, a decrease of 5% from 1990 production. Ground mica sales were 75,000 tons valued at \$17 million, a decrease in tonnage of about 23%.

Almost all sheet mica supply continued to be imported. Consumption of muscovite block mica decreased slightly to 5.9 tons. Consumption of mica splittings increased slightly to 854 tons. The value of sheet mica remained at \$7.8 million. The value of imports for consumption of sheet mica decreased 12% to \$8.4 million. (See table 1.)

DOMESTIC DATA COVERAGE

Domestic production and consumption data for mica are developed by the U.S. Bureau of Mines by means of three separate, voluntary surveys and one mandatory survey. Of the 18 operations to which the crude scrap and flake mica production form was sent, 15 operations, or 83%, responded, representing 87% of the production shown in table 1. Of the 17 operations to which the ground mica form was sent, 14 responded, representing 85% of the production in table 1. Of the five canvassed operations to which the mica block and film consumption form was sent, three, or 60%, responded, representing 72% of the consumption shown in table 1. Of the nine canvassed operations to which the mica splittings consumption form was

sent, seven operations, or 78%, responded, representing more than 98% of the splittings consumption shown in table 1. Consumption for the nonrespondents was estimated using prior-year production data.

BACKGROUND

Definitions, Grades, and Specifications

Mica is a group name for a number of complex hydrous potassium silicate minerals with differing chemical compositions and physical properties. Crystals of mica have excellent basal cleavage and split easily into tough, flexible sheets. The important mica minerals are muscovite and phlogopite.

Commercial qualities of sheet mica are relatively free of defects and tough enough to be punched or stamped into specific shapes. Sheet mica is classified as block, film, or splittings. Block mica is not less than 0.018 centimeters thick and has a minimum usable area of 2.54 square centimeters. Film mica is split to specified thicknesses ranging from 0.0030 to 0.010 centimeters. Splittings are sheets with a maximum thickness of 0.0030 centimeters and a minimum usable area of 1.9 square centimeters. Punch mica, which includes circle and washer mica, is low-quality, hand-trimmed mica up to about 5 centimeters in diameter. The American Society for Testing and Materials (ASTM) designates 13 quality groups for sheet mica, based on quantity of visible inclusions and structural imperfections, ranging from black- and red-stained to perfectly clear. ASTM also designates 12 grades based on the maximum usable rectangle. The sizes

range from grade 6 (with 2.54 usable square centimeters) to grade OOOE special (with 254 usable square centimeters).¹

Block and film mica products are small flat pieces of uniformly thin mica cut or stamped to close tolerances into a variety of shapes and sizes, depending on the use. Shapes can vary from simple circles, squares, or rectangles to very intricate patterns. Fabricators make their own dies to be able to cut the mica into any pattern desired.

Built-up mica, or micanite, consists of partly overlapped and irregularly shaped and arranged splittings cemented together with either an organic or inorganic binder. Large sheets of built-up mica are made by alternating layers of splittings and binder. Sheets of any thickness are made by pressing the layers at high temperatures. Built-up mica is sold in large, uncut sheets or is cut or molded to any size and shape specified by the customer. It is often bonded to another material such as fiberglass cloth to form a composite sheet.

Reconstituted mica or mica paper is a paperlike material made by depositing fine flakes of scrap mica as a continuous mat, which is then dried. The mica paper is sometimes impregnated with an organic binder.

Scrap and flake mica is generally of a quality and size that is not suitable for use as sheet mica. Mine scrap varies greatly in quality but usually is a heterogeneous mixture that must be crushed, screened, and washed to yield the scrap mica in usable form. Mine scrap may be the sole product of mining a pegmatite or may be a byproduct of sheet mica production. Bench scrap or

shop scrap is the mica discarded during the processing of handcobbed mica into sheet. Factory scrap is the waste that results from cutting and stamping sheet mica into pieces of definite size and shape. Factory scrap is usually the highest grade and quality material. Scrap mica that is recovered from schists and from the beneficiation of feldspar, kaolin, and lithium pegmatites is often referred to as flake.²

Industry Structure

The sheet mica industry in the United States is small, consisting of processors and fabricators of imported mica. Worldwide, India dominates the production of muscovite sheet mica. Madagascar is an important producer of phlogopite sheet mica. Sheet mica mining, trimming, and splitting are very labor intensive, and producing countries have the advantage of low wages and a large labor force that is usually trained at an early age. India's sheet mica industry is characterized by a large number of small operations, most of which sell to larger companies or the Government's Mica Trading Corp. of India Ltd. for further processing and export. India is putting more emphasis on exporting fabricated mica products. This is expected to reduce further the amount of mica that will be fabricated in the United States.

The U.S. flake mica industry ranks first in world production. Most production comes from surface mining of mica schists and as a byproduct of feldspar, kaolin, and lithium beneficiation. Nearly all flake mica is ground to final specifications depending on the use. Other countries producing significant amounts of flake mica are Canada, China, India, the Republic of Korea, and the U.S.S.R. Many other countries produce small amounts.

Geology-Resources

Sheet muscovite is obtained from coarse-grained igneous rocks called pegmatites. Pegmatites also contain

feldspar, quartz, and various accessory minerals. Pegmatite dikes and veins range from 1 kilometer or more long and 100 meters wide to thin veins and veinlets of approximately 2 centimeters in width.

The United States has no reserves of sheet mica. Small U.S. reserves were extensively worked in the past, and the high cost of labor has kept the mines shut down since the Government's purchase program ended in 1962. The primary sheet mica resources are in New England, the southeastern Piedmont from Virginia to Alabama, the Blue Ridge Mountains in North Carolina, the Black Hills of South Dakota, and northern New Mexico. Other States with some sheet mica resources are California, Colorado, Idaho, Montana, and Wyoming.

No formal evaluation of world resources of sheet mica has been made, mainly because of the sporadic occurrence of this mineral. The most productive sheet mica districts in the world are in the States of Bihar, Andhra Pradesh, and Rajasthan in India. India's large reserves and resources of sheet mica have been the primary world sources for many years. Large reserves of sheet mica also are found in Brazil and western Africa. In the U.S.S.R., sheet mica reserves are known in the Lake Baikal and Sayan upland areas as well as in the South Eniessy Range. Smaller but substantial reserves occur in Argentina, Australia, and Zimbabwe.

Phlogopite deposits are in areas of metamorphosed sedimentary rocks intruded by masses of pegmatite-rich granitic rocks. The phlogopite is found as veins or pockets in pyroxenite interlayered with or intersecting marble or gneiss. Canada and Madagascar have the world's major reserves of phlogopite. Additional reserves are known in Mexico, Sri Lanka, and the Sludyanka River district and Alden area of the U.S.S.R.

The primary domestic source of flake mica for grinding purposes is weathered alaskite bodies and pegmatites in North Carolina, where most domestic flake mica is produced. The mica is recovered as a coproduct of feldspar and kaolin beneficiation. Flake mica is also recovered from muscovite schists. These

schists bodies range in size from 3 to more than 100 meters thick and several kilometers long. The mica content ranges up to 90%. Another form of flake mica is fine-grained muscovite called sericite, which is an alteration product of various aluminosilicate minerals.

World reserves and resources of scrap and flake mica are not well known but are considered to be very large. All countries with sheet mica reserves or resources have even larger quantities of scrap mica because only a small fraction of the mica present is of sheet quality. Many other countries have reserves or resources of mica that, while not of sheet quality, are suitable for grinding.

ANNUAL REVIEW

Legislation and Government Programs

The Government inventory of stockpile-grade mica remained about the same at 10,000 tons. The U.S. Department of Defense sold 2 tons of muscovite block, stained and better. (See table 2.)

Strategic Considerations

Sheet mica and high-quality scrap mica used for making mica paper are important in the electronic and electrical industries. The United States is not self-sufficient in these materials and imports all its supplies, mostly from India. The U.S.S.R. and other Eastern European countries are currently India's largest customers. The United States and other market economy countries compete for the remaining mica, and availability is sometimes limited, particularly for high-quality mica. Long delivery times and quality inconsistency also adversely affect sheet mica availability.

In a short-supply situation during an emergency, the National Defense Stockpile would be able to meet short-term demand until substitutes could be made available. It is unlikely that domestic sheet mica production could replace or significantly reduce imports. Of the five strategic stockpile categories, only muscovite block mica has ever been

produced domestically in significant quantities, and then only under the stimulus of above-market prices paid by the Government. Domestic production in this century never provided more than a small fraction of domestic requirements.

The domestic supply of flake mica is adequate. Scrap and flake mica are not considered to be strategic materials. The United States is self-sufficient in flake mica but does rely on imports of high-quality scrap for the manufacture of mica paper.

Production

Scrap and Flake Mica.—North Carolina remained the major producing State, with 62% of the total production. The remainder was produced in California, Connecticut, Georgia, New Mexico, Pennsylvania, South Carolina, and South Dakota. Most mica was recovered from mica schist, high-quality sericite schist, and as a byproduct of feldspar, kaolin, and lithium beneficiation.³ The five largest producers were, in alphabetical order, The Feldspar Corp., Spruce Pine, NC; KMG Minerals Inc., Kings Mountain, NC; Lithium Corp. of America, Gastonia, NC; Pacer Corp., Custer, SD; and Unimin Corp., Spruce Pine, NC. These five companies produced 61% of the national total.

Cyprus Foote Mineral Co. closed its mine at Kings Mountain, NC, in December. The closure was expected to be permanent. A new mica producer, Rednour Mining Corp., was engaged in preparatory work on its Twin Mountain Mine at King Mountain, NC. Production was to begin in early 1992.

Low-quality sericite, used primarily in brick manufacturing, is excluded from tabulated data contained in this report. In 1991, four companies, one in North Carolina and three in South Carolina, mined 11,000 tons of low-quality sericite and reported an average value of \$4.67 per ton.

Ground Mica.—Twelve companies operated 15 grinding plants in 7 States. Ten plants produced dry-ground and five

produced wet-ground mica. The dry-ground mica plant of Deneen Mica Co., Micaville, NC, was inactive during the year. The five largest producers accounted for 75% of the total. They were, in alphabetical order, KMG Minerals, Kings Mountain, NC; MICA-A Franklin Limestone Co., Fairview, NM; Mineral Mining Co., Kershaw, SC; Unimin, Spruce Pine, NC; and USG Corp., Spruce Pine, NC.

J. M. Huber was trying to sell its mica operations at Kings Mountain and Spruce Pine, NC. At yearend, the facilities were still for sale. (See tables 3 and 4.)

Consumption and Uses

Sheet Mica.—Sheet mica is used principally in the electronic and electrical industries. Its usefulness in these applications stems from its unique electrical and thermal insulating properties and its mechanical properties, which allow it to be cut, punched, or stamped to close tolerances.

The largest use of block mica is as an electrical insulator in electronic equipment. High-quality block mica is also used to line the gauge glasses of high-pressure steam boilers. Transparency, flexibility, and resistance to heat and chemical attack are the properties that make mica suitable for this use. Other uses include diaphragms for oxygen-breathing equipment, marker dials for navigation compasses, optical filters, retardation plates in helium-neon lasers, pyrometers, thermal regulators, and stove windows.

Muscovite film mica is used as a dielectric in capacitors. Only high-quality mica, at or near the top of the quality scale, is used. The highest quality goes into capacitors that are to be used as standards. The next highest qualities are used for transmitting capacitors. Receiving capacitors use slightly lower quality film.

Consumption of muscovite block (ruby and nonruby) totaled 5.9 tons, a slight decrease from that of 1990. Stained and lower-than-stained quality remained in greatest demand accounting for 86% of consumption. About two-thirds of the

muscovite consumed was grade No. 4 or larger. The decrease in consumption was a continuation of a long-term decrease in block mica use. Five companies continued to consume muscovite block and film in five plants in four States: two in North Carolina and one each in New Jersey, Ohio, and Virginia.

Splittings represent the largest part of the sheet mica industry in the United States. Muscovite and phlogopite splittings are used to make built-up mica. Consumption of mica splittings increased slightly to 854 tons. Muscovite splittings from India accounted for nearly all of the consumption. The remainder was phlogopite splittings from Madagascar. The splittings were fabricated into various built-up mica products by nine companies operating nine plants in seven States.

Built-up Mica.—The primary use of this mica-base product, made by mechanical or hand setting of overlapping splittings and alternate layers of binders and splittings, was as electrical insulation material. Principal built-up mica products are segment plate, molding plate, flexible plate, heater plate, and tape.

Segment plate acts as insulation between the copper commutator segments of direct-current universal motors and generators. Phlogopite built-up mica is preferred because it will wear at the same rate as the copper segments. Muscovite has a greater resistance to wear, causing uneven ridges that may interfere with the operation of the generator.

Molding plate is sheet from which V-rings are cut and stamped for use in insulating the copper segments from the steel shaft at the ends of a commutator. Molding plate is also fabricated into tubes and rings for insulation in transformers, armatures, and motor starters.

Flexible plate is used in electric motor and generator armatures, field coil insulation, and magnet and commutator core insulation. Heater plate is used where high-temperature insulation is required.

Some types of built-up mica have the bonded splittings reinforced with special paper, silk, linen, muslin, glass cloth, or

plastic. These products are very flexible and are produced in wide, continuous sheets that either are shipped in rolls or cut into ribbons, tapes, or any desired dimensions.

Total production, sold or used, of built-up mica decreased 3% from that of 1990. Molding plates and segment plates were the major end products, accounting, respectively, for 36% and 33% of the total. Other end products included flexible plates, heater plates, and tapes.

Reconstituted Mica (Mica Paper).—

Primary end uses for mica paper are the same as those for built-up mica. Three companies consumed scrap mica to produce mica paper. The principal source of this scrap mica was India. Manufacturing companies in 1991 were Corona Films Inc., West Townsend, MA; General Electric Co., Coshocton, OH; and US Samica Corp., Rutland, VT. (See tables 5, 6, and 7.)

Ground Mica.—The largest domestic use of ground mica was in gypsum plasterboard joint cement. The mica acts as a filler and extender, provides a smooth consistency, improves the workability of the cement, and imparts resistance to cracking.

In the paint industry, ground mica is used as a pigment extender that also facilitates suspension, reduces checking and chalking, prevents shrinking and shearing of the paint film, increases resistance of the paint film to water penetration and weathering, and brightens the tone of colored pigments.

Ground mica is used in the well-drilling industry as an additive to drilling muds. The coarsely ground mica flakes help prevent lost circulation by sealing porous sections of the drill hole.

The rubber industry uses ground mica as an inert filler and as a mold lubricant in the manufacture of molded rubber products such as tires. The plastics industry uses ground mica as an extender and also as a reinforcing agent.

Ground mica is used in the production of rolled roofing and asphalt shingles, where it serves as an inert filler and surface coating to prevent sticking of

adjacent surfaces. The coating is not absorbed by freshly made roofing because mica has a platy structure and is not affected by the acid in the asphalt or by weathering. Other uses include decorative coatings on wallpaper and on concrete, stucco, and tile surfaces; as an ingredient in some special greases; as a coating for cores and molds in metal casting; and as a flux coating on welding rods.

In 1991, the major end uses were joint cement, 52%; paints, 20%; and well-drilling muds, 5%. (See table 8.)

Stocks

Reported yearend consumer stocks of sheet mica increased 4% to 639 tons; of this, mica splittings represented 96%, and mica block represented 4%.

Markets and Prices

Prices for sheet mica vary with grade and quality and can range from less than \$1 per kilogram for low-quality mica to more than \$2,000 per kilogram for the highest quality. The average values of muscovite sheet mica consumed in the United States in 1991 compared with 1990 were as follows: Block decreased 8% to \$85 per kilogram, and splittings decreased slightly to \$1.54 per kilogram. The average value of phlogopite block remained at \$26 per kilogram, while the value of phlogopite splittings decreased slightly to \$4.41 per kilogram. The changes in average value are more a reflection of the quality of mica consumed during the year than actual changes in price. The average value of crude flake mica, including high-quality sericite, was \$54 per ton. The average value per ton for North Carolina flake mica, predominantly a flotation product, was \$59. (See table 9.)

Foreign Trade

The United States continued to rely on imports, mostly from India, for nearly all of its sheet mica and paper-quality scrap mica. Imports for consumption of unmanufactured block, film, and

splittings were about 1,400 tons, 12% less than in 1990. Worked mica imports were about 900 tons, 15% less than in 1990. About 9,700 tons of ground mica was imported mostly from Canada, while about 3,400 tons was exported to 29 countries. The combined value of all mica imports decreased 6% to \$14.7 million, while the combined value of all mica exports decreased 7% to \$9.8 million. (See tables 10, 11, 12, 13, 14, and 15.)

World Review

World production of mica decreased 6% to 198,000 tons. The United States continued to lead in the production of flake mica. India continued to lead in the production of sheet mica.

Wood Treatment Ltd., of the United Kingdom, a ground mica producer, decided to get out of the mica business. Microfine Minerals Ltd. agreed to use Wood Treatment's grinding facilities in Chestire and to fulfill Wood Treatment's existing contracts.⁴ (See table 16.)

OUTLOOK

Demand for sheet mica has decreased dramatically during the past 30 years. For block and film mica, the major cause of decreased demand was technological change, specifically the introduction of semiconductor technology in electronics to the detriment of vacuum tube electronics that used large quantities of mica. Although the major impact of the technology change was felt in the 1960's and 1970's, consumption of block and film mica continues to decrease, albeit more slowly. Substitute materials cause part of the decrease, and increased imports of finished electronic gear mean fewer mica parts are fabricated in the United States. Since 1979, consumption block mica has decreased at an average annual rate of about 20%. This decline is expected to continue, and, by 1995, consumption will decrease to 2,500 kilograms. Consumption of mica splittings, the major type of sheet mica consumed in the United States, also decreased sharply through the 1960's and

1970's. During the 1980's, consumption leveled off to between 900 and 1,000 tons per year. Decreases were due to the development of substitute electrical insulating materials, miniaturization of electrical equipment, and increased imports of foreign-built products. Consumption of splittings is expected to decrease very slightly in the near future, remaining between 800 and 1,000 tons through 1995.

Scrap and flake mica enters markets as ground mica, and demand tends to follow construction activity levels. With construction activity depressed, ground mica consumption has decreased steadily from about 103,000 tons in 1987 to 75,000 tons in 1991. In the near future, modest increases are expected in construction activity, which will probably bring ground mica consumption to about 100,000 tons by 1995.

The major end use, as a filler in joint compounds, will continue to account for 55% to 60% of the market. Consumption for other uses—in paints, well-drilling muds, and plastics—is expected to increase slightly by 1995.

¹Estimated. ²Revised.

³Table includes data available through June 8, 1992.

⁴In addition to the countries listed, China, Norway, Pakistan, Romania, and Sweden are known to produce mica, but available information is inadequate to make reliable estimates of output levels.

⁵Reported figure.

⁶Data are for year beginning Mar. 21 of that stated.

⁷Less than 1/2 unit.

⁸Excludes U.S. production of low-quality sericite and sheet mica, if any.

MOLYBDENUM

By John W. Blossom

Mr. Blossom, a physical scientist/engineer with 44 years' industry and Government experience, has been the commodity specialist for molybdenum since 1982. Survey and trade data were prepared by Sherwood C. Jordan, mineral data assistant; and the world production tables were prepared by Harold D. Willis, international data coordinator.

Molybdenum is a refractory metallic element used principally as an alloying agent in steels, cast irons, and superalloys to enhance hardenability, strength, toughness, and wear and corrosion resistance. Primarily added in the form of molybdic oxide or ferromolybdenum, it is frequently used in combination with chromium, columbium, manganese, nickel, tungsten, or other alloy metals to achieve desired metallurgical properties. The versatility of molybdenum has ensured it a significant role in contemporary technology and industry, which increasingly require materials that are serviceable under higher stresses, greater temperature ranges, and more corrosive environments. Moreover, molybdenum finds significant usage as a refractory metal in numerous chemical applications, including catalysts, lubricants, and pigments. The variety of uses for molybdenum materials, few of which afford acceptable substitutions, has resulted in a demand that is expected to grow at a greater rate than most other ferrous metals.

Distribution of molybdenum reserves and productive capacity is concentrated in a few countries of the world. World mine output was an estimated 112 thousand metric tons (molybdenum contained in concentrate) in 1991, of which Canada, Chile, China, and the United States provided 85%. An estimated 19% of world output came from the U.S.S.R. These five countries, led by the United States, are expected to continue as the principal mine producers for the rest of this century. These countries also possess about 90% of the

estimated 11 million tons of molybdenum in world reserve base.

The metric system is the official system of measurement of most countries. The U.S. Bureau of Mines, in an effort to provide statistical data on molybdenum that are consistent with international usage, will henceforth report data in kilograms and metric tons.

DOMESTIC DATA COVERAGE

Domestic production data for molybdenum are developed by the U.S. Bureau of Mines by means of three separate, voluntary surveys. These surveys are Molybdenum Ore and Concentrate, Molybdenum Concentrate and Molybdenum Products, and Molybdenum Concentrates. Surveys are sent to all operations that produce molybdenum ore and products. Out of 14 operations to which surveys were sent, all responded, representing 100% of the total U.S. production shown in table 1.

BACKGROUND

From the period of the Greek and Roman civilizations to the late 18th century, terms such as "molybdous" or "molybdaena" were applied to minerals that were soft and "leadlike" in character, probably including minerals now known as galena, graphite, and molybdenite. This confusion was resolved in 1778 when the Swedish chemist, Karl Scheele, demonstrated that molybdenite, the principal molybdenum mineral, was a discrete mineral sulfide. Four years later, P. J. Hjelm of Sweden reduced the

acid-forming oxide of the element by heating with charcoal, thereby producing an impure powder of the metal, which he named "molybdenum." Various properties of the element and its compounds were determined during the 19th century, and in 1893, German chemists produced a 96%-pure metal by reducing calcium molybdate. The impure metal was reported to have been used experimentally as a substitute for tungsten in tool steels.

Molybdenum-bearing armorplate was produced in France in 1894; this was the first recorded use of the metal as an alloying element in steel. Soon thereafter, Henri Moissiam, a French chemist, succeeded in producing a 99.98%-pure metal by reduction of molybdenum in an electric furnace. Moissiam then conducted studies to establish the element's atomic weight and to determine its physical and chemical properties. These studies stimulated interest in the metal and its compounds and investigations of commercial applications. By the late 1890's, molybdenum was used in certain chemicals and dyes, and in 1898, a self-hardening molybdenum tool steel was marketed.

The first mine production of molybdenite was probably from the Knaben Mine in southern Norway in the late 18th or early 19th century. Because essentially no commercial use for the metal existed, output from the mine remained insignificant until about 1880. By the end of the century, molybdenum ore was also mined intermittently in Australia and the United States.

Molybdenite and wulfenite concentrates were produced from ores in Arizona and New Mexico, but U.S. output was small and ceased entirely in 1906 owing to lack of demand.

World War I generated the first appreciable utilizations of molybdenum, when it was substituted for tungsten in high-speed steels and used as an alloying element in certain steels for military armament. From 1912 to 1920, small output was recorded from several additional countries, and U.S. production was resumed. The flotation process for separating molybdenite from its ores was developed during these years. The Climax deposit in Colorado and the Questa deposit in New Mexico were initially exploited from 1917 to 1919. Development of the Climax deposit, the world's largest, later proved the viability of high-tonnage extraction of relatively low-grade ore and established the United States as the leading producer of molybdenum.

Output terminated in 1920 in the United States and most other countries because nonmilitary consumption of molybdenum was insufficient to support continued production. However, industrial efforts to develop peacetime applications, primarily as an alloy in steels and cast irons, were successful, and by the mid-1920's, demand exceeded that of the war years. Operations resumed at the Climax deposit in 1924. By 1930, world output of molybdenum totaled 4.2 million pounds, of which the United States and the Climax Mine accounted for about 89% and 73%, respectively.

In 1933, the Greene Cananea Copper Co., a Mexican subsidiary of the Anaconda Co., initiated the recovery of molybdenite as a byproduct of copper mining operations. Three years later, Kennecott Corp. began byproduct recovery at its Bingham open pit in Utah. Since that time, molybdenite recovery circuits have been installed at numerous copper concentrating plants, notably in Canada, Chile, and the United States. These sources have supplied 40% to 50% of the world molybdenum output in recent years.

Since the early 1930's, industrial research and marketing programs have considerably expanded the range of metallurgical materials in which molybdenum is a preferred or essential alloy ingredient. The use of molybdenum as a refractory metal and in a variety of chemical applications has also experienced significant growth.

Definitions, Grades, and Specifications

Molybdenum is a silver-white metallic element with an atomic number of 42, atomic weight of 95.95, and a density of 10.2 grams per cubic centimeter. The chemistry of molybdenum is complex; molybdenum exhibits oxidation states from -2 to 6, coordination numbers from 4 to 8, and forms compounds with most inorganic and organic liquids. Molybdenum is a strong carbide-forming element, and much of its alloying effect in steel is imparted through the formation of carbides. It has a melting point of about 2,610° C; among the metallic elements, only osmium, rhenium, tantalum, and tungsten have higher melting points. Other significant physical properties of molybdenum metal are good thermal conductivity (about one-half that of copper), the lowest coefficient of thermal expansion of the pure metals, high strength at elevated temperatures, and resistance to corrosion in a wide variety of mediums. Molybdenum metal is stable in air or water at moderate temperatures, but above 500° C, it oxidizes readily.

Molybdenite is the principal mineral from which molybdenum is obtained. Crude ore containing molybdenite is beneficiated to produce molybdenite concentrate. The concentrate generally contains about 90% molybdenite; the grade may be somewhat lower, particularly if produced at copper byproduct concentrating plants. Technical-grade molybdic oxide is produced by the roasting of molybdenite concentrate. Typically, the oxide has a content of 85% to 90%, or a minimum of 57% contained molybdenum. Other raw materials, including ferromolybdenum, purified molybdic oxide, ammonium, and

sodium molybdate, and molybdenum metal powder are produced from technical-grade oxide. The production of these materials is described in the section entitled "Products for Trade and Industry."

The American Society for Testing and Materials (ASTM) has developed standards for the chemical composition of molybdenum oxide products (Specification A 146-64, reapproved 1979) and ferromolybdenum (Specification A 132-74, reapproved 1979). These standards specify minimums for molybdenum content and maximums for impurity content as an aid to producers and purchasers. Material marketed by the major domestic producers generally meet or exceed ASTM standards.

Products for Trade and Industry

Some commercial-grade molybdenite concentrate is treated in additional grinding and flotation steps to produce lubricant-grade molybdenum disulfide. Oil and water are volatilized by passing an upgraded concentrate through an inert-gas-swept kiln. The oil-free product is about 99% molybdenum disulfide and suitable for use in lubricant applications.

Molybdenite concentrate is converted to technical-grade molybdic oxide, the major form of molybdenum used by industry and the base material for production of ferromolybdenum, chemicals, and molybdenum metal powder. The technical-grade oxide is produced by roasting molybdenite concentrate in the multiple-hearth furnace at temperatures of up to 650° C. Typically, the roasted product contains 90% molybdic oxide and a maximum of 0.1% sulfur. Technical-grade oxide is used to add molybdenum to steels, cast irons, and other alloys.

Ferromolybdenum is typically produced by reduction of technical-grade oxide and iron oxide with a conventional metallothermic process, using silicon and/or aluminum as the reductant. The molybdenum content ranges from 58% to 64%. Ferromolybdenum is used as a

alternative additive in producing alloy steels, cast irons, and nonferrous alloys.

Ammonium molybdate is produced by reacting pure molybdic oxide with ammonium hydroxide and crystallizing out the pure molybdate. Sodium and calcium molybdate are made in a similar manner using sodium hydroxide and calcium chloride.

Molybdenum metal powder is manufactured by reducing pure molybdic oxide or ammonium molybdate with hydrogen. The purest metal powder (99.95% molybdenum minimum) is produced from ammonium molybdate. Metal powder is pressed and sintered into small metal ingots, which are converted into rod, wire, or sheet by hot rolling, swaging, or forging. Large ingots are produced by arc-casting powder under a vacuum or inert gas atmosphere.

Industry Structure

Five countries, Canada, Chile, China, the U.S.S.R., and the United States, mine 90% of world output of molybdenum ore. Plants to convert ore concentrates to technical-grade oxide and other molybdenum products are in Chile, China, the U.S.S.R., the United States, and Western Europe.

Geology-Resources

Almost all molybdenum is recovered from low-grade deposits of the mineral molybdenite. Deposits mined primarily for molybdenum provide 45% of U.S. output and about 21% of world output. The remainder is obtained mainly as a byproduct from mining of large, low-grade copper porphyry deposits. Primary molybdenum deposits generally grade 0.2% to 0.5% molybdenite; copper ores from which byproduct molybdenum is recovered contain 0.02% to 0.08% molybdenite.

The average crustal abundance of molybdenum is 1 to 2 parts per million (ppm). The molybdenum content of igneous rocks tends to increase with increasing silica content. Molybdenum does not occur in nature in its free or native state, but is found only chemically

combined with other elements. Small deposits of molybdenum-bearing minerals occur throughout the world, but the only molybdenum mineral of commercial importance is molybdenite. Wulfenite, powellite, and ferrimolybdite are common but have supplied very little molybdenum.

Molybdenite (MoS_2) is a lead-gray metallic mineral that characteristically occurs in thin, tabular, commonly hexagonal plates and also disseminated as fine specks. It has a specific gravity of 4.6 to 4.7, a hardness of 1 to 1.5, a greasy feel, and it soils the fingers. Superficially, it resembles graphite, for which it commonly has been mistaken.

Molybdenum deposits are of five geological types: (1) porphyry or disseminated deposits, including stockworks and breccia pipes in which metallic sulfides are dispersed through relatively large volumes of altered and fractured rock, (2) contact-metamorphic zones and tactite bodies of silicated limestone adjacent to intrusive granitic rocks, (3) quartz veins, (4) pegmatites and aplite dikes, and (5) bedded deposits in sedimentary rocks.

The first three genetic-type deposits are hydrothermal in origin and as such represent nearly all the known molybdenum resources currently mined in the world. The remaining types do not represent a great volume of molybdenum but are of certain economic importance only when molybdenum is associated with other minerals.

In the hydrothermal deposits, metallic minerals are precipitated from high-temperature aqueous solutions either by changes in temperature and pressure or by evaporation of the liquid. Minerals are deposited in the cavities, cracks, or interstices of the matrix rock.

Most of the porphyry coppers contain small quantities of molybdenite disseminated with the copper minerals through large bodies of granitic rock. The chief minerals are chalcopyrite and chalcocite, with pyrite and small amounts of other sulfides, including molybdenite.

Available information on world reserves and reserve base of molybdenum varies widely in reliability. For certain countries such as Canada, Chile, and the

United States, company annual reports or other published materials enable inventorying minable ore reserves. For most other countries, reserves must be estimated from fragmentary or preliminary data on ore tonnage and grade of known or anticipated sources. In particular, the reserve figures for China and the U.S.S.R. should be considered order-of-magnitude estimates.

It should be noted that the reserve data refer to molybdenum contained in ore. The recovery of molybdenum after milling approximates 75% to 90% of the in-place ore content at primary molybdenum sources. Recoveries achieved at byproduct sources vary markedly from mine to mine, but average an estimated 55% of the molybdenum in ore processed. Overall, an estimated 65% of the total world molybdenum reserves can be considered as recoverable.

Most of the world reserves of molybdenum occur in the western mountain regions of North and South America, extending from Alaska and British Columbia through the United States and Central America to the Andes Mountains of Chile. These regions, roughly bordering the eastern margin of the Pacific Basin, are also regarded as most promising for future discoveries and additions to reserves.

Technology

Exploration.—Prospecting and exploration for molybdenum is basically the same as that for deposits of other metals. Areas generally considered favorable for molybdenite mineralization are those metallogenic provinces that encompass known occurrences of molybdenum stockworked deposits and copper-molybdenum porphyry deposits. An understanding of regional geology, mineral associations, and known patterns of molybdenite mineralization is essential to identify potential sites for field investigation. Sites for detailed study may be selected on the basis of geologic mapping of rock units and structures, geochemical analyses of sediments and soils, and ground geophysical surveys.

An intensive drilling and sampling program is then required to estimate the size, grade, and continuity of the discovery. Exploration drifts may be driven into the ore body to provide more specific geologic information and bulk samples for metallurgical testing.

The evaluation of a deposit may require 2 to 5 years from the time of discovery. During this time, the technical, economic, and environmental aspects of mine development must be evaluated. An additional 3 to 8 years may be required to prepare the deposit for production. Long development times are indicative of the complex planning and considerable capital needed to develop the large, low-grade stockwork and porphyry deposits that are expected to remain the significant sources of molybdenum. As a general rule, development of underground molybdenum deposits would require more time and capital than that of surface deposits.

Mining.—Molybdenum ore is mined by underground and open pit methods, the choice of method determined by the size, configuration, grade, and depth of the ore body. Underground and surface operations accounted for about 40% and 60%, respectively, of the domestic molybdenum output.

Underground deposits of molybdenum ore are mined by block or panel caving methods modified to suit the characteristics of the particular ore body being worked. In these methods, large masses of ore are undercut and blasted at the base to induce the collapse and fragmentation of the ore under its own weight. The broken ore may be drawn off from the caved mass by gravity through finger raises into slusher drifts. The ore is then scraped to draw holes where it falls into ore cars on a haulage level beneath the slusher drifts. Alternatively, the broken ore may be funneled by gravity to crosscut drifts at intervals between production drifts. Ore is moved from the ends of the crosscuts along the production drifts to ore passes where it is dumped and collected in loading pockets on a deeper main haulage level. Ore is then transported from the

main haulage level to the site of the initial milling operations. Caving methods are used to mine underground deposits of molybdenum because the low grade of the ore necessitates extraction of large tonnages of rock at a minimum of cost. However, caving of the ore must be carefully controlled to avoid ore dilution and excessive ground stresses to mine openings.

In open pit mining operations, the ore is exposed by removal of waste rock. The cut in the ore takes the form of benches, which vary in height and width from mine to mine. The cycle of open pit extraction consists of drilling, blasting, loading, and haulage. Primary drilling consists of driving a vertical blasting hole into the ore. Secondary drilling and blasting may be required to break large boulders. Ore is loaded by mechanical shovels into rail cars or trucks and hauled by large trucks for short distances or by train for long distances. Skipways and belt conveyors are used at some mines for transporting ore to the mill site.

Beneficiation.—Because of their low molybdenum content, all molybdenum-bearing ores require beneficiation. After crushing and grinding to a suitable size, both primary molybdenite and copper sulfide ore containing molybdenite are beneficiated by flotation. With primary ores, a final concentrate of 90% to 95% molybdenite is produced by subjecting the ore to several stages of grinding and reflation. Copper, iron, and lead minerals are generally the critical impurities that must be minimized in the final concentrate product. Overall recovery of molybdenite at primary-ore concentrating plants ranges from 75% to 90% of the in-place ore content.

Production of molybdenite concentrate from copper ores is more difficult, however, because molybdenite constitutes less than 0.1% of the ore. As a byproduct value, molybdenite recovery is generally given less priority than recovery of copper values. In some cases, improved molybdenite recovery may be attained only at the expense of reduced

copper recovery or lower grade of copper concentrate produced.

Recovery from copper ores begins with the bulk flotation of copper minerals and molybdenite as the first separation from gangue materials. Molybdenite in the bulk flotation product is then separated from the copper minerals in a selective flotation process, which usually involves the flotation of molybdenite and depression of copper minerals. The separatory flotation requires close control of pH, reagent mix, and several flotation steps. Processing of copper-molybdenum ore varies from plant to plant depending on the grade of mineralization and impurities in the ore. Concentrate produced as a byproduct contains 70% to 90% molybdenite, although most approaches the higher end of the range in content.

Recycling.—Some secondary molybdenum is recovered in the production of alloy steels, superalloys, and the metal, but data on quantities are incomplete and inconclusive. Most of this recycled material is generated and reused directly at metal-forming or fabricating plants (runaround scrap) or shipped to plants that reclaim it (prompt industrial scrap). Very little molybdenum-containing obsolete scrap is processed for its molybdenum content. Although some molybdenum is recycled as a minor constituent of scrap alloy steels, the use of such scrap does not generally depend on its molybdenum content. An increasing quantity of molybdenum is being reclaimed from spent catalysts and chemical residues.

Byproducts and Coproducts

Tin, tungsten, and a very minor quantity of pyrite are recovered as byproducts from molybdenum ore at the Climax deposit in Colorado. Rhenium is extracted from flue gases and dust produced during the roasting of molybdenite concentrate that has been produced as a byproduct of copper mining.

Molybdenum is recovered as a byproduct primarily from copper ores. A

very small amount is also obtained from tungsten and uranium ores. At the Sierrita Mine in Arizona, copper and molybdenum are considered coproduct values.

Substitutes

Historically, molybdenum has been a relatively inexpensive alloying agent used primarily in specialty steels and alloys, and in the United States, it has been readily available. As a result, metallurgical applications for molybdenum were broadened, and its utility as an alloy ingredient became well recognized. The substitution for molybdenum by other alloy metals has had little impetus.

Several factors mitigate the possible replacement of molybdenum to the degree that its overall demand would be significantly affected. First, there is no acceptable substitute in numerous metallurgical and chemical uses. Second, it is commonly added to steels and alloys to enhance several desired properties (such as hardenability, strength, corrosion resistance, etc.), often in synergistic effect with other alloy metals. In such cases, molybdenum could be replaced for particular effects, but at a sacrifice in overall performance. Moreover, the molybdenum content of alloy and specialty steels ranges from less than 1 to a few percent. Therefore, costs of molybdenum raw materials have to increase substantially to appreciably affect the cost of the finished product, thereby stimulating substitution. Finally, the United States is self-sufficient in molybdenum, a situation unlike that of many other ferrous metals. Significant replacement would entail increases in the imports of substituted metals.

Nevertheless, possible alternatives exist in most applications of molybdenum. Steels and alloys containing less or no molybdenum might be used in place of those with higher molybdenum content. In most cases, such substitution would result in lowered or unacceptable performance. Boron, chromium, and manganese can replace molybdenum in steels where hardenability is the only

desired effect. In certain low-alloy steels, columbium, manganese, and vanadium act in similar fashion to molybdenum. Chromium, nickel, and tungsten are possible substitutes in steels and other alloys. Molybdenum has substantially replaced tungsten in high-speed tool steels; a return to tungsten grades is possible, but with a reduction in economy and performance. Nonmetallurgical materials, such as plastics and ceramics, can replace steels and alloys containing molybdenum in certain applications.

Tungsten and tantalum can be substituted for molybdenum in certain refractory metal uses, but as a cost disadvantage. Molybdenum can be replaced by graphite for refractory elements in electric furnaces in the range of 1,000° to 1,600° C, but at the expense of slightly greater difficulty in operation and control. Chrome orange, cadmium red, and organic orange pigments are possible substitutes for molybdenum orange. Acceptable substitutes for molybdenum are not found in most of its major catalytic applications. Graphite and other solid lubricants generally do not perform as well as molybdenum disulfide, especially under high-pressure and high-temperature conditions.

Economic Factors

The prices of molybdenum products are quoted on a contained-molybdenum basis and reflect, at least partially, the cost of conversion. Technical-grade oxide, the major form of molybdenum sold commercially, varies slightly in price depending on purity, type of packaging, and whether it is briquetted.

Price quotations generally fall under two groups, the producer-marketer and the merchant. The producer-marketer mines and concentrates the ore, converts the concentrates into consumer products, and markets these products, while a merchant buys and sells concentrates and may convert concentrates into products that are marketed. The source for the merchant to buy concentrates is the byproduct producer. The byproduct producer prices his byproduct as one that

provides extra credit. Therefore, this type of a producer is not likely to hold back concentrates from sale. The producer-marketer tries to keep the market balanced by setting a price-based cost plus profit and varying the output to maintain a balance.

Operating Factors

Environmental Requirements.—The mining of molybdenum ore and disposal of ore tailings disturb land areas. Land reclamation is part of the ongoing mining operation. Development of new mining and milling complexes present local socioeconomic and land-use problems. Because new potentially economic sources are likely to be found in relatively unpopulated regions with little other industry, development of a major mine can have significant impact on established occupational patterns. Interaction between mining firms and local, State, and Federal agencies are required to ensure that mine development proceeds in as orderly and environmentally sound manner as is possible. The conversion of molybdenite concentrate to technical-grade molybdic oxide involves roasting. Roasting facilities have been modified with sulfuric acid recovery equipment to reduce emissions and thereby comply with stringent environmental restrictions.

Toxicity.—Compared to other industrial metals, molybdenum exhibits very low, negligible toxicity. No significant toxic effects in human beings have been identified in mining or processing of molybdenum materials. As an environmental trace element, molybdenum is an essential micronutrient. Deficiencies of molybdenum can affect the normal growth and development of plant and animal species.

Employment.—Employment in the past decade has reduced by a factor of five with about the same tonnage of production. This improvement in productivity was due to changes in mining and milling equipment and methodologies.

ANNUAL REVIEW

Domestic and foreign molybdenum markets for concentrates diminished in 1991. Domestic stock levels increased 7%. U.S. mine output of molybdenum was about 47% of world production. Reported end-use consumption of molybdenum in raw materials decreased by 6% from that of the previous year. Exports of all forms of molybdenum from the United States decreased, while imports of molybdenum also decreased. Domestic producer stocks of molybdenum products increased about 63% from that of the previous year. Domestic mine production of molybdenum concentrate decreased to a total of 53,000 tons of contained molybdenum compared with 62,000 tons in 1990. World mine production of molybdenum concentrate also decreased from a total of 122,000 tons in 1990 to 112,000 tons in 1991. Canada, Chile, China, the U.S.S.R., and the United States accounted for more than 90% of the molybdenum produced worldwide. (See tables 1, 2, and 3.)

Consumption and Uses

Consumption of molybdenum concentrate decreased 2,500 tons in 1991. Domestic mine production of molybdenum concentrate was either roasted, exported for conversion, or purified to lubrication-grade molybdenum disulfide. The consumption in 1991 of technical-grade molybdc oxide decreased from that of the previous year. Oxide is the chief form of molybdenum utilized by industry, particularly in steel, cast iron, and superalloys. However, some of the material is also converted to other molybdenum products, such as ferromolybdenum, high-purity oxide, ammonium and sodium molybdate, and metal powder. Apparent U.S. consumption (defined as U.S. primary plus secondary production plus imports minus exports plus adjustments for Government and industry stock changes) was about 19,000 tons of molybdenum. (See table 4.)

Stocks

Total industry stocks, which include those of producers and consumers, increased about 1,000 tons of contained molybdenum. Inventories of molybdenum in concentrate at producer locations decreased about 2,400 tons. Producer stocks of molybdenum in consumer products, such as oxide, ferromolybdenum, molybdate, metal powders, and other types, decreased about 3,500 tons. Compared with apparent consumption, yearend producer stocks of these materials represented about a 10-month supply. Domestic consumer inventories of about 2,600 tons, the same amount as at yearend 1990, represented approximately a 2-month supply as measured by average monthly reported consumption. (See table 5.)

Prices

The "Metals Week Dealer" (MWD) price of molybdc oxide (per kilogram of contained molybdenum) decreased from \$5.99 in January to \$4.95 at the end of December 1991. The average MWD price of oxide was \$5.27 or \$0.35 less than the average MWD price in 1990.

The posted producer price (AMAX Inc. and Cyprus Minerals Co.) for molybdc oxide was \$7.39 during 1991. (See table 6.)

Foreign Trade

Exports of molybdenum in concentrate and of oxide decreased compared with those of 1990. Molybdenum concentrate exports were about 63% of domestic mine production. Approximately 95% of reported shipments of concentrate and oxides were made to Belgium, Chile, France, Germany, Japan, the Netherlands, and the United Kingdom. The calculated molybdenum content of all exports was about 37,000 tons in 1991. Total value of exports decreased from \$209 million in 1990 to \$154 million in 1991.

Approximately 2,600 tons of molybdenum in various forms was imported into the United States, about the

same as that in 1990. Total value of all forms of molybdenum imported decreased from \$28 million in 1990 to \$26 million in 1991. In terms of both value and quantity, the major form imported was ferromolybdenum, principally from Chile and China. (See tables 7, 8, 9, and 10.)

World Review

Capacity.—The data in table 11 are rated capacity for mines and mills as of December 31, 1991. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable long-term operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure. Mine capacity for molybdenum is based on published reports, production statistics, and estimates. (See table 11.)

Reserves.—The definitions of reserves and reserve base are published in U.S. Geological Survey Circular 831, "Principles of a Resource/Reserve Classification For Minerals," which is reprinted in the U.S. Bureau of Mines "Mineral Commodity Summaries, 1991."

Estimated world reserves and reserve base of molybdenum appear in table 12. The United States, with a reserve base of molybdenum estimated at 11.8 million tons, has 45% of the world molybdenum reserve base. About 90% of U.S. reserves occur in large porphyry or disseminated deposits mined, or anticipated to be mined, primarily for molybdenum. These deposits are in Alaska, Colorado, Idaho, Nevada, New Mexico, and Utah. Other molybdenum sources contribute insignificantly to U.S. reserves.

Canadian reserves of primary molybdenum are in British Columbia, including 30% of the total in the Endako

primary deposit. Other Canadian reserves are associated with molybdenum and copper-molybdenum porphyry deposits in British Columbia and in relatively minor sources in Quebec and New Brunswick.

Molybdenum reserves in Central and South America are mainly in large copper porphyry deposits. Of several such deposits in Chile, the Chuquicamata and El Teniente deposits are among the world's largest and account for 85% of total molybdenum reserves in Chile. Mexico and Peru have substantial reserves. The La Caridad deposit in Mexico is a large producer. Numerous other copper porphyries that may contain recoverable quantities of molybdenum have been identified in Central and South America. Many of these deposits are actively being explored and evaluated and could add substantially to reserves in the future.

Reserves of molybdenum in China and the U.S.S.R. are estimated to be substantial, but definitive information about the current sources of supply or prospects for future development in the two countries is lacking. Copper ores are being investigated on the islands of New Guinea and Bougainville in the southwest Pacific, but it is not known whether these contain economically recoverable molybdenum. (See table 12.)

OUTLOOK

Capital expenditures are expected to decrease from that of the previous year to a more normal level over the next few years. Alloy and stainless steel demand is forecast to decline in 1992. Short-term molybdenum demand is expected to remain a little below that of 1991. Molybdenum production must be adjusted to reduce inventories that have been built up during 1991. The long-term demand depends on world events and the ability to meet the needs of capital expenditures for environmental controls and to expand the manufacturing capacity.

⁰Revised. W Withheld to avoid disclosing company proprietary data; included with "Producers: Other."

¹Includes technical and purified molybdc oxide and briquets.

²Includes ferromolybdenum, phosphomolybdc acid, molybdenum disulfide, molybdc acid, ammonium molybdate, sodium molybdate, calcium molybdate, molybdenum metal, pellets, molybdenum pentachloride, and molybdenum hexacarbonyl.

³Data may not add to totals shown because of independent rounding.

⁴Includes calcium molybdate.

⁵Includes purified molybdenum disulfide, molybdenite concentrate added directly to steel, molybdenum metal powder, molybdenum metal, pellets, and other molybdenum materials.

NICKEL

By Peter H. Kuck

Dr. Kuck has been a physical scientist with the U.S. Bureau of Mines since 1979 and was previously responsible for iron ore, silicon, and vanadium. Domestic survey data were prepared by Barbara J. McNair, Ferrous Data Section. International data tables were prepared by William L. Zajac, Chief, and Audrey D. Wilkes, Section of International Data.

Nickel is vital to the stainless steel industry and has played a key role since the beginning of the 20th century in the development of the chemical and aerospace industries. The element (symbolized by Ni) is critical in a highly industrialized and technological society because of its myriad of applications. Nickel's greatest value is as an alloying agent with other metallic elements, adding strength and corrosion resistance over a wide range of temperatures.

Domestic and Western World nickel demand dropped slightly in 1991, following 6 years of continuous growth. Demand for nickel in the Western World was about 670,000 metric tons (mt), 3,000 mt less than the record high of 1990.¹ Prices remained at relatively high levels throughout the year in spite of the general economic downturn. In 1990, the United States signed an agreement with the U.S.S.R. that allowed the Soviets to resume exports of nickel and nickel-containing products, such as stainless steel, to the United States. With the dissolution of the U.S.S.R. and the creation of a market economy in the Republic of Russia, large tonnages of primary nickel were shifted from the Soviet military-industrial complex to markets in Western Europe, Japan, and the United States. This influx of Russian material accelerated in early 1992, exerting a downward pressure on nickel prices in the second half of 1992.

The United States produced 1.21 million metric tons (Mmt) of nickel-bearing stainless steel in 1991, a drop of 8% from that of the previous year.² In Japan, however, production of nickel-

bearing stainless steel was up almost 3%.³ Japan has been the largest stainless steel producer in the Western World for more than a decade and made 2.01 Mmt of hot-rolled, nickel-bearing stainless in 1991.

DOMESTIC DATA COVERAGE

The U.S. Bureau of Mines canvassed all known nickel consumers whose annual consumption was greater than 2 mt. Of the 272 annual forms sent, 184 responses were received, representing 68% of the total canvassed. Estimates for nonrespondents were made by comparing data reported in prior years with current consumption trends. Reported primary consumption, based on data from monthly and annual canvass forms and estimates, was 79% of apparent primary consumption. Apparent consumption is defined as primary nickel produced from domestic ores plus scrap recovery plus imports minus exports plus adjustments for Government and industry stock changes. (See table 1.)

BACKGROUND⁴

Definitions, Grades, and Specifications

Primary nickel is normally marketed as either nickel metal, nickel oxide sinter, or ferronickel. Commercial nickel metal is more than 99.5% pure and may be in the form of square plates, powder, briquets, pellets, ingots, disks, or shot. The square plates are referred to as "cathode" because they are cut from an electrolytic cathode sheet at the end of the refining process. The ferronickel produced in the

United States contains 48% to 52% Ni and is sold in 28-pound ingots; that produced in other countries may contain anywhere from 20% to 50% Ni. In 1992, Glenbrook Nickel Co., the sole U.S. producer, began marketing ferronickel shot for the first time—again with a 48% to 52% Ni content. Nickel oxide sinter contains either 77% or 90%+ Ni. Almost all of the 90%+ grade imported into the United States comes from the Yabulu refinery of the Queensland Nickel Joint Venture (QNJV) in Australia.

Most nickel compounds are divalent, although the oxidation state can vary from -1 to +4. The chloride, the sulfate hexahydrate, and the nitrate hexahydrate are used in electroplating. The sulfate is also used as a colorant and as a starting material for some catalysts. The oxide, hydroxide, and peroxide are preferred for fuel cell and battery manufacturing.

Industry Structure

At least 23 countries mined some type of nickel ore in 1991. In almost every case, the nickel came from either a laterite deposit or a sulfide deposit. Four other countries had active smelters and/or refineries. Most producing companies tend to favor one of the two deposit types at the expense of the other because of significant differences in how the ores are processed. Inco Ltd. is an exception owing to the global nature of its operations. Because laterites are formed by surface water percolating downward through ultramafic rock, most laterite deposits are either in the tropics or in

subtropical to temperate coastal regions that have a long geologic history of heavy rainfall. Sulfide deposits, on the other hand, can occur almost anywhere, ranging from central Africa to the high Arctic.

The nickel in laterite ores is usually processed into ferronickel because (1) the ores have a high iron content and (2) the ores are more easily smelted than concentrated. Sulfide ores are more amenable to concentration and hydrometallurgical refining. Over the 5-year period from 1987 through 1991, laterite operations accounted for about 33% of world mine production, with the balance coming from sulfide operations. The Norilsk Nickel Combine of Russia is currently the largest producing company in the world, followed by Inco Ltd. of Canada. For 1987 through 1991, the six largest producing countries and their share of world mine production were as follows: the Commonwealth of Independent States (C.I.S.) (29%), Canada (21%), New Caledonia (9%), Australia (7%), Indonesia (7%), and Cuba (4%).

The Sudbury district of Ontario continues to be one of the principal sources of nickel for the world. Falconbridge Ltd. and Inco operate most of the mines in the Sudbury Basin. Other important nickel mining regions are the Noril'sk district of central Siberia, the western half of the Kola Peninsula, and the Kambalda district of Western Australia. The only U.S. producer is Glenbrook Nickel, which operates a ferronickel smelter at Riddle, OR. Some nickel is also produced in the United States as a byproduct of copper refining and recycling.

Geology-Resources

Nickel is the Earth's fifth most abundant element, but occurs in the Earth's crust only in the range of 0.008% to 0.02% by weight. The bulk of the nickel is believed to be concentrated in the Earth's core. Geologic studies indicate that most nickel deposits have been derived from ultramafic rocks, such as peridotite or serpentinite. These are

igneous rocks that are low in quartz and feldspar, but high in ferromagnesian silicates. The nickel content of ultramafic rocks, although relatively high compared with that of other rocks, seldom exceeds 0.3% by weight. These values are too low to make them economically minable as nickel ore. Because nickel tends to follow iron and can be readily incorporated into either silicates or sulfides, the element is less likely to be concentrated in an economically viable deposit than some less abundant elements, such as copper and lead. To be rich enough to mine, some natural process must have concentrated the nickel. These processes result in the two very different types of nickel deposits mentioned earlier.

Nickel laterites are formed by the weathering of ultramafic rocks. As the rocks weather, nickel, iron, and sometimes cobalt are taken into solution by descending meteoric water and redeposited at greater depth, producing a zone of enrichment. The water is initially acidic because of the presence of organic acids and dissolved carbon dioxide. As the metal-bearing water descends, it reacts with the bed rock and becomes more basic. The cobalt and iron tend to precipitate out first, forming a limonite zone that averages 0.8% to 1.5% Ni and is rich in nickeliferous goethite $[(Fe,Ni)OOH]$. Further down, a point is reached where the bulk of the nickel precipitates out, together with the accompanying magnesium and silica. This second zone of enrichment typically contains 1.8% to 3.5% Ni. Here, the principal ore mineral is garnierite, a hydrous nickel-magnesium silicate.

Nickel sulfide deposits, on the other hand, are formed by some type of igneous or metamorphic activity, such as the intrusion of molten ultramafic rock or the alteration of the host rock by hydrothermal solutions. The principal ore minerals are pentlandite $[(Fe,Ni)_9S_8]$ and nickeliferous pyrrhotite $(Fe_{1-x}S)$. Millerite (NiS) is regarded as a secondary, supergene mineral at Sudbury, but can also occur as a primary mineral in some lower temperature types of deposits. Heazlewoodite (Ni_3S_2) , niccolite/nickeline $(NiAs)$, and the

various linnaeite end members $[(Fe,Co,Ni)_3S_4]$ are normally present in only minor amounts. At Sudbury, pentlandite and pyrrhotite are frequently associated with chalcopyrite $(CuFeS_2)$ and, to a lesser degree, cubanite $(CuFe_2S_3)$. As a result, copper is an important byproduct for both Falconbridge and Inco. Cobalt and platinum-group metals are also being recovered from the sulfide concentrate.

Nickel sulfide deposits are found in both volcanic and plutonic settings. The sulfides can occur as massive ore, disseminated blebs, breccia fillings, or vein fillings. Economic geologists have developed a variety of depositional models to explain these different features. One of the more popular plutonic concepts involves magmatic segregation and crystal settling, in which a molten magma slowly intrudes upward through the country rock. As the magma cools, the nickel and other metals combine with sulfur to form dense immiscible droplets that settle to the bottom of the magma chamber. This model can be used to explain some of the geologic phenomena observed at Sudbury and at the Bushveld Igneous Complex in the Republic of South Africa. However, the segregation model exhibits several inconsistencies and is far from perfect. Sudbury's origin remains controversial, with one group of geologists postulating that ore genesis was initiated by the impact of an asteroid or large meteorite.

Substitutes

With few exceptions, substitutes for nickel would result in increased cost or some sacrifice in the performance of the product. Present and potential nickel substitutes include aluminum, coated steels, and plastics in the construction and transportation industries; nickel-free specialty steels in the power generating, petrochemical, and petroleum industries; titanium and plastics in severe corrosive applications; and cobalt, copper, and platinum in catalytic uses.

Economic Factors

Prices.—Nickel prices have traditionally been quite volatile. Table 2 shows the time-price relationship for the metal over a 50-year span. The upward price trend in the 1970's reflected generally strong demand. In the early 1980's, excess production capacity caused nickel prices to drop. In terms of constant dollars, nickel prices in the mid-1980's were at their lowest levels since the end of World War II. Between 1984 and 1986, producers were forced to close at least six production facilities; some others were on the verge of failure and lost large amounts of money. World consumption, driven by stainless steel demand, rebounded dramatically in late 1987, reaching record levels that year and in each of the next 3 years. Prices soared along with demand. In mid-1992, the cycle began to repeat itself when demand for stainless weakened in Japan and parts of Europe. Nickel prices turned downward after large amounts of Russian cathode appeared in Western warehouses. (See table 2.)

Costs.—There are several significant factors that determine the cost of producing nickel. They include the type and nickel content of the ore, the mining method, transportation, infrastructure, energy prices, labor and materials, regulatory compliance, and credits from recoverable byproducts.

Generally, nickel can be recovered from sulfide ores at a lower cost than from laterite ores because sulfides are more readily concentrated using established mineral dressing methods. On the other hand, virtually all of the laterite deposits are open pit operations and, therefore, less costly to mine. Most sulfide deposits occur at depth and have to be mined from underground. Shaft sinking, timbering, roof bolting, lighting, ventilation, and pumping all drive up costs. The absence of massive, primary sulfide deposits at the surface is understandable. Many sulfide minerals readily oxidize to sulfates when exposed to air for an extended period of time. Sulfuric acid forms when

copious amounts of water are present, accelerating the oxidation process.

Energy consumption is the most significant cost in recovering nickel from laterite ores. Estimates indicate that for every \$1 increase in the price of a barrel of crude oil, there is a corresponding increase of \$0.05 per pound (lb) of nickel produced at operations that are dependent on oil for both drying and smelting. It does not seem to matter much whether the laterite ore is converted to ferronickel or to matte. Sulfide ores, on the other hand, do not have to be dried, and, unlike laterite ores, are more amenable to concentration.

Byproduct revenues can significantly reduce net production costs. Smelters that convert laterite ores to ferronickel produce only slag, iron, and occasionally electrical power as byproducts. Smelters that process laterite ores using a chemical leaching method sometimes recover cobalt as a byproduct. In contrast, sulfide operations generate revenues from the recovery of byproduct copper, cobalt, and precious metals. The Sudbury nickel deposits are an important source of both platinum and palladium. The principal platinum mineral is sperrylite, PtAs₂, while much of the palladium is tied up in bismuthides and bismuth tellurides. Some sulfide facilities also profit from the sale of byproduct liquid sulfur dioxide and sulfuric acid.

The costs of complying with air pollution control regulations can be significant. Dust generated in the processing of laterite ores can be controlled using relatively inexpensive equipment. In contrast, a large capital investment is required to reduce sulfur dioxide emissions from a smelter processing nickel-copper sulfide concentrates. During the past 10 years, Inco has allocated 12% of its total capital expenditures to attain compliance with Canadian regulations limiting sulfur dioxide emissions.

In 1991, the U.S. Bureau of Mines published an information circular entitled "Availability of Primary Nickel in Market-Economy Countries."⁵ This report evaluated the availability of nickel from 36 deposits or districts in 16

market-economy countries, analyzing more than 95% of production capacity in those countries. The study determined the quantity of nickel available on the basis of net production costs and total costs with both a 0% and a 10% discounted cash-flow rate of return. Costs of production were expressed in dollars per pound of recovered nickel. The study also indicated sensitivities of the cost of production to energy, labor, and similar factors. The deposits and properties in the study contained approximately 33 Mmt of recoverable nickel. Sensitivity studies performed for both laterite and sulfide deposits indicated that the total cost of producing nickel from laterites was most sensitive to increases in energy costs and that the total cost of producing nickel from sulfide deposits was most sensitive to increases in labor costs; sulfides were also affected by changes in revenues from byproducts.

Operating Factors

Environmental Requirements.—The principal environmental problem associated with nickel production is the emission of sulfur dioxide (SO₂) from smelters that process sulfide ores. The SO₂ emitted from smelter smokestacks combines with water in the atmosphere to form droplets of sulfuric acid (H₂SO₄), a major component of acid rain. The Provincial government of Ontario has ordered Inco to reduce SO₂ emissions at its Sudbury complex by two-thirds and has imposed a ceiling of 260,000 metric tons per year (mt/yr), starting in 1994. The company is spending \$410 million on state-of-the-art pollution control equipment to meet the new limit. The only alternative would have been to reduce production by two-thirds from 1989 levels.

Nickel smelters have a much higher sulfur burden than their copper and zinc counterparts. As a rule of thumb, 1 mt of sulfur is generated for each mt of copper produced. In contrast, 8 mt of sulfur is generated for each mt of nickel.

Recent environmental legislation and other responses to environmental concerns are expected to significantly

affect future nickel consumption. In some cases, the effect will be positive; in others, negative.

In November 1990, the Congress amended the Clean Air Act (CAA), updating Federal air pollution standards for the first time since 1977 and completely overhauling the hazardous air pollutants program. The amendments (Public Law 101-549), among other things, put controls on airborne emissions of nickel metal, its compounds, and alloys. Nickel compounds were specifically included in the new list of 189 hazardous air pollutants to be regulated. The law also directed the U.S. Environmental Protection Agency (EPA) to develop, by November 15, 1991, a preliminary list of pollution source categories that warranted regulation. A number of nickel consumers appeared on the November list, including steel mills, iron and steel foundries, nonferrous foundries, and sintering operations.⁶ Primary nickel producers, producers of nickel sulfate, and nickel-cadmium (Ni-Cd) battery manufacturers were also listed, together with secondary copper smelters and secondary zinc smelters. At yearend, EPA was assigning priorities to the listed categories as part of a 10-year phase-in of the CAA regulations. Maximum Achievable Control Technology Standards were to have been established for the 40 most important source categories by November 15, 1992.

Because new pollution control equipment will probably be needed to comply with these standards, the enactment of the Clean Air Act Amendments was expected to increase demand for stainless steel and other alloys of nickel. Under the new law, 111 fossil fuel-fired powerplants must reduce their SO₂ emissions by 1995. This particular section of the law was enacted to help control acid rain. The 111 plants—a total of 251 generating units—were specifically targeted because each emits more than 2.5 lb of SO₂ per million British thermal units (mmBtu). Not all of the plants exceeding the 2.5-lb level, though, will necessarily have to reduce their emissions. It appears that the EPA will require compliance on a systemwide

basis. Some utilities may be able to meet the overall compliance requirements by drastically reducing emission levels at a few of their heavier polluting facilities. Some plants can reduce SO₂ emissions by simply switching to fuels that contain lower levels of sulfur; others will be forced to install scrubbers (flue gas desulfurization units).

In any event, electric utilities will need increasing amounts of stainless steel over the next 20 years. Because so few powerplants were built during the 1980's, construction programs may soon have to be accelerated if the projected demand for electricity is to be met. A significant amount of stainless will not only go into pollution control equipment, but also into turbines.

Under the CAA, few, if any, new plants will be permitted to emit more than 1.2 pounds per million British thermal units (lb/mmBtu). Because it is far cheaper and easier to include scrubbers in the design of a new plant than to retrofit an existing facility, many, if not most, of the new plants will be equipped with some type of scrubbing system. About 100 mt of metal will be required for each scrubber. Although it is not clear which alloys will be used, most will probably contain significant nickel because of the element's ability to improve the resistance of different metals to corrosion and heat.

The California Air Resources Board has voted to list all forms of nickel, including metallic nickel, as toxic air contaminants. The board took the action even though the nickel and metal plating industries had questioned the validity of the risk assessment information assembled by the board's staff. The next step was to have been the preparation of a needs assessment, identifying major nickel emitting sources in California. The assessment would involve estimating emission rates together with associated exposure levels and risks. Technically feasible controls and costs would also be identified. The board indicated that issues such as particle size would have to be closely examined as controls are developed.

In July 1990, the EPA published proposed drinking water standards for

nickel and other materials. The maximum contaminant level goal for nickel was set at 0.1 milligram per liter.

Toxicity.—Data compiled by the EPA indicate that, of the 17 substances covered by the Agency's Industrial Toxics Project, nickel and its compounds showed the highest increase of reported releases from 1988 to 1989. This increase has heightened concerns in several areas.

The American Conference of Governmental Industrial Hygienists (ACGIH) postponed action on a proposal to set more stringent recommended workplace limits for nickel and its compounds. The ACGIH had proposed reducing the workplace limits, or threshold limit values (TLV's), for nickel metal and all nickel compounds to 0.05 milligrams per cubic meter (mg/m³) and to designate nickel metal and all inorganic nickel compounds as confirmed human carcinogens. Action on the more stringent values was postponed until 1993 so that existing scientific evidence could be weighed more carefully and additional evidence, expected to become available in the interim, could be evaluated. ACGIH guidelines are important because the U.S. Occupational Safety and Health Administration (OSHA) and regulatory agencies in other countries weigh them carefully in determining mandatory permissible exposure limits for the workplace.

The Nickel Producers Environmental Research Association (NiPERA), among others, had urged the ACGIH not to reduce the current TLV's for nickel metal and all nickel compounds. The 8-hour TLV is currently set at 1.0 mg/m³ for insoluble forms of nickel (e.g., NiO) and 0.1 mg/m³ for soluble forms of nickel (e.g., NiSO₄). In comments to the ACGIH TLV committee, NiPERA argued that new epidemiological information suggests that there would not be a measurable increase in cancer incidence or mortality at the current threshold values. NiPERA felt that it was not necessary to reduce the current TLV to protect against adverse nonmalignant respiratory effects and recommended that

ACGIH wait until the results of ongoing studies being sponsored by the U.S. National Toxicology Program and by NiPERA were released.

In 1990, the International Committee on Nickel Carcinogenesis in Man published a study intended to clarify the nature and extent of the risks that nickel and its compounds pose to humans.⁷ Called the Doll Committee, after its chairman, Sir Richard Doll of Oxford University, the committee's conclusions were based on an analysis of various epidemiological studies of individuals exposed to nickel in the workplace. The main conclusion was that workers exposed to very high concentrations of oxidic and/or sulfidic nickel did indeed have an increased risk of getting lung or nasal sinus cancer. The threshold concentration in air seemed to be about 1 mg/m³ in the case of soluble nickel compounds and more than 10 mg/m³ for less soluble ones. Exposure levels of this magnitude are no longer tolerated at North American smelters and refineries. There was no evidence to suggest that occupational exposure to metallic nickel increased the risk for any type of cancer. However, the metal can cause an allergic reaction in some individuals. The risk to the general population from exposure to extremely small concentrations of airborne nickel compounds (less than 1 microgram Ni/m³) was minute and, possibly, nonexistent. The study was sponsored by, among others, the EPA, NiPERA, and Energy, Mines, and Resources—Canada.

ANNUAL REVIEW

Legislation and Government Programs

The U.S.S.R. resumed exporting nickel and nickel-containing products, such as stainless steel, to the United States under an agreement that took effect on June 28, 1990. In 1983, the U.S. Department of the Treasury banned the importation of these materials from the U.S.S.R. The action was taken to prevent nickel of Cuban origin from being marketed in the United States. At that time, almost one-half of the total nickel production of Cuba

was being exported to the U.S.S.R. Most of that material was concentrate for refining to electrolytic nickel.

As part of the 1990 agreement, Raznoimport, a Soviet trade organization, had to certify that exports of nickel and nickel-bearing products were exclusively of Soviet origin. Certificates of origin were required for products from both the Norilsk Mining and Metallurgical Plant at Norilsk in the Krasnoyarsk region and the Nickel Industrial Amalgamation Plant at Monchegorsk in the Murmansk region. According to the Bureau of the Census, the United States imported 1,429 mt of cathode and 79 mt of powder and/or flake from the former U.S.S.R. in 1991. Combined imports of cathode from Russia and Estonia in 1992 were expected to about triple the 1991 figure. All of the Estonian material was believed to be of Russian origin.

Strategic Considerations

Nickel is an essential ingredient in austenitic stainless steel and most superalloys. As such, its availability is important to the national security. Domestic mine capacity was less than 5% of primary apparent consumption in 1991. Canada, however, a close ally and a geographically secure source, is capable of supplying U.S. needs under normal circumstances.

Issues

The Defense Logistics Agency, of the U.S. Department of Defense, has submitted a plan to the Congress calling for large cuts in the National Defense Stockpile. Under the plan, the proposed goal for nickel would fall from the current 181,437 mt to zero, and at least 29,212 mt of the 33,760 mt of nickel in inventory would be sold or bartered over a 5-year period. Legislation supporting the disposal was passed by the Congress on October 5, 1992, and signed into law by the President on October 23. (Title XXXIII of Public Law 102-484: The Defense Authorization Act of 1992). Several nickel producers were concerned that the proposed long-term selloff would

unduly disrupt an already weakened North American market.

The new law established an advisory committee to oversee stockpile operations and a market impact committee to minimize market disruptions. The advisory committee was to be composed of officials from seven different Federal agencies as well as representatives from a mix of industries. The impact committee also was required to consult with industry on a regular basis.

The EPA was in the early stages of developing regulatory standards for shipping and processing recyclable materials that contain nickel and other transition elements. The Agency was still soliciting comments on the approach it will take to determine whether a solid waste is hazardous. The toxic constituents under review are listed in Appendix VIII of Subpart D of Title 40, Code of Federal Regulations, Part 261—Identification and Listing of Hazardous Waste. Nickel metal and its compounds both appear on the list, with nickel carbonyl and nickel cyanide being singled out for special scrutiny. EPA's approach is to classify appendix VIII constituent-bearing waste as hazardous only after analysis leads the Agency to conclude that the waste is capable of posing a substantial environmental or human health hazard when mismanaged. Some environmentalists disagree and have pressed EPA to presume that a waste containing a measurable amount of any appendix VIII constituent is hazardous, unless the Agency determines otherwise. This second approach could discourage recycling and elevate disposal costs for some relatively benign wastes that contain small quantities of nickel.

Production

Glenbrook Nickel Co., the only domestic nickel producer, continued to mine and smelt local laterite ore at its Riddle, OR, complex. The company is a joint venture of Cominco American Inc. and Cominco Resources International Ltd. The Riddle smelter was also using spent hydrogenation catalysts containing 5% to 10% Ni as supplemental feedstock. The

laterite deposit on Nickel Mountain has been mined intermittently since 1954, when Glenbrook's predecessor, the Hanna Nickel Smelting Co., first developed the property. In 1986, Hanna closed the smelter but left sizable stocks of low-grade coarse ore on hand. Glenbrook decided to acquire the Riddle operation after the 1988 surge in nickel prices and began smelting this stockpiled material in August 1989.

In November 1990, the company resumed mining on a limited basis to supplement the stockpiled feedstock. Ore from the reopened section on Nickel Mountain was averaging 1.18% Ni and was expected to last at least 3 years. At the beginning of 1991, negotiations were under way to open up two other sections of the deposit. The company spent \$2.5 million rehabilitating a dryer and crushing plant needed to treat the fresh ore. In 1991, Glenbrook mined 631,800 mt of ore containing 7,455 mt of Ni.⁸ The ore was used to produce 7,071 mt of Ni contained in ferronickel.

Glenbrook was in the process of doubling its ferronickel production capability to about 16,300 mt/yr of contained Ni. To meet the additional feed requirements, the company will not expand the mine, but instead import higher grade ore from New Caledonia. This decision was made after the company successfully processed an 18,140-mt shipment of New Caledonian ore in July 1991. Soc. Miniere du Sud Pacific has agreed to provide Glenbrook with 800,000 mt/yr of ore. The imported ore is expected to have a Ni content of 2.3%, significantly higher than the 1.0% to 1.25% material available at Nickel Mountain.

The New Caledonian ore was to be unloaded at rehabilitated dock facilities on Coos Bay, a lumber shipping port northwest of Riddle. The imported ore would be dried and crushed at the Coos Bay site and then trucked 137 kilometers (km) (85 miles) across the Coast Ranges to the smelter. Rehabilitation of the docks and construction of the dryer and crushing plant was scheduled to be completed by the fourth quarter of 1992. A shot casting facility was also being

built at the smelter as part of the project. The casting facility would allow Glenbrook to market 1/4-inch ferronickel shot in addition to the 28-lb ingots already being produced. The entire upgrading program was expected to cost \$33.0 million.

Black Hawk Mining Inc. was in the initial stages of developing a nickel-copper sulfide deposit near Warren, ME. The ore also contains significant amounts of cobalt. Formerly known as the Union or Crawford Pond deposit, its name was changed to the Knox deposit—after the name of the county. In 1990, Black Hawk spent \$400,000 on core drilling and metallurgical testing. The results indicate that the deposit contains 2.71 Mmt of resources grading 1.49% Ni, 0.69% Cu, and 0.12% Co for a cutoff grade of 1.1% Ni. In December 1990, the company began a feasibility study that included a mine and mill design as well as cost estimates.

Development of the Knox deposit had to be deferred until the State of Maine finished drafting new mining legislation that directly affected the project. In April 1990, the Maine Land Use Regulation Commission and the Maine Department of Environmental Protection were given the task of developing comprehensive rules for metallic mining in the State (Public Law 1990, Chapter 874). In late 1991, after months of public hearings and meetings, the two agencies finally approved Maine's first Metallic Mineral Exploration and Mining Rules. Black Hawk's next move was to apply for the environmental and mining permits required to bring the deposit into production.

Consumption and Uses

Western World nickel demand dropped slightly in 1991, following 6 years of continuous growth. Demand was estimated to be about 670,000 mt, down 3,000 mt from the record high set in 1990. Total U.S. apparent consumption decreased slightly because of a decline in scrap purchases. Both U.S. and world demand continued to be driven by the stainless steel industry, which accounted

for about 45% of nickel demand in the United States and more than 60% of world demand.

Production of raw stainless and heat-resisting steel in the United States slipped to 1.704 Mmt and was 8% lower than the corresponding figure for 1990.⁹ Nickel-bearing grades accounted for 71% of the production tonnage. Net shipments of all types of stainless totaled 1.314 Mmt. Shipments of sheets and strip amounted to 875,548 mt, breaking the record of 870,546 mt just set in 1990. The next largest category was plate (flat product 3/16 inch or more in thickness). Shipments of plate were 161,377 mt, down almost 14% from those of the previous year. Together, plate and sheet accounted for 79% of total net shipments, compared with 77% in 1990.

Stainless steel sheet is used in the manufacture of a wide range of consumer products, including household appliances, kitchen facilities, machinery, and medical equipment. In the past, automotive trim was an important end use for sheet, but aluminum and plastics have captured much of that market. Plate is primarily used in the fabrication of chemical reaction vessels and similar heavy-duty industrial equipment. The chemical, food and beverage, petrochemical, pharmaceutical, pulp and paper, and textile industries are all large consumers of stainless plate. The decrease in demand for plate was a direct result of cutbacks in spending on new and refurbished plants.

In 1991, U.S. consumption of primary nickel in superalloys decreased 4%. Part of the decrease was due to recessionary forces and weakening demand. However, the decrease was amplified by the increased availability and consumption of superalloy scrap.

In 1990, superalloy scrap was in relatively short supply. The 1990 shortage was the result of two factors. The first factor was that the London Metal Exchange (LME) cash price remained relatively high between 1988 and 1990, encouraging scrap dealers to turn around purchases as quickly as possible and keep stocks to a minimum. Nickel prices averaged more than \$6.00

per lb in 1988 and 1989, which quickly caused supplies of superalloy scrap to be depleted. The bulk of these supplies was never replaced. The second factor is that less scrap is being generated now because of the adoption of near net-shape-casting procedures. (See tables 3 through 5 and figure 1.)

Stocks

The combined stocks of primary nickel maintained in the United States by foreign producers and metal-trading companies with U.S. sales offices increased 46% during the year. At yearend, these stocks represented 34 days of apparent primary consumption. (See table 6.)

Markets and Prices

Nickel prices weakened significantly during the second half of 1991. The average LME cash price for the year was \$8,155.612 per mt, which equates to \$3.70 per lb. In terms of current dollars, this represented a drop of 8% from the 1990 average of \$8,864.100 per mt. The three principal reasons for the weakening were (1) slumping demand for stainless steel in several developed countries, (2) the increased availability of stainless steel scrap, and (3) improved productivity at primary production facilities.

In comparison to the past few years, the LME cash price was relatively stable. The weekly LME cash price began the year at \$8,388 per mt (\$3.80 per lb), gradually strengthened, and peaked at \$9,076 (\$4.12 per lb) at the end of March. In mid-May, the price, however, began to weaken. Some observers attributed the decline to a large increase in LME nickel stocks, which rose from 3,570 mt to 8,201 mt between April 30 and May 16. Several traders were also concerned at the time because (1) Falconbridge's smelter at Sudbury was running at only 40% of capacity because of a power failure and (2) Inco's labor contract was due to expire on May 31.

By August 2, the LME cash price had declined to \$8,165 (\$3.70 per lb). At that point, the rate of decline began to slow considerably, eventually reaching a

low for the year of \$7,068 (\$3.21 per lb) during the week of December 6. Uncertainty about supplies caused the price to recover slightly at the end of the year. The last weekly price (for the week ending December 27) was \$7,176 (\$3.26 per lb). The bid price on December 31 was \$7,170 (\$3.25 per lb).

The LME gave approval for three U.S. warehouses to hold nickel, beginning October 7, 1991. The warehouses were in Granite City, IL, Long Beach, CA, and Toledo, OH. The LME had already approved Baltimore, MD, and Bridgeport, CT, as U.S. warehouse sites in 1990. The Baltimore warehouse was operational in 1991 and, on January 6, 1992, had 24 mt of cathodes on hand from deliveries.

Accurately projecting demand for nickel, chromium, and some of the other strategic metals has been extremely challenging in recent years. One of the stumbling blocks in calculating apparent consumption has been a lack of concrete information about the content of strategic metals in different categories of scrap. To help in this area, the U.S. Bureau of Mines has published a study whose objective was to calculate an accurate, reliable estimate of the contents of chromium, nickel, and other metals in stainless and heat-resisting steels.¹⁰ In this study, IC 9275, the elemental fraction of stainless and heat-resisting steel was calculated as the ratio of the weight of element contained in stainless steel to the weight of stainless steel produced. The elemental fraction was calculated as a time-averaged, grade-averaged value, from 1962 through 1983, including the grades for which production was reported by the American Iron and Steel Institute.

The content data provided in IC 9275 is also helpful in certain life-cycle studies. Modeling the life cycle of different toxic metals is becoming increasingly popular as a means of attacking environmental problems. Unfortunately, determination of representative Ni contents for some of the more poorly tracked components in the life cycle of nickel continues to be a problem. Assigning Ni contents to different categories of stainless steel scrap

is particularly difficult. The IC methodology can be used to determine the average amount of Ni in different grades of stainless steel scrap. The average Ni content of all of the stainless steel produced over the past 20 years turned out to be 7% plus or minus 1%.

Foreign Trade

The U.S. net import reliance as a percentage of apparent consumption was 71% in 1991. The figure remains high, despite the resumption of primary production in Oregon, because of continuing strong demand for stainless steel in the United States. Imports accounted for about 95% of primary supply in 1991. Canada, as usual, supplied most of the imported material. A significant part of the nickel imported from Norway, the second largest source, was also of Canadian origin. Falconbridge's smelters have been shipping matte to Kristiansand, Norway, for refining since 1928. The refined products—principally metal granules, cathode, and crowns—are then exported to the United States for sale.

The high level of demand for primary nickel has also meant high demand for nickel-bearing scrap, both domestically and abroad. The processing of scrap accounted for the balance of domestic production. U.S. exports of stainless steel scrap remained strong in spite of weakening prices. The exported scrap contained an estimated 17,407 mt of Ni, about the same as that in 1990 but down somewhat from the 19,841 mt of 1989. These figures are based on the assumption that the scrap averaged 7.5% Ni during the 3-year period. (See tables 7 through 9 and figure 2.)

World Review

In June 1990, the International Nickel Study Group (INSG) met for the first time at The Hague, the Netherlands. The meeting climaxed 10 years of difficult negotiations and was followed by a second general session in April 1992 as well as several interim statistical meetings. The INSG has two primary

functions. The first function is to provide transparency by gathering, collating, and publishing statistical data on the international nickel market. The second is to provide an intergovernmental forum for discussion of issues of concern to nickel-producing and nickel-consuming countries. To date, Australia, Canada, the C.I.S., Japan, and 10 other nations have joined the INSG. The European Community also participates as a single entity. The United States and another five countries have been sending observers to the meetings.

The INSG has been publishing a monthly statistical bulletin since 1991. The first issues have included quarterly production and trade data for individual countries. Monthly data on LME nickel stocks and daily prices for the month were also being reported. The organization was preparing to publish a directory of worldwide nickel production facilities that may incorporate semi-annual short-term supply and demand forecasts.

Outokumpu Metals & Resources Oy (OMR), the Finnish nickel producer, and Mooney Chemicals Inc. of Cleveland, OH, merged their chemical businesses on September 30, 1991. A newly incorporated holding company, OM Group Inc. (OMG), now controls Mooney Chemicals Inc. as well as two OMR production units—Outokumpu Chemical Oy of Finland and Vasset S.A. of France. OMR believes that the merger will create a fully integrated global group with a high-technology base that can draw upon the long experience of its personnel in the nickel and cobalt chemical business.

Capacity.—The data in table 10 are rated capacity for mines, smelters, and refineries as of December 31, 1991. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable long-term operation rate, based on the physical equipment of the plant, and given acceptable operating procedures involving labor, energy, materials, and maintenance.

Australia.—In mid-1991, OMR and Australian Consolidated Minerals Ltd. (ACM) decided to defer development of the Mount Keith deposit, 70 km northwest of Leinster and Agnew. The decision was taken after some of the Mount Keith ore was found to contain as much as 10% magnesia (MgO). Initial pilot plant tests had indicated much lower magnesia levels. If indeed true, the high magnesia content could make the ore difficult to smelt. Extensive testing was under way to confirm the preliminary findings.

The Mount Keith deposit contains an estimated 270 Mmt of sulfide ore averaging 0.6% Ni. Although the ore is considered low grade in terms of its Ni content, it is low in pyrrhotite. Pyrrhotite is undesirable because it follows the pentlandite into the concentrate, making smelting more difficult by raising already high sulfur levels even higher.¹¹ Because of the low pyrrhotite, tests have indicated that a high-purity, 20% Ni concentrate can be produced from the Mount Keith ore. The deposit is also near the surface and can be mined economically by open pit methods.

The original plan called for the Mount Keith concentrate to be shipped to Finland for processing into ferronickel. A new ferronickel facility was to have been built in Finland to handle the Australian concentrate while the mine was being developed. However, because of the magnesia, the mine will now be developed first. While the ferronickel facility is being redesigned, about 16,000 mt/yr of Ni contained in concentrate will be sent to existing facilities in Finland for processing first into matte and then refined nickel. An additional 9,000 mt/yr of Ni in concentrate will have to be sold on the world market until the new ferronickel facility can be completed.

Because of the delays at Mount Keith, OMR has decided to accelerate the development of its Forrestania nickel deposit north of Lake King. At the beginning of 1991, OMR owned 55% of the Forrestania deposit, with the balance split between Arimco N.L. and Cyprus Gold Australia Corp. Since then, the

Finnish company has bought out its two partners and decided to open the mine. Production was scheduled to begin in early 1993. Forrestania has 4.4 Mmt of ore reserves, enough to permit the mine to operate for at least 10 years. At full capacity, the mine should be able to produce 7,000 to 8,000 mt/yr of Ni in concentrates, all of which will go to OMR's smelter in Harjavalta, Finland.

Western Mining Corp. Holdings Ltd. (WMC), one of the four largest nickel producers in the Western World, seemed intent on gaining an even larger share of the global nickel market. The Australian company was employing a two-pronged strategy to achieve that end. In September 1991, it began expanding production capacity at its currently owned facilities from 54,000 mt/yr to 65,000 mt/yr. At the same time, the company started negotiating with ACM to purchase the Mount Keith deposit. The Mount Keith deposit was important to both WMC and OMR because it had very large reserves of nickel at a time when refinery feed had been tight.

WMC operates a smelter at Kalgoorlie and a refinery at Kwinana. Feed for the smelter comes from the company's mining complexes at Leinster and Kambalda. The capacity of the Kwinana refinery was in the process of being upgraded from 34,900 mt/yr to 42,000 mt/yr. Because smelter capacity will still exceed refinery capacity by about 20,000 mt/yr of contained Ni, some of the nickel will continue to be sold on the open market. The company was also planning to increase capacity at the Leinster Mine from 15,000 mt/yr of Ni in concentrate to about 35,000 mt/yr. However, plans to expand the Kambalda Mine and the Kalgoorlie smelter were on hold, pending the resolution of issues involving freight and power rates.

WMC's expansion program was tied to three company goals. All three goals required action on the part of the Government. The first goal, obtaining approval from Australia's Industrial Relations Committee for continuous mining at one of the Kambalda complex mines, has already been achieved. WMC had been running three 7½-hour shifts, 5

days per week. As a result of the approval, the company began around-the-clock mining in mid-August 1991. Approval seems certain to be granted at the other Kambalda mines. The second goal required a guarantee from the Western Australian Government that environmental standards would not make the expansion unprofitable. The third goal required the Government to set lower energy rates so that WMC could compete more effectively with other Western World nickel producers. The company had been negotiating with the Western Australian Government for 6 months in an attempt to lower energy costs. WMC asserted that moving its refinery to the State of Victoria would result in a 50% cut in energy costs.

Acquisition of the Mount Keith deposit was not easy. ACM held 100% of the equity in the project. To facilitate the takeover, WMC formed a joint venture with Normandy Poseidon Ltd. The jointly owned company, Resplendid Pty. Ltd., was to buy ACM outright. WMC would then take control of the Mount Keith deposit, while Normandy Poseidon would get ACM's copper, zinc, and gold assets. There would be no further association between WMC and Normandy Poseidon once the AMC assets were divided.

The day before the expected takeover, OMR disrupted WMC's plans by agreeing to purchase a 50% stake in Mount Keith for \$60 million. WMC, not willing to concede defeat, asked that ACM's shareholders receive full and timely disclosure of all relevant matters pertaining to the OMR agreement. WMC also requested that the ACM-OMR arrangement be discussed at a shareholder's meeting, at which time an independent analysis would be presented on the relative merits of the WMC and OMR proposals.

In the end, the largest group of ACM shareholders accepted the Resplendid takeover bid, and the balance of shareholders acquiesced. After the takeover, WMC and OMR, ACM's former partner in Mount Keith, signed an agreement to develop the project on a 50-50 basis. OMR was to receive 14,000

mt/yr of Ni in concentrate from Mount Keith instead of the 18,000 mt/yr it would have received under the original agreement with ACM. OMR was hoping to make up the deficit from its European operations and from future production from the Forrestania project. The original AMC-OMR plan called for the production of 28,000 mt/yr of Ni in concentrate. If this plan is adhered to, WMC would receive 14,000 mt/yr of nickel in concentrate, a substantial addition to its supplies of feedstock.

After the successful bid for control of Mount Keith, WMC also moved forward with its plans to expand the smelter at Kalgoorlie. The decision to expand the smelter was reached following an agreement with the Western Australian Government on sulfur dioxide emissions. The expansion at Kalgoorlie would enable the smelter to treat at least 65,000 mt/yr of Ni in concentrate produced from Leinster, Kambalda, and Mount Keith. In 1990, the smelter treated 55,700 mt of Ni in concentrate plus some high-grade nickel sulfide ores. Increased production at the smelter would require the installation of an additional oxygen plant. The materials handling facilities at the smelter would also be upgraded. The new oxygen plant was to be operational by late 1993.

WMC was also studying the feasibility of developing its newly acquired Bulong property, a nickel-cobalt laterite prospect 35 km east of Kalgoorlie. The company purchased a 70% interest in the Bulong deposit in 1990. The study was expected to take 5 years and would require the construction of a pilot plant. Proven and probable reserves were estimated at more than 90 Mmt of ore, grading 1.05% Ni and 0.07% Co.

Dominion Mining Ltd. was considering a joint venture with overseas companies to develop its Six Mile deposit near Yakabindie, again in Western Australia. The Six Mile deposit is about 25 km south of Mount Keith. Results to date have been extremely promising, but the project has been threatened by aboriginal claims that the mine should be blocked on environmental and cultural grounds. At yearend, the Parliament of Western

Australia was considering legislation that would override existing aboriginal heritage laws and allow the Yakabindie project to go forward. If the claims can be successfully thwarted, the deposit could be in production as early as 1994.

In September 1991, Dominion released the results of its final feasibility study and was hoping to begin mine construction sometime in 1992. The feasibility study indicated that, at a cutoff grade of 0.35% Ni, there is a measured and indicated recoverable resource of 96.4 Mmt of sulfide ore grading 0.504% Ni to a depth of 350 meters (m). Additional resources have been found 2 km to the south at the Golden North prospect.

The mine plan called for a 350-m-deep open pit mine producing about 6 Mmt/yr of ore for at least 12 years. The 6 Mmt of crude would result in the production of about 110,000 mt/yr of concentrate containing about 21,000 mt of Ni. The low-impurity, 18%-Ni concentrate could be sold to smelters and some refineries, or a roasted calcine could be produced, which could then be sold to stainless steel mills.

Queensland Nickel Pty. Ltd. imported about 13,000 mt of Ni in ore and concentrate from New Caledonia during the year. An additional 8,900 mt of Ni in ore and concentrate came from Indonesia. The material was being converted to nickel oxide (90% Ni) at the company's Yabulu hydrometallurgical refinery at Townsville. The ore was being unloaded at outmoded berths in the Port of Townsville and railed to Yabulu. About \$70 million was needed to upgrade the berths and handling equipment. Queensland Nickel had wanted to construct a new port facility at Halifax Bay, but environmentalists opposed the construction, fearing possible damage to the Great Barrier Reef. In June 1990, the Great Barrier Reef Marine Park Authority sided with the environmentalists and ruled against the project.

Shortly afterward, Dallhold Nickel Management Pty. Ltd., the principal partner in Queensland Nickel, began having financial difficulties. At that time, Queensland Nickel was a joint venture of Dallhold (72%) and Nickel Resources

North Queensland (28%), a limited partnership owned by the State of Queensland. On July 3, 1991, Dallhold's lenders—a banking syndicate led by the Hong Kong and Shanghai Corp.—took control of both the 24,000-mt/yr refinery and the venture's Greenvale Mine and had Dallhold put into receivership. The lenders then took steps to find a buyer for the 72% interest previously held by Dallhold and eventually approached Inco. Inco agreed in principle to acquire Dallhold's interest for between \$200 to 235 million, depending upon which assets were sold, but later tabled its offer. At yearend, Queensland Nickel was still being operated by the syndicate.

Agip Australia Pty. Ltd. has postponed development of its Radio Hill nickel-copper deposit in the Pilbara. The deposit, about 30 km south of Karratha, had combined proven and probable reserves of 1.0 Mmt of ore grading 2.5% Ni and 1.8% Cu. Production at the underground mine had been scheduled to begin in late 1992 and to continue for at least 7 years. Annual production would have been about 3,000 mt of Ni contained in matte. The facility was to have used Isamelt technology, developed jointly by MIM Holdings Ltd. of Queensland and an Australian Government-owned research organization. This would have been the first time that the technology would have been used for smelting ores other than those of lead and copper.

Botswana.—Bamangwato Concessions Ltd. (BCL), the Botswanan nickel producer, was to have received a loan from the European Community to improve productivity. The company was planning to use most of the money to deepen its Selebi and Phikwe Mines. Ore reserves on the existing levels were almost depleted. The deepening program would allow BCL to mine seams of higher grade ore and maintain existing production levels. BCL produced about 20,000 mt of nickel contained in matte in 1991. The matte was shipped to Falconbridge's operations in Norway for refining.

Brazil.—The Brazilian ferronickel producer, Cia. de Desenvolvimento de Recursos Minerais S.A. (CODEMIN), was planning to increase production 25% by installing a sinter plant at its Niquelandia complex. The sinter plant would increase the efficiency of the overall operation and extend the life of the mine from 20 years to 31 years. The complex is in the State of Goias and has a capacity of 8,000 mt of Ni in ferronickel.

Burundi.—The Government of Burundi was ready to conduct a \$4.4 million final feasibility study on its Musongati nickel deposits. A lack of infrastructure had made development uneconomic in the past, but a study completed in June 1990 indicated that commercial exploitation was now viable. The study concluded that recent improvements in Burundi's transportation system and energy generation capacity, together with planned further development in these sectors, would result in the necessary infrastructure being in place by the time mining began.

Canada.—Inco continued to expand mining operations in the Thompson nickel belt of Manitoba. The company was planning to spend \$248 million between 1991 and 1997 to develop the 1-D ore body and expand operations at the Birchtree Mine. Development of the 1-D ore body was launched during the year, with production scheduled to begin in 1992. A 5-km-long haulage tunnel was being constructed from the main shaft of the Thompson Mine to the 1-D ore body. By 1997, production was expected to reach 17,000 mt/yr of nickel.

Inco also announced the discovery of two nickel deposits in the Sudbury district of Ontario. The larger of the two, called Victor, is 25 km from Sudbury on the northeast rim of the Sudbury basin. Although Inco estimates that the deposit contains between 18 and 36 Mmt of ore grading 2.25% Ni and 7.3% Cu, it is unlikely to be exploited in the near future because it lies between depths of 2,460 and 2,770 m. The other deposit is only

925 m from Inco's existing McCreeley East Mine and is much more likely to be developed. The second deposit is estimated to contain about 7,300 mt of ore grading 0.8% Ni and 11% Cu between depths of 1,075 and 1,540 m.

Falconbridge Ltd. and Flag Resources Ltd., a Calgary-based company, have begun drilling the Wanapitie anomaly east of Levack. Exploration data suggest that the anomaly may be a world-class deposit rivaling that of the neighboring Sudbury Basin, one of the world's more productive and better known nickel deposits. The Wanapitie anomaly (named after a nearby lake) is both a gravitational and magnetic high, a good indicator of commercially valuable mineral deposits in the Precambrian terrain of Ontario. The anomaly is within a few kilometers of and roughly the same size and shape of the Sudbury anomaly, which underlies the Sudbury basin. Flag Resources, the second largest claim owner after Falconbridge, has held 536 claims in the area (approximately 24,000 acres or 9,700 hectares) since 1980. However, much of the surrounding area was off limits to mining until the spring of 1990 under an Indian Land Caution issued by the Canadian Government. Since then, Falconbridge has conducted an aeromagnetic study of the anomaly, staked numerous claims, and quickly became the largest holder in the area.

Falconbridge, Flag Resources, and the Teck Corp. of Vancouver, British Columbia, have staked out much of the western half of the Wanapitie anomaly, but the eastern half was still under an Indian Land Caution. Falconbridge has launched a 5-year drilling program, expected to cost \$3,750,000, to determine if significant amounts of nickel are associated with the anomaly. If Wanapitie turns out to be a world-class deposit similar to Sudbury, it would have major implications for nickel mining not only in Canada, but throughout the world. Mining companies holding claims on the anomaly would have access to a major new source of nickel ore that could be mined at relatively low cost. Many of the deposits in the Sudbury basin are depleted, and some of the mines there are

more than 1.5 km deep. Any deposits found in the Wanapitie anomaly would probably be closer to the surface, permitting open pit mining, at least initially. Surface mining is cheaper than underground mining and would give Falconbridge and the other two companies a competitive edge.

Falconbridge was also conducting a prefeasibility study of the Raglan deposit in northeastern Quebec. If the results of the study are mostly positive, mine construction could start as early as 1992, with production beginning in 1995 or 1996. Preliminary plans called for a production rate of 16,000 to 20,000 mt/yr of Ni in concentrate. The deposit is estimated to contain 17.7 Mmt of ore, grading 3.15% Ni and 0.88% Cu.

The deposit is on the northern tip of the Ungava peninsula where the waters of Foxe Channel mix with those of Hudson Strait. Development would almost certainly require the installation of on-site concentration equipment because of the Arctic location. The concentrates would probably be shipped to Falconbridge's smelter at Sudbury. Should the project come to fruition, the Raglan concentrate would supplement, but not replace, any of Falconbridge's Sudbury production. Output from the Sudbury smelter would rise accordingly. The major difficulty involved in developing the Raglan deposit is its remoteness and the absence of any local infrastructure.

On May 15, the number 1 furnace at Falconbridge's Sudbury smelter lost power when some electrical hardware failed. Partial power was reestablished 2 days later, but the smelter was still able to operate at only 40% of capacity because the number 2 furnace was shut down at almost the same time by an unrelated electrode failure. Mine production continued while repairs were being made, with ore being stockpiled on the ground. By September, Falconbridge had made up the lost production.

Sherritt Gordon Ltd. appears to have cut itself off from much of the world nickel market by importing Cuban feedstock. About 2,000 mt of what was labeled nickel oxide sinter and other immediate products from Cuba arrived in

Canada in the spring of 1991. The shipment reportedly consisted of mixed sulfide concentrates containing about 55% Ni and 5% Co. By the end of the year, a total of 10,700 mt of Cuban material had entered the country. Both Inco and Falconbridge publicly denied receiving the Cuban material. Sherritt has declined to comment on the origin of their feedstocks. By deduction then, the material almost certainly was being used by Sherritt as feedstock for its Fort Saskatchewan refinery in Alberta. The refinery lost 60% of its feed material when Inco decided not to renew its 10-year feedstock contract with Sherritt. The contract expired at the end of 1989, and Sherritt has since been seeking additional sources of feed. The shortage of feed forced Sherritt to close the refinery for 2 months in 1990 and played a role in the subsequent replacement of the company's board of directors.

Future marketing of Sherritt products may prove difficult. Europe, Japan, and the United States are the three largest nickel markets in the world, and all three have various restrictions on the importation of Cuban products. Sherritt could be precluded from selling into the U.S. market because of the trade embargo on Cuban material and materials of Cuban origin, which has been in effect since 1963. In Europe, the United States has bilateral agreements with France, Germany, Italy, and the Netherlands that regulate the export to the United States of nickel-bearing materials produced in those countries that contain more than 2.5% Ni. The agreements require that these materials contain no material of Cuban origin. The first three European countries are major stainless steel producers. A similar agreement exists between the United States and Japan, the world's largest nickel consumer. Sherritt's action appears to have placed the company in a position where it cannot sell to one major world market and is limited in the other two. These three markets previously accounted for more than one-half of Sherritt's sales.

Sherritt nickel could continue to be sold in the United States if the company decided to process its feedstock in

batches, thereby isolating the Cuban material. However, there is currently no bilateral agreement in effect with Canada, and thus no procedures established by which Canadian nickel-bearing products can be certified to be free of Cuban material. Accordingly, Sherritt nickel would not be allowed into the United States. Batch processing would also be inefficient and expensive. There has been speculation that Sherritt could remain in these markets by swapping with other producers to obtain nickel not of Cuban origin. That, too, is unlikely because the other producers would probably ask for a premium, making the swap uneconomical.

The deal makes sense from Cuba's point of view because Cuba would receive desperately needed hard currency for its nickel concentrates. Before the dissolution of the U.S.S.R., Cuban nickel-cobalt sulfides were refined at Orsk in the Urals as part of a barter arrangement. Sherritt may have had little choice but to acquire the Cuban material because of the tight supply of concentrate worldwide in recent years.

Timmins Nickel Inc. and BHP-Utah Mines Ltd. were considering dissolving their partnership in the Redstone Mine. Timmins has obtained an option to buy the 49% share held by BHP. The Redstone Mine at Timmins, Ontario, has been producing about 92,000 to 96,000 mt/yr of sulfide ore grading 2.32% Ni.

Colombia.—Cerro Matoso S.A. was planning to expand the capacity of its ferronickel smelter at Montelibano in Cordoba Province. The addition of a 12,000-mt/yr furnace would permit the facility to raise production from the current 20,000-mt/yr level to about 32,000 mt/yr. Present production was still below the 22,500-mt/yr limit of the smelter, but the company was expecting to operate at full capacity in 1993.

In a related matter, the Government of Colombia announced that a special export tax would be levied on oil, gas, and ferronickel producers. Cerro Matoso would have to pay the tax, even though it is a joint venture between Instituto de Fomento Industrial (an agency of the

Colombian Government) and Shell Oil Co. Ltd. The tax amounts to about 2.5 U.S. cents for every pound of contained nickel exported.

Cuba.—Reports indicate that Cuba plans to more than double its nickel production over the next 5 years after receiving major financial and technical aid from a western mining company. The plans call for \$1.2 billion to be invested in the island's nickel industry. New extractive technology and equipment would enable the Cubans to become more energy efficient and to produce higher purity nickel.

The Punta Gorda nickel refinery was closed in September 1990 as part of a number of energy-saving measures announced by the Cuban Government. Petroleum shipments from the former U.S.S.R., which accounted for more than 70% of Cuba's imports, had been falling increasingly behind schedule. Because Cuba had little foreign currency with which to purchase oil from Arab countries, its energy problems were compounded by the rise in oil prices during the Persian Gulf crisis. Punta Gorda was only one of the country's three nickel production facilities. The other two, at Moa Bay and Nicaro, were also affected by the problem to a smaller degree. The Moa Bay and Nicaro plants were operating significantly below their combined capacity of 44,500 mt/yr of Ni.

Punta Gorda resumed operations in April 1991. The refinery has three production lines, each a separate unit with a nominal capacity of 10,000 mt/yr. The first line had been operating normally, and the second was just coming on-stream after experiencing technical difficulties when the September shutdown occurred. The third line was apparently idle.

A fourth refinery was being built at Los Camariocas. However, construction of the 30,000-mt/yr Ni refinery may be delayed or even canceled as a result of the unification of Germany. Substantial support for the project was to have come from the former Government of the German Democratic Republic. The current German Government has declared

that all cooperative agreements between the former East German Government and Cuba are void. Production had been scheduled to start in 1993.

Finland.—In the fall of 1991, the Government of Finland approved a basic plan to privatize Outokumpu Oy and other state-owned companies. Since then, the Finnish parliament has given the government authority to decide on ownership structures, but no decision has been made on whether the Finnish State will actually relinquish its majority holding in Outokumpu. The Finnish State currently holds 57% of the stock in Outokumpu. The remaining 43% is owned by private Finnish investors and institutions.

During the summer, Outokumpu overhauled and expanded its Harjavalta smelter in Turku ja Pori Province.¹² About \$17 million was spent upgrading the facility and improving environmental conditions. As a result of the upgrading, sulfur dioxide emissions have been reduced 40%; metal in wastewater, more than 50%; and dust emissions, 30%.

In October 1991, the company's technology group bid on the modernization of the Pechenga nickel smelter over the border on the Kola Peninsula. The company submitted a tender of about \$600 million to the Norilsk Nickel Combine. (See section on the U.S.S.R.) Modernization would have reduced sulfur dioxide emissions to a fraction of their current level. The dissolution of the U.S.S.R. has prevented the start of financing negotiations, delaying the project. Financing was to have been provided by Nordic interests.

In 1990, OMR, the base metals subsidiary of Outokumpu Oy, signed an agreement with the former Karelian Autonomous Soviet Socialist Republic to develop the Republic's nickel-copper deposits. As part of the agreement, the Finnish nickel producer would evaluate a nickel-copper deposit in the Kivijarvi region of Russian Karelia, northeast of Aanisjarvi. The work would primarily involve geological and ore-dressing studies. If the deposit were developed,

Outokumpu could receive some feed for the company's Harjavalta plant.

Outokumpu Chemicals has slowly been increasing production of nickel-base inorganic chemicals. Nickel-base and cobalt-base chemicals are made along with fine cobalt powder at the company's plant in Kokkola, northeast of Vaasa on the Gulf of Bothnia. Between 1990 and 1991, output went from 1,644 mt of contained Ni to 1,790 mt. Expansion of the Kokkola plant was completed in late 1991, and production was scheduled to reach 5,000 mt by 1994.

Indonesia.—P.T. Inco had to temporarily shut down the No. 3 furnace at its South Sulawesi plant after one of the electrodes failed. The furnace was damaged by the ensuing electrical fire. The incident resulted in a production loss of 567 mt of nickel (in matte). However, the company was able to make up the tonnage before the end of the year. Inco Ltd. currently owns 58% of the Indonesian company.

Japan.—Sumitomo Metal Mining Co. Ltd. has begun constructing a state-of-the-art nickel refinery that employs new processing technology. The facility uses the Matte Chlorine Leach Electrowinning (MCLC) process, a refining technology developed by Sumitomo. The MCLC process proved successful when part of the company's Niihama cobalt refinery in Ehime Prefecture was converted to nickel refining in 1989. In 1990, the former cobalt facility produced 3,960 mt of nickel using the process. According to Sumitomo, the MCLC process is 30% more productive than conventional electrolytic refining methods.

The new refinery was expected to cost about \$60 million and would replace existing refining facilities at the Niihama plant site. Construction of the new 24,000-mt/yr plant began in late 1991 and was scheduled for completion in March 1993. The new refinery, together with the converted cobalt facility, would increase Sumitomo's refining capacity from about 22,200 mt/yr to at least 27,960 mt/yr. Sumitomo is Japan's only

producer of refined nickel and produced 22,230 mt of the metal in 1990. Sumitomo relies principally on P.T. Inco of Indonesia and WMC of Australia for its feedstock.

New Caledonia.—Societe Metallurgique le Nickel (SLN) shipped 38,469 mt of nickel in ferronickel, up from 35,216 mt in 1990. Twice in 1990, the French nickel producer was forced to declare force majeure on shipments from its ferronickel smelter at Doniambo. In December 1990, one of the smelter's three furnaces was seriously damaged by fire, destroying two of the furnace's transformers, but the company was able to successfully restore operations. The three furnaces have a combined capacity of about 40,000 mt/yr of Ni in ferronickel. The operation can also produce about 10,000 mt/yr of Ni in matte.

ERAMET-SLN, SLN's parent, has agreed to provide Nisshin Steel Co. Ltd. with ferronickel over the next 10 years. Nisshin, Japan's largest producer of cold-rolled sheet, will also acquire a 10% equity position in SLN. The 10% equity is in SLN's New Caledonian ferronickel operation, not ERAMET's refinery in France. The operation at Sandouville, near Le Havre on the English Channel, is set up to produce about 13,000 mt/yr of nickel metal and 3,000 mt/yr of nickel in salts from New Caledonian matte.

Under the terms of the agreement, shipments of Ni contained in ferronickel to Nissin from New Caledonia will increase from 1,500 mt/yr to 5,000 mt/yr. The deal will provide SLN with the financial means to expand the combined capacity of the Doniambo smelter from 47,000 mt/yr to 53,000 or possibly 55,000 mt/yr. It will also allow SLN to consider additional capacity as world demand for nickel grows.

Philippines.—Financial and marketing arrangements needed to bring the Surigao nickel mine and refinery on Nonoc Island back into operation were well under way. In late 1991, the Philippine Nickel Co. (Philnico) purchased the financially

troubled project from the Asset Privatization Trust. The project had been under the control of a parastatal company, the Nonoc Mining and Industrial Corp., for almost 8 years. The Philippine Government took control of the mine and refinery in August 1984 after the original operator, the Marinduque Mining and Industrial Corp., went bankrupt and was liquidated. The refinery had been idle since mid-1986.

The entire Nonoc rehabilitation project was expected to cost at least \$175 million. The International Finance Corp. (IFC), an affiliate of the World Bank, agreed to directly invest \$15 million in Philnico, loan the company \$35 million, and syndicate a loan for another \$80 million. A consortium led by Billiton Marketing and Trading BV has also signed an agreement with Philnico. The consortium was to take a \$15 million equity position in Philnico in return for exclusive marketing agreements. The remaining \$30 million would come from private investors.

If the Nonoc rehabilitation project were fully funded, production could resume as early as 1993. Full production would be about 25,000 mt/yr of nickel briquets and 2,500 mt/yr of Ni in nickel-cobalt sulfide concentrate. Billiton would market the briquets, while Outokumpu, another member of the consortium, would market the concentrate.

At yearend, Philnico had rehabilitated 8 of the plant's 14 roasters, all 8 thickeners, and 3 of 5 boilers.¹³ Three of 5 draglines were also made operational, along with 11 of the 18 75-short-ton dump trucks. Most of the trucks would eventually be replaced by a 6.3-km-long conveyor that would run from the mine to the plant.

Taiwan.—Tang Eng Iron Works, Taiwan's state-owned stainless steel producer, was expanding its production capacity from 130,000 to 260,000 mt/yr. The new capacity would be used to produce stainless steel bars and rods for the domestic market.

Tanzania.—Sutton Resources Ltd. has signed a comprehensive exploration and development agreement with the Government of Tanzania. The Vancouver-based company has been exploring for nickel in the Ngara district since 1990. To date, most of the work has focused on the Kabanga nickel-cobalt sulfide deposit close to the border with Burundi. The program will now be expanded north to include the Kagera region, which borders Rwanda and Uganda. The geology of the Kagera region reportedly resembles that at Thompson, Manitoba.

Geologists with the United Nations Development Program drilled the Kabanga deposit in 1979 and identified a zone of moderately high nickel-cobalt-copper mineralization associated with an ultramafic intrusive. The deposit is one of a string of magnetic anomalies extending for more than 8 km. In 1990, Sutton acquired the rights to the deposit and has conducted infill drilling to confirm the preliminary U.N. findings. According to company officials, the new drilling indicates that the Kabanga deposit contains between 230,000 and 350,000 mt of Ni, 19,000 to 33,000 mt of Co, and 38,000 to 54,000 mt of Cu.¹⁴ The sulfide zone may be near enough to the surface to allow open pit mining. The Ni content of the Kabanga ore ranges from 0.72% to 2.24%. The Co content varies from 0.07% to 0.12% and is sufficiently rich to be considered a coproduct.

U.S.S.R.—Outokumpu has offered to renovate the Pechenga nickel smelter on the Kola Peninsula for \$600 million. The company submitted a formal tender to the Norilsk Nickel Combine, the plant operator, in October 1991. The aging Pechenga smelter has been emitting 284,000 mt/yr of sulfur in the form of sulfur dioxide (SO₂). The Monchegorsk smelter on Lake Imandra emits a similar amount of SO₂. These large quantities of SO₂ reportedly have devastated large areas of the peninsula and caused damage to forests in neighboring Finland and Norway. The Scandinavian governments, particularly Finland, were becoming

increasingly anxious about deteriorating atmospheric conditions in the entire region. Reports indicate that the forests of northern Finland have perhaps only 10 years of life left if SO₂ emissions are not substantially reduced.

The Scandinavians were especially concerned about Pechenga because it is less than 50 km from the Norwegian port of Kirkenes and had been part of Finland until the end of World War II. The renovation of Pechenga would involve the conversion from electric furnaces to flash furnaces and the construction of a sulfuric acid plant. If Outokumpu's plan is accepted, the work would take 3 years to complete. The new furnaces would cut SO₂ emissions by about 95%. At yearend, financing of the project had still not been resolved. The dissolution of the U.S.S.R. has complicated and delayed startup of the financing negotiations. The financing of the renovation work at Monchegorsk was even more uncertain.

The Norilsk Nickel Combine currently controls 80% to 90% of the nickel sold by the newly formed C.I.S. The combine is responsible for nickel production at Norilsk in north-central Siberia as well as at Pechenga and Monchegorsk. Norilsk, the largest of the three complexes, lies between the Yenisey River and the western edge of the Putorana Plateau. In 1991, the Siberian operation had five underground mines and one open pit in operation. Both massive and disseminated sulfide ores were being mined at Norilsk. The complex has been producing about 200,000 mt/yr of Ni in concentrate along with significant amounts of cobalt, copper, and platinum group metals.

Production at Norilsk was temporarily halved in April when the workers struck the combine for better working conditions. The strike lasted only 8 days and ended when the workers were granted pay increases. Norilsk is a major production facility for the world, and a prolonged strike would have put upward pressure on LME prices.

In 1990, Norilsk Nickel was recognized as an independent supplier by the LME, which had previously accepted Soviet nickel registered only under the name of

Raznoimport, the Soviet state trading organization. The Norilsk combine is no longer associated with Raznoimport and was being represented in western Europe by Normaco AB, a joint trading venture with Axel Johnson Resources AB of Sweden. Newco AG, a Swiss trading company with ties to companies in southern Africa, reportedly was responsible for sales outside Europe.¹⁵ More than 110,000 mt of contained Ni was exported from the former U.S.S.R. in 1991.

A decree issued by the newly elected president of the Russian Republic reportedly allows local enterprises to keep more of their earnings than had been permitted in the past. Local industrial and manufacturing concerns, like Monchegorsk and Pechenga, would be allowed to sell 15% of annual production on the open market, with profits going directly to the plant. According to an official from the Monchegorsk plant, the extra revenue was desperately needed for the immediate installation of environmental protection equipment and, eventually, a new plant. To better understand the various retrofitting and renovation proposals, Russian and Finnish officials toured Outokumpu's smelter at Harjavalta after their preliminary discussions. The tour focused on the flash furnaces, which Outokumpu developed in response to increasingly demanding production schedules and emission control standards.

Venezuela.—Corporacion Federal de Minas (Cofeminas) was considering developing the Loma de Hierro nickel laterite deposit in the State of Miranda. The company, a 50-50 joint venture of Jordex Resources Inc. and Caracas Corp., is incorporated in Venezuela and has already received exploration and mining rights to the deposit. Jordex Resources is based in Vancouver, British Columbia. The Loma de Hierro deposit was investigated in the 1960's by the Venezuelan Ministry of Energy and Mines and contains an estimated 38 Mmt of ore grading 1.55% Ni and 0.05% Co. Cofeminas was planning to conduct additional drilling in 1992 and carry out

other activities needed to complete the feasibility study.

Yugoslavia.—The Kavadarci ferronickel production facility in south-central Macedonia was being rehabilitated and was scheduled to reopen in September 1992. Built in 1978 and closed in 1984 because of low nickel prices and high fuel costs, the facility was considered by most industry observers to be uneconomical to operate. The Yugoslavian Government, which had been running the plant, reportedly paid the facility's debts. If reopened, the plant was expected to produce only about 7,100 mt/yr of Ni in ferronickel, despite being rated at 16,000 mt/yr. At yearend, the situation was confused and chaotic because of the ensuing civil war.

At one point, the former Soviet Government had considered becoming a partner in Kavadarci. However, since then, many problems have developed in both Yugoslavia and the C.I.S. Industry observers doubt that a deal can be concluded with the new Russian Republic in the immediate future. Among other problems, the facility is thought to have a break-even point of \$4.25 per lb of nickel. The average annual LME cash nickel for 1991 was \$3.70 and will be considerably less in 1992. (See tables 11 and 12 for individual country data.)

Current Research

Advanced Batteries.—Automobile manufacturers around the world have been trying for more than a decade to develop an advanced battery to propel the electric cars of the 21st century. Impetus was added after the State of California passed environmental legislation in 1990 that put upper limits on future sales of gasoline-powered automobiles. At least 2% of the new automobiles sold in the State in 1998 must be "zero-emission" vehicles. This figure climbs to 10% by the year 2003. Nickel plays a prominent role in many of the latest battery prototypes, being preferable to lead in terms of lower density and environmental benignity.

In early 1991, the Big Three—Chrysler Corp., Ford Motor Co., and General Motors Corp.—formed a consortium to speed battery research. The Electric Power Research Institute (EPRI) and the U.S. Department of Energy (DOE) also joined the venture, now known as the United States Advanced Battery Consortium. In October 1991, DOE agreed to put up a total of \$130 million over the ensuing 4 years. A matching amount was to come from the four private partners.

At that time, the two top contenders were the sodium-sulfur battery and the nickel-metal hydride (Ni-MH) battery. The sodium-sulfur battery was pioneered by Ford and developed in Europe. The Ni-MH battery was less well known and was being developed by Energy Conversion Devices Inc. (ECD) in Troy, MI. The nickel-iron battery made by Eagle-Picher Industries, Inc. was reportedly too expensive for wide-scale passenger car use. An advanced nickel-cadmium (Ni-Cd) battery interested some researchers, but the consortium had strong concerns about its recyclability.

The consortium's first contract, worth \$18.5 million, eventually went to the Ovonic Battery Co. (OBC), a subsidiary of ECD.¹⁶ Ovonic was to build a prototype Ni-MH battery capable of propelling a compact car 300 miles (480 km) on a single charge. In addition, the battery would have to last 100,000 miles (160,000 km) and recharge in 15 minutes. With such a battery, the new electric car would be able to go from 0 to 60 miles (97 km) per hour in 8 seconds and have a top speed of 100 miles (161 km) per hour.

ECD originally developed the battery as a replacement for the small Ni-Cd batteries used in laptop computers and cellular telephones. The positive electrode is made of nickel hydroxide, while the negative electrode is an atomically disordered alloy of transition metals that absorbs large amounts of hydrogen during the charging part of the cycle. When the battery is discharging, hydrogen ions migrate out of the negative electrode into the liquid electrolyte,

where they react with negatively charged hydroxyl ions to form water.

The Ovonic battery has several advantages over its various competitors.¹⁷ First, the protons can penetrate into the interior of the sintered metal hydride electrode and are not restricted to the surface of the electrode, creating a relatively high energy density. Second, the battery can be charged much faster than its traditional lead-acid counterpart. Third, it is a sealed, maintenance-free unit that can withstand continuous overcharge. Fourth, the battery operates at room temperature unlike its sodium-sulfur contender. Finally, the nickel hydroxide electrode is free of toxic cadmium, making disposal and recycling of the battery less of a problem. In the conventional Ni-Cd battery, the negative electrode is made of cadmium. Cadmium is also incorporated in the positive nickel hydroxide electrode of some Ni-Cd units to reduce electrode swelling. The negative metal hydride electrode in the Ovonic battery, in contrast, is composed of chromium, nickel, titanium, vanadium, and zirconium—all of which are less toxic than cadmium and lead.

According to the Cadmium Association, growth in Ni-Cd batteries is running at 15% in Japan, while declining in Canada and the United States. Part of the decline in North America may be explained by the growing popularity of Ni-MH batteries that have nearly twice the capacity of their Ni-Cd counterparts. Part may be due to growing concerns about the disposal and recycling of batteries containing cadmium. The Ni-Cd batteries do have some pluses. At the present time they are less expensive and more tolerant of overcharging than the Ni-MH's.¹⁸ At least 23 U.S. companies were marketing the new portable Ni-MH batteries besides OBC. The list includes Duracell Inc., Eagle-Picher, Gates Energy Products Inc., Panasonic Industrial Co., and Sanyo Energy (USA) Corp.

Several Japanese companies were also heavily involved in battery research. Ni-MH batteries have been developed and were being marketed by Matsushita Battery Industrial Co. Ltd. and Sanyo

Electric Co. Ltd. Matsushita was reportedly producing about 500,000 units per month at its Shonan plant in Kanagawa Prefecture and was planning to expand output to 2 million per month. The new battery, which will be used in video cameras, laptop computers, and other electronic equipment, reportedly has twice the energy density of an equivalent Ni-Cd battery and can be recharged much faster. Sanyo's production was being sold to Motorola Inc. and Toshiba Corp.

Stainless Steel.—Austenitic stainless steel has been gaining increasing acceptance as an architectural material in recent years. Stainless was still an architectural novelty when it was chosen for the dome and gargoyles of New York City's Chrysler Building back in 1929. Since then, the material has won wide respect because of its durability, corrosion resistance, and maintenance-free surface. The new Canary Wharf Tower in London contains more than 1,200 mt of stainless, with at least one-half being austenitic S-31603 cladding [10% to 14% Ni plus 2% to 3% molybdenum (Mo)].¹⁹ Prefabricated, semidetached homes constructed of stainless steel and glass were being evaluated by the Delft City Council in the Netherlands as a low cost solution to their housing problem,²⁰ and at least two prototype stainless apartment buildings have been built in Paris. A 21-m-tall spire of austenitic S-30400 tops the 272-m-high Society Tower in Cleveland, while the minaret and two domes of the new Bait-ul-Islam Mosque in Toronto are clad with 0.4-mm-thick Erzeform 35 sheet containing 7% to 9% Ni.

In Western Australia, stainless steel mesh has been marketed under the name "Termi-Mesh" as a foundation barrier against termites since 1989. Termites can seriously damage a structure, especially in arid environments where buildings seldom have basements. When a new home is to be constructed directly on a concrete slab, the mesh is installed over the sand pad and covered with a waterproof membrane. The slab is then poured on top of the membrane.

OUTLOOK

Between 1981 and 1991, demand for nickel in the Western World grew at an average rate of almost 4% per year. However, demand began to slow in early 1991 as recessionary forces spread from North America to Western Europe and eventually to Japan. Since then, the economic restructuring of Russia and other members of the C.I.S. has allowed stocks of cathode and metal powder originally allocated to the Soviet defense industry to be exported to the West.

The arrival of the C.I.S. material came at a time when Western nickel demand was already weakening, causing LME stocks to build up to excessive levels. By December 1992, the LME warehouse in Rotterdam held more than 61,500 mt of nickel—a month's supply for the entire West. Export controls imposed by the new Russian Government were expected to slow the flow of cathode, but some smuggling will inevitably continue until the ruble stabilizes. Exports of cathode and nickel alloys masquerading as scrap will be especially difficult to control. The push to export is being driven by two forces. First, demand for stainless within the C.I.S. has been declining since 1989. Second, a large disparity still exists between internal nickel prices and the LME cash price. In January 1991, nickel was being sold in the former U.S.S.R. for about \$100 per mt, at a time when the LME price was about \$8,000 per mt. This gap has narrowed considerably since then. By July 1992, the internal price appeared to have skyrocketed to \$3,000 per mt, but the gap was still huge.

The global slowdown in economic activity and large LME stocks put pressure on nickel prices in 1992, triggering a slide in the third quarter. During the first half of 1992, the monthly LME cash price had been relatively stable, ranging from \$7,193 to \$7,862 per mt (\$3.26 to \$3.57 per lb). But, by October, the price had fallen below \$6,614 (\$3.00), the break-even point for some marginal producers and a psychological barrier for others. At one point in mid-November, the price was as

low as \$5,275 (\$2.39). By yearend, it had recovered somewhat after Inco, Falconbridge, Sumitomo, and several other producers announced cutbacks in output for 1993. The LME cash price is expected to range between \$5,000 (\$2.27) and \$7,500 (\$3.40) in 1993. The lower limit will be determined by the willingness of producers to retain market share by selling below cost. The upper limit will be a measure of the eagerness of the Norilsk Nickel Combine to earn hard currency and secure a permanent sales position in the West. Prices could conceivably return to 1990 levels in 1994 if Japan were to emerge from its current recession and increase stainless production. The Diet—Japan's national parliament—was planning to spend \$86 billion on public works to stimulate the Japanese economy, starting in 1993.

Austenitic stainless steel will continue to drive world nickel demand for both the short term (1993-95) and mid-term (1996-98). Japan is expected to be the dominant austenitic producer for the rest of the century and will continue to rely heavily on Australia, Indonesia, New Caledonia, and the Philippines for nickel matte and mine products. Japan is also the largest consumer of stainless of all types on a per capita basis. In recent years, Japanese stainless production has been 1.4 to 1.9 times greater than that of the United States. U.S. stainless production peaked in 1988 at 1.996 Mmt and has since been running between 1.70 and 1.85 Mmt.

Western demand for austenitic stainless in 1993 should be slightly less than the record high of 1990 because of the Japanese recession. The rest of East Asia will continue expanding stainless production capacity, although perhaps at a somewhat reduced pace. Little or no growth is planned for Western Europe, which accounted for 36% of the 12.4 Mmt of stainless (both austenitic and ferritic grades) produced worldwide in 1991. The Republic of Korea is already making more stainless than either Sweden or the United Kingdom, while Taiwan is hard on the heels of Finland, which currently ranks eighth in Western Europe. Consumption of stainless by end use is

also shifting. Decreased demand in traditional areas such as automobile wheel covers will be partially offset by new uses such as state-of-the-art pollution control equipment. Nickel consumption in stainless plate, the bright spot in 1990, may decline temporarily because growth in the capital goods sector is expected to remain sluggish for the next 2 or 3 years.

The long-term (1999-2002) forecast is much more rosy. If the past is any guide to the future, world stainless steel production should grow on the average 3% to 5% per year over the next 10 years. Total nickel consumption should grow at an even faster rate because stainless currently accounts for only 60% of total nickel demand and many novel, nonsteel uses are being developed for the element. The successful revitalization of Russia and the rest of Eastern Europe, coupled with a restructuring of the Chinese economy, could generate unprecedented demand for nickel at the turn of the century.

A significant amount of nickel also goes into superalloys. In the United States, much of this material ends up either in jet turbine engines or in sophisticated chemical processing equipment such as chemical reactors and pumps. Record numbers of orders for civil aircraft are expected to materialize sometime after 1995 because air traffic is steadily increasing and aging fleets need to be replaced. Demand for nickel by U.S. superalloy producers will probably be flat until then. Many domestic airlines are currently experiencing financial difficulties brought on by the recession, Government deregulation, new environmental controls, and escalating costs for jet fuel, but should be able to overcome these problems in time. The sluggish U.S. economy and the slowdown in Europe and Japan have discouraged chemical manufacturers from building new plants. Chemicals companies around the world are currently restructuring, downsizing, and making strategic alliances to penetrate previously closed markets. Orders for new chemical plants and equipment will continue to be weak through 1994, but the situation should change dramatically after Germany

finalizes reunification and Japan escapes from recession. The long-term outlook for superalloys is optimistic.

¹Revised. NA Not available.

²For years prior to 1989, export data for nickel oxide sinter were included with those of salts.

³For the different salts, the nickel contents are assumed to be as follows: chlorides (25%), sulfates (22%), other salts (22%), oxide and oxide hydroxides (65%). The typical catalyst is assumed to have a nickel content of 22%.

⁴Data may not add to totals shown because of independent rounding.

⁵The nickel content of waste and scrap is assumed to be 50.0%, while that of stainless steel has been shown to be about 7.5%.

Total	890,539	917,717	970,493	937,173	922,944

*Estimated. ²Revised.

¹Insofar as possible, this table represents recoverable mine production of nickel. Where actual mine output is not available, data related to a more highly processed form have been used to provide an indication of the magnitude of mine output and this is noted parenthetically or by a footnote following the country name. Table includes data available through May 29, 1992.

²Reported figure.

³Refined nickel and nickel content of oxides and salts produced, plus recoverable nickel in exported matte and speiss.

⁴Estimates are based on metal production after deduction for nickel content of matte imported from Botswana for processing.

¹Estimated. ²Revised.

³Table includes data available through May 29, 1992.

⁴In addition to the countries listed, North Korea is believed to have produced metallic nickel and/or ferronickel, but information is inadequate to make reliable estimates of output levels. Several countries produce nickel-containing matte, but output of nickel in such materials has been excluded from this table in order to avoid double counting. Countries producing matte include the following, with output indicated in metric tons of contained nickel: Australia: 1987—47,834; 1988—45,000 (estimated); 1989—45,000 (estimated); 1990—45,000 (estimated); and 1991—45,000 (estimated); Botswana: 1987—16,528; 1988—22,539; 1989—18,552 (revised); 1990—17,880 (revised); and 1991—17,300 (estimated); Canada: 1987—56,558; 1988—57,703; 1989—44,320; 1990—43,300 (estimated); and 1991—40,000 (estimated); Indonesia: 1987—26,508; 1988—28,864; 1989—29,030; 1990—24,949 (revised); and 1991—34,412; and New Caledonia: 1987—8,283; 1988—10,470; 1989—10,650; 1990—9,683; 1991—8,000 (estimated).

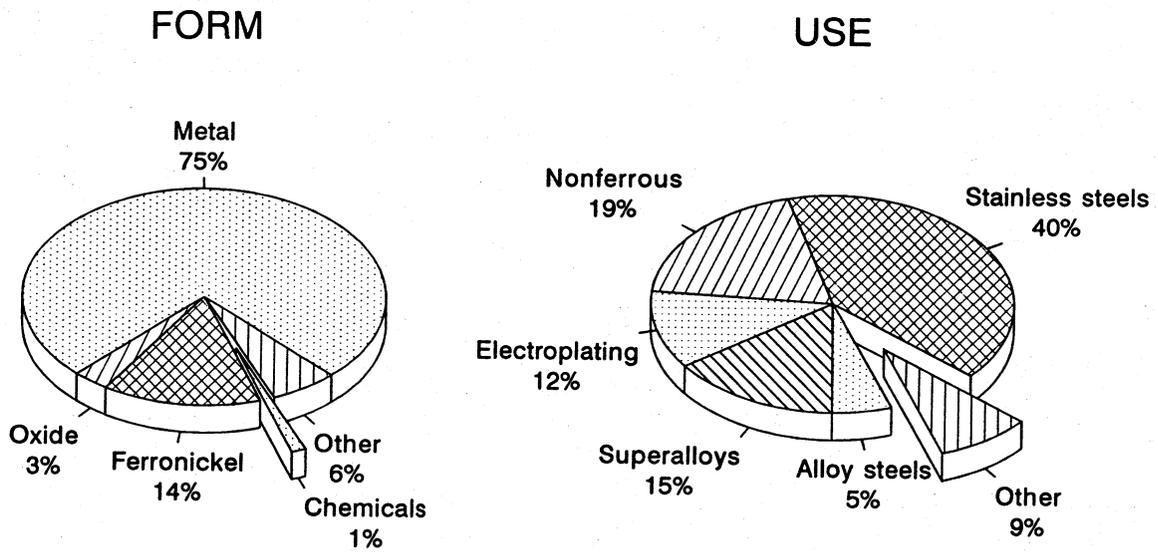

⁵Brazil is believed to also produce nickel oxide, but information is not available on which to base estimates.

⁶Source of data: International Nickel Study Group. World Nickel Statistics, V. 1, No. 1, Dec. 1991, Special Issue, p. 7. Cuba also produces nickel sulfide but, because it is used as feed material elsewhere, it is not included to avoid double counting. Output of processed sulfide was as follows, in metric tons: 1987—16,600; 1988—18,314; 1989—18,475; 1990—16,400 (estimated); and 1991—15,000 (estimated).

⁷Reported figure.

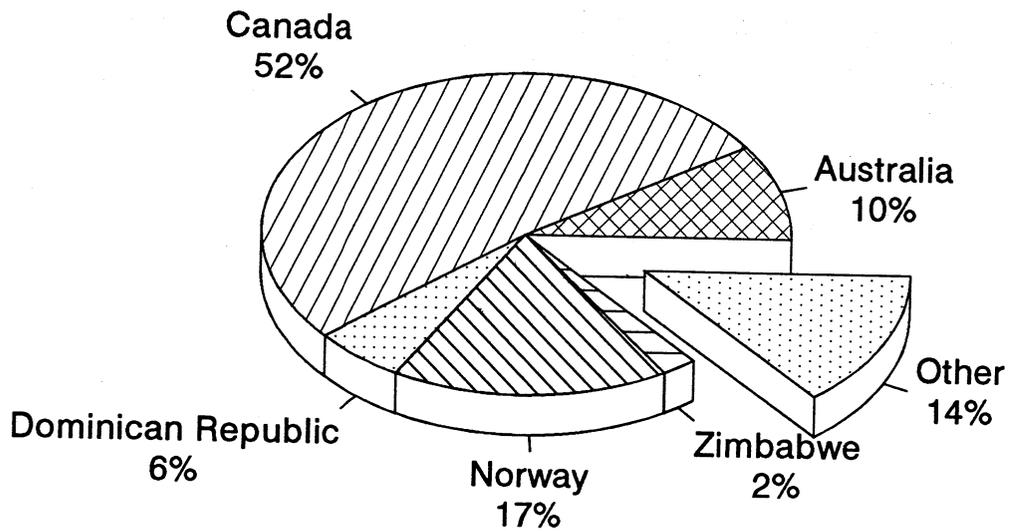

⁸Revised to zero.

FIGURE 1
U.S. PRIMARY NICKEL CONSUMPTION IN 1991, BY FORM AND USE

98,631 METRIC TONS

FIGURE 2
MAJOR SOURCES OF U.S. PRIMARY NICKEL IMPORTS, BY COUNTRY

138,659 METRIC TONS

NITROGEN

By Raymond L. Cantrell

Mr. Cantrell joined the U.S. Bureau of Mines in the capacity of physical scientist, nitrogen commodity specialist, in June 1988. He was previously affiliated with W. R. Grace & Co., Hasbro Industries, and Columbia Nitrogen Corp. Domestic survey data were prepared by Tonya Hardin, statistical assistant; and international data tables were prepared by staff, international data.

War in the Persian Gulf and sweeping political reforms in the U.S.S.R. and Eastern bloc countries commanded global attention in 1991. The Persian Gulf Crisis and Eastern European reforms were not without sacrifice to agriculture, however. Global ammonia production declined by an unprecedented 4.3 million short tons N (4%) to a level of 103.3 million tons.

Strategic supplies of ammonia and urea normally traded from out of the Persian Gulf were cut off altogether or severely curtailed during the Gulf Crisis, and there were severe cutbacks in fertilizer production in Eastern Europe that created food shortages owing to foreign exchange problems.

In the United States, agriculture continued to gain momentum, and ammonia plants ran at near capacity in meeting demand. Global grain stocks declined to the lowest levels since the mid-1970's, which portended a continued strengthening in U.S. agriculture.

The Secretary of Agriculture lowered acreage set-asides for most feed and food grains to 5%, encouraging farmers to bring another 6 to 8 million acres of fallow land back into cultivation during fertilizer year 1991-92. Nitrogen fertilizer consumption was expected to increase 2% to 3% as a result.

Elemental nitrogen gas and liquid (N_2), together with synthetic anhydrous ammonia (NH_3)—a derivative of atmospheric nitrogen and fossil fuels—form the base for an enormous global agricultural and industrial sector. Elemental nitrogen is used extensively by the electronics, metals, food, and

aerospace industries because of its unique inert and cryogenic properties. Nitrogen contained in anhydrous ammonia and its downstream fertilizer derivatives provides more than 50% of the world's essential plant nutrient demand. In the industrial sector, anhydrous ammonia derivatives are important for the production of synthetic fibers, resins and polymers, explosives, animal feeds, and an enormous array of inorganic and organic compounds. (See table 1.)

DOMESTIC DATA COVERAGE

Industry statistics for anhydrous ammonia and derivative products were developed by the Bureau of the Census, U.S. Department of Commerce. Preliminary monthly data were published under product codes 28731, 28732, and 28742 in Current Industrial Reports (CIR), Fertilizer Materials, M28B. In 1991, Census adopted a quarterly format and replaced monthly series M28B with the quarterly series MQ28B, under the same title. Final monthly and quarterly data are subsequently published in a companion annual report MA28B. During 1991, the Bureau of the Census surveyed approximately 250 known producers of inorganic fertilizer materials. Statistics covering industrial gases were reported in the Bureau of the Census CIR publications M28C, M28QC, and MA28C, Industrial Gases.

BACKGROUND

Nitrogen chemical matter developed as part of our solar system about 5 billion

years ago, according to astrophysics. About 4 billion years ago, volcanic activity was believed to have belched gases from the bowels of primordial Earth, forming the nucleus for the nitrogen-rich atmosphere as we know it today. Nitrogen was discovered independently in 1772 by the Swedish druggist, Carl Scheele, and the Scotch botanist, Daniel Rutherford.¹

Nitrogen is an absolute requirement for all life forms on Earth. The gas cycles between its inert diatomic form (N_2) in the atmosphere and chemically fixed forms on Earth, weaving an intricate balance with the carbon cycle that is driven by the photosynthesis processes of living plants. Plants absorb carbon dioxide from the atmosphere, synthesize carbohydrates and essential amino acids and proteins (nitrogen forms), and emit oxygen, all prerequisite to life. The microorganisms of the rhizosphere topsoil supply available mineral nitrogen to nonleguminous plants and biological nitrogen to leguminous (nitrogen fixing) plants for human and animal nutrition.

Planet Earth is enveloped by an atmosphere dominated by nitrogen (N_2), oxygen (O_2), and water vapor (H_2O), above which lies a delicately thin layer of protective ozone (O_3) that screens harmful ultraviolet radiation. Trace gases in the atmosphere such as carbon dioxide (CO_2) absorb much more radiant energy than they release, providing the additional warmth necessary for our habitation of the planet.

The air we breathe consists of about 78% N_2 and about 21% O_2 by volume; argon makes up most of the remainder.

Trace amounts of helium, hydrogen, krypton, neon, and xenon are natural atmospheric sources, together with the greenhouse gases—global warming gases—carbon dioxide (CO₂), methane (CH₄), and nitrous oxide (N₂O). Fossil fuel combustion has been responsible for a significant buildup in atmospheric CO₂ during the 20th century.

At the turn of the 20th century, natural sources of nitrogen chemical materials supplied virtually all of the nutrient requirements for agricultural crop production. Mineralized organic soil nitrogen, domestic animal manures and byproducts, guano, seed meals, and coke oven ammonia predominated. The mineralized occurrences of sodium nitrate found in the Atacama Desert of northern Chile also provided strategic supplies of agricultural nitrogen to the global community.

In the late-1800's, agronomists warned that a global food crisis would materialize unless supplemental nitrogen forms could be found to increase crop production for the exploding world population. Four major industrial nitrogen fixation technologies evolved between 1900 and 1920: (1) the electric arc process, developed by Birkeland and Eyde in Norway, produced nitric oxide (NO) from atmospheric nitrogen and oxygen that was used to produce nitric acid (HNO₃); (2) the cyanamide process, discovered by Frank and Caro in Germany, synthesized calcium cyanamide (CaCN₂) from calcium carbide (CaC₂) and N₂; (3) the cyanide process, developed by Bucher of Brown University in Rhode Island, produced sodium cyanide (NaCN) from N₂ and sodium carbonate (Na₂CO₃) as an intermediate to ammonia production; and, (4) the ammonia process, developed by Haber and Bosch in Germany, reacted N₂ and hydrogen (H₂) under high temperatures and pressures in the presence of a catalyst to form ammonia (NH₃).

The Haber-Bosch process overshadowed all other industrial methods for producing nitrogen chemical materials and fostered today's mammoth ammonia-based nitrogen fertilizer and industrial sectors. This process was ideally suited

for the large-scale commercial production of ammonia (82.2% N) because of the enormous natural resources of essential chemical feedstock elements: nitrogen from the atmosphere, and hydrogen, derived from coal, petroleum, natural gas, and water.

Definitions, Grades, and Specifications²

At ordinary ambient temperature and pressure, anhydrous ammonia is a colorless gas with a very sharp, characteristic odor. Ammonia condenses to a liquid at minus 28° F. Anhydrous ammonia is not a poison and has no cumulative toxic effects on the human body. It, however, is corrosive and may cause lung, throat, mouth, nose, and eye irritation. When liquid anhydrous ammonia comes into direct contact with the skin, a severe burn may result. Anhydrous ammonia is not combustible except when its concentration in the air falls between 16% to 25% at temperatures in excess of 1,560° F.

Ammonia vapor becomes "life threatening" only when exposure levels reach 2,500 to 6,500 part per million (ppm) for up to 30 minutes or "rapidly fatal" if exposure levels reach 5,000- to 10,000-ppm concentrations for up to 30 minutes. Goggles, respirators, gloves, other protective body gear, and plenty of water—in cases of personal exposure or spills—should be readily available when working with ammonia. Steel is the only acceptable metal allowed in the process of transfer, storage, and transport of anhydrous ammonia.

Technology

Elemental nitrogen is mined from the air by cryogenic separation and membrane technologies. In a typical air separation plant, liquefied air is separated into its individual components by fractional distillation. The resources of nitrogen in the air are virtually unlimited and renewable because of the continuous nitrogen cycle between fixed forms on Earth and atmospheric nitrogen.

Mining.—Mineralized occurrences of sodium nitrate (NaNO₃) and potassium nitrate (KNO₃) are mined in significant quantities in the Atacama Desert of northern Chile. The extremely arid nature of this region, with its paucity of soil microorganisms, creates an ideal environment for preserving the nitrate deposits that formed in Miocene times. The nitrate content of the deposits range from about 6.5% to 50%, with an estimated reserve base of about 2.5 billion tons.

Product grades of sodium nitrate and sodium nitrate-potassium nitrate mixtures are obtained through selective precipitation and filtering, followed by granulation. In 1991, Sociedad Quimica y Minera de Chile S.A. (SQM) produced more than 1 million tons of granular sodium nitrate and mixed potassium products for fertilizer and industrial use.³

SQM's principal product line, in order of importance, included sodium nitrate (16% N) and homogeneous chemical mixtures of sodium nitrate and potassium nitrate containing 15% N and 14% potash (K₂O). Sodium nitrate was also blended with potash to produce a mixed fertilizer containing 13% N and 44% K₂O.

Processing.—Anhydrous ammonia is typically produced through a sequence of catalytically driven reactions involving the steam reforming of natural gas in the presence of air to produce hydrogen and nitrogen in the proper ratio to effect ammonia synthesis. The latest state-of-the-art plants operate at less than 25 million British thermal units (Btu) per ton, resulting in an energy efficiency of more than 70%.

Modern ammonia plants employ efficient centrifugal compressors for air and synthesis gas compression. Temperatures and pressures fluctuate throughout an ammonia plant depending on the process, but typically vary between 600° F to 1,800° F, and 500 to 3,000 pounds per square inch gauge, respectively. A nickel catalyst is used in the reformer and associated front-end sections of the plant, while an iron-promoted catalyst is used for ammonia synthesis.

Urea is formed when ammonia is reacted with byproduct carbon dioxide (CO₂) generated during ammonia synthesis. The materials are reacted under high pressure in a two-step reaction at about 400° F to first form ammonium carbamate, which then decomposes to urea (NH₂CONH₂).

Nitric acid is formed when ammonia is passed over a platinum-rhodium catalyst at about 1,700° F and 120 pounds per square inch gauge. As ammonia passes over the catalyst gauze, it reacts with oxygen to form nitric oxide (NO), which is converted to nitric acid by mixing with water in a countercurrent absorption tower.

Ammonium nitrate, in turn, is formed by the simple acid-based reaction between ammonia and nitric acid, and urea and ammonium nitrate may be blended to produce the popular urea-ammonium nitrate (UAN) solutions containing 28% to 32% N.

Economic Factors

The data of table 2 reflect long-term price trends for U.S. ammonia and natural gas over a period of 22 years (1970-91). The ratio of ammonia prices to natural gas feedstock prices provides a measure of ammonia's relative price sensitivity to changing feedstock costs. This relationship, however, does not give an accurate account of the impact of market forces and improvements in production efficiency on indicative profitability in the U.S. ammonia market.

Between 1970 and the early 1980's, natural gas prices rose dramatically, and ammonia production costs became much more sensitive to feedstock costs. Feedstock costs as a percentage of total production costs rose precipitously, from 45% in 1970 to 75% by 1982. Natural gas prices have declined since 1985, and feedstock costs in 1991 represented about 65% of total ammonia production costs.

The U.S. ammonia industry experienced record profitability during 1974-75 because of a tight global supply-demand situation, in spite of the rising dependency on feedstock costs; a similar situation developed during 1979-81.

Conversely, the U.S. ammonia industry suffered substantial losses in 1986-87 owing to a sustained period of oversupply in the world fertilizer and grain markets.

A dramatic recovery in the U.S. agricultural sector since 1987, accompanied by favorable energy prices, has led to a return to respectable profitability in the domestic converted nitrogen industry.

On April 3, 1990, the New York Mercantile Association (NYMEX) established natural gas futures trading in the United States. Natural gas futures trading was designed to allow suppliers, producers, and end users to shift or hedge price risks. NYMEX believed that natural gas futures contracts would provide the same liquidity, unambiguous price reference, and hedge against risk characterized by its successful petroleum contract system. Futures prices reflected price stability in the U.S. natural gas market for the coming year. (See table 2.)

ANNUAL REVIEW

Legislation and Government Programs

The Food, Agriculture, Conservation, and Trade Act of 1990, Public Law 101-624, signed on November 28, 1990,⁴ created the "triple base flexibility" initiative that gave farmers more freedom to make planting decisions and extended many of the highly successful program initiatives of the 1985 bill. Under the provisions of the 1990 "farm bill," 33 million acres was available to be "flexed" to other crops in 1991, but only about 7.5 million acres actually moved out of the original program crops.

Under triple base, farmers lost Government subsidizes on 15% of their base acreage but gained the flexibility to plant virtually any crop except fruits and vegetables on this land and still receive Government price support loans. The triple base initiative provided the impetus for a \$13 billion reduction in Government "entitlement" farm program spending over a 5-year period as prescribed by the Omnibus Budget Reconciliation Act of

1990 (Public Law 101-508), signed on November 5, 1990.⁵

Total Conservation Reserve Program (CRP) acreage was required to increase from a level of 34 million acres in 1990 to between 40 to 45 million acres by 1995. Following the 10th CRP signup, March 4-15, 1991, total CRP acreage was increased 475,000 acres to a total of 34.4 million acres. Another 1.1 million acres was expected to be accepted following the 11th CRP signup, July 8-19, 1991, raising the CRP participation to 35.5 million acres.

Bids for the 12th CRP signup were to be accepted by county offices of the U.S. Department of Agriculture (USDA) Agricultural Stabilization and Conservation Service, June 15-26, 1992. CRP acreage must be withheld from cultivation for a period of 10 years.

The Commodities Futures Trading Commission (CFTC) approved diammonium phosphate (DAP) futures trading on the Chicago Board of Trade (CBOT) on July 25, 1991. Trading was to commence on October 18, 1991. On October 29, 1991, the CFTC also approved ammonia futures trading on CBOT that was scheduled to commence in 1992.

The historic Clean Air Act of 1990 (Public Law 101-549)⁶ will have monumental economic, health, and trade impacts on both the United States and the world. The massive bill contained 11 titles that targeted 3 principal forms of pollution: acid rain, smog, and toxic air pollutants.

The National Energy Strategy report was issued by the U.S. Department of Energy (DOE) in early 1991 to provide guidance in implementing the new clean air bill, pursuant to the President's directive of mid-1989.⁷ In total, about 30 million tons per year of hazardous chemicals and noxious pollutants was to be removed from the air.

One of the major impacts of the new clean air legislation will be the emphasis placed on clean burning alternative fuels and the use of oxygenated fuels as air pollution control strategies. This new Government policy will have broad implications for both the United States

and the international motor fuels market. The principal fuel oxygenates are methyl tertiary butyl ether (MTBE); ethanol, a derivative of corn; ethyl tertiary butyl ether (ETBE); and tertiary amyl methyl ether (TAME).

The Environmental Protection Agency (EPA) Oxygenated Fuel Program will become effective November 1, 1992, requiring gasoline marketers to supply oxygenated fuels for at least 4 months out of the year having a minimum average oxygen content of 2.7% by weight in the 39 cities that do not meet Federal air quality standards for carbon monoxide (CO). If an inadequate domestic supply of, or distribution capacity for, oxygenated fuels can be demonstrated, EPA may delay implementation for up to two 1-year periods.

EPA's Reformulated Fuel Program will commence on January 1, 1995, wherein the nine worst U.S. ozone nonattainment areas (Los Angeles, New York, Greater Connecticut, Baltimore, Philadelphia, Chicago, Milwaukee, Houston, and San Diego) will be required to sell gasoline with a minimum 2.0% by weight oxygen, 1% maximum by volume benzene, 25% aromatics maximum by volume, and no heavy metals (e.g., lead, manganese).

Information Resources Inc., a Washington, DC, consulting firm, estimates that in 1992, approximately 1.1 billion gallons of ethanol (419 million bushel corn equivalent) will be required to help meet the projected U.S. oxygenated fuel demand created by the Clean Air Act, and up to 2.4 billion gallons (894 million bushel corn equivalent) by the year 2000.⁸

Acid rain is caused primarily by sulfur dioxide (SO₂) and nitrogen oxide (NO_x) emissions from coal-fired electrical powerplants. Under title IV, SO₂ emissions were slated to decline 10 million tons from 1980 levels by the year 2000, and NO_x emissions were to be cut by 2 million tons.

Under title III, a list of 190 hazardous chemicals and materials was established for regulation with the requirement that maximum achievable control technology (MACT) be applied to industries emitting major sources of air pollutants. Several

important industrial nitrogen-containing compounds were on the list, including acrylonitrile, aniline, caprolactam, ethyl carbamate (urethane), hydrazine, coke oven byproducts, and cyanides.

EPA released the preliminary results of its 1989 Toxics Release Inventory (TRI), which indicated that 22,650 industrial facilities released about 3 million tons of toxic chemicals into the Nation's environment. The report disclosed that between 1987 and 1989, TRI chemicals decreased by a favorable 18%.

In 1989, a total of approximately 200,000 tons of ammonia was released into the environment: 61% to the air; water, 6%; injection into underground wells, 17%; municipal waste treatment plants, 14%; and disposal in landfills, 2%. Between 1987 and 1989, ammonia losses to the atmosphere declined by a favorable 18%, and discharges into rivers, lakes, streams, and other bodies of water declined 25%. Ammonia processed through municipal waste treatment plants rose 14%, and underground injection disposal methods increased 17%.

Issues

The large Saskferco ammonia and urea project under construction at Belle Plaine, Saskatchewan, continued to be challenged by the U.S. Ad Hoc Committee of Domestic Nitrogen Producers and the Canadian Council of Nitrogen Producers. The International Trade Commission (ITC), U.S. Department of Commerce, Import Administration (IA), and the U.S. Trade Representative were lobbied by the groups that cited potential injury to other North American nitrogen producers and unfair subsidization of the project, a joint venture between Cargill Fertilizer of Minneapolis, MN, the Crown Corp. of Saskatchewan, and Citibank Canada. Saskferco was scheduled to be on-stream in the fall of 1992.

EPA's Phase II Drinking Water Well Survey released in late-1991 gave new merit to industry calls for site-specificity in solving water quality problems. The multiyear study concluded that nitrate occurrence in U.S. waters is a limited,

site-specific problem and cannot be generally predicted by a simple set of factors. EPA concluded that a variety of environmental conditions and human activities combine to affect the occurrence of pesticides and nitrate in drinking water wells and that no one single factor can explain their presence.

The Fertilizer Institute (TFI), Washington, DC, met with EPA to discuss the nitrate in drinking water issue. TFI pointed out that EPA's study had refuted the commonly held theory that a national drinking water quality problem exists and that a simple reduction in nitrogen fertilizer use would solve the problem. TFI also reported that the few documented cases of methemoglobinemia ("Blue Baby Syndrome") on record involved nitrate levels at several multiples of EPA's 10 ppm limit.

Production

In 1991, the U.S. ammonia industry operated at 96% of rated capacity, indicative of the relatively tight supply-demand conditions. Thirty-four firms in 24 States produced 17.0 million short tons of anhydrous ammonia (82.2% N) compared with 16.8 million tons in 1990. Louisiana, Oklahoma, and Texas, in order of importance, provided about 60% of total U.S. production; the Midwest, South, and Southeast, 30%; and the Western States and Alaska, 10%.

U.S. anhydrous ammonia production was bolstered by a relatively tight supply-demand situation in the domestic and global fertilizer and grain markets and a continued reduction in the trade deficit precipitated by the Persian Gulf crisis and Eastern bloc restructuring. Natural gas feedstock was reasonably priced. The Fertilizer Institute Production Cost Survey for 1991 indicated that overall ammonia production costs declined about 2.5% relative to those of the prior year.

About 90% of U.S. ammonia production was for fertilizer products, and about 10% went into industrial products. Major downstream ammonia fertilizer derivatives included urea (46% N), diammonium phosphate (18% N), ammonium nitrate (35% N), and

ammonium sulfate (21% N). Important industrial chemical derivatives were urea, ammonium nitrate, nitric acid (22% N), acrylonitrile (26% N), and caprolactam (12% N). (See tables 3 and 4.)

In January, the W. R. Grace Agricultural Chemicals Group in Memphis, TN, sold its ammonia interests at Point Lisas, Trinidad, to Norsk Hydro a.s. of Norway. Included in the sale were Grace's wholly owned Federation Chemicals Ltd. ammonia plant (255,000 annual tons) and a 49% share in Trinidad Nitrogen Co. Ltd., a joint venture with the Government of Trinidad and Tobago in two ammonia plants (Tringen I & II), having a combined annual capacity of 920,000 tons.

Grace also transferred ownership of its U.S.-based marketing operations and shipping interests that were linked to the output of the Trinidad facilities. Hydro Agri Ammonia, Inc. (HAAI), a U.S. affiliate of Norsk Hydro, was established in Tampa, FL, for this purpose. HAAI was staffed by key personnel from the former Grace marketing team in Memphis, TN.

In November, Norsk became a joint-venture partner in Farmland Industries' Green Bay, FL, phosphate operation. The Farmland Hydro Limited Partnership group began operating from headquarters in Bartow, FL, on November 16. The Green Bay facility had a DAP-monoammonium phosphate (MAP) production capability of 1 million annual tons.

In 1991, Chevron followed through on previous plans to exit the U.S. nitrogen and phosphate fertilizer sectors. The large 530,000-ton-per-year ammonia plant at Pascagoula, MS, was dismantled and rumored to be destined for Pakistan, while Monsanto picked up Chevron's 50% interest in the 490,000-ton-per-year joint-venture ammonia plant at Luling, LA.

Farmland Industries, Inc., purchased Chevron's Finley, WA, nitrogen solutions plant in January and planned to move the unit to its primary nitrogen production complex at Enid, OK.

In November, Chevron signed an agreement in principal to sell the Vernal,

UT, phosphate rock and Rock Springs, WY, DAP operations to a proposed partnership between Farmland Industries and J. R. Simplot, subject to Federal Trade Commission (FTC) approval. Annual DAP production capability at Rock Springs was 450,000 tons.

In December, Unocal purchased Chevron's 140,000-ton-per-year ammonia plant at Finley, WA. Unocal planned to permanently close the ammonia plant and use the facility for storage and distribution. Unocal was to toll ammonia from Chevron's 20,000-ton-per-year El Segundo, CA, plant. Chevron planned to continue operation of an 80,000-ton-per-year ammonia plant at St. Helens, OR, until a buyer could be found.

Cargill Fertilizer of Minneapolis, MN, was building a C\$435 million nitrogen fertilizer complex—the Saskferco project—in Belle Plaine, Saskatchewan, through a corporation formed between its Canadian subsidiary, Cargill Ltd., the Crown Investments Corp. of the Province of Saskatchewan, and Citibank Canada. The plant was scheduled for completion in the fall of 1992 and was designed to produce 560,000 tons per year of ammonia and 750,000 tons per year of granular urea.⁹

CF Industries is one of North America's largest interregional cooperatives, owned by and serving 12 regional cooperatives. Through its members, the company's nitrogen, phosphate, and potash fertilizer products reach more than 1 million farmers and ranchers in 46 States and 2 Canadian provinces.

In June, the Board of Directors authorized an expenditure of \$87 million to reconfigure product mix at CF's Donaldsonville Nitrogen Complex. When completed in the 1994 fertilizer year, this project will increase production capacity for granular urea and UAN solutions. The additional capacity will allow CF Industries to meet the projected needs of its members during the 1990's.¹⁰

CF's Donaldsonville ammonia plants were capable of operating at 2 million tons per year, 120% of design capacity, because of recent revamp and retrofit initiatives that included a significant

reduction in NO_x emissions. The planned expansions will lead to further improvements in the cooperative's competitive economics. (See table 5.)

In November, Koch Industries, Inc., signed a letter of intent to purchase the IMC Fertilizer Group, Inc. (IMCF) large ammonia complex at Sterlington, LA. The Sterlington complex consists of two ammonia trains having a total capacity of 1.1 million tons per year. The acquisition would provide a good fit for Koch Industries, owner of the Gulf Central Pipeline that serves the Sterlington plant. An ammonia supply contract for IMCF's New Wales, FL, DAP-MAP complex was also to be negotiated.

Mississippi Chemical Corp. (MCC) was constructing a new 200,000-ton-per-year nitric acid plant at Yazoo City, MS, scheduled on-stream in late 1992. MCC produces ammonia, nitric acid, ammonium nitrate, urea, and UAN solutions at Yazoo City, MS.

MCC could not find a buyer for its repossessed DAP plant at Pascagoula, MS, and planned to start up late in the year based on imported Moroccan phosphate rock. Atlantic Fertilizer and Chemical Corp. contracted to market the DAP output rated at 700,000 tons per year. The firm also has a 50% interest in Triad Chemical Co., a major ammonia and urea production complex at Donaldsonville, LA.

Nitrogen Products, Inc. brought a revamped 210,000-ton-per-year ammonia plant on-stream at Helena, AR, in January. The Dutch-owned bank NMB contracted with Royster Co. to operate the new venture. Late in the year, Royster was reported to withdraw as the operator owing to its own bankruptcy proceedings. The former Big River ammonia plant at Helena had been purchased by an investment consortium in bankruptcy proceedings during 1989 and renamed Five Rivers. The plant was subsequently closed in mid-1990 owing to a lack of reliable power sources and equipment failures. Ownership was transferred to the original lending institution, NMB.

Diamond Shamrock acquired the Center Plains ammonia facility at Dumas, TX, in bankruptcy proceedings through a repurchase agreement in 1990 and reactivated one of the two 80,000-ton-per-year plants on-site in early 1991.

In October 1991, Agricultural Minerals Corp. (AMC) announced that it would go public on the New York Stock Exchange as Agricultural Minerals Co. LP. AMC assumed control of Agrico's former nitrogen fertilizer production facilities at Verdigris, OK, and Blytheville, AR, effective March 1, 1990, and established headquarters in Tulsa, OK. Ammonia, urea, and UAN solutions are the primary products produced by AMC, along with the highly efficient slow-release Super N fertilizers containing dicyandiamide. AMC was among the top five U.S. nitrogen fertilizer producers.

Terra International, Inc. announced a 75,000-ton-per-year ammonia expansion at Port Neal, IA, scheduled for completion in late 1992. Emissions were also to be reduced 30%.

Coastal Chem, Inc. planned a 175,000-ton-per-year ammonia expansion by late 1992 at Cheyenne, WY, based on the reconstruction of a plant to be moved from Arcadian's Augusta, GA, complex. Coastal was constructing a 130,000-ton-per-year nitric acid plant at Elko, WY, that would be used to produce ammonium nitrate-based explosives.

BP Chemicals announced a \$17 million 90,000-ton-per-year nitric acid replacement-expansion at Lima, OH, that was scheduled on-stream in late 1992.

Consumption and Uses

U.S. apparent domestic consumption of ammonia was 19.7 million product tons in 1991, similar to that of the prior year. Fertilizer materials accounted for about 80% of domestic ammonia conversion disappearance, and about 20% went into industrial applications.

Urea and ammonium nitrate, in solid and liquid form, found extensive use in both the fertilizer and industrial sectors. UAN solution fertilizers that contain 28% to 32% N were growing in popularity

because of their safe handling and storage characteristics and ease of application.

In the industrial sector, urea was used in the production of synthetic fibers, resins, and polymers and as a protein supplement in ruminant animal feeds. Ammonium nitrate fuel oil explosives (ANFO) dominated the industrial explosives sector. Nitric acid was used in chemical synthesis and in metal treatment. Acrylonitrile and caprolactam found respective use in the production of acrylic and nylon fibers, resins, and plastics. (See table 6.)

Other uses for ammonia and ammonia-base compounds were for specialty horticultural and lawn and garden fertilizers, home and industrial cleaners, fuel ethanol derived from corn and other biomass species, and as a propellant in vehicular air bags. Ammonia and urea were also becoming popular low-cost agents that significantly reduced NO_x atmospheric emissions when injected into combustion gas streams.¹¹

In 1991, ammonia and ammonia derivatives accounted for 55% of the 20.3 million ton primary fertilizer nutrient market in the United States. The ratio of nitrogen nutrient consumption to phosphate and potash fertilizer nutrient consumption was 2.7:1 and 2.2:1, respectively.

U.S. nitrogen fertilizer consumption reached 11.2 million tons N in 1991 compared with 11.1 million tons N in 1990. Single-nutrient compounds led by direct application ammonia, UAN solutions, urea, and ammonium nitrate, in order of importance, provided 80% of the total. Direct application ammonia consumption increased 9%. (See table 7.)

The six States that comprise the Midwest Corn Belt—Illinois, Indiana, Iowa, Missouri, Nebraska, Ohio—together with Minnesota, consumed 4.6 million tons N, 42% of the U.S. total. Texas, Kansas, California, and Oklahoma, in order of importance, accounted for 2.4 million tons N, 21% of the total.

U.S. net cash farm income in 1991 was expected to approximate \$56 billion, about 7% below the record \$60 billion

established in 1990. Planted crop acreage approximated 338 million acres, and another 63 million acres was idled by crop programs and the CRP. Carryout inventories of major feed and food grains were at the lowest levels in years.

Stocks

U.S. stocks of major nitrogen compounds increased about 10% at the producer level and ended the year at 1.8 million tons N. This was not surprising in light of the inventory drawdowns experienced in 1990. (See table 8.)

Transportation

Ammonia was transported by refrigerated barge, rail, pipeline, and truck. In late 1990, the Research and Special Programs Administration (RSPA) of the U.S. Department of Transportation (DOT) classified anhydrous ammonia as a nonflammable gas linked to a required "inhalation hazard" label. RSPA officially classified anhydrous ammonia a Division 2.2 nonflammable, nonpoisonous compressed gas for domestic shipments. The inhalation hazard label was to become effective October 1, 1991.¹²

International shipments, however, were classified as a Division 2.3 "poison gas" consistent with United Nation regulations. International shippers were required to comply under the new regulations on January 1, 1991. Because of the documented inhalation hazards of anhydrous ammonia when released in large quantities, RSPA was also requiring the words "INHALATION HAZARD" on packages and shipping papers, in addition to other current hazard communications information.

The Interstate Commerce Commission (ICC) replaced the Federal Energy Regulatory Commission (FERC) as the Federal agency responsible for ammonia pipeline regulation in late-1990. FERC had been responsible for ammonia pipeline regulation since 1977, when ICC transferred power of control under the Department of Energy act. Actions on complaints that had been previously filed with FERC against ammonia pipelines for

alleged excessive rate charges were delayed because of the transfer after the U.S. Court of Appeals ruled in favor of ICC control.

Koch Industries operated the Gulf Central Pipeline built in 1969 that extended about 1,900 miles from the Gulf of Mexico into the Midwest, as far north as Iowa. Koch Nitrogen, a subsidiary, purchased four Midwest ammonia terminals from ConAgra Fertilizer in 1991 having a combined capacity of 150,000 tons. The firm also signed a letter of intent to purchase IMCF's large ammonia complex at Sterlington, LA, along the path of the pipeline.

Mapco Ammonia Pipeline Inc. operated Mapco Ammonia Pipeline and its sister company, Mid-America Pipeline, along a 1,098-mile corridor that extended in a northeasterly direction from Borger, TX, in northern Texas, to Mankato, MN, in southern Minnesota. Mapco built the first leg of the pipeline in 1968-69 and, by 1978, had added six extensions. About 500,000 tons of ammonia storage capacity was located along the pipeline.

Mapco Ammonia Pipeline neither produced nor marketed ammonia independently, but transported ammonia on behalf of five shippers. Competition from the rail and truck transportation sectors was minimized because areas served by Mapco Ammonia Pipeline did not have river access. Mid-America Pipeline had more than 400 shippers and competed with the other transportation sectors.¹³

Seminole Fertilizer Corp. and the Royster Co. operated a joint-venture ammonia pipeline that serves ammonium phosphate producers in Florida. Royster was in chapter 11 proceedings, and several companies, including Norsk Hydro and CF Industries, were bidding on the venture. IMCF also operated an ammonia pipeline in Florida for the same purpose.

Markets and Prices

The dramatic rise in nitrogen fertilizer prices precipitated following Iraq's invasion of Kuwait in early August 1990 continued into the first quarter of 1991 on

the heels of Operation Desert Storm. Anhydrous ammonia prices, f.o.b. barge, New Orleans, held steady at \$115 to \$117 per ton during January and February, and then gradually declined to slightly below \$100 by the end of March when supplies were again available from the Persian Gulf. Granular urea prices, f.o.b. New Orleans, remained firm during the first quarter, and ranged between \$151 to \$155 before beginning a gradual decline in the second quarter.

Ammonia and urea prices began to firm up again during the fall season before weakening during November and December. Ammonia and urea prices peaked in October at an average of \$122 per ton and \$138 per ton, respectively, before ending the year at \$111 per ton and \$130 per ton. (See table 9.)

Foreign Trade

U.S.S.R. anhydrous ammonia import tonnage data continued to be withheld from the public domain during 1991, because of a previous ruling by the Bureau of the Census that determined Occidental Petroleum to be the proprietary U.S. agent.

In 1991, the U.S. ammonia trade deficit was estimated at 2.9 million product tons, the same as that in 1990, and 13% favorable to the record 3.4 million ton deficit established in 1989. Ammonia imports were valued at \$391 million and carried an average landed price of \$106 per ton, c.i.f., in comparison to \$100 per ton in 1990.

About 90% of total U.S. ammonia imports was equally divided between Trinidad and Tobago, Canada, and the U.S.S.R., with Mexico providing most of the remainder. The U.S.S.R. shipped a record 1.0 million product tons of ammonia to the United States in 1991 that was valued at \$101 per ton, according to U.S. Bureau of Mines estimates, and this was somewhat surprising in light of the rapid move toward democratization. (See tables 10 and 11.)

The United States experienced a total converted nitrogen trade deficit of 0.6 million tons N in 1991, 0.6 million tons (50%) favorable to the 1.2 million ton

deficit of 1990. A converted nitrogen trade deficit occurs whenever aggregate U.S. nitrogen compound imports exceed exports. U.S. converted nitrogen trade deficits have occurred consecutively since 1981, reaching a record 2.2 million tons N in 1986.

Anhydrous ammonia (2.4-million-ton N deficit) and urea (0.3-million-ton N deficit) were the predominate trade deficit materials. In contrast, DAP generated 1.9 million tons of positive N export trade. Industry sources indicated that U.S. DAP export tonnage could be approximately 700,000 product tons on the high-side because of double counting of vessels at various U.S. ports.

The United States imported 1.8 million product tons of urea from 15 countries in 1991 that was valued at \$209 million (\$117 per ton, c.i.f.). Urea import volume was down 0.3 million tons (14%) compared to 1990 levels, and the landed price declined \$5 per ton (4%). Canada shipped 71% of the total, Mexico, Trinidad and Venezuela, 15% in aggregate, the Netherlands and France (4% total), and Bulgaria, 3%. Germany shipped 4% of the total at a value of \$149 per ton, c.i.f., well above the \$117 per ton average.

ITC urea antidumping duties levied against the U.S.S.R., the Federal Republic of Germany (Eastern states), and Romania, have been effective in preventing the subject countries from landing urea at prices below fair market value. (See tables 12 and 13.)

World Review

Events in Eastern Europe and the Persian Gulf dominated the global nitrogen fertilizer scene in 1991, causing an unprecedented decline in global ammonia production of 4.3 million short tons N (4%). Production declined 1.2 million tons N (4%) in the U.S.S.R. and 1.7 million tons N (26%) in the Eastern bloc countries. Persian Gulf production declined 0.8 million tons (21%). The total loss in ammonia production for these regions amounted to 3.7 million tons N, or 85% of the global decline.

Operation Desert Storm, the United Nations initiative to liberate Kuwait from Iraqi occupation, resulted in severe damage to nitrogen plants in both Kuwait and Iraq during January and February. Information available on the damage and destruction of nitrogen production facilities in the two countries indicated that it would take a minimum of 5 years to bring nitrogen output back to normal.

Iraq and Kuwait, in combination, had represented about 1.5% of total world ammonia capacity and 2.5% of world urea capacity. In 1989, Iraq and Kuwait accounted for about 5% of total world urea and ammonia N trade. This, together with the supply potential of the other Persian Gulf countries, accounts for about 15% of world nitrogen trade in the form of ammonia and urea.

In Eastern Europe, the drive toward democratization was accompanied by sweeping political reforms that placed downward pressure on local economies. Fossil fuel energy essential to ammonia production was in short supply and portended significant shortfalls in nitrogen fertilizers critical to domestic consumption and trade.

Industry Structure.—Approximately 103 million short tons of anhydrous ammonia N was produced in 65 countries during 1991, of which about 10 million tons N (10%) was directly traded. Ammonia was converted into about 39 million tons of urea N in 55 countries, of which about 10 million tons (26%) was traded. Total world nitrogen fertilizer consumption fell about 3% to a level of about 85 million tons N, and trade accounted for about 21 million tons N, or 25% of the total.

Global ammonia was produced in the developed and developing countries that have access to fossil fuel feedstocks, principally, natural gas, naphtha, petroleum refinery offgases and condensates, and coal and coke gases. The supply pattern, in general, followed the world population trend, with Asia and Eastern Europe—including the U.S.S.R.—accounting for more than 60% of the global ammonia supply. The developed regions—North America (United States and Canada), Western

Europe, and Oceania—produced ammonia primarily for domestic use and accounted for about 25% of the world total. The energy-rich countries of the Middle East accounted for about 5% of the world supply and exported significant quantities of ammonia and urea to the global community.

Capacity.—The data in table 14 are rated capacity for ammonia plants as of December 31, 1991. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable long-term operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure.

In 1991, there was a net loss of about 1.5 million annual tons (1%) in global ammonia capacity owing principally to the damage and destruction of plants in Kuwait and Iraq. In Kuwait, 100% of the country's 1.1-million-ton-per-year ammonia industry was expected to be inoperable through 1993 and not completely restored to 1990 levels until after 1996.

Iraq's 1.1 million-ton-per-year ammonia industry was inoperable in 1991, but the new 365,000-ton-per-year plant at Baiji was expected to come on-stream in 1992. One of the two 365,000-ton trains damaged at Khor Al Zubair was expected to be operational by 1994, bringing Iraqi capacity to 730,000 tons per year. Preinvasion capacity levels were not expected to be operational until beyond 1996.

Major world ammonia capacity contracted or under construction and scheduled on-stream during 1991-94, was as follows: China—1.5 million annual tons in Henan, Liaoning, and Sichuan Provinces; India—1.4 million tons at Babrala, Gadepan, and Kakinada; Indonesia—1.4 million tons at Citampek, Gresik, and Palembang; U.S.S.R.—1.1

million tons at Mendeleevsk and, Novgorod, in the Russian Republic; Bangladesh—0.7 million tons at Jamalpur and Chittagong; Belgium—0.7 million tons, Antwerp; Pakistan—0.7 million tons at Iskanderabad, Daudkhel, and Sadiqabad, Punjab; Canada—0.6 million tons, Belle Plaine, Saskatchewan; Saudi Arabia—0.6 million tons, Al Jubail; Egypt—0.5 million tons at Abu Qir and Suez; Iran—0.4 million tons at Mashad, Khorasan; Turkey—0.4 million tons, Gemlik; South Africa—0.3 million tons, Sasolburg; and Argentina and Trinidad and Tobago—0.1 million annual tons each at Huincul, Neuquen, and Point Lisas, respectively. (See table 14.)

Current Research

In January 1991, USDA and DOE signed a "memorandum of understanding" that will coordinate each Department's efforts in the area of biomass research, accelerating the development of ethanol and other alternative fuels and fuel additives from agricultural and forestry products.¹⁴

This agreement promised significant new markets for U.S. farmers and supported the President's National Energy Strategy that focused on a reduction in foreign energy dependency and a cleaner environment. The President's request for renewable energy research and development for fiscal year 1993 is \$250 million, representing more than a 65% increase over funding in fiscal year 1989. The budget request includes \$46 million for ethanol and biomass research in DOE, representing a 265% increase from fiscal year 1989 appropriations.

In September 1991, the President designated the Solar Energy Research Institute at Golden, CO, as the National Renewable Energy Laboratory (NREL). Elevating the status of this facility to a National Laboratory reflects the strong commitment to renewable energy technology research and development (R&D). During 1991, NREL signed a cooperative R&D agreement with a corn-ethanol producer to test a process to convert the cellulose in corn into ethanol. Later in the year, DOE signed a similar

cooperative agreement with a major oil company to explore ethanol production from waste paper.

In April 1992, work will begin on the National Alcohol Fuels User Facility in Golden, CO. This work will include construction of a process development unit for testing new biofuel conversion technology. DOE will develop a cellulose-to-ethanol process development unit at NREL. The unit will evaluate methods for converting wood cellulose into ethanol fuels and serve as the centerpiece for the National Alcohol Fuels User Facility.¹⁵

M. W. Kellogg of Houston, TX, announced two major advances in its ammonia process technology: the Kellogg Reforming Exchanger System (KRES) and the Kellogg Advanced Ammonia Process (KAAP), a joint technology development with British Petroleum.

Kellogg's KRES design was revolutionary in that it completely eliminated the conventional fired primary reformer from the ammonia production process. KRES is environmentally attractive because without a primary reformer, nitrogen oxide emissions are substantially reduced. The system could be easily installed in new or existing plants and would save up to 10% on capital costs.

The KAAP process employs a novel ammonia synthesis catalyst that was claimed to be the first significant breakthrough in catalyst technology since 1927. The proprietary KAAP catalyst is up to 20% more active than conventional iron catalysts. The KAAP system was to be employed in a retrofit project designed to increase production capability by 40% at Ocelot's ammonia plant in Kitimat, British Columbia.

Exxon Research and Engineering Co. of Florham Park, NJ, developed the THERMAL DeNO_x Process that significantly reduced NO_x emissions by injecting ammonia into flue gas streams emanating from stationary combustion sources. THERMAL DeNO_x is a noncatalytic process for NO_x reduction based on the gas phase homogeneous reaction between NO_x in flue gas and ammonia that produces nitrogen and

water. The patented process was offered for license by Exxon Research and Engineering Co.¹⁶

OUTLOOK

Global ammonia operating rates declined to a weak 81% in 1991 owing to a continuation of the downturn in the Eastern European supply-demand situation and supply disruptions precipitated by the Persian Gulf crisis. Per capita nitrogen consumption dropped to a dismal 38 pounds compared with the previous norm of about 42 pounds.

The world ammonia supply-demand outlook anticipated by the U.S. Bureau of Mines suggests that soft market conditions will prevail between 1992 and 1994, principally because of significant new additions to world capacity and a protracted period of economic recovery anticipated in Eastern Europe. There appears to be a favorable probability that the current imbalance between ammonia supply and demand will begin to improve by 1995. A firm global urea supply-demand situation is anticipated between 1992 and 1994, however, because of the current imbalance between ammonia and urea capacities and strong demand in China and other Asian countries.

The U.S. Bureau of Mines ammonia nitrogen demand forecast was developed from World Bank-United Nations Fertilizer Working Group projections¹⁷ taking into consideration world per capita consumption trends and geopolitical factors in Eastern Europe and the Mideast. Steady-state conditions were assumed for weather. World ammonia capacity projections were provided by the International Fertilizer Industry Association Ltd., Paris, France.

In the United States, the outlook for continued strength in the nitrogen fertilizer and grain sectors is anticipated. The ammonia industry is running at near capacity, grain stocks are at the lowest levels in years, U.S. ammonia capacity expansion plans are minimal, and agronomic fundamentals that were improved by the 1985 farm bill should be further perpetuated by the new 1990 farm bill.

The mechanisms of the new CRP, together with regular farm program acreage reductions, should hold U.S. crop acreage at about the current 340 million acres. This, together with the Export Enhancement Initiative, should control crop inventories and provide favorable crop prices for the U.S. farmer. (See table 15.)

The U.S. nitrogen supply-demand outlook will be critically dependent upon: (1) a continuation of reasonably priced natural gas for U.S. ammonia production; (2) new industrial outlets for U.S. agricultural crops, including corn-based ethanol in reformulated motor fuels under the provisions of the Clean Air Act of 1990; (3) new markets for the massive Saskferco ammonia and urea nitrogen complex scheduled on-stream in the fall of 1992 in Saskatchewan, that would minimize the closure of U.S. nitrogen fertilizer capacity; (4) a favorable resolution of the ongoing Uruguay Round of General Agreement on Tariffs and Trade (GATT) negotiations that would liberalize global agricultural trade and provide opportunities for the United States to compete more effectively in world grain trade; (5) favorable U.S. implications for the proposed Free Trade Agreement with Mexico and for the granting of most favored nation (MFN) status to the U.S.S.R. and other Eastern European countries; (6) a smooth transition in democratic reforms in Eastern Europe; and (7) resolution of the MFN status debate with the Republic of China. TABLE 5—Continued
DOMESTIC PRODUCERS OF ANHYDROUS AMMONIA IN 1991

(Thousand short tons per year of ammonia)

Company	Location	Capacity ¹
Terra International, Inc.	Port Neal, IA	230
Do. (Oklahoma Nitrogen)	Woodward, OK	450
Triad Chemical Co. ²	Donaldsonville, LA ³	450
Union Chemical Co. (Unocal)	Kenai, AK	1,200
Wil-Grow Fertilizer Co. ⁴	Pryor, OK	94
Total		17,712

¹Engineering design capacity adjusted for 340 days per year of effective production capability.

²Plants purchased from Freeport-McMoRan Feb. 28, 1990.

³Revamp and/or retrofit.

⁴Plants purchased late May through early Nov. 1989 by Fertilizer Industries, holding company for the Sterling Group and Unicorn Venture Funds.

⁵Large 530,000-ton-per-year plant idle for more than 3 years reportedly dismantled.

⁶Wycon Chemical Co. assumed parent company's name, midyear 1989.

⁷Plant (140,000 tons per year) mothballed.

⁸Former N-Ren Corp. plants acquired by Great American Management and Investment, Aug. 1987.

⁹Joint venture between First Mississippi Corp. and Mississippi Chemical Corp..

NONRENEWABLE ORGANIC MATERIALS

By Michele R. Simmons and Thomas D. Kelly

Mrs. Simmons, industrial program manager with the Branch of Materials of the U.S. Bureau of Mines, directs work in the analysis of the petroleum, petrochemical, and plastic industries as related to the application of nonrenewable organic materials in major industrial sectors. Mr. Kelly, materials specialist in the Materials Engineering Group at the Minerals Availability Office of the U.S. Bureau of Mines, has over 6 years of experience in the petroleum industry. Some of the data were prepared by John Sznopke, materials specialist in the Materials Engineering Group at the Minerals Availability Field Office.

Nonrenewable organic materials obtained from natural gas-, coal-, and petroleum-derived feedstocks are used in a wide variety of durable and nondurable goods. Plastics, synthetic fibers, and synthetic rubber are important products made from nonrenewable organic feedstocks that traditionally are used primarily as fuels. In addition, lubricants, asphalt, road oil, waxes, and numerous other petrochemicals, also derived from organic feedstocks, fulfill many important nonfuel uses. Products made from these nonrenewable organic materials include such varied items as household goods, eyewear, textiles, tires, engine grease, paving materials, pharmaceuticals, medical devices, and other items vital to society's well-being.

In 1991, consumption fell in three of the four principal nonrenewable organic materials use categories. Chief reasons behind such lackluster performance can be traced to the economic recession, growing environmental concerns, and increases in crude oil prices during the year. Examination of these categories reveals that consumption in the petrochemical industries category grew 12% in 1991 to 73.0 million metric tons. In the lubricants, waxes, and miscellaneous products category, consumption declined 5% to 11.7 million tons. In the petroleum coke and coal category, consumption declined 2% to 8.4 million tons, and in the asphalt and road oil category, consumption decreased 2% to 26.6 million tons.

DOMESTIC DATA COVERAGE

The U.S. Bureau of Mines collects no original data on organic materials use from company surveys. All of the statistical information included in this report was obtained from outside sources. Much of it relies on data collection efforts of other Government agencies and on surveys conducted by various industry publications and materials industry trade associations. The intent of the Bureau is not to duplicate the efforts of those organizations, but to augment those efforts with both data analysis and collection where adequate coverage is not currently available.

The data were obtained from a variety of sources, including the Annual Energy Review 1991 from the Energy Information Administration, U.S. Department of Energy; the Department of Commerce; and a wide variety of industry contacts. In addition, data were obtained from the Society of the Plastics Industry, Inc.; several industry trade associations; other Government data publications; and many industry trade journals, especially, Chemical & Engineering News, Plastics News, and Modern Plastics. The focus of the discussion is primarily on plastics, synthetic fibers, and synthetic rubber. The synthetic fiber data were based on the efforts of Chemical & Engineering News, on surveys conducted by the Fiber Economics Bureau, Inc. and by various industry publications, and materials from the American Fiber Manufacturers

Association, Inc. Data for synthetic rubber were based on reports in the Chemical & Engineering News, Chemical Week, the International Institute of Synthetic Rubber Producers, and the Rubber Manufacturers Association. Other categories of organic materials use are covered as well, but the same level of detailed information is not generally available for them; therefore, little additional detail was provided.

BACKGROUND

At the beginning of the 20th century, the United States satisfied about 59%, in constant dollars, of its material needs from renewable resources. The remaining 41% was met by metals and minerals. The traditional primary renewable resources are agricultural (cotton, oils, etc.), forest (lumber, etc.), and wildlife (furs, etc.) products. Primary nonrenewable resources are inorganic minerals and organic materials derived from coal, petroleum, and natural gas. This pattern of use changed considerably during the years up through mid-century and somewhat less so in later years, as major shifts in feedstock reliance occurred. The first shift marked a decrease in percentage share of material needs obtained from renewable sources, which fell to about 38% in 1950, then to about 26% by 1989. The second major change was the increased use of nonrenewable organic feedstocks in the production of asphalt, plastics, synthetic rubber, synthetic fibers, and

petrochemicals. This trend is shown in figure 1, which displays the relative market shares for competing material feedstocks. Individual data for primary and secondary metals are not available prior to 1935. (This figure is an update based on work by Spencer, et al.¹) (See figure 1.)

Products for Trade and Industry

Only a small amount of the total U.S. consumption of oil, gas, and coal goes to nonfuel uses, compared to the amount of nonrenewable organic resources used for fuels. In 1991, total petroleum products supplied for domestic use, in commonly reported units, amounted to 6.1 billion barrels; 895 million barrels was for nonfuel purposes, of which 284 million barrels was used for such purposes as asphalt and road oil, lubricants, petroleum coke, waxes, and miscellaneous products. The remainder, 611 million barrels, included liquefied refinery gases (LRG's), natural gas liquids (NGL's), petrochemical feedstocks, and naphthas used by the chemical industry. U.S. consumption of natural gas was 19.6 trillion cubic feet in 1991. A total of 596 billion cubic feet of natural gas, primarily methane, went into nonfuel end uses.²

The portion of total U.S. consumption of nonrenewable organic materials that goes into nonfuel uses is often reported in terms of British thermal units (Btu's) or value. Measured in Btu's, it has been approximately 6% for the past several years,³ but when measured in value terms, the proportion is higher. Fraser⁴ calculates that, in value terms, the portion of organic materials consumed in nonfuel uses during the 1980's has been between 8.5% and 10%. He points out that because nonfuel uses consume higher priced petroleum and natural gas, instead of lower valued coal, the value of organic materials going into nonfuel uses is understated when measured in Btu's.

Petroleum products, including NGL's, accounted for approximately 87% of the Btu's from fossil fuels consumed for nonfuel uses in 1991. Asphalt and road oil, lubricants, petroleum coke, wax, and

miscellaneous products, as a subgroup of petroleum products, comprised approximately 41% of total petroleum products used for nonfuel purposes. Natural gas, principally methane, accounted for approximately 12% of the Btu's from the fossil fuels consumed; nearly two-thirds of that was used as feedstock for the production of ammonia-based fertilizers. Coal accounted for the remainder.⁵

A simplified overview of nonrenewable organic materials from well to feedstocks is shown in figure 2.⁶ During the processing of natural gas, NGL's are extracted from wet gas, producing dry gas, or methane. Methane and NGL's are also primarily consumed as fuels. In addition to their fuel uses, however, they are also the principal sources of petrochemical feedstocks used to make resins, fibers, elastomers, adhesives, paints, and pharmaceuticals.

Among the many products of the petroleum refining process are naphthas and LRG's. These are also sources for petrochemical feedstocks, but both are primarily consumed as fuels. Naphthas are a primary constituent of gasoline, and LRG's have a variety of fuel uses. (See figure 2.)

The array of petroleum products produced at a refinery is dependent on a number of factors, including the design of the plant facilities, the characteristics of the petroleum refined, economics, and Government regulations. Crude petroleum varies from source to source, and thus the range of products that can be produced economically also varies. The cost differential to produce one product instead of another and the prices received for the products dictate the economically efficient array of products. Governments can also influence the product array through specifying defense needs or by rationing resources during shortages. The chemical industry, in particular the plastics sector, had limited access to feedstock materials during the oil crisis of the early 1970's, for example.

Lubricating oils are a combination of a small number of crude oil-base stocks blended with a large number of additives. The additives are used to give specific

properties to a wide variety of lubricating oils. These properties include viscosity, viscosity change with temperature, oxidation resistance, acidity, boiling temperature, and pour point.

Petroleum coke comes in three forms. Sponge coke varies from a hard, porous, irregular-shaped lump to a fine powder. It is used in production of pure carbon or artificial graphite used for motor brushes, structural graphite, and dry cells. Needle coke, with its name derived from its shape, is the preferred material for graphite electrodes because of its lower electrical resistivity and lower coefficient of thermal expansion. Shot coke, which is generally produced unintentionally and comes only from residuals of California crude oils, has a variety of uses as carbon or graphite. The nonfuel uses of coal are mainly for its carbon content; it is used as a filter material for boiler water, for example, where it takes out organic contaminants. Coal is also used in the production of cyclic intermediates that feed into the petrochemical feedstocks area.

Asphalt, a product of petroleum refining, is generally the bottom product left after all other products have been taken out. It is always blended with cutter stock, similar to kerosene but with a lower flash point, into three grades: fast cure (less of the kerosenelike material added so it sets up faster), medium cure, and slow cure, for use as road base at different ambient temperatures.

Not all refinery operations produce asphalt. Many refineries are set up to handle light crude oils, and the bottom product is a fuel oil. Asphalt is a natural product only from heavy crude oils, and the amount of asphalt produced will be in rough proportion to the gravity of the crude oil. Further processing is necessary to make the asphaltic material suitable for roofing applications.

Waxes, also a natural product of the refining processes, are derived from the gas oil fraction in the distillation process. Waxes come out of all crude oils. If the crude oil contains a large proportion of wax, then the final "pull" becomes unsuitable for asphalt production, even if it is a heavy crude oil.

Petrochemical feedstocks are the raw materials from which plastics, synthetic fibers, and synthetic rubber are produced. Other significant uses for petrochemical feedstocks are for solvents, paint thinners, and cyclic intermediates that are further processed into dyes, medicinal chemicals, and pesticides. Figure 3 is a simplified flow chart of plastic resins produced further downstream beginning with some basic petrochemical building blocks. (See figure 3.)

Table 1 reports the amounts of selected feedstocks and the relative percentage of total consumption of each feedstock consumed in the production of plastics. Ethylene dominates plastics feedstock consumption, with 26.5 billion pounds consumed. Three quarters of ethylene and benzene consumption, 65% of naphthalene (derived from coal tars), 64% of propylene, and 22% of xylene were consumed in the production of plastics in 1990. Although plastics are the primary use for some feedstocks, they are only a minor use for others. Only small percentages of toluene, butadiene, and methane were used in the production of plastics. (See table 1.)

Methane is used to produce fluorocarbons and produces methanol that, in turn, is used in the production of phenolics. Ethane and propane can each be used to produce ethylene or propylene. Ethylene is used in the production of numerous resins, including polyethylene, fluorocarbons, polyesters, and acrylonitrile-butadiene-styrene (ABS). Propylene is used in the production of resins such as polypropylene, polyesters, acrylics, and polyurethane. Butane is used in the production of ABS and some vinyls. Naphtha is the source of benzene, toluene, and xylene. Benzene is used in the production of unsaturated polyesters (nylon), polysulfone, styrene, and phenolics. Toluene and xylene are used in the production of polyurethanes and polyesters.

Economic Factors

The major sources of petrochemical feedstocks are crude oil and NGL's. And throughout the world, naphtha, a crude

oil fraction, is the main source for ethylene and propylene, the primary olefins involved in plastic resin production. In nations rich with natural gas, there has been a long-term trend to use less naphtha and more NGL's as sources of these olefins. In the United States, NGL's are the major sources of these primary olefins. However, naphtha remains the major worldwide source of benzene.

World crude oil production decreased by 0.9% to 60.0 million barrels per day in 1991.⁷ The decline in production resulted from war damage in Kuwait, sanctions imposed by the United Nations on oil exports from Iraq, and continuing equipment-related production problems in the former U.S.S.R.

The price of crude oil, reflecting market uncertainties during the year, exhibited a number of turnabouts. During the week of January 4, 1991, crude oil was priced at \$24.24 per barrel. Immediately following the end of the Persian Gulf war the price of crude oil fell to a 1991 low of \$15.34 per barrel the week of March 4, 1991. In the following months, the price of crude oil eased up slightly, but fell again in July, before gradually easing upward during the next several months. By September, crude oil had reached about \$19.17 per barrel and continued upward to \$20.18 per barrel in October as refiners increased stocks in preparation for winter demand. In November, however, the price of crude oil dropped to \$19.72 per barrel and continued to slip in December to \$17.56 per barrel. (Reported monthly crude oil prices represent U.S. refiner composite acquisition costs.)⁸

Petrochemical feedstock prices remained up in January 1991, as crude oil prices rose in the days leading up to the Persian Gulf war (table 2). Soon after war began, petrochemical feedstock prices, following crude oil prices, fell and continued to move lower. Factors that contributed to this easing in prices include a sharp drop in the price of crude oil following a successful U.S. and allied forces air campaign against the Iraqi military, lower demand for end products as the U.S. economy continued to

weaken, and ample available petrochemical feedstocks inventories.

By July 1991, prices for feedstocks were down considerably. In the remaining months of the year, feedstock prices had exhibited a mixed pattern, as some prices began moving upward and others hovered near, or fell farther from, prices posted just months earlier. (See table 2.)

Operating Factors

The economic recession affected industrial employment in the organic materials sector during the year. Total industrial employment in the plastics, synthetic fibers, and synthetic rubber category fell by about 2% to 177,000 workers in 1991, compared with 181,000 workers a year earlier. This decline was reflected in the number of male employees for the year; the number of women employees remained unchanged. The decline in employment was more severe for production workers, where the number of workers fell by 5% to 110,000 in 1991, compared with 116,000 in 1990. The average workweek increased by 0.1 hours. Average hourly earnings were up 4.3%, more than the 3.1% increase for all manufacturing. (See table 3.)

No separate accounting of the total number of employees producing feedstocks for organic materials is possible. Nonfuel uses of fossil fuels account for only 6% to 8% of the total on an energy content basis. Employment in the overall oil and gas sectors, the industries that are the source for most organic materials feedstocks, was up slightly in 1991. Oil and gas extraction showed a 0.3% decrease in employment, while petroleum refining and gas production and distribution had employment increases of about 2% and 1%, respectively. Asphalt paving and roofing materials employment declined by almost 4%.⁹

ANNUAL REVIEW

U.S. production of primary materials from nonrenewable organic resources during 1991 increased in all categories,

except one (table 4). For the petrochemical industries category, total feedstocks production increased almost 13% to 65.1 million tons. Production of resins, a subcategory of petrochemical industries composed of plastics, synthetic fibers, and synthetic rubber, increased a little more than 1% to 27.3 million tons in 1991. Imports decreased from 10.1 million tons in 1990 to 8.9 million tons in 1991. Exports fell 42% to 1.3 million tons in 1991. Apparent primary consumption increased slightly more than 12% to about 73.0 million tons in 1991. ("Apparent primary consumption," as used here, measures supply and disposition of organic materials from primary sources and equals production plus imports minus exports plus stock changes. Recycled materials are not accounted for in this calculation.) The price for feedstocks shown in the table represents the price of the organic material that is used to make these products and not the price of the products themselves. It reflects changes in the price of energy and, consequently, fluctuates with energy markets. (See table 4.)

Production of lubricants, waxes, and miscellaneous products decreased to 12.1 million tons in 1991. Imports fell to 580,000 tons for the year, from 740,000 tons in 1990. Exports decreased almost 13% to about 1.0 million tons in 1991. Apparent primary consumption decreased 5% to 11.7 million tons.

Production of petroleum coke and coal rose slightly to 13.1 million tons in 1991. Imports, remaining unchanged from those of a year ago, stood at 40,000 tons. Exports fell slightly to 4.6 million tons. Yearend stocks rose 27% to 520,000 tons. Apparent primary consumption decreased 2% to 8.4 million tons. It should be noted that data for coal were included in production, but not in imports, exports, or stocks because of lack of detailed information on coal not used as a fuel.

Production of asphalt and road oil increased almost 3% to 25.7 million tons in 1991. It has fluctuated between 24 million tons and 27 million tons since 1986. Imports decreased 13% to 1.7

million tons in 1991, from 1.9 million tons a year earlier. Exports increased 12% to 190,000 tons for the year. Yearend stocks rose 19% to 3.7 million tons. Apparent consumption decreased almost 2% to 26.6 million tons in 1991.

The economic recession stifled most activities within the chemical industry, from basic petrochemical feedstock inputs and primary downstream outputs to employment and earnings. Nevertheless, the chemical industry managed to fare somewhat better than manufacturing overall, which fell by 3% from that of a year ago. In 1991, overall production of chemicals remained essentially unchanged from the 1990 level, as the production of organic chemicals rose a modest 2% and that of inorganic chemicals dropped 1%. However, as a result of reduced economic activity and weak demand for most chemicals across key domestic markets, U.S. chemical producers looked to foreign markets, and to build up domestic chemicals inventories, which rose 2% for the year, in anticipation of a recovery in chemical demand. U.S. chemical trade with most regions remained strong, making 1991 an extraordinary trade year for chemical exports and imports. Separately, chemical exports increased 10% in 1991, reaching a new high of about \$43 billion. Chemical imports also set a new high, increasing 8% to about \$24.2 billion. The resulting chemical trade surplus, which totaled \$18.8 billion, marked an alltime high as well. Even with favorable chemical trade in 1991, the U.S. chemical industry saw chemical sales and profits decline overall from those of a year ago, as did earnings, capital spending, and employment.¹⁰

The chemical industry increased downstream production of plastics, synthetic fibers, and synthetic rubber in 1991. Taken separately, production of plastics increased by 3% overall, mainly due to strong growth in thermoplastic polyethylene and thermoplastic polyester.¹¹ Domestic demand for plastics dropped 1% for the year, to 27.5 million tons.¹² Plastics exports rose considerably in 1991, in contrast to imports, which fell.

Production of synthetic fibers increased overall by 1% in 1991 due to production gains in polyester and polyolefins. Production of synthetic rubber decreased overall by 4%, with ethylene-propylene, down 13% from that of a year ago, posting the biggest loss.¹³

World Review

In 1991, chemical industries worldwide experienced downturns in most activities as many nations faced the pressures of economic recession or experienced slower growth. Other factors that affected industry were the Persian Gulf war and its impact on crude oil supplies and prices; environmental mandates; evolving international trade trends; and the disintegration of the U.S.S.R., the world's leading crude oil supplier. Together, these factors for many nations resulted in industry uncertainty and bleak market performance.

Events leading up to the Persian Gulf war brought about increases in the price of crude oil early in the year as uncertainties emerged surrounding the availability of future Iraqi and Kuwaiti oil supplies. These crude oil price increases were reflected in the prices of petrochemical feedstocks and raw materials consumed by the chemical industry. Chemical industry suppliers, however, encountered difficulty in passing along product price increases to their customers-processors and end-product manufacturers, which further eroded supplier's profit margins. In addition, customers changed their product purchasing strategy as they began using more of their own inventories as a hedge against future supply price increases. Replacement of lost Iraqi and Kuwaiti crude oil supplies to world markets by other oil-producing nations and reaction to military successes against Iraq helped ease oil supply concerns and prices and, in turn, petrochemical feedstocks prices.

International trade negotiations continued to make headlines during the year. For the United States, international trade is an important component of the U.S. chemical industry, yielding one of the biggest trade surpluses in the United

States. In 1991, talks continued in attempts to establish a North American Free Trade Agreement (NAFTA). The agreement is intended to open up markets among Canada, Mexico, and the United States and at the same time, enable them to better compete in a global market. Among the major issues of concern to the U.S. chemical industry are future feedstocks, access to markets, and investments. U.S. chemical trade with Mexico has been growing and, while the volume of trade with Mexico is considerably less than that with Canada, future export opportunities are promising. (The United States and Canada have had a free trade agreement in effect since 1989 to eliminate all tariffs on U.S. and Canadian goods by January 1998 and reduce or eliminate many nontariff barriers.) Discussions also continued toward a General Agreement on Tariffs and Trade (GATT), which is expected to have a major impact on the volume of chemicals traded worldwide due to the reduction of tariffs and nontariff barriers and the elimination of import quotas.

Environmental concerns and regulations remained in the forefront during the year, as the 1990 Clean Air Act Amendments, benzene regulations, and other new regulations could result in chemical plant modifications for waste treatment and pollution control worldwide. The United States has had in place a Toxic Release Inventory program since 1987 that tracks domestic sources and types of toxic chemical releases into the air, land, and waters. Under this program, emissions of more than 300 toxic chemicals are monitored, including such chemical precursors to plastic resins as ethylene, propylene, and benzene. This program has attracted international attention, particularly as a vehicle for determining pollution prevention opportunities.

Reauthorization of the Resource Conservation and Recovery Act (RCRA) did not occur in 1991. The proposed legislation seeks, among other things, to encourage the manufacturing sector to produce less waste and for companies to recycle more of the waste they produce.¹⁴ The impact of RCRA on the plastics

industry is expected to be far-reaching because it governs a host of solid waste issues, including environmental labeling, recovery rates and recycled-content requirements, and toxic metals in packaging.¹⁵

With the disintegration of the U.S.S.R., individual Republics will need to critically assess the current state of their economies and the major elements within to ensure a healthy survival and to attract foreign investment and encourage privatization efforts. This will undoubtedly lead to a closer look at their chemical industries and the availability of domestic resources directed to those industries and their outputs. At present, those outputs are largely basic chemicals and not specialty consumer products, such as soaps and pharmaceuticals. Plans for change in this sector will likely emerge over the coming years, moving closer to self-sufficiency and ensuring a viable industry.

The chemical industry, itself global in scope, will likely undergo pivotal changes in the months, and years, ahead as some nations begin to restructure or reform their segments, to upgrade product capabilities, and to increase services to expand their markets.

The next several sections highlight activities of various foreign chemical industries in 1991. This information is based largely on data from Chemical & Engineering News' annual statistical compilation of facts and figures for the chemical industry.¹⁶

Canada.—Economic recession restrained growth in Canada in 1991. That factor led to widespread declines throughout the chemical industry and in manufacturing overall. Chemical producers in general saw production fall in all areas, except in specialty markets such as pharmaceuticals and toiletries. Chemical prices overall posted a modest increase over the year-earlier level. In global trade, chemical exports overall decreased by 2%, while chemical imports overall increased by 1%—causing an existing chemical trade deficit to worsen.

Chemical production of plastics decreased overall by 6% in 1991. This

decrease resulted from lower domestic demand for plastics across most key markets from that of a year ago. High-density polyethylene production, however, rose an impressive 26%, in contrast to low-density polyethylene production, which fell 5%. Plastics exports rose as producers sought foreign markets for their products. Plastics imports declined from those of a year ago.

Japan.—In 1991, a slowing Japanese economy resulted in limited growth throughout the chemical industry and in manufacturing overall. In general, chemical producers posted gains in production of most chemicals for the year, but saw chemical sales slip. More disappointing to producers, however, were the considerably lower earnings and profits realized compared to those of a year earlier. In global trade, Japanese chemical exports and chemical imports rose by 10% and 8%, respectively.

Chemical production overall increased by a modest 2% in 1991, due largely to strong growth in certain organic chemicals. Production of plastics overall grew by 1% for the year, although polyethylene exhibited stronger growth (3%). Synthetic fibers also grew by 1% from those of a year ago, but synthetic rubber declined by 4%.

Western Europe.—The nations of Western Europe struggled to recover from economic slowdowns that curtailed growth throughout the chemical industry in 1991. The major chemical-producing nations, such as Germany (composed of state data for West Germany only), France, and the United Kingdom, fared better than their counterparts, by comparison. For those nations, chemical producers saw modest increases in sales and prices over year-earlier levels. Those same producers experienced moderate growth in chemical production, capital spending, and employment. In other nations, producers saw continued declines or mixed patterns of growth in those areas.

Chemical production throughout Western Europe was dominated by inorganic and organic products (including fertilizers) in 1991 and, to a lesser extent, by plastics, synthetic fibers, and synthetic rubber. Compared to a year ago, overall production of plastics declined, despite the encouraging gains in commodity plastics posted by some nations. Overall production of synthetic fibers and synthetic rubber also declined in 1991. For plastics and synthetic rubber, the large-volume producers were France and Germany. For synthetic fibers, Germany, Italy, and the United Kingdom were the large-volume producers.

Eastern Europe.—The nations of Eastern Europe, hampered by economic recession, posted an overall decline of 19% in industrial production in 1991. This marks the third consecutive drop, each more severe than the last, in industrial output in the past 3 years. Each of the Eastern Europe nations (i.e., Albania, Bulgaria, Czechoslovakia, Hungary, Poland, Romania, and Yugoslavia) contributed to this drop, with separate declines in industrial output ranging from 11.9% to 27.8%.

Chemical production also continued to decline in the Eastern European nations in 1991. Several nations, namely, Bulgaria, Poland, and Romania, even saw production losses exceed those of industry overall. Registering the biggest losses in chemical production from that of a year ago were Bulgaria, with 34%, Czechoslovakia, with 25%, and Romania, with 20%. Production in Eastern Europe was dominated by basic chemicals. On a component basis, the production of plastics, synthetic fibers, and synthetic rubber each accounted for a considerably smaller share of total chemical production compared to chemical fertilizers. Nevertheless, supplies throughout the region were down in nearly all categories from those of a year ago, and, in some cases, by more than 20%.

U.S.S.R.—In 1991, the economy of the U.S.S.R. was also restrained by recession. The gross national product fell

by about 15% in 1991 from that of a year ago; overall industrial production fell by about 8%, and chemical production fell by about 10%.

The chemical industry exhibited production declines in nearly all chemicals in 1991, although some declines were more substantial than others. For those chemicals, the production declines experienced only continued a downward trend set in motion more than 2 years ago. The U.S.S.R.'s chemical industry has long produced large amounts of agricultural chemicals, chemical fertilizers, and sulfuric acid and, by contrast, produced much smaller amounts of plastics, synthetic fibers, synthetic rubber, and other downstream chemical products. In 1991, plastics production fell by 12% to 4.0 million tons. Total synthetic fibers production, composed of both cellulosic and noncellulosic fibers, decreased by 20% to 1.2 million tons in 1991.

With the disintegration of the U.S.S.R., the chemical industry will no longer continue to function in the years ahead as it once did. Each Republic will be forced to examine the various segments of its chemical industry and restructure or reform each as necessary to help ensure a viable industry and to encourage capital investment and future profits. For many of the Republics, this could result in substantial changes to their current chemical industry infrastructure as well as to their product slate.

Pacific Basin.—**South Korea.**—Overall manufacturing grew by 9%, and shipments grew by 11% in 1991. During that same period, overall production of chemicals, petroleum, coal, rubber, and plastic products rose by 12% and overall shipments, by 18%. In global trade, chemical exports increased 27% to \$3,191 million, and chemical imports increased by 12% to \$8,289 million. The increase in chemical exports, however, was not enough to shrink the existing chemical trade deficit, which widened by 4% to \$5,098 million.

Plastics production of polyethylene, polypropylene, and polystyrene posted dramatic gains in 1991. For the year,

polyethylene production rose by 38%; polypropylene, 35%; and polystyrene, 28%. Overall production of plastic products increased by 6% from those of a year ago, and shipments grew by 4%.

Production of rubber products decreased overall by 4% and shipments by 3% for the year.

Australia.—Chemical production overall decreased in 1991, with very few chemicals registering gains amid the general downturn. Chemical exports overall rose by 6% to \$1,082 million, due largely to healthy growth in exports of medicinal products. Chemical imports overall decreased by 2% to \$3,986. However, imports of plastics and polymers in particular dropped by 10%. The overall increase in chemical exports brought about a reduction in the existing chemical trade deficit, which stood at \$2,904 million for the year.

China.—Chemical production in most areas exhibited strong growth in 1991. In particular, production of plastics jumped 17% to 2.6 million tons; synthetic fibers grew 12% to 1.9 million tons; and synthetic rubber rose 6% to 0.34 million tons. In foreign trade, chemical exports overall grew a modest 2% to \$3,818 million for the year. In contrast, chemical imports overall registered a dramatic increase of 40% to stand at \$9,277 million. In particular, imports of plastic materials; i.e., resins, cellulose esters, and ethers, jumped 59% to \$2,378 million in 1991.

Taiwan.—Overall production of chemical materials (i.e., basic chemicals, petrochemicals, fertilizers, synthetic fibers, plastics, and resins) grew by 15% in 1991. In particular, production of plastics and resins rose by 19%, and synthetic fibers grew by 21%. Production of chemical products overall grew by 9% for the year. In foreign trade, chemical exports overall increased by 18% to \$6,743 million in 1991, and chemical imports overall grew by 23% to \$9,344 million.

OUTLOOK

Global trade patterns are expected to change as substantial investments in resin capacity are made over the coming years. Huge increases in polyolefin resin capacity for the Far East, and Republic of Korea in particular, have already been scheduled. In the Far East, olefin monomer capacity is expected to rise at least 90% from 1990 to 1995 to more than 22 billion pounds per year (lb/yr). The ethylene and propylene coming from that capacity will mainly be used to make polyethylene and polypropylene. In the Republic of Korea, low-density polyethylene capacity is expected to rise at least 80% from that of 1990 to 2.06 billion lb/yr by 1995 and high-density polyethylene capacity at least 40% to 2.34 billion lb/yr. Polypropylene capacity is expected to increase by 1 billion lb/yr from 1991 to 1993. Moreover, Japan last year announced plans for capacity increases totaling 4.73 billion lb/yr of ethylene, 1 billion lb/yr of polyethylene, and at least 175 million lb/yr of polypropylene due on-stream in the next several years, but has since postponed or canceled some of them because of concerns about rising capacity in the region and the sluggish economy. The new capacity is expected mainly to help fulfill increasing local demand requirements of newly industrialized countries in the Far East. But so far, growth in demand has lagged growth in capacity. In addition, large polyolefin plants are being built in Indonesia, Malaysia, and Thailand. During the near term, this scheduled new capacity, together with existing capacity, could keep prices for these resins down, competition between suppliers worldwide fierce, and alter trade patterns.¹⁷

Higher volume markets are expected for some plastics, such as ABS, through 1996, as new applications for those plastics take hold around the world.

Consumption of textile chemicals in the United States is expected to slow as growth in the U.S. textile industry slows over the next 5 years, according to Hochberg & Co., New Jersey-based

marketing consultants. Textile fiber use is expected to grow a modest 2% per year to 15.3 billion pounds (lb) in 1996, up from 13.8 billion lb in 1991. However, textile fiber processors used 3.6 billion lb of textile-related chemicals in 1991 and are expected to consume 3.9 billion lb of textile chemicals in 1996 (a growth rate of less than 2% per year). Textile-related chemicals include chemicals associated with dyeing and finishings, such as bleaching agents, soil and water repellents, and backcoating resins. One reason for the slower growth in textile chemical use is a decrease in the use of polymers to bind nonwoven textiles in favor of thermal bonding techniques.¹⁸

PLASTICS

The U.S. economic recession and war in the Persian Gulf put downward pressures on most domestic markets for plastic resins, resin prices, and planned company projects during 1991.

Plastic resin production in the United States rose overall by 3% in 1991, to 22.0 million tons. This growth resulted largely from increased foreign demand for certain thermoplastic resins. By exporting large volumes of thermoplastic resins, many U.S. resin suppliers were able to maintain a level of profitability in spite of depressed economic conditions at home. The surge in export activity caused U.S. resin exports to reach record levels for the year.

Plastic resins sales fell overall by 1.1% to 27.5 million tons in 1991, compared with 27.8 million tons in 1990. Sales were strongest for low- and high-density polyethylene, polyvinyl chloride (PVC), and polybutylene terephthalate, polycyclohexylenedimethylene terephthalate, polyethylene terephthalate (PBT/PCT/PET), while sales were weakest for styrene acrylonitrile, phenolics, and urea/melamine.

Despite recessionary pressures, resin suppliers increased spending on research and development activities to create new products and process technologies to maintain a competitive edge at home and in world markets.

The composition of industry continued to change as moves to address environmental concerns, facilitate recycling, and alleviate the landfill crisis took hold.

Background

Early beginnings of the plastics industry can be traced back to natural compounds such as horn and hoof, tortoise shell, bone, ivory, gutta-percha, shellac, and glue. Forming useful items with these and other compounds necessitated the development of extruders, presses, molds, calendars, and so on, that were later used for synthetic materials as they were developed. In 1929, a generic name for the developing industry was selected by a contest. Synthoid was the winner, but it was shunned by the industry in favor of the word "plastic."

Plastic was favored because the word means that the substance can be molded or formed into any shape, as opposed to nonplastic substances that must be cut or chiseled.¹⁹

Significant dates in the development of synthetic polymers start with Alexander Parkes' introduction of the cellulose nitrate, Parkesine, at the Great Exhibition in London, England, in 1862. (Reference to specific products or companies does not imply endorsement by the U.S. Bureau of Mines.) In the United States, John W. Hyatt independently developed a form of cellulose nitrate and the injection molding machine in 1868. A patent for Celluloid was granted to Hyatt and his brother Isaiah in 1870. It was not until 1877 that A. Kekule postulated that natural products are long-chain molecules. E. Fischer finally verified that the structure of cellulose was indeed a macromolecule in 1893. (See table 5.)

Hendrik Baekeland was responsible for the introduction of the first synthetic thermosetting resin in 1909. The phenolic was known as Bakelite. Commercial development of a number of thermoplastics occurred during the 1930's. W. H. Carothers first synthesized nylon 6/6 in 1935, polyurethanes were invented by O. Bayer in 1937, and R. J. Plunkett discovered

the polymerization of tetrafluoroethylene (PTFE) in 1938. PTFE was developed rapidly to the manufacturing stage under a crash program for use in World War II.²⁰ However, it was not until 1950 that PTFE came into wide commercial production under the trade name Teflon.

Production of PVC and formaldehyde laminates (Formica) began in 1940. Fiber-forming polyesters were developed in 1941, as was PET. The 1950's saw the first commercial production of PET as Dacron, development of polypropylene, polycarbonate, high-density-polyethylene (HDPE), and polyphenylene oxide (PPO). During the 1960's, aromatic polyesters were introduced and the first spun fibers or aramid fibers were developed. Polyimides were introduced, and from them, a whole family of polymers emerged. Several new polymers were introduced during the 1970's. Kevlar, an aromatic polyamide (aramid fiber), became available in 1973, and a modification to PET in the late 1970's made it a popular choice for the blow-molding of beverage bottles. Polyetheretherketone (PEEK), first marketed in 1978, is one example of the newer, high-performance, high-cost polymers that have found applications in the aerospace and computer industries, where high cost is less of a consideration.

The 1980's have seen the introduction of a new melt-processible liquid crystal polymer known as Xydar (Dartco Manufacturing Co., 1984) and the development of new technologies for alloying and blending old polymers to meet specific engineering criteria. Recent developments and trends suggest that many of the "new" polymers will result from future research efforts into the areas of processing and fabrication technologies rather than into the discovery of additional "new" polymers.

As can be seen from table 5, there is often a significant time lag from discovery of a polymer to commercial production of a product. The 12-year lag from discovery in 1938 to wide-scale commercial production of Teflon (PTFE) in 1950, for example, brings up a very important point in the historic

development of the polymers industry. Discovering a new polymer does not necessarily lead to its development or commercialization.

Although the science of polymerization has come a long way in defining how molecules can be engineered to meet specific criteria, development of new polymers into commercially acceptable products can be a lengthy process. Aside from finding new uses for a new polymer, there are patents to consider, processes to be worked out for the large-scale manufacture of the polymer, and cost-effective fabrication methods to be developed. In addition, safety factors and standards have to be met, and in some cases, licenses may need to be issued (such as the Federal Drug Administration's approval for medical uses) before a new product can be introduced into the market. The whole process involves a number of disciplines working together and can take years, even decades, to accomplish. It also costs large sums of money, and that limits the number of participants interested in actively developing new polymers.

Definitions, Grades, and Specifications.—Polymers can be classified according to the structural shape of the polymer molecules. They can be either linear, branched, or cross-linked. Linear polymers have repeating units linked together in a continuous length. When branches protrude from the main polymer chain at irregular intervals, the polymer is termed a branched polymer. Both linear and branched polymers are thermoplastics. They can be softened and hardened by heating and cooling. Fabricating processes like injection molding, casting, and blowing take advantage of this feature to shape thermoplastic resins. The rigidity of thermoplastic resins at low temperatures is attributed to the existence of secondary bond forces between the polymer chains. These bonds lose strength or are destroyed at higher temperatures, thereby causing fluidity of the resin.

Polymers used as textile fibers are linear. However, they must be of high

molecular weight and have a permanent orientation of the molecules parallel to the fiber axis. The chain orientation necessary to develop sufficient strength by crystallization is achieved in the melt during spinning and then by a process known as cold drawing, in which the initially formed filaments are drawn (stretched and further oriented) at a temperature above the glass transition temperature, T_g . (T_g is the temperature at which sufficient energy is available to the molecular segments to cause them to begin to rotate and materials become soft and rubbery.)

Elastomeric materials, like thermoplastic resins and fibers, are essentially linear polymers. Certain distinctive features in their molecular structures make them rubbery. Because their T_g 's are below room temperature, they can be stretched to twice their original length and then can return essentially to their original shape when tension is relaxed.

Polymers or resins that are transformed into a cross-linked product, and thus take on a "set" on heating, are said to be thermosets. Cold flow between molecules can be prevented by cross-links between polymer chains. The structure of polymer chains present in the cross-linked polymers is similar to the wire structure in a bedspring, so chain mobility, which permits one chain to slip by another (cold flow), is prevented. Natural rubber, for example, is a sticky product with no cross linking, and its polymer chains undergo unrestricted slippage. The product has limited use. However, when natural rubber is heated with sulfur, cross linking takes place. Cross linking by sulfur at about 5% of the possible sites gives rubber enough mechanical stability to be used in automobile tires but still enables it to retain flexibility. Introducing more sulfur introduces more cross-links and makes rubber inflexible and hard.

Cross linking is an important process in polymer technology. A high degree of cross linking gives rise to three-dimensional or space network polymers in which all polymer chains are linked to form one giant molecule. Thus, instead

of being composed of discrete molecules, a piece of highly cross-linked polymer constitutes just one molecule. At high degrees of cross linking, polymers acquire rigidity, dimensional stability, and resistance to heat and chemicals. Because of their network structure, such polymers cannot be dissolved in solvents and cannot be softened by heat. Strong heating only causes decomposition. Quite commonly, these materials are prepared, by intent, in only partially polymerized states (prepolymers), so that they may be deformed in the heated mold and then hardened by curing (cross linking).

Polymers generally fall into three major categories: commodity, engineering, and high-performance materials, based on price, volume, and usage of the product.

Commodity materials are the high-volume, low-cost materials that are easily processible. Examples include PVC, low-density polyethylene (LDPE), HDPE, and polypropylene (PP). Some classifiers place ABS in the commodity grouping, but it also finds usage in engineering applications.

Included in the engineering group are polyamides (nylons), polyacetals, polycarbonates (PC), modified PPO, PET, and PBT. These materials are the intermediate grouping in terms of production volume, material costs, and processibility. Engineering polymers have inherent characteristics that make them suitable in areas replacing metals or glass-ceramics. Properties of engineering polymers include good heat resistance, strength, durability, resistance to chemicals and weathering, and good electrical properties (either conductive or insulating).

High-performance materials include polymeric resins and reinforced resins and composites used in more specialized or demanding environments. These materials have a very low production volume relative to the other polymers and a high to very high price, with prices in the hundreds or even thousands of dollars per pound. The polymerization process for high-performance materials is complex, and fabrication is difficult because of their high melting point or

even lack of a true melting point. These materials have exceptional resistance to heat, hostile environments, and chemicals; outstanding strength; and good optical, lubricity, and electrical properties. Polymers included in this classification are polyphenylene sulfide (PPS), polysulfones, polyether-imides (PEI), polyamide-imide (PAI), polyimides, PEEK, fluoroplastics, liquid crystal polymers (LCP), and the aromatic polyamides, polyesters, and copolymers.

Products for Trade and Industry.—Resin suppliers, compounders, and processors, among others in industry, race to create new products or applications to better, if not maintain, their competitive edge in world markets.

Badische Aniline Soda Fabriken (BASF), for example, has plastics applications centers in Europe, North America, and East Asia. In 1992, BASF should be in the final phase of its startup of its new Ultramid nylon 6 resins. Last year BASF increased its domestic Ultraform acetal resins capacity, and, in Europe, Ultrason E polyether sulfone capacity was expanded to meet global market demands. Werner Praetorius, group vice president, has stated, "The fact that we are guided by global forces, supports our continued capital investments."²¹

Thermoplastic elastomers (TPE) have been improved in vapor barrier qualities by Advanced Elastomer Systems, a joint project of Monsanto Chemical Co. and Exxon Chemical Co. The first application for the improved TPE is in blood vial stoppers, which take advantage of the improved water and air vapor barrier qualities. Other medical and general uses are on the horizon.

Akzo Engineering Plastics produced a reduced moisture sensitive polyamide alloy in 1991 by the use of mineral and glass-mineral filled formulations. Other developments have included higher glass loadings in Fiberstran, a long fiber-reinforced thermoplastic, which will enable more metal replacement potential, a nonhalogenated polypropylene with higher modulus, tensile strength, and

flexural strength than halogenated fire retardant polypropylene, and a new Plaslube PL group of thermoplastics that make use of polymeric lubricants like PTFE.

Amoco Performance Products commercialized third generation liquid crystal polymers in 1991 with a range in both heat resistance [up to 671° F heat distortion temperature (HDT)] and cost. Also introduced were Radel polyphenylsulfone (PES) injection molding grades for aircraft interiors, and a PES resin is being tested for aircraft sheet. Twelve grades of Amodel polyphthalamide with melt temperatures of 590° F and HDT of 545° F have allowed the gap to be bridged between traditional engineering thermoplastics and higher cost materials such as liquid crystal polymers. Twenty percent to 30% carbon filler in the polyphthalamide grades are being used to increase friction wear for bearings, and high stiffness is obtained in a cost effective manner with mineral/glass filler.

Arco Chemical Co. introduced three grades of Dylark FG high heat styrene copolymers for microwaveable food packaging in impact, clear, and foam options.

Color stability in thermoplastic olefins (TPO) was increased by D&S Plastics International in both paintability and molded-in color. This combines well with the new 700 TPO's featuring higher stiffness for use in automotive cladding and vertical body panels.

In 1991, Dow Plastics introduced a new hydrochlorofluorocarbon compatible polyurethane foam/styrenic alloy liner system for refrigerators and freezers. This new liner system does not require a coextruded or laminated barrier to prevent the blowing agent from attacking the liner. New grades of high gloss acrylonitrile butadiene styrene and polystyrene are finding applications in small appliance housings and microfloppy diskettes, respectively. Also introduced in 1991 was Derakane 441-400 vinyl ester resin with less than 35% styrene, which helps reduce vapor emissions.

E.I. du Pont de Nemours & Co. introduced a toughened nylon resin with

low mold deposits and a halogen-free nylon for wire and cable coatings. The Delrin line of acetal resins added improved series with better weld line strength and melt stability.

Eastman Chemical Co.'s series of Tenite resins, low-temperature extrusion coating specialty polyethylenes, were marketed so that coextrusion could be accomplished at temperatures 25% to 30% below normal, allowing bonding with heat-sensitive resins such as ethylene-vinyl acetate and ethylene-vinyl alcohol.

Exxon Chemical Co. produced a clarified polypropylene with high moisture barrier, clarity, and impact resistance by increasing the level of molecular linearity in the polypropylene resins. Also, a polypropylene film was developed that offers low-temperature heat seal for bag applications and medical tubing.

GE Plastics introduced a new line of polycarbonate copolymers, Lexan SP resins, that have extended the flow and impact properties. Lexan PK2870 is being molded into the first gallon-size reusable polycarbonate bottle, Lexan F8000 sheet has met regulations for use in aircraft interiors, and Lexan FR700 was introduced as a polycarbonate film for electrical barrier insulation. GE also introduced a paintable thermoplastic elastomer for automotive exterior uses, such as soft bumper fascias, and an ABS resin with higher heat properties for automotive interiors.

Himont Corp. introduced a clear, radiation-resistant PP for injection molding medical products and labware and a superclear grade for housewares. Competitiveness with ABS has been increased by raising the flexural modulus, and low modulus grades have been introduced that make PP suitable for calendaring so that liner material can be produced to line ponds and landfills. In the Far East, foam processing of PP was achieved, allowing the production of PP foam pipe insulation and food trays.

Hoechst Celanese introduced a 40% glass filled polyphenylsulfone resin designed for thin wall, surface-mount electronic connectors with increased heat

deflection temperature, faster cycle times, and better flowability.

LNP Engineering Plastics introduced new formulations of long fiber reinforced plastics in its Vertron line.

Mobil Chemical Co. has introduced a new high impact polystyrene (PS) injection molding resin with faster cycle times. Applications in durable goods, appliance parts, housewares, and toys are being considered.

Monsanto has increased the weatherability, ultra-violet resistance, and color stability in its acrylonitrile-styrene-acrylic (ASA) and acrylonitrile-ethylene propylene diene monomer-styrene (AES) resins. The heat resistance and moldability are comparable to that of ABS. Uses are in custom extrusions for truck caps, pool steps and spas, recreational vehicles, boats, and personal watercraft.

Novacor Chemical Inc.'s Plastics division introduced a new series of TPE, the Sarlink 3000 Series, and a new TPE in its 2000 series. The 3000 series was developed as substitutes for ethylene propylene diene monomer and neoprene rubber. Hardness is available in a variable range for both the 2000 and 3000 series with the 2000 series covering the lower end of the range. Applications are in blood vial stoppers, paper rollers, and copier belts. Four new injection molding grades of compounded methyl methacrylate, styrene, and butadiene were also introduced. Advantages include improved alcohol resistance and stability of color/property retention after gamma sterilization, which should enable these new compounded plastics to find uses in the medical field.

Rogers Corp. phenolic composites are currently being used in automotive power train components. Improvements in properties have been obtained by new compounding technology and resin toughening.

Industry Structure.—Most of the domestically produced resins are produced by a relatively small number of large companies. For example, PE, the largest resin category, has 18 producers, but the top four companies have more

than 50% of nameplate capacity. ABS has only three domestic producers. PVC has 12 domestic producers, but the top 4 account for 66% of capacity. PP has 14 domestic producers, and the top 4 account for 59% of total capacity. PS has 14 producers, 63% from the top 4. Table 6 lists the domestic production capacity of PE, PP, PS, and PVC, along with the capacity utilization rates for each of the past 5 years. (See table 6.)

A survey conducted by Plastics News in 1991 profiled the custom injection molding industry, the most widely used plastics fabrication technology.²² (The extrusion process accounts for more resin usage, but has far fewer facilities.) As of September 9, the number of completed surveys returned totaled 215 from the more than 1,000 companies that were asked to participate. The findings reported here are based on those surveys. The survey identified the top 100 injection molders, ranked by sales of custom injection molded products in their most recent full fiscal year in North America. Together, these companies had sales of more than \$5.13 billion in injection molded resin products and processed more than 1.5 billion pounds of resins.

The top 5, and 14 of the top 20, injection molders were engaged exclusively or in large part in supplying the automotive industry. All of them had more than 1 plant and injection molding-related employment levels between 500 and 2,900 persons. Most of the businesses supplied plastic products to more than 1 industry, but 18 of the 100 were engaged in a single industry; 12 to automotive, 3 to packaging, and 1 each to aerospace and other transportation, housewares/consumer product, and medical/pharmaceutical/health care.

Table 7 gives information on the number of U.S. plants engaged in fabrication of plastics using one or more primary processes. This information indicates that injection molding is the most prevalent method of fabrication, followed by extrusion. As shown by this and figure 6, the structure of the plastics processing sector is such that more than 50% of fabrication is performed by

captive plants. (See table 7 and figure 4.)

When the plastics industry is looked at from a perspective of how much resin is processed using each of the major technologies, a somewhat different pattern emerges. Even though injection molding accounts for the largest number of operations, table 8 shows that extrusion is the dominant technology in terms of the amount of resin processed. In 1991, more than 37% of all resins were extruded, about four times the amount processed with injection molding machinery. Blow molding, the third largest technology used, accounted for more than 7% of total resins. A principal reason for this division is that extrusion machinery can create simple shapes, such as pipes and profiles, at a very high throughput rate and very low costs. Injection molding is a very versatile processing technique, but is not a continuous process. Parts can be molded singly or even in multiple numbers relatively cheaply, but each cycle requires a mold fill, cooling, and ejection of the part before the next cycle can begin. (See table 8.)

Developments in capacity expansions worldwide show that during the past 5 years, capacity of PE in North America increased by 9 billion pounds, a 42% increase in nameplate capacity. In 1991, U.S. domestic demand for PE fell for the first time in 10 years. Despite this decline, new PE capacity, amounting to 2.1 billion pounds, is planned for the United States in late 1992 and early 1993 by Dow, Phillips, Eastman, and two new companies in the PE market, Himont Inc. and Formosa Plastics USA. Dow Plastics forecasts a 3% to 4% rise in domestic demand for 1992.²³ Montecatini of Italy, the parent company of Himont, expects to supply PE earlier than originally anticipated as a result of its plans to retrofit a new PE unit to an existing PP plant in Bayport, TX.

In 1988, PP capacity in the United States was 6.9 billion pounds; it now stands at 9.4 billion pounds—an increase of 36% in nameplate capacity. This increase occurred despite the closure of old-technology process units such as those

of Eastman Chemical, which recently brought up a new Unipol PP unit. Amoco has scheduled a 300-million-pound unit to be on-line in the second quarter of 1992, and Formosa Plastics has a scheduled startup of a 450-million-pound unit at Point Comfort, TX, late in 1992. Last October, a 260-million-pound PP plant employing the Unipol process was brought on-line by Epsilon Products at Marcus Hook, PA.

BF Goodrich (BFG) has plans to shut down more than one-half billion pounds of PVC capacity by 1993 to concentrate on producing lower volume, more profitable specialty grades of resins. The BFG marketing manager predicts that the North American PVC industry will require four new plants to meet the expected annual growth of 3.5%.²⁴ Present needs are met by four primary producers, BFG, Oxychem, Formosa, and Shintech, which account for more than 70% of PVC produced. BFG continues to concentrate on value-added compounds like its new high-stiffness, rigid vinyl extrusion compounds that offer a lower coefficient of linear expansion and higher heat deflection. Oxychem on the other hand tends to deal in large-volume markets, so it concentrates on increasing its chlorine and ethylene production rates. Formosa Plastics is attempting to become the most fully integrated PVC producer in North America so that it does both feedstock production and PVC products. Formosa Plastics is already the largest U.S. PVC pipe producer. Shintech is producing for large-volume markets and exports, which enables it to take advantage of its large reactor technology.

PS production in 1991 was at 75% of nameplate capacity; for this reason there are no plans to increase capacity in the future. Shutdowns of two plants in 1991 by Dow Chemical (200 million lb/yr) at Midland, MI, and Novacor (70 million lb/yr) were balanced by the startup of one new plant, Mobil (120 lb/yr), and a restart of a previously mothballed plant by Deltech (145 million lb/yr) at Willow Springs, IL.

North American production capacity for ABS is currently being boosted to 2

billion pounds per year. Monsanto plans to bring on-line an 80-million-lb/yr plant at Cincinnati, OH, in the third quarter. GE Plastics has plans for a 150-million-lb/yr expansion in 1992 at Ottawa, IL and Bay Saint Louis, MS, and Dow Plastics will start up a new plant producing 60 million lb/yr in Midland, MI. The domestic demand in 1991 was only 1.2 million lb/yr, but the planned expansions in capacity are not expected to create an oversupply of ABS.

There are plans by several of the key producers in the PET industry to expand capacity to keep up with the rising demand. Chief among these producers worldwide is Germany's Hoechst A.G., which has plans to expand capacity by 480 million lb/yr through its U.S. division, Hoechst Celanese, and Mexican division, Celanese Mexicana. This expansion will take place in two phases. The first phase will involve debottlenecking and restarting idle capacity at plants at Greer and Spartanburg, SC, for an increase of 130 million lb/yr in 1992 along with a new solid-state unit to be built in 1993 at Quetaro, Mexico. The second phase will include two new 140-lb/yr plants to be opened at Spartanburg, SC, in 1994 and in 1995. Shell Chemical's Italian branch plans a joint-venture plant producing 130 million lb/yr with Mossi and Ghisolfi at Frosinone, Italy. Startup is scheduled for the middle of 1992. Eastman, the largest producer in the United States, has plans for 340 million lb/yr in the next 2 years. This will be achieved with a debottlenecking in 1992 at a plant in Columbia, SC, boosting production by 100 million lb/yr and by two new plants in the United Kingdom adding 240 million lb/yr. Imperial Chemical Industries has plans for a 113-million-lb/yr expansion in Europe and a production increase of 39 million lb/yr in the United States for 1992.

In the United States, Reichold Chemicals, the largest domestic supplier of TPO and a subsidiary of Dainippon Ink and Chemical of Japan, is attempting to obtain a 75% stake in Alpha Chemicals, which will make their

collective capacity 825 million lb/yr, the world's largest.

In 1992, Du Pont is bringing on-line a 30-million-lb/yr compounding plant in Parkersburg, WV, for engineering resins. Peter Rigby, senior development manager, says that this plant will allow rapid scaleup of materials, custom coloring, and competitive turnaround times. This endeavor by Du Pont is indicative of a trend whereby engineering resin producers are attempting to develop specialty resin grades that closely match the design requirements of the products.

Technology.—Processing.—Products with good performance characteristics can often be produced at low cost with flexible, high-volume, automated methods such as extrusion, blow molding, and injection molding. Those resins that are best suited to these high-volume methods are likely to continue to grow in importance.

Fabrication processes for the thermoplastic and thermoset classifications of plastics take advantage of the chemical differences between the two, although progress in technology has lessened the effective, if not chemical, distinction between them. Thermoplastic resins may be processed hot, cooled, and then reheated and reprocessed, while thermosetting resins cross link in processing and cannot be reheated and used again.

Common thermoplastics include ABS, PVC, SAN, acetals, acrylics, cellulose, PE, PP, PS, polycarbonates, polyesters, nylons, and fluoropolymers. The most important processing techniques for thermoplastics are injection molding, extrusion, and blow molding. Other processes include thermoforming, casting, rotational molding, calendaring, and spinning.

The common thermoset resins include phenolics, ureas, melamines, epoxies, alkyds, unsaturated polyesters, silicones, and urethanes. The most common processing methods are compression and transfer molding, but thermosetting resins are also processed using reaction injection molding (RIM) techniques, pultrusion, casting, and foaming processes.

The machinery used to process plastics comes from suppliers in a large number of countries. In Western Europe, Germany, Italy, and the United Kingdom have large machinery sectors and export a large percentage of what they produce. In Asia, Japan is by far the leading producer of plastics processing machinery. In North America, the United States produces the largest number of machines, but Canada has a surprisingly robust machinery industry. Table 9 shows the number of plastic fabrication machines sold into the U.S. market. (See table 9.)

Domestic manufacturers of plastics processing equipment saw total shipments of U.S.-made injection molding machines drop 9% in 1991, to 1,611 units from 1,770 units in 1990. Shipments in all nine clamp force categories as reported by the Society of the Plastics Industry, Inc. contributed to the decline, except those with clamping forces of 0 to 99 tons and 750 to 1,199 tons. The clamp force category of 0 to 99 tons accounted for the largest number of machine shipments in 1991 with 390 units, up from 373 units in 1990. Shipments of machines with clamping forces of 750 to 1,199 tons rose to 70 units in 1991 from 66 units in 1990. Imports of injection molding machines fell 4.1% to 2,366 units. In terms of market share, U.S.-made injection molding machines, with 41%, and imported injection molding machines, with 59%, accounted for approximately the same percentages of the U.S. market in 1991 as those of 1 year ago.

Total shipments of U.S.-made single-screw extrusion machines dropped 5.5% to 952 units in 1991 from 1,007 units in 1990. Machine shipments fell in five of seven categories based on screw diameter and rose in the two other categories. The sharpest drop in shipments occurred in the less than 2-inch category, while the largest gain was in the 7.5-inch and larger category. The 2.5-inch but less than 3-inch category accounted for the largest number of shipments in 1991 with 318 units, down from 321 units in 1990. Despite the decline in total domestic shipments, U.S.-made extrusion machines

captured a markedly higher percentage share of the domestic market, rising to 72% in 1991 from 57% in 1990. Imports of extrusion machines fell 51.7% to 374 units in 1991 and accounted for 28% of the U.S. market.

Recycling.—The U.S. plastics industry continued to make progress during the year toward meeting its goal of recycling 25% of the country's plastic bottles and rigid containers in 1995, despite the economic recession, low virgin resin prices, and an oversupply of recyclable materials. According to the Partnership for Plastic Progress (PPP), a program of the Society of the Plastics Industry, Inc., plastic bottles and containers were recycled at an 11% rate in the United States in 1991; an increase of 4% from that of a year ago. The recycling rate for PET soft-drink bottles rose 6% in 1991 to 36%, while the rate for all bottles climbed to 14%.

Concerns about toxins in postconsumer plastics contaminating the beverage have kept used beverage bottles from being recycled into new ones. But, major soda producers have entered the market recently with bottles made from postconsumer PET broken down chemically and then regenerated into PET.²⁵ On March 12, 1991, Coca-Cola Co. began testing its 2-liter PET soda bottle containing 25% recycled resin.²⁶ The Food and Drug Administration removed its proscription against the use of recycled resins because the PET resins regenerated by Hoechst Celanese were chemically depolymerized and then repolymerized in a methanolysis reaction process. Pepsi-Cola Co. introduced its recycled-content 2-liter bottle in late 1991 with recycled resins by Eastman Chemical Co., which also uses a methanolysis reaction process. The Pepsi-Cola Co. had originally planned to test-market bottles made from Goodyear's resin produced in a glycolysis process during the summer, but is now expected to introduce these bottles in early 1992.²⁷

Hoechst Celanese is expected to continue to supply the Coca-Cola Co. with its repolymerized PET for inclusion in its beverage bottles, and Goodyear is

expected to supply Pepsi-Cola Co. with its Repete resins. Eastman is expected to supply 50 million lb/yr of its 25% repolymerized-75% virgin blend to molders in 1992.

There is also an uptrend occurring to recover the hydrocarbons from recycled plastics called "tertiary recycling" by more companies as landfill space continue to dwindle. In tertiary recycling, plastics are ground and remelted into fillers and fibers, or minor constituents in resin blends, or processed into fuels. Companies such as Eastman Chemical (Rochester, NY), Du Pont Co. (Wilmington, DE), Goodyear Tire and Rubber Co. (Akron, OH), Sanwa Kako Co. (Kyoto, Japan), Hoechst AG (Frankfurt, Germany), BASF AG (Ludwigshafen, Germany), ICI plc (London, United Kingdom), and Veba AG (Dusseldorf, Germany) are chemically unzipping or thermally cracking polymer chains to recover monomers to make resins that are indistinguishable from virgin material. The remaining hydrocarbons fractions are either refined as petrochemical feedstocks or sold as fuel or fuel additives.²⁸

Tertiary recycling can be accomplished by either a chemical or thermal process, depending on the polymer considered. Glycolysis, methanolysis, and hydrolysis are all chemical ways used to unzip condensation polymers such as polyester, nylon, and polyurethanes. Thermal processes must be used to break down addition polymers such as vinyls, acrylics, fluoroplastics, and polyolefins. Refineries have been experimenting with thermal processes because pyrolysis units are already part of their infrastructure. Obstacles to this process, at present, are contaminants such as chlorine and nitrogen in the plastics waste and the need to turn the plastics waste into a liquid stream. Amoco and Chevron are using bench- and pilot-scale tests to assess the feasibility of several options such as small-scale pyrolysis; dissolving plastics into other refinery feedstocks; or converting the solid waste into a slurry that can be pumped. Two companies producing gasoline fuels from recycled plastic waste are Central Fine Pack and

Fuji Recycle. Central Fine Pack of Fort Wayne, IN, a subsidiary of Chuo Kagaku Ltd. of Kohnosu City, Japan, produces a diesel oil from commingled plastics in a steady stream process. Since 1988, Fuji Recycle Industry K.K. of Aioi, Japan, has produced 500 metric tons per year of gasoline from polyolefin plastic waste.

Europe and Japan now lead the United States in commercializing applications for plastic scrap. In Europe, new packaging applications have provided the stimulus for developing tertiary recycling processes. A European Community directive setting 90% collection and 60% recycling quotas on packaging waste is expected to be presented by yearend 1992, and if enacted by the European Parliament, it will be phased in over 10 years. Meanwhile, several countries have already set their own goals for plastics recycling. Italy, for example, has set a recycling quota of 40% for plastics containers. The Netherlands has set a goal to recycle 35% of all plastics and to recover energy by incineration of another 45% by the year 2000. The most aggressive regulations were enacted in Germany, where, by 1995, 64% of all product packaging must be recycled.

Substitutes.—Polymeric materials are being substituted for glass, ceramics, metals, and paper in many applications. As polymers with improved physical properties are developed, substitution for other polymers also occurs. Everything from microwave food packaging, with its multiple layers with barrier properties, to housewares, to sporting goods, to automobile bumpers, to satellites and aircraft are now made with polymeric materials. Some areas of substitution encourage new product development by the polymer users such as food packaging. Others improve product durability and provide weight savings and/or cost savings.

One new application of PVC is for marine panels such as ShoreGuard-brand extruded marine panels from Universal Bulkhead, using BFG's Geon vinyl. The new panels are stronger than wood in most cases and more durable than steel, according to BFG. Also, the products

resist exposure to water, sun, and temperature cycling, and their light weight simplifies installation along waterways, ponds, and golf courses.²⁹

In another application, PCT is being used instead of metal for some wheelchair components. The moldability of PCT helps in parts consolidation and cost reduction.³⁰

Economic Factors.—U.S. resin prices were affected by the economic recession, abundant resin inventories, and events in the Persian Gulf during the year. An interplay of these factors caused resin prices, in response, to rise and fall and, at times, rise again. Prices for the commodity-grade resins were markedly up, as were prices of crude oil, at the start of the year (table 10). PS, for example, started the year with large-volume prices from 57 to 59 cents; injection-grade HDPE, from 45 to 48 cents per pound; and PP from 43 to 47 cents per pound. A general easing in resin prices toward midyear lead to lower prices in July for those resins. The availability of adequate feedstocks for resin production, ample resin stocks, and weak resin demand were, in large part, the key elements to spur on competitive price cutting. By December, however, prices for most virgin resins had climbed to slightly higher levels. (See table 10.)

Prices for recycled plastics seemed to be less affected by the soft market conditions of midyear, as they remained unchanged or increased only slightly in July, before falling to lower prices in December.

Annual Review

Legislation and Government Programs.—One regulatory issue in 1991 surrounded a heated debate concerning the use of the words "recycled" and "recyclable" on plastic products. Federal agencies were lobbied for a national solution, State governments made proposals for a national solution, and third party organizations such as Green Cross and Green Seal each made their own suggestions. A group of plastic

manufacturers and retailers lobbied the Federal Trade Commission for standards on the use of the words in a context that would clarify their meanings. Among their suggestions were requirements that labeling should include specific statements as to recycled content in a percentage form and that either recycling centers be made available or the disclaimer "recyclable where facilities exist" be included in the labeling. By the end of the year, the issue had not been resolved; however, it is expected that a solution will be arrived at in 1992.³¹

The "Green Laws" passed in Europe regulating the use of PVC in packaging and disposables are still causing some to predict that future legislation is imminent in the United States. No rulings on this front occurred in the United States at the Federal or State level in 1991.³²

New clean water rules issued by the Environmental Protection Agency (EPA) in 1991 could affect plastic processors where bulk loading of resins occurs. Plastic pellets or other raw materials could find their way into rainwater runoff, leading to a violation of the Clean Water Act.

EPA decided not to include styrene as a probable human carcinogen, and two States, North Carolina and South Carolina, relaxed their air quality standards following the release of a report by the Styrene Information and Research Center on the alleged health risks of styrene exposure.

Also, EPA issued new regulations in 1991 under the 1990 Clean Air Act that tighten standards for the "permit to pollute." Former small operators, defined in the past as operators emitting less than 100 tons/year of a smog-causing pollutant, have found themselves reclassified depending on their location. The new regulations permit varying levels of emissions depending on the local air quality, thus some operators previously considered as small are now classified as major polluters. These new regulations will affect resin manufacturers and manufacturers of the basic petrochemicals involved in plastics.³³

In August, the FDA issued a rule on "Colorants for Polymers" that makes the

following assertions: colorants have been shown to migrate to food from polymers, colorants are food additives, and colorants are subject to the Federal Food, Drug, and Cosmetic Act. This may lead to a requirement for colorant or packaging manufacturers to petition the FDA for clearance of all colorants used in their products.³⁴

Issues.—California enacted a law that makes it illegal to claim a product as "recycled," "recyclable," "ozone-friendly," or "biodegradable" without meeting criteria laid down by the U.S. Federal Trade Commission (FTC). "Recycled" is defined by the FTC as meaning an item that contains a minimum of 10% by weight reclaimed postconsumer material and can be recycled in every country having a population of at least 300,000.³⁵

In March 1991, the EPA and Occupational Safety and Health Administration (OSHA) announced a plan to implement cooperative efforts between the two agencies, including joint inspections of petrochemical plants, hazard referrals, and training programs. This action was in response to a recent spate of explosions and fires in petrochemical plants, the most recent example of which was the March 12, 1991, fire at Union Carbide's Seadrift, TX, facility.

In June 1991, the Council for Solid Waste Solutions (CSWS) announced the beginning of a campaign to change the public's perception of plastics in the environment. An opinion poll commissioned by the CSWS in 1990 indicated that a majority of Americans, 54%, rated plastics as unfavorable compared with 34% in 1988. Methods to improve collection and sortation technologies for recycling are being considered by industry leaders. Jean Statler, communications vice president at CSWS, believes that the public is most likely to believe that plastics are recyclable when they become involved in a curbside collection program.³⁶

The Society of the Plastics Industry (SPI) launched a campaign, Operation Clean Sweep, to prevent plastic resins

pellets from finding their way into the oceans and rivers of the world. New regulations from the EPA dealing with stormwater runoff had added a sense of urgency to the SPI's campaign.

The Council on Plastics and Packaging in the Environment (COPPE) commissioned a study on solid waste issues from which it has drawn several conclusions about public misperceptions concerning the solid waste problem. Americans are said to assume that trash disposal is the most pressing environmental issue, curbside collection and recycling of trash is the primary solution to the solid waste problem, and recycling rates of 25% to 50% are entirely feasible. COPPE believes these perceptions are false and that overselling recycling puts source reduction on hold. Furthermore, COPPE thinks source reduction efforts that have occurred in plastics packaging through downgaging and redesign should be publicized more often.³⁷

The Center for Plastics Recycling at Rutgers (CPRR) University is working on a bar code label for plastics bottles to allow sorting of plastics by polymer type, additive and filler content, color, brand name, and other data. The motive for this code being initiated is that the CPRR feels that recycling's success depends on the increased use of automated computer-controlled sortation.

The World Wildlife Fund & Conservation Society, Washington, DC, was given a Federal grant in 1991 to develop guidelines for source reduction policies in solid waste management. Key strategies that have emerged from this study include: product life extension, product life assessments or lifecycle analyses, and design for disassembly. John Kusz, chairman of the environmental affairs committee of the Industrial Designers Society of America, said that incentives can be implemented to combine longer product life with healthy profits. He cited the imposition of recovery fees on durable products as a possibility. The advantages to this fee would be that a collection system would be encouraged because consumers would wish to recover their fees and

manufacturers would be encouraged to extend product life because they would want to postpone the payment of fees. Lifecycle analyses are valuable tools in analyzing the impact of a product on society, but there needs to be established a common methodology for performing these studies so that the information is useful in comparing products. The Society of Environmental Toxicology and Chemistry, Washington, DC, met in February 1991 to discuss the role of lifecycle analyses and their methodologies.

Whirlpool Corp. has issued a mandate that its service units collect chlorofluorocarbon-12 (CFC) in PE bags for recycling to prevent the damaging effects CFC has on the ozone layer.

BFG, Cleveland, OH, started a pioneer program to reclaim the commingled LDPE and PVC fluff from shredded cable jacketing. The impetus for this program is the expectation that under new EPA guidelines this fluff will be classified as hazardous waste leading to much higher disposal costs.

Production.—U.S. plastics production in 1991 rose by 3% overall largely due to increased production of several major thermoplastics, namely, thermoplastic polyester, HDPE, and LDPE (table 11). Taken separately, thermoplastic polyester production increased 12% in 1991, to 1.0 million tons; HDPE production, 11% to 4.2 million tons; and LDPE production, 4% to 5.3 million tons. Epoxy, a thermoset, also contributed to the overall production increase, rising 6% in 1991. Production growth for those resins resulted from strong demand in U.S. export markets. Production of most other resins declined during the year. (See table 11.)

Polyurethane (PUR), the largest volume thermosetting resin, experienced a 9% decline in domestic production in 1991. Flexible PUR foam use declined 12% in 1991 especially in automotive rigids. An environmental concern for PUR is the use of CFC's as a blowing agent. The use of CFC's as a blowing agent declined almost 50% by 1991, and this process is predicted to continue until

there is complete elimination of CFC's use by 1994.³⁸

Phenolics production declined 10% in 1991 from that of a year ago. The United States trails in applications of phenolics to construction and transportation where properties such as low flame and smoke make them useful for safety. Currently European technology is being imported in the form of sheet molding compounds and liquid resins for filament winding, layup, sprayup, and resin transfer molding. Thermosetting polyester or unsaturated polyester experienced a 12% decline in domestic production as a result of the recession and environmental concerns of using nonrecyclable plastics. New applications offering higher heat-distortion temperatures and increased flame resistance have led to an increased use of unsaturated polyesters in the European markets.³⁹

Consumption and Uses.—In 1991, economic recession and environmental concerns continued to place downward pressure on most activities in the U.S. plastics industry, resulting in an overall decrease of approximately 1% in plastics consumption.

Among the large-volume resins listed in table 12, LDPE consumption decreased to 4.7 million tons in 1991, slightly more than 4% below the 1990 level. The biggest declines in LDPE use during the year occurred in the extruded pipe market and extruded film markets for both packaging and nonpackaging purposes. HDPE consumption, which decreased only slightly, stood at 3.9 million tons.

PVC consumption declined 6% in 1991, to 3.5 million tons. The decrease is due, in large part, to weak domestic demand in the building and construction market, a major consumer of PVC pipe, tubing, and siding. In a good year PVC pipe and fittings account for about 60% of the total PVC market. Environmental concerns targeting PVC use in bottles also curbed domestic demand during the year. However, concerns about incineration of PVC appears to be diminishing.⁴⁰ (See table 12.)

Polystyrene consumption in 1991 fell about 6%, a rate that was lower than expected, because of the recession and environmental concerns prompting a decrease in PS packaging and disposables. Principal markets for PS are packaging, disposables, and low-cost consumer goods.

Markets and Prices.—Prices of large-volume resins hit lows not seen in years in the third quarter of 1991 before rebounding in the fourth quarter.⁴¹ At the end of the fourth quarter, however, prices of basic-grade thermoplastics, having bounced back, were still down 17% to 30% from fourth quarter 1990 levels.

The onset of winter and a concurrent rise in crude oil prices spawned increases in ethylene, propylene, and benzene prices during fourth quarter 1991. Those increases, in turn, led to higher prices for the plastic resins derived from those basic petrochemicals. Attempts to raise prices for a second time were later made by some suppliers for select resins. It was expected, however, that a wave of new capacity for basic petrochemical production brought on-line during the year would cause resin prices to fall, but the closings of a number of old-technology plants prevented that effect from being as influential.

U.S. plastic resin sales totaled 27.5 million tons in 1991, or 45% of world sales (table 13). Compared with that of last year, this represents a decrease of 1.1% in domestic sales. Among the major large-volume plastics, HDPE, with 15.2% of sales, ranked first in volume sold during the year, followed by PVC, with 15.1%; and PP, with 13.5%. The fastest growing markets in 1991, in descending order, were the category combining the engineering resins PBT, PCT, and PET; HDPE; and LDPE. (See table 13.)

Foreign Trade.—The U.S. plastics industry became increasingly dependent on foreign markets to help offset losses incurred due to weak resin demand across most domestic markets—making 1991 an extraordinary trade year.

Fewer volumes of the imported resins listed in table 14 were needed to satisfy domestic demand in 1991, compared with those of a year ago. LDPE imports, at 0.38 million tons, exceeded the volume of any other resin imported during the year. HDPE imports, at 0.16 million tons, ranked second in resin volume imported. The least imported resin was PP, with imports amounting to 0.02 million tons. Resin imports posting the biggest volume declines were PS, down 35%; PVC, down 34%; and LDPE, down 19%. (See table 14.)

Exports of the resins listed in table 14 increased significantly in 1991, except PP, which decreased. For many of the resins, the exported volume hit record highs. LDPE, with exports at 0.82 million tons, was the principal resin exported; followed by PP, with exports at 0.71 million tons. The least exported resin was ABS, with exports amounting to 0.09 million tons. Resin exports posting the biggest gains were PVC, up 59%; LDPE, up 55%; and HDPE, up 43%. When net exports are considered, LDPE, followed by HDPE and PS, posted the biggest, and yet spectacular, gains.

World Review.—As slow economic growth or recession prevailed, most countries exhibited declines in plastic resin sales in 1991 compared with levels of a year ago (table 15.)

The United States, with 45%, accounted for the largest share of world plastic resin sales for the year, followed by Japan, with 16%; the U.S.S.R., with 7%; France, with 6%; and Germany, with 5%. Of those countries, only Japan and France posted overall gains in resin sales for 1991 from the year-earlier levels. In each of those countries, nearly all of the plastic resins listed in table 15 contributed to the overall sales increase, but by comparison, growth in PE sales was stronger. (See table 15.)

Outlook

U.S. supply patterns for both commodity plastics and engineering resins

are changing. The economic recession affected distribution patterns in the United States as domestic demand for commodity resins fell by 3% in 1991. However, U.S. commodity resin exports increased 31% for the year, enabling resin suppliers to recover from the decline in the domestic market. Future increases in U.S. resin exports will depend more on global supply patterns, which are themselves changing. In 1992, U.S. shipments of plastic resins are expected to increase to \$27 billion. But as international competition intensifies, U.S. resin exports are expected to decline in the long term. Imports of U.S. resins are expected to rise with increased global production and a stronger dollar.⁴²

Future PE supply will be affected by increased PE recycling and source reduction efforts. A number of companies established PE recycling plants during the year to better their positions in the market. Some suppliers concentrated their efforts on an alternate PE supply source, while others sought to offer high-quality resins containing more post-consumer reclaim. In addition, the application of high-molecular-weight HDPE bimodals (i.e., a combination of short-chain and long-chain molecules) in PE film and blow molding markets has made more downgaging possible. However, source reductions realized by downgaging may eventually be accompanied by new PE demand as high-molecular-weight HDPE processes find potential new markets owing to their benefits, especially higher environmental stress crack resistance. By the mid-1990's, the impact of these efforts on virgin sales is expected to be sizable. According to conservative estimates, reclaim use is expected to reduce demand growth for virgin resin by 1% per year.⁴³

Domestic PP production should grow about 6% per year in the 1990's, says Bob Bauman, vice president of Chem Systems. However, PP production growth may be further affected once planned PP capacity projects come on-line in 1992. An anticipated 1992 sales recovery for PP will be linked to low prices and the benefits of new polymerization technologies. PP

producers have nearly completed a switch to super-high-activity PP catalysts (Unipol process) that produce a resin with high crystallinity (98% plus). The higher stiffness of these resins has created new demand and helped boost PP sales. The switch to the Unipol process has created a shortage of the old atactic PP that is mainly used in roofing. Two companies, Eastman Chemical and Rexene Corp., have converted old technology reactors to make atactic PP. In addition, Rexene is developing new uses for atactic PP such as a coextrusion tie-layer and as an adhesive in auto carpeting. The use of PP-based copolymers, with 25% to 60% synthetic rubber, is growing in the automobile bumper and fascia markets because of gains in their low-temperature impact and low flexural modulus properties.⁴⁴

Domestic PVC consumption is expected to increase in 1992 to approximately 3%, the same rate as projected for the U.S. Gross National Product. Exports of PVC are expected to continue at a level well over 1 billion pounds. An anticipated upturn in the recession-plagued economy is expected to boost the construction industry and, in turn, lift the strongly tied PVC market—where pipe and fittings account for about 60% of total PVC demand. Environmental concerns about PVC use appear to have leveled off in the United States. These concerns stem from the chlorine and the heavy metal content of PVC. A significant decline in the use of PVC in bottles is not expected in the next year. However, legislation in Europe is limiting the use of PVC in packaging.⁴⁵

Environmental concerns are affecting PS consumption. The perception that plastics are a major cause of the solid waste disposal problem is expected to induce additional cutbacks in PS use, especially in packaging and disposables. PS is mainly used in packaging, disposables, and low-cost consumer goods. Market development efforts by PS suppliers to expand PS use are focused on improving impact strength, surface appearance, and environmental stress crack resistance properties in anticipation of changeovers in extrusion

and injection molding applications. Enhancement of these properties will allow PS to be used in more durable goods such as appliance housings and automobile rigids.⁴⁶

Future growth for ABS appears positive for both environmental and product quality reasons. ABS is recyclable, and its miscibility with other resins, including nylons, PVC, and polycarbonate, has contributed to ABS's utility. Higher heat resistance, glossy surface appearance, and custom coloring are properties that are enabling ABS to compete effectively in the automotive and appliance markets.⁴⁷

SAN consumption is expected to increase next year. New high-clarity versions of SAN introduced in 1991 by Monsanto and Dow are expected to compete effectively with the more expensive resins, including polycarbonate and acrylic, for use in durable goods such as housewares.⁴⁸

Demand for PET is expected to continue to increase in the future because of the resin's high degree of perceived environmental benefits and new or expanded applications created by process innovations and materials substitution. PET is competing in the bottle market with PVC as a result of new resin grades that allow PET to be extrusion blow molded. Formerly, PET bottles were injection molded, and PVC bottles were extrusion blow molded. The resin grades of PET will permit material substitution without capital investment in new processing equipment. Also, downgaging and new coating treatments of PET films have created new markets for PET in the packaging industry.⁴⁹

TPO production is expected to undergo global growth as suppliers and fabricators worldwide expand outside their traditional markets, seek new end use applications, and pursue access to TPO technology that meets end-user's universal product requirements. The unsettling effects of the economic recession or sluggish economies on industry activities in the United States, Europe, and parts of Asia have been key influences to bring about those endeavors. Three major suppliers of TPO formed a consortium in 1992 in

which technology will be shared amongst all three companies, Owens-Corning in the United States, BASF in Germany, and Takeda of Japan. A factor promoting this exchange is that automakers in these countries want access to TPO technology and available resin sources.⁵⁰

TPO has traditionally been used in composites such as sheet molding compound used in automobile skin. Technological improvements allowing for unreinforced product applications is the future of TPO growth. Product examples include TPO molds for other plastic products and gel coats for marine use that offer greater blister resistance, flexibility, and UV stability.⁵¹

Growth in phenolic resins production will depend on increasing availability of diverse materials technology. In the United States, phenolic resins use trails in markets like transportation and construction, where resin properties such as low flame and smoke make them important from a safety perspective. Producers strive to offer a range of developments to meet performance requirements and maintain research and development programs, despite the current recession, that will enable them to take advantage of long-range phenolic resin applications. A developing transportation application is automotive parts that are resistant to flexible fuels, in particular, pure methanol or methanol blends, which would allow them to be applied in automotive fuel systems. Rogers Corp. is producing fuel system parts made of methanol-resistant phenolic resins. Resinold Chemical, in another application, is producing down-well parts for the oil industry.⁵²

Growth in PUR production during the 1990's is expected to be much lower than that of the 1980's, according to Gunter Oertel, director of Bayer AG's PUR division and president of the European Isocyanate Association. However, Mr. Oertel does not expect a recovery in PUR domestic sales until the second half of 1992 at the earliest. Environmental problems, in addition to the recession, contributed to the decline in PUR consumption, and thus production. The use of CFC as a blowing agent is perhaps

the most significant problem, but improving recyclability and fire safety are also major concerns. Progress has been made in these areas. The use of CFC as blowing agents in flexible foam is down approximately 50% from previous levels, and complete elimination is expected by 1994. Also, industrywide research and development continues on fire retardant PUR for application in furniture manufacture. ICI has developed a CFC-free, combustion-modified flexible PUR foam, and a phosphorous flame-retardant additive for reduced-CFC rigid-foam formulations is expected to be commercialized in 1992. In the other areas, the recyclability of PUR is affecting its ability to compete in the automotive and other markets. Miles Polymers, Dow, and ICI all introduced pilot recovery systems in 1991 to address this problem. Incineration of PUR waste was investigated in Germany by Bayer AG; its conclusion was that PUR waste could be incinerated without significant emission of pollutants and the energy released could be utilized.

In the United States, the Society of the Plastics Industry, Inc.'s Polyurethanes Recycling and Recovery Council is seeking ways to reclaim materials and energy from a minimum 25% of domestic PUR production by 1995.

Demand for engineering resins has been severely weakened as recession-strapped consumer markets, such as automotive and consumer durables, remain lackluster. In the future, engineering resins are expected to face stiff intermaterial competition. To that extent, producers have stepped up research and development for specialized materials that closely match application requirements, an action that is expected to widen the pool of workhorse engineering resins. Among the newly developed niche-oriented materials are Monsanto's ABS/PET chemical-resistant, impact-modified alloy, Du Pont's polyester analogs of Zytel FN nylon-acrylic rubber alloy with higher temperature retention of mechanical properties, and Hoechst Celanese's high-temperature polyester alloys. Also, Dow Chemical has developed a PC/ABS ignition resistant

alloy and Monsanto is touting a PC/ABS alloy with 10 degree higher heat resistance than competitive resins. Specialty grades of nylon with improved properties are on the horizon as are thermoplastic polyester with improved hydrolytic stability.

SYNTHETIC FIBERS

The current multiple-year recession has curbed fiber use in the apparel, automobile, construction, and industrial sectors. In the beginning of 1991, demand for synthetic fibers suffered a severe decline before gradually recovering later in the year. Overall shipments of synthetic fibers declined more than 1% in 1991, while the value of those shipments decreased more than 2% in both current and constant dollars. And, the longer term trend toward greater use of natural fibers in apparel and household-soft goods continued unabated in 1991, leading to a shrinking share for synthetic fibers in those markets. The competition between natural and synthetic fibers in recent years has caused several large manufacturers to reevaluate their positions in those markets and has precipitated conversions, closures, or outright sales of manufacturing facilities.

Background

Human beings have always sought to improve their surroundings and to maintain satisfactory living conditions. Through the years, fibers have played a very important and extensive role in that quest. Early examples of fiber use include clothing and tents for protection from harsh environments. Others include bows and arrows, which provided a means of acquiring food, and boats with sails, which provided transportation. All of those items were made of naturally occurring fibers because fibrous materials have high strength-to-weight ratios and possess excellent insulating properties.

The earliest fibers used were made from natural plant and animal products. Cotton, flax, sisal, wool, and silk were some of the more important ones. Later

mineral fibers made by spinning melted rocks were used for insulation. Synthetic organic-based fibers can imitate all of those natural (plant and animal) fibers and be further tailored to meet specific applications. Synthetic fibers are typically divided into two major groups, cellulosic, such as acetate and rayon, and noncellulosic, such as polyester and nylon. It was more than 60 years ago when scientists first began their search for methods of creating polymer fibers through chemical processes without using wood or natural substances. The first synthetic fiber, named rayon, followed by acetate, was developed in the early 1920's. During the 1930's, Dr. Wallace Carothers at the Du Pont Chemical Co. developed a polymeric fiber by combining two chemicals (hexamethylene diamine and adipic acid) extracted from coal or oil. It proved to have excellent strength and wear resistance. This unique material was named nylon. Nylon enjoyed extraordinary success, and later became a common household word with the introduction of nylon stockings.

With the 1940's came World War II, and almost the entire production of nylon was incorporated into war-related uses. At that time synthetic fibers, including nylon, rayon, and acetate, provided a mere 10% of America's fiber needs. However, synthetic fibers use grew with the postwar revolution in materials applications. By the mid-1980's, synthetic fibers provided approximately 75% of all the fibers used in America. In terms of major applications, synthetic fibers came to represent 51% of all fibers used in apparel, 60% in home fabrics, and 99% in carpeting. As for industrial uses, synthetic fibers have not fulfilled their potential with respect to their replacement capabilities for metals, minerals, and other traditional materials.

Products for Trade and Industry.—Synthetic fibers are used in all types of diverse applications. The most widely used fiber is polyester, employed both alone and as a blend with natural or other synthetic fibers. Some common applications for polyester include clothing, laundry bags, boat sails,

carpeting, fire hoses, conveyor belts, ropes, and geotextiles for highway construction. Nylon fibers also have a wide range of uses, including carpeting, upholstery, sleeping bags, hosiery, lingerie, and other clothing. Olefin fibers are incorporated in carpeting, drapery, and upholstery. They are used also in clothing, especially sportswear, because of their hydrophobic nature and wicking properties, which allow body moisture to pass to the surface of the fabric and away from the skin. Acrylic fibers are soft and warm and are used more commonly in blankets and sweaters. The cellulosic fibers, rayon and acetate, are used extensively in apparel and home furnishing and less often in industrial applications.

Technology.—In the past several years, exceedingly fine-diameter fibers have become the focus of research efforts by several fiber manufacturers. These "microfibers," usually less than one denier, are finding their way into new and different applications. Most manufacturers of microfibers have concentrated their emphasis on end products that have specific applications and fit special niche situations, such as filtering devices and nonwoven reinforcement materials. Microfiber producers anticipate that production will expand to a myriad of other industrial applications and into high-volume markets such as wearing apparel.

Polyester microfibers have been incorporated into a variety of new fabrics by blending them with wool or cotton. Due to their extraordinary strength, fabrics with unique, lightweight features can be produced. A substantial outlet for these fabrics would be men's and women's suits. In addition, the apparel industry views future development of these silk-like fabrics as a potential stimuli that would lure reluctant consumers back into a purchasing mode.

Economic Factors.—The U.S. textile and apparel industry is one of the most productive and efficient in the world. It provides economic security for a large

segment of the population associated with its various manufacturing and marketing components. But, this industry is finding it increasingly difficult to compete against foreign governments that subsidize their industries, pay workers a small fraction of U.S. wages, and impose severe restrictions on imports from the United States and other countries.

About 130 nations now send their textile and apparel goods to the United States, thereby controlling more than 50% of the domestic clothing market. Imports of these products grew so rapidly during the 1980's that many domestic plants closed down, putting more than 300,000 American workers out of work.

Operating Factors.—Federal law requires that textile products be labeled with three kinds of useful information. A sewn-in label identifying the country in which the product was made, a label or tag that includes those fibers that compose 5% or more of the item, and a permanent label giving care instructions.

Annual Review

Markets and Prices.—Overall domestic production of synthetic fibers in 1991 totaled almost 4.0 million tons, an increase of almost 1% from the 1990 level (table 16). This increase resulted from production gains in noncellulosic fibers, in particular polyester and polyolefins. Noncellulosic fibers production overall grew 1% to 3.8 million tons in 1991, while that of cellulosic fibers declined nearly 4% to 0.22 million tons. Polyester fibers registered the biggest production increase, up 7% in 1991 following a 11% drop 1 year earlier. Polyolefins fibers production, continuing an upward climb, increased 3% for the year. Among the largest volume synthetic fibers produced, polyester accounted for 39% of the total; followed by nylon, with 29%; and polyolefins, with 21%. (See table 16.)

In U.S. trade, the value of synthetic fibers imports grew 4% in 1991. Both cellulosic and noncellulosic fibers contributed to the increase. Cellulosic

fiber imports increased in part due to U.S. capacity constraints and a continuing demand for rayon fibers, while noncellulosic fiber imports rose slightly due to greater domestic polyester demand. Major U.S. suppliers, such as Canada, France, and Italy, posted sizable declines in synthetic fibers imported to the region. In contrast, Japan, the Republic of Korea, Taiwan, Thailand, and Yugoslavia each showed substantial increases in synthetic fibers imported to the United States. In fact, Taiwan surpassed Canada as the top U.S. supplier of noncellulosic fibers for the year.

The value of U.S. synthetic fiber exports climbed 12% in 1991, marking the fourth straight year of growth. Industry also witnessed a synthetic fibers trade surplus in 1991 that increased for the fourth consecutive year as robust export growth continued to overtake import growth, but not enough to help boost production to higher levels. Major export markets for U.S. synthetic fibers included Australia, Belgium-Luxembourg, Indonesia, Mexico, and Turkey. Italy and Spain were also important markets for U.S. synthetic fibers as exports to these regions grew.

Prices of synthetic fibers have been flat or have risen only slightly in recent years. An index for gray synthetic broadwovens, typical for the industry, showed a slight decrease in prices of less than 0.1% from the 1990 level. Over the period 1987-91, increases in price have averaged 2.2% per year.

Total U.S. shipments of olefin, polyester, and rayon staple fibers rose 5% to 1.3 million tons in 1991, compared with 1.2 million tons a year ago (table 17). The overall rise stemmed from increased fiber shipments of polyester staple, up 6%, and olefin staple, up 13%, during the year; shipments of rayon staple dropped 12%. Olefin staple fibers shipped to nonwovens increased 16% in 1991 and represented about 40% of all staples shipped to nonwoven markets. Olefin staple fiber shipments to other markets also increased during the year, by about 7% overall. Polyester staple fibers shipped to nonwovens dropped 1% in 1991, but shipments to other markets,

such as fiberfill and carpet, grew overall by 6%. In addition to olefin, polyester, and rayon fibers, nylon and acrylic fibers are used in nonwovens but only in very selected applications. As a result, these fibers represent a very small portion of total shipments to nonwoven markets by comparison, making them a negligible factor in the overall picture.⁵³ (See table 17.)

World Review.—World production of synthetic fibers dropped to 13.0 million tons in 1991, representing a continuing decline of about 3.7% from the 1990 level for those countries shown in table 18. Leading synthetic fiber producers included the United States, with a production of 4.0 million tons; China, with 1.9 million tons; Taiwan, with 1.5 million tons; and the former U.S.S.R., with 1.2 million tons. Only the Benelux countries and Italy registered production gains in Western Europe. All of the Eastern Europe countries posted substantial losses in production. The bright spot in foreign production was the Pacific Basin. Taiwan's synthetic fiber production rose 12.9%; China's production rose 12.4%, and South Korea's production rose 6.8%. A production index showed a slight increase in synthetic fiber production of slightly less than 1% for Japan. (See table 18.)

Outlook

Encouraging signs during the fourth quarter of 1991 may be the beginnings of a turnaround for the synthetic fibers industry. Overall production of synthetic fibers, led by strong growth in polyester, edged upward by yearend, albeit by only a small percentage. It is expected that synthetic fibers as a group will continue to grow in the near term as a result of strong domestic demand for both polyester and olefin fibers.

SYNTHETIC RUBBER

U.S. production of synthetic rubber in 1991 totaled 2.2 million tons, a decrease of 4% from the 1990 level. This is the

third consecutive year that synthetic rubber production has declined.

More than 50% of all commodity synthetic rubber produced in the United States is consumed by the tire industry. In recent years, however, commodity synthetic rubber has continued to lose market share, both on a volume and a dollar basis. Recessionary pressures, together with technology providing improved tire wear, have diminished industry performance. Total employment in the tire and tire products industry is estimated to have dropped 3.5% in 1991. World production of synthetic rubber in 1991 was approximately 10 million tons, and it appears that this amount is leveling off after several years of increases.

Background

Rubber goods, such as rubber coatings on fabrics, were manufactured in 1823 by Charles MacIntosh in Glasgow, Scotland. In 1838, modern industry was launched, when Charles Goodyear discovered that sulfur could be used to vulcanize rubber and that the cured material had a high degree of elasticity and no residual tackiness. Since that date, there have been many modifications and improvements in the formulation of natural rubber compounds. Also, many synthetic rubber polymers have been developed, and there is now a wide spectrum of natural and synthetic polymers that can be compounded to meet the requirements of different rubber end products.

The development of synthetic rubber was driven by a sharp rise in price due to demand exceeding natural rubber supply in the early 1900's. In 1909, F. Hofman in Germany succeeded in synthesizing isoprene from purely mineral resources and took out the world's first patent for a type of synthetic rubber. In 1929, two new types of synthetic rubber were discovered by the Germans. One was a copolymer of butadiene and styrene similar, but not identical, to the styrene-butadiene rubber (SBR) of today. The other was a copolymer of butadiene and acrylonitrile, more expensive than SBR, but offering a higher degree of oil

resistance. Between 1934 and the outbreak of World War II in 1939, Germany built five large plants capable of producing 175,000 tons of synthetic rubber per year. By 1939, Russia, following Germany's lead for national self-sufficiency, had developed a synthetic rubber industry with a production level of 90,000 tons per year.

In America, efforts were concentrated on the production of oil-resistant rubber. When the war started in 1942, all the main sources of natural rubber became controlled by the Japanese. That stronghold on natural rubber led to the institution of a vast governmental program to develop styrene-butadiene rubber in the United States and Canada. Ultimately, 51 government plants were constructed and operated in North America. Their output by the end of the war reached 700,000 tons per year.

The Korean war and the Suez Canal crisis in 1956 made it clear that orderly deliveries of natural and synthetic rubber from overseas at stable prices could not be relied upon during times of political unrest. These difficulties, combined with the effects of fluctuating currency exchange rates, led to a universal decision to build new synthetic rubber plants. During the late 1950's and early 1960's, plants became operational in Africa, Australia, Europe, Japan, and Latin America. The synthetic rubber industry had finally been established on a worldwide basis.

About 35% of all rubber currently used is natural, obtained from trees chiefly on plantations and small holdings in Malaysia, Indonesia, and other countries of Asia. Smaller areas of cultivation are in West Africa and South and Central America. The remaining 65% is synthetic; i.e., synthesized from petroleum and other minerals at plants mostly in industrialized countries. More than one-half of all rubber produced—natural or synthetic—is used to manufacture tires. The rest of the world's output goes toward the production of an extraordinary variety of industrial and consumer merchandise, ranging in size from huge dock fenders for ships to rubber stoppers, and in

technical sophistication, from domestic tap washers to artificial kidneys.

Examples of synthetic rubbers are styrene-butadiene rubber (SBR), polybutadiene rubber (BR), ethylene-propylene (EPR), nitrile rubber (NR), and other. This "other" category contains a variety of specialty elastomers that include polychloroprene, polyisoprene, silicones, urethanes, and TPE. TPE's are growing faster than the basic elastomers owing to this group's versatility and uniqueness in applications. Within the TPE family exists TPO. There is no industrywide definition of a TPO, nor even common terminology. TPO is also known as olefinic thermoplastic elastomer (OTPE) and elastomer modified polypropylene (EMPP). The most common designation, TPO, is usually applied to any blend of PP and rubber, and physical properties can vary widely.

Technology.—The distinguishing property of rubber is its elasticity. It can be stretched to as much as 10 times its original length without breaking and will return to its original size and shape, virtually unaltered. Rubber is waterproof and airtight, a combination of features found only among certain plastics. It has an astonishingly high abrasive resistance, far higher than steel or any other metal. Rubber is virtually unaffected by the corrosive action of the most common chemicals. Also, it can be bonded firmly to both textiles and steel.

In many of its applications, rubber is not used alone, but reinforced with other materials such as rayon, nylon, polyester, or glass fiber. The effect of the reinforcement is to increase the tensile strength while limiting its freedom to distort. The end result is a composite material that has limited elasticity and provides a combination of strength, toughness, and flexibility—which cannot be equalled in any other way.

Annual Review

Markets and Prices.—The current world market for synthetic rubber is controlled by a few large companies and

is characterized normally by only limited price competition among these large producers. The pricing of synthetic rubber is influenced by the cost of chemical monomers and other energy inputs, such as steam and electricity. In Western Europe and Japan, where oil (or naphtha) is the basic feedstock of the chemical industry and where these industries depend almost totally on imported crude, the cost and price of synthetic rubber monomers fluctuate directly with the cost of oil. However, in the United States, the petrochemical industry depends more on domestically produced natural gas and to a lesser degree on domestically produced oil. As a result, the production cost of synthetic rubber and market pricing tend to be more stable.

Domestic production of synthetic rubber in 1991 totaled 2.2 million tons, down 4% from its 1990 level and down 5% from its 1988 peak level of 2.3 million tons (table 19). Of the large volume products, styrene-butadiene rubber accounted for 38% of total production in 1991, compared with 40% in 1990. Polybutadiene rubber and ethylene-propylene rubber accounted for 19% and 10%, respectively, the same percentage shares held in 1990. (See table 19.)

World Review.—World production of synthetic rubber in 1991 totaled approximately 10 million tons; most of which was produced in a few countries. Japan, the United States, and Western Europe accounted for almost 50% of world production in 1991. France, Germany, and the United Kingdom, all major producers in Western Europe, combined for an output of more than 1.2 million tons in 1991, as shown in table 20. Compared to 1990, each of these countries posted decreases in production for the year. China was the only exception among the large-volume producers to show a production increase, up 6% in 1991 over the 1990 level. (See table 20.)

Current Research.—During recent years, TPE's that have properties similar to vulcanized rubber have been developed and marketed. The vulcanizing or curing process leads to a cross-linked thermoset structure. This structure cannot be softened or melted by reheating to the original molding temperature. Therefore, rejected parts and trim cannot be recycled. In direct contrast, TPE materials can be rapidly softened by heating to the mold temperature. In turn, scrap material and out of specification parts can be efficiently reprocessed. In addition, thermoplastic molding processes, such as injection and blow molding, can provide faster molding cycles than would be attainable with the usual compression or transfer molding of vulcanized rubbers. Also in the extrusion processes, TPE materials allow higher extrusion rates and may require considerably less capital investment in postcuring equipment. As research, design, and process engineers become more familiar with the extensive advantages of TPE's and potential new applications, the relative importance, as well as research expenditures, will probably accelerate.

Outlook

Because of the many advantages of TPE's over vulcanized rubber, it is not surprising that TPE materials have experienced a high rate of growth. Although TPE's currently account for only a relatively small percentage of the total U.S. consumption of elastomers, their rate of expansion is far more rapid than that of conventional cured rubber.

Market penetration is expected to increase for TPE compounds in footwear, adhesives, and wire coating industries. Other growth areas include industrial products such as hoses, bushings, flexible couplings, seals, and solvent coatings.

The International Institute of Synthetic Rubber Producers (IISRP, Houston) estimated a 3.4% decline in synthetic rubber consumption in 1991 for North America due to the economic recession. However, IISRP expects consumption to recover in the short term, increasing, on

average, 2.1% per year through 1996 to 3.1 million tons. Production increases are expected for specialty elastomers, polybutadiene, carboxylated styrene butadiene latex, and ethylene-propylene rubber. The thermoplastic elastomers are expected to exhibit the strongest growth rates, rising 7% per year to 389,000 tons by 1996. From 1992 to 1996, IISRP expects positive growth rates for nearly all elastomers.⁵⁴

¹Revised.

²Total feedstocks are composed of liquefied petroleum gases, petrochemical feedstocks, special naphthas, and dry natural gas as defined in table 13 of the Annual Energy Review 1991.

³Resins are composed of feedstocks for the production of plastics, synthetic fibers, and synthetic rubber.

⁴Others are composed of those feedstocks used in the production of pesticides, coatings, solvents, and other petrochemicals.

⁵Dry natural gas is not included.

⁶Price is based on the British thermal unit value of fossil fuels as close to the point of production as possible as given in table 30 of the Annual Energy Review 1991.

⁷Coal is not included.

TABLE 5
HISTORICAL DEVELOPMENT OF POLYMERS

Date	Event
1862	Alexander Parkes introduced the cellulose nitrate, Parkesine.
1868	J. S. Hyatt discovered a cellulose nitrate and the injection molding machine.
1870	Celluloid patent granted to J. S. Hyatt in the United States.
1877	A. Kekule postulated that natural products are long-chain molecules.
1893	E. Fischer verified that the structure of cellulose is indeed a macromolecule.
1909	L. H. Baekeland discovered phenol formaldehyde resins (Bakelite).
1919	Cellulose acetate available as molding material.
1924	H. Staudinger proposed the linear chain structure for polystyrene.
1927	Introduction of polyvinyl chloride.
1928	O. Rohm commercialized polymethyl methacrylate (PMMA).
1929	Introduction of urea-formaldehyde resins.
1930	First production of polystyrene (PS).
1933	Discovery of polyethylene (LDPE).
1934	Production of polymethyl methacrylate sheet.
1935	W. H. Carothers first synthesized nylon 6/6.
1936	Introduction of polyacrylonitrile, styrene-acrylonitrile copolymers, and polyvinyl acetate.
1937	O. Bayer discovered polyurethanes.
1938	P. Schlack discovered nylon-6 and epoxy resins. R. J. Plunkett discovered the polymerization of tetrafluoroethylene (PTFE). High-pressure polymerization of ethylene was introduced.
1939	Commercial production of LDPE, development of epoxide resins.
1940	Production of PVC, melamine formaldehyde laminates (Formica). G. E. Rochow discovered the direct process for the manufacture of chlorosilanes, the raw material for silicone resins.
1941	Development of fiber-forming polyesters. J. R. Whinfield and J. T. Dickenson discovered polyethylene terephthalate (PET).
1942	Commercial introduction of PAN fibers (Orlon).
1948	Introduction of acrylonitrile-butadiene-styrene, used to manufacture luggage.
1950	Commercial production of PTFE (Teflon).
1952	K. Ziegler developed catalysts for the low-pressure polymerization of ethylene.
1953	G. Natta used Ziegler catalysts to synthesize stereoregular polypropylene (PP). H. Schnell discovered polycarbonate. First PET (Dacron) plant began production.
1955	Development of HDPE and PP.
1956	A. S. Hay discovered polyphenylene oxide (PPO).
1958	Commercial introduction of polyacetal.
1959	Production of acetal (Delrin) and polycarbonate (Makrolon).
1960's	Development of lyotropic LCP films and spun fibers (aramid fibers).
1960's	Introduction of aromatic polyester (Ekonol) for plasma coating.
1963	Introduction of polyimides (Polymer SP).
1964	Production of PPO components for appliances, electrical connectors.
1965	Commercial use of polysulfone (Udel) for electrical components.
1966	Modified PPO introduced as Noryl, cheaper and easier to process than PPO.
1967	Polyarylsulfone introduced as Astrel 360.
1968	Polyphenylene sulfide (PPS) introduced as Ryton.
1972	Polyethersulfone (Vitrex) used in aerospace and automotive applications.
1973	Introduction of Kevlar aramid fibers.
1970's	Introduction of Rynite, a very rigid PET. Blow molding of PET bottles became popular.
1977	Commercial production of linear low-density polyethylene (LLDPE). Polyphenylsulfone (Radel).
1978	ICI first markets PEEK, a high-temperature resistant material used in aerospace and computer applications.
1982	Modified polyimide (polyether-imide) introduced (Utem) for use in high-performance fiberoptic components, coextruded food packaging, and advanced composites.
1984	Thermotropic (melt-processible) liquid crystal polymers (LCP) introduced (Xydar) consumed mainly by Tupperware.

PEAT

By Raymond L. Cantrell

Mr. Cantrell, a physical scientist with 28 years of U.S. Bureau of Mines and industry experience, has served as the Bureau peat commodity specialist since entering public service in 1988. Virginia Harper, statistical assistant, monitored the survey and also prepared domestic data tables. International data tables were prepared by staff, international data.

Peat is a unique natural organic material of botanical origin and commercial significance that is found deposited in abundant quantities at the Earth's surface, where it plays an active role in the dynamics of our planet's ecosystem. Peat deposits function as natural hydrological control sources for vast areas of wetlands, provide an effective natural filtration medium for waterborne contaminants, and also serve as a biomass-related carbon link between the land and air. Today, peat deposits cover about 1 billion acres, or 4.4% of the Earth's total landmass.

The global horticultural and agricultural sectors consume significant quantities of peat for use as a plant growth medium and soil amendment. In addition to its large volume use by the home gardener and professional nursery and landscape businesses, peat also enjoys substantial use in a myriad of industrial applications and consumer products, including potting soils, turf cultivation, golf course greens construction and course maintenance, mushroom cultivation and earthworm culture, poultry litter, fertilizers, composting, seed inoculants, humic acid extracts, toxic waste filtration, oil absorption, hygienic products, and fuel for electrical power generation.

In 1991, the U.S. peat industry continued to be adversely impacted by the recessionary forces of a weakened economy and the pressure of Canadian sphagnum peat, peat mixtures, and other articles of peat. The Bureau's annual survey of domestic peat producers in the 48 contiguous United States reflected a

9% decline in production accompanied by the closure of 6 U.S. peat operations. The value of producer sales, f.o.b. plant, dropped 7%, on a relatively unchanged volume of 0.8 million short tons. A 10% decline in packaged peat prices, f.o.b. plant, was responsible for the overall drop in prices and profitability. The deviation between domestic production and sales reflected an inventory drawdown at the plant level, together with relatively strong movement of field (offsite) inventories.

Alaskan peat production in 1991 was estimated at 75,000 yards by personnel of the State Division of Geological & Geophysical Surveys, Fairbanks, AK. The Alaskan peat carried a value of \$450,000, or \$6 per yard, f.o.b. plant, representing an increase of 15% by volume and 13% in value.

Canadian peat movement across the U.S. border reached new records in terms of volume, value, and market share. Canadian peat was shipped predominately from the Provinces of Quebec and New Brunswick in eastern Canada and from Alberta, Manitoba, and Saskatchewan, in western Canada, and accounted for a record 48% of the total U.S. peat supply. Canadian import volume was a record 631,000 short tons and was valued at \$95.7 million, equating to a price of \$152 per ton at U.S. Customs.

The total U.S. peat supply was valued at \$114 million based on f.o.b. domestic plant and U.S. import Customs values. The monetary significance of peat as a value-added product at the retail level in the United States is many times greater

and may exceed \$1 billion. (See table 1 and figure 1.)

DOMESTIC DATA COVERAGE

The Division of Statistics and Information Services, U.S. Bureau of Mines, conducts an annual survey of domestic peat producers in the 48 contiguous United States. Information obtained from the Bureau's voluntary canvass was used to develop data tables for publication. Of the 105 peat operations surveyed in 1991, 76 were reported to be active, 20 idle, and 9 were reported to have closed permanently. Estimates were made for active operations that did not report data, based on past trends.

Alaskan peat producers were surveyed independently by the Department of Natural Resources, Division of Geological & Geophysical Surveys, Fairbanks, AK. In 1991, operations in the Anchorage and Fairbanks areas reported active production.

BACKGROUND

The U.S. peat industry developed from small "mom and pop" operations that today comprise about 70% of all active peat operations and account for about 20% of total production. They provide essential peat supplies to surrounding communities that contribute significantly to cash-flow and liquidity within local economies. About 80% of U.S. peat is produced in high-volume operations by 30% of the producers. Large operations

move peat in interstate commerce owing to economies of scale.

Peat deposits developed typically through the gradual decomposition of plant matter under anaerobic conditions in shallow aquatic basins. Most of the peat deposits in existence today lie at the Earth's surface and have formed since the last ice age approximately 10,000 years ago, although much older Pleistocene peats, typical of the deposits buried beneath the sands of Trail Ridge in Bradford and Clay Counties, FL, are known. Peat is a precursor of lignite and coal.

Peatlands, or mires as they are sometimes called, are more extensive in the temperate, boreal, and subarctic zones of the Northern Hemisphere and more limited in the cool and humid zones of the Southern Hemisphere. Peat deposits may be called bogs, fens, or "poor fens"—combinations of bog, fen, or swamp formations—depending on the aquatic mechanisms of the particular setting.

Most of the world's peatlands are classified as bogs. Bog is from the Celtic word "bocc," meaning "soft," which is an apt description for these waterlogged terrains. A bog is typically an acidic peatland that depends principally on rainfall to perpetuate the waterlogged conditions necessary for its survival. Because there is less decomposition in these nutrient-poor, acidic environments, the more fibrous peats—sphagnum moss, hypnum moss, and reed-sedge—may be found as the predominant species in the upper zone of the deposit.

The term "fen," as derived from the Anglo-Saxon language, translates to "mud" in modern day English. Fens are peatlands that depend mainly on ground water sources for their formation and survival and, thus, are less dependent on rainfall. Fens, unlike bogs, are found in less acidic nutrient-rich environments. Plant matter tends to decompose more rapidly under these relatively chemically neutral conditions, leading to a less fibrous, more mineralized material that in advanced stages of decomposition is known as muck or peaty muck. The majority of fens are over sites of sand

and gravel deposits that are buried within more clayey glacial materials (intertill), providing a ground water seep over which the peat forms. It, therefore, is not uncommon to find fens situated on hillsides.¹

Definitions, Grades, and Specifications

Methods adopted by the American Society for Testing and Materials (ASTM) find widespread use for the characterization of peat matter.² The ASTM Classification of Peats, Mosses, Humus, and Related Products requires the use of three parameters: ash content, fiber content, and botanical composition. Earthy organic materials must have an ash content of no more than 25% by dry weight to be classified as "peat." Botanical characteristics and fiber content govern peat types. Fibrous peat is defined as material retained on an ASTM No. 100 screen; that is, material 0.15 millimeters or larger.

Sphagnum moss peats must have a fiber content greater than 66%, all of which must be derived from the genus Sphagnum, as determined by screening and botanical analysis. Hypnum moss peats must have a 33% minimum fiber content, of which at least 50% must be derived from the genus Hypnum. Reed-sedge peats must have a 33% minimum fiber content containing more than 50% reed-sedge and other nonmoss fibers.

The U.S. Department of Agriculture Soil Conservation Service subdivides peat into three general categories: (1) fibric (peat moss), which is composed of sphagnum, hypnum, and other mosses; (2) hemic (reed-sedge), which is formed from reeds, sedges, swamp plants, and trees; and (3) sapric (humus), which is composed of materials that are decomposed beyond recognition of botanical origin.³

Fibric peats such as sphagnum and hypnum are relatively young moss species that are light in color in comparison to other peat varieties. Fibric peats, because of the lower order of decomposition, have a relatively high water-retention capacity and, in general, are quite acidic. Fibric peats have a low

bulk density that averages about 250 pounds per cubic yard on an air-dried basis and very little ash. These peats are not suitable for fuel owing to the low degree of decomposition.

Hemic, or reed-sedge peats, are somewhat older and more decomposed than fibric peats and originate from reeds, sedges, and other nonmoss type plants. Hemic peats are considered to be intermediate between fibric and sapric in degree of decomposition, bulk density, and ash content. The average density of air-dried reed-sedge peat is about 950 pounds per cubic yard. Reed-sedge peats are usually slightly acidic and have a high energy value owing to fixed carbon content and low ash.

Sapric, or humic peats, are the oldest and most decomposed peats, with color ranging from dark brown to black. Normally, sapric peats are the first peats formed in the filling of basins and are the most dense and colloidal. Sapric peats, because of their colloidal nature, take on less water, but retain it more strongly than other peats. Many sapric peats are excellent energy sources and are quite acidic. Sapric, or humus peat, has an average bulk density of about 1,300 pounds per cubic yard.

The von Post scale was developed in Sweden as a field method, or squeeze test, for determining the degree of peat humification or breakdown and is utilized by peat enthusiasts worldwide. According to the von Post method, peats are ranked on a scale from H 1 to H 10 relative to their degree of humification. A von Post of H 1, for example, would represent undecomposed peat that ejects colorless, clear water when squeezed, with the remainder containing easily discernible plant matter. At the opposite end of the scale, at H 10, the peat would be completely decomposed, with no plant remains recognized, and, upon squeezing, the whole amount would come out between one's fingers as a homogeneous material. In general, fibric peat mosses are in the von Post range between H 1 and H 3; hemic reed-sedges, H 4 to H 6; and sapric humus peat, H 7 to H 10.⁴

A typical proximate analysis for peat would yield a moisture content of about

50%; carbon, 26%; oxygen, 16%; hydrogen, 3%; nitrogen, 1%; sulfur, 0.1%; and ash, 4%. Fuel-grade peats may vary between 4,000 British thermal units (Btu's) per pound to as high as 10,000 Btu's per pound depending on moisture content and peat type.

Geology-Resources

In the United States, peat is deposited to some extent in all 50 States. About 25 million acres of peatlands has been identified in the lower 48 States, representing an estimated reserve base of 7 billion tons. Alaska contains an enormous peat resource estimated at 125 million acres. Minnesota, Florida, Michigan, Wisconsin, and Maine, in order of importance, account for the major reserves that are available for commercial harvesting in the 48 contiguous United States. At current mining rates, the U.S. permitted reserve base estimate of 16 million tons could theoretically be depleted within the coming 20 years. (See table 2.)

Although Florida, Maine, Minnesota, and many other States have done a credible job in estimating individual State peat reserves, there has not been a comprehensive effort to consolidate individual State reports to establish the extent of U.S. peat resources since the 1922 U.S. Geological Survey (USGS) publication, "The Occurrence and Uses of Peat in the United States."⁵

As a result of the energy crisis in the mid-1970's, the Department of Energy (DOE) initiated a Peat Resource Estimation project in several States to provide information on the extent of our Nation's availability of peat resources for energy utilization, but the results were incomplete and never fully tabulated.

In the mid-1980's, the University of North Dakota and the U.S. Geological Survey (USGS) submitted a joint proposal to the U.S. Department of the Interior designed to survey the peat resources of the United States. The principal objective of the proposal was to systematically bring together and analyze the information obtained from DOE's Peat Resource Estimation program that had

been conducted by the individual States. Other non-DOE-sponsored research in other States was also to be included. To date, a Federal program has not been established to research and publish a comprehensive report of U.S. peat reserves and resources.

Technology

Mining.—Peat is mined or harvested by numerous methods in the United States dependent upon the prevailing conditions and the type of peat involved.

Sphagnum peat is mined through a combination of milling, aeration, and vacuum harvesting. A wide variety of equipment is required, including light and heavy power equipment; ditching machines to provide drainage; stumper, wood rake, and turner-aerator equipment to clear and aerate the surface; milling machines; vacuum harvesters; and wagons or trucks for transporting the harvested peat to the processing plant.

Reed-sedge peat may be harvested with conventional agricultural disking equipment, wide track bulldozers, and front-end loaders. Alternate methods involve milling or bulldozing, followed by windrowing and product pickup with a force feed loader equipped with a side-loading attachment. Smaller operations sometimes mine humus peat with power shovels, small draglines, and front-end loaders.

Fuel-grade peat, following conventional field preparation methods, is compressed into 4-inch-diameter cylinders with sod harvesting equipment. The cylinders break off at lengths ranging from 8 to 12 inches and drop to the surface for air drying. After windrowing to effect complete drying, the cylinders are picked up by a force feed conveyor loader and discharged into trailers for transport to the powerplant.

Processing.—All peat usually requires screening to remove debris and to produce a desirable marketable product. In state-of-the-art sphagnum operations, harvested peat is fed to a radar screen for sifting and the removal of large debris.

The raw product is next discharged to a double-deck vibrating screen to effect sizing and to remove the smaller debris. Product oversize passing over the primary screens is hammermilled and recycled to the screening process. Processing is effected in a closed system equipped with an overhead vacuum takeoff for fine or dusty material. The fines may be recycled or conveyed to a closed waste bin outside the plant.

Product-grade material is discharged to a surge bin from which peat is processed in a four-step automated turntable process, wherein product is gravity metered into plastic containers, compressed into bales on a 2:1 volume ratio, sealed, and conveyed to storage. Four-cubic-foot bales are the most popular size produced, but 2-cubic-foot and 6-cubic-foot bales are also produced in significant quantities.

Reed-sedge and humus peats are screened, packaged in bags, or sold in bulk. The materials may also be blended with perlite, vermiculite, sand, and sphagnum moss and packaged as potting soils or for a variety of other uses. Peat-sand mixtures are popular bulk materials that are sold to golf courses for greens construction and for top dressing greens, tees, and fairway turf.

Economic Factors

The data of table 3 show the long-term peat price trend for the period 1970-91. Actual prices, without adjustment for inflation, increased at an average annual rate of 5% per year over the 21-year period. Prices expressed in terms of constant 1991 dollars, however, declined at an average annual rate of 2% per year over the same period. The U.S. peat industry has overcome inflationary pressures principally through the rationalization of capacity, together with a move to higher volume modern and efficient plants, the proliferation of value-added consumer products, and through the importation of more peat and finished peat products from Canada. (See table 3.)

ANNUAL REVIEW

Legislation and Government Programs

The U.S. Fish and Wildlife Service continued to act as custodian for the preservation of a 93,000-acre peatlands on the environmentally sensitive Pamlico Peninsula in northeastern North Carolina. About 35 million dry tons of high-energy, fuel-grade peat was deposited to an average depth of 6 feet over 70,000 acres of the property, formerly owned by First Colony Farms.

Fish and Wildlife planned to combine these lands with its adjacent 10,000-acre Pungo National Wildlife Refuge to form Pocosin Lakes National Wildlife Refuge. The development was to include fire control, maintenance of drainage canals, provision of grain for feeding, and enforcement of wild game hunting. Deer, black bear, and wood duck were native to the area.⁶

The Pamlico Peninsula is the site of North Carolina's largest peat reserves. The peninsula is estimated to include 360 square miles of peatlands containing about 210 million tons of peat on a moisture-free basis. Only two small peat operations are currently active on the peninsula.

Large-scale commercial composting programs, fueled by environmental regulation, continued to proliferate in both the public and private sectors during 1991 and competed with peat in selected applications. Compost could lead to further growth in mulching and soil amendment activity dependent upon economic factors and consumer acceptance. In any event, several peat-compost product blends were marketed by major U.S. peat producers in 1991, representing a new trend that will most probably continue to increase in proportion to the availability of quality compost materials.

Issues

Peat deposits along the U.S. Eastern Seaboard, extending from Maine to Florida, are heavily regulated by Federal,

State, and local environmental agencies owing to population density and sensitive wetlands areas; this is also true in California along the U.S. West Coast, and to an extent in several Midwestern and Northeastern States. Conversely, the northern tier Great Lakes States are situated, for the most part, in more environmentally friendly surroundings. This is particularly true in Minnesota, where the prudent development of the State's tremendous peat reserve base—representing about 30% of total reserves in the 48 contiguous United States—is encouraged to generate employment and contribute to economic growth.

Between 1987 and 1990, U.S. domestic peat sales declined 17%, total domestic consumption declined 11%, and 10 U.S. peat operations were closed. During the same period, imports of Canadian peat increased 16%, and the U.S. import reliance rose 9% points, from 35% of total demand in 1987 to a record 44% in 1990.

About one-half of the decline in domestic peat production and demand was in the leading States of Florida and Michigan, but equally disturbing was the fact that one-third of the loss was attributable to 5 States in mid-America (Illinois, Indiana, Iowa, Ohio, and Pennsylvania); New Jersey dropped 9%, and California, Washington, and Georgia, 4% each. Production in California has ceased altogether.

About 30 U.S. peat operations were idled or pressured out of the business between 1987 and 1991. Many producers and consumers felt that a more equitable balance between environmental regulation and peat mining was needed, given the importance of peat to the U.S. economy and its value to the U.S. consumer. Industry sources were becoming increasingly cognizant of the role that Minnesota's tremendous sphagnum peat reserves will play in advancing future competitiveness and growth in the U.S. peat business.

Production

U.S. peat production declined 9% in 1991, according to the U.S. Bureau of Mines annual survey of domestic peat producers in the 48 contiguous United States. The harvest season in the Great Lakes States was restricted because of bad weather. A total of six peat bogs reportedly closed in the States of Georgia, Maryland, Michigan, New Jersey, North Dakota, and Pennsylvania during 1991. Fisons Horticulture, Inc. transferred the jurisdiction of its peat bogs in Minnesota and Iowa to State regulatory agencies. Plans by EcoPeat Co.—a U.S. affiliate of the Finnish firm Outokumpu Oy—to develop 360 megawatts of peat-fueled electrical powerplants in cooperation with south-central Florida utility companies were postponed.

Peat was harvested and processed by 76 operations in 19 contiguous States. The States of Georgia, Maryland, and North Dakota did not report production in 1991. The majority of U.S. peat production, about 80%, was conducted in high-volume operations that accounted for about 30% of the total number of active facilities. Twenty-two peat operations in Florida and Michigan produced about 60% of the U.S. total.

Geographically, about 50% of the total U.S. peat output was from seven contiguous States in the Midwest and north-central Great Lakes region, together with three Western States. Four States in the southeast accounted for about 40% of the total, and five States in the northeast provided 10%. (See tables 4 and 5.)

On a weight basis, reed-sedge peat was 63% of total U.S. production; humus, 21%; sphagnum moss, 6%; hypnum moss, 5%; and other forms, 5%. On a volume basis, reed-sedge was 64% of the total; humus, 16%; sphagnum, 12%; hypnum, 5%; and other forms, 3%.

In Alaska, A&A Services, The Dirt Co., and Landscape Supply Corp. produced peat in the Anchorage area, while Great Northwest, Inc., was active near Fairbanks. Alaskan peat demand increased dramatically during the early-1980's coincident with the economic

boom precipitated by the development of the Alaskan Oil Pipeline. Production peaked at 125,000 cubic yards in 1984 and carried a value of \$859,375 or \$6.88 per yard. The potential for future development of Alaska's tremendous peat resources will be dependent upon Alaska's economic growth, peat's emergence as an effective filtration medium for the control of toxic waste effluents in mining, and logistical factors.

Hyponex Corp. and Michigan Peat Co. are major producers and distributors of peat products in the United States. In 1991, Hyponex harvested and processed reed-sedge peat from facilities in 6 States extending from New Jersey to Colorado. Hyponex markets peat and peat blends throughout much of the United States. Hyponex operates from parent headquarters, the O. M. Scott & Sons Co., in Marysville, Ohio. The O. M. Scott Co. is a recognized leader in the lawn and garden fertilizer market, and the recent acquisition of Hyponex has added a new dimension to the Scotts family of products—a full line of quality organic landscape/garden products and indoor plant care items.

Michigan Peat Co. is a major supplier of retail soil amendments and professional grower horticultural products in the north-central States, providing a wide range of peat-based products to an area containing more than 40% of the Nation's population. Peat is harvested and processed in five locations, including sphagnum moss production at Cromwell, MN, two facilities in the "Thumb" area of Michigan, near Sanilac, together with one operation each in north-central Colorado and Central Florida.

Today, all operations are headquartered in Houston, TX, from which a \$15 million annual business is coordinated. Michigan Peat has the capacity to harvest 150,000 tons of reed-sedge peat and sphagnum peat moss annually, or about 20% of current U.S. production.

Production and sales volume, f.o.b. plant, declined in Minnesota during the year owing to inclement weather. Nine producers were active during the year, of which there were three major sphagnum

producers in Carlton County and St. Louis County and one major bulk producer of reed-sedge in Aitkin County, all near Duluth, MN. Minnesota's premium peat was valued at \$53 per ton or 130% above the U.S. average.

Aitkin Agri-Peat began harvesting and selling reed-sedge at its bog in Aitkin County in 1984. The operation was improved and expanded through the lease and later purchase of specialized equipment from the Natural Resources Research Institute (NRRI), at Duluth. Aitkin also designed and constructed unique harvest machinery that provides an efficient and economical method of harvesting bulk peat. Production capacity is about 20,000 cubic yards annually, from 100 acres of the 300-acre deposit. Aitkin Agri-Peat markets bulk reed-sedge to general contractors and golf courses within a 250-mile radius of the harvest site near McGregor, MN.

Peatrex Ltd. began sphagnum production in 1985 near the town of Cromwell, MN, in Carlton County. The operation is of Finnish design with good drainage. The fields are profiled for fast turnaround after heavy rains. In 1989, Peatrex was purchased by Premier Enterprises of Canada, and since, has constructed a state-of-the-art sphagnum processing facility on the property. Harvested sphagnum from the 250-acre operation is processed into 2-, 4-, and 3/4-cubic-foot bales or sold in bulk.

Minnesota Sphagnum, Inc. (MSI) commenced sphagnum harvesting in 1987. The past 4 years have been devoted to improvements in processing facilities and field expansion. Expansion of this operation will continue for the next 3 to 5 years. MSI currently harvests peat from 250 acres and markets sphagnum peat in bale and bulk in the Midwestern and Southwestern States. The MSI organizational structure is through Hyde Park Products and Conrad Fafard, Inc.

New horticultural peat projects were reported to be under consideration in the States of Georgia, Maine, New Mexico, North Carolina, and North Dakota.

Down East Peat LP was operating a 22.8-megawatt, peat-fired electric

powerplant near Cherryfield, ME. At full capacity, the powerplant will require about 165,000 tons of bone-dry peat annually. Fuel-grade peat was extracted from the adjacent Denbo Heath Bog by a private contractor.

Humates were mined from the San Juan Basin deposits of New Mexico and sold for use as a soil conditioner. In 1985, the last year of available data, humate production was about 23,000 cubic yards, with an f.o.b. mine value of \$404,000. Mining and processing were conducted by three companies in McKinley, Sandoval, and San Juan Counties.

Consumption and Uses

During 1991, the U.S. peat business continued to reflect the general downturn in the U.S. economy that has subsisted since 1989. During this 3-year period of recession, U.S. apparent domestic consumption and sales have not changed significantly. Apparent domestic consumption has held level in the 1.3- to 1.4-million-ton range, and domestic sales volume has held constant at 0.8 million tons.

Domestic bulk and packaged forms, on a weight basis, continued to command equal shares of the market. About 90% of U.S. producer sales was for general soil improvement and horticultural use. In horticulture, peat was used predominately for general soil improvement, as an ingredient in potting soils, and in the nursery business.

In agriculture, peat was used for general soil improvement, in mixed fertilizers, as a carrier and coating agent in seed inoculants, for vegetable cultivation, and as poultry litter. Specialty applications included peat's use in golf course greens construction and course maintenance, as an earthworm culture medium, and for mushroom cultivation. Minor amounts of peat were used as fuel for electric power generation.

The U.S. Department of Agriculture (USDA) reported that the U.S. mushroom industry had just capped a decade of growth, but faces a number of challenges

arising from increasing environmental sensitivity, some uniquely related to the nature of mushroom production. The United States is the world's largest commercial mushroom producer, with 21% of the world's 3.3 billion pounds in 1990. Cash receipts ranked fifth among all vegetables in 1990, with sales totaling \$671 million in 1990-91, nearly doubling over a decade.

One major challenge facing U.S. mushroom growers, according to USDA, arises when compost is substituted for peat as a growing medium. The storage and disposal of used compost can reportedly lead to environmental problems, not just for growers but for their nonfarm neighbors as well.⁷ (See tables 6, 7, and 8.)

Stocks

In 1991, primary producer peat stocks declined 16% to 0.3 million tons, according to the Bureau's annual survey of domestic peat producers. Stocks of peat in all forms were about 50% of production, typical of the industry. Reed-sedge peat accounted for about 63% of total stocks. (See table 9.)

Transportation

Peat was moved predominately by truck in both bulk and packaged form. Small producers were restricted to local market areas because of the sensitivity of peat prices to transportation charges. High-volume producer costs were less sensitive to transportation charges, allowing for interstate movement of peat and peat products.

Markets and Prices

The average price for domestic peat, f.o.b. plant, declined 5% to about \$23 per ton. Packaged and baled peat sold for about \$27.50 per ton, a 10% decline, while bulk peat prices were down about 4% to \$18.50 per ton. Packaged and baled peat were sold at a 48% premium relative to bulk peat. Sphagnum moss sold at a premium \$62 per ton or 170%

above the national average. (See table 10.)

Foreign Trade

In 1991, Canada continued to provide more than 99% of total U.S. peat imports—principally sphagnum moss—and new records were again established for both volume and value. Canadian imports reached a record 631,000 tons, 48% of the total U.S. peat supply, and carried a U.S. Customs value of \$95.7 million, equating to \$152 per ton. The value of Canadian shipments at the U.S. border exceeded total U.S. domestic peat sales, f.o.b. plant, by \$76.5 million or 400%.

The United States accounted for roughly 90% of total Canadian export shipments in 1991. About 70% of the total was shipped from Central and Atlantic Canada, with the remaining 30% from western Canada. Officials of Energy, Mines and Resources Canada in Ottawa, Ontario, said that Canada's improved performance in the United States was attributable in part to a greater visibility brought about by an intensive promotional campaign.⁸ Canada typically exports about 80% of its total peat output. (See table 11.)

Another \$2 to \$3 million in Canadian peat merchandise was recorded by U.S. Customs under the "Articles of Peat" category. Peat pots and other specialty peat-based products, including some peat mixtures, were reportedly included under this category. Although Canadian peat shipments in all forms entered the United States duty free, a tariff of 4.7% was imposed by Canada on U.S. peat. The United States, to date, has not exported peat to any destination, according to U.S. Bureau of the Census data.

Energy, Mines and Resources Canada reported that about 77% of all Canadian shipments in 1991—domestic and export—originated from Quebec and New Brunswick in eastern Canada. Alberta, in western Canada, supplied about 10% of the total. The remaining 13% was reported to originate principally from Manitoba and Saskatchewan in western Canada, with minor contributions from

the eastern Provinces of Newfoundland, Nova Scotia, and Prince Edward Island. (See table 12.)

World Review

Global peat production was estimated to have declined about 6% in 1991, based on news of a continuing downturn in U.S.S.R. agricultural productivity in the midst of significant political and economic restructuring. Production in all other countries was believed to be comparable to 1990 levels. The total value of world peat production, assuming an average f.o.b. plant value of \$20 per ton, was about \$4 billion.

Although peat was known to be deposited in the tropics of Africa, Argentina, Brazil, China, Indonesia, Malaysia, New Zealand, Paraguay, and Uruguay, production data were not available. (See table 13.)

Industry Structure.—The U.S.S.R. accounted for about 90% of global peat production in 1991, followed by Ireland, 4%; Finland, 3%; Germany (Western states) and Sweden, 1%; the United States and Canada, 1%; and all other countries, 1%.

In the U.S.S.R., production was confined to the Baltic Republics, the Moscow-Gor'kiy area, and Belorussia, although peat was known to be deposited throughout much of the country. Peat was burned in thermal powerplants in European U.S.S.R. and was also used to fire industrial boilers and large heating plants.

The use of peat in the U.S.S.R. was reportedly declining because of insufficient reserves in the primary consuming areas and restricted demand in the energy and agricultural sectors owing to a radical shift in sociopolitical and socioeconomic philosophy. The chemical industry produced methanol and synthetic natural gas from peat.⁹

Ireland and Finland, in order of importance, accounted for about 68% of the estimated 19 million tons of peat produced outside the U.S.S.R. in 1991. In Ireland, greater emphasis was being placed on fuel peat technology transfer,

environmental technology, and the marketing of horticultural peat, while in Finland, plans for additional peat-fueled powerplants were under consideration. (See table 14.)

In 1990, Ireland's Bord na Móna produced about 7.5 million tons of peat, well above targeted levels, and record operating profits were achieved. These positive results were a reflection of the success of a major reorganization effected in 1988.¹⁰

Bord na Móna, established by the Turf Development Act of 1946 to develop Ireland's peat resources, sells milled peat to the Electricity Supply Board for use in domestic peat-burning power stations, briquettes and machine turf on the domestic fuel market, moss peat and other growing media in the garden and horticultural industries on a worldwide basis, and manufactures pollution abatement products.

The reorganization in 1988 established four core business divisions. The largest of the new divisions is the Peat Energy Div., which is responsible for milled peat operations, with sales accounting for one-half the group's turnover. Milled peat productivity has been doubled and unit costs dramatically reduced. The division's principal objective was to continue to improve the comparative economics of milled peat relative to oil, gas, and coal.

The Solid Fuels Div.—"briquettes and machine turf"—accounts for about 25% of total sales. The outlook for solid fuels, however, has been clouded by a swing in demand to natural gas by industrial users of solid fuels as an inevitable consequence of the extension of the national gas grid and a significant rise in privately produced turf in the Midlands region, a traditionally strong market area for briquettes. Production of private turf—promoted by the Turf Development Act of 1981—rose to 1.5 million tons in 1990, representing a fourfold increase over that of the past decade. The division anticipates a rationalization of capacity to accommodate the private sector.

The Horticultural Products Div. is a major exporter with more than 90% of

production being sold abroad, mainly to markets in the European Community (EC). A minority holding in a Netherlands cooperative was established in 1990 to enhance the division's presence in what is regarded as Europe's leading market in horticultural products. Effective January 1990, the division established its own distribution subsidiary, Du Móna France S.A., with offices in Lyon. This strategy, together with the previous acquisition of the French horticultural peat subsidiary Pouget Solami, should further enhance the division's competitive advantage in the French peat market.

The United Kingdom is the largest market for the division's exports, and much effort was spent in restructuring marketing strategy to deal with declining disposable income in the United Kingdom and an increasing awareness of environmental considerations on the part of consumers. Bord na Móna reiterated its opposition to the unacceptable practice of exploiting boglands of special scientific interest and continued to transfer environmentally sensitive boglands to the Wildlife Service. Ultimately, 8,400 acres of boglands will be protected in accordance with Government policy.

Peat accounts for about 4% of Finland's present energy supply, but plans were formulated to increase future peat production dramatically as a fuel for electric power generation. Finland's product distribution consists of about 80% milled peat and 20% sod peat. Plans were also formulated to increase the production of peat for horticultural purposes and for industrial and environmental applications. Finland's current production capability is about 6 million annual tons.¹¹

Sweden currently produces about 1 million cubic meters of horticultural peat and about 2 million cubic meters of fuel-grade peat annually. Swedish peatlands cover an area of about 15.6 million acres, or about 15% of the total land area. About 865,000 acres of peatland is available for fuel peat production. The overall area suitable for horticultural peat production has not yet been surveyed.

Sweden has about 50 producers of horticultural peat, mainly in the south and middle regions. Roughly 400,000 cubic meters is produced as milled peat and 600,000 cubic meters as sod peat, of which 30% to 35% is exported. More than one-half of the domestic consumption is used by amateurs for home and garden applications.

After reaching a maximum production and sales of about 2.5 million cubic meters in 1950, fuel peat declined dramatically because of its economic disadvantages to cheaply priced fuel oil. By 1970, fuel peat production in Sweden was nonexistent. There was a subsequent revival in fuel peat demand beginning in the early 1980's, however, as an aftershock of the global energy crises of the 1970's.¹²

Capacity.—The data of table 13 are rated capacity for peat operations as of December 31, 1991. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable long-term operating rate, based on the physical equipment of the plant and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure.

Current Research

The United States National Committee of the International Peat Society (IPS) hosted the International Peat Symposium in Duluth, MN, August 19-22, 1991, under the title, "Peat and Peatlands: The Resource and Its Utilization." The symposium was organized in cooperation with the Iron Range Resources and Rehabilitation Board (IRRRB) and the Natural Resources Research Institute (NRRI), University of Minnesota, Duluth.¹³

An international contingent of peat scientists and industry representatives heard technical papers on a variety of

subjects in two areas: Commission I—Survey, Classification, Ecology and Conservation of Peatlands, and Commission II—Winning, Harvesting, Storage, Transportation and Processing of Peat and Sapropel for Industrial, Agricultural and Horticultural Purposes. Commission papers were presented by representatives from Canada, China, Finland, Ireland, Sweden, and the United States.

Researchers from NRRI gave presentations under the titles: Oil Sorptive Properties of Several Minnesota Peats;¹⁴ The Physical Characterization of Selected Peat-Based Composts;¹⁵ Peat as an Amendment in Poultry Manure Composting;¹⁶ and, Minnesota Peat Producers, Their Deposits and Products, and a Proposed Standard for Minnesota Peat Products.¹⁷ NRRI scientists reported that the oil absorption and compost products should be commercially feasible in the near future.

STS Consultants, Ltd., Minneapolis, MN, presented a paper entitled, "A Peat/Wetland Treatment Approach to Acidic Mine Drainage Abatement."¹⁸ The firm reported that peat wetlands demonstration plots constructed and operated during the past 2 years had effectively removed 80% to 95% of copper and nickel emanating from acid mine drainage streams. STS is currently constructing the first commercial peat wetlands system in Minnesota. The system will be designed to treat a flow of approximately 10,000 gallons per day, constructed for subsurface flow utilizing 1 foot of limestone as a substrate, covered by about 3 feet of fibrous screenings and peat mixture.

Peat research continued at a heady pace during 1991, and many projects were reaching commercial fruition. Commercial ventures were established to produce and market peat-based oil absorbent products in significant quantities in the United States. Consumers of the peat-based products liked the superior absorbency and environmentally friendly aspects of disposal relative to clay-based products. Peat was also shown to be an effective filtration source for the removal of toxic

wastes from secondary sewage effluents, urban stormwater management control, for the elimination of offensive odors, and as a superior carrier for value-added commodities.

D M S & D Associates, Inc. of Eatontown, NJ, developed and test marketed Sorbital AP, a unique hydrophobic sphagnum peat moss product having superior hydrocarbon absorption properties. The firm reported that 1 pound of the product would effectively absorb 1 gallon of oil typically weighing about 8.2 pounds. D M S & D personnel said that the new product represented an advanced concept in spill cleanup.

The new peat product was reported to be cost efficient and safe to use compared with traditional products. Savings per gallon for the cleanup and disposal of a 1-gallon spill were favorable to traditional clay products, corn-based materials, and paper absorbents, in respective order of magnitude.

In addition to its unique hydrocarbon absorbent properties, the product has disposal advantages. It is biodegradable, fuel blendable, EPA qualified as an alternative fuel with a low ash content, and is vapor suppressive. Thus, the product is environmentally friendly, helping to minimize waste going into diminishing landfills. Its native population of microorganisms assist in bioremediation, and it can be recycled as an alternative fuel. When used on water, it locks in the hydrocarbons, protecting wildlife and reducing environmental impact.

Michigan Peat Co. of Houston, TX, developed a unique compacted peat, Bacctite, that served as a natural potting soil additive, providing improved aeration and drainage. Michigan peat representatives said that Bacctite particle size could be tailored to individual needs, while maintaining its integrity and resistance to breakdown during watering cycles.

Prodex Inc. of Ravenna, OH, continued research into humic acid extracts. The firm developed Biogene products that were sold as agricultural and horticultural plant stimulants, animal feed additives for improved nutrition and

health, and as an accelerator in anaerobic biological sludge digestion in municipal and industrial wastewater treatment. Prodex was developing processes for improved peat fuel and horticultural applications, together with the separation of organic and metal contaminants from industrial wastewater streams.¹⁹

In 1991, several domestic and foreign parties expressed interest in sphagnum moss bioaccumulation processes developed by the U.S. Bureau of Mines Salt Lake City, UT, Research Center that were effective in extracting toxic metal ions from a variety of wastewaters.²⁰ Bureau researchers developed porous polymeric beads, designated BIO-FIX beads, that were prepared by blending sphagnum peat moss or algae into a polymer solution and spraying the mixture into water.

Batch and continuous tests demonstrated that BIO-FIX beads removed arsenic, cadmium, lead, and other toxic metals from acid mine drainage waters collected from several sites. Selectivity for heavy and toxic metal ions over calcium and magnesium was demonstrated. The sorption process was reversible, and metal ions were eluted from the beads using dilute mineral acids. Cyclic tests indicated that the beads continued to extract metal ions after repeated loading-elution cycles.²¹

After 15 years of research, Johnson & Johnson (J&J) launched a new line of ultrathin feminine hygiene napkins in Canada having an absorbent core of processed peat moss. J&J officials said the processed moss could absorb 20 times its weight in liquid. The firm claimed that its peat moss pad provided the same absorbency at one-fifth the thickness of ordinary hygienic pads and was slightly thinner and superior to "ultra thin" pads that relied on superabsorbent polymers.²²

The product, named Sure & Natural Prima, was developed by the company's Montreal-based Canadian unit. Energy, Mines and Resources Canada reported that the equivalent of 500,000 bales of Quebec sphagnum peat moss was consumed in the manufacture of Sure & Natural Prima during 1991.

In Canada, fuel peat projects were under consideration in Alberta, Newfoundland, Nova Scotia, Ontario, and Saskatchewan. Energy, Mines and Resources Canada cited peat as being increasingly perceived as a low-sulfur fuel alternative to coal for power generation.²³

SaskPower and a Meadow Lake company in Saskatchewan planned to build a \$22 million peat-burning powerplant at Jans Bay, north of Meadow Lake. It would reportedly generate 15 megawatts, enough to heat a community of 3,000 homes.

Peat Resources was planning a \$4.5 million pilot plant to produce fuel-grade peat at a prime peatland 35 miles northwest of Thunder Bay, Ontario, Canada. Data collected from the pilot plant operation would be used for the potential design of a \$95 million commercial plant capable of producing 1 million tons per year of peat fuel. The fuel would reportedly be used as an environmentally attractive alternative energy replacement for coal in electrical power generation plants.

The pilot plant would test a process for producing high-grade industrial peat fuel with a heating value comparable to bituminous coal. In a recent test burn completed by Ontario Hydro, the experimental peat fuel produced less than 5% ash, and a mixture of coal and peat fuel reduced sulfur emissions in direct proportion to the quantity of peat blended. Peat Resources, which had been developing the peat fuel process since 1984, applied for a Canadian patent.²⁴

Peat also showed promise as a biodegradable medium in disposable diapers and in food packaging.

OUTLOOK

The history and outlook for peat supply-demand in the United States is shown in table 15. During the past 21 years, U.S. domestic peat production has grown at an average annual rate of about 2.0% per year and apparent domestic consumption by about 3.5%.

The most recent upturn in the U.S. peat supply-demand cycle was experienced between 1981 and 1987. Domestic peat production hit the bottom of the latest cycle in 1981 at 0.7 million tons and gradually increased to a record 1.0 million tons by 1987, representing average annual growth of about 7%. Total apparent domestic consumption during the same period followed the domestic production trend and grew at an average annual rate of 7%, from 1.1 million tons in 1981 to a record 1.5 million tons in 1987.

Between 1987 and 1991, domestic peat production and total apparent domestic consumption have declined 7% and 2%, respectively, owing to a downturn in the U.S. economy. Canadian imports as a percent of the total U.S. supply, however, increased from 35% in 1987 to a record 48% in 1991.

A review of the projections by various members of the U.S. horticultural and community substantiates the existence of a widely held opinion that horticulture will continue as a strong growth industry. The Horticulture Research Institute, National Landscape Association, Society of American Florists, and the National Gardening Association all forecast significant future growth.²⁵

In December 1991, USDA officials were optimistic about future growth in the floriculture and environmental horticultural industry. USDA officials said that the greenhouse and nursery industry business remained on the verge of another wave of expansion. Mr. Doyle C. Johnson, an agricultural economist with USDA, in speaking before the Annual Agricultural Outlook Conference in Washington, DC, stated: "If economic activity accelerates in 1992 and 1993, the outlook will be for double-digit growth for most categories of greenhouse and nursery crops. If the economy continues on its current track, overall sales growth is still expected to range 6% to 8% percent above that of this year. This holds true for producer sales as well as wholesale and retail sales."

The U.S. Bureau of Mines forecast for horticultural peat during the next 5 years

is based on a recovery in the economy and a resultant rebound in domestic production and total apparent domestic consumption. Domestic production of horticultural peat is forecast to grow at an average annual rate of about 5% to levels approaching 0.9 million tons by 1996.

Total apparent domestic consumption for horticultural purposes is forecast to grow at an average annual rate of about 3% per year to about 1.6 million tons by 1996. Canadian imports are forecast to rise by another 110,000 tons by 1996 and to compose 46% of the total U.S. horticultural peat supply. Per capita consumption is forecast to approximate 12.5 pounds by 1996 and might approach the 12.7-pound average experienced during the peak years of 1986 and 1987.

The Bureau's forecast for domestic peat production and demand could be optimistic in the event that Canadian competition becomes more intense, environmental regulations inhibit growth, composting captures an increasing market share, or a continued downturn in the economy persists. On the upside, new uses for peat as a filtration medium for the cleanup of waste streams, oil absorption, composting natural organics, and for hygienic and other purposes could potentially drive U.S. peat demand to levels higher than forecast, regardless of the supply source, domestic or Canadian.

The outlook for growth in domestic fuel peat demand for electric power generation has been deferred beyond the forecast period because of the loss of four 80-megawatt power contracts in Florida to the competitive economics of natural gas. Natural gas is currently in oversupply, and gas prices have declined significantly since last year. Additionally, the capital costs associated with the construction of natural gas powerplants are favorable to peat-based plants.

Florida Power and Light and Florida Power Corp. had previously signed letters of intent with EcoPeat—a U.S. subsidiary of the Finnish firm, Outokumpu—to purchase peat-fueled electrical power from proposed plants adjacent to vast peat reserves to the northwest and southeast of Lake Okeechobee in south Florida. The

plants were to be brought into production sequentially beginning in mid-1995 and, at full capacity, would have required about 2.5 million tons of peat annually, representing a threefold increase in current U.S. peat production.²⁶ (See table 15.)

The global outlook for peat supply-demand is shown in table 16. Last year's outlook for balanced supply-demand conditions, long-range, has been clouded by the continuing downturn in U.S.S.R. production. If the projected downturn only impacts the U.S.S.R.'s internal supply-demand situation, then the world outside the U.S.S.R. should still anticipate reasonably balanced conditions during the next 5 years. If the U.S.S.R. becomes pressured to move surplus product to the international marketplace, however, a global imbalance in peat supply-demand may be precipitated for an indefinite period. (See table 16.)

The U.S. Bureau of Mines basic forecast methodology has been modified to include the assumption that production in the U.S.S.R. will gradually return to 1990 levels by 1996. Otherwise, the former methodology that based global demand on the historic trend in per capita consumption has not changed.

The long-term trend based on the current forecast shows that, between 1991 and 1996, global peat demand is projected to grow at an average 1% per year, about one-half of the projected 2% growth in population. This forecast is consistent with historic trends.

FIGURE 1
PRODUCTION AND IMPORTS OF PEAT IN THE UNITED STATES

PERLITE

By Wallace P. Bolen

Mr. Bolen, a physical scientist, is a graduate of the University of Virginia and has been the commodity specialist for perlite since September 1989. Domestic survey data were prepared by Robin L. Richardson, statistical assistant, and the international production table was prepared by Audrey Wilkes, international coordinator.

U.S. production of processed perlite decreased 11% in quantity and 14% in value, according to the U.S. Bureau of Mines. Expanded perlite sales decreased 6% in quantity but increased 11% in value compared with that of 1990. Construction uses of expanded perlite accounted for 65% of total domestic sales in 1991. (See table 1.)

DOMESTIC DATA COVERAGE

Domestic production data for perlite are developed by the U.S. Bureau of Mines, from two voluntary annual surveys, one for domestic mine operations and the other for expanding plants. All of the mining operations to which a request was sent responded, and all were active. These 10 respondents accounted for 100% of the total processed ore sold and used in table 1. Of the 64 expanding plants canvassed, 62 were active; of these, 48 plants or 77% responded, representing 70% of the total expanded perlite sold or used.

PRODUCTION

Perlite mined for processing came from 9 companies with 10 operations in 6 Western States. New Mexico operations accounted for a large majority of the total tonnage mined. The remaining tonnage came from Arizona, California, Colorado, Idaho, and Nevada. Domestic apparent consumption is defined as production plus imports minus exports. Domestic apparent consumption of processed perlite in 1991 was 595,000 short tons, a decrease of 11% from that of 1990.

Ore producers were Harborlite Corp. and Nord Perlite Co. in Arizona; American Perlite Co. in California; Persolite Products Inc. in Colorado; National Perlite Co. in Idaho; Delamar Perlite Co. in Nevada; and Grefco Inc., Celite Corp. (formerly Manville Products Corp.), and USG Corp. in New Mexico.

The quantity of expanded perlite sold and used from 62 plants in 33 States decreased 6% in quantity compared with that of 1990. However, the value of expanded perlite increased 11% in 1991. The higher value of expanded perlite was mainly attributed to increased usage of higher unit-valued perlite for filler and horticultural applications even though there was decreased consumption of lower unit-valued perlite for construction uses.

Construction-related uses, the major market for expanded material, decreased slightly to 329,100 tons. Expanded perlite used as filter aid, fillers, and in agricultural markets totaled 161,800 tons, a small increase compared with that of 1990. Leading States, in descending order of sales, were Mississippi, Pennsylvania, California, Illinois, Georgia, Virginia, Texas, Kentucky, Florida, Indiana, and Minnesota.

Perlite exports, primarily to Canada, were estimated to be 32,000 tons. Imports of perlite ore, mainly from Greece, decreased slightly to an estimated 60,000 tons compared with those of 1990. (See tables 2, 3, and 4.)

OUTLOOK

Consumption of perlite is directly related to building activity as perlite is used in various building products.

Increased demand is expected as the economy recovers but large, sustained growth in perlite consumption is unlikely. Expanded perlite sold or used in the United States should range between 400,000 and 600,000 tons per year through the middle of this decade.

PHOSPHATE ROCK

By William F. Stowasser

Mr. Stowasser, a physical scientist with 21 years experience, has been the commodity specialist for phosphate rock since 1974. Domestic survey data were prepared by Christopher Lindsay, statistical assistant; and the international data table was prepared by Audrey D. Wilkes, international data assistant.

The historic events of recent years that include the restructuring of the U.S.S.R., the Persian Gulf War, and the significant changes in Eastern Europe will change the demand for phosphate fertilizers. The immediate effect of these events caused a decline in fertilizer consumption, in production, and in trade. In Eastern Europe and the former U.S.S.R., political changes will encourage markets rather than state planning organizations and will determine production and trade patterns in this region. The fertilizer plants and infrastructure in Iraq and Kuwait were damaged by the Gulf War. These events were some of the reasons the world demand and production of phosphate rock declined during the past few years.

World grain stocks increased dramatically in the mid-1980's. The oversupply was caused by a slowdown in the world economy in the early 1980's that lowered the demand for grain. The purchasing power of importing countries was constrained by their debt levels and a strong dollar. In addition, the reputation of the United States as a reliable supplier was damaged by the U.S. embargo on exports to the U.S.S.R. High U.S. price supports stimulated grain production and fertilizer consumption and depressed demand. Finally, weather conditions were favorable for growing from the late 1970's through the mid-1980's.

World grain stocks have dropped markedly since 1986. U.S. Department of Agriculture data show world grain stocks declining from 462 million metric tons in 1986 to 304 million tons in 1991. World grain stocks dropped because of

U.S. supply management policies and unfavorable weather in recent years; U.S. supply management programs idled 60 to 80 million acres per year and caused reduction in grain production and stocks.

World grain consumption has increased steadily over time, reaching an alltime record of 1.74 billion tons in 1991. Grain production reached a record level of 1.77 billion tons in 1991. World fertilizer consumption increased rapidly in the 1960's and 1970's. The increase was from 50 million tons of total nutrients in 1965 to 145 million tons in 1988. World fertilizer consumption has declined since 1988 because of the loss of markets in the U.S.S.R. and Eastern Europe that were not balanced by demand increases from India, China, and North America. World phosphate rock production has declined as the demand for phosphate fertilizers was reduced.

A highlight of the 1990-91 crop year was the increase in diammonium phosphate exports that reached 9.5 million tons, an increase of 5.6% over that of 1990. Exports to India declined in 1991 after the phosphoric acid pricing dispute with Morocco in 1990 was settled. U.S. exports of diammonium phosphate to China increased 30% in crop year 1990-91 to more than compensate for the shortfall to India. The demand for phosphate rock benefited from the record production of 12.9 million tons of diammonium phosphate in the 1990-91 crop year. (See table 1.)

DOMESTIC DATA COVERAGE

Domestic production data for phosphate rock were developed by the U.S. Bureau of Mines from two separate, voluntary surveys of U.S. operations. Of the 16 operations to which a survey request was sent, all responded, representing 100% of the U.S. production data shown in table 1.

BACKGROUND

Phosphate rock deposits occur as marine phosphorites, apatite-rich igneous rock, and modern and ancient guano. All U.S. production was from marine phosphorites. It is the practice of the U.S. industry to express production and reserves in terms of beneficiated product. The grade of the product may be reported as percentage of phosphorus pentoxide (P_2O_5) or as tricalcium phosphate or expressed as percentage bone phosphate of lime (BPL). Conversion factors are: $P_2O_5 = \%BPL \times 0.4576$; $\%BPL = P_2O_5 \times 2.1853$; and $P = P_2O_5 \times 0.436$. The phosphate ore bed or the zone of phosphorus-bearing material is commonly called the matrix in Florida and North Carolina.

Marketable phosphate rock was produced by 16 companies in the United States. Nine companies in Florida and one in North Carolina produced 87% of the phosphate rock. The balance of 13% was produced in Idaho, Montana, Tennessee, and Utah. Approximately 95% of the phosphate rock was used to produce agricultural fertilizers and animal feed supplements. The balance was used in a variety of industrial chemicals.

Sedimentary apatite has a range of chemical compositions. The general formula for marine carbonate-apatite is $\text{Ca}_{10}(\text{PO}_4\text{CO}_3)_6\text{Fe}_{2-3}$. Apatite is host to many cation, anion, and anionic radical substitutions for PO_4 . Accessory elements may be associated minerals or those that are chemical substitutions in the phosphate mineral.

The part of phosphate resources that can be profitably recovered is called reserves. Reserves may increase as new deposits are discovered and as technology is improved. Estimates of phosphate rock reserves are made for a specific date and are subject to changing economic or environmental conditions. Operating companies and companies holding phosphate lands estimate the recoverable tonnages based on current and future economics. Mining plans evolve from this planning. Estimates indicate that about 1 billion tons will be recoverable from the North Carolina deposit and another 1 billion tons will be recoverable from Florida deposits.

The deposits of phosphate rock in Tennessee in the Bigby-Cannon formation are small in size and irregular in shape. They were stripped and mined with 1.5- or 2.3-cubic-meter (2- or 3-cubic-yard) draglines. The ore was trucked or railed to washing and classification plants before agglomerating into electric furnace feed to produce elemental phosphorus. Unfavorable economics caused the suspension of mining phosphate rock in Tennessee in 1991.

The phosphate rock bed of the Pungo River Formation in North Carolina is a primary marine phosphate 6 to 12 meters (20 to 40 feet) thick, overlain with 27 to 40 meters (90 to 130 feet) of sand, clay, and marl overburden. The underlying aquifer was depressurized by pumping water to the surface to ensure a dry pit. Currently, bucket-wheel excavators have replaced dredges to strip the top 12 meters (40 feet) of overburden. Large-capacity draglines with buckets as large as 55 cubic meters (72 cubic yards) were used to strip the remaining overburden and mine the matrix. The matrix was slurried with high-pressure waterjets, pumped to the beneficiation plant,

washed, and classified to produce a minus 16-mesh, plus 200-mesh flotation feed. Flotation concentrate was either calcined or dried.

Most of the phosphate mines in central Florida recover phosphate rock from the Bone Valley Formation. In north Florida, the formation is of equivalent age. Overburden averages about 6 meters (20 feet). The overburden consists of a lay sand and a leach-zone material that overlays the matrix. The materials were selectively strip-mined with large electric draglines. The matrix was slurried in a sump and pumped to the washing plant. Cleaned, screened material from the washer that was plus 14 or 16 mesh was separated and may be a salable pebble product. The minus 16-mesh fraction was deslimed, and the 16-by 150-mesh fraction was floated to produce a concentrate.

Improvement in recovery percentages from phosphate rock deposits in the United States with the introduction of the flotation process occurred in 1927 and 1928. Values in the 14 mesh by 150 mesh became recoverable, adding to the coarser plus 14-mesh pebble fraction. Conversion of phosphate rock to single superphosphate with sulfuric acid was followed by manufacturing high analysis triple superphosphate with phosphoric acid and finally producing the ammonium phosphates by reacting phosphoric acid with anhydrous ammonia. The ammonium phosphates have become the preferred fertilizer for domestic consumption and international trade. At the farm level, advances in the use of mineral-base fertilizers have been made by following recommended application rates, timing and methods of application, using efficient spreaders, and having sufficient material and technical resources. The effect of correct use of mineral fertilizers can double crop yields and minimize the waste of fertilizer.

ANNUAL REVIEW

Legislation and Government Programs

The conversion of phosphate rock to phosphoric acid by acidulation with

sulfuric acid generates about 5 tons of phosphogypsum for each ton of 100% phosphoric acid. Phosphogypsum disposal and control has become a serious problem for the phosphate industry. About 30 million tons of phosphogypsum is produced and stored in stacks in the United States each year. The phosphogypsum, in addition to its large volume, retains some of the radioactive uranium from the host phosphate rock as well as phosphoric acid and other toxic elements. There is concern over leakage of effluent from the stacks into ground water and emissions of radionuclides into the atmosphere. It is understandable that Federal, State, and local governments will have an interest in how phosphogypsum stacks are constructed, operated, and closed. Regulations have been proposed to line new phosphogypsum stacks to prevent ground water contamination and cap completed stacks with a polyethylene sheet and earth cover. The Environmental Protection Agency (EPA) ruled on May 20, 1991, that byproduct phosphogypsum produced from the manufacture of phosphoric acid will be regulated under the more flexible Toxic Substances Control Act (TOSCA). EPA has studied how to regulate phosphogypsum and the associated process wastewater during the past 10 years. Consideration was given to regulating under subtitle C or D of the Resource Conservation and Recovery Act (RCRA). It was concluded that if the hazardous waste C subtitle regulation was implemented, the cost would be sufficiently high to put the industry out of business. If regulated under subtitle D that covered solid wastes, while less onerous than subtitle C, the costs would also jeopardize the financial health of the industry. EPA determined that although the law requires regulation under RCRA and the waste was considered hazardous, it would regulate the industry under TOSCA. TOSCA will allow EPA to regulate on a site-specific and process specific basis. Developing the standard is a process that will take 2 to 3 years.

State and local jurisdictions in Florida studied regulations to control the disposal of phosphogypsum and process

wastewater. Final rules may be less than 1 year away. A consensus appears to have developed from phosphoric acid producers on how to prevent ground water contamination and emissions from stacks. Polyethylene liners and caps probably will be required by Florida regulations.

Strategic Considerations

The 1991 attempted coup in the U.S.S.R. and the dissolution of the Union increased the threat of a Soviet famine over the 1991-92 winters. The Administration extended credit to the U.S.S.R. to ensure some assistance. Technical assistance was advocated; however, large grain shipments from the United States were not expected because U.S. grain stocks were relatively low, the European Community had excess supplies and the political incentive to use them, and the U.S. economy did not encourage massive aid to the dissolving U.S.S.R. Agricultural credits and food aid to the U.S.S.R. did not substantially improve the outlook for fertilizer demand in the United States.

World production of phosphate rock has declined or remained stable since 1989. Production declined again in 1991. World demand for phosphate rock was forecast by the WEFA Group to increase from 155 million tons in 1991 to 178 million tons in the year 2004. The percent changes in demand over this period was forecast to vary from a high of 1.3% to a low of 0.7% per year. Demand for food will drive the demand for phosphate fertilizers and the demand for phosphate rock. The world will become increasingly dependent on the large discovered deposits of phosphate rock and undiscovered deposits in Morocco as other countries deplete their known reserves. The dependency can be modified if technology is developed that will permit recovery of the mineral from leaner deposits and if the cost of recovery will permit recovery of the investment in new mines.

Issues

Mining phosphate rock is an earth-moving exercise. Washing and floating the gangue constituents from the mineral consumes large volumes of water. Processing phosphate rock into phosphoric acid creates phosphogypsum and process wastewater to store and recycle. Runoff from excessive or inefficient application of fertilizer can contaminate ground water and receiving waters. The concern over negative environmental impacts frequently overshadows the understanding of the importance of mineral fertilizers. Without providing and replenishing soil nutrients, production of food to satisfy a world population that will exceed 6 billion by the year 2000 will not be possible. The inevitable increase in world population puts extreme pressure on higher food production by increasing acreage and increasing productivity with fertilizers.

The primary U.S. sources of phosphate rock available for conversion into phosphate fertilizer for domestic consumption and foreign markets are the phosphate mines in central Florida and eastern North Carolina. A number of mines will close in Florida in the 1990's as the deposits are mined out. A tightening of supply does not appear probable as a summation of mining plans of operating companies in the Eastern United States shows that the current level of supply can be maintained through the year 2000. If the supply forecast is correct, pressure to increase phosphate rock prices will not develop, and it will be difficult to justify investment in new mines.

Production

Production of marketable phosphate rock in the United States increased 3.8% in 1991 to 48.1 million tons. This was in close agreement with the 47.7 million tons planned by U.S. producers. Following the closure of Monsanto Co. phosphate rock mines in Tennessee in 1986, Stauffer Chemical Co. and Occidental Chemical Corp. closed their

Tennessee mines and elemental phosphorus furnaces in March of 1991. The economies of producing thermal phosphoric acid were not competitive with purified wet-process phosphoric acid as power costs rose in Tennessee.

Florida and North Carolina.—Phosphate rock was produced in central Florida by Agrico Chemical Co., a division of Freeport-McMoRan Resource Partners L.P.; CF Industries Inc.; and Estech Inc., which closed the Silver City Mine in February 1991 and ended phosphate mining. Phosphate rock also was produced by Gargill Fertilizer, Inc.; IMC Fertilizer Inc. (IMCF); Mobil Mining and Minerals Corp.; U.S. Agri-Chemicals Corp., owned by Sinochem (USA) Inc.; Seminole Fertilizer Corp., owned by Tosco Corp.; and Nu-Gulf Industries Inc., owned by Wingate Creek Acquisition Corp. In northern Florida, Occidental Chemical Agricultural Products Inc. produced phosphate rock for production of phosphoric acid, superphosphoric acid, and diammonium phosphate. In north-central Florida, low-fluorine soft phosphate rock was recovered from hard phosphate rock tailing ponds.

Texasgulf Chemical Co., a division of Texasgulf Inc., a subsidiary of Elf Aquitaine Inc., produced phosphate rock from the Aurora Mine in eastern North Carolina. Dredges were used prior to 1988 to remove the top layer of overburden covering the phosphate ore. The dredges were replaced by bucket-wheel excavating systems in January 1989 to remove the top 12 meters of overburden. Draglines were used to remove the remaining overburden and mine the 10 to 12 meters of matrix.

Western States.—Phosphate rock was mined in Idaho by J. R. Simplot Co., Monsanto, and Rhône-Poulenc Basic Chemicals Co. Simplot produced phosphate rock from the Gay Mine on the Fort Hall Indian Reservation. Mainbed ore was used by Simplot to manufacture phosphoric acid, and the lower grade shale was used in FMC Corp. electric

furnaces in Pocatello, ID. Simplot also produced phosphate rock from the Smoky Canyon Mine in the Caribou National Forest. The concentrate was pumped from the mine to Simplot's fertilizer plant west of Pocatello, ID. Monsanto supplied its electric furnaces in Soda Springs, ID, with phosphate rock from its Enoch Valley Mine in the Caribou National Forest. Rhône-Poulenc produced phosphate rock from the Wooley Valley Mine, Caribou National Forest, ID, and shipped to its electric furnace plant in Silver Bow, MT. Nu-West Industries Inc., a member of the Conda Partnership with Western Coop Fertilizer Co., produced phosphate rock from the Mountain Fuel Mine, Caribou National Forest, ID. The phosphate rock was shipped by rail to Conda, ID, beneficiated, calcined, and used to produce phosphoric acid. Cominco American operated the only underground phosphate rock mine in the United States near Garrison, MT. Chevron Resources Co. produced and concentrated phosphate rock near Vernal, UT. The concentrate was slurried and pumped to Rock Springs, WY. In November, Chevron agreed to sell its phosphate rock mine, the slurry pipelines, and its fertilizer plant at Rock Springs to FS Industries. FS Industries was formed by Simplot and Farmland Industries.

Consumption and Uses

The demand pattern for phosphate rock was similar to that of 1990. In 1991, approximately 94% of the U.S. primary demand was used to manufacture fertilizer, and 6% was used for other applications. Both domestic and foreign markets were supplied by the industry. Of the total demand, 31% was consumed domestically as fertilizer, and 63% was converted to fertilizer and exported. About 5% of the total demand was consumed as phosphorus chemicals domestically, and 1% of the chemicals was exported. The increase in the export of phosphate fertilizers plateaued to new highs in 1990 and 1991. Correspondingly, the export tonnage of phosphate rock declined to 6.2 million

tons in 1990 and 5.5 million tons in 1991. The decline in phosphate rock exports was expected as the availability of high-grade and high-quality phosphate rock in the United States for export was limited and the demand for ammonium phosphates from abroad was strong.

More than 94% of the phosphate rock used domestically was used to manufacture wet-process phosphoric acid, to produce single superphosphate, and triple superphosphate; and the balance was used to produce elemental phosphorus. Production of elemental phosphorus was expected to continue to gradually decline. Rhône-Poulenc started a 72,600-ton-per-year purified wet-process phosphoric acid plant at Geismar, LA, in 1991. The purified acid will be used for food-, pharmaceutical-, and technical-grade phosphates. Rhône-Poulenc's electric furnace plant at Mount Pleasant, TN, was closed. Occidental Chemical also closed its elemental phosphorus plant in Columbia, TN. Olin Corp.'s industrial and detergent phosphate business was acquired by Albright & Wilson Co. Olin closed its purified wet-process phosphoric acid plant in Joliet, IL.

The restructured elemental phosphate industry consists of FMC's electric furnace plant at Pocatello, ID, Monsanto's thermal plant at Soda Springs, ID, and Rhône-Poulenc's two-furnace plant at Silver Bow, MT.

In addition to the electric arc furnaces in the United States, phosphorus furnaces were operated in Canada, France, the Federal Republic of Germany, Italy, Mexico, and the Netherlands. There were 36 electric arc furnaces for smelting phosphate rock in Kazakhstan and an unknown number in Togliatti, U.S.S.R. China, Japan, and India had electric arc furnaces, and there was one furnace in the Republic of South Africa. (See tables 2, 3, and 4.)

Stocks

Phosphate rock stocks were maintained in wet rock piles in Florida and North Carolina and, after drying or calcining, were stored in silos. In the Western

States, phosphate rock was stockpiled during the nonfreezing months of the year near electric furnaces or wet-process phosphoric acid plants to avoid railroad car or truck unloading problems in the wintertime. Phosphate rock inventory levels are of interest to analysts who follow inventory levels to indicate the strength of the demand for phosphate rock. In the United States, ending stocks in 1990 were 8.9 million tons. In 1991, phosphate rock ending stocks were 10.2 million tons, a 15% increase. Stock levels in the United States varied from 8.9 million tons to 10.2 million tons throughout the year. (See tables 5, 6, 7, 8, 9, and 10.)

Transportation

From production centers in central and north Florida, phosphate rock was moved by rail to terminals on Hillsborough Bay, FL, and Jacksonville, FL. In central Florida, CSX Transportation railroad moved phosphate rock to terminals on Hillsborough Bay. The Rockport terminal was owned and operated by the CSX railroad; Port Sutton was owned and operated by IMCF. Eastern Associated Terminal (E.A.T.) was owned and operated by E.A.T., and Big Bend terminals were owned and operated by Agrico Mining Co.

In North Carolina, barges were used to transport phosphate rock from the Aurora Mine to the port at Morehead City for export. Railroad facilities were also available at the Aurora Mine to move phosphate rock to the port or domestic markets. Both railroads and trucks were used in the Western States to move phosphate rock from mines to plants. Two pipelines were used to move slurried phosphate rock from mines to plants. One pipeline was used to pump slurried concentrate from Vernal, UT, to Rock Springs, WY, and another was used to pump phosphate rock from the Smoky Canyon Mine in the Caribou National Forest to Pocatello, ID.

Markets and Prices

The price or value of phosphate rock, f.o.b. mine, was obtained from a semiannual survey of producing companies. The data from the survey were used to develop the weighted average price or value for each grade of phosphate rock sold or used in the domestic market or exported. In the 1950's, the actual selling price of phosphate rock varied from \$5.67 per ton in 1950 to \$6.12 in 1959. In the 1960's, the price varied from \$6.57 in 1960 to \$6.14 in 1969. In 1970, the price was \$5.80 per ton and, in 1974, the average price increased to \$12.04 per ton. The price increased to \$25.00 per ton in 1975 and decreased to \$21.15 in 1976. The abrupt increase in price was initiated by an arbitrary price increase by Morocco's Office Cherifien des Phosphate for exported phosphate rock. Although the actual price declined to \$17.39 per ton in 1977, cost increases caused the price to plateau at more than \$20.00 per ton in 1979; the price peaked again in 1980 to \$22.78 per ton, responding to a strong demand. The price gradually declined to \$19.37 per ton in 1987 and increased to \$23.06 per ton in 1991. Historical average selling prices from 1970 through 1992 are shown in table 12.

Estimates of phosphate rock export prices, unground, f.o.b. vessel, Tampa Range or Jacksonville, FL, by grade were made. Estimates of Moroccan phosphate rock export prices, U.S. dollars per ton, f.a.s. Laayoune, Casablanca, or Jorf Lasfar were made. The price or value of Florida and North Carolina, Tennessee and the Western States, and the U.S. phosphate rock are listed, respectively, by grade for domestic and export markets and average selling prices. (See tables 11, 12, 13, 14, 15, 16, 17, and 18.)

Foreign Trade

Exports of phosphate rock from Florida and North Carolina declined from 14 million tons in 1979 to 5.2 million tons in 1991. Imports of phosphate rock into the United States will probably increase as more phosphoric acid plants on deep water exercise the import option.

Although phosphate rock exports continued to decline, exports of diammonium phosphate reached 9.7 million tons in 1991. The U.S. Department of Commerce reported that diammonium phosphate exports increased from 4.1 million tons in 1986 to 9.7 million tons in 1991. Exports to China increased sharply from 0.5 million tons of diammonium phosphate in 1990 to 5.0 million tons in 1991. Exports to India declined markedly from those of 1990 when it increased diammonium phosphate imports from the United States rather than resolve a price dispute with Morocco.

Exports of diammonium phosphate to destinations other than China and India accounted for 32.7% of U.S. exports. The U.S. industry produced 14.4 million tons of diammonium phosphate and exported two-thirds of this production. (See tables 19, 20, 21, 22, 23, 24, 25, and 26.)

World Review

World phosphate rock production was less in 1991 compared with the peak year 1988. Production from major producing countries has either remained constant or has declined.

It was estimated that world fertilizer consumption declined by 4% in 1991. This was principally caused by reduced consumption in Eastern Europe, the former German Democratic Republic, and the U.S.S.R. The stagnating or declining consumption of phosphate fertilizers in Central and East Europe, in Australia, and a flat demand from developing countries were the principle reasons for a decline in phosphate rock production and trade in 1991.

China increased imports of diammonium phosphate by about 53% in 1991, reaching 2.05 million tons P_2O_5 . India imported a record total of 0.851 million tons P_2O_5 in 1991. Brazil increased phosphoric acid imports in 1991 and increased phosphate rock production. In Western Europe, phosphate rock imports again declined as did imports of processed phosphates. Imports declined to 11 million tons in 1991.

Eastern Europe reduced imports of phosphate rock from Western producers by 38% in 1991 following a 51% decrease in 1990. Imports of phosphate rock from the Kola Peninsula into Central Europe declined 29% in 1990, and it is probable, because of the political changes, imports will again decline.

In the Republic of Russia, production of phosphate rock from Kola is forecast to stabilize at 18 million tons per year. The supply of phosphate rock from the Soviet Republic is decreasing; however, it has no plans to import phosphate rock. Imports of superphosphoric acid were reduced from 700,000 tons P_2O_5 in 1988 to about 500,000 tons in P_2O_5 in 1991.

Moroccan phosphate rock production declined to its 1989 level in 1991. Phosphoric acid exports increased as shipments to India resumed. Diammonium phosphate and triple superphosphate exports from Morocco were unchanged from those of 1990. Western Europe was the principal market for these Moroccan commodities. Tunisian phosphate rock production decreased 6%, and exports decreased 31%. Phosphate rock production and exports from Jordan decreased in 1991 because of the Persian Gulf War.

The world trade talks held under the auspices of the General Agreement on Tariffs and Trade (GATT) reached an impasse when European Commodity negotiators refused to reduce agricultural subsidies. Large agricultural-producing countries, including Argentina, Australia, Brazil, and Chile, have supported U.S. proposals to reduce agricultural subsidies. Other countries, including Austria, Israel, Japan, Mexico, the Republic of Korea, and Switzerland, would benefit from a reduction in subsidies. Scandinavian countries supported the European Community's position. The impasse will not improve the market for increased agricultural exports from the United States.

The U.S. Bureau of Mines estimates of world phosphate rock reserves and the reserve base are shown in tables 28 and 29. Included are reserves and reserve base estimates with costs of less than \$40

and \$100 per ton, respectively. (See tables 27, 28, 29, and 30.)

OUTLOOK

The supply of phosphate rock that is planned to be produced in the United States during the 1990's is listed in table 31. (See table 31.)

The U.S. supply of phosphate rock will be restrained by competition for world markets of manufactured fertilizers and chemicals, by the difficulty of obtaining permits to mine environmentally sensitive deposits, by escalating capital investment and operating costs, and by the inability to develop new beneficiation techniques to efficiently recover the mineral from associated gangue.

The WEFA Group's February 1992 report, "World Demand for Fertilizer Nutrients for Agriculture," emphasized the inevitable population growth that will put pressure on food production. To meet the food needs of the 1990's and beyond, increased fertilizer use will be necessary.

Annual growth rates of world demand for phosphate rock was forecasted by WEFA to vary from 0.7% per year in 1992 to a high of 1.3% per year in the year 2000. The forecast increases in phosphate rock world demand were substantially less than the growth rates in the 1980's.

*Estimated. Revised.

¹Table includes data available through May 19, 1992. Data for major phosphate rock-producing countries derived in part from the International Fertilizer Industry Association; other figures are from official country sources where available.

²In addition to the countries listed, Belgium and Uganda may have produced small quantities of phosphate rock and Namibia may have produced small quantities of guano, but output is not officially reported, and available information is inadequate for formulation of reliable estimates of output levels.

³Reported figure.

⁴Less than 1/2 unit.

⁵Beneficiated.

⁶Includes only output used to manufacture fertilizers.

⁷Production from Western Sahara area included with Morocco.

⁸Does not include aluminum phosphate production, gross weight, in thousand tons: 1987-191; 1988-119; 1989-140 (estimated, revised); 1990-127 (estimated, revised); and 1991-130 (estimated).

PLATINUM-GROUP METALS

By J. Roger Loebenstein

Mr. Loebenstein, a physical scientist with 17 years of industry and U.S. Bureau of Mines experience, has been the commodity specialist for platinum-group metals for 11 years. Domestic survey data were prepared by Evangeline Hemphill, mineral data assistant; and international data tables were prepared by Harold Willis, international data coordinator.

The platinum-group metals (PGM) are composed of six closely related metals: platinum, palladium, rhodium, ruthenium, iridium, and osmium. They commonly occur together in nature and are among the scarcest of the metallic elements. In terms of commercial importance, platinum and palladium are the two most important metals of the group. All of the metals are valued for their corrosion resistance and catalytic activity.

Johnson-Matthey PLC, United Kingdom, reported that Soviet sales of platinum reached an alltime high of 34 metric tons in 1991. In the previous year, Soviet platinum sales were 22 metric tons, and in 1989, they were only 17 metric tons.

Demand for PGM in the United States declined as automotive vehicle production fell to its lowest level in 10 years. This decline was offset by an increase in demand for new cars carrying catalysts in Western Europe in anticipation of European Community legislation that requires all new models introduced after July 1, 1992, to have emissions controls.

DOMESTIC DATA COVERAGE

Domestic production data for PGM are developed by the U.S. Bureau of Mines from a voluntary survey of U.S. refiners. Of the 18 refiners to which a survey request was sent, 8 responded. These represent 44% of the total refined metal production shown in tables 5 and 6. Production for nonrespondents was estimated using prior-year levels adjusted for general industry trends.

BACKGROUND

Products for Trade and Industry

The basic forms of PGM are sponge or powder, which may be converted to other forms such as bars, pastes, or chemicals. The industry employs an extensive number of homogenous and heterogeneous catalysts containing PGM. A typical PGM catalyst may consist of a platinum-rhodium gauze woven from wire. The electronics industry purchases PGM pastes, and the dental industry uses wire and a variety of alloys.

Geology-Resources

PGM deposits are associated with magmatic intrusions of mafic and ultramafic rocks. They also occur to a lesser extent as placer deposits. Layered deposits associated with stratiform complexes are the only ones mined principally for the PGM, with nickel, copper, and cobalt sometimes produced as byproducts. These are found in the Bushveld Complex, Republic of South Africa, and the Stillwater Complex, United States.

In other PGM deposits, such as those found in the Sudbury Complex, Canada, and Noril'sk, U.S.S.R., the PGM are produced as byproducts of nickel and copper mining.¹

In the Republic of South Africa, it is interesting to note that base metals such as nickel and copper are important in generating revenues from the Merensky and Platreef ores. This is not the case at

the Stillwater Mine in the United States, where platinum and palladium contribute almost 100% of revenues.

Technology

Processing.—The processing of PGM ore entails four general steps: mining, concentrating, smelting, and refining. In the concentrating step, platinum ore is crushed and treated by froth flotation. The concentrates are dried, sometimes roasted, and then fused in a smelter furnace, producing a sulfide matte containing the PGM. The matte is treated in a refinery using solvent-extraction techniques to separate and purify the six PGM.

Recycling.—In North America, PGM are recovered by a small number of scrap refiners, as shown in table 1. Other companies collect scrap materials such as catalysts and PGM-bearing solutions and process them to increase the grade. These upgraded secondary materials are then sold to refiners. For example, Multi-Metco Inc., Anniston, AL, produces about a 90% concentrate of PGM from scrapped autocatalysts, which in turn is refined by another company. World Resources Co., McLean, VA, collects electroplating solutions, upgrades them, and sells the concentrate to another refiner. Most companies specialize in refining or upgrading a particular type of scrap, such as petroleum catalysts, autocatalysts, or electronic scrap.

Refiners often charge a fee or toll to "toll refine" scrap, ownership of the

PGM content of the scrap remaining with the customer. For example, a refiner and/or fabricator would replace worn out catalyst with fresh catalyst and charge the customer for the refining and fabrication costs. In other cases, refiners purchase scrap, process it, and sell the refined metal. When scrap changes ownership in this way, it is referred to as nontoll scrap.

For statistical purposes, nontoll refined scrap is considered as old scrap and is added to supply, along with newly mined metal.

Because of their high value, PGM are routinely recovered from petroleum catalysts, chemical catalysts, automobile catalysts, glass fiber bushings, electronic scrap, laboratory equipment, dental materials, and jewelry.

Major collectors and refiners of autocatalysts are shown in table 2. In the United States, only Multi-Metco refined any substantial quantities of autocatalyst PGM. Multi-Metco's output required further processing by other companies to produce commercial-grade metal. The other major refiners of scrapped automobile catalysts are in Belgium, Canada, and Japan.

Japanese companies that recycled precious metals from spent catalysts were: Asaka Riken Kogyo, Ishifuku Kinzoku Kyokai, N.E. Kemkat, Nippon Kogyo, Hakko Kagaku Kogyo, Matsuda Precious Metals, Sankin Recycling, Yokohama Metals, and Chugai Kogyo.²

Because used precious-metal scrap varies widely in value and grade, proper sampling and assaying is important to the industry. Fire assay techniques have long been used to determine the presence of precious metals. In addition to fire assays, PGM can be determined by chemical methods and instrumental methods such as X-ray fluorescence and spectrochemical methods.³

A list of independent PGM assayers is shown in table 3. The list is meant to be a sample rather than a complete list of assayers.

The U.S. Bureau of Mines released a new publication that traces the flow of PGM through their metallurgical, catalytic, and chemical applications and

highlights areas in which significant losses occur because of downgrading, export, or disposal.⁴

Economic Factors

Futures contracts are traded on the New York Mercantile Exchange (NYMEX) and the Tokyo Commodity Exchange for Industry (TOCOM), and to a lesser extent on the MidAmerica Exchange.⁵ Futures contracts help producers and consumers of platinum and palladium lock in prices and allow speculators an opportunity to make profits. By comparing the current price with the price for future delivery, one can surmise whether market participants expect prices to rise or fall.

Platinum and palladium futures contracts, specifying 99.95% metal content, were traded on the NYMEX in units of 50 and 100 troy ounces, respectively. Table 4 shows the number of contracts traded on the last trading day of the year for 1988 through 1991.

Trading of platinum futures contracts on the TOCOM began in 1984. The contract unit is 500 grams, the quality specifications are 99.9% purity, and prices are quoted in Japanese yen per gram.

In London, prices of physical platinum and palladium bullion are set each day in the morning and afternoon for the wholesale market. The eight companies participating in establishing prices are members of the London-Zurich Good Delivery Agreement, which sets standards for platinum and palladium trading in Europe. London and Zurich are the two most important European trading centers for platinum and palladium.

A time series of historical prices for each of the six PGM and a brief discussion of factors influencing prices are given in a U.S. Bureau of Mines publication entitled, "Nonferrous Metal Prices in the United States Through 1988."⁶

ANNUAL REVIEW

Legislation and Government Programs

The California Air Resources Board, Mobile Source Div., issued a summary of its mobile source emissions standards. All 1995 and later passenger cars and light-duty trucks, weighing up to 3,750 pounds, are required to emit no more than 0.25 gram per mile (gpm) nonmethane hydrocarbons (NMHC), 3.4 gpm carbon monoxide (CO), and 0.4 gpm oxides of nitrogen (NO_x) for the first 50,000 miles. From 50,000 miles up to 100,000 miles, the requirement becomes 0.31 gpm NMHC, 4.2 gpm CO, and no requirement for NO_x. The requirement for diesel cars and light-duty trucks weighing up to 3,750 pounds, up to 100,000 miles, is 0.31 gpm NMHC, 4.2 gpm CO, and 1.0 gpm NO_x.⁷

Strategic Considerations

Although some platinum and palladium was produced at the only PGM mine in the United States, the Stillwater Mine, the great majority of PGM consumed in the United States was imported.

There were no changes in inventories of platinum, palladium, and iridium in the National Defense Stockpile in 1991. No purchases of rhodium or ruthenium were made, even though there is a stockpile goal for these two metals.

Production

The Stillwater Mine, southwest of Billings, MT, was operated by the Stillwater Mining Co. (SMC), owned 50% by Chevron Corp. and 50% by Manville Corp. Estimates from published sources showed that production of PGM at the mine increased slightly in 1991. As a result of weak prices for platinum and palladium, a plan that was to have doubled ore production to 2,000 short tons per day was postponed. Small amounts of PGM were recovered by other companies as byproducts of domestic copper refining.

Consumption and Uses

Reported sales of PGM by refiners is shown in table 7. For comparison purposes, the calculated apparent consumption for the individual PGM is also shown. Reported consumption for all PGM, with the exception of osmium, declined in 1991.

A summary of the typical uses for each PGM is shown in tables 8 and 9. Platinum, palladium, and rhodium were used in emission catalysts for light trucks (trucks weighing 14,000 pounds or less, gross weight) and automobiles. An informal survey of automobile catalyst manufacturers indicated that a typical emission catalyst in 1991 contained a total of about 2.7 grams PGM (approximately 2.18 grams platinum, 0.31 gram palladium, and 0.31 gram rhodium).

There were variations in the quantities of PGM in each catalyst, depending on the vehicle's engine size, the normal operating temperature of the engine, and the manufacturer of the catalyst.

In electronic applications, ruthenium was the principal PGM used in thick film resistors, and palladium was the principal PGM used in thick film conductors, multilayer ceramic capacitors, and connectors. Platinum "targets" were used for sputtering thin films on circuit boards. Platinum-rhodium alloys were used for manufacturing thermocouples for precise temperature measurement.

For glass applications, most of the PGM, specifically platinum, rhodium, and palladium, were used in bushings for the extrusion of textile (continuous filament) glass fiber.

The nonautomotive catalyst applications of PGM were numerous. The petroleum refining industry used PGM, principally platinum, in reforming, cracking, and isomerization reactions. Chemical catalysts containing platinum and rhodium were used in inorganic syntheses of nitric acid and hydrogen cyanide. Palladium was used in the production of hydrogen peroxide. A wide variety of organic chemicals and pharmaceuticals were produced using PGM catalysts.

Stocks

In addition to the reported stocks held by refiners, importers, and dealers, end users held sizable quantities of PGM that were not reported to the U.S. Bureau of Mines.

Markets and Prices

The average dealer price for platinum was \$371 per troy ounce in 1991, its lowest level in 6 years; while the average dealer price for palladium was \$87 per ounce, its lowest level in 9 years. A recession in the U.S. automobile industry and record-high exports of platinum by the U.S.S.R. contributed to a surplus of supply relative to demand for platinum and palladium.

In May, Nissan Motors announced that it had developed a palladium-only catalytic converter. News of the announcement caused an immediate reaction in markets in New York, causing platinum prices to drop and palladium prices to rise temporarily. In June, Isuzu Motors announced that it had developed a palladium catalytic converter for use on its 1994 model 3-ton trucks for the U.S. market. The Isuzu announcement further depressed platinum prices.

Foreign Trade

Imports of rhodium were down sharply from the record-high level of 13 metric tons imported in 1990, as shown in table 13. In 1991, imports from the Republic of South Africa represented 62% of total U.S. rhodium imports, 73% of total platinum imports, and 31% of total palladium imports.

World Review

Capacity.—Capacity for PGM production is generally cited in terms of platinum capacity. The data in table 14 represent rated capacity, defined as the maximum quantity that can be produced on a normally sustainable long-term operating rate, based on the physical equipment of the plant and routine operating procedures for labor, energy,

materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure.

Japan.—Japan PGM, a joint venture owned by Dowa Mining and Tanaka Kikinzoku Kogyo, planned to build a plant to recover PGM from spent autocatalysts in Kosaka, Akita, Japan. The plant was scheduled to start up in April 1992 with an annual capacity of 5,000 metric tons of catalysts to recover 4.5 metric tons of platinum, 1.8 metric tons of palladium, and 0.5 metric ton of rhodium.

Demand for platinum in Japan was about 64 metric tons, up from 58 metric tons in 1990. Of this amount, about 39 metric tons was used in jewelry.

South Africa, Republic of.—Barplats canceled development of its underground Crocodile River (formerly Lefkochrysos) platinum mine because of prevailing low PGM prices and high operating costs. The mine would have produced annually about 2,800 kilograms of platinum and 370 kilograms of rhodium. Only a month earlier, in August, Impala Platinum Holding Ltd. acquired a 38% stake in Barplats.

Labor problems and refining bottlenecks at Impala caused the company to lose production and required it to buy metal to maintain supplies to its customers.

Rustenburg Platinum Mines Ltd. confirmed plans to develop the Potgietersrust Mine on the Platreef by mid-1993. The mine was expected to produce about 1,600 kilograms of platinum per year.

U.S.S.R.—Soviet sales of platinum to the West reached a record high of 34 metric tons in 1991, with a large amount initially going to Switzerland. Johnson Matthey PLC reported that some of the platinum was lent or swapped, but most had been sold by the year's end to raise foreign exchange. In addition to

platinum, the U.S.S.R. reportedly shipped a large quantity (1,550 kilograms) of rhodium to Switzerland in May 1991 to be used as collateral against foreign exchange loans. Johnson Matthey, in its Platinum 1992 report, speculated that this large quantity of rhodium was never sold but rather returned to the U.S.S.R.

During 1991, sales of PGM were shared by Almazjuvelirexport (Almaz) and the Soviet Bank for Foreign Economic Affairs, Vneshekonombank. By the end of the year, the Government declared that Almaz would resume its monopoly role for selling PGM.

Current Research

The Bureau's Reno Research Center investigated the use of bacteria to oxidize flotation concentrate from the Stillwater Mine. After bacterial pretreatment, tests were conducted to determine if the PGM could be extracted from the biooxidized residue using cyanide. In the most successful test, 34% of the platinum, 75% of the palladium, 94% of the rhodium, and 97% of the gold was removed from the biooxidized concentrate.⁸

In another study, the Reno Research Center investigated leaching automobile catalysts with sodium cyanide (NaCN) solutions at high temperatures to recover PGM. The feed was virgin monolith rejects, used monoliths, and used pellet catalysts. Leaching with a 5% NaCN solution for 1 hour at 160° C dissolved more than 97% of the PGM in the virgin monolith, 85% of the PGM in the used monolith, and 90% of the PGM in the used pellet catalyst. More than 99.8% of the dissolved PGM was recovered as a precipitate by heating the solution to 250° C for 1 hour in an autoclave. The cyanide complexes were decomposed, and free cyanide was destroyed.⁹

Corning Inc. said it had developed a new substrate for catalytic converters that incorporates an electrically heated metal monolith used in conjunction with a conventional ceramic monolith, all contained within the same catalytic converter unit. The metal monolith is

designed to heat up exhaust gases almost instantly after an automobile has been started and thus promote catalytic activity. After the first 2 minutes of engine operation, the ceramic monolith begins to operate, replacing the function of the metal monolith. Using both monoliths will help automobile companies meet future strict emission regulations.

In July, ARCO Incorporated announced that it had developed a low-sulfur, reformulated gasoline designed to reduce automobile emissions. While not designed to eliminate the use of PGM in autocatalysts, reformulated gasoline may enhance the appeal of palladium-base autocatalysts that are easily "poisoned" by contaminants. The reformulated gasoline, called EC-X, reportedly reduces emissions of hydrocarbons, nitrous oxides, and carbon monoxide by about 25%; however, the gasoline costs about 16 cents per gallon more than conventional gasoline. Because of its high cost, ARCO will not produce EC-X unless it becomes mandatory in order to meet clean air requirements in California, which has traditionally had the toughest standards in the Nation. The Western States Petroleum Association, representing most of California's major refiners, estimated that reformulated gasoline, if needed to meet present air quality standards for California, will require between \$6 billion and \$10 billion in capital investment. There is considerable debate within California about how strict the air standards should be. The question of whether other States will adopt California's standards or possibly adopt stricter standards than California remains unanswered.

OUTLOOK

It is difficult to predict future supplies for PGM from the former U.S.S.R., given that region's tenuous economic circumstances. However, assuming that enough economic aid from Western countries is forthcoming, PGM production will probably continue to rise or at least be maintained. The Republic of Russia has nearly all of the former

U.S.S.R.'s PGM reserves within its borders.

Future demand for PGM should continue to grow worldwide given the strong demand for a cleaner environment. Catalytic converters for controlling automobile emissions are currently used in Australia, Canada, Japan, Mexico, the Republic of Korea, Taiwan, the United States, and many Western European nations. Brazil, Hong Kong, Indonesia, Malaysia, Singapore, and Thailand are expected to start using catalytic converters in the very near future. The potential market for the catalytic converter is huge given the fact that there are 500 million motor vehicles worldwide.

In the United States, California has for years had the most stringent automobile emission regulations, setting the tone for Federal standards. The California Air Resources Board is seeking to introduce zero emissions for 2% of vehicles by the year 2000. Some other States, such as New York and Massachusetts, are opting for California standards instead of the more lenient Federal standards.

Rhodium	\$1,222	\$1,218	\$1,300	\$3,565	\$3,739
World: Mine production	270,281	280,160	279,726	288,502	291,678

¹Estimated. ²Revised.

³The platinum-group comprises six metals: platinum, palladium, iridium, osmium, rhodium, and ruthenium.

⁴Estimates for the Stillwater Mine are from published sources. A very small quantity of byproduct platinum and palladium produced from gold-copper ores was excluded.

⁵Value based on dealer prices.

⁶Excludes ores and scrap.

⁷Includes mine production plus nontoll-refined production plus refined imports for consumption minus refined exports plus or minus changes in Government and industry stocks.

⁸Refined imports for consumption minus refined exports plus or minus changes in Government and industry stocks.

¹Revised.

²Comprises primary and nonrefined secondary metals.

³Data may not add to totals shown because of independent rounding.

⁴Defined as mine production plus nonrefined production of secondary metal plus refined imports minus refined exports plus beginning stocks minus ending stocks. In 1987 and 1988, unspecified PGM imports and exports were divided evenly between platinum and palladium. Export data for iridium, osmium, and ruthenium are not available separately; in this calculation, the collective export figure was assigned to ruthenium.

⁵1987-91 platinum, palladium, and rhodium sales to the automotive industry are estimated based on U.S. light truck sales and U.S. automobile production.

**TABLE 8
TYPICAL USES OF PLATINUM, PALLADIUM, AND RHODIUM**

Platinum	Palladium	Rhodium
Automobile catalyst	Automobile catalyst	Acetic acid catalyst.
Cancer drugs	Dental alloys	Automobile catalyst.
Coins	Hydrocracking catalyst	Glass bushings.
Cracking catalyst	Hydrogen peroxide catalyst	Nitric acid catalyst.
Crucibles	Multilayered capacitors	Thermocouples.
Fuel cell electrode	Thick films pastes	
Glass bushings	Vinyl acetate catalyst	
Hydrogen cyanide catalyst		
Isomerization catalyst		
Jewelry		
Nitric acid catalyst		
Reforming catalyst		
Targets for thin films		
Thermocouples		

**TABLE 9
TYPICAL USES OF RUTHENIUM, IRIDIUM, AND OSMIUM**

Ruthenium	Iridium	Osmium
Caustic soda electrode	Caustic soda electrode	Biological staining.
Chlorine electrode	Chlorine electrode	Pharmaceutical catalyst.
Resistor circuits	High-temperature crucibles	
	Reforming catalyst	

**TABLE 10
REFINER, IMPORTER, AND DEALER STOCKS OF REFINED
PLATINUM-GROUP METALS¹ IN THE UNITED STATES, DECEMBER 31**

(Kilograms)

Year	Platinum	Palladium	Iridium	Osmium	Rhodium	Ruthenium	Total
1987	19,004	17,356	506	1	996	549	38,412

¹Estimated. ²Revised.

¹Table includes data available through Apr. 29, 1992. Platinum-group metal production by Germany (western states), Norway, and the United Kingdom is not included in this table because the production is derived wholly from imported metallurgical products and to include it would result in double counting.

²In addition to the countries listed, China, Indonesia, Papua New Guinea, and the Philippines are believed to produce platinum-group metals, and several other countries may also do so, but output is not reported quantitatively, and there is no reliable basis for the formulation of estimates of output levels. However, a part of this output not specifically reported by country is presumably included in this table credited to Japan. (See footnote 7).

³Partial figure; excludes platinum-group metals recovered in other countries from nickel ore of Australian origin; however, a part of this output may be credited to Japan. (See footnote 7).

⁴Unless otherwise indicated, Canadian data show estimated proportions of platinum, palladium, and other platinum-group metals within the reported total. Yearly totals have been reported, in kilograms, as follows: 1987—10,930; 1988—12,541; 1989—9,870; 1990—11,209; and 1991—10,960 (estimated).

⁵Reported figure.

⁶Data are for years ending June 30 of that stated.

⁷Japanese figures do not refer to Japanese mine production, but rather represent Japanese smelter-refinery recovery from ores originating in a number of countries; this output cannot be credited to the country of origin because of a lack of data. Countries producing and exporting such ores to Japan include (but are not necessarily limited to) Australia, Canada, Indonesia, Papua New Guinea, and the Philippines. Output from ores of Australian, Indonesian, Papua New Guinean, and Philippine origin are not duplicative, but output from Canadian material might duplicate a part of reported Canadian production.

⁸Includes osmiridium produced in gold mines.

⁹Estimates for the Stillwater Mine, from published sources. A very small quantity of byproduct platinum and palladium produced from gold-copper ores was excluded.

POTASH

By James P. Searls

Mr. Searls, a physical scientist and economist, has been the commodity specialist for potash for 12 years. Domestic survey data were prepared by Carleen Militello, statistical assistant; and international data were prepared by Theodore T. Spittal, international data coordinator.

U.S. potash production in terms of potassium oxide (K_2O) equivalent increased about 2% relative to that of 1990, and apparent consumption increased about 3%. The average price, f.o.b. mine, was essentially unchanged (less than 1% increase). Yearend stocks increased about 13% over the ending stocks of 1990 due to unexpectedly slow sales in November and December.

DOMESTIC DATA COVERAGE

The U.S. Bureau of Mines developed potash domestic data from voluntary semiannual surveys of U.S. operations. Of the 12 survey requests sent to operations, 11 responded, representing 98% of total production shown in table 1.

ANNUAL REVIEW

Issues

A competition for the land use in the known potash geographical area has arisen in 1991. An oil and gas industry expressed wishes to drill near or through several potash reserves in the area. Some recent, successful wells have led the oil industry to believe that there was a strong chance of oil underneath unmined potash reserves. The oil well executives have approached the Bureau of Land Management and the U.S. Department of the Interior requesting permission to drill through the potash reserves for the suspected pools of oil.

Drilling through a potash seam precludes the mining of potash in a radius of 305 meters (1,000 feet), equal to the

depth of the seam, around the drill stem. That would diminish reserves by at least 710,750 cubic meters (25,100,000 cubic feet) of ore. Assuming 2,002 kg/cu meters (125 lbs. per cubic foot), this equates to 1,425,000 metric tons¹ (1,570,000 tons) of ore lost per drill hole. Should the companies be searching for oil and drill in the center of every 40 acres, as is the industry accepted practice, the drill holes are close enough together to preempt all of the potash reserves in each of the 40-acre tracts. Beyond this there is a major concern that the methane gas associated with the oil may leak up around the drill string or from a cracked drill string into the mine over miles of distance, which would convert the mine into a "gassy" mine under Mine Safety and Health Administration rules. In that event, vast and expensive modifications would have to be made to the mining, lighting, and power distribution equipment of the whole mine. The costs of these modifications would severely reduce operational profitability and possibly result in the cessation of mining at the affected operations, even in the section of the mine distant from the oil or gas drilling. (See tables 1, 2, 3, and 4.)

Production

Domestic potash production, in K_2O equivalents, increased about 2% in 1991 over that of 1990. Of the total production for the year, 75% was standard, coarse, or granular muriate of potash, also known as potassium chloride, and 12% was sulfate of potash, also known as potassium sulfate. The remaining production included manure

salts, soluble and chemical grades of muriate of potash, and sulfate of potash-magnesia, also known as potassium magnesium sulfate. The terms "standard," "coarse," and "granular" muriate of potash refer to their particle sizes and comprise the "three muriates," a term that ignores the soluble and chemical grades of muriate of potash. "Standard" and "soluble" grades of muriate of potash and sulfate of potash also have industrial end uses. The "sulfates" category combines the sulfate of potash-magnesia data and the sulfate of potash data. "Manure salts" formerly referred to high-grade "run-of-mine" ore and was put on a few crops; 25% K_2O sylvinitic ore is approximately 40% KCl that can be used on sugar beets. The term now refers to a mixture of white muriate of potash and common table salt for industrial uses.

The New Mexico potash producers accounted for 86% of the total marketable potash salts production. Production of crude salts (ore) in New Mexico was 16.3 million tons with an average K_2O content of 13.2%, a 4% decrease in ore grade compared to that of last year. The producers were AMAX Potash Corp. of AMAX Inc., Eddy Potash Inc. of Trans-Resources Inc., IMC Fertilizers Inc. (IMCF), Mississippi Chemical Corp., New Mexico Potash Corp. of Trans-Resources Inc., and Western Ag-Minerals Co. of Rayrock Resources of Canada. All the New Mexico producers, except Western Ag-Minerals, mined sylvinitic ore (the mixture of sylvite and halite from which most muriate of potash originates) and beneficiated the ore into muriate of potash. Several forms of beneficiation

were used: The flotation of sylvite (potassium chloride) away from halite (sodium chloride) occurred at AMAX Potash, Eddy Potash, and Mississippi Chemical. The IMCF plant used both heavy-media separation and flotation, and New Mexico Potash used selective crystallization in its plant. Western Ag-Minerals and IMCF mined langbeinite ore and beneficiated the ore to sulfate of potash-magnesia. The IMCF personnel mined both sylvinitic and langbeinitic ores and reacted fractions of each potash product to produce sulfate of potash. Some muriate of potash from New Mexico was sold to a domestic potassium nitrate manufacturer who produced about 50,000 tons.

In Utah, Moab Salt Inc. produced muriate of potash for Texas-Gulf Chemical Co. from underground bedded deposits by two-well solution mining and solar evaporation. The sylvinitic salts from the solar ponds were beneficiated by flotation to separate the sylvite from the halite. Great Salt Lake Minerals & Chemicals Corp. (GSLMC) produced sulfate of potash from the brines of the North Arm of the Great Salt Lake by solar evaporation and a proprietary process of beneficiation. GSLMC sometimes purchases muriate of potash from other sources for conversion to sulfate of potash owing to an excess of sulfate ions in the lake brine concentrate. For 1991, GSLMC purchased a small amount of muriate of potash from domestic sources; this amount was subtracted from the muriate of potash production and sales data to prevent double counting in the U.S. apparent consumption calculation. The Reilly-Wendover operation of Reilly Industries Inc. plant produced muriate of potash and manure salts by solar evaporation and flotation from near-surface brines at the west end of the Bonneville Salt Flats.

One plant in Utah manufactured sulfate of potash from muriate of potash and sulfuric acid. They reported production of about 12,500 tons for the year. The amount is not included in table 4 because the company does not mine any ore.

In California, the muriate and sulfate of potash (and other products) operation at

Searles Lake owned by North American Chemical Corp. continued to produce by solar evaporation and selective crystallization from the underground brines of the lake bed.

In Michigan, Kalium Chemical Ltd. continued pilot plant development of a deep ore body and the technology to extract potash from that ore body.

Greensand, also known as glauconite, a natural silicate of potassium, aluminum, iron, and magnesium, was produced by Inversand Co., a subsidiary of Hungerford and Terry Inc., near Clayton, NJ. Production and sales information are withheld to avoid disclosing company proprietary data. Processed greensand was sold as a filter media for the removal of manganese, iron, and hydrogen sulfide from drinking water supply systems. Classified raw greensand was resold by Zook and Ranck Inc. as a soil conditioner and as a slowly released potash, with a K_2O equivalent between 5% and 10%, to the organic farmers of North America. (See tables 5 and 6.)

Consumption and Uses

Apparent domestic consumption of all forms of potash in 1991 increased 3% compared with that of last year when all sources of potash are considered.

Shipments from North American potash producers to that region through the first half of the year were above 1990's shipments. After October, heavy rains, sleet, ice, and snow slowed potash shipments in the Midwest. North American producer total shipments were down at the end of the year by about 5% relative to those of last year. Offshore sources of potash apparently reached consumers who were not bothered by the adverse weather. The West South-Central and West North-Central regions were below last year's shipping levels due to the rains in the South and lower wheat plantings in the North. For the domestic potash producers, about 59% of the sales was in the first half of the year.

According to the Potash & Phosphate Institute, the shipments of agricultural potash from Canadian and United States producers decreased 5% from 1990 to

1991. The shipments of nonagricultural potash increased 6% for a total (agricultural plus nonagricultural) decline of 4%. The major States receiving agricultural potash from Canadian and United States producers, in decreasing order, were Illinois, Ohio, Iowa, Indiana, Minnesota, Missouri, and Wisconsin. These seven States received 55% of the total. Domestic producers accounted for 9% of the shipments to Illinois, 4% of the shipments to Ohio, 8% of the shipments to Iowa, 7% of the shipments to Indiana, 2% of the shipments to Minnesota, 65% of the shipments to Missouri, and 1% of the shipments to Wisconsin. The major receivers of domestically produced potash, in decreasing order, were Missouri, Texas, California, Illinois, Arkansas, Florida, and Kansas. These seven States accounted for 61% of the total. The major consumers of sulfates of potash, in decreasing order, were Florida, California, Georgia, Kentucky, and Texas. These five States accounted for 55% of the total. These figures do not account for the imports from the rest of the world. Those tonnages are counted only at the entering port, and the State in which the potash was consumed is not known.

The major States for shipments of nonagricultural potash from Canadian and United States producers, in decreasing order, were Alabama, Ohio, Delaware, and Mississippi. These four States accounted for 66% of the total.

Stocks

Yearend producers' stocks were about 13% higher than those of 1990. Granular muriate of potash product stocks made up about 37% of the total stocks. Sulfates of potash stocks made up about 32% of the total stocks. Yearend stocks represented about 20% of annual production or about 10 weeks of average production. (See table 7.)

Prices

The average annual price, \$178.32 per ton f.o.b. mine, of U.S. potash sales of all types and grades was about 1% greater, less than the rate of inflation of 3.6%, than that of 1990. The average price was \$177.21 per ton for the first half of the year and \$179.85 per ton for the second half of the year. The average annual price of the three grades of muriate was \$132.24, up less than 2% from last year. Standard grade of muriate averaged \$128.75 per ton; coarse grade, \$136.18; and granular grade, \$133.60. The average annual price for all grades of sulfate of potash averaged \$319.43 per ton, an increase of about 0.6%. (See tables 8, 9, 10, and 11.)

Foreign Trade

Total potash exports of the United States as reported by the Bureau of the Census increased 33%, by ton K₂O. Muriate of potash exports increased 64% while sulfate of potash decreased 17%. The major destinations for U.S. potash exports were Latin America and the Pacific Basin. Latin America received about 64% of all U.S. potash shipments. In this region, receiving about 83% of the shipments, in decreasing order, were Brazil, Mexico, Venezuela, Costa Rica, Dominican Republic, and Chile. Muriate of potash was the important shipment to this region, amounting to 88% of total shipments; sulfate of potash only accounted for 7% of the total. The Pacific Basin received about 27% of all U.S. potash shipments. China and Japan, in declining order, received about 92% of the region's shipments. Sulfate of potash was 40% of the shipments to the Pacific Basin, while muriate of potash was 39%, sulfate of potash-magnesia was 19%, and nitrate of potash was 2%.

Potash imports for consumption into the United States as reported by the Bureau of the Census increased about 9% compared with those of 1990. Muriate of potash imports increased about 8%, while sulfate of potash imports increased about 10%. The Federal Republic of Germany increased its imports into the United

States over those of 1990 by about 2% when compared to the combined imports of the former East and West Germany of last year.

Canada provided 93% of all muriate of potash imports and 92% of all imports by K₂O. Canada exported to the United States about 4.17 million tons equivalent or about 74% of apparent consumption. The Commonwealth of Independent States (CIS) was the second largest seller to the United States at 117,700 tons. Israel fell to third place, importing about 1,000 tons less than the CIS but providing both muriate of potash and nitrate of potash. Israeli muriate of potash imports fell to about 50% of 1990's level. (See tables 12, 13, 14, and 15.)

World Review

World production declined about 8% from that of 1990. This is the third year of potash production declines. World prices, as exemplified by the per ton price of standard muriate of potash, f.o.b. Vancouver, Canada,² rose from approximately \$162 per ton (\$97 per metric ton of product) in January-February to \$172 per ton (\$103 per metric ton of product) in March, and \$183 per ton (\$110 per metric ton of product) in April, remaining at that level for the rest of the year. Granular muriate of potash is no longer tied directly to the price of standard, and ranges above and below the price of standard grade at this port according to its own supply-demand balance.

Argentina.—Potasio Rio Colorado S.A., formed by Grupo TEA companies, is investigating a 150,000-ton-per-year production site near Malargue, Province of Mendoza, by solution mining and solar evaporation. The company has received a loan from the Inter-American Investment Corp. The American firm FMC Corp. has commenced exploration for lithium in the Salar del Hombre Muerto. Should this site be developed there is a slight chance that potash will be coproduced from this site.

Bolivia.—The American firm FMC Corp. is continuing exploration for lithium in the Salar de Uyuni. Should this site be developed there is a slight chance that potash will be coproduced from this site.

Brazil.—Companhia Vale do Rio Doce leased the Taquari-Vassouras potash mine from Petrobras with the intention of profitable production after some additional investment.

Commonwealth of Independent States.—The Uralkali Combine north of Perm was divided into two combines, one retaining the name Uralkali but including only the Berezniki plants. The Solikamsk mines were renamed the Silvinit Combine. The Byeloruskaliy Combine, the Soligorsk mines, came under the control of the Byelorussian Government. The Byeloruskaliy mines produced about 50% of CIS production. The Ukraine Government assumed control over the mines in the Kalush-Stebnik regions. A potash storage building was being built near Vladivostok at the Vostochny seaport with the help of the National Federation of Agricultural Co-operative Associations, known as Zen-noh, of Japan.

The miners at the Soligorsk Mines struck for 9 days starting April 17, during a confrontation with President Gorbachev concerning the then-Republics' powers and control over internal resources.

Soyuzagrokhimexport, the former Soviet agricultural chemical exporting agency, formed a joint-venture company, known as Agrovit, with a U.S. company that was to handle potash and urea in to the Americas.

Germany, Federal Republic of.—Kali und Salz AG closed the Salzdetfurth Mine and its 350,000 tons of annual capacity late in the year and projected closure of the Niedersachsen-Reidel Mine and its 200,000 tons of annual capacity in 1994. This would reduce the Kali und Salz capacity to 2.35 million tons of annual capacity in 1992 and 2.15 million tons in

1995. *Mitteldeutsche Kali AG* of the former East Germany closed down five mines, Bleicherode, Dorndorf, Sollstet, and Volkenrode, by midyear, and Sondershausen by yearend. *Mitteldeutsche Kali* has shut down about 0.9 million tons of annual capacity, bringing it to 2.2 million tons. The remaining mines will be Bischofferode, Merkers, Rossleben, Unterbreizbach, and Zielitz.

Israel.—*Haifa Chemical Ltd.* began a study for an additional 45,000-ton annual capacity potassium nitrate plant. In 1990, a fire in an adjoining phosphoric acid facility stopped production for a week in the present 135,000 tons of annual capacity of potassium nitrate facility. Twenty-five percent of the *Israel Chemicals Ltd.* stock was sold on the Tel Aviv stock market to Israeli owners. Another 15% was to be sold to a "strategic" partner. Thirty-two percent is planned to be sold on the Tel Aviv and other, foreign stock markets. The Government of Israel will continue to own 28% of the company.

Jordan.—During the summer of 1990 the Arab Potash Co. announced plans to expand from 0.84-million-ton-per-year capacity to 1.1 million tons per year by mid-1994. The company envisions an expansion to a 1.3-million-ton-per-year capacity by the year 2000. The Persian Gulf War in Iraq and Kuwait had little effect on the operation of the potash operation except to briefly raise shipping insurance premiums and thereby diminish shipping traffic from Aqaba for several weeks.

Spain.—*Instituto Nacional de Industria (INI)* bought the *Potasas de Llobregat* subsidiary of *Ercros*. *Potasas de Llobregat* includes the *Sallent* and *Balsareny* Mines. Potash mining in Spain is now Government-owned as *INI* owns all of *Minas de Potasa de Suria* and 50% of *Potasas de Subiza*, south of Pamplona, along with the government of the Province of Navarra.

Thailand.—The *ASEAN Potash Mining Co. Ltd.* was established at the beginning of the year. This company is formed to produce muriate of potash from the carnallite deposit at Bamnet Narong, Chaiyaphum, on the western edge of the Khorat-Ubol Basin. Under the system designed by *Kali und Salz AG*, the magnesium chloride will be washed away for underground injection, and the potash will be recovered by dissolution-recrystallization. Capacity is planned to be 0.6 million tons, starting up in 1995.

OUTLOOK

The U.S. Bureau of Mines recently financed an update to The WEFA Group of the 1989 BOM World Fertilizer Demand Outlook Study. The study uses a model that is an adjunct to the main WEFA model through population. This connection assumes 5 billion world population in 1987 with a population growth of 1.6% from 1988 to 1994, 1.5% from 1995 to 1998, 1.4% from 1999 to 2003, and 1.3% from 2004 to 2005. From its worldwide data base on crops it uses major crop hectares of 741.8 million hectares in 1987 increasing unsteadily to 814.3 million hectares in the year 2005. Using an increase in application rates from 78 pounds per hectare in 1987 to 83 pounds per hectare in the year 2005, the model forecasts potash worldwide consumption growing from 26.3 million tons in 1987 to 30.5 million tons in the year 2005.

This submodel divides the world into the following regions: Africa, Asia, East Europe, Latin America, North America, Oceania, U.S.S.R./CIS, and Western Europe. (See table 16.)

¹All tonnages are reported in metric tons, K₂O equivalent, unless otherwise noted.

PUMICE AND PUMICITE

By Wallace P. Bolen

Mr. Bolen, a physical scientist, is a graduate of the University of Virginia and has been the commodity specialist for pumice and pumicite since September 1989. Domestic survey data were prepared by Robin L. Richardson, statistical assistant; and the international production table was prepared by Virginia Woodson, international data assistant.

ANNUAL REVIEW

Production

Pumice and pumicite sold or used in the United States decreased about 10% compared with that of 1990, according to the U.S. Bureau of Mines. Apparent consumption decreased about 28% to 506,000 metric tons, a 9-year low. In 1982, consumption was 486,000 tons. Both 1991 and 1982 were economic recession years. These recessions adversely affected building activities that caused lower demand for building materials, the major use for pumice.

Domestic Data Coverage

Domestic production data for pumice and pumicite were developed by the U.S. Bureau of Mines from one voluntary, annual survey of U.S. operations. Twelve active operations contributed 100% of the sold and used quantity and value. Two of the operations did not respond to the 1991 survey. The sold and used data for these companies were estimated. Besides the 12 active operations, two pumice companies were idle. (See table 1.)

Domestic producers were Tufflite Inc., Phoenix, AZ; California Industrial Minerals Co., Friant, CA; Glass Mountain Pumice Inc., Siskiyou Co., CA; U.S. Pumice Co., Chatsworth, CA; Hess Pumice Products, Malad City, ID; Producers Pumice, Meridan, ID; Kansas Minerals Inc., Mankato, KS; Calvert Corp., Norton, KS; Copar Pumice Co. Inc., Espanola, NM; General Pumice Corp., Santa Fe, NM; Cascade Pumice

Co., Bend, OR; and Central Oregon Pumice Co., Bend, OR.

Pumice and pumicite sold and used decreased to 401,376 tons with a value of \$9.2 million. The average price of pumice fell from \$24.13 per ton to \$22.90 per ton. Oregon remained the largest source of pumice followed by, in descending order, California, New Mexico, Idaho, Arizona, and Kansas. (See table 2.)

Consumption and Uses

The most important market for pumice remained building block, consuming 65% of the total. Pumice consumed by textile laundries and abrasive uses accounted for 9% and 6%, respectively. Other uses for pumice and pumicite included adsorbents, horticultural, concrete aggregate, diluents, fillers, filter aids, insulating medium, and landscaping.

Markets and Prices

Imports in 1991 were also affected by the recession and plummeted almost 58%. Imports from Greece decreased substantially, dropping about 82% compared to that of 1990. While imports from Guatemala also fell drastically, imports from most other countries rose.

Generally speaking, imports for construction-related uses fell while imports for more specialized uses increased or were unaffected because of the recession. Exports, which are relatively minor, declined from 20,000 to 13,000 tons. (See table 4.)

Beginning with this report, the author will begin to include brief comments on

individual pumice companies operating in the United States. Eventually all companies will be reviewed, but this year only three are included because of their uniqueness. U.S. Pumice Co. produced block pumice from a unique pumice deposit in Mono County, east-central California. This pumice was sawed for use as an affective and lightweight abrasive. It was also desirable and suitable as a carved and easily movable landscaping stone. There was an especially high demand for this block pumice in Japan. Kansas Minerals and Calvert Corp. both produced a true pumicite in north-central Kansas. Because of the fine-grained nature and location of this pumice, it was well suited for specialty uses, including filter aids, adsorbents, and abrasive. (See table 3.)

OUTLOOK

Consumption of pumice is directly related to building activity, which decreased in 1991 from that of 1990. Increased demand is expected as the economy recovers but large sustained growth in pumice consumption is unlikely. Pumice and pumicite sold or used in the United States should range between 350,000 to 550,000 tons per year through the middle of this decade.

QUARTZ CRYSTAL

By Joyce A. Ober

Mrs. Ober, a physical scientist with 14 years industry and U.S. Bureau of Mines experience, has been the commodity specialist for quartz crystal since 1986. Domestic survey data were prepared by Linder Roberts, statistical assistant.

Cultured quartz crystal production was unchanged, and consumption increased in 1991 from levels recorded in 1990. Production and sales of domestic lascas as feedstock for cultured quartz crystal was higher in 1991, and reported consumption was slightly lower than in 1990. The single domestic producer of lascas, the raw material from which cultured quartz crystal is produced, operated its mine to supply material to consumers. Demand for specimen-quality natural quartz continued; quartz crystal for this application is discussed in the Gem Stones chapter.

Electronic-grade quartz crystal is single-crystal silica that is free from all visible defects and has piezoelectric properties that permit its use in electronic circuits for accurate frequency control, timing, and filtration. These uses generate practically all the demand for electronic-grade quartz crystal. A smaller amount of optical-grade quartz crystal is used as windows and lenses in specialized devices, including some lasers.

More natural quartz crystal was consumed in electronic and optical applications until 1971 when cultured quartz crystal took the lead. Since that time cultured (synthetic) quartz has replaced natural crystal in practically all these applications. In 1991, synthetic quartz crystal producers consumed about 556,000 kilograms of lascas in their production, and about 1,200 kilograms of natural quartz crystal found application in electronic devices.

DOMESTIC DATA COVERAGE

The U.S. Bureau of Mines collected

domestic production and consumption data for quartz crystal through a voluntary survey of U.S. operations. Six companies responded to the canvass for the production of cultured quartz crystal, and the five active operations represented 100% of total production shown in table 1. Of the 34 operations canvassed concerning consumption of quartz crystal, 32 responded, 11 of which did not consume quartz crystal in 1990. These companies represented almost 100% of total consumption, also shown in table 1. Consumption for the nonrespondents was estimated using reported prior-year consumption levels. (See table 1.)

ANNUAL REVIEW

Legislation and Government Programs

The National Defense Stockpile contained about 642,000 kilograms of natural quartz crystal valued at about \$8.5 million. This quantity represented an excess of about 533,000 kilograms above the stockpile goal of 109,000 kilograms. During the year, quartz crystal stockpile sales amounted to about 44,000 kilograms, with a value of about \$276,000. The stockpile material, which primarily consists of large natural crystals, could be absorbed by the specimen and gem material industry. Very little, if any, of the material would be consumed in the same applications as synthetic quartz crystal.

Strategic Considerations

Natural electronic-grade quartz crystal was initially designated as a strategic and critical material after World War II.

Cultured quartz crystal was not commercially available at the time of U.S. stockpile acquisition. With the changing patterns of quartz consumption, the Federal Emergency Management Agency asked the National Materials Advisory Board to assess the requirements and related trends for stockpiling quartz. The final report was published in early 1985 and recommended changes in stockpile goals to reflect the declining dependence on natural quartz crystal.¹ The President has set the quartz crystal goal for the stockpile at 110,000 kilograms of quartz crystal.

The National Defense Stockpile contains natural quartz in several weight classes and grades, including about 13,000 kilograms of material consisting of individual crystals weighing more than 10,000 grams each. Some of the individual quartz pieces in this weight class are suitable for generating mother seeds for cultured quartz crystal production. These large pieces were acquired from Brazil because similar materials were not available from a domestic source.²

Production

Coleman Quartz Inc., Jessieville, AR, the only domestic company known to produce lascas, supplied the feed material for cultured quartz crystal from mine production. Production in 1991 was about 7% higher than that in 1990. Coleman mined only during the summer months, but processed lascas year-round. Lascas was mined, crushed, and sized. Crushed and sized material was transported to the processing plant where operators rinsed it in oxalic acid and then

in deionized water to remove external contaminants. Finally, hand sorting, drying, and examination on a light table completed the necessary processing. The material was then shipped to cultured quartz crystal producers in 45-kilogram (100-pound) bags.

Production of cultured quartz crystal was unchanged in 1991. Five companies were active. The two largest producers, Sawyer Research Products Inc. of Eastlake, OH, and Thermo Dynamics Corp. of Merriam, KS, were independent growers that produced crystal bars for domestic and foreign consumers in the crystal device fabrication industry. Motorola Inc. of Chicago, IL, produced quartz crystal for both internal consumption and the domestic device fabrication industry. P. R. Hoffman Material Processing Co. of Carlisle, PA, also reported outside sales. Bliley Electric Co. of Erie, PA, produced only for internal consumption.

These companies produced cultured quartz crystal using a hydrothermal process in large pressure vessels, known as autoclaves. Seed crystals, very thin crystals cut to exact dimensions, were mounted on racks and suspended in the upper growth region of the vessel. Lascas was loaded in an open-mesh wire basket that was placed in the bottom of the autoclave.

A solution of sodium hydroxide or sodium carbonate (the mineralizer), with additives such as lithium salts, and deionized or distilled water was used to fill the vessel to 75% to 85% of its volume. The bottom half of the growing vessel was heated to temperatures averaging between 350° C to 400° C; the temperature of the top portion is maintained at 10° C to 50° C less. At these temperatures, the solution expands and creates an internal pressure in the vessel between 10,000 and 30,000 pounds per square inch. Under these conditions, the lascas dissolves to create a solution saturated with silica.

Through convection, the saturated solution transports dissolved silica to the cooler upper half of the vessel where it becomes supersaturated, and the excess dissolved quartz deposits on the seed

crystals in the top half of the autoclave. The process continues until the growing crystals reach their desired size. The process may take 30 to 60 days, and sometimes longer.

The processing of quartz crystals for various end uses is the same whether natural or cultured crystal is used. Crystals are examined for physical defects before cutting. They are then cut, usually with diamond or slurry saws, along a predetermined crystallographic plane to a thickness slightly larger than that desired. Each wafer is inspected and diced into blanks of the desired dimensions. The blanks then progress through a series of lapping stages until they reach the final thickness; electrodes are attached and the crystals are mounted in suitable holders. The final assembly, called a quartz crystal unit, is ready for insertion into an electronic circuit.

Consumption and Uses

Consumption of lascas by the five domestic quartz crystal producers increased about 6%, from 527,000 kilograms in 1990 to 556,000 kilograms in 1991. The 21 active device-fabricating companies in 9 States consumed 8% more quartz crystal in 1991 than that in 1990. Of these companies, 13 consumed only cultured quartz crystal. One company consumed only natural quartz crystal.

Lascas and quartz crystal were used in piezoelectric, optical, and glass industries. The piezoelectric effect is achieved when a suitable electrical signal is applied to a quartz wafer or blank with appropriate electroding and the wafer then vibrates mechanically throughout the bulk of the material at a characteristic natural resonance frequency. The quartz resonators are uniquely suitable for military-aerospace and commercial bandpass filter applications that require very high selectivity or in oscillator applications that require very high stability. In addition, for many applications requiring only moderate stability, a quartz resonator offers a unique combination of high performance, small size, and low cost. Quartz resonators were used for many less

demanding applications such as providing timing signals for watches, clocks, and microprocessors in industrial, automotive, and consumer products.

The quartz wafer becomes too thin for practical use for very high frequencies (above 100 megahertz). Quartz crystal structures that use surface vibrations, in which the frequency is determined by electrode dimensions rather than wafer thickness, have become more important at these higher frequencies. These structures are called surface acoustical wave (SAW) devices. Most optical applications used quartz in the fused form as silica glass. Relatively small quantities of cultured quartz crystal were used directly for special optical considerations. Quartz's crystal properties are responsible for its uses that deal with normally polarized laser beams. Quartz retardation plates (especially quartz wave plates), Brewster windows and prisms, birefringent filters, and tuning elements are used in laser optics.

Historically, quartz crystal has been a material of strategic importance. During World War II, quartz was used principally in analog communications (e.g., in telephone multiplexing and in mobile military radios). Today, because of military emphasis on command, control, and communications (C³) surveillance and the growth of more sophisticated electronic systems, the importance of quartz crystal devices has grown. Many of the military applications are at the leading edge of technology. It has been U.S. Department of Defense policy to require that all military systems be hardened to nuclear radiation. To meet this special requirement, cultured quartz crystal must be radiation hardened by sweeping, a technique to remove certain impurities from the quartz.

Cultured quartz was used almost exclusively by the crystal device industry because of cost advantages. For resonator applications, raw quartz must be cut into thin wafers oriented precisely with the raw material crystal axes. The uniformity and convenience of cultured quartz have made its use almost universal. Unlike cultured quartz, natural electronic-grade quartz requires special

orientation, cutting, grading, and sizing to produce a quartz wafer. As a result, most device manufacturers that cut natural quartz in the past have discontinued its use. One of the remaining uses of natural electronic-grade material was in pressure transducers used in deep oil wells.

Stocks

Crystal growers' stocks of as-grown cultured quartz crystal were reported as 97,000 kilograms at the beginning of 1991. At yearend, these stocks had decreased to 89,000 kilograms.

Prices

The average value of as-grown cultured quartz, based on reported sales of about 353,000 kilograms, was \$28.04 per kilogram (\$12.76 per pound), a slight decrease compared with that of 1990. Sales volume increased about 9%. The average value of lumbered quartz, as-grown quartz that has been processed by sawing and grinding, decreased 38% to \$66.37 per kilogram (\$30.13 per pound), based on reported sales of 29,000 kilograms. Sales volume decreased 12%.

Foreign Trade

The Bureau of the Census began using the Harmonized Tariff Schedule in 1989 to identify material passing through U.S. customs. This system makes classification codes for imports and exports consistent internationally. With the adoption of the new codes, imports and export codes for quartz crystal changed, and some formerly listed details are no longer available. The import code for Brazilian crude pebble, which represented nearly all lascas imports recorded, was eliminated. Although this material probably continued to enter the United States, the new code system aggregated several categories, making information about specific materials unavailable. Likewise, the export data for natural electronic-grade quartz crystal were no longer available.

World Review

Synthetic quartz crystal production is concentrated in the United States and Japan, with several companies producing crystal in each country. Smaller production capacity exists in Belgium, Brazil, Bulgaria, France, the Federal Republic of Germany, the Republic of South Africa, and the United Kingdom. Details concerning quartz operations in China, the U.S.S.R., and other Eastern European countries is unavailable.

OUTLOOK

Domestic production of cultured quartz crystal has grown or remained relatively stable since 1986. Demand for crystal devices for electronic consumer products and microprocessor controlled devices should continue to grow, and quartz crystal production should remain strong well into the future. Because crystal devices continued to be used in an increasing variety of applications from kitchen appliances to military hardware in addition to the traditional items such as watches, demand should continue to increase and additional production capacity may be required worldwide.

RARE EARTHS

THE LANTHANIDES, YTTRIUM, AND SCANDIUM

By James B. Hedrick

Mr. Hedrick is a physical scientist in the Branch of Industrial Minerals. He has been the commodity specialist for rare earths since 1981. Domestic survey data were prepared by Kevin Bacon, statistical assistant; and international data were prepared by Harold Willis, international data coordinator.

Performance of the rare-earth industry in 1991 was weak because of a recession in the domestic economy coupled with continued competition from foreign sources. Principal foreign markets for rare earths, such as Japan, also experienced downturns in their economies. Most domestic rare-earth markets experienced a decline. Significant activity was seen from the Commonwealth of Independent States (C.I.S.) (previously the U.S.S.R.), as export restrictions on rare earths were lifted. New applications and the development of emerging markets highlighted the otherwise down year.

Domestic mine production of rare earths decreased in 1991. Significant growth was reported only in the permanent magnet sector as demand for neodymium-iron-boron magnets expanded. Traditional major rare-earth markets, petroleum cracking catalysts and metallurgical applications, were essentially unchanged from those of the previous year.

The domestic use of scandium in 1991 was small. Scandium's principal use remained lighting applications. (See table 1.)

DOMESTIC DATA COVERAGE

Domestic mine production data for rare earths are developed by the U.S. Bureau of Mines from the voluntary

survey, "Rare Earths, Thorium, and Scandium." The two mines to which a survey form was sent responded, representing 100% of known production. Production data are withheld to avoid disclosing company proprietary data.

BACKGROUND

Definitions, Grades, and Specifications

The rare earths are a group of 17 elements comprised of scandium, yttrium, and the lanthanides. Rare earths are classified chemically as members of the third subgroup of the periodic table.

Scandium, atomic number 21, is the lightest rare earth. It is the 31st most abundant element in the Earth's crust with an average crustal abundance of 22 parts per million. Although its occurrence in crustal rocks is greater than lead, mercury, and the precious metals, scandium rarely occurs in concentrated quantities as a result of its affinity to combine selectively with the common ore-forming anions.

Yttrium, atomic number 39, is chemically similar to the lanthanides and commonly occurs in the same minerals. The average concentration of yttrium in the Earth's crust is 33 parts per million and it is the second most abundant rare earth in the Earth's crust.

The lanthanides comprise a group of 15 elements with atomic numbers 57

through 71 and include: lanthanum, cerium, praseodymium, neodymium, promethium, samarium, europium, gadolinium, terbium, dysprosium, holmium, erbium, thulium, ytterbium, and lutetium. Cerium, the most abundant of the group at 60 parts per million, is more abundant than copper. Thulium, the least abundant of the lanthanides at 0.48 part per million, occurs in the Earth's crust in higher concentrations than thallium, antimony, cadmium, and bismuth.

Due largely to differing ionic radii, the rare-earth elements are broadly classified into two groups: the light rare-earth elements (LREE) or cerium subgroup, comprised of the first seven lanthanides (atomic numbers 57 through 63) and the heavy rare-earth elements (HREE) or yttrium subgroup comprised of the remaining lanthanides and yttrium (atomic numbers 64 through 71 and 39). Yttrium is classed with the heavy subgroup because of its occurrence, ionic radius, and other similar properties.

Bastnasite can theoretically contain 74.81% rare-earth oxide (REO).¹ Flotation concentrates of bastnasite average 60% REO, which can be upgraded to 70% REO by acid leaching and to 85% REO by a combination of acid leaching and calcining.

Monazite can theoretically contain 69.73% REO. Monazite concentrate is usually sold at 55% minimum REO

contained plus thorium, with product grading from 55% to 65% REO. Thorium contents are variable, but typically occur in the range of 4% to 10% equivalent thorium oxide.

Xenotime can theoretically contain 61.40% yttrium oxide. However, xenotime concentrates from Southeast Asia and Australia typically contain 25% to 30% yttrium oxide. Xenotime is often upgraded by acid leaching to produce an yttrium concentrate grading 60% yttrium oxide and the balance primarily other rare earths.

Various metallic rare-earth products are produced. The term "mischmetal" is used to denote a mixture of rare-earth elements in metallic form. It generally has the same ratio of rare-earth elements as that found in the ore and is typically 98% to 99% pure. Recently, a higher purity "battery-grade" mischmetal was produced to supply the market for rechargeable rare-earth-nickel hydride batteries.

Ferrocium is a pyrophoric alloy of mischmetal and iron. A typical ferrocium alloy contains 74% mischmetal, 23% iron, 2% copper, and 1% magnesium.

Rare-earth silicide is an alloy typically containing about one-third mischmetal, one-third iron, and one-third silicon. The rare-earth content of a silicide may be as high as 50%.

The rare-earth content of master alloys range from tenths of a percent in nodularizing alloys for ductile iron to tens of a percent in inoculants for gray cast iron. Alloys containing almost 100% rare-earth metals, such as mischmetal, are additives to certain steels.

The purity of separated rare-earth elements, produced primarily by solvent extraction or ion exchange, usually grade 96% or higher in purity. High-purity rare-earth compounds and metals are produced up to 99.9999% purity. Rare-earth products grading higher than 99.9% purity are often produced to specification. As a result of the wide range of products in which rare earths are consumed, many grades of rare-earth concentrates, compounds, alloys, and metals are produced. Analyses of the

rare-earth contents of selected ores are shown in table 2. (See table 2.)

Products for Trade and Industry

A wide variety of products is available for trade and industry, including concentrates, individual and mixed compounds, and pure and alloyed metals.

Bastnasite concentrate from a domestic source is available in three grades, an unleached concentrate grading 60% REO, an acid-leached concentrate containing 70% REO, and a calcined concentrate upgraded to 85% REO.

A mixed bastnasite-monzazite concentrate (predominately bastnasite) from China is produced in three grades, a 30% minimum REO, a 60% minimum REO, and a 71% minimum REO.

Mixed compounds derived from bastnasite include rare-earth chloride, rare-earth nitrate, lanthanum-rare-earth carbonate, lanthanum carbonate, cerium carbonate, cerium nitrate, cerium fluoride, neodymium carbonate, neodymium fluoride, praseodymium fluoride, cerium-rare-earth hydrate, and rare-earth hydrate.

Monazite is marketed by processors and trading firms as a concentrate containing 55% to 60% minimum REO plus contained thorium. Mixed compounds produced from monazite include cerium chloride, ceric ammonium nitrate, ceric sulfate, cerium carbonate, cerium hydroxide, cerium nitrate, cerium octoate, rare-earth carbonate, lanthanum carbonate, lanthanum-neodymium carbonate, lanthanum-neodymium nitrate, neodymium carbonate, neodymium nitrate, praseodymium oxalate, rare-earth octoate, and yttrium nitrate.

Xenotime concentrate with a minimum 25% yttrium oxide content is a major source of yttrium. It is usually upgraded chemically to a 60% yttrium oxide product known as yttrium concentrate, the balance of the concentrate being mostly other rare earths. The primary product derived from yttrium concentrate is high-purity yttrium oxide.

Rare-earth ion adsorption ore is produced in southern China. It is also a major source of yttrium. The ore varies

by locality, but the two principal concentrates are an yttrium concentrate and a europium concentrate. The yttrium concentrate is enriched in heavy-rare earths and grades greater than 60% yttrium oxide. The europium concentrate grades from 0.5% to 1% europium oxide, 12% yttrium oxide, but is predominantly enriched in lanthanum oxide, 33% to 43%. Both ion adsorption concentrates are low in cerium oxide, typically less than 2%.

Individual rare-earth oxides and other compounds, except promethium, are produced from bastnasite, monazite, xenotime, and ion adsorption ore. Purities from 96% up to 99.9999% are available for most oxides. Compounds for almost all of the rare earths are available as oxides, acetates, carbonates, chlorides, fluorides, nitrates, oxalates, and sulfates.

High-purity rare-earth metals are marketed in the form of sponge, lump, ingot, rod, wire, chips, powder, sheet, foil, plate, sputtering plates, and custom cast and machined shapes. Alloys such as mischmetal, rare-earth silicide, ferrocium, and other rare-earth alloys are available in a variety of ingot shapes and sizes.

Rare-earth magnet alloys are produced in a variety of compositions to meet individual requirements. Magnet alloys are marketed in ingot form, crushed ribbon, or may be purchased as mixed oxides for powder metallurgical processes. Magnets are available in finished and semifinished shapes, bonded and unbonded, magnetized and unmagnetized, and either coated or uncoated.

Scandium concentrate previously was produced as a byproduct during uranium extraction and from tailings remaining from a previously operated fluorite operation. Scandium is marketed primarily as a high-purity oxide. Oxide purities from 98% to 99.9999% have been produced in the United States. In addition to the oxide, scandium compounds are available as the acetate, bromide, carbonate, chloride, fluoride, hydride, iodide, nitrate, oxalate, acetylacetonate, and sulfate. Scandium

metal is produced in ingot, powder, lump, and foil form.

Industry Structure

Few companies in the rare-earth industry are fully integrated. Rare earths are typically mined and processed by different companies. In the United States, MolyCorp, Inc., is the only fully integrated producer from its mine at Mountain Pass, CA. The other domestic producer, in Florida, operates a mine with wet and dry mill concentrators.

Rare-earth ore is beneficiated by mine producers into concentrates that are sold directly to processors or, to a lesser extent, are sold to brokers for resale.

Rare-earth concentrates undergo extensive processing to produce mixed and separated compounds. The major processes used in separating rare earths are precipitation, solvent extraction, and ion exchange. Processors sell refined rare-earth products directly to consumers or brokers.

The scandium industry, for the most part, is separate and distinct from the lanthanide and yttrium industry. Its high price and very limited demand have made scandium one of the smallest commodity markets in the world. As with lanthanides, the scandium industry is rarely fully integrated. Due to limited demand, scandium is not currently mined in the United States. Byproduct mine production is presently only from China and the C.I.S. Although minor amounts of scandium are separated from lanthanide and yttrium ores, most scandium is produced as a byproduct from other ores.

In the United States, scandium has been recovered as a byproduct during processing of byproduct uranium at a copper mine, from tailings from a mined-out fluorite mine, and from tungsten byproduct from a molybdenum operation. Tailings and concentrates from these sites were shipped to processors for production of high-purity scandium oxide and other compounds. Three processors in the United States refine scandium oxide. Scandium is also refined in China, the C.I.S., Norway,

and the United Kingdom. Most scandium is sold in oxide form. Metal production is often effectuated by a small group of separate companies, primarily for research purposes.

Geology-Resources

Rare-earth minerals occur in a variety of geologic environments. Concentrations exist in igneous, sedimentary, and metamorphic rocks. The rare earths are mined primarily from igneous and sedimentary deposits.

The rare earths are constituents in more than 100 minerals, but only a few are recovered. Bastnasite, monazite, xenotime, and rare-earth-bearing clay are the principal sources of the world's rare-earth supply. Other sources are loparite, uraniferous phosphorites, synchisite, and byproduct solutions from processing uranium. Future production may include rare earths recovered from the minerals cheralite, secondary monazite, rhabdophane, cerianite, florencite, churchite, gadolinite, and eudialyte.

Bastnasite.—Bastnasite, a rare-earth fluorocarbonate, is found in vein deposits, contact metamorphic zones, pegmatites, and carbonatites. It is typically enriched in the LREE (bastnasite-Ce), however a rare HREE variety (bastnasite-Y) is found in Kazakhstan, C.I.S. Bastnasite forms in the trigonal crystal system and ranges in color from yellow to reddish-brown. It has the following mineralogical properties: transparent to translucent; vitreous to greasy luster; density of 4.78 to 5.2 grams per cubic centimeter; and a Mohs' hardness of 4 to 4½.² It forms as an igneous or hydrothermal mineral and occurs as an accessory mineral in several large deposits. Deposits containing bastnasite as a high-grade accessory mineral are at Mountain Pass, CA, United States; Bayan Obo, Nei Monggol Autonomous Region, China; Wigu Hill, Tanzania; and Karonge, Burundi.³ Bastnasite and other independent rare-earth minerals commonly form by hydrothermal processes, although its occurrence at Mountain Pass, CA, is

considered primary igneous. Concentration of the rare earths can occur in nature as a result of coprecipitation with calcium carbonate or by precipitation in the presence of fluorine. While the Mountain Pass bastnasite is believed to have formed by the coprecipitation process, the Bayan Obo bastnasite is hydrothermal in origin and formed by alteration of dolomite in the presence of large amounts of fluorine.⁴ Most of the world's rare-earth resources are recovered from bastnasite.

Monazite.—Monazite, a rare-earth phosphate, is one of the most abundant rare-earth minerals, and it is the world's second leading source of rare earths. Monazite occurs as an accessory mineral in granitic and metamorphic rocks, pegmatites, vein deposits, as a detrital mineral in placer deposits, and as a hydrothermal and supergene mineral in carbonatites. It is classified as a LREE and is usually enriched in cerium (monazite-Ce). Rarer monazite varieties are a lanthanum-rich monazite (monazite-La) and a neodymium-rich monazite (monazite-Nd) found in Italy and from Marmara, Greece.⁵ Monazite, which forms as a monoclinic mineral, is found in a wide range of colors, including honey yellow, greenish brown, reddish brown, yellowish brown, brown, pink, yellow, grayish white, dark gray, and black. It has the following mineralogical properties: transparent to subtranslucent; resinous, waxy, vitreous, or subadamantine luster; density 4.6 to 5.4 grams per cubic centimeter; and a Mohs' hardness of 5 to 5½.⁶ Monazite forms primarily as an accessory mineral in igneous and metamorphic rocks, including granites, gneisses, aplites, and pegmatites, and occasionally as a vein mineral (VanRhynsdorp, Republic of South Africa).

Economic placers develop where monazite has been weathered from its original host rock and concentrated by wind and water. Placer monazite is mined as a byproduct of titanium and zirconium minerals or tin minerals. Significant placer deposits are in

Australia, Brazil, Malaysia, Thailand, and the United States.⁷

Monazite of hydrothermal and supergene origin in carbonatites also represents a large rare-earth resource. Deposits of this type occur at Araxá, Minas Gerais, Brazil; Catalao I, Goiás, Brazil; Bayan Obo, Nei Monggol Autonomous Region, China; and Mount Weld, Western Australia, Australia.⁸

China's Bayan Obo deposit is known primarily as the world's largest bastnasite deposit; however, it contains substantial tonnages of monazite. Formed by hydrothermal alteration of dolomite, the Bayan Obo monazite occurs in veins and stockworks in the footwall rocks.⁹

One of the richest grade rare-earth deposits in the world is the Mount Weld carbonatite, grading 15 million metric tons at 11.2% REO, including a 1.3-million-ton zone at 23.6% REO.¹⁰ Enriched by supergene solutions, the deposit's primary ore minerals are secondary monazite and cheralite, along with lesser amounts of monazite, rhabdophane, cerianite, florencite, and churchite.

Technology

Exploration.—Exploration for rare-earth minerals (primarily thorium) began in the 1880's, for the purpose of locating thorium and cerium for incandescent gas mantles. After electric lighting came into general use about 1912, demand for gas mantles fell. Subsequently, most rare-earth deposits have been located during the search for other minerals, especially ilmenite, rutile, zircon, uranium, and gold.

Exploration techniques to locate rare earths include surface and airborne reconnaissance with magnetometric, electromagnetic, and radiometric equipment. Other methods used include satellite imagery, various types of aerial photography, and remote sensing. The application of geologic principles to develop depositional models is also applied to locate rare-earth deposits. After identifying a match for a depositional model, a surface study of the area would follow. The surface study is

typically composed of a literature and background search; geologic mapping; rock, soil, and gas sampling; geophysical testing; surface radiometric surveying; geochemical testing of water, rocks, and plants; and data analysis.

Following an acceptable surface study, a systematic subsurface sampling program would be conducted to determine ore grades and individual rare-earth contents.

Because many rare-earth minerals are associated with radioactive elements and minerals, several rare-earth deposits were discovered during exploration for uranium and thorium. Prospectors searching for radioactive minerals discovered the Mountain Pass, CA, bastnasite deposit.

Most monazite-bearing heavy-mineral deposits were discovered by exploring for recent and ancient alluvial deposits with radiometric and magnetometric equipment. Discoveries of buried alluvial deposits are typically located by depositional modeling.

Mining and Beneficiation.—Bastnasite is mined domestically as a primary product from a hard-rock carbonatite. The carbonatite is mined via bench-cut, open pit methods. Ore is drilled and blasted, loaded into trucks by rubber-tired loaders, and hauled to the mill. At the mill the blasted ore is crushed, screened, and processed by flotation to produce a bastnasite concentrate.

In China, bastnasite and lesser amounts of associated monazite also are mined from a hard-rock carbonatite. The ore is recovered as a byproduct of iron ore mining by hard-rock, open pit methods. After primary crushing at the mine site, the ore is transported by train 135 kilometers southeast to the mill because of the scarcity of water at the mine site. After separation from the iron ore by flotation, a bastnasite concentrate and a mixed bastnasite-monzazite concentrate are produced.

Heavy-mineral sands are the source of most monazite and xenotime mined in the world. Most of these minerals are recovered by surface placer methods from unconsolidated sands. Almost all mining of these sands is done by floating cutterhead or bucket wheel dredges that

concentrate the heavy minerals ("heavies") onboard and discharge the unwanted tailings back into previously mined areas. An onboard wet mill separates the "heavies" (specific gravity greater than 2.9) from the lighter weight fraction through a series of wet-gravity equipment that includes screens, hydrocyclones, spirals, and cones.

Consolidated and partially consolidated sand deposits that are too difficult to mine by dredging are mined by dry methods. Ore is stripped by typical earth-moving equipment with dozers, scrapers, and loaders. Sand recovered by these techniques is crushed and screened and then processed by the wet mill equipment previously described.

Wet mill mixed heavy-mineral concentrate is sent to a dry mill to separate the individual heavy minerals and produce a concentrate. Dry mill processing includes a combination of scrubbing, drying, screening, electrostatic, electromagnetic, magnetic, and gravity processes. Monazite, in contrast to ilmenite, rutile, and many other heavy minerals, is nonconductive and can be separated, with zircon, by electrostatic methods. Monazite, which is moderately susceptible to induced magnetism and may be slightly higher in specific gravity, can be separated from zircon by electromagnets or by additional gravity methods. Xenotime, which has a specific gravity and magnetic properties similar to monazite, is usually separated from monazite by precise gravity methods. Certain deposits also require acid-leach treatment and calcining to eliminate iron oxide or other grain coatings.

Economic Factors

Prices.—Time-price relationships for bastnasite and monazite concentrates, based on 1991 constant dollars, are shown in table 3. Price trends for bastnasite and monazite concentrate are shown in figures 1 and 2, respectively.

Concentrates of bastnasite and monazite traditionally have been low priced. Significant value is added when the concentrates are separated into the

individual rare-earth oxides or other compounds. Mischmetal prices have also been historically low, with prices remaining in the \$7 to \$12 per kilogram range over the past 20 years. Individual high-purity metals have commanded the highest prices of the rare-earth products. Metal prices typically run from two to six times the separated rare-earth oxide price.

Initially available in 1954, bastnasite concentrate was priced at \$3.31 per kilogram. By the early 1960's, the development of the first significant commercial applications for the rare earths caused its price to drop to less than \$0.50 per kilogram. Bastnasite prices have increased progressively since that time, doubling in price between 1974 and 1980 as a result of the domestic energy crisis and inflation.

Monazite pricing is more complex than that of bastnasite. As a byproduct, the supply and price of monazite is partially dependent on production and demand of the primary minerals. As a result of Australia's dominant position as a monazite producer, fluctuations in monazite's domestic price are also based on United States-Australian foreign exchange rates. Monazite's historical price trend, shown in table 3, shows an overall increase in price through 1985. In the 1950's, its price ranged from \$0.33 to \$0.40 per kilogram of REO, decreasing to \$0.22 to \$0.33 per kilogram in the early 1960's. By the mid-1960's, monazite's price began to increase steadily, with a major increase appearing in 1985, the result of a weak Australian economy and increased competition for monazite supplies. Balanced supply and demand was shown in monazite's price stability through 1990. In 1991, however, a decline in monazite's price signaled an oversupply, which was the result of the availability of low-cost separated rare earths from China, a downturn in the U.S. economy, and decreased domestic demand.

(See figures 1 and 2.)

Costs.—Mine and mill operating costs to produce bastnasite and monazite in the United States are withheld to avoid disclosing company proprietary data.

The cost to mine bastnasite is higher than that for monazite. Bastnasite, as a primary product, incurs all costs of production, whereas monazite, as a byproduct, is responsible for only a fraction of the costs. The cost to recover monazite is based almost entirely on the expenses incurred to recover the primary minerals. Mine production costs for bastnasite are also higher than monazite's because of the type of deposit. Costs to mine a hard-rock deposit (bastnasite) are significantly higher than mining a placer deposit (monazite).

Because both domestic mines have been in production for several years, mining costs are related to direct costs, which include labor, mining equipment (trucks, drills, loaders, dredges, pumps, etc.), supplies (explosives, drill bits, etc.), and utilities (fuel, natural gas, water, and electricity).

Costs to comply with environmental regulations, including waste treatment and disposal, water purification, systems monitoring, and reclamation, have continued to increase.

Tariffs.—U.S. tariff rates, specific to the rare earths, including scandium and yttrium, are shown in table 4. The duties reflect results from the 1979 Tokyo Round of Multilateral Trade Negotiations under which the tariffs on many items were reduced in several stages over the period January 1, 1980, to January 1, 1987. Tariffs are expected to remain at the present rates until new negotiations are completed. (See table 4.)

Depletion Provisions.—Depletion is the exhaustion of mineral or oil and gas reserves by mining or drilling of wells and the resulting production from these mines or wells.¹¹ Depletion allowance is a tax deduction that may be taken against income provided by the U.S. Internal Revenue Code to compensate mining companies in the United States for decreasing capital brought about by production. The allowance is based on gross income.

There are two ways of figuring depletion—cost depletion and percentage

depletion.¹² Cost depletion is usually figured by dividing the adjusted basis of the mineral property by the total number of recoverable units, and multiplying by the number of units sold during the tax year.

Percentage depletion is a certain percentage, specified for each mineral, of the gross income from the mineral property during the tax year. The depletion deduction may not be more than 50% of the taxable income from the property figured without the deduction.

The percentage depletion allowance for monazite is 22% on the thorium content and 14% on the rare-earth content when mined from domestic deposits and 14% on the thorium content and 14% on the rare-earth content from foreign deposits.

Bastnasite's depletion allowance is 14% on the rare-earth content on both domestic and foreign production.

Operating Factors

Toxicity.—The rare earths are considered only slightly toxic.¹³ However, the production of skin and lung granulomas after exposure to oxides, fluorides, chlorides, and metals by prolonged breathing, intradermal injection, or subcutaneous implantation requires extensive protection to prevent exposure through cuts and abrasions of the skin and by inhalation. Symptoms of toxicity include writhing, ataxia, labored respiration, walking on the toes with arched back, and sedation. Research has shown that males are less susceptible than females to the toxic effects of rare earths. Extreme care must also be taken when exposed to finely divided rare-earth metals and metallic powders to avoid pyrophoric burns from rapid and possibly instantaneous oxidation, especially if inhaled. Certain finely divided rare-earth metals, alloys, and powders may also present the additional hazard of oxidizing rapidly enough to explode.

It should also be noted that rare earths often exist in ore and concentrates in association with other elements that have vastly different properties, including lower and higher toxicities, and sometimes radiological hazards. Care

should be taken to assess the health factors associated with each substance present.

Employment.—Rare-earth mine and mill employment statistics, based on the quarterly average number of employees on site, are shown in figure 3. Data were furnished by the U.S. Department of Labor and compiled by the U.S. Bureau of Mines. (See figure 3.)

Productivity Trends.—The 11-year trend for U.S. rare-earth mine productivity, based on capacity utilization for bastnasite concentrate and monazite concentrate, are shown in figures 4 and 5. (See figures 4 and 5.)

Decreased bastnasite production in 1991 changed its previous 11-year trend from a slight increase to a decrease.

The 11-year trend for domestic monazite capacity utilization exhibited a decrease. However, monazite's decrease, because it is a byproduct of titanium and zirconium minerals, is primarily a function of demand for the primary products.

ANNUAL REVIEW

Legislation and Government Programs

The calendar year 1991 included the U.S. Government fiscal years for 1991 and 1992. Public Law 101-189, the National Defense Authorization Act for Fiscal Years 1990 and 1991, covered the first 9 months of 1991 and continued the authorization for disposal of all stocks in the National Defense Stockpile (NDS) classified as excess to goal, including rare earths. Stocks of rare earths in sodium sulfate classified as excess to goal at yearend 1991 were 457 tons (504 short tons). In the last 3 months of 1991, Public Law 102-190, the National Defense Authorization Act for Fiscal Years 1992 and 1993, did not continue authorization to dispose of rare earths from the stockpile.

Issues

Development of the Pajarito project, a joint venture of Molycorp and the Mescalero Apache Tribe, was suspended pending an improvement in prices for yttrium and zirconium. Economic factors stalling the project were the availability of low-cost imported yttrium, primarily from China, and decreased demand for zircon and zirconium resulting from substitution in the late 1980's, a period when market prices skyrocketed. The Pajarito deposit is on the Mescalero Reservation in southeastern New Mexico and contains yttrium and zirconium in the silicate mineral, eudialyte.

Associated Minerals (USA) Inc. changed its name to RGC (USA) Minerals Inc. in an effort to unify the company under its parent company's name, Renison Goldfields Consolidated Ltd. (RGC).

RGC Minerals, as part of an environmental rehabilitation project at its Green Cove Springs operations in Florida, planted 500,000 slash pine and 14,000 native hardwoods on 300 hectares in 1991. More than 1 million trees reportedly have been planted on 730 hectares since the mine began operating. RGC Minerals also maintained the Seminole Forest Wildlife Refuge, a 930-hectare tract near the Green Cove Springs mining site.

RGC Minerals and its parent company continued to study three heavy-mineral sands deposits, two in North Carolina and one in Virginia. The principal deposit is the Old Hickory, near Stony Creek, VA. A \$10 million feasibility study, approved in 1990, proceeded during the year. Development of the Old Hickory deposit is not expected to proceed until demand for titaniferous feedstocks and zircon improves.

Production

Two domestic mines produced rare-earth concentrates. The United States was the world's largest producer of rare earths in 1991. Producers were Molycorp, a wholly owned subsidiary of Unocal Corp., and RGC Minerals, a

wholly owned subsidiary of the Australian company, RGC.

Bastnasite was mined by open pit methods by Molycorp at Mountain Pass, CA. Molycorp's mine was the leading producer of rare earths in both the United States and the rest of the world. Mine production decreased from the previous year's level of 22,713 tons REO¹⁴ to 16,465 tons REO.¹⁵ Molycorp reportedly increased production efficiency of its high-purity lanthanide operations.

Monazite was produced as a byproduct of titanium and zirconium minerals production by RGC Minerals. Associated Minerals operated a placer dredging operation at Green Cove Springs, FL.

Reactive Metals and Alloys Corp. (REMACOR), the only domestic producer of mischmetal, operated reduction furnaces at West Pittsburg, PA.

Principal domestic producers of neodymium-iron-boron magnet alloys were the Delco Remy Div. of General Motors, Anderson, IN; Molycorp, York, PA; Neomet Corp., West Pittsburg, PA; and Rhône-Poulenc Basic Chemicals Co., Phoenix, AZ. Leading U.S. producers of rare-earth magnets were Delco Remy, Anderson, IN; Hitachi Magnetics, Edmore, MI; Crucible Materials, Elizabethtown, KY; and IG Technologies, Valparaiso, IN.

Consumption and Uses

Domestic rare-earth processors consumed 23% less rare earths in 1991 than they consumed in 1990. Bastnasite consumption was 15% lower than that in 1990, while monazite consumption decreased 10%. Shipments of rare-earth products from domestic processors of ore, concentrates, and intermediate concentrates was equivalent to 13,753 tons of REO, up 6% from the 12,975 tons shipped in 1990.

Consumption of mixed rare-earth compounds increased 10% from the 1990 level, while consumption of purified compounds decreased 16%. Higher consumption of purified compounds was primarily the result of continued strong demand for neodymium-iron-boron magnets.

The producers of mischmetal, rare-earth silicide, and other rare-earth alloys consumed 35% more rare earths in 1991 than in 1990, while shipments of these goods gained 47% during the same period. Shipments of high-purity rare-earth metals decreased 11% during the year.

The approximate distribution of rare earths by use, based on information supplied by primary processors and some consumers, was as follows: catalysts in petroleum, chemical, and pollution control, 34%; metallurgical uses as iron and steel additives and as alloys, 22%; ceramics, glass polishing compounds, and glass additives, 33%; and miscellaneous uses in phosphors, electronics, permanent magnets, lighting, and research, 11%.

Rare earths are used in hundreds of applications, ranging from 19th century traditional applications to modern high-technology uses. The applications encompass a wide range of products from mixed rare-earth compounds and metals to ultrahigh-purity products. Quantities vary by application and range from tonnage quantities to milligrams.

The following listing of uses by rare earth includes metals, alloys, oxides, and inorganic and organic compounds:

Scandium.—Metal halide lamps to improve color appearance and produce high output, laser crystals (GSGG), aluminum alloys, dual-anode tube in X-ray spectrometers, analytical standards, tracer material, and collimators in neutron lenses.

Yttrium.—High-temperature superconductor (YBaCuO), incandescent lamp mantle, phosphor for cathode-ray tubes (reddish orange), trichromatic fluorescent lighting phosphors (reddish orange), metal halide lamp phosphor (reddish orange), high-temperature sensing phosphor, oxygen sensor ceramic, laser crystal (YAG, YLF), gemstone simulants (CZ and YAG), microwave ferrites (YIG), cast iron alloys, magnesium castings, superalloys, dispersion strengthened nickel and titanium alloys, aromatization of

n-hexane, prostheses, stabilizer for silicon nitride and zirconia ceramics, microwave filters, semiconductors, acetylene lights, deoxidizer for vanadium and other nonferrous metals, solid oxide fuel cell electrolyte and anode, refractory crucibles and coatings, and high-temperature furnace electrodes.

Lanthanum.—Petroleum fluid cracking catalyst, glass additive to increase refractive index and decrease dispersion (eyeglasses, cameras, binoculars, rifle scopes, and telescope lenses), nickel hydride rechargeable batteries, hydrogen storage alloys, optical glass, solid oxide fuel cell cathode and interconnect, trichromatic fluorescent lighting phosphor (green), X-ray intensifying screen phosphors (violet, blue, yellow-green, and blue green), low-temperature sensing phosphor, phosphor lamp coating, laser glass, calcium lighting, lighting electrode, tungsten welding electrode, cast iron alloys, steel alloys, superalloys, aromatization of n-hexane, fluoride determination, conductive ceramic heating elements (chromites), dielectric ceramic capacitors (titanates), electrooptical ceramics, oxidative dimerization of methane to ethylene, antiseptic, electronic thermoemissive cathode (boride), insulation, reducing agent to convert nitrogen oxides to nitrogen, low-temperature superconductor, cryogenic refrigerant using hydrogen (LaNi₅), and semiconductors (LaAs, LaSb, LaP).

Cerium.—Glass, metal, and gemstone polishing, radiation shielding glass, glass colorization and decolorization, discolorization stabilizer, photochromic glass opacifier, ceramic pigment, ceramic glaze, enamel opacifier, carbon arc lighting, incandescent lamp mantle, trichromatic fluorescent lighting phosphor (yellow green), pyrophoric alloys including lighter flints, cast iron alloys, steel alloys, aluminum alloys, magnesium alloys, superalloys, automotive catalytic converter monolith, heat stabilizer in alumina catalyst, fluid cracking catalyst,

hydrolysis of phosphoric acid esters, oxidation of naphthalene, polymerization catalyst for olefins, corrosion inhibitor, getter in azide manufacture, getter in vacuum tubes, developing agent for aniline black, heavy metal soaps for lubricating greases and flattening agents, waterproofing and mildewproofing, dyeing and printing of textiles, ceramic capacitors, semiconductors, cathodes, desulfurizing catalysts, high-strength glass, catalyst for ammonia production, illuminant in photography, radiation dosimeter, diluent in plutonium nuclear fuels, fluorinating agent, oxidant for organic compounds, antiknock fuel additive, and pharmaceutical for sea sickness and morning sickness.

Praseodymium.—Ceramic pigment (yellow), glass colorization (light green), refractory ceramic heating element, laser crystal, aluminum alloys, magnesium alloys, permanent magnets, oxidative dimerization of methane to ethylene, and cryogenic refrigeration (PrNi₅).

Neodymium.—Permanent magnets (NdFeB), glass colorization (violet), glass decolorization, dopant in laser crystals and glass, ceramic capacitors, ceramic glaze (pinkish-violet), magnesium alloys, welder's protective glass, carbon arc lighting electrodes, catalyst for polymerization of olefins, and fiber-optic temperature sensor.

Promethium.—Fluorescent lighting starter, coatings for self-luminous watch dials, beta particle source for thickness gauges, miniature atomic batteries, semiconductor battery, X-ray source (Pm-147), and tungsten cermet for space power systems.

Samarium.—Permanent magnets (SmCo), dopant in laser crystals, neutron absorber, nuclear reactor control rod, catalyst in dehydrogenation of ethyl alcohol, catalyst in oxidative dimerization of methane to ethylene, and infrared absorbing glass.

Europium.—Cathode-ray tube phosphor (reddish-orange), trichromatic fluorescent phosphors (reddish-orange and blue), X-ray intensifying screen phosphor (violet), metal halide lamp phosphor (reddish-orange), high- and low-temperature sensing phosphors, nuclear reactor neutron absorber, nuclear reactor control rods, ceramic sensor, organic shift reagent in nuclear magnetic spectroscopy, dopant in laser crystals, and tagging agent in postage stamp glue.

Gadolinium.—Trichromatic fluorescent lighting phosphor (yellow-green), X-ray intensifying screen phosphor (yellow-green), nuclear reactor control rods, nuclear reprocessing, neutron absorbing paint, high refractive index glass, synthetic garnet for computer memory (GGG), scavenger for oxygen in titanium production, dielectric ceramics, laser crystal, cryogenic refrigeration, pharmaceutical isotope to allow scanning devices to detect osteoporosis (Gd-153), and magneto-optical recording.

Terbium.—Trichromatic fluorescent lighting phosphor (yellow-green), X-ray intensifying screen phosphors (yellow-green, violet, and blue), magnetostrictive alloys for transducers (TbFeNi), and dopant in laser crystals.

Dysprosium.—Permanent magnet addition (NdFeB), nuclear reactor control rods, semiconductors (DyAs, DySb, DyP), measurement of neutron flux, atomic weight determination, and high-temperature sensing phosphor.

Holmium.—Dopant in laser crystal, getter in vacuum tubes, and refractories.

Erbium.—Fiber-optic amplifier, glass colorizing of crystal and glassware (light pink), additive for colorization and nonreflective coating for sunglasses, infrared-absorbing glass, colorization of simulant gemstones, lasers, burnable poison in nuclear reactor, chemical catalyst for n-hexane, and permanent magnet additive.

Thulium.—X-ray source (Tm-170), dopant in laser crystal, ferrites.

Ytterbium.—Portable X-ray source for blood irradiation, dielectric ceramics, carbon rods for industrial lighting, dopant in synthetic garnet, dopant in laser crystal, and additive in special glass.

Lutetium.—High-temperature sensing phosphor and nuclear technology.

Stocks

U.S. Government stocks of rare earths in the NDS remained at 457 tons throughout 1991. Rare-earth stocks held in the stockpile were contained in sodium sulfate and were inventoried on a contained-REO basis. Rare-earth stocks in the NDS were all classified as excess to goal.

Industry stocks of rare-earth ores and concentrates held by 18 producing, processing, and consuming companies increased 25%. Bastnasite concentrate stocks held by the principal producer and three other processors increased 51% from the 1990 level. Yearend stocks of monazite decreased 24%.

Stocks of mixed rare-earth compounds increased 27%, as stocks of purified compounds increased 7%. Yearend stocks of mischmetal, rare-earth silicide, and other alloys containing rare earths gained 15%, as inventories of high-purity metals were up 79%.

Prices

Published prices for the rare earths were generally nominal and subject to change without notice. Competitive pricing policies remained in effect in 1991 with prices for most rare-earth products quoted only on a daily basis.

The price range of Australian monazite (minimum 55% REO, including thoria, f.o.b.),¹⁶ as quoted in Australian dollars (A\$),¹⁷ decreased from A\$800 to A\$900 per ton at yearend 1990 to A\$650 to A\$700 per ton at yearend 1991. Changes in the United States-Australia foreign exchange rate in 1991, resulting from a

slightly weaker Australian dollar, caused the corresponding U.S. dollar to be up \$0.02 against the Australian dollar at yearend. The U.S. price range, converted from Australian dollars, decreased substantially from US\$618 to US\$695¹⁸ per ton in 1990 to US\$494 to US\$532¹⁹ per ton in 1991.

Prices quoted by Molycorp for unleached, leached, and calcined bastnasite in standard quantities, containing 60%, 70%, and 85% REO, were \$2.87, \$2.98, and \$3.42 per kilogram (\$1.30, \$1.35, and \$1.55 per pound) of contained REO, respectively, at yearend 1991. The price for each grade of concentrate was unchanged from last year's quote.

The price of cerium concentrate quoted by American Metal Market was \$5.07 per kilogram (\$2.30 per pound) of contained cerium oxide at yearend 1991, an increase of \$0.75 from that of the previous year. The yearend price of lanthanum concentrate was unchanged from the 1990 level of \$3.09 per kilogram (\$1.40 per pound) of contained REO.

The nominal price for basic neodymium-iron-boron alloy, compiled by the U.S. Bureau of Mines, was \$22.60 per kilogram (\$10.25 per pound) at yearend, f.o.b. shipping point, 1,000-pound minimum.

Molycorp quoted prices for lanthanide (rare earth) and yttrium oxides, net 30 days, f.o.b. Louviers, CO, Mountain Pass, CA, or York, PA, effective June 1, 1991, and through the end of the year. (See table 5.)

Molycorp also quoted prices for lanthanide (rare earth) compounds, net 30 days, f.o.b. York, PA, Louviers, CO, or Mountain Pass, CA, effective June 1, 1991. (See table 6.)

Rhône-Poulenc quoted rare-earth prices, per kilogram, net 30 days, f.o.b. New Brunswick, NJ, or duty paid at point of entry, effective at yearend 1991. (See table 7.)

No published prices for scandium oxide in kilogram quantities were available. Yearend 1991 nominal prices for scandium oxide, per kilogram, compiled by the U.S. Bureau of Mines

from information from several suppliers and processors, were as follows: 99% purity, \$2,000; 99.9% purity, \$3,500; 99.99% purity, \$6,000; and 99.999% purity, \$10,000 to \$14,000. Scandium metal prices, as listed by the Johnson Matthey Aesar Group, were as follows: 99.99% purity, lump, sublimed dendritic, \$312.00 per gram; 99.9% purity, 250-micron powder, \$559.00 per 2 grams; and 99.9% purity, lump, vacuum remelted, \$405.00 per 2 grams. Historically, prices for kilogram quantities of scandium metal in ingot form have been about twice the cost of the oxide, while higher purity distilled scandium metal was approximately five times the cost.²⁰

Foreign Trade

Rare-earth imports increased in 1991 from those of the previous year. Imports of ore and compounds are shown in tables 8 and 9. As in the previous 2 years, France dominated the import market. The principal sources of U.S. imports are displayed in figure 6. (See tables 8 and 9 and figure 6.)

Domestic exports of rare earths are shown in table 10. Based on the available export data, Canada, Japan, and Brazil were the leading destinations of rare earths from the United States in 1991. This was a shift from 1990 data when Brazil, Canada, and Japan were the leaders. Principal destinations of U.S. exports are displayed in figure 7. (See table 10 and figure 7.)

World Review

Industry Structure.—Bastnasite, the world's principal source of rare earths, was mined as a primary product in the United States and as a byproduct of iron ore mining in China. Significant quantities of rare earths also were recovered from monazite, a byproduct of heavy-mineral sands mined for titanium and zirconium minerals or tin minerals in Australia, Brazil, China, the C.I.S., India, Indonesia, Malaysia, the Republic of South Africa, Sri Lanka, Thailand,

Taiwan, and the United States. Smaller amounts of rare earths, especially yttrium, were obtained from the mineral xenotime. Xenotime was recovered primarily as a byproduct during processing for tin minerals in Malaysia, Thailand, and Indonesia, but was also produced as a byproduct of processing titanium and zirconium minerals in Australia and China. Rare earths, including yttrium, were also produced from rare-earth-bearing clay in China. The C.I.S. also produced rare earths from the minerals loparite and synchisite-(Y), and from uraniferous phosphorites.

Scandium was recovered as a byproduct of processing ore for tungsten, tin, iron, and beryllium in China, and was previously produced as a byproduct of uranium processing in the United States. (See tables 11 and 12.)

Reserves.—World reserves of rare earths were estimated by the U.S. Bureau of Mines at 83 million tons of contained REO. World reserves were revised upward for 1991 as a result of additional data on the C.I.S. Rare-earth reserves for the Commonwealth of Independent States, which were previously estimated, were reported at 21.4 million tons.²¹ The effect of the large adjustment in world reserves was that China's share of world reserves dropped to 50%.

Australia.—Carr Boyd Minerals Ltd., a subsidiary of Ashton Mining Ltd., continued feasibility and pilot plant studies at its Mount Weld rare-earth-bearing carbonatite. The company also completed an extensive environmental plan, and approval for permitting was expected. Located 35 kilometers south of Laverton, Western Australia, the carbonatite's principal ore minerals are secondary monazite (thorium-deficient) and cheralite. Other rare-earth ore minerals in the deposit are rhabdophane, monazite, cerianite, florencite, and churchite. Mount Weld, one of the richest grade rare-earth deposits in the world, lists reserves at 15.4 million tons grading 11.2% REO,

which includes 1.3 million tons grading 23.6% REO.²² A decision on the project is expected by the end of 1992.

RGC cut back production of separated mineral sand products in 1991 in response to decreased demand. Commissioning of a new mine, the Eneabba West, is expected to occur in 1992 to replace the Eneabba North deposit, which was closed in 1991. RGC noted that 140 hectares at Eneabba and 20 hectares at Capel, were rehabilitated during the year, bringing the total land rehabilitated to 985 hectares. RGC also operated a wetlands habitat center at Capel, which showed a dramatic increase in waterbird population during the year.²³

OUTLOOK

In 1992, domestic demand is expected to remain flat, except for a few growing applications consisting of neodymium-iron-boron permanent magnets, ultraviolet-blocking glass additives, and medical diagnostic agents for magnetic resonance imaging (MRI) enhancement. International demand is also expected to remain level except for a select group of rare-earth-containing products, including permanent magnets, rechargeable batteries, and automotive catalytic converters. International markets are forecast to remain very competitive for the next several years. Rare-earth supplies from the C.I.S. are expected to increase on world markets and be increasingly competitive over the next few years. If developed, Australia's Mount Weld deposit promises to be the most significant new source of rare earths of the decade. New sources and supplies of rare earths have expanded at a faster-than-expected rate during the 1980's and 1990's, a trend that is forecast to continue. The long-term outlook, therefore, is for increasingly competitive markets for the lanthanides, yttrium, and scandium.

RECYCLING—NONFERROUS METALS

By Janice L. W. Jolly, John F. Papp, and Patricia A. Plunkert

Mrs. Jolly is a physical scientist (geologist) with more than 30 years in the mining industry, including 16 years with the U.S. Bureau of Mines. Mrs. Jolly is currently the copper specialist for the U.S. Bureau of Mines, a position she has held since 1983. Dr. Papp, a physical scientist with 20 years of U.S. Bureau of Mines experience, has been the commodity specialist for chromium since 1983 and was the coordinator for this report. Ms. Plunkert, a chemist with 23 years of U.S. Bureau of Mines experience, has been the commodity specialist for aluminum since 1987.

INTRODUCTION¹

Recycling, a significant factor in the supply of many of the key metals used in our society, provides environmental benefits in terms of energy savings, reduced volumes of wastes, and reduced emissions associated with the energy savings.

The estimated value of recycled nonferrous metals in 1991 exceeded \$7.5 billion and is an increasingly important component of economic activity in the United States. Table 1 shows salient U.S. recycling statistics for selected metals. Table 2 shows salient U.S. apparent consumption and recycling statistics for those same metals. Figure 1 shows a general flow scheme for recycling. (See tables 1 and 2 and figure 1.)

Legislation dealing with recycling was introduced in Congress during 1991. Although this legislation was not enacted, similar legislative proposals are anticipated. In January 1991, a bill was introduced in the Senate that would have created a Bureau of Recyclable Commodities within the Department of Commerce. Another bill was introduced in the House of Representatives as H.R. 2746, which would have established such a Bureau within the Department of Commerce. The function of this Bureau would be to collect statistics on recyclable materials, including metals and glass, and report on such factors as technology, types, grades, prices, recycling rates, and

capacities, in addition to promoting purchasing of recycled goods. A number of the materials and objectives described in the proposed bill are currently part of the activities of the U.S. Bureau of Mines.

As part of its Commodities and Materials Program, the Bureau provides information and analysis on more than 100 raw and/or processed minerals. Collected data are assessed by commodity specialists, and information is disseminated to government, industry, and academia through consultative services and more than 100 recurring publications. This work examines and reports on minerals and materials trends as well as environmental aspects of the entire life cycle of minerals use.

The Bureau's Research Directorate included studies on recycling of advanced materials and of metallurgical residues and effluents currently discarded, on impurity control during recycling, and on design for reuse or waste minimization. Fiber-reinforced alloys, dispersion strengthened metals, titanium aluminides, and rechargeable battery replacement alloys are examples of advanced materials for which recycling technology was investigated by the Bureau. Metallurgical residues such as steelmaking sludges, fine particle slurries, rare-earth processing residues, and titanium pickle liquors were also investigated to reduce the volumes of these materials and recover contained values. To increase the efficiency of recycling, the Bureau investigated the

control of impurities such as magnesium and zinc in aluminum scrap and the removal of copper from ferrous scrap. The Bureau also investigated methods to remove heavy-metal contaminants from mineral processing and manufacturing wastes and to stabilize those heavy metals not removed. Recent research addressed copper smelter wastes, primary and secondary lead smelter wastes, and steel industry furnace dust.

Because of the increasing importance of recycling to domestic metal supply and the intense public interest, the U.S. Bureau of Mines is initiating this separate chapter on nonferrous metal recycling as part of its Annual Report series. A separate chapter on iron and steel scrap has already been part of this series for many years. The focus of this initial chapter is on aluminum and copper recycling. In subsequent years, contents will be expanded to include all nonferrous recycling information currently included as part of the chapters covering the primary commodities. These will include lead, tin, zinc, and precious metals, among others.

ALUMINUM²

Domestic Data Coverage

Domestic recycling data for aluminum are developed by the U.S. Bureau of Mines from a voluntary survey, "Aluminum Scrap," of U.S. operations. Of the 96 companies and/or plants to

which monthly or annual survey requests were sent, 74 responded, representing 78% of the total scrap consumed shown in table 5.

Background

Definitions, Grades, and Specifications.—New aluminum-base scrap, generated in the production of intermediate and end products of aluminum metal, may be pure (unalloyed), segregated (one alloy type), or mixed (two or more alloys). It includes solids, such as new casting scrap; clippings or cuttings of new sheet, rod, wire, and cable; borings and turnings from the machining of aluminum parts; and residues, drosses, skimmings, spillings, and sweepings.

New scrap is further defined as either "runaround" (home) scrap or purchased scrap. Runaround or home scrap is new scrap that is recycled by the same company that generates it; such scrap by definition never leaves the company generating it and, therefore, is never marketed as scrap. Purchased scrap is new scrap that is purchased, imported, or treated on toll by secondary smelters, the original aluminum product suppliers, or others. New aluminum scrap that is purchased from manufacturers of end products may be referred to as consumer scrap. Purchased new scrap is sometimes referred to as prompt industrial scrap.

Old scrap, all of which is considered as purchased, comes from discarded, used, and wornout products. It includes such products as aluminum pistons or other aluminum engine or body parts from junked cars, aluminum used beverage cans (UBC's) and utensils, and old wire and cable. Sweated pig is scrap that has been sweated or melted into a pig or ingot form for convenience and economy in shipping and storage. Obsolete scrap is new, unused, but technologically obsolete aluminum end products, outdated inventory materials, production overruns, and spare parts for machines and equipment no longer being used. In the United States, both sweated pig and

obsolete scrap are considered old scrap. (See figure 2.)

Industry Structure.—The secondary aluminum industry was born shortly before World War I at a time when the United States had only one primary aluminum producer. There was little need for a secondary industry prior to that time because the supply of aluminum scrap was limited. Although the secondary industry did grow during World War I and after, that growth was modest until World War II. World War II created many changes in the domestic aluminum industry. The primary industry had changed from a monopoly to a triopoly, while the secondary industry had progressed from a remelter to a smelter. Secondary smelters thus emerged from the war years with the technology needed to process huge quantities of aircraft scrap and other partially manufactured aluminum products. It was at this point in history that the secondary aluminum industry started its phenomenal growth.

Aluminum recovery from scrap has become an important component of the supply-demand relationship in the United States. Between 1950 and 1974, aluminum recovered from old scrap (post consumer scrap) accounted for approximately 5% of the total domestic demand for aluminum. Increased costs for energy and growing concerns over waste management have provided the impetus for increased recycling rates. (See figure 3.)

Aluminum recovered from scrap has shown a tenfold increase since 1950. (See figure 4.) The recovery of aluminum from old scrap has shown an even more rapid expansion over the same period of time. In addition to improvements in recycling technologies, some of the increase in aluminum scrap recovery can be attributed to a changing and growing end-use consumption pattern. Aluminum products, developed for the construction, transportation, and electrical industries, tend to have a fairly long life and are slow to enter the scrap supply stream. The emergence of the aluminum beverage can in the mid-1970's with a life cycle of less than 1 year added

dramatically to the potential aluminum scrap supply. (See figure 5.)

Aluminum scrap, in one form or the other, is recovered by almost every segment of the domestic aluminum industry. Primary producers (integrated aluminum companies), independent secondary aluminum smelters, independent fabricators, foundries, and chemical producers can recover aluminum from scrap. Primary producers and independent secondary smelters are the major consumers of aluminum scrap.

The independent secondary aluminum smelter is the core of the commercial secondary aluminum industry. Unlike scrap dealers, who buy and sell many different metals, and diecasters, who cast other metals, the secondary aluminum smelter is totally dependent on one metal—aluminum. The sole purpose of the secondary smelter is to transform aluminum scrap into a marketable product. Scrap is purchased by smelters wherever it can be purchased economically. Purchasing habits can also depend on how badly a smelter needs scrap. During periods of excess scrap supply, smelters tend to be very selective in their scrap purchases. When the supply of aluminum scrap becomes short, however, it is frequently necessary to buy scrap that would not ordinarily get recovered.

Independent secondary aluminum smelters, by definition, consume scrap and produce alloys for the diecasting industry. A cursory look at the distribution of these secondary smelters in the United States consequently reveals a heavy concentration of smelters in the automotive and appliance manufacturing areas of the country.

The other major consumers of aluminum scrap are the primary aluminum producers (integrated aluminum companies). The types of scrap processed by the primary producers tend to be more segregated than those processed by the secondary smelters. Primary producers participate in either the collection or utilization of new aluminum scrap. They frequently purchase scrap from their industrial customers or on a contract conversion

basis. Major primary aluminum producers also operate can recycling programs. These producers have set up thousands of collection centers around the country for UBC's. The large-scale aluminum beverage can reclamation programs of these aluminum producers have added substantially to the rate of aluminum recovery from old scrap. The UBC component of old scrap consumption has doubled since 1975. (See figures 6 and 7.)

Aluminum scrap is also traded in the international marketplace. Price and shipping costs are usually the determining factor in choosing whether to sell scrap in the domestic or international markets. U.S. trade in aluminum scrap has grown dramatically over the past 30 years. Most of the scrap shipped into the United States comes from Canada. However, since the mid-1970's, the major recipient of U.S. scrap exports has been Japan.

The secondary aluminum industry has developed into a major market force in the domestic aluminum industry. The recycling of scrap provides a source of aluminum that not only helps the aluminum industry to maintain its growth but also helps to conserve energy and to slow the depletion of bauxite resources.

Technology.—In recycling, aluminum-base scrap is usually melted in gas- or oil-fired reverberatory furnaces of 30,000- to 100,000-pound capacity. The furnaces have one or two charging wells separated from the main bath by a refractory wall that permits only molten metal into the main bath. The principal refining of aluminum-base scrap is the removal of magnesium by treating the molten metal with chlorine or with various fluxes such as aluminum chloride, aluminum fluoride, or mixtures of sodium and potassium chlorides and fluorides. To facilitate handling, a significant proportion of the old aluminum scrap, and in some cases new scrap, is simply melted to form a solid ingot called "sweated pig," which must be treated further to produce specification-grade ingot.

Aluminum drosses containing about 30% metallics are usually crushed and

screened to bring the metallic content up to about 60% to 70%. They are then melted in a reverberatory furnace, with the molten aluminum metal collecting on the bottom of the furnace. Salt slags containing less than 30% metallics may be leached with water to separate the metallics.

Annual Review

In 1991, an estimated 2.5 million metric tons of metal was recovered from purchased aluminum scrap. Of this total, approximately 60% was recovered from old scrap. The recovery of metal from old scrap satisfied almost 30% of the total domestic aluminum metal demand for the year. The predominant type of purchased scrap processed was UBC scrap, accounting for more than one-half of the old scrap consumed. (See tables 3, 4, 5, and 6.)

Production.—According to a survey conducted by the Aluminum Association Inc., the Institute of Scrap Recycling Industries (ISRI), and the Can Manufacturers Institute, a record 56.85 billion aluminum UBC's were recycled in the United States in 1991. This was the 20th consecutive year that the number of recycled aluminum beverage cans increased. An industry representative attributed the increase to a growing consumer recycling ethic, an increased number of communities that collect recyclables at curbside, and greater involvement and investment in can recycling by brewers, soft drink fillers, airlines, charities, and the military. Despite the increase in the number of cans recycled, the recycling rate for 1991, 62.4%, was down slightly from the 1990 rate, 63.6%. The president of the Aluminum Association cited the continuing increase in can usage and the possibility that some recyclers held cans collected during 1991 in the hope that their value might be higher in 1992 as possible reasons for this slight downturn.

Aluminum Co. of America (Alcoa) and Reynolds Metals Co. launched major promotional efforts to increase the recycling of formed aluminum containers

and household aluminum foil food wrap. In May, Alcoa announced a new program to increase the recycling of formed aluminum containers, including those used for frozen entrees, baking items, and deli trays. Alcoa and participating members of its 2,800 owned and contracted buyback and processing centers around the country began accepting clean, dry, and separated containers. In addition, Alcoa developed two pilot curbside programs designed to test the level of consumer participation.

Reynolds began a program in five market areas to promote the recycling of household aluminum foil food wrap. The cities involved were the Baltimore, MD/Washington, DC, area; Richmond, VA; San Francisco, CA; Seattle, WA; and Tampa, FL. The "Great Balls of Foil" program included television advertisements and school activities where schools competed to collect the largest ball of clean foil. Cash prizes were awarded to the winners, and the schools earned money for various programs by selling the used foil to Reynolds. Reynolds reported that their recycling centers collected almost 153,000 pounds of foil scrap during the year. Schools in Baltimore and Richmond participated in the foil contest and together collected more than 2.5 tons of aluminum foil.

Golden Aluminum Corp. announced that construction had been completed at its new 130-million-pound-per-year canstock plant in San Antonio, TX. The company noted that the rolling mill would use continuous casting technology to manufacture sheet products for the food and beverage can market. The feedstock for this plant would be recycled material, primarily UBC's. The company expected the plant to come on-line by the end of the year and to begin full-scale operations early in 1992.

Roth Brothers Smelting Corp. announced plans to increase capacity at its East Syracuse, NY, secondary aluminum smelter by 25,000 tons per year. The company said the decision was based on projections for increased use of secondary aluminum in the automotive industry.

Two companies announced plans to build plants to process saltcake, a byproduct of aluminum dross processing. Imco Recycling Inc. planned to build a salt recovery plant at its Morgantown, KY, plant, and Solar Aluminum Technology Services planned to build a plant in Wendover, UT. Both plants were expected to recover both aluminum metal and reusable fluxing salts.

Markets and Prices.—Purchase prices for aluminum scrap, as quoted by American Metal Market (AMM), fluctuated during the year, but closed the year at much lower levels than those at the beginning of the year. The yearend price ranges for selected types of aluminum scrap were as follows: mixed low-copper-content aluminum clips, 38 to 39 cents per pound; old sheet and cast aluminum, 33 to 35 cents per pound; and clean dry aluminum turnings, 34 to 36 cents per pound.

Prices for UBC's fluctuated during the year, but closed 10 cents per pound lower than prices at the beginning of the year. Aluminum producers' buying prices for processed and delivered UBC's, which began the year in a range of 42 to 46 cents per pound, reached a high for the year of 49 to 53 cents per pound in March. The price range at the end of the year was 32 to 37 cents per pound.

Secondary aluminum ingot prices, as quoted by AMM, also fluctuated during the year, but generally trended downward and closed much lower than prices at the end of 1990. The yearend 1991 price ranges for selected secondary aluminum ingots were as follows: alloy 380 (1% zinc content), 59.5 to 61 cents per pound; alloy 360 (0.6% copper content) and alloy 413 (0.6% copper content), 62.5 to 63.5 cents per pound; and alloy 319, 61 to 62.5 cents per pound.

The London Metal Exchange (LME) continued its investigation into the potential for an LME secondary aluminum ingot contract. A final decision on the introduction of such a contract was expected by mid-1992.

Foreign Trade.—Exports of aluminum scrap continued to decrease after reaching a 5-year high of more than 575,000 tons in 1989. Japan continued to be the principal destination of aluminum scrap exported, accounting for more than one-half of the total in 1991.

Imports for consumption decreased slightly in 1991 after increasing steadily over the previous 5-year period. Canada remained the major shipping country to the United States, supplying almost three-fourths of the total aluminum scrap imports in 1991. (See tables 7 and 8.)

World Review.—According to preliminary data published by the World Bureau of Metal Statistics in June 1992, world production of secondary aluminum was about 5.6 million tons in 1991. According to their statistics, the United States was the world's largest producer of secondary aluminum, followed by Japan at about 1.5 million tons, and Germany at about the 0.5-million-ton level.

Aluminum Can Recycling Europe (ACRE) published figures showing that 21% or 32,350 tons of used aluminum cans was recycled in Europe in 1991. ACRE, organized in 1987, was funded by the major aluminum can sheet producers, Alcan Aluminium Ltd., Alcoa, Pechiney, Reynolds, and Vereinigte Aluminium-Werke AG (VAW). In countries where ACRE has been active since 1987, recycling rates have grown on average 20% to 25% per year. Some of the reported UBC recycling rates for various countries were as follows: Austria, 25%; Greece, 26%; Italy, 15%; Sweden, 85%; Switzerland, 50%; and the United Kingdom, 11%.

Australia.—The UBC market in Australia was estimated to be about 30,000 tons per year. Almost 63% of all aluminum cans was reported to be recycled, and aluminum UBC's accounted for almost 38% of Australia's total aluminum scrap market. Most of the UBC's were collected through clubs, self-help agencies, and charities using one of the more than 1,100 collection centers scattered throughout the country.

Although most of the UBC's were recycled locally, some were exported, primarily to Japan.

The total Australian scrap aluminum market was estimated by industry leaders at 80,000 to 90,000 tons per year. The non-UBC scrap market was dominated by three companies: Simsmetal Ltd., Nonferral Pty. Ltd., and Affinity Metals Pty. Ltd. Simsmetal had secondary aluminum plants in Melbourne and Adelaide; Nonferral had plants in Sydney and Melbourne; and Affinity had an ingot smelter in Melbourne and a dross recycling plant at nearby Geelong.³

France.—Pechiney announced plans to build two specialized foundries for aluminum beverage can recycling in anticipation of greater quantities of cans being used in the European market in the next few years. The first was in Nogueres, where the company closed a primary aluminum smelter in October of this year. The company expected the plant to be processing 20,000 tons per year of cans by early 1992. The second plant was to be built at Pechiney's strip mill at Neuf Brisach on the French-German border. This foundry was expected to be operational some time in 1992 and to have the same capacity as the plant in Nogueres.

Germany.—Subject to the approval of the German Federal Cartel Office, Klockner and Co. and SMG Metallwerke GmbH announced an agreement to merge their secondary aluminum activities to form a new company, Sekundaraluminiumwerke GmbH (SAW). Sommer Metallwerke would own 80% of the new company, and the remainder would be owned by Klockner. Included in the merger were Sommer Metallwerke's three secondary aluminum plants, which produced about 130,000 tons per year of aluminum, and Klockner's 38,000-ton-per-year secondary aluminum plant.

Japan.—According to the Japan Aluminum Alloy Refiners Association, production of secondary aluminum and alloys in fiscal year 1991 was 1,252,300 tons, a decrease of 1.3% from the

1,268,463 tons recorded in fiscal year 1990. The association had a membership of 39 secondary aluminum producers.

Daiki Metals, a wholly owned subsidiary of Daiki Aluminium, reported the completion of a new scrap processing plant in Kameyama. Since 1985, Daiki Metals had operated a plant in Yuki that used a gravity separation process to treat scrap and to separate various metal values, including aluminum, copper, lead, and zinc. The company reportedly bought the residue left over from the shredding of automobiles, processed it at Yuki, kept the aluminum for its own use, and sold the other metals in the domestic market or exported them to neighboring countries. The new plant at Kameyama was expected to process between 1,000 to 2,000 tons per month of scrap initially. The company hoped to expand the plant to 4,000 tons per month sometime in the future.

Japan announced plans to implement a new program to increase the recycling of aluminum and steel cans. The program set a goal to raise the recycling rate on both aluminum and steel cans to 60% by 1994 from the 1990 rate of 42.6% for aluminum and 44.8% for steel.

Spain.—Production of secondary aluminum in 1991 totaled 96,000 tons, an increase of 11% compared with that of the previous year and reportedly the highest level of production in 10 years. Spain's secondary aluminum industry included about 33 companies employing approximately 500 people. Thirteen of these companies were members of Spain's secondary aluminum producers' association, Aseral, which reportedly accounted for about 86,000 tons of Spain's production in 1991.

United Kingdom.—Alcan announced the opening of a new UBC recycling plant in Warrington. The 50,000-ton-per-year plant reportedly was the first recycling plant in the European Community (EC) dedicated solely to the recycling of aluminum beverage cans.

Cookson Aluminium announced that construction had begun on a new

secondary aluminum smelter at Repton near Derby. Although the new smelter would have a design capacity of 30,000 tons per year, the net increase in capacity for Cookson would be only 5,000 tons per year. The new smelter was to replace the recently mothballed 10,000-ton-per-year smelter at North Cave on Humberside and the existing 15,000-ton-per-year smelter at Repton. The company expected the new smelter to be completed in 1992.

Europe's largest can market was in the United Kingdom, where total sales reportedly expanded from less than 6 billion cans in 1988 to more than 7 billion cans in 1991. During the same period of time, the aluminum contribution to the market reportedly increased steadily from 42% to 60%. The United Kingdom began its national can recycling activities in 1989, and recycling rates for aluminum cans have doubled from a reported rate of 5.5% in 1990 to an 11% recycling rate in 1991.

Current Research.—Production of aluminum extrusions involves the generation of relatively large quantities of process scrap in the form of billet butt ends, extruded section cutoffs, and rejected lengths of extrusions. As a rule, the quantity of scrap generated amounts to about 20% to 25% of the metal used. The quantities of recyclable in-house scrap for extruders usually ranges between 2 and 30 million pounds per year. Some extruders had expressed an interest in remelting their own recyclable scrap in-house. However, conventional billet casting shops reportedly could not be economically built and operated for these small production quantities. A new concept was therefore developed in which a melting and casting furnace was designed so that scrap could be continually charged and molten metal continuously tapped. The molten metal was then cast continuously in a small horizontal continuous casting unit. The cast logs were automatically cut into billets of any desired length by a saw integrated into the casting unit and conveyed to a billet storage table.

Instead of the usual batch operations, continuous production took place.⁴

All molten aluminum processes generate dross: from 1% to 2% for holding furnaces at primary smelters, 3% to 5% for scrap melting furnaces, and even higher for thin gauge materials. Dross can contain up to 70% metallic aluminum. The classical dross-recycling process is the rotary salt furnace process. The patented Alcan dross treatment process uses a water-cooled plasma gas arc heater (plasma torch) installed in a specially designed rotary furnace. A stack from the furnace conducted dust emissions to a bag collector. The new process completely eliminated the salt flux used in the conventional dross treatment process. Alcan reported metal recovery efficiencies of 85% to 95% for this new plasma process.⁵

Most of the major producers of aluminum-lithium (Al-Li) alloys have taken the position that the airframe manufacturers must segregate scrap. The airframers have resisted this, and most of them have insisted that recycling, particularly lithium recovery, should be addressed by the producers. So far, only a few have processed the small quantities of Al-Li scrap available by diluting with large quantities of conventional aluminum scrap and then removing the lithium by chlorine fluxing. This worked for very small volumes or on a trial basis, but was impractical for long-range operations. When larger quantities are available on a continuous basis, it is not known how much producers will or can process with dilution, whether they can handle it with environmental acceptability, whether or not they will be interested, and just how much they will be willing to pay for it. Alcoa reported the development of a process for handling mixed scrap that stripped the lithium into the dross and resulted in a recovered ingot with less than 10 parts per million (0.001%) lithium residual. The company noted that it was also working on a process for lithium recovery from that dross.⁶

Outlook

The driving forces behind the increasing use of resource recovery as an alternative to sanitary landfill are both economic and political. The increasing costs of suitable land for landfills, the stringent regulations on leachate control, and other costs are making resource recovery more attractive. Aluminum scrap has been the highest unit valued commodity recovered from municipal refuse. It has been estimated that metals represent about 9% by weight of municipal solid waste (MSW), but only about 3% in terms of volume. While the aluminum can composes less than 1% by weight of MSW, it frequently represents more than one-half of the revenue collected by municipal recycling programs. The public and industry have recognized the economic and ecological value of recycling aluminum cans. Through aggressive promotion and expanding collection methods, the volume of aluminum cans being recycled into the aluminum supply stream has increased dramatically year by year.

As the public and industry become more sensitive to the issue of waste management, the benefits of recycling will become more evident. The aluminum industry, with its long history of recycling experience and its vast network of collection centers, will be well-positioned to take advantage of this increased interest. The domestic and world secondary aluminum industries should continue to expand. In the short term, the growing acceptance of aluminum beverage cans (with their very short life cycle) in overseas markets could lead to a more rapid growth in the recovery of secondary aluminum in countries outside the United States, where the aluminum beverage can already dominates the market. However, as more and more aluminum is used in products with longer life cycles, such as automobiles, more scrap will enter the market for recovery and increase the secondary production levels in both the domestic and world markets of the future.

COPPER AND COPPER ALLOY SCRAP⁷

Background

Definitions, Grades, and Specifications.—The Institute of Scrap Recycling Industries Inc. (ISRI) recognizes about 53 classes of copper and copper alloy scrap and issues a scrap specifications circular each year that is widely used in the trade.⁸ Although there are several grades of scrap within each, the major unalloyed scrap categories were known generally as No. 1 copper (common names—Barley, Berry, Candy, and Clove), which contained greater than 99% copper and often is simply remelted, and No. 2 copper (common names—Birch, Cliff, and Cobra), which usually must be re-refined. In addition to the many copper and copper alloy scrap types, there are many special types such as lower grade skimmings, ashes, and residues, which contain 12% to 30% copper, and others of lower copper grade such as electronic scrap, refining slags, printed circuit and other clad materials, and metal-laden waste liquors.

Copper scrap is classified into two general categories called old and new scrap. *New scrap*, or manufacturing scrap, is generated during the fabrication of copper products and returned to the mill for reprocessing, or sold, and is not considered a new source of copper supply. *New scrap* is termed "runaround" or *home scrap* when it was generated internally at the plant reusing it, or it may be called *purchased return scrap* when returned by a customer from a plant external to that purchasing and reusing it.

Old scrap is generated from worn out, discarded, or obsolete copper products and thus, is considered to be a new source of supply.

Resources.—Since World War II, the ever-increasing reservoir of copper products in use, much of which was eventually recycled as "old" copper, has provided annually between 19% to 33% of U.S. apparent demand and, on

average, has provided about 18% of world copper demand. The U.S. scrap reservoir of items in use, or abandoned in place, over the same period has increased from about 16.2 million tons in 1940 to about 69.8 million tons, increasing since 1983 at the rate of about 1.2 million tons per year. This scrap "reservoir" does not include a sizable and growing pool of "new" scrap that is recycled every year. As shown in figure 8, new scrap currently comprises about 25% of total U.S. copper consumption; total scrap comprises about 44% of consumption. In 1940, the world copper reservoir of copper materials in use, or abandoned in place, was about 32.9 million tons; by 1991, this potential reservoir of scrap exceeded 189.5 million tons, as shown in figure 9. The U.S. share of the world's copper scrap reservoir has been decreasing, from 49% in 1940 to about 37% in 1991. (See figures 8 and 9.)

The U.S. Bureau of Mines reported⁹ that in 1974 about 70% of all copper products that were on the market, or had become obsolete, was not being recovered. If recovery methods and scrap prices continued as they were at that time (1961-70), the annual increase of unrecovered copper in the U.S. scrap reservoir was expected to be more than 2.2 million tons by the year 2000. Of this amount, about one-half would lie in the consumer and general use areas. Copper that is not recovered may be placed in one of three categories: (1) still in use and unaccountable, (2) solid waste disposal, and (3) dissipated and lost. It was estimated that as much as 30% to 50% of the unrecovered copper products was entering solid waste disposal sites. Copper has few applications that are dissipative by nature; only about 0.5% of total copper consumed may be lost and unretrieved, such as copper used in chemicals. Items still in use, or unaccountable, may be recycled at some future time, but because of copper's long life, this is not immediately necessary or convenient in many cases. The recovery of some items may be delayed because of the economics involved; for example, some buried cables may not be recovered

until such time as market prices permit the cost and time needed to recover them.

The availability of copper scrap is linked with the quantity of products consumed and their life cycles, or duration. Many estimates have been made about individual products, and these product lives may even vary from country to country, according to construction methods and concepts. However, according to one source, copper in electrical plants and machinery averages 30 years; in nonelectrical machinery, 15 years; in housing, 35 years; in transportation, 10 years; and in all other end-use sectors, about 10 years. The average for the industry was roughly estimated to be about 25 years.¹⁰

Using this 25-year average for copper recyclability, one analyst calculated a theoretical scrap availability trend.¹¹ The total amount of available scrap can be obtained by comparing annual consumption of past years with statistics of scrap to be recycled 25 years later; the result gives 75% as the average rate of recovery from 1959 to 1965. This theoretical calculation further predicted that scrap availability would increase by 39% over the period between 1984 and 1990, or about 5% to 6% per year. Because total world copper consumption increased only an average of 2.4% over this time, the percentage contributed by world scrap should always get higher. If this were always the case, scrap might be expected to not only become gradually more abundant, but also more available. However, there are many more considerations in the recovery of copper scrap that limit the economics of its immediate recovery according to this theoretical schedule. For example, some analysts recently have estimated that, because of manufacturing efficiencies developed, the percentage of "new" scrap generated by U.S. manufacturers has fallen to one-half that of 20 years ago. Thus, while manufacturing levels may recover after the 1991 recession, the new scrap level will be lower. In addition, because of the move toward low-lead alloys, consumers will become more reliant on No. 1 copper. The industry predicted that there will be a decline in

the use of leaded auto radiators and other high-lead scrap.¹²

The rate of old scrap recovery is limited not only by copper's long life, but also by its essential uses and by the sensitivity of scrap collection to market prices. On average, the rate of old scrap recovered in the United States, as a percentage of total scrap consumption, declined from 50% to 60% in the 1940's to almost 40% in the 1980's. The decline in the old scrap component was the result of an increasing manufacturing base from which to generate new scrap and of a demand pattern changing to one dominated by electrical uses. Electrical items, which now account for more than 70% of copper consumed, were less likely to be substituted, replaced, and scrapped than items in other end-use sectors. The long service life for utility and building cable, among other reasons, results in a practical limit to the amount and rate at which old scrap from this source can be recovered. Historically, old scrap recovery not only improved during periods of high refined copper prices, but also increased at any time that primary supplies became scarce, including the deep recessionary years of the 1930's. Scrap recovery is very price and cost sensitive. More obsolete scrap surfaces as the value of primary copper increases. Public utilities with obsolete and unused cable, either buried under the earth or lying in sewers, begin to study the cost of recovery when the prices are high enough.

Preparation and Processing Technology.—Because scrap is a bulky material, the customary practice is to bale light scrap and cut heavy scrap to size so that it can be handled. An important copper recycling material is cable scrap. Whereas burning the cable to remove the plastic parts previously was acceptable, this is no longer always possible or desirable. Thus, mechanical dismantling of the cables is common practice through cutting, granulating, and use of various metal separation techniques to separate the plastics and fluff from the metal. The cable is granulated to about 30 millimeters. The plastics are removed

during the granulation stages by air classification. Iron impurities can be removed by magnet and aluminum and copper separated by weight. Cables with lead or tin impurities have to be refined after processing at a secondary smelter.

Most old scrap retrieved from the marketplace must be reprocessed either by smelting and refining, or by leaching and electrowinning to form a pure copper product. Fire refining in a reverberatory or other furnace may be sufficient for the better grades of scrap. The fire-refining process uses oxidation, fluxing, and reduction, and a refined ingot, wirebar, slab, or billet is usually poured. The reduction is accomplished by partly covering the molten metal with coke and inserting green wood poles through the furnace door. Copper oxide in the melt is converted to copper by the reducing gases formed. For higher grades of refined cathode, however, the poorer grades of scrap must be first smelted with various fluxes, poled to remove oxygen, and then poured into anode form for further processing in an electrolytic refinery. Byproducts, such as tin and precious metals, may be retrieved during the preliminary procedures of smelting or during refining from the tankhouse sludges. Other impurities, such as antimony, arsenic, iron, and lead may be removed in the slag by fluxing.

The most complex copper-containing recycling material is electronic scrap. Electronic scrap arises from computers and increasingly from other durables and printed circuit boards. The relatively high gold and silver content makes this scrap economically attractive. On the other hand, electronic scrap not only contains valuable metals, but also plastics, organic flame retardants, and ceramics. Mechanical dismantling by crushing and separation by means of density or conductivity is one way to process this material. Thermal dismantling also can be done, but with some problems in controlling the toxic pyrolysis gases. More recently, some companies have developed leaching, solvent-extraction, and electrowinning procedures for treatment of certain types of electronic and circuit board scrap, as

well as waste fluids that contain copper and other metals. A low-grade copper cathode, copper sulfate, copper oxides, copper precipitates, and byproduct metals can be produced through this method.

Black copper (75% to 80% copper) is the principal product of the blast furnace and still contains some iron and zinc along with most of the lead, nickel, and tin of the charge. Traditionally, this material is refined in a scrap converter, which is of a more modest size than its primary cousin; also, coke is added liberally to the charge, adding extra heat and providing a mildly reducing condition, thus facilitating removal of lead, tin, and zinc in the gas stream. A copper anode is poured for final refining in an electrolytic tankhouse.

The flue dust of the smelter or converter process contains mainly lead, tin, and zinc, most of which is recovered when the dusts are processed. A Pierce Smith converter or a Top Blow Rotary Converter (TBRC) can be used for the converting process of alloy scrap. The TBRC consists of a cylindrical vessel that rotates on its midaxis. Processing of complex copper-containing materials, such as drosses, flue dust, catalysts and collector dust, slimes from electroplating wastewater, and metal-rich slags from converter processes, also requires versatile production processes. Reverberatory or electric rotary melting furnaces are used for casting various copper forms, such as slabs, cakes, or billets. Asarco shaft furnaces may be used with holding furnaces in conjunction with continuous casting systems.

Metallurgical wastes, such as mine waters, effluents, and sludge from hydrometallurgical and electrochemical plants may contain many valuable metals along with toxic chemicals. These wastes, if discharged directly into the sewage system, cause pollution. Most plants have built-in water recirculation systems where practical, attempting to reuse and recapture some of the metal content. Many of these wastes must be treated for metal recovery. In general, a combination of various hydrometallurgical techniques such as precipitation, cementation, ion exchange, solvent

extraction, reverse osmosis, gaseous reduction, and electrolysis are used. Cementation has been successfully employed to recover copper from waste effluents. Solvent extraction and ion exchange are highly selective methods for treatment of solutions to separate copper from other common metals.

There have been various analyses of energy costs of refining, but an Italian study reached the conclusion that the cost of producing secondary copper was about one-half the cost of producing primary copper. In fact, excluding the energy content of materials used, which can be estimated at about 5 gigajoules (Gj) per ton, refined copper from ore would require about 70 Gj of total energy, while to recover pure copper from scrap would require only about 35 to 40 Gj per ton.¹³ Another source indicated 28.2 million kilocalories per ton for producing primary copper from ores and only 4.5 million kilocalories per ton for secondary copper.¹⁴

Industry Structure.—The scrap consuming industries of the United States include secondary smelters and refiners, ingotmakers, brass and wire rod mills, foundries, and miscellaneous manufacturers and chemical plants. Fabricators such as the brass and wire rod mills prefer to use clean scrap as much as possible to conserve on using more expensive primary refined metals. Certain technical limitations can limit how much scrap can be used, but it is generally possible to use 100% scrap if it is available in proper form and composition. Factors affecting the maximum amount of scrap used include the greater manual effort needed to charge to furnace; longer melting times for scrap if it is fine or loose, resulting in fewer pounds produced per furnace and worker-hour; and lastly, the availability of suitable scrap. Parts of the copper industry are very scrap intensive. Certain industries, such as the brass rod industry (80% to 90% scrap) use higher amounts of scrap than others by tradition. Others, such as brass sheet and strip (10% to 75% scrap), use less.

In both Europe and the United States, many smelters and refiners use scrap as feed, a trend that has been increasing along with the need for purer forms of copper. In addition to secondary smelters, the concentrate smelters also are strong competitors for some classes of scrap, prompted by the lower unit cost. In recent years, about 40% of refined copper produced in Western Europe and about 22% of refined copper in the United States were derived from copper scrap. Copper scrap accounts for about 19% of the world's refined copper production. A manufacturer may generate up to 60% of scrap as clippings, trimmings, stampings, borings, and turnings when processing copper and copper-base products into finished articles. This "new" scrap is readily used by brass and copper tube mills to generate new semifabricated forms with very little treatment. Because minimal cleanup procedures are needed, this type of scrap is commonly called "direct melt" scrap. In the United States, direct melt scrap provided about 66% of the total scrap supply in 1991, or about 807,000 tons.

Most wire rod mills use very little scrap as direct feed without further processing. Advances in continuous-cast rod technology require some mills to use very clean, high-grade scrap, if used directly at all. Scrap comprises less than 5% of feed used. Brass mills are principal consumers of No. 1 copper scrap and account for more than 75% of the copper alloy scrap intake. Scrap purchases by brass mills are based primarily on activity levels at the mills and the relative price between cathode and No. 1 scrap, rather than upon overall copper prices. When business conditions are strong, brass mills have access to large volumes of return scrap. Scrap imports also help. When both manufacturing and imports decline, mills may increase their cathode purchases.

Almost all of the copper raw material used to make specialty alloy ingot for use in foundries was scrap, much of it used in a direct melting process. In the United States, four secondary smelters and refineries are associated with copper tube

mills or wire rod mills. Three companies fire refine for direct use or sale to the market or smelt low-grade copper scrap to produce anode, blister, or black copper for further refining by another company. There are about 28 ingotmakers, 1 of the largest of which is associated with a foundry, and about 700 foundries. All of these companies consume scrap as their basic raw material.

Large quantities of slags are produced in copper smelting plants. Depending on the ore or scrap quantity being processed, up to 4 tons of reverberatory slags will be generated in the production of 1 ton of copper. Limited space in many plants has encouraged research activities into finding uses for slag. This resulted in the development of a number of uses, such as railroad ballast, aggregate for roadmaking, soil conditioners, slag wool, in foamed form as porous aggregate for lightweight concrete, and in granulated form for cementmaking and so forth. In recent years, demand for home insulating materials, due to the increasing cost of energy, has prompted researchers to promote making mineral wool from copper reverberatory slags. The aforementioned products are only manufactured when the metal content of the slag is very low. Whether a slag is discarded is a matter of economics as well as of environmental considerations. Metal recovery from the slag is worth considering if it contains more than 1% of primary nonferrous metal.¹⁵

Annual Review

Legislation and Government

Programs.—Under consideration in the United States in 1991 were stricter regulations for emissions, higher costs for waste disposal, legislation limiting the lead content of alloys and in drinking water, and the Basel Convention. Legislation limiting the content of lead in copper alloys was being considered. The industry claimed that improperly applying waste-handling laws to scrap could have a stifling effect on recycling.

On June 7, 1991, the EPA published the final rule for the National Primary

Drinking Water Regulations and Maximum Contaminant Level Goals for Lead and Copper in Drinking Water (56 FR 264460). Under the rule, water delivery systems would be required to optimize corrosion control treatment if one of the following action levels was exceeded at consumers' taps: an average lead level greater than 0.010 milligrams per liter (mg/l); a copper level in 5% of the samples exceeding 1.3 mg/l; or a pH of less than 8.0 in 5% of the samples. In addition, water delivery systems would be required to implement public education, as specified, if the level of lead exceeded 0.02 mg/l in 5% of the tap samples. The final rule would apply the lead and copper action levels as a trigger for corrosion control treatment only to systems serving less than 50,000 persons. Larger water systems would have to install treatment to minimize lead and copper levels at consumer taps. Based on source water and tapwater monitoring, a State may determine that source water treatment is necessary to minimize lead and/or copper levels.

The secondary processing industry claimed that a major portion of the scrap export market could be curtailed if the Solid Waste Disposal Act (SWDA)(H.R. 3736) was implemented. If scrap metals are found to be hazardous waste under Section 201 of the SWDA, then the export controls of SWDA would govern their entry into international trade. In addition to adverse scrap export effects, at proposed 0.1% heavy-metal concentration, the legislation defined many discarded consumer goods as hazardous even though these same goods currently were being recycled safely with no harmful release of hazardous constituents, according to the industry. Metallic products that would come under the hazardous definition included such commonly used items as stainless steel flatware and foil wine wrappers. For many, if not most, metals recyclers, becoming classified as hazardous waste facilities would be economically disastrous. The legislation defined as hazardous many millions of tons of metals recycled each year, based on the presence of certain heavy metals, with no

evidence for low level toxicity of these metals. This legislation would deem as hazardous waste any discarded material that contained more than 0.1% of any heavy metal, such as beryllium, cadmium, chromium, lead, mercury, and nickel. This proposal grew out of concern that wastes bearing heavy metals could release those metals to the environment. Thus, stainless steel, with far more than 0.1% nickel and chromium, would be deemed hazardous, regardless of whether the heavy metals could escape into the environment. Copper, brass, bronze, galvanized steel, and other metals that are commonly and safely recycled also would not pass this test.

Issues.—The cost for dumping hazardous materials, such as lead-containing plastic wire coverings and fluff, is high. While acceptable in some other nations, such as in Japan, incineration to destroy some of the unwanted plastics in the United States does not appear to be an acceptable solution for much of the covered wire. Cable scrap is an important source of metal, and whereas the plastic parts of the cable were removed previously by burning, stringent legislation on emissions has restricted this procedure. Thus, mechanical dismantling of cables has become common. An estimated 340,000 tons of cable is chopped every year in the United States, resulting in about 158,000 tons of plastic waste that must be disposed of in some way. Thermoplastic resins are recyclable, but some high lead-containing plastics are not. Lead is used as a stabilizer in plastic cable coverings. Although choppers do not present the air pollution problems that incinerators do, there are landfill problems with plastic byproducts. For some types of wire, such as the so-called grease wire, which tends to gum up choppers, wire-burning is preferable and continues to be done. The wire scrap processing industry continued to investigate all areas of plastics use.

A new joint venture between U.S. and Canadian interests was formed to process thousands of tons of vinyl fluff generated by a wire chopping operation. B.F.

Goodrich, I. Waxman & Sons, and Plastic Recovery Systems Inc. were planning to have a pilot plant built and operational by early 1992.¹⁶ Plastic Recovery Systems developed reclamation technology to separate complex wire and cable fluff, and B.F. Goodrich developed the process to further refine the scrap polyvinyl chloride into new products. Waxman planned to build the 15-million-pound-per-year upscale pilot plant. First to make a commercial product as a result of the technology was Utility Plastics, a subsidiary of Brooklyn Union Gas, which was making traffic cones for the U.S. Department of Transportation.

In late 1990, the EPA issued a strategy for reducing lead exposure based on a goal of reducing lead exposures to the fullest extent through market-based incentives to limit or eliminate lead use; using regulatory mechanisms, such as the Toxic Substances Control Act (TSCA), to reduce the use of lead in current and future products; and identifying and encouraging cleaner technologies for mining, smelting, and processing lead. Studies were to be made on potential hazardous exposures that might occur in the future after disposal of any lead-bearing product, including copper alloys. The EPA would explore the desirability and feasibility of discouraging overall consumption of lead in any form.

The Lead Exposure Reduction Act (S. 2637 and H.R. 5372) and Lead Ban Act of 1990 (S. 2593) were viewed by the scrap industry as having the potential to impede copper alloy recycling in the United States. Restrictions would have been placed on solder (greater than 0.1% lead), copper alloy plumbing fixtures (greater than 2% lead), and many other items, such as soldered copper pipe, many lead-containing plastics wire coatings, and brass and copper plumbing fittings and construction materials, as well as the scrap materials derived from them. The Brass and Bronze Ingotmakers testified that these bills, which sought to restrict all lead-containing products, could actually result in more lead being released into the environment if such laws were passed. Currently, much of the lead-bearing

copper alloy material is safely recycled, but the legislation could result in at least 6 to 10 million tons per year going to landfills, where lead could leach into the ground waters. The industry asked for rewording of the legislation to state clearly that it does not apply to the processing or distribution of copper alloy products of the recycling process. A new organization, Recyclers of Copper Alloy Products (RE-CAP), was formed to make the industry's views known. Among the members were the following: the Brass and Bronze Ingot Manufacturers, Inc.; the Copper Development Association; the Copper and Brass Fabricators Council (CBFC); the ISRI; the American Foundrymen's Society; the American Cast Metals Association; the Non-Ferrous Founders' Society; the Plumbing Manufacturers Institute; the Air-conditioning and Refrigeration Institute; and the American Pipefittings Association.

Leaded copper alloys were presenting numerous problems to foundries in the United States, from disposal of wastes and industrial hygiene, to increasingly stringent requirements on the lead content of plumbing fittings. Alternatives to leaded copper alloys were being developed; however, any of these alternatives would require a source of lead-free copper scrap for ingot producers. Currently, much of the copper scrap available to ingot producers contains lead. Without a viable process to remove lead from the recycle stream, the costs of lead-free alloys may be prohibitive because of the demand on lead-free scrap. Alternative leaded-copper substitutes under consideration include the bismuth-copper alloys; however, bismuth also has a deleterious effect on other classes of copper alloys. Therefore, a way must also be found to remove bismuth, as well as lead, from the copper scrap stream to successfully implement the new lead-free alloys.

The Basel Convention, negotiated in 1989 under the auspices of the United Nations Environment Program (UNEP), eliminates uncontrolled transboundary movement of hazardous and other wastes between nations, provides for

accountability for waste movement, and encourages self-sufficiency in waste treatment. As currently written, the convention separates recyclables from other waste and recognizes the international community's need to trade in recyclables; however, "hazardous waste" is defined much more broadly than in current U.S. law and regulations. The convention becomes effective 90 days following 20 countries ratifying the document. EC ratification and implementation was not expected until early 1992. Eleven countries had ratified the treaty by yearend 1990. Another 53 countries, including the United States, have signed a United Nations document indicating an interest in ratifying the agreement. Although the United States was a signatory to the convention, the ratification process will take 3 years or more. Because the convention prohibits trade in wastes with nonparticipants, U.S. metal scrap trade with other countries could be limited if the convention is activated prior to U.S. ratification. In addition, the regulatory scheme under Basel could be cumbersome and documents may duplicate existing procedures.

The Organization for Economic Cooperation and Development (OECD) was developing a protocol for issues relating to the convention. A three-tier scheme was proposed that would designate a "green list," requiring no controls other than those normally applied in commercial transactions. Most copper scrap would be included in the "green list." Wastes that would be on an "amber list" would be subject to some restrictions of the Basel Convention and would include most metal ashes, sludges, and residues. Wastes on the "red list" would be subject to most restrictions. No metal wastes are on the latest version of the red list.

Complaints surfaced in the press regarding the use of ferrous scrap waste, such as food cans, to recover copper from leached copper ore. Some critics felt that this process was setting a "dangerous precedent for the use of recycled materials." The process was considered by others as a legitimate use

of steel scraps that would otherwise add to already overloaded garbage dumps and would reduce the amount of mining needed to produce the same amount of copper.¹⁷

Production.—Smelting and Refining.—In the United States, a shift toward refining more scrap has been evident for a number of years, as shown in figure 10. This change was coincidental to a change in wire rod technology that resulted in a requirement for a higher grade of cathode for continuous casting machinery. It also coincided with the growth in smelting and refining in other countries, which served to deprive the United States of sufficient blister and concentrate imports during the 1960's and 1970's. With the exceptions of the Great Depression and World War II, refined copper from scrap was only 7% to 15% of production. Since 1940, the proportion of scrap being refined has increased significantly while the foreign component decreased in equal magnitude. In 1941, 30% of refined production was derived from foreign materials, while about 8% was from scrap. In 1991, only 3.9% of U.S. refined production was from foreign materials, while 21% was from scrap. (See figure 10.)

Ingotmaking.—Some ingotmakers were concerned over the viability of the domestic ingot industry. U.S. brass and bronze ingot production has contracted from about 250,000 tons in the early 1970's to only 162,000 tons in 1991, and may be facing further contraction. The ingot category most severely affected was the leaded-red brass and semired brass ingot alloy group, which has decreased from about 150,000 tons in the early 1970's to only 98,600 tons in 1991. High-leaded tin bronze has also decreased from about 26,000 tons per year in the 1970's to less than 9,000 tons per year since the mid-1980's. However, one major ingotmaker believed that the exacting requirements of new lead-free alloys could stimulate exports of alloy ingot, in lieu of scrap, to offshore foundries that lack the technical expertise

to produce these alloys.¹⁸ This trend would increase demand for already tight supplies of No. 1 copper scrap, while creating a pool of unusable leaded brass scrap.

Foundries and Chemical Plants.—The number of U.S. foundries has diminished over the years, following the fate of the steel, automobile, space, and other industries that they service. Currently numbering about 700, only a few foundries are really large; most foundries are very small operations that cast select parts for many U.S. industries from a wide variety of cast copper alloys. Most copper chemicals are made from scrap, which is leached, formed as cupric and cuprous oxides, and copper sulfate and, eventually, a variety of other copper chemicals. Copper and copper alloy powders are also made from refined copper and copper alloys that were derived from scrap.

Consumption.—In 1991, about 1.6 million tons of copper-base scrap containing an estimated 1.23 million tons of copper was consumed in the United States. The largest scrap categories were: No. 1 copper, 28%; No. 2 copper, 22%; leaded yellow brass, 16%; low-grade ashes and residues, 9%; yellow and low brass, 7%; automobile radiators, 6%; red brass, 4%; and cartridge cases, 4%. A wide variety of alloys made up the remaining 4%. Brass and copper tube mills processed 66% of No. 1 copper and most of the cartridge cases and yellow brass, while the secondary smelters and ingotmakers processed 89% of the No. 2 scrap and most of the auto radiators and red brass scrap. With a few exceptions, U.S. wire rod mills did not consume purchased scrap directly. One U.S. wire rod-producing company constructed a continuous-process scrap refining and wire rod casting plant in which No. 1 return scrap from its own plants was processed.

According to industry sources, the quantity of scrap available during 1991 was the lowest in some time. Along with the generally lower refined copper prices, this was having an impact on scrap

prices, reducing spreads and profits. Observers listed several reasons for the scrap shortage. Normally high during periods of slow economic activity, scrap inventories were low, having been worked down over the long period of healthy prices since 1987. In addition, the slower economy had reduced manufacturing (production of new scrap) and reconstruction (demolition) and thus, the opportunity for generation of old scrap. Manufacturing processes also were becoming more efficient with less generation of scrap. Some observers estimated that the amount of scrap generated by the U.S. industry has declined by more than 50% per manufactured item over the past 20 years. A global shortage of scrap also was stimulating export demand for scrap and further tightening domestic availability. The net result was that, regardless of price, many scrap dealers were at times unable to provide more than one or two trailerloads at a time. It was anticipated that when the economy recovers, scrap supplies may be tight because no stocks will have accumulated during the current slow-growth period.

Markets and Prices.—Scrap prices are related to the refined copper price, but the price spread must be sufficient to allow for processing costs and the inherent costs of scrap preparation (collection, sorting, shipping, chopping, briquetting, etc.). If the spread is too narrow, the copper processor cannot charge enough for the end product, which also is determined by the refined copper price, to compensate and, thus, cannot make a profit. Unlike primary production, where numerous factors combine to keep a mine open at prices below operating costs, scrap processors and dealers need to meet operating costs. At times of high refined copper prices, more copper scrap is offered to processors, if available. On the other hand, if refined prices are low, less scrap material enters the market. The terms that scrap smelters can charge for processing becomes uneconomic as the gap between scrap price and refined price narrows.

Trends for Brass Mill No. 1, Refiners No. 2, and Dealers No. 2 prices are compared with the Commodity Exchange of New York (COMEX) first position price and with the U.S. producers, delivered, refined copper prices from 1970 to 1991 in figure 11. It can be observed that Brass Mill buying prices for No. 1 scrap generally track that of the delivered producers refined price and COMEX first position price, but is generally below them. The No. 2 scrap prices are below these, allowing for differences in processing costs. The spread between refiners buying price for No. 2 scrap and the producers' refined copper price has varied from 9 cents in 1970, 27 cents in 1980, to 21 cents in 1991. The low spreads in the early 1970's were caused by price controls placed on U.S. copper prices during this period. The very high spreads of the late 1980's, as shown in figure 12, which averaged above 30 cents per pound, were the result of high refined copper prices and a good supply of scrap. Prices also tend to widen when speculative interest is active on the futures exchanges, such as is the case when the copper price is high. The spreads have been decreasing since the high point of 1987, as a result of lower refined prices since that time. (See figures 11 and 12.)

In 1991, scrap prices were higher in the first 4 months of the year, but softened beginning in May. By September, scrap prices again recovered, closely paralleling that of refined copper. Scrap prices, like refined prices, were generally lower than those in 1990.

Yearend scrap inventories, as reported to the U.S. Bureau of Mines, at smelters, refiners, ingotmakers, and brass mills decreased from 94,381 tons in 1987 to 85,919 tons in 1991. However, these figures disguise opposing inventory trends between smelters and refineries, which increased from 48,276 tons of copper scrap in 1987 to 53,970 tons at yearend 1991, and brass mills, where scrap inventories decreased markedly from 46,105 tons in 1987 to 31,949 tons at yearend 1991. Scrap consumption trends would also appear to be diverging. In 1991, compared with 1990, scrap

consumption was 3% higher at smelters and refiners (including refiners at copper tube and wire mills), but was 8.4% lower at ingotmakers and 7% lower at brass mills.

Foreign Trade.—U.S. scrap shipments have dominated the international scrap market in recent years, taking advantage of the fall in the value of the dollar against European and Asian currencies since 1986 and relatively cheap freight rates. Trends in U.S. scrap exports are shown in figure 13. In 1991, exports of copper scrap were below the record-high level of 1989. In 1991, 254,028 tons of copper in alloyed and unalloyed copper scrap was exported from the United States, compared with 293,074 tons in 1990. Shipments to China, Japan, and the Republic of Korea, however, posted significant gains. China, in particular, had become a significant purchaser of U.S. scrap compared with previous years. U.S. exports to China had increased from a total of 22,554 tons of copper in unalloyed and alloyed copper scrap in 1990 to 45,582 tons in 1991. (See figure 13.)

World Review.—As a component of world supply, scrap has been increasing at a slightly faster rate than primary copper production. Scrap recovery represented 18% of total world copper supply (primary + scrap) in 1974, but has increased to about 20% of world supply in the 1980's. The Western European countries comprise the largest single market for scrap consumption in the world. France, Germany, Italy, and the United Kingdom are the largest consumers of copper and copper alloy scrap. The United States is second after the EC in scrap consumption. Asia, mostly Japan, is the third largest scrap-consuming area of the world. Scrap consumption in the Asian countries has continued to grow parallel to increased refined copper consumption as these countries have developed their manufacturing industries since the 1960's. In the United States, about 44% of total annual copper consumption was from

copper in old and purchased new scrap. Copper scrap accounted for a similar percentage, 36%, in the countries of the EC, which collectively comprise one of the largest sources of copper scrap in the world.

As shown in figure 14, the United States is the largest exporter of copper scrap in the world, followed by France, Germany, and the United Kingdom. The EC, as a group, makes up the largest single scrap trading area in the world. Nearly all imports and exports from the EC are to or from other European nations. Scrap imports have increased significantly since 1983 in Belgium, Germany, Italy, and the Netherlands. In Italy, the increase since 1985 corresponded with new processing and semifabrication plants constructed during this period. The Asian countries export very little scrap, and most of this goes to other Asian countries. Asian imports of scrap from western countries has grown significantly in recent years. (See figure 14.)

Current Research.—There have been some serious efforts in developing hydrometallurgical processes for secondary copper, some of which have been very successful and are currently being put into place. Bronzes and gun metals have been directly electrorefined into pure copper using complex electrolytes. Investigations have also been conducted for consecutive electrorefining of copper and zinc directly from copper alloy scrap. Some researchers have suggested aqueous $\text{CuCl}_2\text{-NaCl}$ leaching of copper-brass scrap. For large-scale operation, the scrap is leached under vigorous agitation at 90° C at an initial pH of 2. The impurities from the leach liquor were precipitated as oxides, hydroxides, or carbonates by pH adjustment. Pure cuprous solution obtained after filtration was electrolyzed to obtain pure copper powder.¹⁹

An extensive review of the recovery of metals from electronic scrap described several processes currently in use or under investigation.²⁰ The literature on electronic scrap recycling dates to 1969,

when the U.S. Bureau of Mines began to investigate procedures for recovering precious metals from old military scrap, which at that time reportedly totaled more than 9,100 tons per year. The U.S. Bureau of Mines has developed a hydrometallurgical method for processing electronic scrap that consists of a three-stage leach procedure, and which has been developed to a pilot scale. The scrap is mechanically processed, and the fraction that emerges from the high-tension separator is the portion hydrometallurgically treated. This fraction contains most of the gold and silver. It is first leached with sodium hydroxide to remove aluminum and washed and incinerated to remove organics. This is followed by pressure leaching with sulfuric acid to dissolve silver, nickel and copper at higher temperatures (150° C). Silver is leached under pressure with nitric acid and then precipitated with NaCl. Copper is recovered from both nitric and sulfuric acid solutions by cementation with the steel fraction. Essentially all of the gold, silver, and 92% of the copper were recovered from the scrap.

A German patent described the recovery of copper, gold, lead, palladium, silver, and tin from electronic scrap, which also includes plastics (such as in connectors and printed circuits). The scrap is leached with 30% to 50% HNO₃ at 35° C to yield metal nitrates in solution, gold, and SnO₂. After removal of undissolved plastics, the suspension is treated with concentrated sulfuric acid to precipitate sulfate crystals containing gold and tin oxide. After cooling, the sulfates are added to water, forming a copper-, palladium- and silver-containing solution, and the insoluble gold, lead, and tin materials are filtered off. The filtrate is cemented with copper at 40° to 50° C to produce a silver-34% lead alloy. Copper metal is electrodeposited from solution, and the silver palladium alloy is electrorefined to give palladium and silver. The recovery rates for copper, gold, palladium, and silver exceed 97%.²¹

Bell Telephone Laboratories Inc. announced a new lead-free brass alloy, using bismuth and small amounts of tin or

phosphorus. Lead is added to brass to make it malleable and easier to machine. However, lead may leach from the metal and contaminate water in plumbing systems. By adding 1% to 2% bismuth, the machinability was equal to that of lead-copper alloys. This could increase demand for bismuth to about 4,500 tons per year, according to some estimates. World capacity for bismuth production was estimated by the U.S. Bureau of Mines to be almost 8,000 tons per year, but only about 4,000 tons was produced in 1990.²²

Outlook

As discussed in the resource section, the reservoir of unclaimed copper in use is large, but recovery from this base is limited by the following factors: (1) refined copper prices, (2) useful life of products, (3) available recovery technologies, and (4) rate of copper consumption. The average useful life for copper products is about 25 years before being scrapped and entering the market as "old" scrap. New (manufacturing) scrap, on the other hand, has a short life of about 30 days, and its recovery is limited by domestic manufacturing rates and efficiencies. This wide difference in turnaround and availability has resulted in a gradual increase of "new" scrap versus "old" scrap as a component in all scrap collected in the United States since the 1930's. Recently, however, industry sources claim that the amount of new scrap being generated by manufacturing plants has been cut by as much as 50% owing to increased production efficiencies. Although U.S. copper (primary + scrap) consumption will increase in 1992, scrap consumption will remain at about the 1991 level owing to the effects of lower copper prices, increased manufacturing efficiencies, and decreased manufacturing rates during the 1991 recession. In addition, increased exports of scrap to the Far East will cause domestic tightness in available scrap. Because scrap is usually a lower cost alternative to primary metal, it will continue to be of great interest to countries such as China, India, the

Republic of Korea, and Taiwan as they expand their industries.

Over the next decade, copper scrap will remain a premium material of essential use to the U.S. semifabricating industry. Because of its intrinsic value and usefulness, copper scrap of all types has always been extensively recycled. This was particularly true during times of high demand, such as war years. Demand for scrap during those periods was such that scrap export controls were put in place through most of the 1940's, 1950's and 1960's. Export controls on scrap were finally removed in September 1970.

Another factor expected to affect the way copper scrap is collected and processed over the next decade is the legislative limit on lead in copper alloys, to 2% or less of lead. Some in the industry believe that, since the average copper alloy contains about 8% lead, the scrap to be used in the future will have to be diluted. This would mean that No.1 copper could be in greater demand in the future and that the production of these particular alloys will be higher in cost. Following the current decreasing trend, fewer high-lead copper alloys will be produced in the United States within the next decade.

Without successful implementation of new recovery technologies, the recovery of copper in all parts of the economy will be impeded by stricter legislative requirements. New technologies for the recovery of copper from wastewaters, electronic scrap, and other scrap with low copper content will enable more metal to be retrieved. Some solvent extraction plants are already in operation. With increased environmental and labor safety requirements, some types of ingot will be difficult to produce economically. New technologies will be required to decrease the lead content of machinable and other leaded-copper alloys. In addition, new uses must be found for some of the associated products, such as shredded plastics, that are generated in the preparation of copper scrap.

*Estimated. NA Not available.

¹Recycled metal is metal recovered from purchased new plus old scrap supply.

²New scrap is scrap that results from the manufacturing process, including metal and alloy production.

³Old scrap is scrap that results from consumer products.

⁴Quantity is the calculated metallic recovery from aluminum-base scrap, estimated for full industry coverage. Value is estimated based on the average annual U.S. market price for primary aluminum metal.

⁵Recoverable copper values in scrap based on annual averages for refined copper.

⁶Transaction value estimated to be LME average cash value plus 6.5 cents/lb.

⁷Nickel scrap is Ni contained in ferrous and nonferrous scrap receipts. Value is average annual LME cash price of Ni cathode.

⁸Value estimated based upon Metals Week Tin Composite price. Data for 1991 are not available because they are being re-evaluated.

⁹Value based on average annual U.S. zinc metal price published in Metals Week (MW); for 1987-90, the MW average prices were based on U.S. or North American Producer's High Grade zinc delivered prices and for 1991, the London Metal Exchange spot prices for Special High Grade zinc plus premiums based on market conditions.

*Estimated. NA Not available.

¹Apparent consumption is production plus net imports plus stock changes. Production is primary production plus recycle. Net imports are imports minus exports. Apparent consumption is calculated on a contained weight basis.

²Recycle is metal recovered from reported purchased scrap.

³Same as apparent consumption defined above calculated on a monetary value basis.

⁴Monetary values estimated based on the U.S. market price for primary aluminum ingot. Recycle calculated as metal recovered from reported purchased new and old scrap estimated for full industry coverage. Apparent consumption referred to as apparent supply in aluminum tables.

⁵Copper recovered for consumption valued on average annual refined prices.

⁶Lead processors are segregated by primary and secondary producers. This segregation permits inclusion of stock changes in recycle lead supply. Transaction value for U.S. primary production and net imports estimated to be LME average cash value plus 5 cents/lb delivered. Transaction value for U.S. secondary production estimated to be LME average cash value plus 6.5 cents/lb. Stock adjustment value based on actual proportion of stock change to secondary production.

⁷Value of apparent consumption and recycle estimated as average annual LME cash price.

⁸Value estimated based upon Metals Week Composite price. Data for 1991 are not available because they are being re-evaluated.

⁹Value based on average annual U.S. zinc metal price published in Metals Week (MW); for 1987-90, the MW average prices were based on U.S. or North American Producers' High Grade zinc delivered prices and for 1991, the London Metal Exchange spot prices for Special High Grade zinc plus premiums based on market conditions.

TABLE 3
U.S. APPARENT ALUMINUM SUPPLY AND CONSUMPTION

(Thousand metric tons)

	1987	1988	1989	1990	1991
Primary production	3,343	3,944	4,030	4,048	4,121
Change in stocks: ¹					
Aluminum industry	+341	+11	+61	+2	+32
LME stocks in U.S. warehouses	—	—	—	—	-168
Imports	1,850	1,620	1,470	1,514	1,490
Secondary recovery: ²					
New scrap	1,134	1,077	1,043	1,034	979
Old scrap	852	1,045	1,011	1,359	1,522
Total supply	7,520	7,697	7,615	7,957	7,976
Less total exports	917	1,247	1,615	1,659	1,762
Apparent aluminum supply available for domestic manufacturing	6,603	6,450	6,000	6,298	6,214
Apparent consumption ³	5,469	5,373	4,957	5,264	5,235

¹Revised.

²Positive figure indicates a decrease in stocks; negative figure indicates an increase in stocks.

³Metallic recovery from purchased, tolled, or imported new and old aluminum scrap expanded for full industry coverage.

⁴Apparent aluminum supply available for domestic manufacturing less recovery from purchased new scrap (a measure of consumption in manufactured end products).

TABLE 4
U.S. CONSUMPTION OF AND RECOVERY FROM PURCHASED NEW AND OLD ALUMINUM SCRAP,¹ BY CLASS

(Metric tons)

Class	Consumption	Calculated recovery	
		Aluminum	Metallic
1990			
Secondary smelters	982,011	800,918	860,902

RHENIUM

By John W. Blossom

Mr. Blossom, a physical scientist and engineer with 44 years of industry and Government experience, has been the commodity specialist for rhenium since 1983. Trade data were prepared by Jo-Ann Sterling, statistical assistant.

Rhenium's two most important uses in the past decade have been in platinum-rhenium catalysts used primarily in producing lead-free, high-octane gasoline and in high-temperature superalloys for jet engine components. Other uses of rhenium, primarily as tungsten-rhenium and molybdenum-rhenium alloys, though smaller in quantity, are more diverse. These include use in thermocouples, heating elements, temperature controls, flashbulbs, vacuum tubes, X-ray tubes and targets, metallic coatings, and electrical contact points. Research by industry continues in rhenium recovery from ore and concentrate and on development of new catalysts and alloys.

In 1991, domestic demand for rhenium metal and other rhenium products was met by domestic recovery, domestic stocks, and imports.

DOMESTIC DATA COVERAGE

Domestic mine production data for rhenium are developed by the U.S. Bureau of Mines from reported molybdenum production at the eight operating porphyry copper-molybdenum-rhenium mines in the United States. (See table 1.)

ANNUAL REVIEW

Rhenium is a byproduct of molybdenite recovered as a byproduct of porphyry copper ore from eight mines in the Western United States. Consumption of rhenium increased about 15% in 1991. Imports for consumption increased 62% in 1991. The major uses for rhenium

during the year were bimetallic platinum-rhenium catalysts and jet engine high-temperature components. The price of rhenium products varied during 1991. The prices on January 1, 1991, for unwrought metal had a range of \$1,610 to \$1,653 per kilogram and ammonium perrhenate had a range of \$1,376 to \$1,453 per kilogram. These prices changed August 1, 1991. Unwrought metal was \$1,213 to \$1,268 per kilogram and ammonium perrhenate was \$1,120 to \$1,157 per kilogram. These prices held through December 31, 1991.

Consumption and Uses

The major uses of rhenium are in petroleum-reforming catalysts and in high-temperature superalloys used in jet engine components. These two uses represent about 30% and 60% of the total demand.

Rhenium is used in petroleum-reforming catalysts for the production of high-octane hydrocarbons, which are used in the production of lead-free gasoline. Bimetallic platinum-rhenium catalysts have replaced many of the monometallic catalysts. Rhenium catalysts tolerate greater amounts of carbon formation and make it possible to operate at lower pressures and higher temperatures, which leads to improved yields and octane ratings.

Catalytic units employing platinum-rhenium catalysts are used in about 80% of total U.S. reforming capacity. Platinum-rhenium catalysts are also used in the production of benzene, toluene, and xylenes, although this use is small

compared with that used in gasoline production.

A significant property of rhenium is its ability to alloy with molybdenum and tungsten. Molybdenum alloys containing approximately 50 weight-percent rhenium have greater ductility and can be fabricated by either warm or cold working. Unlike other molybdenum alloys, this alloy is ductile, even at temperatures down to 196° C, and can be welded. Also, alloys of tungsten with 24 weight-percent rhenium have improved ductility and lower ductile-to-brittle transition temperature than pure tungsten. Rhenium improves the strength properties at high temperatures (1,000° C) of nickel alloys. Some of the uses for these alloys are in thermocouples, temperature controls, heating elements, ionization gauges, mass spectrographs, electron tubes and targets, electrical contacts, metallic coatings, vacuum tubes, crucibles, electromagnets, and semiconductors. These various uses represented only 10% of total demand in 1991.

Foreign Trade

Imports for consumption of ammonium perrhenate came from Chile, the Federal Republic of Germany, Japan, the Netherlands, and Sweden, whereas Chile, the Federal Republic of Germany, and Japan supplied rhenium metal.

World production of rhenium was estimated to be 34 metric tons (75,000 pounds); however, the quantity of rhenium actually recovered is much lower because not all concentrates are processed

to recover the rhenium values. Rhenium was recovered from some byproduct molybdenite concentrates from porphyry copper deposits in Canada, Chile, China, Iran, Peru, the U.S.S.R., and the United States. In addition, the U.S.S.R. also recovered rhenium as a byproduct from the Dzhezkazgan sedimentary copper deposit in Kazakhstan. Rhenium metal and compounds were recovered from molybdenum concentrates in Chile, France, the Federal Republic of Germany, Sweden, the U.S.S.R., the United Kingdom, and the United States. (See tables 2, 3, and 4.)

World Review

The definitions of reserves and reserve base are published in U.S. Geological Survey Circular 831, "Principles of a Resource/Reserve Classification For Minerals," which is reprinted in the introduction of "Mineral Facts and Problems, 1985 Edition" and "Mineral Commodity Summaries, 1990."

Estimated world reserves and reserve base of rhenium appear in table 5. They are contained primarily in molybdenite in porphyry copper deposits. U.S. reserves are concentrated in Arizona and Utah, but are also found in Montana, Nevada, and New Mexico. Canadian reserves are in British Columbia, primarily on Vancouver Island. Chilean reserves are found primarily at four large porphyry copper mines and in lesser deposits in the northern half of the country. In Peru, reserves are concentrated primarily in the Toquepala open pit porphyry copper mine and in about a dozen other deposits in the southern half of the country.

Soviet reserves are in several porphyry copper deposits and one sedimentary copper deposit mainly in the south-central part of the country between the Caspian Sea and northwestern China. Other world reserves are in Europe and in sedimentary copper-cobalt deposits in Zaire, Africa. (See table 5.)

OUTLOOK

In the next 5 years, demand for rhenium metal could increase to about 20

metric tons (45,000 pounds) annually, with propulsion component needs (superalloys) at 60%, petroleum-reforming catalysts at 30%, and the various other uses consuming 10%. This increase in demand may be met by processing a greater amount of concentrates containing rhenium and increasing the rate of recovery into the 90% range. Recycling of rhenium-bearing waste and scrap must be greatly improved. This area will require the development of new technologies.

SALT

By Dennis S. Kostick

Mr. Kostick, a physical scientist with 13 years U.S. Bureau of Mines experience, has been the commodity specialist for salt since 1980. Domestic survey data were prepared by Ms. Carleen Militello, statistical assistant; and international data tables were prepared by Mr. William Zajac, Chief, International Data Section.

Salt is a universal commodity that is known and used by virtually every person in the world. Sodium chloride, commonly known salt, is an important compound that has a multitude of applications. Most individuals usually only associate salt with highway deicing and food processing; however, the largest end use of salt is as feedstock for chlorine and caustic soda manufacture. These two important inorganic chemicals have a multitude of consumer-related end-use products, such as polyvinyl chloride (PVC) plastic made from chlorine and pulping chemicals manufactured from caustic soda.

DOMESTIC DATA COVERAGE

Domestic production data for salt are developed by the U.S. Bureau of Mines from an annual voluntary survey of U.S. salt-producing sites and of company operations. Of the 73 operations to which a survey request was sent, 71 responded, representing 98% of the total production shown in this report. Production for the nonrespondents was estimated on the basis of their prior response to the 1991 production estimate survey or brine production capabilities for chlor-alkali manufacture.

BACKGROUND

Salt has been an important commodity throughout history. Its presence has determined the location of cities, migration of populations, and routes of trade caravans. One of the earliest accounts of using salt in political-economic societies was traced to 2200 B.C. in China where Emperor Hsia Yu

decreed that Shandong Province would supply the court with salt. The Phoenicians (1200 B.C. to 300 B.C.) were one of the first maritime civilizations to trade salt. Salt became an important universal medium of exchange. The English word "salary" is derived from the Latin term "Salarium argentum," which were the salt rations that Roman soldiers were partially paid for their services. Aside from its use as a medium of monetary exchange, salt has also been used to signify hospitality. The custom of presenting newlyweds wine, bread, and salt shows salt as a life-giving and sustaining substance. In many areas of the world, it is still the custom for the host to offer bread and salt upon entering the home. The custom is also practiced "out of this world"—it has been a tradition that all U.S.S.R. staffed spaceflights carry aloft bread and salt and leave them behind on the orbiting space station as presents for the next visiting crew.

The first production of salt in the United States was in 1614 by the Virginia colonists who evaporated seawater. The practice of extracting salt from subsurface brine was first employed in the United States at Onondaga, NY, in 1788. The first salt "mine" in the United States was dug in 1799 at Saltville, VA. A 6-foot-wide by 200-foot-deep shaft was dug to the top of the salt formation before ground water flooded the workings. The saline water in the shaft provided the feedstock to iron kettles, in which the water was evaporated and the salt recovered. In 1862, the first commercial rock salt mine in North America began operating at Avery Island, LA. Solution mining of salt began in about 1882 and

consisted of drilling a small diameter well down to a salt bed, pumping freshwater down to dissolve the salt, and pumping the resultant brine to the surface for subsequent evaporation. In 1887, the vacuum pan was adopted for salt production, which incorporated a vacuum during evaporation to allow the water to boil from the brine at a lower temperature. This technological achievement reduced fuel consumption below that of direct-heated units.

Definitions, Grades, and Specifications

Technically, salt is a generic term that describes compounds formed by the partial or complete replacement of the hydronium ion of an acid by a metal or metallic radical. Water and salts are the end products from the chemical reaction between acids and bases. Through time, however, "salt" has become synonymous with sodium chloride (common salt) and will be considered synonymous throughout this chapter.

Naturally occurring sodium chloride is mineralogically known as halite. Pure salt contains 39.3% sodium and 60.7% chlorine by weight. Halite deposits usually contain between 1% and 4% impurities, mainly gypsum, shale, dolomite, and quartz. Rock salt is halite that is mined underground by conventional room-and-pillar techniques.

Evaporated salt is the term applied to fine crystals of salt obtained by evaporating brines, either natural or manufactured from solution mining, in large, vacuum-enclosed or open steam-heated kettles. Solar evaporated salt is the product harvested from shallow ponds

after the brine has been exposed to solar and wind evaporation.

The physical characteristics of salt vary with the type of production process. Salt specifications from vacuum pan operations are the same because the process is similar throughout the country. Rock salt, however, can vary in color and composition with locality, and these characteristics influence the specifications of the final product. Some impurities must be removed by chemical treatment or filtration to meet specifications for certain end uses.

There are various standards issued by different organizations that apply to salt. These standards may vary, depending on the intended end use. For example, salt for human consumption requires different specifications than those of salt for deicing highways. (See table 1.)

Products for Trade and Industry

Salt for human consumption is packaged in different sized containers for several specialized purposes. Table salt may contain 0.01% potassium iodide as an additive that provides a source of iodine that is essential to the oxidation processes in the body. Kosher salt, seasalt, condiment salt, and salt tablets are special varieties of salt.

Water conditioning and animal feedstock salt are made into 50-pound pressed blocks. Sulfur, iodine, trace elements, and vitamins are occasionally added to salt blocks to provide missing nutrients not found naturally in the diet of certain livestock. Salt is also compressed into pellets and used for water conditioning.

Geology-Resources

The definitions of reserves and reserve base are published in the U.S. Geological Survey Circular 831, "Principles of a Resource/Reserve Classification for Minerals."

The oceans are the world's largest resource of salt. Seawater contains 3.5% dissolved solids by weight with sodium chloride representing the major component, approximately 2.5% by

weight. The world's oceans contain about 44×10^{15} short tons of sodium chloride, which is equivalent to 4.5 million cubic miles in volume or a cube measuring 165 miles on edge.

Domestic salt resources are found mainly in four large depositional basins, covering an area totaling about 0.5 million square miles in 18 States. These basins are (1) the gulf coast, which covers part of Florida, Alabama, Mississippi, Arkansas, eastern Texas, and all of Louisiana; (2) the Permian, which is in part of New Mexico, Colorado, Kansas, Oklahoma, and Western Texas; (3) the Salina, covering part of New York, Pennsylvania, West Virginia, Ohio, and Michigan; and (4) the Williston, encompassing part of North and South Dakota, Montana, and Wyoming. The gulf coast and Permian basins extend into Mexico; the Salina and Williston both extend into Canada. The identified salt resources of the United States are estimated at 61×10^{12} tons and are being depleted at the rate of about 39 million tons annually. At the present level of production, the United States has enough salt to mine for more than 1.6 million years. Solar evaporation of coastal seawater would extend this timespan to virtually forever.

Salt can be geologically classified by its occurrence as evaporite deposits and in solutions.

Evaporite Deposits.—Bedded, diapiric flow, and playa salts are the major types of dry salt deposits. Bedded salt deposits were formed by the accumulation of precipitated salts on the seafloor of ancient landlocked marine bodies of water. Extensive and widespread evaporation was essential to form these massive rock salt deposits, some of which measure up to 3,000 feet in thickness.

Salt domes form when vertical or lateral pressures are applied to stratified salt deposits in which low-density salt will flow plastically through the surrounding rocks of higher density. The salt domes of Romania, Germany, and the gulf coast of the United States are examples of diapiric salt flows. The appearance is usually cylindrical with

circular or elliptical diameters. A cap rock of anhydrite is common with overlying layers of gypsum and calcite. Oil, gas, and sulfur are associated with many domes and represent large mineral resources. There are 329 proven salt domes in the gulf coastal province and offshore regions of the United States. Louisiana has 183 domes onshore and offshore; Texas, 83; Mississippi, 61; and Alabama, 2.

Playas are flat, vegetation-free floors of an undrained desert basin that may occasionally be covered by water. Postevaporation minerals such as sodium carbonate, sodium sulfate, sodium chloride, borates, nitrates, phosphates, and potash result from the leaching of the rocks surrounding the basin by water flowing into the playa. Searles Lake in California is a classic example of a salt-bearing playa lake.

Salt in Solution.—Ocean, lake, and ground water are the primary aqueous mediums in which salt is dissolved. Seawater contains many dissolved minerals, the major one being sodium chloride. Other dissolved minerals include various sulfate, magnesium, calcium, and potassium compounds.

Water tends to accumulate on land in topographic depressions created by tectonic uplifts or subsidences of the Earth's upper crust. As mineralized solutions from upland sources drain into these basins, solar evaporation concentrates the salts to form saline lakes. The Aral Sea in the U.S.S.R., Great Salt Lake in Utah, and the Dead Sea between Jordan and Israel are examples of this process.

Ground water is composed of mineralized connate and meteoric water found in permeable sedimentary formations. In some areas, sodium chloride-rich brines migrate to the surface through intersecting fractures and joints in the rock strata to form local salt springs. These springs have attracted animals because they are a source of salt. The springs also indicate where buried salt deposits are located. The salt springs at Saltville, VA, are an example of a

locality that was developed based on an occurrence of salt springs.

Technology

Exploration.—Exploring for new salt deposits is based on examination of various geochemical and geophysical information. Analysis of the underlying strata by core drilling, oil and water well logs, or other techniques is the basis for establishing the size of the deposit. Usually the most favorable areas for mine development will be near the market regions and convenient transportation routes.

The development of mines incorporates strict safety precautions while permitting for the maximum economic recovery of salt. During shaft sinking, water-bearing strata may be encountered, and waterproofing techniques must be employed to prevent mine flooding. At least two access shafts are constructed in room-and-pillar mines to provide adequate safety and ventilation.

Mining.—**Rock Salt.**—Rock salt is mined by the room-and-pillar method, which is similar to that used in coal and trona mining. The salt is drilled, cut, blasted, mucked, crushed, and transported to the surface for processing, which usually involves removing the impurities and screening the material to finer size fractions.

Underground mining practices of bedded rock salt and domal salt formations are similar except for the height differences within the mines of the two types of operations. For example, bedded formations usually are laterally extensive but are vertically restricted. Salt domes are laterally restrictive but are vertically extensive. Many salt domes have depths in excess of 20,000 feet, yet many outcrop at the surface. Most gulf coast salt mining operations are generally less than 1,000 feet below the surface. Working at deeper depths is difficult because of higher temperatures and denser rock.

Solar Evaporation.—Solar evaporation is an effective method of producing solar salt in areas of high evaporation and low precipitation. Along coastal margins in many parts of the world, seawater is collected and allowed to evaporate in specially constructed evaporating ponds. Saline lakewater is also processed using this method. The ponds are separated by levees that isolate the brine during different stages of fractional crystallization.

The initial step concentrates the brine to increase the salinity and allow many calcium, magnesium, and iron compounds to precipitate from solution. The brine is circulated among a network of interconnecting ponds, with salinity increasing with each transfer. The brine is then treated with lime to remove excess calcium sulfate and then pumped to evaporation ponds and then transferred to harvesting ponds to permit the salt to crystallize. After about 85% of the salt is precipitated, the remaining supernatant liquid, called "bitterns," can be drained to adjacent ponds for subsequent extraction of magnesium, potassium, bromine, and sodium compounds. The harvesting pond is flooded again with new brine from the lime pond to repeat the cycle. It takes about 5 years once seawater is first introduced into the system for the completion of the crystallization process. The salt is harvested by special tractors equipped with scrapers and ready for processing.

Solution Mining.—The first reported use of solution mining was about 250 B.C. in China when holes were drilled into deep salt deposits. The brine was brought to the surface by pipes made of bamboo. The brine was evaporated over fires fueled with wood, coal, or natural gas. The basis of current technology began in France about A.D. 858. An injection well is sunk, and pressurized freshwater is introduced to hydraulically fracture the bedded salt. Once communication with the production well is established, the brine is pumped to the surface for treatment.

Roof collapse of the overlying strata and surface subsidence are potential problems associated with solution mining; however, producers have taken precautions to minimize these hazards. One method that was once used was injecting air with the water into the salt caverns. The air formed a protective cover between the water and the top of the cavity that reduced the amount of dissolution of the roof.

Processing.—**Rock Salt.**—About 64% of total rock salt produced and imported is for highway deicing. Crushing and screening to the proper physical size is usually the only processing that road salt undergoes. In many operations, these steps are done underground in the mine to minimize haulage and storage costs. In addition, the extremely fine fraction, which often is unusable, remains underground rather than on the surface, which would represent a waste product to be disposed.

Solar Salt.—After harvesting, the salt crystals are washed with dilute brine to remove residual bitterns and impurities. The salt is transferred to processing facilities where it is washed with saline water, dried for about 8 minutes at approximately 300° F, and screened into fine to coarse sizes, depending on the end use of the salt to be sold. Most operations ship solar salt in bags and in bulk, using barges, truck, and rail transportation.

Mechanical Evaporation.—Salt obtained by dehydrating brine using heat alone or in combination with a vacuum is vacuum pan salt. The vacuum pan process conserves energy by utilizing multiple-effect evaporators connected to vacuum pumps. A saturated salt solution will boil at a higher temperature than pure water. When a vacuum is applied, the brine boils at a lower temperature, enabling the superheated vapor that is generated to act as the heating medium for the next evaporator.

The grainer or open pan process uses open, rectangular pans with steam-heated

immersion coils to evaporate the water in the brine. Rotating rakes scrape the salt precipitate into a sump or up a ramp, depending on the method, and onto conveyors for debrining and drying treatment. The final product is usually flake shaped rather than the typical cubic form. Flake salt is preferred for production of cheese, butter, and baked goods.

The Alberger process is a modified grainer operation that produces cubic salt with some flake salt. The pans are shallow, circular units with external heating units, rather than heating coils. The open pan process cannot be operated successfully in regions with high humidities because the evaporation rate is too slow and more energy is required to evaporate the brine.

Desalination.—The conversion of saline water into freshwater has important municipal, industrial, and agricultural applications. Aside from obtaining pure water, desalination also produces byproduct salt. There are four processes presently employed in water desalination, and each has different cost and energy factors. The processes are distillation, membrane, freezing, and ion exchange. Some salt from these processes is used by the chemical industry. In some regions, salt is returned to the saline water source. Seawater typically contains 3.5% to 4.5% salt, or 35,000 to 45,000 parts per million. The standard for drinking water in the United States is 500 parts per million.

Byproducts and Coproducts

Salt is a coproduct from various seawater and saline lake operations. Depending on the cost of recovery and processing, certain magnesium, potassium, and bromine compounds can be produced from the bitterns. Subterranean brines also contain borax, calcium chloride, sodium carbonate, and sodium sulfate in addition to the above. Certain potash operations in the world also produce salt as a coproduct. When discharged to tailing ponds as a byproduct

of potash mining, salt is often harvested and sold by second parties.

Economic Factors

Energy and labor costs are important factors that affect production costs, and ultimately the selling price, for all types of salt. After the salt is produced, shipping costs become very important when attempting to sell to a customer that is in proximity to other salt producers. Industry sources indicate that within the United States, a 300-mile radius is an effective limit of competition for a producing location before the influence of other competitors is noticed. Some of the major U.S. producers also have foreign subsidiaries that produce salt, which is imported at prices favorable to many consumers because transportation costs are less.

Capital investment and energy costs are important factors that influence the selling price of the type of salt produced. Vacuum pan and open pan processing requires more equipment and energy than solution mining, and consequently, the average value of evaporated salt is considerably higher than that of salt in brine.

Prices.—Each of the four types of salt that are produced have unique production, processing, and packaging factors that determine the selling prices. Generally, salt sold in bulk is less expensive than salt that has been packaged, pelletized, or pressed. Salt in brine is the least expensive salt sold because costs are less. Vacuum pan salt is the most expensive because of the energy costs involved in processing. Table 2 lists the historical values of the different types of salt since 1970. The data are compared with 1991 constant dollars to show the effect of inflation and general economic conditions on the values. (See table 2.)

Tariffs.—The United States historically imports more salt than it exports. In 1991, U.S. salt imports were 3.5 times the level of salt exports. Imports from countries having most-favored-nation

(MFN) status enter duty free. However, salt imported from non-MFN countries have a 26% ad valorem tax imposed.

Operating Factors

Environmental Requirements.—The environmental problems associated with salt mining are few and tend to be localized without major impacts on the environment. A major concern in solution mining is the potential of land subsidence. As the salt is dissolved, some roof collapse may occur, causing sections of the surface to partially or totally fill the cavity. Subsidence is unpredictable, and once the process begins, it must be allowed to finish and reach equilibrium. Another issue pertaining to solution mining is the potential problem of well casing leakage. Any excursion of salt brine could affect ground water supplies, which are protected by various State and Federal water quality regulations. Solar evaporation facilities may substantially disturb coastal marsh areas because of the large extent of the lagoons needed for efficient operation.

Employment.—According to the Bureau of Labor Statistics, 1,522 people were employed in the mining and processing of rock salt in 1991. Of the 12 rock salt facilities surveyed, 773 personnel worked 1.49 million hours underground, 278 people worked 533,810 hours on surface duties, and 471 people worked 913,300 hours in the mills. Total employment in the domestic rock salt industry amounted to 1,758 individuals who worked a total of 3,395,967 hours. Employment data for solar salt, vacuum pan salt, and salt in brine were incomplete or not surveyed by the Bureau of Labor Statistics.

Transportation.—The locations of the salt supplies often are not in proximity of the consumers location, and transportation can become an important cost. Pumping salt brine through pipelines is an economic means of transportation, but cannot be used for dry salt. Large bulk

shipments of dry salt in ocean freighters or river barges are low in cost, but are restricted in points of origin and consumption. River and lake movement of salt in winter is often severely curtailed because of frozen waterways. As salt is packaged, handled, and shipped in smaller units, the costs are increased and are reflected in higher selling prices.

Oceanborne imports of salt have been increasing in some areas of the United States because they are less expensive with respect to transportation costs than what could be purchased from many domestic suppliers using rail transportation. Salt continued to be one of the most heavily traded chemical industry ores in the world, representing about 66% of world seaborne mineral trade.

ANNUAL REVIEW

Issues

The U.S. Environmental Protection Agency (EPA) announced that it plans to set up water quality standards to protect the Nation's rivers, streams, and lakes. A group of 106 toxic pollutants in 22 States and territories was included in the project, especially those compounds that are discharged from various chemical or other industrial facilities. Chlorine-base bleaching agents made from salt have been shown to generate various levels of dioxin (2, 3, 7, 8 tetrachlorodibenzo-p-dioxin or TCDD) and a furan (2, 3, 7, 8, tetrachlorodibenzo furan or TCDF) released by the processes. Dioxins are toxic synthetic compounds that have been identified as carcinogenic to some animals, but studies investigating their effect on humans are controversial and inconclusive. Many pulp mills have begun voluntarily converting from chlorine-base bleaching chemicals to environmentally safe oxygen-base chemicals, such as hydrogen peroxide and sodium chlorate. Although less chlorine would be made, more sodium chlorate, which also uses salt as feedstock, would be produced.

EPA has called for a review of the dioxin risk to humans based on a 1-year

study with new scientific data. EPA's prior assessments may have been too high or too low, but hopefully the new scientific evidence may provide a better evaluation regarding the risk of dioxin contamination.

Production

According to the U.S. Bureau of Mines survey for 1991, 31 companies operated 73 salt-producing plants in 14 States. Ten of the companies and 11 of the plants produced more than 1 million short tons each and accounted for 88% and 53%, respectively, of the U.S. total. Several companies and plants produced more than one type of salt. In 1991, 12 companies (15 operations) produced solar-evaporated salt; 5 companies (17 operations), vacuum pan salt; 10 companies (16 operations), rock salt; and 18 companies (35 operations), salt brine. (See tables 3, 4, 5, and 6 and figure 1.)

The five leading States in terms of total salt sold or used were Louisiana, 37%; Texas, 23%; New York, 13%; and Kansas, 6%. Although Louisiana, New York, and Ohio were major rock salt-producing States, a substantial amount of salt was produced in Alabama, Kansas, Louisiana, New York, Ohio, Texas, Utah, and West Virginia as brine for the chemical industry. (See tables 7 and 8.)

Four companies were involved in a multimillion dollar land and money exchange in Utah in mid-1991. As part of Kennecott's \$270 million expansion near Salt Lake City, the company acquired the 2,600-acre Saltair solar salt facility owned by Morton International Inc. In turn, Morton purchased the Grantsville salt works of North American Salt Co. on the southern shore of the Great Salt Lake with the money it received from the transaction. This provided Morton with greater solar salt production capacity than it had previously. Great Salt Lake Minerals and Chemicals Corp. (GSL), which is a sister-company of North American Salt, planned to expand its solar evaporation ponds on the western shore of the lake with some of North American's profits from the Grantsville sale. Approximately

\$20 million will be spent by GSL to increase potash production from 200,000 tons per year to about 340,000 tons per year.¹

Olin Corp.'s Niagara Falls, NY, chlor-alkali plant that closed in 1990 was dismantled and shipped to El Pasa, Nicaragua. The cells will be used to replace the older cells at the Nicaraguan facility.² New shutdowns of chlor-alkali plants were also announced in 1991. In July, Akzo Chemicals Inc. closed its chlor-alkali unit at LeMoyné, AL. Dow Chemical, which had begun to shut down its Pittsburg, CA, plant in 1990, placed the plant on standby in May 1991; however, by yearend the plant was shut down. Dow reactivated 220,000 tons of chlor-alkali capacity at its Freeport, TX, site to compensate for the closure in California. Hanlin Chemicals—West Virginia, Inc. closed its Moundsville, WV, chlor-alkali plant in midyear.³ LCP Chemicals, a part of the Hanlin Group, Inc., filed for protection under chapter 11 of the Federal Bankruptcy Code in July. The company continued operating its other plants in Georgia, Maine, and North Carolina.

Effective September 1, 1991, Leslie Salt Co. merged with its parent company, Cargill Inc. The Amboy, Napa, Newark, and Redwood City solar salt plants of Leslie were acquired in 1978. All of Leslie's California facilities will be known as Cargill Salt Western Area.⁴ In addition, Cargill implemented a \$4 million expansion project for its salt processing and food products distribution service facility at White Marsh, MD. The operation will include a new 50,000-square-foot salt processing plant.⁵

U.S. salt production accounted for about 20% of total world production. Production and trade of salt increased slightly compared with those of the previous year. World production of all types of salt increased slightly. The depressed market for chlorine and environmental problems associated with emissions of chlorinated compounds may affect the short-term status of the world chlor-alkali industry, which is the largest single consumer of salt.

Consumption and Uses

More than 44.7 million tons of domestic and imported salt was consumed in the United States in 1991, based on the annual survey of the U.S. salt producers. The reported percent distribution of salt by major end use was chemicals, 49%; ice control, 23%; distributors, 11%; food and agricultural, 7%; industrial, 4%; primary water treatment, 1%; and other combined with exports, 5%. Distributors represent a substantial share of salt sales by the salt industry; however, all the salt ultimately is resold to many end users. Some customers have specific uses. For a more complete analysis of end-use markets, specific sectors of distribution in table 9 can be combined, such as agricultural and water conditioning with agricultural and water conditioning distribution, respectively.

The chemical industry is the largest consumer of salt, primarily salt brine. Although most salt brine is captively produced by chemical producers, many chlor-alkali manufacturers purchased brine from independent brine supply companies. In certain cases, brine is captively produced by one chemical company, and any excess brine is sold to neighboring competitors. According to a survey of domestic salt-based chlorine facilities, about 48% of the salt used to manufacture chlorine was captive and 31% was purchased brine. Purchased solar or rock salt comprised 12%, and imported rock, solar, and vacuum pan salt was 9%. (See tables 9 and 10.)

Using Bureau of the Census data, the chlorine and caustic soda industry consumed about 1.97 million tons of salt for feedstock, based on the industry average ratio of 1.75 tons of salt required to produce 1.0 ton of chlorine and 1.1 tons of coproduct sodium hydroxide. Reported consumption of total domestic and imported salt for chlorine manufacture was 20.9 million tons, as noted in table 9. The difference between the calculated and reported quantities was the amount of salt unreported to the U.S. Bureau of Mines from imports or captive brine production of chlor-alkali producers. Production of chlorine gas

and liquid sodium hydroxide, as reported by the Bureau of the Census and The Chlorine Institute, is shown in table 11. (See table 11.)

Table 12 lists the domestic chlorine-producing facilities that used only salt as feedstock. Based on these estimates and using Bureau of the Census chlorine production data, the U.S. salt-based chlorine industry operated at 88% of capacity. According to The Chlorine Institute, the industry operated at an average of 88% of nominal capacity and 93% of effective capacity in 1991. Because these capacities include chlorine produced from nonsalt sources; i.e., from the electrolysis of magnesium chloride and the oxidation of hydrochloric acid, this data may differ from other reported chlorine capacity utilization information. (See table 12.)

Stocks

Total yearend stocks estimated at 2.5 million tons. Most of these inventories were rock salt and solar salt. Because complete inventory data are difficult to determine, many producers do not report this information; therefore, accurate stock data are not available. For discussion purposes, the net increase or decrease in annual inventories is assumed to be the change between salt production and salt sold or used. Many States, municipalities, distributors, and road-deicing contractors stockpiled additional quantities of salt in anticipation of adverse weather conditions.

Markets and Prices

Price quotations are not synonymous with average values reported to the U.S. Bureau of Mines. The quotations do not necessarily represent prices at which transactions actually occurred, nor do they represent bid and asked prices. They are quoted here to serve only as a reference to yearend price levels. Yearend prices were quoted in Chemical Marketing Reporter, as shown in table 13. (See tables 13 and 14.)

Foreign Trade

Under the Harmonized Tariff Schedule nomenclature, imports only have one category known as "Salt (including table and denatuted salt) and pure sodium chloride, whether or not in aqueous solution, seawater." The same classification also applies to exports. The trade tables in this report list the previous and current identification codes for salt.

Based on Bureau of the Census statistics, the United States imported 6.82 million tons in 1991, or about 3.5 times more than the quantity of salt that it exported. Although this would indicate that the United States is import reliant on salt to meet its salt requirements, the majority of imported salt was brought into the country by foreign subsidiaries of major U.S. salt producers. Generally, imported salt can be purchased and delivered to many customers at costs lower than the comparable domestic product because production costs are lower abroad and currency exchange rates are more favorable.

The Journal of Commerce's Port Import/Export Reporting Service (PIERS) reported that 5.23 million tons was imported; however, PIERS data include only ocean freight and does not include salt shipped by rail or truck over the U.S. land borders with Canada and Mexico. Therefore, Census data and PIERS data often are dissimilar. Using PIERS data, Akzo Salt Co., Cargill Inc., Morton International, and North American Salt Co., imported 49% of the total imports. Five companies that manufacture chlorine, which was the single largest domestic salt market, consumed 18% of total imports, which were primarily solar salt. These companies were Atochem North America, Georgia Pacific Corp., LCP Chemical & Plastics Inc., Occidental Chemical Corp., and Weyerhaeuser Co. The salt and chlor-alkali producers imported 67% of total imports; the remainder were to many small direct buyers. Five domestic salt-producing companies exported 65% of the 601,929 tons exported in 1991, according to PIERS. Tables 15 through 18 list the import and export statistics reported by

the Bureau of Census for 1990 and 1991. (See tables 15, 16, 17, and 18.)
