On June 5, 1980, the Government announced short-term policy changes to stimulate the economy that included a 1% to 2% reduction in business loan interest rates, revisions in terms of export financing

loans to Korean manufacturers, restrictions on imports of agricultural commodities other than rice, and a $300 million public works program concentrated in the housing and agricultural development sectors. On September 16, the Government provided a further reduction in bank interest rates and further stimulus to the construction industry. Also, the won was allowed to drop in value to help export performance and to ameliorate the country's balance of payments. In early November, interest rates were lowered further, excise taxes on some consumer durables were cut, and credit was infused into the economy by direct loans to firms and by providing consumer credit to stimulate domestic demand.

On September 25, the Government liberalized regulations governing foreign investments. The principal changes were as follows: New eligible industry projects introduced; minimum permissible investment lowered from $500,000 to $100,000; up to 100% equity allowed for high technology projects or skills that diversify investment sources, contribute to exports, or meet other special conditions; no restriction imposed on withdrawal of investment funds; preferential tax measures; and foreign acquisition of land simplified and rules governing thereof will be enforced in a flexible manner.

In an initial move to relax statutory controls gradually, the Government gave permission for the establishment of a joint venture bank with foreign participation. In another directive, Korean businesses were to divest themselves of speculative land holdings and subsidiary companies. This move would, purportedly, lower the average debt-equity ratio of the industry and permit industry to meet future economic downturns more easily.

To shore up the country's growth potential, the Government proposed plans to improve the domestic industrial structure, stimulate private investment, and promote small- and medium-size industries. Korea has large corporate conglomerates; the 10 largest business groups control 251 subsidiary companies and dispose of assets totaling $22.5 billion. Gross sales by the top 10 conglomerates accounted for 38.4% of the GNP in 1979. The four largest companies each has annual sales of over $3.5 billion. Hyundai Corp., the largest, had sales of $4.6 billion followed by Samsung Co., Daewoo Industries, and Lucky Development Co., in that order.

According to a survey by major Korean business organizations, business operating expenses in 1980 were to increase overall by 60%, principally as a result of increased prices for raw material, and to a lesser extent wages and banking costs. Factors such as higher oil prices (higher utility costs) and devaluation of the won were expected to result in a net profit-to-sales ratio of only 1% to 2%. Past borrowings have lowered the net worth to total assets ratio of Korean enterprises to an average of 21%, and this ratio was expected to deteriorate and increase industry vulnerability to economic slowdowns. Moreover, reduced profits and retained earnings decreased investment capital. A large part of industrial investment funds (42.4%) was for maintenance, replacement, and repair. Although there has been overexpansion in certain sectors of heavy industry, large investments were needed overall for facility modernization and for research and development.

Korean entrepreneurs claimed that the present tax system penalized domestic businesses compared with competitors in Japan and Taiwan. Assuming $17 million in pretax profits and an $8.5 million capital investment, the Federation of Korean Industries estimated that a Korean firm, subjected to a 53% corporate tax rate and with additional surtaxes and charges totaling $3.8 million, has a deficit of $4.3 million. However, a firm in Japan, which is subject to a 40% tax rate and for a firm in Taiwan with a 35% corporate tax rate, in contrast would retain $2.6 million after investment. Moreover, interest costs on borrowings constituted 5% to 9% of each sales dollar. In a survey of 311 firms on the Korean Exchange, total assets rose 37.6% in 1979 while total liabilities were up 39.8%. The Bank of Korea reported that one-third of total industry investments in 1979 were from internal savings and another third was from foreign loans.

In mid-1980, the Government directed the realinement of six industries. Initial restructuring called for the consolidation in the automotive and power-generation industries based on excess capacity and unproductive investment in duplicated facilities. In October 1980, the Government announced the reorganization of the next four industries—copper smelting and refining, electronic switching systems (ESS), marine diesel engines, and heavy electrical equipment. Except for ESS, the industries were weak or experiencing financial diffi-

culties. In the restructuring, there was to be only one surviving firm or an industry with a domestic monopoly for a specific product.

To stimulate the economy, new projects for industry or public infrastructure were being planned or on the drawing boards. Large port expansion projects for both Pusan and Inchon were in the design stage. An integrated steel mill and an industrial port were being planned for Asan Bay. A major ESS for telecommunications equipment was awarded to a U.S. company. A third and fourth subway line was to be constructed in Seoul, and a subway system was planned for Pusan. The Government was to contract for an environmental master plan for the Han River that includes Seoul. A multimillion dollar sewage treatment project was being considered for the Seoul metropolitan area.

The Government's mining policy emphasizes the development of domestic mineral resources, especially strategic minerals, and on improving miners' wage levels. Both state-run and private mines were encouraged to continue surveys on the feasibility of deep seam mining. In addition, the Government conducted geologic surveys in central Korea for developing uranium and thorium.

In 1979, the Government budgeted $112 million in loans and investments for mining. This amount represented 2.9% of total Government loans in 1979 compared with 2.8% in 1978. The value added of the domestic mining industry output totaled $642 million at current prices in 1979 or $301 million in 1975 constant market prices, a real growth of only 0.1%.

PRODUCTION

South Korea is a significant mine producer of only six mineral commodities—anthracite, graphite, kaolin, pyrophyllite, talc, and tungsten. While mineral raw materials for most of the country's needs are imported, there is limited domestic mine output of iron ore, copper-lead-zinc, gold and silver, and fluorite. The industrial production index (1975=100) for all items in 1980 was 209.7 compared with 111.2 for mining and 215.8 for manufacturing. The 1980 index for coal mining was 105.4; for metal ore mining, 103.9; and all other mining, 139.2. The 1980 index for petroleum refining was 152.5; nonmetal mineral products, 185.2; iron and steel, 310.8; nonferrous metals, 354.7; and fabricated metal products, 274.8.

There is no domestic production of oil and natural gas. Most of the country's production of primary metals, such as aluminum, copper, and iron and steel, is from imported ore and concentrates. At the end of 1980, the total production capacity for refined oil was 640,000 barrels per stream day; cement, 23.45 million tons per year; nitrogen fertilizers, 0.744 million tons per year; and steel, 8.8 million tons per year.

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.

[1]Includes data available through Sept. 24, 1981.

[2]Revised to zero.

[3]In addition to ferromanganese and ferrosilicon (listed separately below), silicomanganese also apparently was produced during 1976-80; for the years 1976-78, it apparently is included with either ferromanganese or ferrosilicon, while for the years 1979-80, it is included with other.

[4]Figures presented are those published by the National Bureau of Statistics, Economic Planning Board, Government of the Republic of Korea, and are believed to represent salable production; another set of figures produced by the Ministry of Energy and Resources, and believed to represent crude mine output, is as follows in metric tons: 1976—470,251; 1977—534,591; 1978—549,940; 1979—698,432; and 1980—577,761.

TRADE

In 1980, Korea's total trade reached $39.8 billion ($17.5 billion for exports and $22.3 billion for imports). Imports of mineral products, comprised of nonmetallic minerals, mineral fuels, and metallic ores, totaled $7.2 billion; mineral fuels alone accounted for $6.6 billion. Imports of base metals were $1.9 billion, and for gem stones and precious metals, $44 million. Imports of nonmetallic articles, not elsewhere classified, were $114 million in 1980. Receipts of chemicals totaled $1.6 billion, which included inorganic chemicals ($138 million) and fertilizers ($37 million). The country's largest export categories by value were textiles and miscellaneous clothing accessories, $5.7 billion; base metals and articles thereof, $2.5 billion; machinery, mechanical appliances, and electrical equipment, $2.3 billion; and motor vehicles and associated transport equipment, $1.2 billion.

The principal sources for imports in 1980 were Japan, $5.9 billion; the United States, $4.9 billion; Saudi Arabia, $3.3 billion; Kuwait, $1.8 billion; Australia, $0.68 billion; the Federal Republic of Germany, $0.64 billion; and Indonesia, $0.48 billion. Major destinations for Korea's exports were the United States, $4,607 million; Japan, $3,039 million; Saudi Arabia, $946 million; the Federal Republic of Germany, $875 million; Hong Kong, $823 million; the United Kingdom, $573 million; Indonesia, $366 million; the Netherlands, $349 million; and Canada, $343 million.

COMMODITY REVIEW

According to the Ministry of Energy and Resources (MER), Korea's imports of key mineral resources (including petroleum) were $921 million in 1980 compared with comparable exports of $121 million. In 1979, imports of raw mineral resources were valued at $702 million against exports of $95 million, a 33% increase in deficit over that of the previous year. The growing demand for vital mining products in the course of rapid industrialization was cited as a key factor behind the deteriorating trade balance in this sector.

By value, the single largest mineral import class in 1980 was bituminous coal, used mainly for domestic power generation, and steel. Receipts of soft coal during the year were valued at $284 million, accounting for about one-third of the total import bill for raw mineral resources. The value of imported iron ore was up 40%, totaling $170 million. The cost for copper ore in 1980—$155 million—was double that of 1979. Copper was used mainly to manufacture communication equipment such as cables. The value of imports of platinum had the highest growth rate for raw mineral expenditure. Receipts for this class were $5 million, a sevenfold increase over the value in 1979. However, the value of uranium imports decreased from $44.7 million in 1979 to $26.3 million in 1980.[6]

Korea's self-sufficiency for minerals (excluding coal) has steadily declined. According to MER, the value for mineral demand in 1978 totaled 315.1 billion won, of which domestic production accounted for 86.6 billion won, a self-sufficiency rate of 27%. In 1979, the domestic demand for minerals was up sharply to 400.4 billion won, while domestic production increased only 9% to 94.5 billion won, a self-sufficiency rate of 22%. Furthermore, the self-sufficiency rate was expected to drop to 16% in 1980.[7]

METALS

According to estimates given by MER, Korea is dependent on foreign suppliers for about 20 kinds of minerals, and in most cases, to meet more than 90% of domestic demand. Domestic production meets the demand for only a few mineral commodities. Output from indigenous resources accounts for 100% of the domestic demand for molybdenum and tungsten; 76% for silver; 75% for zinc; 13% for gold; 8% for iron; 7% for tin; and 1% for copper. However, Korea is entirely dependent on imported nickel and aluminum.

Under a threefold plan proposed by the Ministry of Commerce and Industry (MCI) there was to be an increase in production of nonferrous metals, an ensured supply of raw materials, and an increase in trade activity. Also, as part of the plan, MCI proposed the stockpiling of lead, tin, zinc, copper, nickel, and aluminum and that the industry be granted various governmental financial and tax concessions. The stockpiling program was to be administered by the Korean Supply Administration Agency and the task of ensuring a smooth supply of raw materials by the Korea Mining Promotion Corp.[8]

Aluminum.—All of the country's output of primary aluminum was by one company, Korean Aluminum, Ltd. (Koralu), at its plant in Ulsan. Koralu is jointly owned by Hyundai Heavy Industries Ltd. (acquired the shares held by the Korean Development Bank) and by Aluminum Pechiney. Koralu imports alumina for all of its smelter requirements.

Domestic demand for aluminum was expected to reach 180,000 tons in 1981. In 1971, the largest use for aluminum was for kitchenware, 45%; followed by construction, 23%; electric cable, 19%; automotive, 3%; and miscellaneous, 10%. By 1978, aluminum consumption in Korea had greatly diversified: Construction, 32%; electric cable, 15%; automotive and kitchenware, each 12%; special uses and canning-packaging, each 11%; and miscellaneous, 7%.

Copper.—Consumption of copper in 1979 was estimated at 120,000 tons, but the demand for metal was projected to reach 180,000 tons in 1981. Total domestic copper refining capacity at yearend 1980 was 120,000 tons per year. The smelter, owned by Korea Mining & Smelter Co., Ltd., at Changhang, has an annual capacity of around 40,000 tons per year and the newly constructed smelter (commissioned in 1979) at the Kyongnam industrial estate of Onsan Copper Refinery Co., Ltd., has an annual capacity of 80,000 tons per year. Additionally, other annual output by Onsan Copper was to include sulfuric acid, gold, silver, selenium, and nickel sulfate. Contracts for concentrate for Onsan Copper included Mexico, Canada, and the Philippines.

In 1980, the Government directed a realinement of the copper industry, whereby Onsan Copper was to be the surviving company responsible for the country's output of copper. If additional capacity was needed to meet demand, priority would be

given to expand production at Onsan Copper.

Iron and Steel.—Almost half of the domestic mine output of iron ore was from the Yangyang Mine in Kangwon Province, operated by Dai Han Iron Mining Co., Ltd. During 1979-80, domestic mine production accounted for about 8% of the total supply, with the remainder supplied by imports of iron ore primarily from Australia and India. At the completion of the fourth-stage expansion program of the integrated steelworks of Pohang Iron and Steel Co. (Posco) in 1981, about 96% of the total demand for iron ore and all of its requirement for coking coal will be met by imports. Commissioning of the completion of Posco's expansion program was scheduled for February 1981, whereby the company's crude steel production capacity would increase from 5.5 million tons to 8.8 million tons. Total industry output capacity in 1981 would amount to 11,612,000 tons when the capacities of independent producers—Dongkuk Steel Mill Co., Inchon Iron Works Co., Kuckdong Steel Co., and Pusan Iron and Steel Co.—are included. Moreover, there were preliminary plans to increase the country's crude steel capacity further by constructing a 6-million-ton integrated steelworks on the west coast, perhaps at Asan Bay, or on the south coast at the Changwon industrial complex at Masan.

Posco produces a wide range of steel products such as hot- and cold-rolled sheet, coils, plates, billets and wire rods, and silicon steel sheets and strips. About 80% of its output are flat products that will be increased by the expansion. Posco's expanded output will be for both domestic demand and export. Domestic consumption of steel rose from 2.4 million tons in 1973 to 7.3 million tons in 1979, and was expected to reach almost 9 million tons in 1981.[9]

Construction in the fourth-stage expansion included the installation of a No. 4 blast furnace (inner volume of 3,795 cubic meters and capacity of 7,540 tons per day); a second hot-strip mill with four roughing stands and seven finishing stands, giving a total capacity of 3.2 million tons per year; a No. 2 continuous-casting plant (two 2-strand slab machines with a total capacity of 2.2 million tons per year); a No. 4 sinter plant; expansion of the cold mill; and doubling of the capacity of the No. 2 melting shop to 6.5 million tons per year.[10] The integrated steelworks at Pohang was claimed to be the 11th largest in the world.

Lead and Zinc.—Zinc consumption, estimated by MCI, was 80,000 tons in 1979 and was expected to reach 92,000 in 1981. The Onsan refinery of Korea Zinc Co. produces 50,000 tons per year of zinc, 100,000 tons per year of sulfuric acid, and 300 tons per year of electrolytic cadmium. The Sukpo zinc refinery of Young Poong Corp. (owns 41% of Korea Zinc) has a 31,000-ton-per-year capacity of electrolytic zinc, 55,000 tons per year of sulfuric acid, 170 tons per year of electrolytic cadmium, 1,400 tons per year of copper sulfate, and 1,700 tons per year of zinc dust. A small smelter (3,500 tons per year) in Seoul, operated by Tong Shin Co., was shut down in 1978.

The largest use of zinc was for galvanizing and the largest single user was Posco. Zinc consumption in Korea was as follows: Dry cell battery, 15%; galvanizing and tubes and pipes, 40%; sheet, 15%; die casting, 8%; paint, 5%; and alloys and brass, 15%.

Lead consumption in 1979 was estimated at 32,000 tons and demand was to reach 45,000 tons in 1981. Currently, the only lead production in Korea is by the copper smelter of Korea Mining and Smelter at Changhang with a lead production capacity of 4,200 tons per year. Korea Zinc began site preparation for the construction of a 30,000-ton-per-year lead smelter (to be expanded later to 50,000 tons per year) at Onsan in 1979. The $40.5 million smelter was to be financed by the International Finance Corp., Korea Development Bank, and Korea Zinc.[11]

Tungsten.—South Korea's production of tungsten concentrate (70% WO_3) was from ores averaging 0.8% to 1.9% WO_3. The Sangdong Mine of the Korea Tungsten Mining Co., Ltd., produced about 90% of the country's tungsten output. The remainder of the output was by Chungyang Co., San-Nae Mine; Okbang Mining Co., Ltd., Wol-Ak Mine; Ssangjon, Daewha Mine; and other small operations. The mill at Sangdong has a capacity to process 2,000 tons of ore per day; the concentrate produced is shipped to Korea Tungsten's plant at Taegu where it is processed to produce tungsten powder, carbide, and about 1,500 tons of ammonium paratungstate. South Korea's production of tungsten constitutes about 8% of the total world output.

The Korea Mining Promotion (KMPC) Corp. announced the discovery of a new tungsten deposit near the Sangdong Mine. The new find was said to have 1.4 million tons of ore containing 0.5% elemental tungsten.[12]

Other Metals.—Bismuth concentrates were produced as a byproduct of tungsten processing by Korea Tungsten Mining Co., Ltd. The bulk of silver metal output was by Korea Mining and Smelting and the Boonpyong operations of Young Poong Mining. Close to 65% of the country's output of gold metal was from the smelters of Korea Mining at Changhang and Onsan. Mine production of other metal values during the year included minor amounts of antimony, arsenic, manganese, molybdenite, and tin.

KMPC announced the discovery of Korea's largest molybdenite deposit at the Sangdong Mine in Yongwol County, Kwangwon Province (130 kilometers southeast of Seoul). The deposit was estimated to contain 80 million tons of 0.41% molybdenite ore.[13]

NONMETALS

In addition to construction aggregates, Korea has abundant resources of limestone and dolomite. According to MER, Korea's self-sufficiency for diatomaceous earth was 92%; fluorspar, 43%; and asbestos, 20%. However, Korea was totally dependent on foreign sources for phosphorus.

Cement.—Total cement production capacity by eight companies at yearend 1980 was 23,450,000 tons. Ssanyong Cement Industries Co., Ltd., the largest cement manufacturer in Korea, completed the expansion of its Donghae plant. The expanded plant has a cement capacity of 9 million tons per year. The Donghae area has extensive limestone deposits and is located just 8 kilometers from Bukpyung, a seaport undergoing development. The Donghae plant is serviced by a good transportation network with distribution terminals at Ulsan, Pusan, and Masan. The plant supplies Korea's east coast and interior demand as well as export markets.

Sung Shin Cement Co. expanded its Tanyang plant to 2 million tons per year. Sung Shin was also adding a grinding plant in Ulsan to supply the growing demand in the south.[14] In addition to Ssangyong and Sung Shin, other producers of cement were Asia Cement Manufacturing Co., Halla Cement Manufacturing Co., Hanil Cement Manufacturing Co., Hyundai Cement Co., Koryo Cement Co., and Tong Yang Cement Co.

Fertilizer Materials.—Total industry capacity to produce chemical fertilizers in 1980 were as follows, in thousand tons: Nitrogen, 850; phosphorus, 450; and potassium, 130. Total production of fertilizer increased during the past decade from 590,000 tons in 1970 and 860,000 tons in 1975, to 1,350,000 tons in 1980 (peak production of 1,438,000 tons occurred in 1979). During this period, consumption averaged 750,000 tons per year compared with 827,000 tons consumed in 1980; the highest consumption level was 886,000 tons in 1975.[15] Excess production is exported to countries in Asia and the Middle East. The major fertilizer manufacturers included Chinhae Chemical Co., Ltd.; Hankook Caprolactan Co., Ltd.; Korea General Chemical Corp.; Kyunki Chemical Co., Ltd.; Namhae Chemical Corp.; Posco; Pungnong Chemical Co., Ltd.; and Yong Nam Chemical Co., Ltd.

Korea Potassium, a joint venture of Oriental Chemical Industry of Korea and Diamond Shamrock of the United States, will establish the country's first potash plant at Inchon. Initial production was scheduled in 1981. Plant capacity is expected to be 10,000 tons per year each for caustic potash and for potassium carbonate.

Other Nonmetals.—Korea has been a large producer of natural graphite; although some crystalline graphite has been produced, it is best known for its amorphous graphite. The principal deposits are located near anthracite occurrences in Shung Chong Puk Do, Kiong Sang Puk Co, and Kang Won Do.

Production of other nonmetallic minerals during the year included agalmatolite, andalusite, asbestos, barite, diatomaceous earth, feldspar, fluorite, marine salt, and talc.

MINERALS FUELS

There is no commercial production of oil or natural gas on the Korean Peninsula. The principal domestic fuel source is anthracite. Total installed capacity for electric energy at yearend 1980 was 9,391,000 kilowatts. Thermal powerplants accounted for 81.4% of total installed capacity, followed by hydropower plants, 12.3%, and nuclear plants, 6.3%. Electric power generation during the year was 31,777 million kilowatt-hours for thermal plants; 1,984 million kilowatt-hours for hydropower plants, and 3,477 million kilowatt-hours for nuclear plants. Electric power consumption by the mining sector in 1980 totaled 674 million kilowatt-hours; primary metal producers, 4,681 million kilowatt-hours; metal products, 2,314 million kilowatt-hours; nonmetal sector, 2,608 million kilowatt-hours; and chemicals, 4,277 million kilowatt-hours.

Coal.—Under a long-term energy supply-

demand program (1981-91) planned by the Government, Korea's demand for coal was to grow 11.1% annually during the decade, from 14.6 million tons (oil equivalent) to 27.4 million tons in 1986, and to 39.0 million tons in 1991. The share of coal to total energy demand was to change from 30.4% in 1981, to 35% in 1986, and to 32.1% in 1991.

The current anthracite production level is around 18.3 million tons. Virtually all of the country's production was domestically consumed, primarily for space heating. The Government-owned Dai-Han Coal Corp. (DHCC) produced 26% of the country's output in 1980. Tangseong, the largest mine worked by DHCC, produced 2,250,000 tons in 1980; followed by Dogye, 986,000 tons. The remainder of DHCC's output was from a number of smaller mines. Private mines account for 74.3% of the national output. Production by private mines in 1980 were as follows: Consolidated coal mines, 4,020,000 tons, and small-scale mines, 9,818,000 tons. MER revised Korea's coal reserves downward to 830 billion tons in 1980. In a move for increased efficiency, the Government planned to designate DHCC in 1981 to monopolize the import of coal.

Exploratory work to delineate underwater coal deposits was to be undertaken on the east and west coasts. First-phase operations will begin with exploring the coastal area of Kangnung and Pukpyong in the east, and the coastal area of South Chung Chong in the west, as well as the Kanghwa and Kimpo areas in Kyonggi. Certain underground coal deposits in Korea extend deep out into the ocean, and exploration will be conducted to determine quantity, depth, width, and quality of underwater coal deposits.

Posco was participating in the development of the Tanoma coal mine in Pennsylvania (United States) and the Thorley Mine in Australia. Daewoo Industrial Co. was negotiating a plan to develop the Baralaba hard coal mine in Australia as well as one in the United States.

Petroleum.—Korea and Japan continued oil prospecting in the Continental Shelf between the two countries. Data from seismic surveys, collected by a West German group between October 30 and December 3, 1979, were being studied and processed. Two unproductive wells were drilled in 1980, the first drillings under the 8-year Korea-Japan joint development program of the Continental Shelf. Under this agreement, at least 11 wells were to be drilled in search for oil until 1987.

Korea's total oil refinery capacity at the end of 1980 was 630,000 barrels per day. Korea Oil Corp. operates an oil refinery with a daily refining capacity of 280,000 barrels at the Ulsan Petrochemical Industrial Complex on the southeast coast. Homan Oil Refinery Co. has a daily refining capacity of 230,000 barrels at Yosu. The refinery of Kyong-In Energy Co. has a daily refining capacity of 60,000 barrels, and the refinery of Korea-Iran Oil Co. has a capacity of 60,000 barrels.

Under the Government's economic development plan, the country's daily oil refinery capacity was to reach 1 million barrels in 1986. Moreover, the country's dependence on foreign oil was to be reduced through conservation and substitution. Oil-burning powerplants account for 74.2% of the total electric energy generation capacity. This will be reduced to 35% of the projected 17.6 million kilowatts in 1986 by switching to coal and by increased output capacity by nuclear reactors. Also, to stabilize the foreign supply of oil, the Government was to invest $373 million to expand oil refining and storage facilities.

Uranium.—Geologic drilling has confirmed the occurrence of uranium in Kapyong, Chinchon, and Pyonghae. Uranium ore near Okchon reportedly was sufficiently rich to yield 7,500 tons of refined uranium. A deposit in Kumsan County was estimated to contain around 12.55 million tons of 0.04% uranium. Uranium and vanadium were discovered at Koesan that was associated with low-quality coal. Based on the surveys for uranium through 1980, the Korea Energy-Resources Research Institute estimated that domestic uranium resources totaled 43.6 million tons, equivalent to about 10,000 tons of pure uranium. Geologic reconnaissance was to continue to discover new resources, especially in Chungchong and Kyonggi Provinces.[16]

The Mineral Industry of Kuwait

By Roman V. Sondermayer[1]

During 1980, as in the past, the economy of Kuwait remained completely dominated by the Government-owned petroleum industry. About two-thirds of the gross domestic product (GDP) was generated by the oil industry; the oil industry contributed approximately 85% of the total Government revenues, and crude oil exports accounted for close to 93% of total export earnings. Although crude oil output was far lower than in 1979, Kuwait retained its high position among all countries in per capita value of the GDP because of higher prices charged for crude oil.

Development of the refining and petrochemical sectors and utilization of natural gas (all associated gas) were given priority in Government planning. About $16.6 billion[2] was allocated for investments in the present 5-year plan (1977-81) for these purposes.

During 1980, major events in the mineral industry of Kuwait were the establishment of the Government-owned Kuwait Petroleum Corp. (KPC) and the planning for expansion and modernization of two refineries and drilling of two wells to reach the Khuff producing zone, this zone yields chiefly gas elsewhere in the Arabian Penninsula.

PRODUCTION AND TRADE

During 1980, according to preliminary reports, Kuwait was among the 10 largest producers of crude oil in the world. In addition to crude oil and associated gas production, Kuwait had three petroleum refineries and one gas processing plant in operation. Total capacity of the refineries was 594,000 barrels per day and that of the gas plant was 3 billion cubic meters per year. Output of other minerals was minimal and had only domestic significance. The petroleum sector was Government-owned or controlled, while production of other minerals was in private hands. Table 1 shows Kuwait production trends for the most recent 5-year period.

The trade tables 2 and 3 show the trend in Kuwait foreign trade for 1978, the latest year for which the complete data were available. Except for petroleum exports, foreign trade in minerals was modest by world standards. The United States exported to Kuwait steel pipes, bentonite, radioactive materials, lubricants, and bituminous mixtures.

Table 1.—Kuwait: Production of mineral commodities[1]

Commodity and unit of measure	1976	1977	1978	1979[p]	1980[e]
Cement ---------- metric tons	351,122	329,339	621,334	[e]630,000	625,000

COMMODITY REVIEW

METALS

Kuwait did not report production of metals during 1980. Iron and steel products, mostly welded pipes, were produced by Kuwait Metal Pipe Industry at its works in Safat. By yearend, the Aluminum Extrusion Co. had not announced any decision to build a planned plant for the production of 6,000 tons per year of aluminum products.

NONMETALS

Cement.—In the Kuwait-Saudi Arabia Partitioned Zone, construction continued on a 2-million-ton-per-year cement plant. Kuwait Cement Co. held 45% interest in the venture, and the Saudi-Kuwait Cement Co. of Saudi Arabia held the remainder. Plans call for completion of construction in 1981.

MINERAL FUELS

Petroleum and Natural Gas.—Kuwait was among the major Organization of Petroleum Exporting Countries producers of crude oil during 1980. However, Kuwait limited its crude oil output, with an aim to lowering the supply on a market that had more oil than the world needed. As all natural gas produced in Kuwait was associated gas, cuts in production of crude oil resulted in lower production of natural gas. This affected production of the new gas processing plant at Shuaiba, which operated only two of the three existing production lines.

In the oilfields, very few new developments were reported. Activities were mostly limited to continuations of old projects like deep drilling to reach the deep Permian Khuff formation. At the beginning of 1980, two test wells, up to 20,000 feet, were being drilled in the Burgan Field, and one development well was being drilled in the Magwa Field. In addition, modest seismic work was conducted by Kuwait Oil Co. (KOC) offshore and onshore, and plans were made for extensive exploration in the northern and western parts of the country. Exploration was targeted for discovery of hydrocarbons, but hope was expressed that new discoveries would be in the form of natural gas. A natural gasfield would make possible a cut in oil production without affecting operation of the gas processing plant. For the domestic market, production of propane, butane, and other gas plant products was important in the past and should remain so because these gases are the principal source of energy consumed domestically. As only the 200,000-barrel-per-day Shuaiba refinery has modern technology in use, plans for modernization of the other two were drawn up during 1980. According to reports, the modernization contract for the Mina al Ahmadi refinery was awarded to the Japan Gasoline Corp. When completed, the refinery should have capacity of about 250,000 barrels per day; the cost of modernization should be between $500 million and $700 million. The expansion and modernization of the refinery at Mina Abdullah reportedly should cost near $1.5 billion, increasing capacity to 250,000 barrels per day. When all programs for refineries are completed, Kuwait should have a refinery capacity of about 700,000 barrels per day and should be able to process almost one-half of its output of crude oil. The cuts in production resulted in drastic changes in Kuwait's contracts with oil purchasers. Volumes of crude oil contracted by Gulf Oil Corp., British Petroleum Corp., and Shell Oil Co. were slashed from 1.3 million to 850,000 barrels per day. Kuwait's oil industry administrative organization was changed. The new KPC had four wholly-owned subsidiaries as follows: KOC operated facilities for production of natural gas and crude oil; Kuwait National Petroleum Co. operated refineries which managed local distribution of products and production of liquefied gas; Kuwait's Oil Tankers Co. which was in charge of crude and products shipping; and Petrochemical Industries Co. which produced petrochemicals. In addition, KPC controlled 70% of the Kuwait International Petroleum Investments Co. (KIPIC). KIPIC was also organized during 1980; the company's capital was reported at $347 million. The company was authorized to undertake the following activities outside Kuwait: To build petroleum refineries and sell products; to build petrochemical plants, produce chemicals, and market them; to transport processed petroleum and chemical products and to own means of transportation; to construct storage facilities for crude oil, products, and natural gas; to prepare studies for, and undertake construction of, pipeline networks; and to manage projects related to the petroleum industry. The statute also permited KIPIC to acquire interests in or purchase companies similar to itself.

The Mineral Industry of Liberia

By William F. Keyes[1]

Confidence in the Liberian business community was shattered in April by a coup which replaced the former Government with the People's Redemption Council, dominated by the military. Imports fell off, new investment decisions were postponed, and the Government encountered a severe liquidity squeeze, causing it to request a general debt rescheduling under the Paris Club of industrial countries. The coup also led to the postponement of consideration by new investors, including major companies already in the country, of construction of a steel mill, a new oil refinery, and several tree crop plantations. The investors' uncertainty was more severly felt because the coup followed stagnant economic conditions in 1979.

The iron ore industry dominated Liberia's gross domestic product (GDP) and exports, making Liberia greatly dependent on this one mineral. Production of about 20 million tons of iron ore annually is about 2% of the world total.

Other mineral production in Liberia included essentially small worker output of alluvial diamonds and gold, plus a cement clinker grinding plant in Monrovia.

PRODUCTION AND TRADE

Production of minerals in Liberia in 1980, and for the previous 4 years, is given in table 1.

Value of Liberian minerals exports for 1979, was as follows: iron ore $310 million; diamonds $39.1 million; and gold $377 million.

Table 1.—Liberia: Production of mineral commodities[1]

[1]Table includes data available through July 10, 1981.
[2]In addition to the commodities listed, a variety of crude construction materials (clays, stone, and sand and gravel) were produced, but available information is inadequate to make reliable estimates of output levels.

COMMODITY REVIEW

METALS

Gold.—Liberian gold production in 1979 was reported during 1980 as 1,086 troy ounces, all produced by small surface miners.

Bruce J. Clayman Associates, which had conducted a detailed exploration of its concession area in 1978 and 1979, indicated that it might commence commercial production in 1980. The group found placer gold along the common boundary of Grand Gedeh and Maryland Counties and along the course of the Kana and Dabawolo Creeks in southeastern Liberia.

The Ministry of Lands and Mines launched a campaign aimed at promoting the mining of gold in Liberia. It was reported that there were many gold deposits across the country that could be worked economically by small miners, and with the increase in the price of gold these could contribute significantly toward helping the Liberian economy. The Ministry was to help by providing tools and equipment and by teaching simple methods of gold mining. Several suitable major areas were named, located in Cape Mount, Lofa, Bong, Grand Gedeh, and Sinoe Counties.

Iron Ore.—The iron ore industry continued to dominate Liberia's GDP and exports, and the country was uncomfortably dependent on this one commodity. The continued slump in the world steel industry in 1979 and 1980 left the demand for, and price of, iron ore only slightly above 1978 levels; iron ore consequently accounted for only about 54% of export revenue in 1979 compared with 71% in 1976, the last strong year for the industry. The Liberian Finance Minister reported that iron ore producers showed a $50 million total deficit in 1979, of which the major producer Liberian-American Swedish Minerals Co. (LAMCO) suffered a loss of $26 million. It was feared that revenues would remain low in 1980 and 1981, and Liberian Government support would be required to keep the mines operating through that period.

Three large companies produced iron ore in Liberia in 1980. All three were hard hit during 1980 by the world steel crisis and by inflation, which raised their operating costs significantly. The largest company was LAMCO Joint Venture (LJV) and its operating arm, LJV Operating Co., which produced about 10 million tons annually of beneficated products. LJV was controlled 75% by LAMCO which, in turn, was an equal partnership of Liberian Iron Ore Ltd. (LIO) and the Liberian Government; 25% of LJV was owned by Liberia Bethlehem Iron Mines Co. (Libeth). The largest participant in LIO is the Swedish mining company, Granges AB, which is the operator; Libeth is a subsidiary of Bethlehem Steel Co. of the United States. LAMCO early in the year obtained Government approval to layoff over 700 of its 4,800 workers on the condition that the layoffs apply equally to Liberians and expatriates (an earlier Liberianization decree had required LAMCO to reduce its expatriate staff of 523 by 70% by 1983).

LAMCO decided to open new resources at Tokadeh, near the major mine Mount Nimba (in northeastern Liberia on the Guinea and Ivory Coast borders), to exploitation by early 1981, at an estimated cost of $7.5 million. Tokadeh had yielded about 6.2 million tons of iron ore between 1973 and 1977, and smaller quantities since. The new reserves in the area, with 40% to 55% iron content, would require beneficiation; the ore would ultimately replace Mount Nimba ore, which contains 65% iron, but which was expected to be exhausted by 1986.

The second largest iron ore mining company was Bong Mining Co. (BMC). BMC, which produced about 7 million tons annu-

ally of finished products (concentrates and pellets) at its open pit mine in the Saladea district, north of Monrovia, was owned half by the Liberian Government and half by German steel companies through Exploration und Bergbau GmbH (33.75%) and the Italian steel company Finsider International S.S. (16.25%). BMC continued drilling to establish further ore reserves, and it expected to complete its program at Bong Peak by early 1981. A preliminary calculation showed 134 million tons of iron ore at Bong Peak, in addition to the 215 million tons already known at the main Bong Mines area.

The third iron ore producer was National Iron Ore Co. Ltd. (NIOC). Its Mano Mines operation at Kakata, northeastern Liberia, was still experiencing grave financial and technical problems. NIOC was owned by the Liberian Government (50%), and the other half was owned by private, largely Liberian, investors. NIOC's production (or shipments) was only about 1.6 million tons in 1980, and future operations were dependent on the outcome of discussions (in progress at year-end) with the World Bank and other lending institutions.

The Mifergui iron ore project in Guinea was predicated upon the use of LAMCO's railroad from Nimba to the Port of Buchanan. The LAMCO management was however concerned about taking on this added responsibility and also permitting the use of its facilities at Buchanan. A decision by the Liberian Government was awaited.

Investigations in the Wologisi concession were suspended after the April coup by the Liberian Iron & Steel Corp., 51% owned by the U.S.-controlled Liberian International American Corp. (LIAC). A group of Japanese steel companies, led by Kawasaki Steel Corp., had an option to acquire LIAC's share.

Manganese.—The Geological Survey of Liberia commenced a preliminary investigation of the manganese deposits at Mount Dorthrow, Grand Gedeh County, in eastern Liberia.

NONMETALS

Barite.—An exploration program was carried out by the Senwein Mining Corp. on the barite deposits in Monserrado, Bong, and Grand Bassa Counties of the Gibi Mining Agency (district), northeast of Monrovia. Three field parties identified previously reported outcrops and located three additional ones. It was hoped to bring in mining equipment during 1980, in view of the favorable market for barite in the world petroleum industry. Fuel costs were, however, a mounting concern.

Cement.—The capacity of the clinker grinding plant on Bushrod Island, Monrovia, was expected to be doubled from its current capacity of over 100,000 tons. The plant grinds only imported clinker.

Diamond.—The Ministry of Lands and Mines began surveying some 1,970 acres of diamond-bearing land, along the banks of the Lofa River in Grand Cape Mount County. The area was formerly held by the Globex Minerals Co., which had lost the concession by default. It was intended to grant the demarcated area to about 79 small miners. At the beginning of 1980, there were 1,201 prospecting licenses and 1,164 mining licenses for alluvial diamonds in force in Liberia.

Weasua Mining and Development Corp. applied for and was granted a concession in 1979, with the exclusive right to produce gold and diamonds, with associated minerals. The concession area, of approximately 230 square miles, was located in Grand Cape Mount County.

Delta Engineers (Liberia) Inc. was engaged in exploration activities, under terms of the contract granted in 1978, on a diamantiferous gravel area in Grand Cape Mount County. Twenty-two Liberians and four expatriates were employed.

Phosphate Rock.—The U.S. Geological Survey published a report[2] of a deposit of high-grade phosphate rock near Bambuta, 70 kilometers north of Monrovia and 25 kilometers east of the Bomi Hills iron mine, which holds 1.0 million tons containing about 32% P_2O_5 or 1.5 million tons containing 28% P_2O_5; additional tonnages may be available. The ore may be suitable for detergents, medicines, and other products; it contains iron and alumina and would have to be mixed with lime to serve as a fertilizer.

MINERAL FUELS

Petroleum.—Bidding documents were prepared for a 2,500-kilometer offshore seismic survey and were to be available after midyear. A loan from the International Bank for Reconstruction and Development (IBRD) was applied for as a continuation of the $5 million IBRD-financed analysis of existing offshore, seismic and test, well data.

The refinery of the Liberian Petroleum Refining Co. at Monrovia operated below its

designed 15,000-barrel-per-day capacity. This was because of disruptions and financial problems resulting from the political coup in April, and disagreement between Liberian Government officials and the Lummus Co. of the United States, which had a management contract due to expire about 1983.

Uranium.—Coastal Liberia Uranium Enterprises Inc. was conducting an investigation of about 29 radioactive anomalies, including three geologic field crews working for approximately 6 months. Projected exploration costs through March 1980 were estimated at $4.5 million.

The Mineral Industry of Libya

By Roman V. Sondermayer[1]

Libya remained basically a country with a one-commodity economy during 1980. Production of crude oil and natural gas was by far the most important economic activity. More than half of the gross national product (GNP) was generated by the petroleum and natural gas sector of the economy. Although production of crude oil during the year was the lowest since 1975 and exports of crude in 1980 dropped by 13.7%, when compared with exports in 1979, a price increase of about 35% kept the foreign trade balance in the black and increased foreign exchange reserves. To postpone the harsh economic consequences of ultimately running out of petroleum, the Government took a number of measures. One was to cut back oil production with increases of prices up to the maximum permitted by Organization of Petroleum Exporting Countries (OPEC) and to intensify exploration. The second was to prepare a comprehensive 5-year plan for 1980-85 aiming at reducing dependence on oil and gas by increasing industrial and agricultural production and by expanding the country's infrastructure. The 5-year plan was part of the comprehensive "Transformation Plan," which aimed to convert Libya to a welfare state largely independent of oil by the year 2000.

The major events related to the mineral industry of Libya were as follows: Planning for construction of an integrated steel works and development of an iron ore mine; completion of a petrochemical plant at Abu Kamash; construction of a petroleum refinery and a petrochemical plant at Ras Lanuf; cutting back all oil production allowables by more than 16.5%; and planning installation of the first offshore production platform in the country by Azienda Generale Italiani Petroli S.p.A. (AGIP).

PRODUCTION AND TRADE

The only mineral-related activities in private hands were those producing oil and gas. Almost all other private mineral companies have been nationalized. The recent trends in production of minerals in Libya are shown in table 1.

Libya's trade balance improved in 1980 because of higher prices charged for oil.

Table 1.—Libya: Production of mineral commodities[1]

[e]Estimated. [p]Preliminary. [r]Revised.

[1]Table includes data available through Aug. 3, 1981.

[2]In addition to the commodities listed, a variety of construction materials (sand and gravel, crushed stone, brick, and tile) is produced, but available information is inadequate to make reliable estimates of output levels. Natural gas liquids are also produced but are blended with crude petroleum and are reported as part of that total.

[3]Series revised to exclude gas reinjected into reservoirs.

[4]Reported figure.

COMMODITY REVIEW

METALS

Iron and Steel.—During 1980, preliminary planning for development of an iron ore mine in the Wadi Shati Valley and construction of an integrated iron and steel works at Misurata on the Mediterranean coast were underway.

The Misurata plant was to be based on the Wadi Shati Valley iron deposit in western Libya, about 770 kilometers south of Misurata. A railway line will have to be constructed before mining can start.

The iron ore deposit follows the Wadi Shati Valley, a depression about 200 kilometers long and 20 kilometers wide. The ore is a sedimentary minette type of Jurassic age, and the formation dips gently from north to south. A magnetite central body is overlain and underlain by siderite and limonite. The principal gangue mineral is chlorite.

Reserves of magnetite were estimated at 420 million tons at a cutoff-grade of 47.5% Fe. At a 45.3% Fe cutoff-grade, reserves of nonmagnetic ores were reported at an additional 375 million tons.

The following tabulation shows the average composition of Wadi Shati Valley iron ore, as reported during 1980, in percent:

	Percent				
	Fe	SiO	CaO	AlO	P
Magnetic	47.5	4.5	2.2	4.10	0.90
Others	45.3	3.5	2.8	3.15	.85

The mine at Wadi Shati was planned for an output of 10 million tons of ore per year, probably by opencast nonselective mining methods. The ore will be trucked to the nearby site of a primary crusher where, in two stages, the ore will be reduced to 80 millimeters. Crushed ore will be transported from a storage area to Misurata by a standard gage railway, to be completed by 1986.

The mine site will have to have all ancillary facilities needed for operation of a mine in a remote area. The total labor force of about 5,000 persons will be housed in a small mining town planned near the mine. Reportedly most of the labor force will come from Chad, Niger, Tunisia, and Sudan.

NONMETALS

The only significant nonmetal produced in Libya was cement. Five cement plants

with a total capacity of 5 million tons per year were in operation during 1980. National Cement Co., with two plants near Homs, and Libyan Cement Co., with two plants near Benghazi, had an annual capacity of 2 million tons of cement each. The country was well supplied with raw materials for cement production, and cement companies produced most of the raw materials they consumed. Gypsum was produced south of Tripoli and east of Benghazi and Suk el Khamis. Salt from seawater was produced from several small plants along the coast. In addition, two larger salt-producing plants, one near Tripoli (22,000 cubic meters of brine per day) and another near Tobruk (24,000 cubic meters per day) were in operation. In addition to salt from seawater, large salt beds near Abu Kamash provide ample raw materials for salt production used in the Abu Kamash chemical plant.

MINERAL FUELS

Petroleum and Natural Gas.—During 1980, the petroleum and natural gas sector of the Libyan economy continued to slow down as a result of Government decisions. Implementation of a new program encouraging foreign oil companies to invest more in the oil and gas industry of the country in exchange for crude oil export rights was under way. Reportedly certain oil companies, not considered adequately active in investing in development of the Libyan oil and gas industry, had their contracts terminated or oil export quotas lowered. Some 13 new production-sharing exploration contracts were thus concluded with the operating companies, which agreed to invest about US$1 billion over 5 years in the country's petroleum industry. In these contracts, the share of the Libyan Government in future production was determined by the potential, as follows:

Oil and gas producing potential	Share in future production
Good	85% Government - 15% oil company
Medium	81% Government - 19% oil company
Low	75% Government - 25% oil company

In early 1980, the Government informed the oil companies in Libya of a reduction in allowable production rates as follows, in thousand barrels per day:

Operator	Before Apr. 1, 1980	After Apr. 1, 1980	Volume cut	Cut (percent)
Oasis Group	750	630	120	16.0
National Oil Corp. (Government of Libya)	560	540	20	3.6
Occidental	300	190	110	36.7
AGIP	200	160	40	20.0
Esso	185	135	50	27.0
Mobil	90	81	9	10.0
Elf-Aquitane	14	10	4	28.6
Wintershall	4	4	--	--
Total	2,103	1,750	353	16.8

Reasons for cutbacks were reportedly technical in nature. The notice did not specify field-by-field or well-by-well allowables as in the past.

Information on petroleum and natural gas exploration in Libya was fragmentary during 1980. It is estimated that about 12 to 15 drilling rigs drilled between 35 and 45 wells; apparently completed were 15 to 20 wells, and the total of meters drilled was between 80,000 and 100,000. Two offshore wells drilled by AGIP had oil and gas. Onshore AGIP announced discovery of oil in west Libya. Mobil had a discovery in the west Sirte Basin and one in the eastern part of the basin. Oasis reported two oil discoveries but details were not readily available, and Occidental made three discoveries in the Focha Dolomite in southwest Sirte.

Most of the development drilling was conducted in the Messla, Sarir, Aswad Sabah, and Zela Fields and Mobil started development of the Ghani Field in west Libya. In addition, AGIP was planning to install a production platform for 30 wells in the Gulf of Gabes, which will be the first offshore production facility in the country.

Nippon Kokan Kaisha and Marubeni Corp. of Japan received an order from Arabian Gulf Exploration Co. to lay 611 kilometers of 42-inch-diameter pipe. The new system will link the Misla Oilfields in the southeast with Ras Lanuf on the Mediterranean coast, where a new 220,000-barrel-per-day petroleum refinery and a petrochemical plant to be completed in 1984 were under construction.

The refinery, being built by Snamprogetti of Italy, and a 300,000-ton-per-day ethylene plant, being built by Stone & Webster,

comprise phase one of the Ras Lanuf project, which was about 20% to 25% completed by yearend 1980. Phase two of the project includes construction of a 50,000-ton-per-year ethylene glycol plant, a 50,000-ton-per-year butadiene plant, a 68,000-ton-per-year polypropylene installation, a 50,000-ton-per-year low-density polyethylene facility, and a 50,000-ton-per-year high-density polyethylene facility. Total cost of the project was reported at US$3 billion, of which US$1 billion was for the construction of the petroleum refinery.

During the celebration marking the 11th anniversary of Libya's "First September Revolution," a new petrochemical complex at Abu Kamash near the Tunisian border went onstream. The plant has an annual capacity of 60,000 tons of polyvinyl chloride, 50,000 tons of caustic soda, and 8,000 of hydrochloric acid. Total cost of the complex was reported at US$500 million, and Salzgitter Industriebau GmbH of the Federal Republic of Germany was the principal contractor.

[1]Physical scientist, Branch of Foreign Data.

The Mineral Industry of Madagascar

By Suzann C. Ambrosio[1]

Madagascar's mineral industry was a minor contributor to the 1980 gross domestic product (GDP), estimated at $2.4 billion in constant 1976 prices. The mineral industry, however, continued to provide an important source of foreign exchange during 1980. Chromite and graphite comprised approximately 90% of Madagascar's mineral trade. Other important minerals produced and exported included semiprecious, ornamental, and industrial stones. The value of mineral exports declined in 1979 to approximately $12 million and remained relatively low in 1980. Madagascar was the sole world producer of phlogopite mica, and remained an important supplier of U.S. mica and natural graphite during the year.

The Malagasy national economy, as measured by GDP, continued to grow at an annual rate of nearly 10%, in constant 1976 dollars. Large capital expenditures continued to be made for economic development. Investments for plant and equipment increased 17% between 1979 and 1980, reaching $190 million[2] by yearend 1980. The money supply grew at a rate of 23.2% in 1979 and 6.5% in 1980. Inflation was running at 16% annually in February 1980.

The Malagasy Government controlled over 75% of the national economy, over 90% of the exports, and 6% of the imports by yearend 1980. The Government was approaching $320 million in deficit financing by yearend 1980, and the Central Bank was estimated to show a deficit of nearly $640 million. Increased foreign borrowings and trade deficits have contributed to the relatively high ratio of debt service to export revenues (between 25% and 30% during 1980). The 1980 balance of trade was adversely affected by increased crude oil import bills and a decline in agricultural exports. The petroleum bill was reported to have tripled in 4 years, and drought conditions resulted in poor agricultural production. Imports increased approximately 20% in value in 1980, and restrictive controls continued to favor goods earmarked for development projects.

Ambitious plans have been outlined by the Minister of Economy to progressively develop the country's natural resources with a concurrent emphasis on import substitution. Agriculture, education, and other infrastructural support projects have consistently received the most favorable budget allocations. New mineral industry plans have focused on developing steel and expanding cement production. In addition, expansion of the nation's large chromite reserves and exploitation of the extensive iron, nickel, and coal deposits have received priority development status.

The future of Madagascar's mineral industry depends on the development of relatively inexpensive energy resources. The Andekaleka 116-megawatt hydroelectric plant under construction during 1980 was expected to be operational by yearend 1982. Construction was assigned to the Malagasy Electric and Water Co., with assistance from a Canadian engineering consulting firm. The first stage included setting up two 29-megawatt turboalternator units, and was estimated to cost $142 million. Madagascar was expected to finance approximately 10% of the cost, while various international and bilateral assistance programs were expected to provide the balance. By yearend 1980, over one-half of the civil engineering work was estimated to have been completed.

Exploration projects for petroleum, tar sands, and bituminous shale were delineated and investigations were conducted. Bids

for hydrocarbon exploration projects were submitted, and negotiations were under way in 1980. Law 80-001, the Madagascar Petroleum Code, was promulgated on June 6, 1980. The legislation covered mining titles, pipeline transportation, ocean hydrocarbons, the financial system, and all the rights and infractions associated with exploration, prospection, research, exploitation, and transportation of hydrocarbons. The code insured the country's control of the exploration and exploitation of its hydrocarbons by outlining the parameters of foreign participation.

PRODUCTION AND TRADE

Chromite, graphite, and mica continued to be the most important mineral commodities produced and exported in Madagascar during 1980. The mineral trade balance continued to worsen despite an overall increase in the total production of mined materials and metals products. Major mineral imports continued to be comprised of crude oil, metals, and cement.

Chromite outperformed other commodities in the mineral industry during the year. Production increased by approximately 40%, recovering from a 5-year low reported in 1979. Exports were estimated to decline, however, because of transportation and marketing difficulties. Chromite contributed approximately 50% of total mineral exports (excluding mineral fuels) and approximately 2% of total commodity exports between 1970 and 1975. Subsequent declines in production and trade have resulted in part from softened world demand for steel products, and the lack of chromite processing facilities in Madagascar. Approximately 40,000 tons of chromium ore, grading 40% to 46%, was exported to the United States in 1980.

Malagasy graphite production hit a 5-year low in 1980. Graphite was surface mined along the weathered parts of the deposits. Poor meteorological conditions and equipment failures were primarily responsible for declines in production and trade. Malagasy exports of crystalline graphite to the United States decreased 40% from 1979 to 1980, and comprised 57% of U.S. imports in 1979 and 28% in 1980. The world market for natural crystalline flake graphite continued to exhibit strong demand and short supplies during the year.

Madagascar's 1980 phlogopite mica production increased by 48%, and export growth exceeded 100% of the levels reported in 1979. Approximately 15% of Malagasy's mica production was classified as phlogopite splittings, and the majority of the remainder was classified as phlogopite sheet mica. The U.S. percentage of Malagasy mica imports declined from approximately 4% in 1979 to less than 1% in 1980. This was in part because of the growing competition from synthetic products and the varying requirements of the General Services Administration's strategic stockpile materials.

The majority of Madagascar's trade continued to be with the European Communities (EC). France had the largest market share of Madagascar's trade, and over 50% of Madagascar's trade deficit with the EC was with France. Slight shifts in Madagascar's geographic trade distribution were evident since 1978. Africa's share of Madagascan exports increased to 10%, and imports grew to 3%, along with increased trade volumes with China, Japan, and Canada. Algeria and Reunion became the principal African buyers, and Mozambique and the Ivory Coast became the principal African suppliers. Trade with the United States has substantially declined since 1978, primarily because of decreased purchases of coffee and vanilla.

COMMODITY REVIEW

METALS

Chromite.—Kraomita Malagasy continued to control the two operating chromite mines in Madagascar during 1980. The combined maximum production capacity of the mines were estimated at 215,000 tons per year. The Andriamena Mine was estimated to have an annual capacity of 175,000 tons, and reserves were estimated to contain 4 million tons of concentrates. The Andriamena ores graded 48% on the average, and were concentrated prior to shipment. The Befandriana Mine capacity was estimated at 40,000 tons per year, and identified resources were estimated at 250,000 tons. The higher quality Befandriana ores were fine and friable and did not require processing prior to exportation.

Transportation inadequacies continued to

result in overall production efficiencies of less than 80% during the year. Approximately 75% of the chromite produced in Madagascar found its way to international markets during 1980. Andriamena chromite production was trucked over a 90-kilometer asphalt road to a railhead at Morarano. The ore was then transferred to 30-ton capacity rail wagons to the port of Tamatave. The rail line was subject to washouts, derailments, and other problems. The Befandriana ores were transported by truck to Narinda Bay on the Northwest coast, loaded onto pontoon barges, and towed out to ships in the Bay. Both routes were limited by inadequate storage and loading facilities, and the total transport costs were very high.

An experimental ferrochrome plant was expected to be set up in Andriamena, with financial backing from the European Investment Bank (EIB). If the pilot test were determined successful, a ferrochrome facility would be designed and constructed at a 60,000-ton-per-year capacity. The Andekaleka hydroelectric plant, under construction during 1980, was expected to be the source for the energy-intensive processing plant.

Iron Ore.—Field studies continued on the Soalala iron ore deposits during 1980. The deposits were estimated to contain 300 million tons of ore reserves, with iron content ranging from 25% to 60%. Details of the known iron-ore resources in Madagascar appear in table 4.

Table 4.—Iron ore resources in Madagascar, 1980[1]

Deposit	Location	Type of ore	Principal mineral	Iron content (million tons)	Estimated reserves potential (million tons)
Ambatory-Analamy	Moramanga	Residual Lateritic	Goethite Hematite	46	38
Betioky	Betioky	Residual Lateritic	Goethite Hematite	24	30

Marorangata-Ambatoloana	Tananarive	Lake Superior	Magnetite, Hematite.	25	8
Soalala	Kizomby	Lateritic	--	60	300
Total	--------	--------	-------- --------		551

[1] Mineral Raw Materials in Africa Iron Ore. Paper presented at the Regional Conference on the Development and Utilization of Mineral Resources in Africa, United Nations Economic Commission for Africa, Tanzania, Aug. 15, 1980, E/CN.14/Min.89/31, pp. 28-39.

Source: United Nations Economic and Social Council.

Feasibility studies conducted over a 2-year period were expected to include extensive drilling and metallurgical studies. Investigations were initiated by Madagascar's Mining and Industrial Board and Italsider S.p.A. (Italy). The financing was handled through the European Development Fund, together with Italian and French bilateral assistance programs. A European consortium of steelmakers were reported to be interested in exploiting the Soalala deposits.

Other.—Bauxite deposits studied during the last decade estimated conditional resources of 70 million tons at Manantenina, grading 40% Al_2O_3 and over 40 million tons at Marangaka, grading 38% Al_2O_3. The Government Geologic Service revealed that the bauxite was of the crystalline type and was of a high iron content. Softened world demand for this type of ore and large infrastructure costs associated with development of the deposits have inhibited exploitation.

Nickel ore deposits were identified in the Moramanga area of eastern Madagascar and were examined during 1980. North Korea and Madagascar signed an agreement to develop the resource at a projected rate of 150,000 tons per year. Plans were made to construct a refinery that would draw energy from the Andekaleka hydroelectric complex.

NONMETALS

Cement.—In 1980, Madagascar imported approximately 180,000 tons of cement out of the 245,000 tons required by domestic industries. E. S. Cement d'Antsirabe planned to

construct facilities to makeup for the shortfall. The new projects being considered were a 580,000-ton-per-year cement plant at Mahajanga, a 115,000-ton-per-year plant at Ibity, and a 500,000- to 1,000,000-ton-per-year plant at Soalara-Toliara.

Technical studies were completed and commerical agreements were made in 1980 for the Mahajanga plant. The facility was expected to utilize coal from Sakoa, and substantial quantities of the product were expected to be exported to the Middle East. Investments worth approximately $95 million were expected to be shared by Spain, while the bulk of the financing was expected to be furnished by an unnamed Arab country. The Soalara-Toliara cement plant was in the planning phase by yearend 1980.

A cement facility was under construction at Antsirabe during 1980. The 115,000-ton-per-year plant was estimated to cost $4.5 billion and was projected to be operational in 1982. A vertical kiln design was envisioned, with future expansion capability projected at 180,000 tons per year.

Fertilizer Materials.—The Ze-Ren fertilizer project, a joint venture between Madagascar and N-Ren International (United States), entered the construction phase during 1980. The engineers and contractors were Dominion Bridge and N-Ren International, and the Haldor Topsoe process was expected to be employed. The production of a total of 100,000 tons per year of ammonia and urea was expected, with a startup date of 1982.

Graphite.—Madagascar's graphite deposits occur in micaceous gneiss and schist and extended throughout the eastern half of the island. Resources were estimated to be very large, grading 3% to 10% graphite. About two-thirds of the conditional resources were classified as large flake and one-third was fine flake graphite.

Total graphite production decreased by approximately 28% in 1980 to 12,000 tons. There were five major private producers of flake graphite by yearend 1980. The Gallois Mines, owned by Etablissements Gallois (France), produced slightly over one-half of the total output. The interest of Société Lyonnaise Agricole Minière et Industrielle, one of the private producers of graphite, were taken over by a company owned by Sweden—Société Minière de la Grande Ile. Approximately 25% of the graphite produced in 1980 was attributed to this company. Another independently owned and operated facility at the Sahanavo Mine shut down operations during the second half of 1980.

Mica.—The total output of mica increased substantially during 1980. Mica exports doubled the levels reported in 1979 to approximately 1,500 tons. Four mines located at Ampandrandava, Benato, Ambararata, and Sakamasy were producing mica during 1980. Three private companies operated these productive mines in the southern part of Madagascar; Société Minière de la Grande Ile, Société des Mines d'Ampandrandava (SMGI/SOMIDA group) and the Fils de Jenny Co.

MINERAL FUELS

Coal.—Madagascar's known reserves of coal were estimated at 500 million tons in 1980, of which approximately 60 million tons were classified as steaming-grade coal. Most of the reserves were located within the Sakoa deposit in southwest Madagascar. An easily accessible outcrop of the Sakoa reserves were estimated to contain 40 million tons, and pilot exploitation was expected to begin sometime during 1981.

Investigations of the coal deposits continued throughout 1980 and focused on transportation and marketing aspects, as well as the project's overall energy and economic worth. A protocol was signed in 1980 by a Yugoslav construction and industrial company to develop Madagascar's coal mining. Specifics of the agreement were unknown by yearend 1980. The initial development of the Sakoa coal reserves, including necessary infrastructure, was projected to be very large. The construction of a new port at Toliara and a railroad connecting the deposit to the coast were under consideration.

Petroleum.—Exploration of petroleum, indigenous tar sand, and bituminous shale deposits were undertaken by various international organizations between 1964 and 1975. After the 1975 nationalizations, the National Military Office for Strategic Industries (OMNIS) became responsible for hydrocarbon exploration and eventual exploitation. The Malagasy Petroleum Co. was responsible for pricing and distributing imported petroleum supplies. Late in 1980, a new national hydrocarbons firm, AKORAMA, was proposed. OMNIS was to remain the chief shareholder of the new organization. AKORAMA was expected to be the executive organ of the State, charged with research, exploitation, and transportation of hydrocarbons.

The Karoo sediments located in the western part of the island, contain sizable resources of oil equivalents in the Morondava (southwest) and Majunga (northwest) Basins. The Bemolanga tar sands, also called bituminous sandstones, and the Tsimiroro heavy oil deposits lie within the Morondava Basin. Bituminous sandstone reserves were estimated at 2 to 3 billion tons, and heavy oil reserves were estimated at 9 billion tons. The Bemolanga deposits were estimated to contain the equivalent of 27 billion barrels of oil in approximately 400 square kilometers. The total area of possible oil and gas extends approximately 200,000 square kilometers within the Morondava Basin and 110,000 square kilometers within the Majunga Basin. The ratio of possible offshore to onshore deposits within the two basins were 67% and 57%, respectively, indicating that the majority of the combined possible oil-bearing sites were located onshore.

The International Development Association of the World Bank granted $12.5 million in credit to support petroleum exploration efforts during 1980. The project provided for consulting services in geological exploration and law. Madagascar was expected to contribute $2.1 million toward the cost of the project. The EIB loaned Madagascar $170 million in 1980 to exploit 3 billion tons of the bituminous sandstone deposits. Approximately 17% of the deposit was determined to be extractable by opencast mining, for the eventual annual production of 200,000 tons of synthetic petroleum products.

The Klöckner Industrie Anlagen of Duisburg (Federal Republic of Germany) conducted laboratory tests on the bituminous samples, utilizing the Lurgi conversion process. Results of the analyses were not made public by yearend 1980. OMNIS was planning to operate a pilot plant in northwest Madagascar and undertake an intensive drilling program during 1981. The petroleum refinery in Tamatave, which was rated at 9,670 barrels per day, continued to operate in 1980, and plans were made to construct another refinery at Tor Masina. Details of the pilot plant and new refinery were not available by yearend 1980.

Uranium.—A cooperative agreement between OMNIS, the United Nations Development Program and the International Atomic Energy Agency to evaluate uranium prospects over a 3-year period, made progress during the first full year of 1980. Metamorphic and sedimentary formations were investigated in the Fort Dauphine region, southern Madagascar, and in Antsirabe, south of the nation's capital, Antananarivo. OMNIS concluded an agreeement with the Croation Construction and Industrial Complex (Yugoslavia) during 1980, to survey and exploit uranium deposits near Tolagnaro. Under the agreement, a group of Yugoslavian technicians and engineers were to conduct field work in southern Madagascar.

The Mineral Industry of Malaysia

By John C. Wu[1]

The mining industry is and will continue to be an important sector of Malaysia's economy. Although the mining sector (nonfuel) contributed only 5% to the gross domestic product (GDP) of Malaysia in 1979, mineral exports of tin alone amounted to US$1 billion, or 9.1% of Malaysia's overall export earnings (US$11 billion) in 1979.[2] Other mineral exports of Malaysia were copper, bauxite, and byproduct minerals such as ilmenite, monazite, and zircon. Malaysia remained the world's largest tin producer in 1980. Its production constituted over 35% of the world's total tin supply. A joint-venture agreement between Malaysia Mining Corp. and the Selangor State Government worth US$91 million was signed in 1980 to develop the Kuala Langat deposit with an estimated tin reserve of 139,000 tons. The project is expected to come onstream in 1985, with an initial output of 2,200 tons of tin concentrate per year, gradually increasing to 3,000 tons per year after 1988.

In the mineral fuel sector, Malaysian oil reserves are less significant by world standards; however, Malaysia's nonassociated natural gas reserves will become important to the world in the 1980's. The newly discovered natural gasfield off the State of Trengganu, along the east coast of peninsular Malaysia, is larger than the Bintulu Gasfield of Sarawak, where the gas reserves are estimated at 10 to 14 trillion cubic feet. Malaysia will become one of the world's largest liquefied natural gas (LNG) producers, when the US$1 billion Bintulu LNG plant comes onstream in 1983.

Malaysia's crude oil exports are currently the second largest commodity export earner after rubber. In 1979, crude oil export earnings were valued at US$1.8 billion, or 16.4% of Malaysia's total export earnings. Output of crude oil rose 30% to 283,000 barrels per day in 1979 from 217,000 barrels per day in 1978. However, the Government of Malaysia, in an effort to conserve its oil reserves, in June 1980 began to enforce the National Petroleum Depletion Policy, which allowed Petronas, the State-owned oil and gas company, to regulate the overall oil production to average 270,000 barrels per day in 1980, and to reduce production to 260,000 or 250,000 barrels per day in later years.

Malaysia's GDP grew 8.3% in real terms between 1978 and 1979. A 7.7% real growth in Malaysia's GDP was estimated for the 1979-80 period. Malaysia's real GDP in 1980 was estimated at US$13.2 billion. This growth of Malaysia's economy was sustained largely by economic expansion in domestic demand and by favorable but weakening export earnings. Production in the agriculture, manufacturing, construction, and service sectors increased in 1980. Output in the mining sector, however, declined slightly as a result of lower production of tin and crude oil. Export earnings also slowed slightly owing to the lower level of economic activity of industrial countries, which in turn has weakened the overseas markets of some of Malaysia's export commodities. The export earnings of tin and crude oil remained high because of higher prices for oil and raw materials. Malaysia's imports of machinery, transport equipment, chemical commodities, and manufactured goods continued to grow in 1980. The higher gross imports were stimulated by the strong expansion in domestic demand for the intermediate goods. The overall balance of trade in 1980 was estimated as a favorable trade surplus of US$3.1 billion, only slightly lower than that of 1979.

In formulating a national mineral policy to encourage mineral exploration, a new National Mining Code was introduced by the Government to streamline procedures and policies related mainly to land use. The code was comprised of two acts: A National Mining Act, covering the issue of mining rights; and a Mines Control Act, regulating the mining operations. However, the joint Federal-State National Land Council reportedly has rejected the draft National Mining Code. The opposition came mainly from the State governments, which insist on preserving their rights over mining lands.

PRODUCTION

In 1980, most of Malaysia's mineral production declined except copper, bauxite, and clay. Crude oil production estimated for 1980 was 100.4 million barrels at an average of 275,000 barrels per day compared with 283,000 barrels per day in 1979. This was owing to the production cutback mandated by the National Petroleum Depletion Policy to conserve Malaysia's limited oil reserves. The tin-in-concentrates produced during the first 9 months of 1980 totaled 46,229 tons, a decrease of 2.2% from 47,289 tons produced during the same period of 1979. The lower level of tin output reflected the declining grade of existing ore bodies. Despite the favorable prices of tin, Malaysia's tin miners were unable to boost their production in 1980, because of the higher cost of production, especially the energy costs. Iron ore production in the first 9 months of 1980 declined 3.2% compared with output in the comparable period of 1979, from 258,664 tons to 250,452 tons. Copper concentrate production for the first 9 months, however, registered a 6.2% gain from 79,441 tons in 1979 to 84,336 tons in 1980. The only significant gain in the mining sector for 1980 was in bauxite mine production, which was 700,514 tons during the first 9 months of 1980 compared with 249,522 tons during the same period of 1979. This spectacular increase was due to the opening of an additional mine in Johore. Malaysia's china clay production increased 45.2%, from 24,891 tons for the first 9 months of 1979 to 36,134 tons for 1980.

[1]All production is from peninsular Malaysia (Malaya) unless otherwise specified. Table includes data available through July 30, 1980.

[2]In addition to the commodities listed, a variety of crude construction materials (clays, sand and gravel, and stone), salt, and fertilizers are produced, but output is not reported and available information is inadequate to make reliable estimates of output levels.

[3]Estimates based on exports of copper concentrates.

[4]Based on export figures.

[5]Includes small amounts of tin from the smelter in Singapore.

[6]Includes production from Malaya and Sarawak.

TRADE

Tin and crude petroleum of the mineral sector, along with rubber, sawed logs and timber, and processed palm oil of the agricultural sector, remained by far the major export earners of Malaysia.

In 1979, tin exports earned US$1 billion in foreign exchange, and crude and partly refined petroleum earned US$1.9 billion. Tin and petroleum accounted for 26.4% of Malaysia's overall foreign exchange earned in 1979 and remained substantially the same in 1980.

The main buyers of Malaysia's tin in 1979-80 were Japan, the Netherlands, the United States, the U.S.S.R., Italy, and India. The major importers of Malaysia's crude oil were Japan, Singapore, the United States, the Philippines, and Thailand.

Malaysia's gross major imports in 1979 were machinery and transport equipment, valued at US$2.9 billion; manufactured goods, valued at US$1.3 billion; and mineral fuels, valued at US$938 million. These three major imports accounted for over 65% of the value of overall gross imports in 1979 and about the same in 1980.

The main supplying countries of Malaysia's major imports in 1979-80 were Japan, the United States, Singapore, the Federal Republic of Germany, the United Kingdom, and Australia.

Malaysia imported most of its mineral fuels from Saudi Arabia, Singapore, and Kuwait. The reasons for Malaysia to import substantial volumes of mineral fuels are (1) it is more profitable for Malaysia to export its lighter crude and import the heavier crude from other countries, (2) Malaysia's refineries were designed to process a mixed crude, using 70% imported crude and 30% Malaysian crude to produce the domestic requirement of refined products, and (3) Malaysia's existing refining capacity could not meet the growing domestic demand for the refined products.

During the 1979-80 period, Malaysia's major trading partners, based on the overall value of two-way trade, were Japan, the United States, Singapore, Australia, the United Kingdom, and the Federal Republic of Germany.

COMMODITY REVIEW

METALS

Aluminum.—Two bauxite mines are currently operating in the Pengerang area (Telok Ramunia Mine) and the Johore area (Sri Medan Mine) of the southern portion of peninsular Malaysia. The ore from Pengerang is essentially derived from volcanic material and to a lesser extent from sediments and granite-micropegmatites. The ore reserves in the Pengerang area are estimated at 9 million tons, and should last for another 15 years at the current rate of production.

The total bauxite production was down substantially in 1979 since only one mine was in operation during the first 7 months of 1979. During the third quarter of 1979 to the third quarter of 1980, production was at a much higher level with two mines operating. Most of Malaysia's bauxite was exported to Japan. Malaysia's exports of bauxite were valued at US$6.1 million, up 22% from US$5.0 million in 1978.

A US$27 million, 180,000-ton-per-year aluminum smelter complex planned for Sabah was shelved in September 1980, because there was not enough natural gas in the area to generate the required electric power for the proposed smelter.

Copper.—The only copper producer of Malaysia, Overseas Mineral Resources Development Sabah Bhd (OMRDS), operates an open pit porphyry copper mine at Mamut in the foothills of Mount Kinabalu, 70 miles from the State capital of Sabah, Kota Kinabalu. Copper deposits in the Kinabalu area are a low-grade porphyry type associated with tertiary adamellite-granodiorite intrusions. At the Mamut Mine, the ore reserves are estimated at 77 million tons, with an average grade of 0.608% copper and associated gold and silver content. Mining and production of copper concentrates started in 1975. In 1980, the production of copper concentrate was near full capacity at a rate of 9,200 to 10,000 tons per month. For the fiscal year ending March 1980, the company for the first time earned a pretax profit, which amounted to US$6 million. This was largely due to the extraction of 2 tons of gold and 12 tons of silver which were valued at US$28 million. Malaysia exported most of its copper ore and concentrates to Japan. OMRDS has been exporting about 90,000 to 100,000 tons of copper concentrates to Japan each year, which accounted for 3% to 4% of Japan's annual consumption.

OMRDS, a joint-venture company, was originally owned by Overseas Mineral Resources Development of Japan (51%) and Malaysia's local private interests (49%). In mid-1980, the Sabah State government acquired all of the 49% interests from the local stockholders, through the State Economic Development Corp., and there was speculation that the State planned to acquire a majority interest in OMRDS. The Sabah Government was also interested in building a US$136 million copper smelter with an annual capacity of 60,000 to 100,000 tons of copper, and the acquisition of the local shareholders' 49% interests was seen as a first move in setting up the smelter. A feasibility study of building the smelter was expected to be undertaken soon.[3]

Gold.—Gold in Malaysia is recovered as a byproduct of tin mining in the Bidor area of Perak and in the Kuala Lumpur area of Selangor. It is also produced by small-scale mining operations in the Raub area of Pahang and in the Bau mining district of Sarawak. In recent years, an appreciable quantity of gold was extracted from the Mamut copper mine in Sabah. In 1980, there were 10 small-scale gold mines operating in the States of Pahang and Sarawak.

As a result of a detailed 2-year ground survey by the Malaysian Government, with the cooperation of experts from the Canadian Industrial Development Authority, a number of gold deposits have been discovered in several areas in Ulu Kelantan. The areas where alluvial gold deposits were found are Gua Musang, Manik Urai, Sokor, Dabong, Sungai Pergau, and Sungai Galas. It was reported that the mining activities to extract the gold from the areas are expected to be carried out by a joint venture between the State Economic Development Corp. of Kelantan and a local mining firm.[4]

Iron and Steel.—Malaysia's iron ore output of 1980 increased slightly from the output of 1979. In 1980, there were 10 mines in operation. The largest mine, at Gunung Jerain in Kedah, produced 148,000 tons of iron ore, accounting for 40% of Malaysia's total output in 1980. The small-scale operations include one at Bukit Iban in Pahang, six in Perak, and two in Johore. Most of the

iron ore was consumed domestically by Malaywata Steel Bhd for its steel mill in Prai.

The Government of Malaysia announced in September 1980 that it will build a direct-reduction iron processing and electric furnace steelmaking complex at Teluk Kalong near Kemaman in the State of Trengganu. The total cost of the project is estimated at M$500 million (US$227.3 million). The complex would have an iron ore storage area, a sponge iron plant (projected cost US$151.7 million), an electric furnace steelmaking shop, a billet plant, and a steel rod producing plant. This steelmaking complex is expected to be operational in 1985.[5]

Malaysia's Amalgamated Steel Mills has awarded a contract to Danieli, an Italian plant maker, for the construction of what will be Malaysia's largest electric arc furnace steelworks. The plant includes a 70-ton electric furnace and a six-strand continuous billet caster. The furnace will be supplied by Tagliaferri, and Danieli will build the caster, which will supply the feed for the existing wire rod plant.[6]

Tin.—Malaysia was still the world's largest tin producer in 1980. The output of tin-in-concentrate for the first 9 months of 1980 was down slightly from the output of the same period in 1979. The number of active mining units at the end of September totaled 872, compared with 936 and 873 at the end of 1978 and 1979, respectively. Of the total tin concentrates produced by the end of September 1980, 56% was mined by gravel pumping, 30% by dredging, 4% by open casting, 2% by underground mining, and 8% by retreatment, dulang, and other methods.

Of the total number of tin production units active at the end of September 1980, 766 units were gravel pumps, 54 were dredges, 27 were opencasts, 20 were underground, and 5 were others. These active tin mines were operated mainly in the following States: 556 units in Perak, 181 in Selangor, 33 in Pahang, 30 in Johore, 21 in Kedah, 18 in Perlis, 17 in Trengganu, 8 in North Sembilan, and 8 in Malacca. Malaysia's tin industry employed a total of 39,720 persons at the end of September 1980. Over 85% of this total labor force was employed by gravel pumping and dredging mines concentrated in the States of Perak and Selangor.

The value of tin output accounted for an estimated 4.6% of Malaysia's GDP. Malaysia's tin exports were valued at M$2.3 billion (US$1 billion) in 1979, up 15% from M$2 billion (US$909 million) in 1978. Export earnings of tin for the first 9 months of 1980 were valued at M$1,934.2 million (US$879 million), up 12% from M$1,728.0 million (US$785 million) for the same period in 1979. Export duty imposed on tin provided for an estimated 5.4% of Malaysia's total Federal revenue in 1979.[7] Tin in Malaysia remains the fourth largest primary commodity export, following rubber, petroleum, and processed palm oil. In an effort to encourage increased tin production, the Federal Government of Malaysia introduced a two-part tax structure in October 1979. The two-part tax structure is basically a restructure of tin export duty, which is intended to encourage the development of the marginal tin mines affected by a decrease in tin price. A "cost plus" concept was used in this newly introduced duty structure which provided a reference average tin production cost of M$1,110 per picul. If the tin price exceeds M$1,400 per picul,[8] a 20% export duty will be imposed up to M$1,450 per picul; a 5% duty will be added for each M$50 per picul beyond M$1,450 per picul, up to a maximum export duty rate of 50%. On the other hand, the Federal Government of Malaysia amended the upper limit of tin profit tax from 12.5% to 15% when annual profit exceeded M$400,000.

Despite the introduction of this two-part tax structure, Malaysia's tin output remained stagnant over the 1979-80 period. The industry faces problems of high production cost, depletion of the exisiting mines, and inability to gain mining rights to new deposits. According to a recent estimate, Malaysia's established ore reserves on (or adjacent to) existing mining operations could provide for an average future mining life of only about 10 years at current output levels with an additional "possible ore reserves" to allow another 2 to 3 years of tin production.[9]

Malaysia Mining Corp. (MMC) reached a joint-venture agreement with Kumpulan Perangsang Selangor (KPS), the mining arm of the Selangor State government, on June 21, 1980, to develop the deep alluvial tin deposit at Kuala Langat in Selangor. According to the agreement, a new company called Kuala Langat Mining Serdinian Berhad will be established. KPS will have a 65% majority interest in the M$200 million (US$91 million) joint venture, while

MMC will own 35%. The agreement took 3 years of intense negotiation, and 10 years have passed since it was first proposed by Charter Consolidated Ltd., which discovered the Kuala Langat deposit in 1970.[10] Kuala Langat Tinfield is the second richest alluvial tinfield in Malaysia after Kinta Valley in Perak. The established reserves are estimated at 2.3 million piculs (139,100 tons) and the possible total reserves at 5 million piculs (302,400 tons). Much of the tin deposit lies under the Brooklands Estate, which covers 4,200 acres. The tin-bearing material is covered by overburden to a depth of 100 to 150 feet. The thickness of the tin ore body underneath the overburden ranges from 100 to 200 feet. The development of this Brooklands Estate represents the first phase of the entire Kuala Langat tin project. The Brooklands palm oil estate is owned by Plantation Holdings, and the Selangor State government has an agreement in principle to buy the land required for mining on a progressive basis. The first phase of the project is expected to come onstream in 1985 with the first dredge, which is estimated to cost US$23 million, in operation. Preliminary output during the first-phase operation for 1985-89 is projected as follows:

Year	Quantity of tin concentrates (metric tons)
1985	2,238
1986	3,205
1987	2,903
1988	2,963
1989	3,024

The second phase is expected to be completed in 1990 with at least three large dredges in operation, and the output level is expected to reach 6,000 to 7,000 tons of tin concentrates per year after 1990. The entire project is forecast to last 22 years.[11]

The significance of this new agreement is twofold. First, it tends to give new hope to the Malaysia tin industry, which in the last few years has been unable to lease new land or renew existing mining leases. Second, it will augment the country's dwindling tin production from the existing tin mines, which are facing depletion in 10 years.

MMC reportedly is negotiating with Datuk Kramat Holdings to acquire a majority interest in its 70,000-ton-per-year smelter after Straits Trading declined to offer MMC equity participation in its 60,000-ton-per-year Penang smelter. If the talks should fail again, MMC plans to build a tin smelter at Budit Rajah near Kelang in Selangor. The smelter would have an initial capacity of treating 20,000 tons per year of tin concentrates and refining 15,000 tons per year of tin metal. A prequalification invitation for tenders to construct a tin smelter has been issued by MMC in April 1980.

A new tin mining company, Modal Seri Pandan Sendirian Berhad (MSPS), was formed in Malaysia in early 1980. MSPS is a joint-venture company, owned 30% by Conzinc Riotinto Malaysia and 70% by the State government of Pahang. The company will mine a 3,000-acre alluvial plain for tin at Sungai Pandan, 10 miles northwest of Kuantan in Pahang. The joint-venture project will cost M$16 million (US$7.3 million). Production is expected to begin in 1982 and to last 25 years based on the estimated ore deposits in the area.[12]

In June 1980, an agreement for the merger of six tin mining companies was reached. Proposal for the merger was initiated by Malayan Tin Dredging. The companies involved were Malayan Tin Dredging, Southern Malayan Tin Dredging, Southern Kinta Consolidated, Kramat Tin Dredging, Lower Perak Tin Dredging, and Bidor Malaya Tin. These six companies have two things in common; MMC has a holding in each of them, and all their tin mines are in the State of Perak. One reason for the merger is to create a single State-based company which can simplify administration of the companies and make it easier to negotiate with the State government for gaining new mining rights or renewing leases.[13]

Titanium.—Ilmenite production in Malaysia is recovered as a byproduct of tin mining operations in alluvial deposits of peninsular Malaysia. Much of the ilmenite produced in Malaysia was exported. In 1979, total exports of ilmenite amounted to 199,819 tons, of which 187,165 tons went to Japan. For the first 9 months of 1980, total output of ilmenite was estimated at 94,300 tons. Mining of alluvial deposits of ilmenite in the Kampung Ajil area in Trengganu was initiated in the late 1970's, but owing to lack of water and excessive losses of ore during treatment, the mining project was dropped.

Other Metals.—Manganese ore production in Malaysia declined substantially from 1978 to 1979. Production of manganese

ore dropped to less than a quarter of the 1979 level and ceased in mid-1980. Other metallic minerals including columbite, monazite, scheelite, wolframite, xenotime, and zircon were recovered as byproducts of alluvial tin operations and from tailings of dredging operations in peninsular Malaysia.

Two significant uranium deposits have been discovered and identified in the Ulu area of Kelantan, 35 miles from the Thai border, and in an area near the Titiwangsa Range in Pahang. An aerial geophysical survey will be conducted by the Government of Malaysia in cooperation with the Canadian International Development Agency (CIDA). The experts from CIDA indicated that the "quality" matches that of Canadian deposits, based on the data obtained from a 2-year ground survey conducted in those two States.[14]

NONMETALS

Cement.—Total production capacity of Malaysia's cement industry in 1979 was 2.4 million tons. Actual production in 1979 and 1980 was near full capacity at 2.5 million tons. The second largest cement producer, Associated Pan Malaysia Cement Sd. Berhad, has undertaken an expansion program of its plant at Rawang. The expansion project involves replacement of the existing uneconomical wet-kiln operation with a 1.2-million-ton dry-process kiln complex. Blue Circle Group, an associated company of Associated Pan Malaysia Cement, provides technical and engineering services to the project. The expansion project was expected to be completed late in 1980.[15]

Fertilizer Materials.—Total chemical fertilizer production of Malaysia in 1979 was at about the same level as in 1978 at 320,000 tons. Production in 1980 was up 39%, based on the comparison of the first 9 months' production for 1979 and 1980. However, Malaysia still imported substantial amounts of fertilizer materials and manufactured chemical fertilizer to meet its domestic demand. In 1979, Malaysia imported a total of 935,592 tons of fertilizer valued at M$276 million (US$125.5 million). Imports of fertilizer for the first 9 months of 1980 were 708,264 tons, up 8.4% from 653,352 tons in the same period of 1979. The major overseas suppliers of Malaysia's fertilizer in 1979 were Togo, Jordan, Nauru, Banaba, and Christmas Island for phosphate rock; Indonesia, Romania, the U.S.S.R., and the German Democratic Republic for urea; Japan, the Republic of Korea, and Romania for ammonium nitrate and ammonium sulfate; and the United States for superphosphate.

In 1980, Albright and Wilson of Malaysia doubled the capacity of its high-quality thermal phosphate acid plant in Port Kelang. The company is the only producer of good-quality phosphoric acid in Southeast Asia. It not only supplied much of the Malaysia market, but exported 65% of its total production to other countries in 1979.[16]

Other Nonmetals.—Clays suitable for the manufacture of cement, brick, roofing tiles, and pottery are abundant in Malaysia. The ball clay used as raw material with kaolin in pottery bodies, wall and floor tiles, and chinawares was produced from alluvial tin mines and from the freshwater swamp in peninsular Malaysia. Kaolin has been mined at Bidor in Perak, at Semiling in Kedah, at Bukit Mertajam in Pahang, at Cheras and Rawang in Selangar, and at Jemalnang and Pontian in Johore. In 1980, mine production of kaolin (china clay) came from nine operating units in Perak, two units in Selangor, and two units in Johore. Kaolin production for the first 9 months of 1980 increased 45% to 36,134 tons, compared with 24,891 tons in the same period of 1979. The increase of kaolin mine production in 1980 was due to two additional operating units in Perak and one addition in Johore. Large kaolin reserves occur in the area of Bidor in Perak and in the area of Jemaluang in Johore.

Malaysia also produced limestone in Kelantan, Perak, Perlis, Pahang, Kedah, and Selangor. Presently, limestone is produced mainly for consumption by the domestic cement industry and is used as road metal and concrete aggregate.

MINERAL FUELS

Coal.—Coal resources in peninsular Malaysia are insignificant. However, a number of relatively significant low-grade coal deposits have been discovered in Sarawak. For example, in 1970 the coal deposits in the Silatek area of western Sarawak were discovered and identified by two Japanese companies to contain 1 million tons of coking coal, 4 million tons of anthracite, and 1.3 million tons of semianthracite. Utah Pacific Inc. has also discovered several coal deposits near the Bintula area of Sarawak in 1978. The areas identified by Utah Pacific to have economic potential are Sungai Segan, Kampung Jepak, Sungai Sepadok,

Sungai Sera, and Sungai Kelabat.

At present, there is no coal production in Malaysia. For the past few years, 15,000 to 20,000 tons of anthracite were imported annually, mainly from Indonesia, for domestic consumption. Malaysia's iron and steel industry also imported 15,000 to 20,000 tons of coking coal each year, mainly from Japan and Taiwan.

Natural Gas.—Petronas, the State-owned national oil and gas company, signed an agreement with Shell Royal/Dutch and the Sabah State government on July 31, 1980, to undertake two gas-related projects worth a total of more than M$1 billion (US$455 million). Under the agreement, Petronas and Shell will supply gas from three offshore fields in Sabah to the Sabah State government at the rate of 60 million cubic feet per day over a 20-year period for distribution to industries and other consumers. A liquefied petroleum gas plant will also be built at Labuan in Sabah to utilize gas produced in the Labuan area.

A natural gasfield off the coast of Trengganu State, discovered recently by Esso Production Malaysia, is estimated to be one of the world's largest nonassociated gasfields, having an economic life of 70 years. Although the quantities of reserves have not yet been confirmed, the gas reserves in the area are believed to be larger than those of Bintulu Gasfield in Sarawak.[17] Petronas, in cooperation with one of the major oil companies, will start further exploration work off the coast of Trengganu soon.

Malaysia will become one of the world's largest producers of LNG when the US$1 billion Bintulu LNG project comes onstream in 1983. Annual capacity is projected to reach 6 million tons in 1986. According to Petronas, the gas reserves in Sarawak are estimated at 10 to 14 trillion cubic feet.[18] Based on the latest publicly released figure by Petronas, Malaysia now has a total nonassociated gas reserve in excess of 30 trillion cubic feet.[19] In conjunction with the Bintulu LNG project, which was originally scheduled to come onstream in 1981, five LNG tankers were ordered by Malaysia International Shipping Corp. (MISC) in 1975, to be delivered in 1981 by a French shipyard. Since the Bintulu LNG project would not be completed until the end of 1983, the five tankers with a capacity of 13,000 cubic meters each would have to be leased out in the interim period. If the tankers were delivered on schedule and attempts to lease them out were unsuccessful, the only alternative would be to preserve them until 1983. However, an official of Malaysia indicated that despite their potential loss, these five tankers may in fact turn out to be a bargain owing to the cost differentials between 1975 and 1980.[20]

Petroleum.—Malaysia's production of crude oil reached a record high at 283,000 barrels per day in 1979 from a previous high of 217,000 barrels per day in 1978. Crude oil output in the first half of 1980 was reduced to 278,000 barrels per day. In line with Malaysia's National Petroleum Depletion Policy, which became effective on June 1, 1980, Petronas regulated crude oil output to 270,000 barrels per day in the second half of 1980 to slow depletion of its oil reserves. It is anticipated that the flow will be further cut to between 250,000 and 260,000 barrels per day later.[21] Malaysia's recoverable oil reserves were estimated in 1980 by Petronas at 1.8 billion barrels, which would be exhausted in 17 years at the present rate of production.

Malaysia exported about 90% of its crude oil produced in 1979. Export earnings from crude oil rose by 81% from M$2.2 billion (US$1 billion) in 1978 to M$4 billion (US$1.8 billion) in 1979, owing to the higher world prices. Much of Malaysia's crude oil was exported to Japan, Singapore, and the United States in 1979.

The Government of Malaysia, through Petronas, announced in October 1980 that it will build a M$300 million (US$136 million), 150,000-barrel-per-day refinery in the State of Melaka along peninsular Malaysia's southwestern coast, and a 30,000-barrel-per-day refinery in Trengganu on the eastern coast. The two refineries are scheduled to come onstream in 1984-85. It was reported that Kuwait had indicated interest in equity participation and had pledged to provide technical assistance in gas separation from extracted crude. The main reasons for selecting Melaka as the site for the larger refinery were that the project will help boost the industrialization programs of Melaka, which has poor land and natural resources, and that the refinery will be able to utilize the newly completed ocean port at Tanjong Kelling.[22]

The Mineral Industry of Malta

By Roman V. Sondermayer[1]

During 1980, exploratory drilling for oil by Texaco Inc. started on offshore Malta, but immediately problems were encountered with Libya. Although drilling was on Malta's continental shelf, a Libyan submarine and a missile-launching frigate approached the platform and forced the drilling to be stopped. The Libyan Government claimed that the drilling area was under Libyan, not Maltese, jurisdiction.

Libya's action evoked an angry reply by the Maltese Government, and the Libyan Government agreed to settle the border dispute in the International Court of Justice. The Government of Malta then ordered the companies to renew drilling operations in accordance with the license they obtained in 1974. Standard Oil Co. of Indiana declined, and its license was revoked, but Texaco subcontracted Ente Nazionale Idrocarburi (ENI), the Italian corporation, to drill a well 60 miles southeast of Malta. After further Libyan intimidation, drilling was abandoned by ENI, and by yearend it had not been resumed.

PRODUCTION

Table 1 shows the latest trends in production of minerals in Malta. The industry was mostly made up of small family-run enterprises.

Table 1.—Malta: Production of mineral commodities[1]

Commodity and unit of measure	1976	1977	1978	1979[e]	1980[e]
Lime ____ thousand metric tons__	27	32	28	30	31
Limestone ____ thousand cubic meters__	[2]962	[2]802	[e]386	400	400
Salt ____ metric tons__	290	797	600	500	550

[e]Estimated.
[1]Table includes data available through June 24, 1981.
[2]Figures represent reported output plus an estimate for quantitatively unreported output.

TRADE

Malta depended on imports of a number of mineral commodities, but all in small quantities.

Fuels were major import and export items; bunkering was the principal category of exports. Foreign mineral trade is shown in tables 2 and 3.

The Mineral Industry of Mauritania

By Peter J. Clarke[1]

Continued weakness of the world market for iron ore caused the virtual stagnation of Mauritania's economy in 1980. For the past 20 years, the mining sector has been central to the development of the economy, and the recent supply disruptions from guerrilla operations in Western Sahara and the lagging world demand for iron ore has caused considerable economic and political problems for the country. Withdrawal from the Western Sahara conflict and rapprochement with Algeria precipitated a small economic recovery in 1979, but the mineral sector's percentage of total gross domestic product (GDP) continued to decline from 21% in 1979 to 17% in 1980.

The country's economy is highly dualistic, with about 25% of the $546 million[2] GDP originating in the traditional sector, principally from fishing, livestock, and cereal cultivation. The modern sector, which includes mining, transportation, and a small manufacturing sector, contributed another 20% to the total GDP, with Government and other services representing the remainder.

Mauritania's balance of payments has also deteriorated, mainly because of the closing of the Akjoujt copper mine in 1978, a decrease in iron ore exports, and a correspondingly large increase in imports. The Government of Mohamed Khouna Ould Heydalla attempted to bring Government spending and the external trade balance under control late in 1978, but succeeded only in holding the situation stable. Improvement in the balance of payments remained tied to the level of iron ore exports, which account for 60% to 70% of the country's total foreign exchange receipts.

The organization responsible for the country's mining activity was the Société Nationale Industrielle et Minière (SNIM). It was a Government-owned holding company until 1979, when it sold 49% of its stock to obtain financing for the country's main development project, the Guelbs iron ore project. The company planned to start exploitation of low-grade iron ore reserves, near the existing mines, by 1983. The new shareholders in SNIM were the Arab Mining Co., the Islamic Development Bank, and the Governments of Morocco, Kuwait, Iraq, and Libya.

Another major infrastructure and development project in the country was the deepwater port at Nouakchott, under construction supervised by a group from mainland China. The port was scheduled for completion by 1984, which would coincide with increased shipments of iron ore from the Guelbs project. Development in the agricultural sector was centered around the $80 million Gorgol irrigation project on the Senegal River. The project, which was to lead to a large-scale expansion of cereal and rice production, was being financed by a consortium of international donors. Also under construction was the Nouakchott to Nema road, linking the Mauritanian coast to the eastern borders of the country. Saudi Arabia was a major aid donor for this project.

PRODUCTION

Production of Mauritania's major mineral commodity—iron ore—declined slightly in 1980, mostly because of poor market conditions. Iron ore output was down 8% from 1979, but still well above the low of 7 million tons in 1978, when the conflict with Western Sahara was at its peak. Market conditions precipitated the decline in production as well as an overall decline in export value for the year. Crude steel production, from a new scrap mill in Nouadhibou, increased considerably from 6,200 in 1979 to over 9,000 tons of reinforcing bars in 1980. Since the closing of the Akjoujt copper mine in 1978, the only other minerals being exploited were gypsum and salt. Gypsum production increased about 6% in 1980 and salt production remained stable.

Table 1.—Mauritania: Production of mineral commodities[1]

[e]Estimated. [p]Preliminary.
[1]Table includes data available through Sept. 3, 1981.
[2]In addition to the commodities listed, modest quantities of unlisted varieties of crude construction materials (clays, stone and sand and gravel) presumably are produced, but output is not reported quantitatively, and available information is inadequate to make reliable estimates of output levels.

TRADE

Mauritania's balance of payments situation did not improve in 1980, despite the austerity program instituted by the old Government, and upheld by the military Government. The 1979 balance of trade showed a $146 million deficit, and the current accounts deficit rose to $230 million. The increased level of foreign aid from international organizations, Saudi Arabia, France, and others reached $127 million, which caused a significant reduction in the overall balance of payments deficit, to about $7 million.

Iron ore exports in 1980 remained at nearly the same level as the previous year—about 9 million tons—but the weakness of the world market for iron ore caused a slight decline in export revenues, which represent over one-half of the country's total export revenues. Iron ore was exported to France, 35%; Italy, 22%; Japan and other Western European countries, the remaining 43%. The country's other major exports were livestock, fish, cereals, and gypsum. Gypsum production was exported entirely to Senegal. Mauritania's major imports were fertilizer, cement, petroleum products, and manufactured goods.

COMMODITY REVIEW

METALS

Copper.—Several feasibility studies concerning reopening the Akjoujt copper mine have been conducted since 1979 by various consultants. The mine, which began production in 1970, closed in 1978 because of heavy financial losses. The mine was originally designed to extract copper oxide ores (average grade 2.7% copper), but the treatment process used to concentrate the ore encountered technical problems, and only a limited amount of concentrate was ever produced. By 1978, the oxide ores were nearly exhausted. Financial losses, caused by low production levels, and the use of a highly energy-intensive treatment process caused the mine to close.

Since 1978, the Government has attempted to attract investors to exploit the estimated 17 million tons of copper sulfide ore (average grade 2.25% copper) remaining at Akjoujt. In October 1980, a new company, Société Minière d'Inchiri, was formed to reactivate the mine, provided the feasibility studies were positive. The Mauritanian Government held a majority share in the company, along with the Iraqi Government (25%), and the Arab Mining Co. (20%). The Kuwaiti Foreign Investments Co. and the Arab Investment Co. of Saudi Arabia also planned to participate.

Iron Ore.—Iron ore output declined slightly in 1980, mostly due to the weakness of the world market for iron ore. Mining was carried out under the direction of Complexe Minière du Nord (Cominor), which was owned entirely by SNIM. Cominor operated three mines—Tazadit, F'Derik, and Rouessa—all in the Kedia d'Idjill deposit, near the city of Zouirat. The average ore grade from the mines was around 65% iron. Production from these deposits began in 1960, under the direction of the Société Anonyme des Mines de Fer de Mauritanie, in which the Government held a 5% interest. The mines were nationalized in 1974, and iron ore output peaked at 11.9 million tons that year. Output has declined in recent years owing to both poor market conditions and guerrilla warfare operations near the mines and transportation routes.

At the country's current rate of production, reserves at Kedia d'Idjill were expected to be depleted in the early 1990's. To ensure continued production of the country's major export, SNIM was beginning a major iron ore project to exploit the El-Rhein and Oum Arwagen deposits. The so-called Guelbs project was the country's top development priority, and work on the first stage of the project began in 1980.

The word Guelbs, which means "rocky outcrop or hills," was actually applied to a group of about 25 deposits, all within a 50-kilometer radius of Zouirat. The first stage of the project was to develop the El-Rhein deposit, which contained over 260 million tons of ore, grading 37% to 40% iron. The deposit was to produce around 3 million tons per year at the start, sometime in 1983, and then rise to 6 million tons per year by 1987. Included in the plan was the construction of a concentrating plant to raise the iron content to 65% iron. Concentration was to be dry magnetic separation, which is very important for a country with limited quantities of water. Total investment in the first stage of the project was estimated at nearly $500 million. At the end of 1980, about $22 million had been spent on development.

The second phase of the Guelbs project was centered around the Oum Arwagen deposit, where reserves were estimated at an additional 200 million tons, with an iron content of about 38%. Annual production capacity from Oum Arwagen was to be 4 million tons in 1990, rising to 6 million tons by 1992. This phase of the project, along with commissioning the second part of the concentration plant, was to take place in 1990. Concentrates from both deposits were to be transported by the 650-kilometer railroad that already links the Kedia d'Idjill deposit to Nouadhibou.

A pilot plant for research in iron ore concentrating and separating techniques began operating in Zouirat in 1974. The pilot plant produced a concentrate containing 64% to 66% iron as magnetic and oxidized sinter feed, utilizing autogenous grinding and dry magnetic separation techniques. This process was to be used at the new beneficiation plant in Zouirat for both the El-Rhein and Oum Arwagen ores.

A small steelworks began operating at the port of the rail line from Kedia d'Idjill to Nouadhibou in 1979. Design capacity at the plant was 12,000 tons per year of raw steel. Total production from the plant in 1980 was around 9,000 tons, about 66% of which was exported to neighboring countries.

NONMETALS

Gypsum.—Since the closing of the Akjoujt copper mine, the only other mining operation under SNIM's authority has been the extraction of gypsum from a deposit at Sebka N'Drhamcha, located about 65 kilometers north of Nouakchott. The entire quantity of gypsum produced was exported to Senegal for use in the Société Ouest-Africaine des Ciments plant at Rufisque. SNIM planned to expand its output of gypsum when the new deepwater port at Nouakchott is completed. Mauritania had no cement plants operating in 1980, although SNIM was reportedly considering construction of a 150,000-ton-per-year plant which would utilize locally derived raw materials.

Phosphate.—Phosphate deposits near the southern border of the country, in the Aleg-Boghe-Khaedi area, were being studied to determine their economic potential. Reserves at the deposit were estimated at between 20 and 40 million tons of ore. The mining rate being considered was around 500,000 tons per year, but infrastructure remained a critical problem.

Salt.—A small amount of rock salt was produced in Mauritania, mostly by small operators. Annual production averaged 1,000 tons which was sufficient for domestic consumption. Feasibility studies were conducted by the Compagnie pour Etudes Techniques et Economiques of France for exploitation of salt deposits at Sebkha N'Drhamcha. Reserves at the deposit were estimated at 11 million tons of salt. No decision was made to exploit the deposit.

MINERAL FUELS

Petroleum.—All petroleum exploration efforts conducted thus far in Mauritania have proven unsuccessful. Initial efforts in the 1960's and 1970's were carried out in the Atlantic Basin area, near Nouakchott and in the Tindouf Basin, near the Algerian border. The El Djouf Basin in the west-central part of the country near the Mali border has also been explored without success. Recent exploration has concentrated on the onshore and offshore Nouadhibou region. A consortium including Hispanoil (Spanish State Oil Co.), Philips Petroleum Co. (United States), Shell Oil Co. (United States), and Azienda Generale Italiana Petroli (Italy), held a 24,000-square-kilometer concession both onshore and offshore Nouadhibou. Elf Aquitane (France) also began exploring a concession offshore Nouakchott in 1980, but with no significant results.

Refining.—The Nouadhibou refinery, which had been closed since its first test run in 1978, remained idle in 1980. The refinery, built by Vöest Alpine (Austria), was closed following crude oil supply problems and the need for technical modifications, but because of financial constraints it was never able to reopen. Output of the refinery was to be 1 million tons of refined products per year, which would satisfy domestic requirements and provide a substantial surplus for export. There was no indication in 1980 that the refinery would commence operating soon.

The Mineral Industry of Mexico

By Orlando Martino[1]

Mexico is one of the leading producers of mineral commodities in the world. The development of new oil reserves and the surge in oil and natural gas production since 1976 have overshadowed the traditional roles played by the metallic and nonmetallic mineral industries. By the end of 1980, Mexico became the fifth most important oil producer in the world and was a rival to Venezuela as the leading oil producer and exporter in Latin America. In 1981, Mexico is expected to overtake Venezuela and gain fourth rank as a world oil producer after the U.S.S.R., the United States, and Saudi Arabia.

Mexico's rapid economic growth continued in 1980. The gross domestic product (GDP) increased in real terms by 7.4% compared with the 8% growth in 1979. The economic performance in 1980 registers the third straight year of growth exceeding 7%. Growth was stimulated by significant increases in Government and private investments that counteracted the negative impact of serious bottlenecks in the transportation system and shortages of skilled labor and certain raw materials. At current prices, the GDP was valued in 1980 at $167 billion.[2] The inflation rate was 30% compared with the 20% rate in 1979.

The record high output of petroleum (not including petrochemicals) in 1980 represented 4.5% of the GDP, or a value of $7.5 billion, while output of metallic and nonmetallic minerals represented 1.1% of the GDP, or about $1.8 billion. The latter value does not include certain processed commodities such as steel and cement. The mineral industry (including hydrocarbons) accounted for 69% of Mexico's total exports.

The petroleum sector's contribution to Mexico's GDP increased almost 18% in 1980, the second highest annual growth rate registered by this sector since 1950. The relative importance of the mining sector has decreased from 1.5% of the GDP in 1970 to 1.1% of the GDP in 1980. During the decade prior to 1979, mining output increased at an average of 2.5% per year. The value of mining output in real terms is estimated to have increased 6.6% overall in 1980 compared with the 4% growth in 1979 and is expected to continue in an expansive phase in response to a growing economy's need for more raw materials. The increase in foreign exchange earnings generated by petroleum exports has made it possible to increase imports of capital equipment needed for expanded investments in the nonfuel minerals sector. In 1980, investment in exploration, new projects, expansions, and modernization programs at existing operations rose to about $540 million compared with the $433 million expended in 1979. The Cámara Minera de México estimates that $853 million will be invested in 1981.

Regarding nonfuel minerals, Mexico is the world's leading producer of silver, fluorspar, and strontium minerals (celestite). It ranks second in arsenic and natural graphite; third in antimony and bismuth; and is a significant world producer of cadmium, lead, mercury, zinc, selenium, sulfur, feldspar, and natural sodium sulfate. Continued development toward full capacity of the La Caridad copper project and the opening of other mining sites at Cananea will significantly improve Mexico's position as a copper producer. The San Juan de la Costa and Santo Domingo phosphate projects in Baja California State are expected to reduce Mexico's dependency on foreign sources of fertilizer materials.

Within Latin America, Mexico shares

leadership with Peru as a lead producer; is the second most important producer of steel, zinc, cement, and petroleum; and is a significant producer of aluminum, gold, iron ore, manganese ore, coal, and ferroalloys.

Petróleos Mexicanos (PEMEX), the state monopoly responsible for oil and gas operations since 1938, achieved outstanding results in 1980 with a 33% increase in production of crude petroleum and a sizable increase in proven reserves. In January, PEMEX initiated natural gas shipments to the United States after a period of difficult negotiations. PEMEX's exploration efforts during 1980 continued to focus on discovering new reserves of hydrocarbons and to evaluate the oil potential of other areas in Mexico not currently productive. Potential oil reserves were estimated by PEMEX at 250 billion barrels, including proven reserves.[3]

Two decentralized Government agencies operating in the mineral sector are the Consejo de Recursos Minerales (CRM), founded in 1955, and the Comisión de Fomento Minero (Fomento Minero), founded in 1976. CRM actively engages in mineral exploration, supports the exploration efforts of others by conducting specific geologic studies, and annually publishes Mexico's mineral production and trade statistics. CRM has participated in a number of important mineral discoveries such as the La Caridad copper deposit, Las Truchas and Peña Colorado iron ore deposits, and the phosphate deposits of Baja California. High-priority minerals targeted in CRM's current exploration program include bauxite, iron ore, nickel, and coal. In 1980, CRM had a technical staff of 750 workers and a budget of $53 million, 70% of which was related to exploration.

Fomento Minero holds the Government interest in large mineral operations (especially where private capital is lacking); it promotes and finances small- and medium-sized mining companies and provides them with technical assistance. Fomento Minero is the 100% owner of the phosphate rock mining projects in Baja California, Macocozac copper project, Minera Santa Rosalía, Cía. Real del Monte y Pachuca, and Zincamex S.A. Fomento Minero is a majority owner in Azufrera Panamericana S.A. (APSA) (sulfur), Cía. Exploradora del Istmo (sulfur), and Exportadora del Sal (salt). As a minority partner, Fomento Minero has an interest in a number of large and small mineral operations, including Cananea copper (13%), La Caridad copper (6%), Real de Angeles silver (33%), and Micare coal (40%).

In the area of new developments and expansion programs, 1980 was the scheduled completion date of various projects. These included Cuale, Jalisco (nonferrous metals); Cumobabi, Sonora (molybdenum); Velardeña, Durango (nonferrous metals); San Juan de la Costa, Baja California (phosphate rock); and La Minita, Michoacán (barite and nonferrous metals). In 1981, completion of the following projects was expected: Cananea, Sonora (copper); Santa Bárbara, Chihuahua (nonferrous metals); Taxco, Guerrero (nonferrous metals); and La Caridad, Sonora (molybdenum plant).

Government Policies and Programs.—In April, the Government issued the long-awaited master development plan for Mexico—Plan Global de Desarollo (PGD)—designed to provide a unified framework for sectoral development plans, some of which were issued before. The industrial development plan was issued in 1979. The national energy plan issued in November is a subplan under the PGD. The PGD outlined the goals of the López Portillo administration: To reaffirm Mexico's independence, provide adequate employment, encourage economic growth, and improve the distribution of income.

When the Alliance for Production was first announced, projected investment goals for López Portillo's 6-year term (sexenio) were $2.2 billion for the mineral industry. The $800 million invested in 1980 indicates that Mexico's mineral industry will have reached this goal before the sexenio ends in July 1982.

There were no significant changes in the mining law since publication of the 1977 law. In early 1980, there were changes in the tax system for gold and silver, finally resulting in a variable tax (0% to 40%) based on existing market prices for these precious metals. The tax on silver begins at 6% when the price reaches $17.14 per troy ounce and graduates to 40% when the price reaches $23.30 per troy ounce. The tax on gold begins when the price reaches $404 per troy ounce and graduates to 40% when the price reaches $504 per troy ounce.

Regarding taxation, the Mexican mining law provides that, in addition to the standard corporate income tax of 42%, mining operations will pay three classes of taxes: Production, concession, and exploration. The concession taxes are levied at $1.33 per

hectare for nonmetallic minerals and $2.65 per hectare for metallic minerals. Production taxes vary according to the mineral being produced. Gold, silver, and sulfur are taxed at 9%; iron, magnesium, and coal are taxed at 4%; and other minerals are taxed at 7%. The exploration tax is levied at $0.44 per hectare per year.

Article 16 of the 1977 mining tax and development law established four general classes of subsidies. These are: (a) a subsidy of 2% on the value of the minerals produced, which is deductible immediately upon payment of the production tax (this subsidy is to be used to offset the cost of prospecting, exploration, and development that is carried out during the same calendar year); (b) an additional 1% of the above subsidy is allowed if the taxpayer has a gross annual income from mineral sales of less than $1 million; (c) a subsidy of up to 75% of the general import tax on machinery, equipment, parts, and replacements (when these are not manufactured in Mexico, except passenger vehicles); and (d) other incentives which, because of special economic circumstances, are considered necessary to safeguard or foment the development of the mining industry.

Experience to date indicates that the 1977 law succeeded in simplifying mining operations and making it easier for new operations and investments to take place. Government officials in the mining sector reported in 1980 that new changes were being considered, which will further simplify mining operations and investment. A new mining law has therefore been prepared and was expected to be approved by the end of 1980.

Foreign investment in Mexico's mineral sector remained strictly controlled. Mexican law provides for three separate classes of mining companies: State-owned, mixed, and private. In the private sector, foreign ownership is limited to a maximum of 49%, and it is limited to 34% in the mixed sector. Firms with foreign participation are largely excluded from mining such minerals as sulfur, potassium, phosphates, iron, and coal. Oil and gas production and uranium mining and processing are carried out completely by state-owned firms.[4]

In 1980, the World Bank granted a $40 million credit to the Ministry of Patrimony and Industrial Development to stimulate exploration and production from small- and medium-sized mining operations.

During 1980, output in the transportation sector showed good progress. Railroad services increased 11%; road transport increased 10%; and maritime transport increased 21%. Despite this progress, mineral production and its growth continued to be hampered by an inadequate and antiquated railroad transportation system. The lack of rolling stock has impacted on the flow of concentrate from the mines to the smelters and refineries, as well as the subsequent flow to the manufacturing plants. In 1979, mineral cargo represented about 27% of the freight handled by railroad, comprised mostly of iron ore, coal, coke, and manganese. Certain steel plants suffered from the timely supply of coke and pellets, forcing them to import iron ore pellets. Drilling operations by PEMEX have been hindered by delays in rail deliveries of barite.

In late 1980, the World Bank approved a $150 million loan to Ferrocarriles Nacionales de México to rehabilitate and expand Mexico's largest railroad network. Ferrocarriles Nacionales has 70% of Mexico's 20,200-kilometer system (mostly single-track) and handles 80% of total rail traffic. In May 1980, a rail link was inaugurated from Siderúrgica Lázaro Cárdenas Las Truchas, S.A.'s (SICARTSA) Las Truchas steel plant to Mexico City. In remote areas, trucking is often used to haul mine output. Mexico has 207,000 kilometers of highways, of which 30% are paved.

Mexico was engaged in a large port development program involving two new ports on the gulf coast at Altamira and Laguna de Ostión, and the expansion of existing port capacities at Lázaro Cárdenas and Salina Cruz on the Pacific coast. Port development at Altamira, north of Tampico, is based in part on a need for improved handling facilities for imports of iron ore. The new port will be able to service ships of up to 100,000-deadweight-ton capacity. The greatest part of crude oil exports was from the Port of Coatzacoalcos on the gulf. Mexico has a large system of pipelines to transport crude oil, refined products, and natural gas totaling about 13,000 kilometers. According to a PEMEX program, by 1990 the national system of gas pipelines will cover three times the distance of the rail system. Mexico was restoring the cargo land bridge between Coatzacoalcos on the gulf coast and Salina Cruz on the Pacific coast. The 300-kilometer trans-Isthmus rail-highway system, based on a railroad originally built by the British around 1890, was expected to be operational in late 1981.

There are approximately 920 operating companies in Mexico involved in well over 15,000 separate mining ventures. Employment in the mining sector continues to grow, reaching approximately 165,000 persons in 1980, an increase of 3% over that of 1979. Although the number of mining operations is impressive, approximately 90% of all mining operations are conducted by only five major companies. The Government of Mexico continues to emphasize the development of medium and small mines to be assisted by the World Bank loan.

PRODUCTION

Mexico's output of minerals continued to be dominated by the mineral fuels. Production of crude oil in 1980 increased 33%, following a 21% increase in 1979. Total production of natural gas also increased—22% in 1980, compared with a 14% increase in 1979. Crude oil, gas liquids, and condensate production in 1980 averaged 2.1 million barrels per day, a 32% increase over the 1979 rate. Output of barite increased in line with the demand by PEMEX for more drilling mud.

Output of copper increased 64% to a record high. Production of silver, Mexico's most valuable metal, decreased 4% despite record high prices, reflecting the drop in output of lead and zinc, which are coproducts in many of the country's mines.

Production of iron ore increased 26%. Mexico continued to expand its capacity for making steel. Output of crude steel in 1980, however, increased slightly from lower utilization of installed capacity. Production of ferroalloys (mostly ferromanganese) reached new highs, and output of manganese ore decreased.

Among the important nonmetallic minerals, production of fluorspar increased 5% and continued above the depressed level of 1977. Output of phosphate rock rebounded from the low level of 1979. Sulfur output was up slightly.

According to data published by the Secretaría de Patrimonio y Fomento Industrial,[5] the breakdown in value of total nonfuel minerals output in 1978 (the latest year available) was 18 metals contributed 72%, and 28 nonmetallics contributed 28% of the total. The value of the precious metals—gold and silver—alone accounted for almost 30% of the total value produced. In 1978, the States of Mexico that were leading producers of the most important minerals (not including oil and gas) were Sonora (copper); Durango and Guanajuato (gold); Chihuahua, Colima, and Jalisco (iron ore); Chihuahua (lead and zinc); Hidalgo (manganese); Chihuahua and Zacatecas (silver); Coahuila and Nuevo León (barite); Coahuila (coal); San Luis Potosí and Guanajuato (fluorspar); and Veracruz (sulfur).

As for the structure of Mexico's mining industry in 1979, the large private miners accounted for 55% of output value, followed by miners with Government equity (30%) and medium and small miners (15%). In 1971, mining companies with Government equity accounted for 21% of the total.

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.

[1]Table includes data available through Aug. 24, 1981.

[2]In addition to the commodities listed, pumice and additional types of crude construction materials are produced, but output is not reported and available information is inadequate to make reliable estimates of output levels.

[3]Sb content of ores for export plus Sb content of antimonial lead and other smelter products produced.

[4]Calculated white As equivalent of metallic As content of products reported.

[5]Bi content of refined metal, bullion, and alloys produced indigenously, plus recoverable Bi content of ores and concentrates exported for processing.

[6]Calculated from reported Fe content on the basis of ore containing 66.67% iron.

[7]Calculated from reported Mn content of mine production on the basis of ore containing 36% manganese.

[8]Estimates by the International Tin Council.

[9]Excluding that for cement production.

TRADE

Mexico's international trade in mineral commodities is given in table 2 for exports and in table 3 for imports.

In 1980, Mexico's total exports increased 74% to $15.3 billion, and imports increased 55% to $18.6 billion. The value of crude oil exports increased by almost 150% in 1980 following a 114% increase in 1979. Increased foreign exchange earnings from oil exports reflect higher prices as well as increased shipments.

Since 1976, the volume of exports of petroleum has grown dramatically to become the dominant factor in Mexico's export sector. Crude oil exports in 1980 of 303 million barrels were almost seven times greater than the exports in 1976. Exports of crude oil, petroleum products, and natural gas by PEMEX in 1980 amounted to $10.3 billion. In 1980, Mexico exported 43% of its crude oil production, mostly to the United States. Mexico was approaching Venezuela as the leading producer and exporter of petroleum in Latin America. The tabulation with values shown in million dollars below shows that while oil exports have increased their share of Mexico's total exports, the mining-metallurgical share has decreased. As a comparison, in 1970, exports of mining and metallurgical products were 15% of total exports. On the other hand, Mexican imports of mining-metallurgical commodities have been at the level of 5% of total imports over the past decade. In 1980, exports of products from the extractive industries (not including oil, gold, and silver) amounted to $503 million.

	1976	1977	1978	1979	1980
Total Mexican exports	3,317	4,418	6,063	8,798	15,308
Crude oil exports	440	988	1,774	3,811	9,449
Crude oil share	13.3%	22.4%	29.3%	43.3%	61.7%
Mining, metallurgical exports	441	450	503	789	1,307
Mining, metallurgical share	13.3%	10.2%	8.3%	9.0%	8.5%

According to data recently published by the Government,[6] Mexico has had a surplus in its nonfuel minerals trade over the past decade. Between 1970 and 1978, the value of nonfuel mineral exports increased 626%. Of the metallics, silver, copper, iron ore, and manganese had the greatest growth in export value. During the same period, the nonmetallics with the greatest export growth were alabaster, asbestos, dolomite, marble, perlite, silica, salt, and sulfur. Fluorspar exports grew by 300%. The Government report provides the following breakdown in the destination of nonfuel mineral exports and the source of imports for 1978 on a percentage basis.

Region	Exports	Imports
Western Hemisphere[1]	72%	75%
Europe	21%	13%
Asia	7%	3%
Africa	(2)	8%
Oceania	(2)	1%

[1]Including Canada and the United States.
[2]Negligible amount.

In 1978, the main market for Mexican mining-metallurgical exports was the United States, with 60%, followed by Great Britain, 6%; Japan, 6%; Brazil, 5%; the Federal Republic of Germany, 5%; Belgium-Luxembourg, 4%; and Italy, 2%. In the same year, the United States supplied 62% and was the main source of mineral imports, followed by Canada, 7%; Morocco, 6%; and Great Britain, 3%.

One of the significant mineral trade events in 1980 was the initiation on January 15 of the shipment of natural gas to the United States via a new pipeline from San Fernando to McAllen, Tex., at the average rate of 281 million cubic feet per day. The gas earnings for 1980 were $448 million, based on the initial rate of $3.36 per thousand cubic feet that was later increased to $4.47 per thousand cubic feet. Beginning January 1, 1981, the rate was scheduled to increase to $4.82 per thousand cubic feet.

During 1980, Mexico and Japan negotiated an agreement to supply Japan with 300,000 barrels per day of crude oil by 1982 in exchange for technical and financial assistance for Mexico's steel industry.

Despite the remarkable growth of Mexico's steel industry, imports of steel continued to grow. Steel imports in 1979 were valued at $1.05 billion compared with $360 million expended in 1975.

In the private sector, Industrias Peñoles, S.A. de C.V. was the most important exporter of metallic and nonmetallic minerals.

COMMODITY REVIEW

METALS

Aluminum.—Mexico has no current bauxite production, and there is little prospect for the development of bauxite mines. Alumina, primarily from the United States, is imported as the raw material for the sole producer of aluminum ingot, Aluminio S.A. de C.V., which operated a 90,000-ton-per-year plant in Veracruz since 1963. Because this plant cannot meet domestic demand, imports of aluminum increased notably in 1979 at a cost of $138 million.

Preliminary plans were being made to construct aluminum plants at Altamira to take advantage of its expanded port facilities for importing alumina and the availability there of natural gas as an energy source.

In particular, ALCAN Aluminium Ltd. is to undertake a feasibility study for a 45,000-ton-per-year aluminum smelter in Mexico. The study is a joint venture with Comalum S.A., owned by Mexico's three leading aluminum transmission cable producers. The smelter would be located near Altamira on the Gulf of Mexico and would supply Mexican domestic requirements. If results of the study are favorable and the Mexican Government gives approval, then production could begin within 3 years.

Copper.—Mexico's plans to increase its capacity to produce copper during 1980-90 are shown in table 4.

Mexicana de Cobre, S.A., a joint venture of private Mexican interests (56%) and Government agencies (44%), had its first full year of operation of La Caridad project since startup during the second half of 1979. The new mine operated below capacity because of a number of startup difficulties. The mine, with a design capacity of 72,000 metric tons per day of ore, is the first stage of an integrated project that will include a 180,000-ton-per-year smelter.

During 1980, construction of the smelter was begun under a construction management contract with Fluor Mining and Metals Inc. Until the smelter is completed, most of the 32% copper concentrate produced will be exported from the Pacific Port of Guaymas.

The La Caridad Mine is located in northwestern Sonora State, about 200 kilometers from Hermosillo. The project is based on a copper deposit of 680 million tons grading 0.6% copper and 0.02% molybdenum with a 30-year operating life. Mine capacity will eventually be increased to 90,000 tons per day of ore to compensate for declining ore grades. The CRM participated in the exploration of the La Caridad copper deposit.

Also in Sonora State, Cía. Minera de Cananea (owned by Fomento Minero, 13%; private Mexican interests, 53%; and Atlantic Richfield Co., 34%) embarked on an expansion program to increase mine and mill capacity from 30,000 to 70,000 tons per day by 1986 at a cost of $250 million. Expansion of smelter capacity was being studied.

Mine production of the Cananea pit was discontinued in 1980. Future mine output from the Cananea project area will come from the Kino and Colorado-Veta open pits and the West Area under development. Major stripping of overburden for the new mine sites was expected to begin in 1982.

Basic engineering for the first-stage expansion of the concentrator, up to 50,000 tons per day, was completed in 1980, and production was scheduled for 1983. The second-stage expansion, up to 70,000 tons per day, was planned for 1984. The Cananea concentrating plant first entered produc-

tion in 1943. In the summer of 1980, a new grinding line in this plant was installed, consisting of a rod mill and two ball mills. The new reverberatory furnace at the Cananea smelter produces a matte of 36% to 40% copper.

The Cananea deposit ranks among the largest porphyry copper deposits in the world. Cananea copper reserves are estimated at 1,850 million tons, with an average grade of 0.7% copper, classified as proven (49%), probable (32%), and possible (19%). A computer model developed in 1972 is being used to evaluate alternate mining plans for the Kino, Colorado-Veta, and West Area pits.

Iron Ore.—Although Mexico currently has installed mine capacity to meet domestic demand for iron ore, it has been necessary to import some iron ore (chiefly from Brazil) because of bottlenecks in the railway system. Imports of iron ore in 1980 amounted to 381,000 tons. There have been shipping delays from the mine to the concentrator or pellet plants and from these plants to the steel companies. Within the 1980's, Mexico's iron ore mine capacity is expected to stabilize at about 15 million tons per year of marketable iron ore. Considering that Mexico's steelmaking capacity is expected to expand to 24 million tons by 1990, it will be increasingly necessary for Mexico to import iron ore. The port expansions planned at Altamira take into account this need for additional iron ore imports.

Table 5 shows that the major iron ore producers are Mexico's integrated steelmakers. In Latin America, Mexico ranks third as an iron ore producer, but second after Brazil in installed capacity for producing iron ore pellets.

Table 5.—Mexico: Major iron ore producers

(Million metric tons)

[1]A 3-million-ton-per-year pellet plant is to be built by AHMSA at Monclova.

Altos Hornos de México, S.A. (AHMSA) was engaged in a major slurry pipeline and pellet plant project to increase iron ore supply for its steel expansion program. This project will be executed in a joint venture of AHMSA and the Dravo Corp. A 379-kilometer pipeline will transport iron ore from the La Perla Mine on the Chihuahua-Coahuila border to the pellet plant to be built at Monclova. La Perla's current operations produce lump ore, fine ore, and pellets which are shipped by railway to Monclova, northwest of Monterrey, in Coahuila State.

The Consorcio Minero Benito Juarez-Peña Colorado, which started up its second pellet plant in 1979 near Manzanillo, in Colima State on the Pacific coast, was programed to produce 2.2 million iron ore pellets in 1980 and up to its capacity of 3 million pellets in 1981. The two pellet plants received concentrate via two parallel slurry pipelines from the Peña Colorado Mine in northwestern Colima.

In 1980, mine output from Peña Colorado of about 4.5 million tons came from the Espinazo del Diablo ore body and was mined out by yearend. La Encantada I and Anexos a Chula ore bodies were planned for exploitation during 1981 at 5.1 million tons, a level to be maintained by the Consorcio for the balance of the 1980's. The Consorcio is owned by AHMSA (46.5%), Hojalata y Lamina S.A. (HYLSA) (28.5%), Tubos de Acero de México, S.A. (15%), Fundidora de Monterrey, S.A. (FMSA) (5%), and the Secretaría de Patrimonio y Fomento Industrial (5%).

HYLSA-Acero y Tecnologia Siderúrgica produced 2.07 million tons of iron ore in 1980, of which 1.63 million tons was in pellet form. Its El Encino Mine was expected to become exhausted by 1986. HYL-

SA was studying development of an iron ore deposit at Aquila, Michoacán, with projected production of 1.4 million tons per year of feed to be sent to the Alzada pellet plant via a 90-kilometer slurry pipeline.

Iron and Steel.—Although expansion of installed capacity in Mexico's steel industry has generally kept pace with the rapid growth of the economy, actual production has lagged behind domestic demand. The steel industry operated at about 70% of capacity. Apparent steel consumption in 1980 was about 10.2 million tons. In 1979, imports of about 1.6 million tons of steel products valued at $1 billion were necessary. Demands by PEMEX continued to exceed the industry's ability to supply flat and pipe products. With the auto industry projected to grow 10% per year for the next 5 years, no relief of domestic shortage of flat steel products was expected.

Mexico plans to continue the strong growth in the steel industry, such that output is projected to grow to 15 million tons by 1985 and to about 24 million tons by 1990. Demand by 1990 is expected to reach 26 million tons. The Government-controlled steel plants, coordinated under Siderúrgica Mexicana (SIDERMEX) (AHMSA, FMSA, and SICARTSA), were expected to achieve the greatest expansion in capacity, especially SICARTSA.

The SIDERMEX group accounted for about 60% of Mexico's steel output. By 1990, SIDERMEX expected to increase the Government's share of the steel market to 72% after an investment of $18 billion in steel expansion projects.

A new 5-million-ton plant (Steel Plant No. 3) was in the final planning stages, to be located at Altamira, just north of Tampico.

Table 6.—Mexico: Production of crude steel by company

Sources: Instituto Latinoamericano del Fierro y el Acero. Siderurgía Latinoamericana No. 245, September 1980; México '80: Panorama Siderúrgico, pp. 5-15; and National Chamber of the Iron and Steel Industry, (Monterrey), Annual Report 1980.

After 13 years of research and development, HYL, the direct-reduction (DR) technology arm of Mexico's Grupo Industrial Alfa, announced the development of a continuous DR process, having previously only offered its batch process know-how. The new process, named HYL III, requires lower capital and operating costs than any other existing DR process.

The HYL III process will be available in three module sizes: 250,000, 500,000, and 750,000 tons per year. HYLSA will operate one unit of each size at Monterrey. HYLSA's No. 3 DR plant, which is currently a batch plant, is now being converted to the new process and will slightly increase its capacity to 500,000 tons per year. In addition, a new No. 4, 750,000-ton-per-year plant will be built at Monterrey to come onstream by mid-1983.

The HYL III contract signed with SICARTSA will be the first time that a DR unit has been incorporated into a conventional hot-metal integrated steelworks. The Las Truchas steelmaker will install four 500,000-ton-per-year modules.

PREREDUCIDOS Mexicanos S.A., a consortium of 10 Mexican minimill operators, signed an agreement with HYL in September 1980 to supply the two 500,000-ton-per-year DR modules at Altamira Port.

In 1980, Mexico produced 1,636,000 tons of primary iron as sponge iron, or 31% of the total. Mexico continued as the major sponge iron producer in Latin America.

During 1980, a Mexican-Japanese agreement was negotiated to supply financial and technical assistance to Mexico's steel industry in exchange for an increase of oil shipments up to 300,000 barrels per day by 1982. SICARTSA is also included in the basic agreement relative to expansion of the

Las Truchas steel plant. In October, two Mexican-Japanese companies were established to construct and operate a large diameter pipe plant and a casting and forging plant in the Lázaro Cárdenas region.

A total of 55 Mexican and Japanese firms will be involved in the agreement. The Japanese interest will be led by Kobe Steel, Nippon Steel, and the Sumitomo Metal Industries.

Manganese.—The Cía. Minera Autlán, S.A. de C.V., which was formed in 1953, continued as Mexico's major producer of manganese ore and ferroalloys. The manganese carbonate ores are mined in the Molango district of Hidalgo State in the Sierra Madre Oriental. The ore is calcined and nodulized for use in ferroalloys and steel. The nodules of manganese oxide are shipped to Autlán's ferroalloy plants—two in the State of Puebla; one at Tamos, Veracruz; and one in Mobile, Ala. Autlán also exported nodules produced at Molango district to the United States, France, and Japan.

During 1979, Autlán increased its proven reserves from 21.3 to 29.4 million tons of manganese carbonate ores, with an average grade of 27% manganese. Possible reserves are estimated at 1.5 billion tons. Autlán was pursuing an active exploration program in the difficult terrain in Molango.

Autlán's sales of ferroalloys in 1979 increased to a record 168,800 tons, a 22% increase over the prior year. The Mexican steel industry absorbed 62% of the total, and 38% was sold to the United States, Venezuela, and Colombia. Autlán has gained a 7% share of the U.S. market for ferromanganese and a 17% share of the market for silicomanganese. Mexico's demand for ferroalloys was expected to grow to 360,000 tons per year by 1990. Domestic consumption of ferroalloys amounted to 158,000 tons in 1980, while imports of ferroalloys were 11,300 tons.

Mexico's output of nonmetallurgical grades of manganese has been rising and has become the second largest world producer of battery-grade ore, with an output of 37,000 tons in 1979. Autlán is also Mexico's major producer of this raw material from the Cerro Prieto deposits near Nonoalco. Production capacity has been doubled to 30,000 tons per year. Reserves are estimated at 1 million tons of battery-grade ore.

Two other producers in Mexico produce only small tonnages, all of which are for nonmetallurgical applications. Cía. Minera Buena Vista, S.A., has concessions both in the Nonoalco and Molango areas. It mines 12,000 tons per year of ore—some of battery-grade and some a manganous oxide produced by calcination. Cía. Minera San Martín y Anexas produces about 8,000 tons per year of ore, about one-half of which is a 76% MnO_2 battery-grade ore, and the rest is a 60% MnO_2 grade used for chemicals and fertilizers.

Molybdenum.—In the recent past, Mexico has been a negligible producer of molybdenum. Although small relative to world output, Mexican production almost doubled in 1980. The molybdenum recovery project of La Caridad's copper operations and the Cumobabi project of Frisco, S.A. de C.V. offer the prospect that Mexico will become a significant world producer of molybdenum.

The Cumobabi deposit, where stripping of overburden began in early 1979, was being exploited by Minera Cumobabi, S.A. de C.V., a wholly owned subsidiary of Frisco. The copper-molybdenum discovery is located in the La Verde mining district southwest of Cumpas, Sonora State, 190 kilometers south of Cananea.

The 2,000-ton-per-day open pit mining operation at Cumobabi may be expanded to 30,000 tons per day of ore in the future. The Cumobabi concentrator was started up in September 1980, and it produces molybdenum sulfide and copper concentrates. Molymex, S.A. de C.V., another Frisco subsidiary, converts the moly concentrate to molybdenum trioxide at a new roasting plant at Cumpas. Copper concentrate is shipped to smelters outside the mining area.

Proven ore reserves at Cumobabi are estimated at 70 million tons, with an average grade of 0.1% molybdenum and 0.25% copper. Reserves may eventually go beyond 200 million tons.

Silver.—Mexico maintained its position as the leading world producer of silver, continuing a long history of output since the early 1500's. Output in 1980 was well below the record year of 1929 when output reached almost 109 million troy ounces. Excluding petroleum, silver was Mexico's most valuable mineral product ahead of zinc, copper, and lead.

Despite slightly lower production in 1980, Mexico benefited from high prices. Owing to investment demand and speculative activity, the price of silver reached a high of $50 an ounce in mid-January and then collapsed to $10 an ounce in late March. The average price in 1980 was $20.63 an ounce, compared with $11.09 an ounce in 1979 and $5.40 an ounce in 1978. Worldwide, the

excess of production over consumption was absorbed by investors.

Mexico's supply of silver from mine production is expected to increase in the near future as current mines are expanded or new mines developed in response to the historically high prices prevailing in 1980.

Peñoles was Mexico's dominant silver producer in 1980, with a reported output of 34,146,000 troy ounces of refined silver, slightly above the 1979 output, but below its recent high of 34,931,000 troy ounces in 1978. Peñoles accounted for 72% of Mexico's total refined silver output in 1980. From its own mine operations, mainly at the Fresnillo and Naica units, Peñoles produced 1.5 million troy ounces in 1980. The company had record high profits in 1980 and the highest level of silver sales in part because of higher world prices. During 1980, higher prices permitted the working of lower grade silver deposits.

At its Fresnillo Mine, Peñoles continued exploration of new, rich silver veins and began preparations for mining. By yearend, installations were completed at its new Cuale mining unit located near Puerto Vallarta, west of Guadalajara in Jalisco State. The beneficiation plant, with a capacity of 1,200 tons per day, will be able to treat ores with metallic content of silver, gold, lead, zinc, and copper. Cuale is a project of Zimapán, S.A., a subsidiary of Cía. Minera Fresnillo, owned 60% by Peñoles and 40% by AMAX Inc.

Zinc.—Industrial Minera México S.A. (IMM) continued construction of a new zinc refinery in San Luis Potosí, with an annual capacity of 125,000 tons of refined zinc and zinc alloys. The $175 million plant was scheduled for completion in December 1981. IMM is held by Grupo México Desarrollo Industrial Minero S.A. (MEDIMSA), in which ASARCO Incorporated has a 34% interest.

NONMETALS

Barite.—Mexico's demand for barite has increased as a result of increased use of drilling mud for oil exploration and development by PEMEX. Demand for barite by PEMEX increased about 25% in 1980 to an estimated 550,000 tons, one-half of which was imported. New productive capacity installed in 1980 is expected to reduce imports of barite.

During 1980, the Fideicomiso No Metalicos Mexicanos completed installation of Mexico's largest barite operation at Mazatan in Sonora State, about 100 kilometers east of Hermosillo. Barita de Sonora S.A. de C.V., the operating company, planned to begin production in late 1980 at an initial rate of 165,000 tons per year. After expansion in stages, ultimate capacity was expected to reach 330,000 tons per year. Another new operation, with a capacity of 20,000 tons per year, was started up near Acapulco in Guerrero State by Cía. Minera Guadalcazar S.A.

Two major companies already established and producing at the 60,000-ton-per-year level were Baramin de México S.A. in Nuevo León State and Barita de Apatzingan in the States of Michoacán and Puebla.

Fluorspar.—Mexico has the world's largest production capacity for fluorspar and in 1980 accounted for about 20% of world output. It is the country's second most valuable nonmetallic mineral product, after sulfur. Even higher values could be expected as Mexico increases its domestic production of hydrofluoric acid, most of which is exported to the United States. Mexican fluorspar accounts for about 66% of U.S. fluorspar imports.

In addition to the large fluorspar ore producers, there are many small independent mines that sell their ore to the nearest mill or to Reynolds Metals Co. for processing in Texas. Fluorspar is also recovered as a byproduct of sulfide ore concentrators at Minera San Francisco del Oro and Zinc de México. Compañía Minera Las Cuevas, S.A., operating in the State of San Luis Potosí, is one of the major world producers of fluorspar.[7] The company is owned by Noranda Mines Ltd. (49%) and Mexican private interests (51%).

Phosphate.—In late 1980, Roca Fosfórica Mexicana, S.A. de C.V. (ROFOMEX) brought onstream its San Juan de la Costa phosphate mine located in Baja California Sur. Plant capacity is rated at 730,000 tons per year of concentrate. First concentrate production was expected in January 1981. The second ROFOMEX project at Santo Domingo, also located in Baja California Sur, is in the construction phase and should come onstream in mid-1982. These latter deposits are beach sands grading under 5% P_2O_5, compared with the 17% to 18% P_2O_5 ore recovered at San Juan de la Costa. However, the Santo Domingo sands have a 90% liberation of individual phosphate grains, enabling direct feed to the flotation circuit. The sands also contain iron oxide, zircon, titanium minerals, and silica. Plant capacity has been estimated at 1.5 million

tons per year of concentrate containing more than 31% P_2O_5. Later expansions have been planned to increase capacity to 4.5 million tons per year.

The National Commission on Industrial Development, established in July 1979 under the National Industrial Development Plan, has singled out the development of fertilizer materials as one of its priority goals.

Sulfur.—Mexico's leading French-process sulfur producer is APSA, majority owned (96%) by the Mexican Government. The second largest producer is Compañía Exploradora del Istmo S.A. (CEDI), owned by the Government (66%) and Texasgulf Inc. (34%).

APSA operates on the Isthmus of Tehuantepec in southeast Mexico near Jaltipan, Veracruz, where production capacity is about 1.2 million tons per year. In early 1981, APSA plans to bring another plant onstream for production from the Coachapa Dome, also located on the Isthmus near San Cristóbal on the Río Coachapa. APSA's combined capacity from both plants is expected to be about 2.5 million tons per year.

CEDI also operates on the Isthmus of Tehuantepec near the older APSA plant. The CEDI plant has a capacity of 620,000 tons per year.

MINERAL FUELS

In November 1980, Mexico published its national energy plan through the year 1990, including some projections through the year 2000. The preponderance of public attention was placed on those parts of the plan concerning petroleum.[8]

Projections of future electric power generation were also included in the plan. Although past growth in power generation has been about 10% per year, future growth was projected at 12% to 13% per year, with cost being a strong factor in the selection of future plant types. Important roles are foreseen for nuclear, coal, hydro, and geothermal power sources, as well as for traditional oil and gas plants. In 1980, Mexico had 15,130 megawatts of installed electric-generating capacity based on thermal (57%), hydropower (42%), and geothermal (1%) plants.

Nuclear power is expected to contribute 20,000 megawatts to Mexico's electric capacity by the year 2000. Mexico expects to have two nuclear powerplants operational by 1990.

A determination of Mexico's hydroelectric potential and other water resources uses is to be undertaken by the Commission on Energy Sources of the Ministry of Patrimony.

Coal is projected to contribute about 12% to Mexico's overall future power generation. The role of coal in the energy picture has started with the construction of one 1,200-megawatt coal-fired plant, and two more plants of 1,400 megawatts each are planned for the 1980's.

Minimum goals for geothermal energy capacity were established at 620 megawatts by 1990. In 1980, geothermal capacity was 150 megawatts. Possible geothermal capacity increases after 1990 are another area that the commission is expected to investigate.

Estimates for generating costs per kilowatt-hour were calculated for geothermal (1.6 cents), coal (2 cents), hydro (2 cents), nuclear (2.3 cents), and oil (3 cents). Despite the cost-factor importance in determining new electric plant types, oil- and gas-fired plants are expected to dominate and provide a similar proportion of electrical power capacity in 1990 as they did in 1980, that is, over two-thirds of total generation.

Of more concern to world energy markets is Mexico's view of the future economic role of the petroleum sector and the relationship between this energy resource and the external sector. The plan relates that the expansion of hydrocarbon production is a function of the needs of the country and not of the size of reserves or the needs of foreign countries.

For the decade of the 1980's, the new national energy plan proposed an export limit per day of 1.5 million barrels of petroleum and 300 million cubic feet of natural gas. It is hoped to confine the sum of these oil and gas exports to no more than 50% of the value of Mexico's total exports. In 1980, Mexico's exports of crude oil, petroleum products, and natural gas represented 67% of all exports. Furthermore, Mexico hopes to avoid concentrating more than 50% of its hydrocarbon exports to one country, and to keep these exports to an amount below 20% of any country's total imports of petroleum products and crude oil. An exception was made for Central American countries where Mexican petroleum exports may total up to 50% of a country's import needs.

Coal.—In 1980, the Palau coal mine Mimosa II in the State of Coahuila began production. The mine, owned by AHMSA, has reserves of 30 million tons. Coal is mined at an average depth of 270 meters,

and initial extraction is by the longwall method. Production from this mine is expected to be about 1 million tons per year, all of which will be consumed at the Altos Hornos blast furnace in Monclova.

The Conchas Norte coal mine also began production in 1980. This deposit contains an estimated 8 million tons of reserves and is located on the east bank of the Sabinas River in Coahuila State.

The State of Coahuila contains about 90% of Mexico's total proven coal reserves, now estimated at 2.4 billion tons. New Coahuila coal discoveries in 1980 were located in the Rancho de Garcia and Abasolo areas. The coal reserves at Rancho de Garcia cover about 125 acres (9.3 square kilometers) and are divided into three exploitable zones, containing a total 9.7 million tons of coal in situ with the coal-bearing strata averaging 21 meters in thickness. At Abasolo, reserves were estimated at 3.3 million tons in a 200-acre (7-square-kilometer) area with the coal-bearing zone ranging from 27 to 30 meters in thickness. Exploratory drilling in these two areas has not exceeded 50 meters in depth.

Petroleum and Natural Gas.—At the end of 1980, PEMEX estimated proven hydrocarbon reserves at 60.1 billion barrels of crude oil, natural gas liquids, and natural gas equivalents. In early 1981, this figure increased to 67.8 billion barrels. This 31% increase over the 1979 yearend estimate was attributed to the addition of reserves from the Kutz, Ha, and Ek Fields in the Campeche area as well as to revisions of estimates for other fields in this area. The hydrocarbon reserve components include 44.2 billion barrels of crude oil, 3.1 billion barrels of natural gas liquids, and 12.8 billion barrels of dry natural gas liquids equivalent. Mexico's proven crude oil reserves ranked fifth in the world, following Saudi Arabia, Kuwait, Iran, and the U.S.S.R. Proven reserves for 1979-80, by producing area, are shown in table 7. Potential reserves are estimated at 250 billion barrels.

Table 7.—Mexico: Proven hydrocarbon reserves

Zone	Dry natural gas (billion cubic feet)	Petroleum (million 42-gallon barrels)				
		Crude	Condensate	Dry natural gas liquids equivalent	Total 1980[1]	Total 1979
Northern	10,159	445	286	2,030	2,761	3,182
Central[1]	4,013	1,521	202	803	2,526	2,508

Source: Petróleos Mexicanos. Memoria de Labores, 1979, 1980.

In 1980, total crude oil production increased almost 33% over production of 1979, mainly because of a 38% production increase from the Southern Zone, and more specifically from the Cantarell complex in Campeche Sound where the Nohoch and Akal Fields have become highly productive. In 1980, the Southern Zone contributed almost 90% of total crude oil production and 77% of natural gas production. The Central Zone accounted for almost 7% of crude oil production and for 6% of natural gas production. The Northern Zone contributed 3% to crude oil production and 17% of natural gas production. Total petroleum and natural gas production during 1979 and 1980, by region and district, are shown in table 8.

On November 15, 1980, oil production from offshore Campeche reached 1 million barrels per day for the first time, pushing total oil production to 2.3 million barrels per day. Because there was no production from Campeche in 1979, this was a notable achievement for PEMEX.

A total of 349 developmental wells were drilled in 1980, of which 54 were gas, 202 were oil, 35 were for injection, and 58 were abandoned. Gas wells (numbers in parentheses) were drilled in the Reynosa (38), Monclova (9), Central Papaloapan (1), and Comalcalco (6) districts. Oil wells were drilled in the districts of Ebano (12), Cerro Azul (40), Poza Rica (47), Central Papaloapan

(20), El Plan (4), Agua Dulce (19), Comalcalco (30), and Campeche Sound (30).

PEMEX carried out exploration activities in virtually all states, as well as on the Continental Shelf areas of Sinaloa and Oaxaca, the Gulf of Mexico, the Gulf of California, and the Pacific Ocean. In 1980, exploration work resulted in the discovery of 34 fields with potential producing possibilities.

A total of 85 exploratory wells were drilled by PEMEX in 1980, of which 6 produced gas, 29 produced oil, and 50 were abandoned. Gas discoveries were made in the Reynosa and Monclova districts; crude oil discoveries were made in the Cerro Azul, Poza Rica, Comalcalco, and Campeche Sound areas. Other positive exploratory work was carried out in the regions of Michoacán, Guerrero, Tlaxiaco, Oaxaca, Zongolica, Veracruz, Eje de Neovolcanico, Chihuahua, and Baja California. PEMEX continued to employ the latest exploration technology, including the geochemical "Sniffer" method and three-dimensional marine seismic studies.

Source: Petróleos Mexicanos. Memoria de Labores, 1979, pp. 69-71; 1980, pp. 73-75.

In 1980, the seven major and two minor refineries operated by PEMEX refined an average of almost 1.2 million barrels of crude oil per day, a 19% increase over the 1979 figure. The largest production gains were in liquefied petroleum gas production (33%) and residual fuel oil (29%).

In 1980, Mexico's refining capacity was about 1.3 million barrels per day. An additional 450,000-barrel-per-day capacity will be available when expansions under construction at the Madero (150,000) and Salina Cruz (150,000) refineries are completed. The new national energy plan envisages concentrating refinery investment in facilities to handle the increasing proportion of heavy crude oil in Mexico's crude oil mix to ensure an adequate yield of light products. The plan refers to a doubling of refining capacity of 1990.

In August 1980, Mexico signed an agreement with Venezuela to jointly guarantee nine Central American and Caribbean countries a total of 160,000 barrels per day of crude oil on concessionary terms. The agreement has a 1-year lifespan, with Mexico's contribution to be one-half of each recipient country's crude oil imports and associated financing. Recipients have the option of receiving 30% of the cost of the oil

returned in the form of a 5-year loan at 4% interest. The loan terms can be extended to a 20-year repayment schedule at 2% interest if the proceeds are used for approved development projects, preferably those directed toward developing indigenous energy resources.

One of PEMEX's important fuel-related activities was the December 1980 agreement with Cuba for cooperation in petroleum affairs. The agreement provides for an exchange of petroleum products and derivatives; Mexican technical assistance in expanding the catalytic cracking section of Havana's Nico Lopez refinery to increase production of liquid gas; and a joint offshore exploration program of the continental shelf areas of the Yucatan Peninsula, Caribbean Sea, and an area north of Cuba. Exploration work was expected to begin immediately and include seismic surveys and drilling. This agreement marked PEMEX's first foreign exploratory program. Compañía Mexicana de Exploraciones S.A., a state entity in which PEMEX is majority shareholder, signed a contract to carry out seismic exploration work in Costa Rica.

Uranium and Nuclear Energy.—Mexico was considering both French and Canadian technology and reactors as the foundation for the national nuclear program. Delays in arriving at a decision were because of the need for more data on the extent and quality of Mexico's uranium reserves. This information would influence any decision regarding the more appropriate technology.

The Mineral Industry of Morocco

By George A. Morgan[1]

The mineral industry contributed about 15% to Morocco's gross domestic product (GDP) in 1980. The country continued to experience balance of payments problems despite increases in worker remittance, tourism, and exports, thus necessitating foreign borrowing. The increases in revenue from phosphate rock exports early in the year were negated for the most part by the high cost of imported fuel. About 80% of the total energy requirements were met by imported fuel; the remainder was derived from coal and hydroelectric power. Cost of imported energy accounted for nearly one-third of total imports. By yearend, the country was the recipient of loans from major financial lending institutions, led by a $1 billion[2] standby credit from the International Monetary Fund. Bilateral loans or grants were also secured, some of which were for military spending. Although the country was not on a war footing, about 40% of the State budget was to be directed to the Western Sahara and defense in 1981, compared with 27% in 1980. The Moroccan Parliament created an exclusive maritime economic zone, extending 200 miles offshore and including the coastal waters of Western Sahara. All resources in, under, and on the surface of the water were given Moroccan sovereignty.

The Government's most ambitious plans continued to be for phosphate fertilizer production and development of indigenous energy resources. About $4 billion was to be spent to expand phosphate fertilizer output by 5% per year to 1985. Capacity to process phosphate rock to fertilizer was to double, utilizing 30% of total output. Port facilities were being expanded to facilitate the additional production. About $1 billion was also planned for exploitation of oil shale over the next 5 years.

PRODUCTION AND TRADE

The index of crude mineral production showed a small decline from the 1979 level. The index for energy production, which included coal, refined petroleum, and electricity, was up slightly for the year. Numerous projects were planned or underway for copper, lead, zinc, and silver mine production, while technical and economic studies continued on a new copper smelter to be built at Agadir. Indigenous energy sources received considerable attention in light of the very high cost of imported fuel and the effect such cost was having on the economy as a whole. Uranium exploration and resource assessment established a number of favorable mining sites, and at least one preliminary report indicated output of some uranium. The uranium was expected to be consumed internally for power generation. Reports relating to bituminous shales indicated that they were amenable to retorting for recovery of heavy oil and for use as direct feed to a boiler because of their self-combustion property.

Although major traditional trading partners continued to be France and Spain, Morocco attempted to establish and maintain bilateral trade relationships with a number of countries such as Japan, the U.S.S.R., the United States, and Iran. Sever-

al trade arrangements involved technical and capital investment in exchange for future production. The country's balance of trade deficit was expected to increase again, and was a continuing source of concern to the Government, which had already implemented restraints to limit imports.

COMMODITY REVIEW

METALS

Antimony.—About 170 occurrences of the metal have been recorded, mainly in the north and north-central part of the country. Bureau de Recherches Géologiques et Minières (BRGM) of France has provided technical assistance to the Directorate of Mines for assessing antimony resources since the conclusion of a bilateral cooperative agreement in 1977. A geologic study was underway which was to provide exploration targets for determining additional reserves of antimony. The work was to be performed by the holders of mineral rights, and a treatment process adapted to the ore was to be tested in a pilot plant.

Copper.—Output of copper ore was relatively stable in 1980 following a near doubling of production between 1978-79. Lower copper prices and increased operating costs were the causes for the decline. The new underground copper mine at Bleida came into operation in 1979. When fully operational, production at the mine would be about 54,000 tons per year of copper concentrate grading 32% copper.[3] Overall reserves at the site were put at 2.5 million tons grading 7.5% copper. Nearly all output in Morocco was exported as concentrates. The following tabulation lists mines in operation in 1979, along with quantity and value of copper concentrates produced.[4]

Mine	Quantity (tons)	Value (thousand dollars)
Ouansimi	11,971	4,580
Bleida	6,973	2,805
Tazalaght	2,156	1,178
Assif Imider	1,732	1,356
Tanfif	370	103
Taourirt	171	31
Taliouine	110	3
Imililte	40	12
Total	23,523	10,068

Some copper production was also realized as a byproduct of lead-copper mining at Beddiane by Campagnie Minière de Touissit (CMT). Production at Bleida has largely offset the loss of output which occurred in 1977 and 1978 owing to the closure of the Bous Kour, Talaat N'Ouamane, and Tannsriff Mines.

Preliminary technical and economic studies continued on the planned 50,000-ton-per-year copper smelter at the Port of Agadir, which was to treat both domestic and imported concentrates. The Bleida deposit was to be the source for the domestic material, while 110,000 tons per year of concentrate containing 27% copper would be imported. Production would include gold, silver, and sulfur, and total employment upon completion was to be 350 people.[5]

About $3.4 million has been spent thus far on the Tizert copper-silver project in Agadir. Total reserves were 3 million tons grading 1.69% copper and 1.7 ounces of silver per ton. First-phase development would involve production of 84,000 tons per year of ore yielding 4,000 tons per year of concentrate containing 40% copper and 31 troy ounces of silver per ton. Overall cost of the project was estimated at $12.3 million, and when completed it will employ 150 people.

Iron and Steel.—The first stage of a steel mill to be constructed at Nador was to have a capacity of 360,000 tons per year of wire and bars for concrete reinforcement. Société Nationale de Siderurgie was to be the operator, with production expected to commence in 1983. Ultimate capacity at the plant would be 1 million tons per year.[6]

Lead and Zinc.—About 75% of the lead produced in Morocco was exported as concentrates. The remainder, about 40,000 tons, was smelted locally at Oued El Heimer and exported as primary metal. Total receipts from lead exports were valued at $112 million in 1979. The following tabulation lists mines and mining groups according to level of output of concentrates in 1979.[7]

Mines and/or organization	Quantity (tons)
Beddiane, Oued Mekta	70,000
Zeida	44,640
Djebel Aouam	18,600
CADETAF	14,000
Aouli, Mibladen	8,600
Adrar	6,400
Draa Sfar	3,060
Total	165,300

Production at the Beddiane and Oued Mekta Mines in Oujda Province near Touissit was by CMT. About 750 people were employed at the mining operations at Touissit. Data for Central d'Achat et Developpement de la Region Minière du Tafilalet et de Figuig, a mining cooperative, include production from small mines and artisanal workers at Tafilalet and Figuig.

Technical, economic, and commercial studies were completed for a lead smelter to be built at Midelt for Fonderie Centrale de Plombe. Feed to the smelter was to be

100,000 tons per year of lead concentrate, containing 68% lead with silver and copper byproducts. Annual output would include 70,000 tons of lead, 1.6 million troy ounces of silver, and 560 tons of 45% copper concentrate. Offers for construction of the smelter had been received and were under review.

Feasibility studies for exploitation of the lead-zinc deposit at Bou Madine in Errachida Province were completed. Reserves were 6 million tons grading 1.3% lead, 5% zinc, and 4.8 troy ounces of silver per ton. Initial production for the first phase of operations was to be 60,000 tons per year of crude ore, with a work force of 120 people.

Exploration conducted about 18 kilometers east of Chaouen revealed two potentially exploitable zinc deposits. The Cadnar deposit had reserves of 7.5 million tons grading 3% zinc, with a potential of 40 million tons of ore indicated. The Khemis Tikenziguen deposit, although of limited tonnage, contained 10% zinc with associated germanium and cadmium. Pilot-plant metallurgical studies on ore samples from both sites yielded concentrates grading 50% zinc.

The Arab Mining Co. had a 40% interest and the Bureau de Recherches et de Participations Minières (BRPM) had a 60% interest in a lead-silver mine which was to be opened at Sidi Lahcen at a cost of $11.5 million. Ore reserves were estimated at 1 million tons, while output from the mine was to be 84,000 tons per year of crude ore grading 5.5% lead, 0.8% zinc, and 0.2% silver.[8]

Silver.—Production of silver in Morocco has been from the Imiter Mine in the Ouarzazate region and from lead ores smelted at Oued El Heimer. The Imiter deposit had proved reserves of 2.4 million ounces of silver. Production was in the form of a precipitate containing 92% silver. Several million tons of additional ore were inferred in the area.

The Zgounder deposit, northwest of Sirwa, had reserves of 600,000 tons grading 16 troy ounces of silver per ton. The deposit was being developed by the Société Metallurgique du Sirwa, which was 40% controlled by Arab Mining Co. and 60% by BRPM. Production of 56,000 tons of ore per year was planned for Zgounder, yielding about 830,000 troy ounces of silver. Cost of the project was estimated at $11 million.

Tungsten.—Joint exploration conducted by BRPM and Klöckner in Marrakech Province resulted in several finds of extensive scheelite mineralization. At Azegour, 500,000 tons of rock grading 0.20% WO_3 were reported, while at Sidi Bou Azzouz, 160 kilometers south of Casablanca, 1 million tons grading 0.25% WO_3 were found. Both sites were in the final stages of feasibility and engineering studies as potential mining projects.

Exploration drilling was underway at Taourirt N'Tamelalt in Ouarzazate Province and at Zguit in Khemisset Province. Preliminary estimate of scheelite mineralization at Taourirt N'Tamelalt was 800,000 tons grading 0.20% WO_3.

Uranium.—An assessment of uranium resources in Morocco has been underway to evaluate potential exploitable ore for expanding the country's energy base. At Jbel Waffaga, in the Western High Atlas, 2,000 tons of uranium (U) as carnotite and pitchblende in ore grading 0.15% to 0.2% U_3O_8 were recorded. At Assaka, in the Anti Atlas Mountains, uranium was found in fractures and alteration zones of Precambrian granites. The deposit was considered to have 4,000 tons of uranium in ore grading 0.15% U_3O_8. At Akka Bou Tiouit, 570 kilometers east of Agadir, a potential of 2,000 tons of uranium in ore grading 0.075% U_3O_8 was reported. Exploration of the Ouarzazate Tertiary Basin was planned based on geologic evidence of uraniferous sediments derived from the Precambrian rocks of the High Atlas and Anti Atlas.

NONMETALS

Fluorspar.—Geological and production feasibility studies were completed on the Zrahina fluorspar deposit near Khenifra. Reserves were 1 million tons grading 31% fluorite, 11% barite, 1.83% lead, 0.6% zinc, and 2 ounces of silver per ton. Operation of the deposit would involve an annual output of 70,000 tons of ore yielding 14,700 tons of 96% fluorite, 3,500 tons of barite, and 1,400 tons of concentrate containing 65% lead and 64 ounces of silver per ton.

Magnesite.—A magnesite-bearing zone, located 60 kilometers south of Ceuta, was the subject of exploratory drilling which indicated reserves of 9 million tons of material grading 43% magnesia. One million tons was reported to have a grade exceeding 44.5% magnesia, with a portion of the zone extractable by openpit mining.

Phosphate Rock.—At the Youssoufia phosphate mining center on the Ganntour Plateau, white phosphate rock was pro-

duced for direct export through the Port of Safi and to supply the fertilizer plants of Maroc Chemie I and II and Maroc Phosphore I at Safi. White phosphate was expected to become relatively less important as production of black phosphate rock at Youssoufia expanded. Black phosphate was produced from Bed I and calcined at 750° C to produce 75% bone phosphate of lime. The largest expansion at Youssoufia was to be for black phosphate from new underground workings as at Recette 7. Production from new Ben Guerir Mine, also on the Ganntour Plateau, was destined solely for the new Maroc Phosphore II fertilizer plant at Safi. About 23 phosphate-bearing beds were identified at Ben Guerir, with 20 beds potentially exploitable.

At the Khouribga mining area on the Oulad-Abdoun Plateau, phosphate rock from Bed I was nearly exhausted. Beds O, I, and II, formerly mined selectively, were mined together which allowed for the use of larger and more economical draglines for exploitation. Selective mining of high-grade lenses of phosphate material overlying the main beds occurred at Meraa al Arech. The mining of Bed III was restricted by the availability of water, while overburden stripped from current operations was being dumped on the bed. Geologic studies and ore beneficiation tests were also underway at Sidi Hajjaj, west of Khouribga on the Oulad-Abdoun Plateau. Output was to be used as feed to the phosphoric acid plant at Jorf Lasfar.[9]

Production of phosphoric acid was centered at Safi where Maroc Chemie I and II and Maroc Phosphore I were operational. Maroc Phosphore II was built at Safi, with three sulfuric acid and one phosphoric acid stream. Output of phosphoric acid from Maroc Chemie I and II was mainly used for further downstream processing, while production from Maroc Phosphore I was exported primarily as 54% phosphoric acid. Output from Maroc Phosphore II was designated for export. Civil engineering work on the Port of Jorf Lasfar resumed following a temporary suspension in 1979. Full operation of the port was planned for 1983, at which time equipment for the new phosphoric acid plants to be built at the port would be shipped in. Phosphoric acid and phosphate fertilizer facilities were also planned for the Port of Nador. Phosphate rock supplies for Nador would be shipped by sea from Jorf Lasfar.

Overall loading capacity for phosphate rock at the Ports of Casablanca and Safi was 25 million tons, and was expected to be insufficient in view of production expansion plans for the industry by 1985. Upgrading of raw phosphate rock to phosphoric acid of fertilizer at Safi, Jorf Lasfar, and Nador was expected to account for about 30% of total P_2O_5 produced compared with 12% currently. New capacity may reach 37 million tons by 1985 compared with 24 million tons in 1980. Marphocean, a Moroccan shipping line 46% controlled by Office Cherifien des Phosphate, had four 27,000 deadweight tons (dwt) vessels and two 11,000 dwt vessels for use in phosphate fertilizer operations. Orders have been placed for two 24,000 dwt and two 6,600 dwt vessels from Chantiers Naval de Dunkerque of France.[10]

MINERAL FUELS

Bituminous Shale.—Research on oil shale processing increased as more effort was made to attract investor interest in development projects. BRPM operated two small retorts at Timhadit for testing heavy oil recovery. Two pilot plants with capacities of 80 and 100 tons were to be completed in 1981 for testing recovery processes on a larger scale. Reserves at the Timhadit oil shale deposit were estimated at 20 billion tons, yielding about 17 gallons of heavy oil per ton of shale.

Natural Gas.—New gas finds were made near Mechra bel Ksiri in the Gharb Basin. An oil and gas discovery was also made by BRPM at Meskala in Essaouira Province. If commercial, the additional output could be tied into existing production lines. BRPM, Elf Aquitaine Maroc, and the Société Cherifienne des Petroles (SCP) were to continue their exploration in the Pre Rif in 1981 with the assistance of the Kuwait Petroleum Corp.

Petroleum.—Elf Aquitaine and SCP were awarded five oil prospecting permits covering a portion of the Gharb area and the foothills of the Rif Mountains. The project, estimated to cost $90 million, was to be conducted in association with BRPM which received a $50 million loan from the World Bank for petroleum exploration. Actual work was to entail 36 months of seismic study and the drilling of 17 exploratory wells. The loan was for a 10-year term with 4 years of grace, at 8.25% interest per year. The Islamic Development Bank granted a loan of $15 million to finance the purchase of crude oil. Actual terms of the agreement were not released.

The Mineral Industry of Mozambique

By Miller W. Ellis[1]

Since Mozambique became independent on June 25, 1975, most of the 250,000 Portuguese who dominated the industry, trade, and commercial aspects of the country's farming have departed. The subsequent closure of the Rhodesia-Mozambique border was followed by a stagnating economy and despite aid, chiefly from Western Europe, there were few indications of economic recovery until the end of the conflict in neighboring Rhodesia-Zimbabwe. Following the exodus of thousands of small industrialists and shopkeepers, their enterprises were nationalized and run by the Government of the People's Republic of Mozambique (GPRM) with indifferent success. In successive speeches on February 27 and March 18, 1980, the country's President called on Western capital to rescue the country's economy and on the former owners of nationalized enterprises to return to Mozambique and resume their management. He also invited the investment of capital from the United States and other Western nations in Mozambique projects. Despite the reiteration of these invitations during the remainder of 1980, there were many other events that indicated the continuing strong affiliation of the GPRM with the centrally planned economies of Eastern Europe.

On February 12, 1980, the newspaper, Noticias da Beira, reported that a 30-member expedition of scientists from the U.S.S.R. stopped at Maputo on their way to Antarctica as part of the first Soviet air expedition to that subcontinent. The expedition was to make a detailed study of the Molodezhnaya polar station and to determine the feasibility of constructing another airfield at the Mirnyy station. Those stations were about 4,670 kilometers from a staging base established at Maputo, approximately 8 hours flight for the IL-18-D aircraft.

From February 24 to February 27, 1980, the Bank of Mozambique acted as host and organized a "Round Table on Western Investment in Mozambique," arranged by Business International (BI) for delegates from 22 firms in 8 countries. The delegates were addressed by the President of the GPRM, and by several Ministers including the Secretary of State for Coal, Gas, and Oil, as well as the Agriculture Minister and the Secretary of State for Fisheries. The delegates were reportedly favorably impressed by the country's economic potential but had reservations about current investment because of the dearth of hard economic data and the conspicuous lack of trained personnel to staff new undertakings. The GPRM's vagueness about terms and conditions of investment, profit margins, and repatriation (to be arranged on a case-by-case basis), produced some skepticism on the part of the delegates that the GPRM was ready to make the necessary adjustments in order for Mozambique to become a favored environment for Western investment.

In a speech at a political rally on March 22, the President stated that the efficiency of small businesses had fallen below acceptable standards because of excessive state involvement. The GPRM was ready to restore nationalized industries and businesses to their former owners. Portuguese nationals who had left Mozambique were encouraged to return and resume their former activities. Western investment in Mozambique enterprises was to be encouraged.

On July 12, 1980, the Electricidade de Mocambique invited tenders for implementing the second stage of the Cabora Bassa

hydroelectric power project. The Cabora Bassa first stage was started in 1967 and was completed 10 years later. It comprised a 170-meter-high reinforced concrete dam wall, impounding a 60-billion-cubic-meter reservoir, 250 kilometers long and 30 kilometers wide at its widest point. It has five generator groups with a unit capacity of 415 megawatts each (total 2,075 megawatts), and the complex was valued at $656.2 million. Most of the output was fed through two direct current high-tension lines to consumers in the Republic of South Africa, 1,440 kilometers to the south. The Maputo area, Tete, and the Moatize coal mining center also received power from Cabora Bassa. Stage II plans included an underground power station in the north bank of the Zambezi River with about 1,750 megawatts capacity and power transmission lines to all parts of the country. The Maputo thermal powerplant has supplanted diesel generators for the supply of electricity to the Costa do Sol tourist district and adjacent fishing area a few kilometers from the city. In June, the two thermal generators supplying electricity to the Chimoio area, 75 kilometers east of Umtali, Zimbabwe, were destroyed by an explosion. Since that time, the Umtali thermal power station has been exporting up to 20 megawatts of power to Chimoio.

The anti-Frelimo Mozambique National Resistance Movement was blamed for the closure of the Umtali-Beira Railroad from September 20 to October 3 and for increased guerrilla activity in the western part of the country in the latter part of 1980. Despite the October signing of a security pact between the GPRM and the new Government of Zimbabwe, the direct current, high-tension line transmitting power from the Cabora Bassa Dam to the Republic of South Africa was cut on December 9, 1980.

A study entitled "Economic Justification for a Comprehensive Mineral Resource Program for Mozambique" was commissioned by GPRM in 1980. The study outlined a comprehensive airborne geophysical survey of 423,500 square kilometers and appropriate followup strategies, with an overall cost of $32.5 million. It was speculated that the survey could produce investments in Mozambique's mineral sector on the order of $313 million and sales revenues on the order of $5.3 billion over a period of 35 years. Such an increase in mineral development would increase the average rate of growth in gross domestic product (GDP) by about 16% during the next 20 years. Under the medium mineral development scenario, mineral exports were projected to increase by $155 million per year in a decade and by $290 million per year in 20 years.

The Mozambique National Geology Board has awarded a $15 million contract to Aquator, part of the Italian Ente Nazionale Idrocarburi (ENI) group. The work involved geochemical survey of a 19,000-square-kilometer area and geological mapping at a scale of 1:50,000, as well as geochemical sampling of another 29,000 square kilometers with mapping at 1:250,000 scale in the Zambezi and Nampula regions. Two French companies were also awarded a 2 1/2 year contract for surveys in the northern Provinces of Niassa and Cabo Delgado. They were Bureau de Recherches Geologiques et Minieres (BRGM) and Compagnie General de Geophysique. It was reported that about 100 young Mozambicans were being trained in electrical and various other aspects of mining engineering in the German Democratic Republic. Meanwhile, a professional training center was under construction at Moatize, in Tete Province.

PRODUCTION AND TRADE

Fragmentary reports of production of Mozambique's mineral commodities have been used to compile the production estimates shown in table 1.

In 1980, Mozambique's largest import commodity and supplier was petroleum from Iraq, which made up 17.7% of the country's total import costs. Imports from the Republic of South Africa for 1980 were valued at $103 million and composed 14.4% of the total. Mozambique exports to the Republic of South Africa totaled only $12 million. Figures released by the GPRM National Planning Commission indicate that imported crude and refined petroleum products in 1979 were valued at U.S. $116 million, or nearly one-fifth of the country's total imports for that year. Petroleum exports during the same year were valued at $37 million, and transit operations through the ports of Beira and Maputo, of petroleum destined for Malawi, Swaziland, and the Republic of South Africa, earned an additional $20 million to $25 million.

Table 1.—Mozambique: Production of mineral commodities[1]

(Metric tons unless otherwise specified)

Commodity[2]	1976	1977	1978	1979[p]	1980[e]
METALS					
Aluminum: Bauxite, gross weight	2,000	2,000	--	--	--
Beryllium: Beryl concentrate, gross weight	(3)	NA	NA	28	20
Columbium and tantalum ores and concentrates, gross weight:

Kerosine do	195	178	296	NA	NA
Jet fuel do	56	128			
Distillate fuel oil do	613	865	634	NA	NA
Residual fuel oil do	1,003	1,438	1,132	NA	NA
Other do	167	63	85	NA	NA
Refinery fuel and losses do	278	299	270	NA	NA
Total do	2,785	3,592	2,927	NA	NA

[e]Estimated. [p]Preliminary. NA Not available.

[1]Table includes data available through July 2, 1981.

[2]In addition to the commodities listed, crude construction materials and additional varieties of gem and ornamental stones presumably are produced, chiefly for local consumption, but information is inadequate to make reliable estimates of output levels.

[3]Less than 1/2 unit.

[4]Reported figure.

The following table shows the number of ships and the amount of freight moved through Mozambique's major ports, January through December of 1979 and 1980.

Port	Ships		Thousand tons	
	1979	1980	1979	1980
Maputo	808	928	4,030	4,063
Matola[1]	244	212	4,107	3,540
Beira	770	528	1,722	1,520
Nacala	229	218	784	752

[1]The Matola port was built in 1964 as an annex to the port of Maputo (formerly Lorenzo Marques) to handle bulk liquid fuels and bulk minerals.

By mid-1980, plans were announced for a $515 million program of extensions to Maputo harbor, the country's major port. Initially, South African contractors were to add 2.2 million tons of coal export capacity per year to the existing facilities. Subsequent work was to involve overseas contractors and construction of a new port to export 6.5 million tons of coal annually, for completion in 2 years. The port of Nacala in the northeastern part of the country is one of Africa's best natural Indian Ocean harbors, and upgrading was in hand, as was rehabilitation of the railroad line to Malawi. Nacala harbor has been specifically equipped for handling the roll-on, roll-off container freight that has become popular. The 1980 quota for Nacala harbor of handling 3,000 containers was exceeded by 300%.

The railway line connecting Maputo's ports with the Republic of South Africa was the first to be renovated for increased traffic. Heavier weight rails at 54-kilograms-per-meter length were installed in place of the old intermediate weight 45-kilograms-per-meter length rail. The Caminhos de Ferro Mocambique (CFM) established a fabricating plant at its Machava yard, between Maputo and Matola, where the normal 12- to 18-meter lengths of rail were flash butt-welded into 144-meter continuous lengths as they were loaded on a track-laying unit for transport up the line toward the town of Ressano-Garcia at the Mozambique-South African border. Each 144-meter length was then thermite-welded in place on new reinforced concrete crossties or sleepers, and the track was leveled and reballasted to carry greater loads at faster speeds. Lightweight (30-kilograms-per-meter) rails on the shunting or switching tracks were also replaced with 45-kilograms-per-meter rail on concrete ties. The first freight train from Zimbabwe to Maputo since February 1976 arrived at the port in early October 1980, but extensive repairs necessary for full-time resumption of service included relaying heavier rail on new concrete sleepers on much of the line and repairing a number of bridges. In the northern part of the country, some 600 kilometers of antiquated railroad track west from Nacala was also slated for renovation, including replacement of 30-kilograms-per-meter rail with heavier 45-kilograms-per-meter rail laid on concrete sleepers.

COMMODITY REVIEW

METALS

Tantalum.—Delegations led by the GPRM Minister of Public Works and Housing and the German Democratic Republic's Minister for Ore Mining met in Quelimane on July 6, 1980, for discussions before visiting the Muiane, Marropino, and Morrua tantalum-rich pegmatite deposits, 200 kilometers to the northeast. Subsequently, an agreement was signed whereby exploration and exploitation of these deposits were reserved for the German Democratic Republic. Production of the two tantalum minerals, tantalite and microlite, was not reported, but it was estimated that all such minerals recovered were exported to the German Democratic Republic.

NONMETALS

Limestone, Lime, Cement.—The State-owned company, Cimentos de Mocambique, continued to operate lime-burning plants at Dondo and Salamanga, and cement kilns at Dondo, Matola, and Nacala. Casting of prestressed concrete sleepers (crossties) for the rehabilitated railroad line contributed to increased demand for concrete aggregate. The State Marble Co. operated a quarry near Montepuez in the southern Cabo Delgado District, about 200 kilometers northwest of the port of Nacala, that reportedly produced about 75 tons of block marble per month during the early part of the year.

Salt.—Early in May, it was announced that the operation of the Fabrica de Higien-

izacao de Sal at Matola would be headquarters for a newly established National Salt Producing Co. that would open branches in remote provinces where salt-drying enterprises had been abandoned by their preindependence owners. The first such branch was to be the Diezo project in Pemba Bay where a salt-drying pond had the capacity of extracting 5,000 tons of salt per year. New equipment to be installed at Matola would enable the export of 3,000 tons of salt, with a foreign exchange value of $270,000, to Zimbabwe and Swaziland.

MINERAL FUELS

Coal.—The Moatize coal mine was reportedly shutdown in late 1979 because of major damages to three bridges allegedly inflicted by Rhodesian forces. The resulting shutdown lasted for 3 months and was blamed for the failure to produce 550,000 tons of coal projected in the plan for 1980. Production at 408,000 tons was 142,000 tons short of the target. The country remains plagued by inadequate rail facilities from Moatize to Beira, a severe shortage of trained manpower and technical staff, and a critical lack of spare parts for its aging equipment.

Petroleum.—The GPRM State enterprise responsible for refining and for most domestic distribution of petroleum, Empress Nacional Petroles de Mozambique (Petromac), was formed by the amalgamation of two former Portuguese companies, SONAREF (refining) and SONAP (distribution), both of which were nationalized in 1977. Compensation was promised to the shareholders, but no payment had been made by late 1980. Two South African subsidiaries of U.S. companies traded locally in Mozambique as Caltex Oil S.A. (Pty.) Ltd. and Mobile Oil of Southern Africa (Pty.) Ltd. British and Dutch interests were represented jointly by BP and Shell Mocambique. "Total Oil" at Maputo was responsible only for bonded storage of petroleum in transit to the Republic of South Africa, and CALTEX and MOBIL operated out of Beira as transit agents for Malawi. There were no oil or gas exploration permits in force in Mozambique, but both ENI and Braspetro were reported to be negotiating with the GPRM.

The Mineral Industry of Namibia (Territory of South-West Africa)

By Miller W. Ellis[1]

The mineral industry of Namibia provided about 50% of the country's $1,717 million[2] gross domestic product (GDP) in 1980 and established its position as the fourth largest producer of nonfuel minerals on the African Continent in terms of total value. Most of Namibia's mineral products were produced and exported by three mining companies; Tsumeb Corp. Ltd., largely controlled by United States base-metal mining companies; Consolidated Diamond Mines (Pty.) Ltd. (CDM), a major subsidiary of De Beers Consolidated Mines Ltd. of the Republic of South Africa; and Rossing Uranium Ltd. (RUL), owned 46.5% and managed by the British firm Rio Tinto-Zinc Corp. Ltd., with other South African firms and Total Compagnie Miniere et Nucleaire of France as partners.

CDM contributed about 30% of the country's GDP in 1980 and exported diamonds earned about half of its foreign exchange. CDM also generated 60% of the country's tax revenue and was its largest employer. Tsumeb was the second largest employer in the country with 6,043 employees on the payroll at yearend. About 350 people were hired late in the year to start up the Otjihase Mine, which was purchased in December. Tsumeb was not a heavy taxpayer despite its declared sales of $161.9 million. Net income declined by 35% to $18.2 million, and because of the capital expenditure of $52.6 million including the purchase of a 70% interest in the Otjihase Mine from the Johannesburg Consolidated Investment Co. Ltd. (JCI), Tsumeb paid about $12.9 million in taxes. The company's normal tax rate was increased from 35% to 40% of taxable profits during 1980, but the 5% surcharge and the 15% loan levy were abolished. RUL, as a newly producing mining venture, paid no taxes in 1980 despite its profits of $123 million and was not subject to taxation until its investment has been amortized.

All three companies continued exploration programs during 1980. CDM allowed some results of its mineral surveys to be placed on open file with the Geological Survey of South-West Africa and has applied for coal prospecting rights on both sides of the Nossob River, west from the Botswana border. Namibia's offshore areas and the northern part of the country have been leased for oil exploration. Resumption of exploration for oil in the Etosha Pan area was planned for 1982. The South-West African Oil Exploration Corp. (Pty.) Ltd. was not active in 1980.

In June 1980, the minimum starting wage for unskilled mine employees was increased by 14.3%. This was in addition to an "average minimum living level for an urban family of five" that has been established from time to time by the University of South Africa as a measure of the amount and quality of the housing, food, clothing, medicine, and social services provided free to employees.

The country's electricity supply and grid of transmission lines interconnecting its mines were improved substantially during 1980 by the South-West Africa Water and Electricity Corp. Generation of power at the recently completed Ruacana Falls hydro-

electric station near the Angolan border was restarted in January when the Kunene River gates (in Angolan territory) were forcibly jammed allowing water to flow through the diversion weir and into the power station penstocks. The station generated 240 megawatts of power, which was transmitted over a 600-kilometer transmission line to a power-switching station at Omaruru, 160 kilometers northwest of Windhoek. In April, some of the transmission line pylons were destroyed by the South-West Africa People's Organization, which interrupted the power supply. The pylons were replaced and power was restored in May, and precautions were taken to ensure against a repetition of the outage. Ruacana's capacity was subsequently able to handle most of the country's demand for power which has averaged about 140 megawatts.

The Van Eck 120-megawatt power station at Windhoek and the 45-megawatt emergency generator at Walvis Bay continued to be available as backup power sources, and a total of 100 megawatts was available from the Electricity Supply Commission's (ESCOM) power grid in the Republic of South Africa. One of the connecting links with the external grid was through the CDM installations north of the Orange River mouth. CDM's power consumption increased from 23 megawatts average half-hourly maximum demand in 1979 to 33.6 megawatts and was expected to increase further by 1982 with the commissioning of a central food preparation depot and the possible electrification of overburden stripping. CDM's 10-megawatt standby power station underwent a major overhaul in 1980 and its capacity was increased to 18 megawatts. Other power links with ESCOM were along the road north from Springbok, and along the railroad that crossed the Orange River at Upington in the Republic. An additional 100 megawatts from ESCOM's grid was expected to be available in 1982,when a new $90 million power hookup with Aggeneys in northern Cape Province was to be completed.

PRODUCTION AND TRADE

The production statistics in table 1 were compiled largely from annual reports of some of the companies operating within Namibia. Publication of separate production statistics was suspended by the South-West African Administration in 1965. Although the country's economy depends on mineral exports, specific reporting of their magnitude and value remained unavailable and were no longer included in statistics published by the Minerals Bureau of the Republic of South Africa.

Diamonds continued to be marketed through De Beers Central Selling Organization and were exported to the Republic of South Africa and overseas. RUL's uranium concentrates were exported from Walvis Bay to contract customers in Western Europe and Japan. Tsumeb's metal production was transported on the company's 640-kilometer railroad to its loading facilities at Walvis Bay for export to overseas customers. Other metal concentrate was railed to smelters and refineries in the Republic of South Africa.

Table 1.—Namibia: Production of mineral commodities[1]

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.

[1]Table includes data available through Sept. 22, 1981.

[2]In addition to the commodities listed, Namibia, prior to 1967, produced bismuth concentrates, cesium ore, columbite-tantalite concentrates, gold, manganese ore, molybdenum concentrates, graphite, lime, mica, precious stones, kyanite, sillimanite, and a variety of crude construction materials (clays, stone, sand and gravel). No official statistics have been published since yearend 1966, and available information is inadequate to ascertain whether production has been continued or not, and if so, at what levels.

[3]Data are compiled from operating company reports as follows: Tsumeb Corp. Ltd. (arsenic, white and refined cadmium, mine and blister copper, mine and refined lead, mine and smelter silver, mine zinc, and pyrite concentrate); South-West Africa Co. Ltd. (SWACO) (mine lead, mine tin, mine tungsten, mine vanadium, and mine zinc); South African Iron and Steel Industrial Corp. Ltd. (ISCOR) for Imcor Zinc (Pty.) Ltd.'s Rosh Pinah Mine (mine lead and mine zinc), and for ISCOR's own Uis mine (mine tin); General Mining and Finance Corp. Ltd. for Klein Aub Koper Maatskappy Ltd.'s mine near Rehoboth (mine copper and mine silver); and Falconbridge Nickel Mines Ltd. for Oamites Mining Co. (Pty.) Ltd.'s mines (mine copper). Data from Tsumeb and Falconbridge are for calendar years; data from other companies for fiscal years ending June 30 of that stated.

[4]White arsenic equivalent of all arsenic products reported as being produced.

[5]Figures comprise reported production of Tsumeb and Oamites plus estimates for Klein Aub and Otjihase copper mine (bought by Tsumeb in December 1980).

[6]Figures comprise reported production of Tsumeb plus estimates for Oamites, Rosh Pinah, and Klein Aub.

[7]Figures comprise reported production of Tsumeb Corp, a reported figure for SWACO for 1976, and estimates for SWACO for 1977 and 1978, as well as estimates for Rosh Pinah.

[8]Total figures reported by DeBeers Consolidated Mines Ltd. in company annual reports for calendar years. Detail on gem and industrial diamonds are estimates, assuming output to be 95% gem quality.

[9]Output has not been officially reported since 1966, but presumably has continued since a number of countries record imports from "South Africa," which in total quantity considerably exceed the reported output of the Republic of South Africa and presumably include shipments from Namibia. Quantities given represent imports of the United States and the European Communities reported as originating in South Africa, but the reader is cautioned that a portion of the material may have been mined in Zimbabwe.

COMMODITY REVIEW

METALS

Copper.—Tsumeb continued to be the country's foremost producer of nonferrous metals, its leading exporter of copper, lead, and silver, and its sole producer of arsenic and cadmium. The company was managed and 29.6% owned by Newmont Mining Corp. of the United States. Another U.S. company, AMAX Inc., owned 29.6%, the British firm Selection Trust Ltd. owned 14.2%, the O'okiep Copper Co. Ltd. of South Africa owned 9.5%, and the remainder was held by other firms including the South-West Africa Co. Ltd. (SWACO)with 2.4%.

The Tsumeb Mine has continued to be the largest in the area north of the capital at Windhoek, and in 1980 it produced and milled 498,149 tons of ore, containing 3.61% copper, plus lead and zinc, from which 18,788 tons of copper concentrate containing 43.81% copper and 37.6 troy ounces of silver per ton was recovered. The company also operated the Matchless Mine, 42 kilometers south of Windhoek, which produced 126,647 tons of pyritic copper ore containing 1.82% copper and 12.83% sulfur in 1980. The Matchless mill produced 11,170 tons of concentrate which contained 19.13% copper, 33.05% sulfur, and 2.2 troy ounces of silver per ton. Tsumeb also produced 332,736 tons of 2.67% copper, 2.32% lead ore from its Kombat and Asis West Mines. The Kombat mill treated the ore which yielded 23,230 tons of copper concentrate containing 26.26% copper, plus lead, and 7.4 troy ounces of silver per ton. The Asis West Mine was also operated by a Tsumeb subsidiary, the Tsumeb Exploration Co. Ltd. (TECO), which produced 14,144 tons of ore containing 3.99% copper and 0.76% lead. This ore was milled at the Kombat concentrator and yielded 1,972 tons of concentrate containing 26.59% copper, some lead, and 4.9 troy ounces of silver per ton.

JCI expended $1.4 million for under-

ground development and exploratory drilling at its Otjihase Mine, 27 kilometers northeast of Windhoek in the first half of 1980. Tsumeb subsequently purchased a 70% share in the property and commenced mining in December to produce 4,150 tons of 1.69% copper ore from which the Otjihase mill recovered 203 tons of concentrate containing 14.03% copper. The Tsumeb copper smelter treated all of the company's copper concentrates, and produced 26,036 tons of blister copper, down 9.5% from that of 1979. The smelter also produced 12,441 tons of blister copper from other mines' concentrates treated on a toll basis, and recovered 1,527 tons of blister copper from purchased concentrates.

The Oamites Mining Co. (Pty) Ltd., jointly owned by Falconbridge Nickel Mines Ltd. of Canada (74.9%) and the International Development Corp. (IDC) of the Republic of South Africa, continued to be the country's second largest copper producer. The Oamites Mine, 55 kilometers south of Windhoek, was extracting low-grade (1.1% copper) ore by a sublevel open-stoping method coupled with a high degree of automation that allowed production cost to be maintained at a satisfactory level. The nearby Swartmodder Mine also contributed to Oamites overall production.

Lead and Zinc.—All of Tsumeb's established mines produced complex ores with a mixture of lead, zinc, and copper minerals containing other valuable constituents. The Tsumeb Mine was the country's largest lead producer and one of its two sources of zinc. The 498,149 tons of ore contained 7.13% lead and 2.26% zinc, from which the Tsumeb concentrator produced 96,421 tons of lead concentrates that contained 31.37% lead, with 8.57% copper, 6.56% zinc, and 6.6 troy ounces of silver per ton. Its zinc concentrate weighed 3,019 tons and contained 52.43% zinc, 2.93% copper, 8.06% lead, and 9.9 troy ounces of silver per ton. Ores from the Kombat and Asis West Mines also contained lead and the Kombat mill recovered 12,294 tons of lead concentrate with 36.65% lead, 17.66% copper, and 5.5% troy ounces of silver per ton on behalf of the parent company, and 45 tons of lead concentrate containing 35.12% lead, 20.04% copper, and 3.9 troy ounces of silver per ton from Asis West ore on behalf of TECO.

Tsumeb's lead smelter produced 33,455 tons of refined lead from its own concentrates, an increase of 6.6% over the 1979 output. It also produced 8,168 tons of refined lead from purchased concentrate and 1,031 tons of metal from concentrates smelted on toll for other producers. Tsumeb's complex ores also produced 1,288 tons of arsenic, down 42% from the 1979 output, and 69 tons of cadmium, 15% less than the previous year. Its silver production totaled 1.65 million troy ounces.

The country's top zinc producer was the Rosh Pinah open pit mine in the Namib Desert, 27 kilometers north of the Orange River, operated by and for Imcor Zinc (Pty.) Ltd., a subsidiary of the South African Iron and Steel Industrial Corp. Ltd. (ISCOR). Rosh Pinah Mine's capacity was 160,000 tons per month of ore to produce about 50,000 tons of 40% zinc concentrate and 15,000 tons of 45% lead concentrate per year. Both concentrates were trucked 180 kilometers to railhead at Aus, where they were railed to ISCOR's steelworks at Vanderbijlpark in the Transvaal Province of South Africa.

Kiln Products Ltd., a subsidiary of SWACO, was administered by Gold Fields of South Africa Ltd. (GFSA), and partly owned by Anglo American Corp. of South Africa Ltd. (AAC). It continued to retreat old tailings material at the Berg Aukas Mine using jigs to make a zinc-rich silicate concentrate that was treated in the Waelz Kiln with imported coke or anthracite to produce zinc metal. Consumption of coke was reduced by reclaiming unconsumed carbon from the slag dump with jigs. Production of vanadium from this former source has not been reported.

Tin and Tungsten.—Most of the country's tin production continued to be derived from ISCOR's Uis Mine near Brandberg, northeast of Swakopmund. The tin concentrate was shipped directly to the Vanderbijlpark Steel Works in the Republic of South Africa where it was smelted and used to produce electrolytic tin plate for local consumption. GFSA reported the closing of SWACO's Brandberg tin mine in mid-1980 because of an uneconomic yield.

Uranium.—The Rossing Uranium Ltd. operation, 65 kilometers east of Swakopmund, was reported to have approached its designed capacity with 4,767 tons of U_3O_8 (yellow cake) concentrate in 1980, and a profit of $123 million for its managers and part owners, Rio Tinto Zinc Corp. Ltd. of the

United Kingdom. Partners included the General Mining and Finance Corp. Ltd. (GMF) and IDC of the Republic of South Africa, Total Compagnie Miniere et Nucleaire of France, and Rio Algom Mines Ltd. of Canada.

Exploration for uranium deposits continued through 1980 including GMF at the Langer Heinrich deposit, GFSA at the Trekkopje deposit, two deposits at Tubas and Assinanis where the French ELF-Aquitaine oil company, operating as Omitaramines, and AAC were jointly interested. In all cases, it appeared that the ore grades were too low to warrant production until a more favorable political and economic climate prevails.

NONMETALS

Diamond.—Production of diamonds by CDM continued to decline slightly as total ore treated increased to 16,822,600 tons containing 9.27 carats per 100 tons. The ore consisted of marine gravels and was covered by 56,577,400 tons of barren sand and gravel overburden. The availability of the bucket wheel excavator for this work increased from 65% in 1979 to 71% in 1980. A revised bedrock cleaning bonus system was implemented throughout the operation during 1980 and productivity increased from 18.1 to 20.2 square meters per workshift. The cleaners also picked up 46,042 carats of diamond during this operation. Prospecting of new deposits continued and included treating 308,800 tons of samples of potential ore.

MINERAL FUELS

Coal.—In the early 1950's, AAC discovered coal on the north bank of the Nossob River near the Aminuis Reserve and during 1980 its affiliated company, CDM, applied for extensive prospecting grants on both sides of the Nossob River in the Aranos area. The results of diamond drilling indicated extensive coal deposits to depths of 300 meters, and that artesian water might be tapped underlying the coalbeds. Exploration for coal was reported to have continued in the Etosha Pan area and along the Kaokoveld coast.

Petroleum.—The Etosha Petroleum Co., owned by Briland Mines Ltd., has held an oil and gas exploration concession near the Angolan boundary in northern Namibia for a number of years and in February 1980 signed a letter of intent giving Superior Oil Co. a contract to execute test drilling operations over a portion of Etosha's area. Financing was reportedly arranged through Allen & Co. Inc. of New York. There were no changes in concession boundaries during the year. The Southern Oil Exploration Corp. (South-West Africa) (Pty.) Ltd. continued to be responsible for granting oil exploration concessions, and its parent company, Southern Oil Exploration Corp. (Pty.) Ltd., continued to hold offshore concessions south of Walvis Bay, but no drilling was reported in 1980.

[2]Where necessary, values have been converted from South African Rand (R) to U.S. dollars at the rate of R1 = US$1.189 for 1979 and R1 = US$1.2854 for 1980.

The Mineral Industry of the Netherlands

By William F. Keyes[1]

The Netherlands economy during 1980 paused at a high level. Unemployment was relatively high (by the Netherlands standards) and increasing slowly. The severe rise in oil prices in 1979 was adversely affecting the exposed economy, which exports 40% of its national product and imports a similar amount. The oil price increase was estimated to have increased the balance of payments current account deficit from about $2 billion[2] in 1979 to $2.5 billion to $3 billion in 1980. However, with the rise in the export price of Netherlands natural gas being negotiated in 1980, the deficit was optimistically estimated at only $500 million in 1981. Domestic roots of this stagnation were also to be found in the costs of high wages and social amenities brought about largely by the benefits of natural gas production.

The Netherlands is a major producer and the world's largest exporter of natural gas. Nevertheless, it was disappointing to the Netherlands authorities that a large contract to import liquefied natural gas from Algeria, saving domestic supplies, was canceled by the Algerian Government. The major Hoogovens steel plant, representing most of the Netherlands industry, was also in difficulties, and there was talk of dissociating it from its even more distressed sister plant in Dortmund, Federal Republic of Germany.

PRODUCTION

The index of mineral production rose from 124 to 133 during 1980 owing to a rise in the natural gas figure from 125 to 134. Other mineral production was steady at 99 at the end of 1980. The general industry figure rose from 113 to 118 during the period. The figures were calculated based on 1975=100. Production of minerals in recent years is given in table 1.

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.

[1]Table includes data available through July 10, 1981.

[2]In addition to the commodities listed, a variety of crude construction materials (clays, stone, and gravel) presumably is also produced, but output is not reported and available information is inadequate to make reliable estimates of output levels.

[3]In previous editions, refined lead production, both primary and secondary, was erroneously captioned as smelter lead production, and actual smelter output was unreported; these errors have been corrected in this edition.

[4]Coke oven and blast furnace gas only.

TRADE

Total Netherlands exports increased 19.9% in value during the period January to August, compared with that of a year earlier. There was a particular demand for Netherlands petroleum and petrochemical products before the delayed effect of higher crude oil prices was fully passed along. The minerals trade of the Netherlands for 1978 and 1979, latest years available, is reported in tables 2 and 3.

NONMETALS —Continued				
Sulfur:				
Elemental	r9,705	11,015	--	Belgium-Luxembourg 8,681; West Germany 2,126.
Sulfuric acid, oleum	156,981	160,579	938	Belgium-Luxembourg 113,741; Spain 16,381.
Talc and steatite	3,674	4,066	NA	West Germany 1,002; Italy 941; Belgium-Luxembourg 850.
Other nonmetals, n.e.s.:				
Crude	228,367	263,859	54	Belgium-Luxembourg 85,415; France 80,223; West Germany 79,462.
Slag, dross, similar waste, not metal-bearing:				
From iron and steel manufacture	r39,401	137,543	NA	West Germany 93,433; Belgium-Luxembourg 41,834.
Other	77,824	131,103	108	Belgium-Luxembourg 61,279.
Building materials of asphalt, asbestos and fiber cements, unfired nonmetals[2]	14,125	17,836	NA	Belgium-Luxembourg 12,234; West Germany 4,003.
MINERAL FUELS AND RELATED MATERIALS				
Asphalt and bitumen, natural	51	7	NA	NA.
Carbon black	72,555	84,091	12	France 34,097; West Germany 18,192.
Coal and briquets:				
Anthracite and bituminous coal thousand tons	485	1,032	NA	Belgium-Luxembourg 459; West Germany 409.
Briquets of anthracite and bituminous coal	3,376	9,862	--	Belgium-Luxembourg 7,596; Switzerland 2,266.
Lignite and lignite briquets	1,452	1,259	--	Belgium-Luxembourg 1,203.
Coke and semicoke	731,593	739,373	15,412	Belgium-Luxembourg 256,788; West Germany 204,192; France 120,705.
Gas, hydrocarbon:				
Manufactured	220,055	235,346	1,064	Belgium-Luxembourg 147,912; West Germany 48,218.
Natural million cubic feet	r1,840,110	1,990,439	--	West Germany 908,514; France 423,044; Belgium-Luxembourg 382,015.
Hydrogen, helium, rare gases	24,225	28,371	NA	West Germany 13,558; Belgium-Luxembourg 7,164; France 3,097.
Peat including briquets and litter	123,689	112,425	NA	Belgium-Luxembourg 54,029; West Germany 27,825; France 23,762.
Petroleum and refinery products:				
Crude 42-gallon barrels	20,189	104,878	--	Belgium-Luxembourg 86,570; West Germany 16,801.
Refinery products:[3]				
Gasoline thousand 42-gallon barrels	r69,911	84,115	600	West Germany 44,363; United Kingdom 10,269; Belgium-Luxembourg 6,865.
Kerosine do	r19,660	24,626	41	West Germany 10,981; United Kingdom 2,722; Denmark 2,661.
Distillate fuel oil do	r101,939	107,759	581	West Germany 61,246; Belgium-Luxembourg 12,330; Denmark 6,367.
Residual fuel oil do	r106,265	99,956	364	Belgium-Luxembourg 13,062; United Kingdom 12,734; West Germany 10,126.
Lubricants do	r4,116	4,357	229	Belgium-Luxembourg 954; United Kingdom 422; West Germany 271.
Other:				
Liquefied petroleum gas do	3,048	3,363	58	Belgium-Luxembourg 1,934; West Germany 518; Portugal 290.
Mineral jelly and wax do	740	605	6	West Germany 204; United Kingdom 188; France 41.
Petroleum coke, bitumen, other residues do	2,439	2,482	38	West Germany 666; Denmark 532; Norway 430.

COMMODITY REVIEW

METALS

Iron and Steel.—The major Netherlands steel producer, at IJmuiden, was renamed Estel Hoogovens BV by Estel NV, the Netherlands-West German parent company; it was formerly known as Hoogovens IJmuiden BV. The West German affiliate, at Dortmund, was simultaneously renamed Estel Hoesch Werke AG.

Estel, which had suffered a 174 million guilder (f.) loss ($87 million) in 1979, and had hoped to reverse this in 1980, instead reported a record loss of f.488 million ($244 million). Cumulative losses since 1974, shortly after the 1972 merger of the two subsidiaries, totaled about f.1,500 million ($750 million), apparently largely suffered on the West German side. This disparity caused continuing concern and speculation about a possible dissolution of Estel.

A f.1,200 million ($600 million) investment plan for Hoogovens was jeopardized during the year by an "unsatisfactory cash flow," according to the chairman of Estel. The plan was to include modernization of the No. 1 coking plant, and a revamp of the No. 1 hot strip mill. Late in the year the Netherlands Government's National Institute Investment Bank authorized Hoogovens a loan of f.350 million ($175 million); both the coke plant modernization and the steelmaking and processing plant were to be aided. The State aid, the first of its kind in the Netherlands, was considered a "subordinated loan"; i.e., considered as a capital liability. The Netherlands Government owns 28.4% and the City of Amsterdam 8% of Hoogovens; Estel controls the remainder.

In spite of the State assistance, Hoogovens decided at yearend to further reduce its output to 4.8 million tons in 1981. Production in 1980 was about 5 million tons, and capacity is about 7 million tons. Two of the five blast furnaces will remain banked, and short shifts will be worked. There was also expected to be a 3% personnel reduction in 1981, all through attrition.

Magnesium.—Billiton Delfstoffen BV, a subsidiary of Royal Netherlands Shell, was authorized by the Netherlands Government's Department of Economic Affairs to mine 750,000 tons per year of brine containing magnesium and potassium from a maximum depth of 2,000 meters.

Mining will be by Noordelijke Zoutwinning NV, owned equally by Billiton and the Government's Northern Development Co. Starting in 1981 the brine will be used for the production of around 100,000 tons per year of magnesium oxide at the Veendam facility of Magnesia International BV, also owned by Billiton and the Government. Total investment in the mining project was put at f.50 million ($25 million) and the magnesium oxide plant represented a cost of about f.250 million ($125 million).

Zinc.—The electrolytic zinc plant of Kempensche Zink Maatschappij BV, a subsidiary of Shell and Australian Mining and Smelting Ltd. located at Budel near the Belgian border, planned to expand its production capacity to 180,000 tons per year from 150,000 tons (actually exceeded in practice), at a cost of about f.37 million ($18.5 million). Completion was due by April 1981.

NONMETALS

Fertilizer Materials.—N.V. DSM's subsidiary, Unie van Kunstmestfabrieken BV, was planning to close a 150,000-ton-per-year line of ammonia capacity at its Geleen plant, leaving capacity of 300,000 tons. This line was 20 years old and was considered obsolete.

MINERAL FUELS

The Netherlands Government was pursuing an energy policy that included conservation, aiming at an improvement of at least 30% in overall energy efficiency by the year 2000 (presented to Parliament in 1979); increased use of coal (introduced early in 1980 and discussed here last year); and expanded use of nuclear power, if political considerations permit. The net result hoped for was a decrease in the proportion of national energy consumption contributed by domestic natural gas, the country's sole major mineral resource, from 50% at present to 30% in 2000.

Nuclear energy policy remained a large question mark. A decision in 1974 to build three additional nuclear plants (in addition to the commercial plant at Borssele, 470 megawatts electrical) was eventually shelved, but in mid-1980 a Government white paper presented to Parliament resurrected this plan. The white paper made it clear

that the final decision would not be taken by the Government and Parliament until after an extensive public debate, expected to last at least 2 years. A controversial feature of the plan was the possibility that nuclear waste would ultimately be stored underground in the Netherlands' extensive salt domes or on the seabed. Public opposition by many environmental groups continued.

Coal.—The Netherlands, having closed its last coal mine in 1974, remained a relatively small consumer of coal. Of the approximately 6 million tons imported annually, about 4.5 million is used by industry, chiefly iron and steel, and the remaining 1.5 million tons is used by three electric powerplants. The "Coal Memorandum," reported on last year, envisions an increase from 1.5 million tons to 26 million tons by the end of the millenium, when about 40% of electricity will be generated by coal. A contract with Poland for 750,000 tons annually of coking coal was signed in 1977, and another, for steam coal, was signed by the Netherlands Prime Minister on the occasion, late in 1979, of his visit to Warsaw; this called for a total of 8 million tons, to be delivered over 10 years. Under the Government's policy of diversifying supplies, a coal delegation visited the United States in October 1980. Supplies were also being sought from the Republic of South Africa, Canada, and Australia.

Another coal gasification project, the fourth planned in the Netherlands, was announced in June by Esso Nederland BV. An experimental plant in the Rotterdam-Europoort area will gasify 100 tons of coal per day. Construction will commence in 1982, and the plant will start operations in 1985. Design will follow the small unit operated by Exxon Corp. at Baytown, Tex. Total cost will exceed $500 million.

Natural Gas.—The Netherlands Government finally scored a breakthrough in its campaign to increase the export price of natural gas when Ruhrgas of the Federal Republic of Germany accepted a new contract in August. Terms were not announced, but the Netherlands Prime Minister stated that the Netherlands should earn $800 million to $1 billion in additional revenue in 1981 if contracts with all 14 foreign country customers were renegotiated on this same basis. If the gas price is brought into line with that of 1% sulfur fuel oil, as the Netherlands deems equitable, earnings would increase by $2 billion per year over 1980 earnings. In a separate study, the total value of gas production to the Netherlands was estimated at $10 billion, half in exports and half in import substitution.

A contract was being negotiated with Nigeria late in the year for the supply of 0.9 billion cubic meters of liquefied natural gas (LNG) per year by 1985. The Netherlands natural gas supplier, Nederlandse Gasunie NV (subsidiary of Exxon, Shell, and the Netherlands Government) also met with representatives of the Soviet gas company Soyudgas-export and the Soviet trade ministry to discuss importing an estimated 5 billion cubic meters of Siberian gas annually, starting in 1985. It was hoped to obtain a total supply of roughly 14 billion cubic meters of LNG from Algeria and 2.5 billion cubic meters in the pipeline from Norway's Ekofisk Field. However, it was reported late in the year that Algeria's natural gas company, Sonatrach, had announced that its LNG terminal at Arzew would not be built during its current 5-year plan ending in 1984, thus effectively canceling agreements to deliver to the Netherlands and the Federal Republic of Germany. Algeria was known to favor delivering its gas to European customers via the pipeline to Italy now under construction and the Sagamo line to be built through Spain, thus saving the expensive liquefaction facilities at Arzew. It was expected that plans to build a regasification terminal for LNG at Eemshaven would go ahead in spite of the Algerian decision, perhaps being used for the Nigerian gas.

Natural gas reserves in the Netherlands increased slightly, and on January 1, 1980, amounted to 2,327 billion cubic meters, of which 74% was in the Groningen Field in the northeast. A summary of the reserves is presented below:

Area	Proven reserves	Non-proven	Total reserves
Groningen	1,407.7	321.6	1,729.3
Other onshore	103.9	189.5	293.4
Continental Shelf	114.5	189.7	304.2
Total	1,626.1	700.8	2,326.9

At the beginning of the year there were 151 known gas deposits in the Netherlands, of which 90 were on land and 61 in the Netherlands sector of the North Sea.

Petroleum.—Exploration for gas and oil continued apace in the Netherlands, with especially increased activity in the North

Sea. Nevertheless, indigenous crude oil production contributes less than 3% of total crude consumption, and that, to date, has been from onshore fields.

Offshore, the Netherlands subsidiary of Union Oil Co. of California, having located oil in its Helm Field of Block Q1 in 1979, in 1980 discovered additional oil in the Helder Field and in a separate structure 3.5 miles north, both also in Block Q1. The latest discoveries were in shallow (75 feet) water some 23 miles from the Netherlands coast. The flow rate in Q1 was 1,446 barrels of 25.5 gravity from the interval 5,289 feet to 5,312 feet. Reserves in this block were estimated at 14 million barrels, and Union Oil, in cooperation with Royal Nedlloyd, requested approval to start production; this would be the first commercial oilfield in the Netherlands offshore. Nederlandse Aardolie Maatschappij (NAM) also filed an application for a production license for its Block F 3, where estimated reserves are 44 million barrels.

Total crude oil reserves in the Netherlands as of January 1, 1980, were as follows, in millions of barrels:

Area	Proven reserves	Non-proven	Total reserves
Schoonebeck (Eastern Region)	44.0	164.2	208.2
Rijswijk (Western Region)	25.7	37.4	63.1
Continental Shelf	38.1	31.5	69.6
Total	107.8	233.1	340.9

All production in the Netherlands was by NAM, a joint venture of Shell and Esso, of which the Netherlands Government owns half. In October, NAM brought additional facilities into operation, which should have the effect of roughly doubling annual production from 14,000 barrels per day to about 28,000 barrels per day.

Total primary distillation capacity of the eight Netherlands refineries reportedly dropped slightly to 84.8 million metric tons (about 1.6 million barrels per day) in 1980. There was a moderate rise in utilization of capacity in 1979 to about 72%. Netherlands refineries continued to function chiefly as balancing refineries, with over 60% of their production sold abroad in the Federal Republic of Germany, the United Kingdom, Belgium, and Denmark. Consequently the decline in consumer and industrial demand for petroleum products has been harder on them than on European refineries with a broad base of domestic consumption.

[1]Supervisory physical scientist, Branch of Foreign Data.

[2]Where necessary, values have been converted from the Netherlands guilder to U.S. dollars at the rate of f.2.0=US$1.00, the approximate average rate in 1980.

The Mineral Industry of New Zealand

By Charlie Wyche[1]

New Zealand's mineral industry showed little change during 1980, and production of most mineral commodities was at about the same level as that of 1979. Construction materials (aggregates, clay, limestone, and sand and gravel) remained the most active industry and the value of this production was the greatest of any mineral product. Coal, iron sands, natural gas, and a little gold and silver accounted for essentially all of the remaining mineral value. Several prospects, including asbestos, gold, and molybdenum, were being investigated and could contribute to the mineral value by 1985.

The Government announced comprehensive plans for energy development based on the country's large reserves of natural gas. Gas-based projects are expected to cost $2.5 billion during the next few years, and will include substantial foreign direct investment. It is planned to produce synthetic fuel, compressed natural gas, liquid petroleum gas, a methanol plant, and an ammonia-urea plant from the natural gas.

To meet energy supply problems, New Zealand established a Department of Energy. This new department intends to strengthen and unify the country's energy administration by bringing together the Ministry of Energy Resources and Electricity, and the Mines Department. In addition, a Liquid Fuels Trust Board was created to finance research into indigenous transport of fuels, especially those that could be derived from natural gas.

The Natural Gas Corp. and the Offshore Mining Co. combined to form the Petroleum Corp. of New Zealand Ltd., which would be responsible for the Government's oil exploration. Exploration programs to prove New Zealand's resources of petroleum, coal, and geothermal and hydroelectrical energy were being intensified.

The only export commodities of any importance were titaniferous iron sands and small quantities of steel products. Crude oil and refinery products were the principal commodities imported, and they supplied about one-third of the national energy requirements. Planned development of coal, natural gas, hydroelectric power, and geothermal power were expected to reduce petroleum imports to 20%-25% of the total energy requirement by 1990.

PRODUCTION

New Zealand's value of mine and quarry output for 1980 (metals and nonmetals, but not the mineral fuels) was estimated at $160 million,[2] 0.8% of the gross national product of $17.3 billion. Values of the most significant minerals produced during 1979 (in thousand dollars) were as follows: Sand and gravel ($55,000); coal ($50,000); iron sand concentrate ($25,000); limestone for agriculture, roads, cement, and other industries ($14,000); clays for brick, tile, and pottery ($2,000); and gold ($3,000).

Natural gas production, with associated condensates, was playing an increasingly important role in New Zealand's energy program. Natural gas and some condensate were produced at the Kapuni offshore field and the gas was supplied to Auckland, Wellington, and the New Plymouth and Stratford power stations.

[e]Estimated. [p]Preliminary. [r]Revised.

[1]Table includes data available through Sept. 1, 1981.

[2]Reported figure.

[3]Average 57% Fe.

[4]Includes crushed rock for building aggregate, roads, and ballast.

[5]Excludes carbon dioxide component of natural gas, which is reported separately.

[6]Includes field condensate.

TRADE

According to the Department of Statistics at Wellington, principal mineral exports during fiscal year 1980 (year ending June 30, 1980) were aluminum and aluminum alloys ($165.5 million) and iron ore and concentrates ($29.2 million).

Crude petroleum, partly refined petroleum, and petroleum refinery products dominated mineral imports; they were valued at $900 million in fiscal year 1980. Iran remained the principal import source, but Kuwait and Saudi Arabia were also significant suppliers. Imports of iron and steel, mainly semimanufactures, and aluminum oxide, totaled $218.3 million and $42.6 million, respectively. Phosphate rock from Nauru, sulfur from the United States, and alumina from Australia were also imported by New Zealand during 1980.

The Government was preparing to begin exporting up to 250,000 tons of coal annually from the Buller Coalfield located in the northwest area of Southland. The trade, estimated at $10 million annually, would constitute the first major coal export of recent times. Probable customers are Hong Kong, Japan, the Republic of Korea, Singapore, and Taiwan.

METALS

Aluminum.—New Zealand Aluminium Smelters Ltd. (NZAS), at present New Zealand's only aluminum smelting operation, was engaged in an expansion project which would increase its annual production capacity by 57% over the present 150,000 tons per year. The expansion is scheduled for completion in 1983. Comalco Ltd. of Australia, in which the U.S. firm Kaiser Aluminum & Chemical Corp. has a major interest, owns 50% of NZAS and two Japanese firms own the remainder. Although the smelter was the subject of some criticisms by environmentalists, NZAS enjoys considerable support from a large majority of the residents in New Zealand's Southland area where the plant is located.

The New Zealand Government approved the construction of a smelter on South Island by CSR Ltd. The total cost of the smelter was estimated by CSR Ltd. and partners (Swiss Aluminium Ltd. and Fletchers Holdings Ltd.) at $640 million. The first stage, with a single potline capacity of 100,000 tons per year, would be commissioned by the mid-1980's, and a second potline of 100,000 tons per year would be added by 1990.

New Zealand Aluminium Smelters Ltd.'s current output accounts for over 1% of the total world production of aluminum metal. The completion of the current expansion project and the scheduled new construction project would increase New Zealand's share of world aluminum production to about 3%.

Approximately 80% of NZAS's output of 150,000 tons per year of aluminum was exported and the remaining 20% was used by New Zealand fabricators to produce a wide range of aluminum products for domestic needs. Aluminum exports went primarily to Japan and Southeast Asia. Under

the terms of the agreement with the New Zealand Government, the Japanese partners exported their combined 50% share.

Gold.—Mine production of gold declined slightly in 1980 from that reported for 1979. Kanieri Gold Dredging Ltd. produced 6,000 troy ounces of gold in 1980 from 2,700,000 million cubic meters of gravel in the Taramakau River, near Kumaru, South Island. The alluvial gold being mined was among the lowest grade in the world. Three percent uranite was also contained in the alluvial sands, and tests were currently underway to see if the uranite could be sold as a byproduct. The Kanieri gold dredging operation is a wholly owned subsidiary of Amoil New Zealand Ltd. All gold from the Kanieri operation was purchased by the Government. Because of the high gold prices in 1980, interest in possible gold-bearing areas remained high over the past year. This has led to large-scale dredging operations being proposed for the west coast of South Island.

Mineral Resources (New Zealand) Ltd. continued exploration throughout 1980 at the Marthu Mine, Waihi, North Island. Mine dumps at Union Hill were being worked, and bulk samples were evaluated. Blackwater Gold Ltd. and Carpentaria Exploration Co. Pty. Ltd. continued testing ore extensions at a former property of Blackwater Mines. Amoco Minerals New Zealand Ltd. began prospecting in the Monowai gold area.

Iron Sands.—The mining of titanomagnetite (iron sands) was by far New Zealand's largest metallic mineral industry, and second only to sand and gravel in tonnage and value of output. In terms of value, iron sands accounted for 16% of all nonfuels mineral output and over 85% of all metallic ore production. Output of iron sand concentrate by the two producing companies New Zealand Steel Mining Ltd. (a wholly owned subsidiary of New Zealand Steel Ltd.) and Waipipi Ironsand Ltd. was substantially below that of 1979. The decline was attributed to the cutback in steel production by the Japanese steel industry, New Zealand's principal customer. Although these two companies were the sole source of iron ore for New Zealand's iron and steel industry, about 90% of the iron sands were exported.

The iron sand deposits consist of extensive, horizontal beds located on or near the western coast of New Zealand's North Island. The deposits range from 5 to 20 meters thick and contain concentrations of up to 17% titanomagnetite sand grains. The grains originated from nearby andesite volcanic formations and were sorted and concentrated by wind, stream, and wave action. The three sand deposits currently being worked commercially were at Waverley, Taharoa, and North Waikato. The Waverly deposit was being mined by Waipipi Ironsands Ltd., and the other two by New Zealand Steel Ltd., which also owns the Glenbrook Steel Works, New Zealand's only steel plant.

Steel.—New Zealand Steel produced iron sands at its Waikato North Head deposit for use in its direct-reduction steelmaking plant at Glenbrook. The plant at Waikato North Head was designed to produce 200,000 tons per year of concentrate, but in 1978 the capacity was expanded to 250,000 tons of concentrate. About 200,000 tons of raw steel was produced during 1979 and about 220,000 tons was produced in 1980. This figure is expected to increase to about 750,000 tons per year within 10 years. A cold-rolling mill and coat line for plain and galvanized sheet were being considered. Long-range plans included a new melt shop, continuous-slab facilities, and more direct-reduction kilns.

Other Metals.—In 1980, the Department of Scientific and Industrial Research continued its investigation of black, heavy-metal beach sand deposits on the west coast of South Island. The sands contain gold, ilmenite, monazite, and zircon.

Amoco Minerals New Zealand Ltd. was conducting airborne magnetometry on the Ceromandel Peninsula, North Island, for base metals. Otter Minerals Exploration Ltd., in partnership with Gold Mines of New Zealand Ltd., continued exploration in Nelson Province and the drilling operation on D'Urville Island. Gold Mines of New Zealand Ltd., a partnership of Australian Anglo American Corp. Ltd. and Amoil New Zealand Ltd., remained active in the Raukumara, East Cape, and Kaikoura regions.

NONMETALS

Asbestos.—Chrysotile asbestos, mainly associated with serpentines, occurs at a number of locations on South Island. However, further work is required to determine the limits of mineralization. The most significant deposits were those of the northwest Otago (Pyke River) area, but no production was reported in 1980.

Phosphates.—The most promising source

of phosphate was thought to be the nodules occurring on the sea floor on the eastern half of the Chatham Rise (west of Chatham Island). Research carried out by the New Zealand Oceanographic Institute in 1979 indicated the presence of phosphorite nodules ranging from 10 to 150 millimeters in diameter. Most of the deposits were found in water from 400 to 500 meters deep and none were found in depths less than 200 meters. The P_2O_5 values for the phosphorites generally range between 18% and 24%, with the highest recorded content 27.7%. Evaluation is continuing.

Sulfur.—Fletcher Mining Co. Ltd. has ceased excavating and development work on a deposit of sulfur at Rotokawa in the Taupo area, North Island. The deposit, with reserves estimated at 6 million tons, was mixed with pumice and research on the development of a separation process was not completed. The Frasch process cannot be applied here owing to the porosity of the overlying beds. Further development will await conclusion of research and finance.

Other Nonmetals.—In 1980, serpentine was mined at Piopio (near Te Kuiti) and North Cape on North Island, and Lee Valley, Collins Valley, and Mossburn on South Island. At Lake Grassmere, in Marlborough (South Island), salt was produced by the solar evaporation of seawater.

An analysis by the Department of Scientific and Industrial Research (DSIR) of beach sands on the west coast of South Island indicated reserves of over 50 million tons of ilmenite bearing sands. DSIR was conducting extensive laboratory tests aimed at producing a synthetic rutile from the rather low-grade (46% TiO_2) ilmenites.

MINERAL FUELS

Coal.—New Zealand produced 2.0 million tons of coal in 1980 from about 70 mines in various fields on North and South Islands. Nearly 75% of the production was from open pit mines. There was an increase in production from private mines, and development work on three new coal mines was on schedule. Prospecting for new deposits on both North and South Islands continued during the year. On North Island, extensive exploration drilling took place at Maramarua, Rangiriri, Huntly, and Ohinewai, with smaller drilling programs at Naike, Waerenga, Whatawhata, and Lake Waikare. On South Island, work commenced on the Greymouth Coalfield with reserves of 2 million tons being indicated in the Strongman West Block of this field. In addition, 4.4 million tons of lignite with open cast mining potential have been outlined in eastern Southland during a major drilling program.

A coal mining bill introduced into Parliament was being examined by Parliament's select committee on commerce and mining. The coal mining bill would give the Government much more control of all private coal mining without involving the Government with taking over the ownership of land or coal mines. Under the proposals all coal mining activity would be licensed by the Minister of Energy.

The Department of Mines' 5-year coal exploration program estimates recoverable coal reserves at 1.2 billion tons. However, measured reserves of coal totaled 210 million tons. The exploration program started in the eastern part of the Southland lignite field, Mataura Valley, South Island, and was to continue in the Waikato area, North Island, and in the west coast deposits, South Island.

Natural Gas.—The Maui offshore gasfield came onstream in 1979, but at severely restricted rates because of a lack of market for the gas. Only 6 of the 14 wells completed on the Maui-A platform were onstream. In addition to Maui, New Zealand's Kapuni Field on North Island's west coast was producing about 6.2 million cubic meters per day of natural gas and some condensate. This was a significant drop from 1979, as production was cut back to allow gas from the Maui Field to enter the market. The Government has a take-or-pay contract for the Maui gas, necessitating its production.

The Government was encouraging increased exploration by foreign companies by liberalizing its handling of taxes, allowing more writeoffs such as exploration and development losses against other operations in New Zealand. Field development costs can be written off at a rate of 20% per year, beginning in the year of the first commercial production.

Petroleum.—The Government's comprehensive petroleum exploration policy is now in effect. In instances where the Government accepts a company's petroleum exploration proposal, it would retain the right to acquire a 51% interest in the discovery in exchange for a 40% contribution to the exploration the Government would accept a lower share of the venture. Should either party to such an arrangement decide not to contribute to the costs of a particular well, the remaining parties could proceed on a sole risk basis. In the event of a discov-

ery, the parties contributing to the cost of drilling would be permitted to recover 60% of their expenditure as a prior charge against first production. Royalties to be paid to the Government on oil found were set at 12.5% of sale value. The price of indigenous oil was raised to that of world crude.

New Zealand's only known major oil resources were in the Maui and Kapuni natural gasfields. Production by Shell-BP-Todd Oil Services (in equal partnership with the Government) continued to increase over that of the previous year. A light crude oil, or condensate, was produced as a joint venture with the natural gas.

Shell-BP-Todd signed an agreement with the Government of New Zealand to undertake a $40 million, three-well oil search on the western tip of North Island. Drilling began in mid-1980. New Zealand Petroleum, a local exploration firm in which Triton Oil of Dallas (United States) has an interest, also resumed its oil search off the southwest coast of South Island.

Production of liquefied petroleum gas at Kapuni reached a record high level, but market demand still exceeded supply. An extraction plant being constructed to strip liquefied petroleum gas from the Maui gas stream was on schedule and could be operational in 1981. Proposals from distributors to import liquefied petroleum gas from Australia were under consideration by the Government, and were expected to be approved during the year.

The Mineral Industry of Nigeria

By George A. Morgan[1]

Although a slight decline in crude oil output occurred in Nigeria, petroleum remained the mainstay of the economy in 1980. Three increases in crude oil prices during the year added substantially to Government revenue. The Government emphasized completion of the steel plants at Ajaokuta and Aladja in order to diversify the economy and to reduce the high level of iron and steel imports. The gross domestic product was estimated at $94 billion,[2] about 25% higher than the 1979 estimate. Petroleum revenue accounted for over 80% of Government income, and revenue from the sale of oil increased 40% to $24 billion. At yearend, foreign exchange reserves were nearly double the previous years to over $10 billion. The country entered a period of higher inflation, although official estimates of inflation were under 10%. Government expansion of the minimum wage for the public sector led to increased pressure by the private sector for similar treatment. A number of strikes occurred, some in critical industries such as oil refining and steel plant construction.

The Fourth National Development Plan, covering the period 1981 through 1985, called for Government investment of $152 billion. Included in the plan was $2.2 billion to be allocated for a new standard gage railroad from Port Harcourt to the Ajaokuta steel plant. Construction startup of the liquefied natural gas (LNG) facility near Port Harcourt was being reexamined because of the financial strain it was expected to make on other Government projects. Environmental impact statements were to be required on all major projects after January 1, 1981.[3]

PRODUCTION AND TRADE

Output of crude oil increased to 2.2 million barrels per day by yearend 1980 after a sharp decline from 2.1 million barrels per day early in the year to 1.6 million barrels per day in September. The major cause for the decline was lower world market demand. However, the potential shortfall in world supply of crude oil following the outbreak of hostilities between Iran and Iraq led to the yearend production increase. About 140 oilfields were in production in the Niger delta swamps, most with output under 10,000 barrels per day. The Government's plan for allocation of total revenue, most of which was derived from petroleum, among 19 States was met with disapproval by the five oil producing States. Division of total revenue as proposed by the Federal Government was to be 55% to the Federal Government, 30% to State governments, 8% to local governments, and the remaining 7% to a special fund. Included in the fund were monies to be made available as compensation for States with oil wells.

The Government lessened its pressure on imports by exempting spare parts and industrial raw materials from preshipment inspection requirements as of March 1, 1980. Only established manufacturers could receive exemption for raw materials imported. The inspections were performed by the Société Generale de Surveillance as part of a Government program instituted on January 1, 1978, to reduce the trade deficit.

COMMODITY REVIEW

METALS

Bauxite.—Nigeria and Ghana held preliminary negotiations on the possible joint exploitation of the bauxite deposits at Kibi in Ghana.[4] Located approximately 80 kilometers from the coast, the deposit had reserves of 182 million tons of ore.

Iron Ore.—About $275 million was allocated for development of the iron ore deposit at Itakpe Hill in Kwara State.[5] Several hundred million tons were located at the site, with production forecast at 7.3 million tons per year of iron ore for blast furnace reduction at the Ajaokuta steel plant currently under construction. Associated Ores Mining Co. Ltd. was to work the deposit and provide for transportation of output to the steel plant.[6]

Iron ore for the Midrex direct-reduction process at the Aladja sponge iron plant near Warri was to be imported, although ore from Itakpe Hill may also be used.

Iron and Steel.—Development of infrastructure continued with construction of housing units and 60 kilometers of rail

linking the Itakpe iron ore deposit with the Ajaokuta steel complex. The U.S.S.R. commenced shipment of equipment for the plant which was to use conventional blast furnace technology. The first phase of production, planned for June 1983, would require consumption of 2 million tons of iron ore, 1.2 million tons of coking coal, 700,000 tons of limestone, 240,000 tons of dolomite, and 90,000 tons of manganese ore annually.[7] Initial production was to be light sections and wire rod. The second phase of output could total 2.6 million tons per year, including production of billets and medium sections. Upon full completion, the plant was expected to yield 5.2 million tons of steel per year. About $920 million has been spent for the facility thus far.

About $827 million has been spent for construction of the Midrex direct-reduction plant at Aladja, near Warri. Trial production of billets and rods at the adjacent Delta steel plant was scheduled for July 1981. Employment was to reach 6,000 at the Aladja project and 10,000 at Ajaokuta.[8]

Three steel rolling mills were under construction at Jos, Katsina, and Oshogbo. The Jos and Katsina mills were to be commissioned about September 1982, each with an initial capacity of 220,000 tons per year. The Oshogbo steel rolling mill, valued at $143 million, was to initially produce 210,000 tons per year of rods and bars. Ultimate capacity was to increase to 720,000 tons per year.

Tin.—Realization of majority control of tin mining companies by the Government-owned Nigerian Mining Corp. (NMC) through implementation of the Nigerian Enterprise Promotion Decree of 1977 continued in 1980. NMC gained 60% control of Gold & Base Metal Mines of Nigeria Ltd. at a price of $1.83 per share. Bisichi-Jantar Nigeria Ltd. was also 60% owned by NMC, with Bisichi Tin. Co. Ltd. and Jantar Ltd. of the United Kingdom each retaining 20% ownership. Permission from the Government was required for the transfer of dividends and capital funds from the Nigerian-based concern to the two London shareholders.[9]

Amalgamated Tin Mines of Nigeria Ltd. announced that it planned to conduct a mining feasibility study on a sub-basalt tin find. Location of the deposit was not reported.

Uranium.—The Nigerian Uranium Mining Co., headquartered at Gombe in Bauchi State, conducted exploration for uranium in the Gombe area. The company was 60% Government-owned through NMC, and 40% controlled by Minatome. Exploration by the company was restricted to the Gombe area, with other areas available to interested organizations.

NONMETALS

Fertilizer Materials.—A phosphate rock deposit at Ifo in Ogun State was reported to have 40 million tons of reserves. Beneficiation produced a concentrate yielding 78% tricalcium phosphate. A $600 million contract was signed with Kellogg Fertilizer Co. for construction of a fertilizer plant utilizing the Ifo deposit. Other potential deposits were located in the States of Imo, Oyo, and Ondo.

The Government-owned Federal Superphosphate Fertilizer Co., the sole producer of manufactured fertilizer in the country, produced about 40,000 tons of single superphosphate at its Kaduna plant. Capacity of the plant was 100,000 tons per year. Output accounted for only about 14% of the country's total consumption; the remainder was imported.

Limestone.—Although limestone has been found in every State, total reserves were unknown, and only a few deposits were exploited. Most limestone quarrying has been for production of cement, and some has been used as a flux by the Makeri Tin Co. at Jos. Over 110 million tons of limestone in beds varying in thickness from 3 to 10 meters were located at Nkalagu in Anambra State. The Nigerian Cement Co. was the sole operator of the deposit. A 35-million-ton limestone deposit at Ewekoro in Ogun State was being quarried by the West African Portland Cement Co., and at Yandev a 70-million-ton deposit was worked by the Benue Cement Co. The purity level of the limestone at Calabar, currently worked by the Calabar Cement Co. for cement production, was sufficient for its projected use as a fluxing agent at the iron and steel plant under construction at Ajaokuta.[10]

MINERAL FUELS

Coal.—It was reported that the two underground mines at Enugu in Anambra State, which were recently equipped with mechanized longwalls at a cost of $37 million, had experienced operational problems. Technicians from Katowice Arebow (KOPEX) of Poland, which installed the equipment, were called upon to rectify the problem at the Onyeama and Okpara Mines. A

coal washery with a 250-ton-per-hour capacity was also completed by KOPEX at a cost of $25 million. Production at Enugu was to yield 2 million tons per year of coal.[11]

A coke plant was planned for the opencast mine at Okola, but had not received Government financial support by yearend 1980. Production at the mine was to be expanded to 500,000 tons per year by 1985.

The 1975-80 5-year plan had envisaged considerable contribution from the coal industry to the country's energy sector. However, production from Enugu must be blended with imported coal to produce coking coal suitable for use in blast furnaces under construction at Ajaokuta. This process was expected to continue until coking coal from the Obi and Lafia Coalfields in Benue State was brought into production. About 125,000 tons per year of coal were consumed for production of cement at Nigerian Cement Co. Ltd.'s plant at Enugu. The coal-fired electric generating station at Oji in Anambra State used the remaining coal produced. No coal was available for export.

Natural Gas.—A military decree of September 1979 required oil companies to submit to the Government by October 1980 plans for utilizing associated gas that was currently being flared. All flaring of associated gas was expected to be halted by January 1, 1984. About 95% of all associated gas produced was flared, and there was no production of nonassociated gas. The crude oil equivalent of natural gas reserves was reported to exceed crude oil reserves. Proved gas reserves were estimated to be 80% nonassociated gas.[12]

The construction of a LNG plant near Port Harcourt was expected to utilize about 16 billion cubic meters per year of the approximately 21.5 billion cubic meters currently produced. Phillips, operator for the 60% State-owned consortium, called for tenders for design and construction of the plant. Profitability of the plant was to be guaranteed by 15- to 20-year supply contracts with eight European companies. Capital cost for the project, which was to have six process units, were estimated at $12 billion.

Power stations at Ijora, Delta, and Afam utilized gas turbine generating units, while the 750-megawatt Sapele steam turbine station burned gas from nearby fields. Additional utilization of flared gas was planned by the construction of a 750-megawatt thermal power station in Lagos, which was to be supplied by a 200-mile trunk gas line. Operation of the Lagos plant was to commence in 1984, utilizing 300 to 500 million cubic feet per day of natural gas. The Afam and Sapele power stations were to be expanded to utilize 140 and 150 million cubic feet per day, respectively. Natural gas was also expected to be used as feedstock for a fertilizer plant.

Petroleum.—*Production.*—Output of crude oil was down in 1980 from 1979, mainly as a result of lower world demand. However, output was also affected somewhat because of a well blowout in the Funiwa Field and the closure of a Shell oil facility at Opuna in Bendel State. Production in Nigeria fell from about 2.1 million barrels per day in early 1980 to 1.6 million barrels per day in September. Overall reduction in output for the year was limited to about 10% as the Iraq-Iran conflict resulted in losses of crude oil supplies to the world market which led to production increases elsewhere.

The Nigerian National Petroleum Corp. (NNPC), established in 1977, was the majority holder of most oil-producing groups operating in Nigeria. It generally controlled about 60% of the assets of private oil companies except for 80% control of Shell's operations. The British Petroleum portion of Shell was nationalized in August 1979. In August 1980, the NNPC was found to have inappropriately conducted some of its administrative procedures by a Government tribunal investigation of possible misallocation of funds. The tribunal also declared that three oil companies—Shell, Mobil, and Gulf—were to allocate nearly 183 million barrels of crude oil to the Federal Government for failure to maintain production levels as proscribed by the NNPC.[13] The amount was later reduced to 80 million barrels.

Shell was the principal crude oil producer, with about 57% of total output, followed by Gulf, Mobil, and Azienda Generale Italiani Petroli S.p.A. (AGIP). Private companies sought renegotiation of profit margins in order to obtain a more realistic return on investment, as well as redefinition of terms for new product sharing contracts. Reexamination of private company crude oil production levels in conjunction with sales by NNPC was also expected to take place.

Exploration.—The Government announced that NNPC was to spend nearly $890 million in 1980-81 (April-March) fiscal year for exploration and development. The NNPC employed 4,300 people, with an in-

crease to 20,000 employees expected in 5 years. All reserve acreage belonging to NNPC, as well as offshore areas, were opened to exploration. However, the volume of newly discovered oil to be used in refineries outside the country was predicted to be small. In addition, exploration was to be aimed primarily at increasing the reserve-production ratio, rather than expanding output, which was to remain at about 2.15 million barrels per day.[14] Only three companies took preliminary action to acquire concessions on the newly offered acreage, AGIP, Elf-Nigeria Ltd., and Crown Central Petroleum Co. of the United States in association with Nigus Petroleum of Nigeria. These three companies also commenced operations in the Niger Delta and the Anambra Basin on concessions they had acquired the previous year. The NNPC contracted seismic studies in the Chad and Anambra Basins through a French company while undertaking its own seismic studies in Abudu in Bendel State, in parts of Benue and Ondo States, and offshore both rivers and Bendel State.

Refining.—Emphasis was placed on expanding domestic crude oil refining capacity in order to reduce imports of refined products and to increase local use of oil and gas. Three refineries were operational in Nigeria at yearend 1980. The crude oil refinery at Kaduna, 100% owned by NNPC, was inaugurated in October, with a capacity of 100,000 barrels per day. Feedstock for fuel production was Nigerian crude oil, while Venezuelan crude was used in production of lubricants, waxes, and asphalt. The heavy Venezuelan oil was obtained through crude oil bartering. The refinery at Warri, inaugurated in September 1978, was 100% controlled by NNPC, with a capacity of 100,000 barrels per day. However, because of technical problems, it operated at 50,000 barrels per day. The Port Harcourt refinery had a capacity of 60,000 barrels per day. Ownership was 80% by NNPC and 20% by Shell. Plans were being prepared for an additional 200,000-barrel-per-day capacity at the Port Harcourt oil refinery.

The Mineral Industry of Norway

By Joseph B. Huvos[1]

In 1980, production in Norwegian industry, with the exception of the oil sector, moved only sluggishly. This was because Norway's most efficient industrial sectors, including the major export industries such as aluminum, base metals, and ferroalloys, had already been operating close to capacity for some time. Conversely, other industries such as iron and steel, which were less competitive in export markets, had unused capacity and therefore expected no expansion. Norway's gross national product (GNP) at current prices was about $50.7 billion,[2] an increase in real terms of only 3% compared with the 1979 GNP. Per capita GNP was $12,400, the retail sales price index rose 4.5%, and unemployment was only 1% during the year.

There were few changes in Norway's mineral industry, although the Government released its white paper on energy. Commissionings included a Svalbard coal mine, a northern quartzite mine, and a northern hydroelectric plant. A rare-earth mineral deposit in the north, and several oilfields in the North Sea were discovered. Drilling was started in the North Sea, north of the 62d parallel. Elkem Spigerverket AS purchased Union Carbide's ferroalloy plant, and Norsk Hydro AS bought the Nederlandse Stikstof Maatschappij, a producer of fertilizer materials.

PRODUCTION

In 1980, there was no important change in the mineral industry's production except for continued expansion of the oil and gas sector. Production of major mineral commodities in 1980 and the 4 previous years is shown in table 1.

Table 1.—Norway: Production of mineral commodities[1]

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.
[1]Table includes data available through July 1, 1981.
[2]Reported figure.
[3]Less than 1/2 unit.
[4]Data represent exports, presented in lieu of actual production data, which are reported in official sources as not available for publication. A part of these exports may be derived from imported materials.
[5]Excludes nepheline syenite, which is included under "Stone."
[6]Excludes a quantity of stone reported at 4,774,485 cubic meters in 1976 and subsequently not reported.
[7]A small quantity may have been used for fuel in the fields, but there was essentially no marketed production.

TRADE

In 1980, Norway's trade surplus became substantial, owing to further increases in oil and gas production and the rise in the price of hydrocarbons. There was little change in the general trade pattern of the remaining mineral commodities, consisting principally of raw material imports for energy-intensive industries such as aluminum, and exports of oil and finished metals. Norway's mineral commodity trade in 1978 and 1979 is shown in tables 2 and 3.

Table 2.—Norway: Exports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1978	1979	Destinations, 1979	
			United States	Other (principal)
METALS				
Aluminum:				
Alumina	1	20	NA	NA.
Metal including alloys:				
Scrap	21,520	23,841	NA	West Germany 10,998; Brazil 3,423; Sweden 2,736.
Unwrought	630,241	565,304	37,244	West Germany 157,069; United Kingdom 122,790; Sweden 53,887.
Semimanufactures	56,826	65,196	10,424	United Kingdom 14,645; Denmark 8,419; West Germany 3,483.
Cadmium metal including alloys, all forms	97	156	NA	NA.
Cobalt metal including alloys, all forms	559	885	NA	NA.
Copper:				
Ore and concentrate	98,239	98,797	--	West Germany 69,320; Sweden 27,924; Finland 1,553.
Oxide and hydroxide	2,752	2,892	NA	NA.

See footnotes at end of table.

COMMODITY REVIEW

METALS

Aluminum.—In 1980, Norway's primary aluminum capacity was approximately 700,000 tons per year, making it the world's sixth largest producer. Almost 90% of the primary metal produced was exported, mainly to the European Economic Community (EEC), other Scandinavian countries, and to the United States.

Release of the Government's Energy White Paper (No. 54) aroused controversy with the aluminum industry. The paper laid down guidelines to the Storting (Parliament) for raising the price of electric power to more nearly reflect the replacement cost and to allocate consumption. The industry felt higher power prices would make production of the metal insufficiently profitable, while keeping production from reaching the market's potential. Electric power consumption by the industry was about 12 billion kilowatt-hours per year.

Major events in the aluminum industry in 1980 were: Aardal og Sunndal Verk AS (ASV group) commissioned a hydroelectric powerplant in the Gautingsdal Valley near Höyanger, near the west coast, which will supply the aluminum industry about 270 Gigawatt hours per year. Modernization of

the ASV group's Höyanger smelter continued, with expansion of its capacity from 30,000 to 75,000 tons per year. Completion was expected in 1981. Norsk Hydro AS and Alusuisse Norge AS have agreed to expand Norsk Hydro's ownership of Sör-Norge Aluminium AS from 19.5% to 40%. Alusuisse has a controlling interest in Sör-Norge.

The ASV group decided to increase the capacity of its Karmöy reduction plant, located on the west coast, from 110,000 to 160,000 tons per year. No date for completion was given.

Discussions have started between the Ministry of Industry, DNN Aluminium AS, and the ASV group on the planning of the Government-approved expansion of an existing reduction plant at the same location. The increase will be from 18,500 to 60,000 tons per year.

According to the ASV group, Norwegian producers of primary aluminum were as follows:

Company and facilities	Ownership	Products (domestic)	Capacity (tons)
Aardal og Sunndal Verk AS (ASV group) (Aardal, Höyanger, Sunndal).	Norwegian State 100%	Primary	330,000
		Semis	70,000
Mosal Aluminium AS (Mosjöem and Lista).	Elkem 55%, Alcoa (U.S.A.) 45%	Primary	170,000
Norsk Hydro AS (Karmöy)	Norsk Hydro AS 100% (51% of Norsk Hydro AS is owned by the Norwegian State).	Primary	110,000
		Semis	50,000
Sör-Norge Aluminium AS (Husnes)	Swiss Aluminium Ltd. 74.8%; Sopindus SA, Luxembourg 5.2%; Norsk Hydro AS 19.5%; and other 0.5%.	Primary	68,000
DNN Aluminium AS (Tyssedal)	Norwegian State 100%	Primary	18,500

Copper, Lead, and Zinc.—In 1980, the Norwegian copper fund continued to operate with a trigger price of NKr11 per kilogram which had been in effect since 1978, when a lower price had caused the fund to be exhausted. Accordingly, the falling of copper prices on the London Metal Exchange (LME) by 10% below this value (NKr9.90), triggers the disbursement of the difference from the fund to the mining companies, while the rise of the LME price by 10% above the trigger results in the companies transferring the difference into the fund. Transfers into or out of the fund are made in February or March of each year.

In the fall of 1980, the eight copper mining companies that participated in the copper fund proposed to the Government to raise the lower threshold from 10% to 5% below trigger price of NKr11 (from NKr9.90 to NKr10.45), starting with operations in 1981. Following Government-industry discussions, the proposal was expected to be ratified by the Norwegian Parliament.

Norway continued to be a moderate producer of complex sulfide ores, with independent companies operating nine nonferrous ore mines and employing about 530 people. Technically detailed descriptions of the mines and beneficiating plants appeared in 1980 in the professional literature.[3]

Iron and Steel, Ferroalloys.—Norway has expressed to the EEC displeasure at proposals for concluding a new trade agreement to restrict steel imports to the EEC. While willing to negotiate a new bilateral agreement, Norway recalled that it was one of the few European steel markets that were expanding, while the EEC demand is expected to drop during the lifetime of the proposed new trade agreement. In 1979, Norway imported about 700,000 tons of steel from the EEC, while exporting 440,000 tons of steel products of a different kind to the nine EEC countries. In case of a 10% reduction of Norway's exports to the EEC, as sought by the EEC, Norsk Jernverk is closing its steel plants, laying off several hundred workers by yearend at its Mo-i-Rana west coast steel plant.

In the meantime, AS Sydvaranger was preparing to lay off its entire work force of 1,200 persons at its Kirkenes iron ore mine in northern Norway from November 1 until further notice, because of full stockyards and falling demand for iron ore pellets. In Emden, Federal Republic of Germany, construction work neared completion at Nordeutsche Ferrowerke GmbH. This plant, a joint venture of AS Sydvaranger and Korf Stahl, is to use Norwegian natural gas for the direct-reduction of Scandinavian ore pellets.

In 1980, Norway's three largest iron ore mines were Government owned: AS Sydvaranger's Sör Varanger Mine near Kirkenes (capacity 2.3 million tons of concentrate per

year); Norsk Jernverk's Rana Gruber Mine near Mo (1.2 million tons); and Fosdalens Bergverks AS's Verran Mine in Nord-Trondelag (510,000 tons). Privately owned AS Rödsand Gruber was located near the west coast (150,000 tons). Minor quantities of iron ore were also produced as a byproduct of ilmenite mining at Titania AS's Sokndal Mine in south Norway, and at Elkem Spigerverket's vanadium production at Nesset on the west coast of Molde.

In 1980, Norway's ferroalloy industry held the strongest position in the world market. At the 1979 level, ferrosilicon capacity was about 300,000 tons per year (about 15% of world capacity); ferromanganese exports reached 293,000 tons; silicomanganese reached 171,000 tons; and other metallic-silicides production capacity totaled about 65,000 tons per year, also about 15% of world capacity. Norway's ferroalloy companies are shown in the following tabulation:

Company, ownership	Plant location
Elkem Spigerverket	Salten Verk, Fauske; Bremanger Verk, Svelgen; Fiskaa Verk, Kristiansand.
Fesil Nord (38% Elkem)	Sales organization of the Fesil group.
Icelandic Alloys (45% Elkem)	Straumsvik smelter, Iceland.
Tinfos Jernverk (member of Fesil group)	Tinfos Jernverk, Notodden; Oye Smelterverk, Kvinesdal.
Ila & Lilleby Smelterverker AS (member of Fesil group)	Lylleby Smelterverker, Trondheim; Holla Verk Kyrksaeterora.
Union Carbide Corp	Sauda Smelterverk AS Sauda; AS Meraker Smelterverk, Meraker (also 7 ferroalloy plants in the United States and Canada).
AS Hafslund (Fesil group) (also coowner of AS Björlvefossen)	Skeberg smelter, Ostfold.
AS Björlvefossen	Alvik Smelter, Hardanger.

By yearend, Elkem Spigerverket AS, already one of the world's largest producers of ferrosilicon, ferromanganese, ferrovanadium, and silicon metal, was buying Union Carbide ferroalloy facilities at 10 locations in Canada, the United States, Norway, and the United Kingdom for about $205 million, with annual capacity of about 600 thousand tons of manganese alloy and 450 thousand tons of silicon alloy. Elkem formed a consortium for the deal, holding a 40% share, while Shieldings Investments of Canada, a major Canadian investment banker, held another 40% and a group of Norwegian investors held 20%. Elkem was to be the operator.

Magnesium.—Although at present, the output of Norsk Hydro AS magnesium plant at Porksgrunn, south of Oslo, is in the 50,000-ton-per-year range, recent modernization of the process enables the plant to increase production up to 75,000 tons per year. The Porksgrunn plant, the only one in Norway, supplies about 20% of the Western World's magnesium.

A description of the metallurgical process used at Porksgrunn appeared in the technical literature.[4]

Nickel, Cobalt, Platinum-Group Metals.—Titania AS's Sokndal Mine, on the south coast, produced a concentrate byproduct with about 3.9% nickel content. This ore, plus imported nickel matte from Canada containing cobalt and platinum, was processed at Falconbridge Nikkelverk AS's Kristiansand refinery on the south coast.

Rare-Earth Metals.—Surface studies made in the Fens Field at Ulefoss in Telemark County have indicated a considerable rare-earth deposit—containing cerium, yttrium, europium, gadolinium, and thorium—set aside for drilling in the summer of 1981. The operator was a company called Fenco, established for this purpose by S.D. Cappelen, together with Aardal og Sunndal Verk AS, Elkem Spigerverket AS, AS Sydvaranger, and the U.S. concern Union Mineral Norway, a subsidiary of the Union Oil Co.

NONMETALS

Cement.—Plans for a new cement plant in Tromsdalen, near Tromsö, where plentiful reserves of industrial limestone were available, were canceled by Norcem, Norway's only cement concern. In 1980, the company operated three cement plants, totaling 3.2 million tons of capacity.

Fertilizer Materials.—In 1980, Norsk Hydro AS purchased the Nederlandse Stikstof Maatschapij. Norsk Hydro thereby became the world's largest exporter of urea, and was said to be the world's third or fourth largest producer of fertilizer materials. The sharp increase in raw material costs in 1980 put the ammonia plants at Porksgrunn,

which use heavy oil, naphtha or natural gas liquids, at a disadvantage compared with competitors using natural gas as a feedstock and fuel. The company was therefore considering establishing new ammonia capacity based on natural gas. The plant location had not yet been chosen.

Graphite.—In 1980, the only Norwegian graphite producer was AS Skaaland Grafitverk, a subsidiary of Ever Ready Holdings (U.K.) Ltd., also known as the Berec group, and an associate of the U.K.-based Chemical and Carbon Products Ltd. Skaaland mines, a crystalline flake deposit on Senja Island, in the far north, just south of Tromsö, was established in 1931. Reserves of over 1 million tons of ore which contain 25% to 30% carbon are said to be available. About 40,000 tons per year of ore were being mined, and a 88% to 90% concentrate was obtained. The beneficiation plant was expanded recently.

Industrial Minerals.—A number of industrial minerals continued to be produced in Norway. AS Sydvaranger had started a quartzite mine near Tana, west of Kirkenes. The quartzite was shipped to Iceland and used by Icelandic Alloys Ltd., partly owned by Elkem Spigerverket AS. There were experiments to produce an oil-drilling mud compound from the heavy components of ilmenite concentrates of Titania AS. Norsk Nefelin AS, a subsidiary of Elkem Spigerverket AS, produced nepheline syenite of various grades. Norfloat AS, a subsidiary of the H. Björum group companies, continued production of potassium and sodium feldspar and quartz concentrates from pegmatites in southern Norway.

Olivine.—In 1980, AS Olivin was the world's largest producer of olivine, from a mine located at Aaheim in the Sunmore district of western Norway. The company's production in 1980 was expected to reach about 1 million tons, 80% of which was for export. According to estimates, about 750,000 tons were sold to smelters for slag-conditioning purposes in 1980. Both wet and dry processing were used to produce a wide range of products including olivine flour. The Federal Republic of Germany and France purchased a total of about 500,000 tons in 1980, and Belgium, Finland, the United Kingdom, and the Netherlands were also important customers. The Aaheim plant also has a 50,000-ton-per-year facility for the production of olivine bricks, but this plant operated at a rate of only 18,000 tons per year as the demand for night storage heater blocks, the principal use for the bricks, had decreased. Blasting sand and molding sand were also among the company's products. Norway's second largest olivine producer was KS Norddal Olivin AS & Co., a member of the H. Björum group companies. Production in 1980 was expected to reach approximately 105,000 tons, and even more in 1981. Normally, the company produced 150,000 tons of olivine per year, but closing of the older Norddal Mine and development of the Lefdal Mine caused a temporary decrease in output. About 70 % of sales was said to be used as a slag conditioner.

Although AS Olivin and KS Norddal Olivin were Norway's only olivine producers in 1980, a third company was preparing to enter production. A consortium composed of Orkla Industrier AS, Sigval Bergsen D.Y., and Stokke Olivine AS undertook test drilling of olivine deposits around Robbervika in west Norway. The new company, temporarily called Industriterminaler AS, was not yet firmly committed to startup, because of softness in the olivine market.

Silicon Carbide.—In 1980, Norway had three producers of silicon carbide, with total capacity exceeding 70,000 tons per year. Arendal Smelterverk AS, a subsidiary of Carborundum Co. of the United States, operated a 42,000-ton-per-year plant in Arendal on the south coast. Norton AS, a subsidiary of the U.S. Norton Co. of the U.S.A. operated a 17,000-ton-per-year plant at Lillesand, also on the south coast. Orkla Exolon AS & Co., a company jointly owned by Orkla-Gruve AB, Elkem Spigerverket AS, and the Exolon Co., operated a 12,000-ton-per-year plant at Orkanger in the, north near Trondheim.

MINERAL FUELS

In 1980, Norway was well on its way to becoming a major oil exporter in Western Europe. Growing North Sea oil output exceeded home consumption more than six-fold, and accounted for a substantial foreign trade surplus. The country's gross energy consumption in 1980 was about 41% electric power, mostly hydroelectric, of which a small percent was imported from the U.S.S.R. through Kirkenes in the north; about 52% of consumption was hydrocarbons; and about 7% was coal, of which more than two-thirds was imported.

Coal.—The first sample load of coal from the new Svea Mine on Svalbard Island arrived in November 1980 at Norcem's cement plant in Dalen. In 1981, Svea coal is to be used on a regular basis. The coal is of

higher quality than the imported Polish coal used previously.

Hydroelectric Power.—Much of Norway's mineral industry owes its existence to abundant and inexpensive hydroelectric power. Virtually all of the 29.6 billion kilowatt-hours generated in the country came from hydroelectric power stations. In 1980, the Parliament approved the Government's plan for hydroelectric power development and pricing (White Paper No. 54). The plan called for steep increases in electricity prices to encourage efficient use and conservation. Prices were to be based on long-term marginal cost of new power. Development of new hydropower sources are to be a compromise between industrial and environmental needs. By 1990, two major hydroelectric plants are to be built, and existing ones will be expanded, with capacity thereby increased from 83 to 94 billion kilowatt-hours per year. About 75 waterways are to be excluded from development.

Petroleum and Natural Gas.—In 1981, oil and gas production in the Norwegian sector of the North Sea increased by approximately 25% to 49.5 million tons of oil equivalent. Of the total, about 24.4 million tons was oil and about 25.1 billion cubic meters was natural gas production. The main oilfields contributing to oil production in the North Sea were the Ekofisk Field, which produced 21.4 million tons of oil and 15.1 billion cubic meters of natural gas; the Frigg Field which produced 10 billion cubic meters of natural gas; the Statfjord Field, which produced about 2.8 million tons of oil (Norwegian share); and the Murchison Field, which produced 75,000 tons of oil (Norwegian share). Besides the producing oilfields, there was development work in the Valhall and Ula Fields, also in the North Sea.

There were negotiations between the United Kingdom and Norway, for the sale of Statfjord natural gas to the United Kingdom. Other negotiations centered around the sale of Ula natural gas to the Federal Republic of Germany.

Shell Oil Co.'s gas discovery in Block 3 1/2, made in 1978, was said to exceed in size the Groningen Field in the Netherlands, which is one of the largest in the world. Shell, the operator of the field, owns 35%, Statoil (the Norwegian Government Oil Co.) owns 50%, and Norsk Hydro AS, Conoco, and the Superior Oil Co. each own 5% of the equity. Reserves were said to exceed 1.5 trillion cubic meters of gas and unspecified quantities of oil.

Statoil discovered hydrocarbons in block 30/5, that was said to be substantial. Phillips cut its reserve estimate for the Ekofisk area to about 400 million tons of oil equivalent. Ekofisk and Statoil crude, of a particularly high quality, being light and low in sulfur, was priced by yearend in the range of $39.80 to $40.50 per barrel.

On March 27th, a five-legged floating rig, the *Alexander L. Kielland*, located near the Edda platform, which was used as a hotel, collapsed in a heavy storm. A total of 42 persons died, 81 were listed missing, and 89 survived. The accident was apparently caused by stress cracks and corrosion.

Drilling north of the 62d parallel started in the summer by Statoil in block 7119/12 of the Tromsö area, in 200 meters of water. Hydrocarbons were found in sandstones, but indications were not sufficient to judge their importance, and it was planned to sink the well further to 3,500 meters. Statoil owns 50% of the exploration group, Esso Exploration and Production Co. owns 25%, Norsk Hydro Produksjon owns 10%, and Saga Petroleum, Deminex, and Hispanoil owns 5% each.

A white paper issued by the Norwegian Government in 1980 reaffirmed the earlier decision to hold total oil and gas production to 90 million tons per year of oil equivalent. According to the report, new reserves discovered in both oilfields and gasfields make it possible that the limit will be exceeded if development of both hydrocarbons is now vigorously pursued, and the Government will thus be forced to choose to limit one or the other.

The Mineral Industry of Pakistan

By Suzann C. Ambrosio[1]

The mineral industry of Pakistan contributed less than 1% to the 1979-80[2] gross national product of approximately $23 billion[3] at current prices. The importance of fuel and nonfuel minerals was reflected in record Government budget allocations of approximately $75 million and $12 million, respectively. Although the public sector continued to dominate most of the mining industry, including iron and steel, fertilizers, cement, chemicals, petroleum, and natural gas, the Government decided to allow the private sector minority shareholdings in various industrial projects. The private sector has already been involved in fertilizer and cement industries on a small scale, and has been encouraged to initiate production of soda ash and other mineral-derived products.

Although moderate growth was achieved by most mineral producers, large advances occurred through the completion of various mineral projects, enhanced exploration efforts, and infrastructure development. Major accomplishments were made during 1980 in a variety of areas. The Saindak copper mine project advanced from feasibility status to the planning and design stages. The first blast furnace was "blown in" at the Pipri Steelworks near Karachi. Cement plant expansion projects were nearing completion, and additional plants were proposed to meet growing domestic demands. The National Fertilizer Corp.'s Mirpur Mathelo plant, a joint venture between Pakistan and Saudi Arabia, was brought online, and new fertilizer projects were planned. The Gudu thermal power station financed by the Soviet Union was completed. Various gas and oil pipeline projects made headway. The Adhi Oilfields were brought into production after overcoming persistent drilling problems. Expenditures made in the above areas were expected to generate significant returns through increased production and trade throughout the 1980's.

Intensive explorations were carried out on various oil and gas sites, and drilling activities were expected to double 1979 levels. Attention was also given to the relatively remote and unexplored North West Frontier Province (NWFP). Late in 1980, an "economic breakthrough" was reported in Kohistan, nestled in the high mountains of the Karakoram Range between Pakistan and mainland China. Vast deposits of major minerals were discovered, including iron minerals, and substantial quantities of chromite, copper, lead, and zinc ores. In addition, the Gemstone Corp. of Pakistan Ltd. started exploration in the Swat district of NWFP, for the purpose of locating new emerald deposits.

The Government initiated a number of mineral-based projects to meet the needs of Pakistan Steel Mill Corp. (PASMIC) and other mineral industries during the year. Port Qasim, which was built especially for the steel complex, was expected to be open to traffic early in 1981. The opening of Port Qasim was expected to alleviate the handling of iron ore and fertilizer imports, which were subject to extensive delays at the Port of Karachi. The Pipri Steelworks marshaling yard and other storage facilities were completed. The Government also granted nearly $3 million for the construction of numerous 13,000-ton-capacity fertilizer depots.

Pakistan's 1980 gross domestic product (GDP) measured in 1969-70 constant prices grew at a rate of 6.2% compared with 5.9% for 1979. The agricultural sector, representing 30% of the GDP, grew 40% during the

year primarily due to production increases in wheat, rice, and cotton crops. The net effect was an improvement in the balance of payments situation, as agricultural products accounted for one-third of all exports. Growth in the industrial sector, which comprised 14% of the GDP in 1980 was driven by an 8.1% increase in the manufacturing sector.

The 1980 Balance of Payments (BOP) deficit registered an improvement from $999 million to $752 million. Worker remittances climbed at a rate of 23% since 1979 and peaked at approximately $2 billion during 1980. Export income contributed significantly to the BOP primarily because of higher export unit values. Improvement in the BOP situation was expected if Pakistan's debts were rescheduled. The Government's external debts amounted to over $10 billion by yearend 1980. The International Monetary Fund (IMF) approved a 3-year loan of $1.7 billion to Pakistan in December 1980. The loan was targeted to reduce Pakistan's BOP deficit from 5% of the GDP to under 4% by 1983. The net inflow of foreign aid has declined since 1975, because of increasing debt service liability. In addition, the Soviet invasion of Afghanistan required additional military expenditures and refugee aid. The IMF and Aid to Pakistan Consortium were considering debt rescheduling in conjunction with strict budgetary controls. Declines in deficit financing and monetary expansions were expected to curb inflation, running at approximately 11% during 1980.

The Government of Pakistan initiated some fiscal policy changes during 1980. The overall goal was to increase self-sufficiency by expanding industrialization and exports and by limiting nondevelopment expenditures. Various tax incentives were geared to stimulate private industrial investment. The most significant move was the extension of the capital gains tax exemptions through 1982.

PRODUCTION

Mineral production continued to account for less than 1% of the nation's GDP during 1980. Mineral fuels continued to be the most valuable mineral commodity produced and exported. Natural gas provided approximately 90% of the industrial sector's energy requirements. Natural gas was distributed among fertilizer factories (28%); thermal power stations (19%); cement factories (11%); other industrial users, including iron, steel, and chemical producers (33%); domestic and commercial users (9%). Production of crude petroleum increased 5%, petroleum products increased 2%, and natural gas increased 11% between 1977 and 1979. These trends were expected to continue because exploration, production, and refinery capacities have all increased over the past year. Increased exploratory drillings and expansion wells were projected to be capable of tripling 1980 oil production levels to 36,000 barrels per day by 1984.

Production of other important nonfuel minerals grew moderately between 1978 and 1980. Fertilizer production has grown steadily: 1980 output increased 26% over the previous fiscal year. The largest gains were reported for ammonium nitrates and nitrophosphates. Output from the cement, chemical, and steel industries increased approximately 10% over 1979 levels. Commissioning of all the proposed fertilizer plant expansion and construction projects was expected to leave production short, necessitating imports of 123,000 tons in 1983.

[2]Reported figure.

TRADE

Pakistan's trade gap continued to widen during 1980, despite record growth in exports and a decline in the growth of imports. Export revenues rose 38% over the previous fiscal year, reaching $2.3 billion. Imports rose 29% to $4.7 billion, resulting in a $2.4 billion trade deficit for 1980. The import bill for crude oil and refined products accounted for 30% of all imports and 50% of the total export earnings. Although Pakistan is an exporter of certain refined oil products, such as furnace oil and naphtha, approximately 22% of the country's refined oil products were imported.

Mineral trade constituted a significant portion of the trade deficit. Pakistan's most important mineral exports included refined petroleum products, barite, and some manufactured ferrous-metal products. Price increases of over 100% for crude oil and petroleum products and 34% for iron and steel materials were primarily responsible for large import expenditures between 1979 and 1980. The value and volume of chemical fertilizer imports, however, declined during the same period. Approximately 7 million tons of fertilizers were imported at an estimated cost of $400 million.

The restrictive import policy that was in effect at the end of 1979 was modified during April 1980. Relaxed import controls for industrial raw materials and spare parts included a 10% increase in import allowances over the previous base. The importer may select the base as either the value licensed in 1978-79, or the average value licensed over the past 3 fiscal years. Several specific import policy changes that concern the mineral industry were made. Steel producers may import sponge iron in lieu of iron and steel scrap; import licenses were declared eligible for unserviceable ships (used for iron and steel scrap); mineral imports such as mercury, aluminum, copper, zinc, and lead, previously limited to the public sector, were opened to the private sector; new items were added to the "free list," including various chemicals, nickel waste, copper powders, and flakes; authorization of machinery imports ($1 million maximum) was permitted for new investment projects (worth $2 million) without Government approval; and monetary ceilings were doubled to $10,100 for imported machinery parts and accessories.

COMMODITY REVIEW

METALS

Bauxite.—General Refractories Ltd. constructed an alumina brick factory which was subsequently transferred and revised by the Industrial Development Board of Pakistan (IDBP) during the late 1970's. The refractory had an installed kiln capacity of 10,000 tons per year in 1980, and it produced high- and low-grade alumina bricks, insulated bricks, tiles, and mortar.

Chromite.—Chromite production significantly declined since 1978, due to the expensive transport costs from the chromite mines in Baluchistan to the Port of Karachi. The Pakistan Council for Scientific and Industrial Research (PCSIR) successfully raised the Cr_2O_3 content of low-grade chromite reserves from 25% to 48% at a pilot plant constructed during 1979. Chromite production was expected to feed two proposed refractory plants and to supply local chemical and metallurgical industries. The Pakistan Mineral Development Corp. (PMDC) proposed to locate the refractory manufacturing plants at Malakand in Baluchistan, and Hatar in NWFP. The Malakand plant was designed to produce 15,000 tons of magnesite and/or chromite bricks and 10,000 tons of dead-burned magnesite. Mainland China and the Pakistan Industrial Development Corp. (PIDC) were conducting geological surveys by yearend 1980. The Hatar refractory plant was still in the planning stage.

Copper.—Feasibility studies completed for the proposed Saindak Mine project delineated three porphyry copper deposits. Proven reserves located in the extreme northwest corner of Baluchistan were estimated to contain 412 million tons of copper ore, with an average grade of 0.37% copper. Pakistan's Resource Development Corp. (RDC) was negotiating a loan for $155 million with foreign firms and an equity share of 6.3%, for the $315 million Saindak project. Operations were projected to commence in 1982, with an annual production capacity of 17,000 tons of blister copper, 225,000 tons of sulfuric acid, 40,000 troy ounces of gold, 100,000 troy ounces of silver, and 140 tons of molybdenum.[4] Large infrastructure expenditures were required to achieve projected production levels and accessibility of the remote deposits.

Iron Ore.—Nine deposits were estimated to contain 500 million tons of iron ore in 1980. The bulk of the proven reserves equivalent to 335 million tons, were located within the Chichali deposits in Kalabagh, Punjab. Lack of financial support for the Chichali ores, with a low 32.5% metal content, has hindered further development. High-grade iron ore deposits with a 50% average metal content were discovered during 1979 in Pachinkoh and Chigendik, Baluchistan. Drilling studies have revealed proven reserves exceeding 13 million tons. PIDC's drilling program and comprehensive geological reports were expected to be complete by June 1981. Metallurgical studies conducted by PCSIR and the Japanese Consulting Institute have reported encouraging beneficiation results.

Iron and Steel.—Pakistan's iron and steel demand was approximately 1.5 million tons in 1980. Projected demand was estimated to increase 50% by 1987, when the Pipri steel mills were expected to achieve full production (1.15 million tons). PASMIC completed the steelworks at Pipri during 1980. Pig iron production was scheduled to commence in December 1980, with the commissioning of the first blast furnace. The steelmaking plant and 800-millimeter billet mills were expected to be operational in 1981. Pakistan signed import agreements with Liberia, Brazil, and India for 4.2 million tons of iron ore, during 1980. PASMIC was planning additional projects based on semimanufactured steel from the integrated steelworks.

Molybdenum.—Investigations of the Darbanchah molybdenum reserves in Baluchistan continued throughout 1980. Small amounts of molybdenum were expected to be recovered in 1982 when the Saindak project comes online.

NONMETALS

Barite.—Bolan Mining Enterprises Ltd. continued to increase the output of Khuzdar barites during 1980. Approximately 70% of the barites were ground in Khuzdar and Karachi mills. Nearly 75% of the barite was purchased locally, and most of the exports were sold to oil-producing Middle East countries. Transportation continued to be a problem as the Khuzar-Karachi section of the highway network remained incomplete by yearend 1980.

Cement.—The State Cement Corp. of Pakistan Ltd. continued to address 1980 supply shortfalls by achieving 96% production capacity at the State-run factories, and by extending the cement industry into the

private sector. The Government approved three new cement plants, which were expected to increase production capacity by 900,000 tons per year. Each new plant was designed to produce 300,000 tons of cement annually and was estimated to cost $50 milllion. The Government was expected to cover the foreign exchange component of $28 million, and has required the sponsoring companies to finance the difference for the purchase of domestic plant machinery and equipment. Plant sponsors and locations include Messrs. Naseer A Shaikh and Co. in Taraki, Jhelum district; Farug Ltd. in Lakrai near Nowsherea; and Fecto Ltd. in Sangjiana near Rawalpindi. Construction continued at the Dandot and Thatta Cement projects, and expanded production was scheduled to commence in September 1981.

Fertilizer Materials.—Five fertilizer plants were operating in Pakistan by year-end 1980. Annual production capacities were approximately 1.4 million tons of nitrogenous fertilizers and 0.7 million tons of phosphatic fertilizers. Although output increased through the expansion of the Multan plant and the startup of the Mirpur Mathelo plant during 1980, domestic suppplies have not kept up with demands. Pakistan's objective for nitrogenous fertilizer was self-sufficiency by 1984. Nitrogenous fertilizer production increased 15%, and natural gas consumption, used for fertilizer feedstock, increased 17% over 1979 levels. Pakistan's operating and planned fertilizer plants are listed in table 4.

The Pakistani Government acceded full control of the fertilizer industry in 1972, in accordance with the Industrial Reforms Order. Exceptions included Exxon Chemicals (Pakistan) Ltd. and Dawood Hercules, which have foreign participation, and the proposed Fauji Foundation project, considered neither private nor public because of its multilateral aid sponsors. Although the National Fertilizer Corp. of Pakistan controlled approximately 60% of the production capacity during 1979-80, the private sector contributed roughly 65% of the output. The fertilizer plants were operating at an average production capacity of 55% during 1980, with approximately 70% and 40% plant capacities achieved for nitrogenous and phosphatic fertilizer materials, respectively. Technical problems encountered in the starting up of the new Multan plant were largely responsible for decreased overall efficiencies.

Phosphate.—Extensive phosphate deposits in the Hazara region, NWFP, have been explored since 1975. Preliminary investigations estimated 45 million tons of phosphate rock deposits. A feasibility study was commissioned in July 1980 to establish the economic viability of using the ore for fertilizer production. British mining consultants were expected to aid in the mine design, beneficiation, and transportation requirements. The proposed facility was to be located at Haripur. Phosphate fertilizer production was projected at 89,000 tons per year.

Table 4.—Existing and proposed fertilizer plant operations in Pakistan, 1980

Fertilizer plant	Location and Province	Products	Production capacity (thousand tons per year)	Gasfield	Natural gas consumption (million cubic feet per day)
Dawood Hercules Ltd.	Chickoki, Punjab	Urea	345	Sui	42

Other Nonmetals.—Fluorite and salt continued to be produced in small quantities during 1980. Pakistan's only iodized salt project, located in the Peshawar division, NWFP, was scheduled to commence production late in 1980. The design capacity was expected to be roughly equivalent to 50% of the iodized salt required in the country during 1980.

MINERAL FUELS

Coal.—Modest amounts of lignite coal continued to be produced in Pakistan during 1980. The largest consumer was the brick industry (80%), and the remainder was divided among the railways, small industries, and domestic users. An estimated 442 million tons of recoverable reserves were thought to exist in the Baluchistan, Punjab, and the Sind Provinces. PMDC geologic investigations have estimated that 60 million tons of the reserves were located at Lakhra, Sind. Detailed investigations of the Lakhra Coalfields were completed during 1980. A feasibility report for the coal mine and/or thermal power station complex was expected to be submitted by a Japanese company early in 1981.

Pakistan's Water and Power Development Authority (WAPDA) continued to operate a 15-megawatt coal-fired plant at Sheikh Manda, Baluchistan, during 1980. WAPDA planned to expand thermal facilities by proposing a 125-megawatt plant at Jamshoro, Sind, and a 200-megawatt plant at Kot Adu, Punjab. Both projects were pending Government approval by yearend 1980.

PMDC initiated a $2.5 million coal washing plant at Sharigh, Baluchistan, in May 1980. Approximately 75,000 tons of washed coal per year (containing 4% sulfur) was expected to be combined with better-quality imported coal at Karachi, and utilized in steel production. The washed coal supplies represent 10% of the quantity required by PASMIC's Pipri steel mills at full production. Sharigh colleries improved their facilities during 1980 through the completion of six electrohydraulic winches, with reported line pull capacity of 21 tons at 400 feet per minute.

Natural Gas.—Thirteen known fields were estimated to contain approximately 14 trillion cubic feet of gas reserves during 1980. Gas-producing fields including Sui, Mari, Sari Sing, and Hundi comprised nearly 90% of the reserves. The Sui Fields were the largest producing fields in Baluchistan, with estimated proven reserves at 8 billion cubic feet. The Sui Fields production capacity was 900 million cubic feet of high-quality, 88% methane gas in 1980. Other gasfields including Dhodak, Kandhkot, Khairpur, Kothar, Mazarani, Pirkoh, and Rodho were awaiting market development by yearend 1980.

Pakistan Petroleum Ltd. (PPL) held the concession rights for Sui, Kandhkot, Khairpur, and Mazarani Gasfields during 1980. PPL acquired Attock Oil Co. Ltd. (U.K.) in July 1980, which expanded PPL's scope of petroleum and natural gas production and distribution. Under the agreement, the Dhulian liquefied petroleum gas (LPG) plant was transferred to PPL, and a new price formula for crude oil and LPG was agreed upon.

Pipelines extending from Peshawar in the NWFP to Karachi in the southern part of Baluchistan, connected most of the operating gas-producing areas. Sari Sing and Hundi were tied into the Sui-Karachi section of the pipeline and contributed 10% of the gas supplied to the national gas grid during 1980. The Pirkoh Field, 72 kilometers northwest of Sui, was expected to be integrated with the grid, adding 120 million cubic feet per day by 1983. A new pipeline connecting the Pirkoh Field and extending supplies west to Quetta, was expected to be financed by international aid agencies.

The Sui-based Gudu power station was expected to become Pakistan's largest thermal powerplant. Phase 2 of the project, adding a 210-megawatt capacity to the existing 229-megawatt plant, was nearing completion by yearend 1980.

Petroleum.—Pakistan had an estimated 0.5 to 1 billion barrels of recoverable oil located primarily in the Potwar and Indus Basins during 1980. Average production increased nearly 5% in the following oilfields between 1979 and 1980; Balkassar, Dhulian Joya Mair, Khaur, Meyal, and Tut. The Meyal Fields continued to supply the largest output, representing over 50% of the total production. The Adhi Fields, discovered in the Potwar Basin in 1979, were brought into production during March 1980.

Oil exploration and development received an 87% increase in 1980-81 Government allocations. The Pakistani Government Oil and Gas Development Corp. (OGDC) implemented a $73 million drilling program. Thirty wells were expected to be drilled during 1980-81, double the amount drilled in the previous year. Eleven exploration companies were active in Pakistan during 1980, including OGDC, two private Pakista-

ni companies, and eight major international companies. Pakistan Shell Petroleum Development, a subsidiary of the Royal Dutch/Shell Petroleum Co., signed an agreement for extended exploration and petroleum production. The 2,792 square miles located near the borders of the Baluchistan and Punjab Provinces, were part of Shell's original concession and have already undergone seismic surveys. British Petroleum Co. Ltd. (BP) signed an exploration contract with Pakistan in October 1980, making BP the ninth international oil company with interests in the country. BP was expected to conduct and finance 97.5% of the cost for three deep wildcats. Exploration of 5,460 square miles was to take place in southeastern and central Pakistan in the Baluchistan and Sind Provinces, at a cost of $22 million.

Refinery capacities were increased from 4.7 million tons per year in 1978 to 5.2 million tons per year in 1980. Pakistan's objective was to become self-sufficient in refined products by 1983. National Refinery Ltd. was negotiating a design contract with Lumus Co. Ltd. to enlarge the Karachi refinery. The expansion program was expected to add vacuum distillation, deasphalting, extraction, and dewaxing units. Consequently, refinery capacity for lube base stocks was expected to increase by 100,000 tons per year. A new pipeline transporting various finished petroleum products, and extending 865 kilometers between Karachi and Multan, was expected to be commissioned by yearend 1980.

The Mineral Industry of Peru

By Doris M. Hyde[1]

In 1980, the Peruvian economy registered a gross domestic product (GDP) of $7.7 billion.[2] The real growth rate of 3.1% was slightly lower than the 3.8% rate for 1979, but still compared favorably to the declines experienced during 1977 and 1978. The 1980 rate of inflation was almost 61%, only slightly below the 67% recorded for 1979.

Peru's mining sector accounted for 9.5% of the GDP in 1980, and the value of mineral exports represented 48% of total export earnings, a slight gain over the 45% contribution in 1979. The increased value of mineral exports was primarily a result of the high average price of silver, which practically doubled relative to the 1979 price average.

The value of 1980 petroleum exports reached $810 million and for the first time exceeded the export value of copper, estimated at about $759 million. Petroleum exports contributed almost 21% to the $3.9 billion value of total exports.

The large mining sector, composed of three state-owned companies and the privately owned Southern Peru Copper Corp. (SPCC), suffered to varying degrees from labor unrest and a severe drought in the north. SPCC has traditionally been Peru's major copper and molybdenum producer. During 1980, the company was negotiating with the Government concerning a major expansion program at the Toquepala and Cuajone mining areas in southern Peru.

In addition to operating its six mining units and the La Oroya metallurgical complex in central Peru, Empresa Minera del Centro del Perú (CENTROMÍN) was actively involved in an exploration program in the southeastern jungle region where it already owns two large gold placer concessions. The company also ventured into southern Peru, where a polymetallic deposit northeast of Tacna was under study.

Empresa Minera del Perú (MINERO PERÚ) inaugurated the Cajamarquilla zinc refinery in May 1980. Considerable public criticism was aroused because of the possible environmental hazards resulting from transporting the sulfuric acid byproduct from the refinery to the Cerro Verde Mine in Arequipa Department in southern Peru.

In 1980, the small and medium mining sectors both achieved production gains over those of 1979 by 19% and 12%, respectively. The decreased tonnage from the large mining sector offset these gains for the most part, and Peru's overall mining production of the five leading minerals—copper, lead, silver, zinc, and iron ore—was down almost 5%.

Government Programs and Policies.—Following a 1980 review of problems affecting the mining industry, the Government drafted a series of provisions to modify the existing petroleum and mining laws in an effort to revitalize production, which, except for copper, has not shown significant growth for the last decade.

The mining legislation did not pass in 1980, but action was expected early in 1981. Changes in the mining law were expected to reduce the 17.5% export tax, which has been an important revenue source for the Government but has also discouraged investment. Other changes are expected to affect the reinvestment allowance. The Government announced the Minero Perú Commercial (MINPECO) may lose its monopoly on the internal and external marketing of metals and minerals. Such an action would not have an impact until existing company contracts with MINPECO expire. MINPECO now receives a 2% commission on sales,

an amount viewed unfavorably by the mining community. Under the proposed changes, MINPECO would continue to market production from the state-owned enterprises and any private corporations requesting their services.

It was also announced that the structure of the state-owned enterprises MINERO PERÚ, MINPECO, Electricidad del Peru, and Petróleos del Perú (PETROPERÚ) may be altered so that they can function as private corporations. The Government would maintain its 100% ownership, as in the case of CENTROMÍN and Empresa Minera de Hierro del Perú (HIERRO PERÚ), which are already organized in this manner.

It was under the shadow of steadily declining crude oil reserves and production and increasing domestic consumption that the Government enacted the 1980 changes in the petroleum law. This action followed the December 1979 publication of guidelines to govern oil contracts with the then active foreign contractors.

Law No. 23231 of December 28, 1980, permits tax credits of up to 40% of net income for foreign and mixed oil companies operating north of latitude 7° S. (northern Peru), and 50% for those operating south of latitude 7° S., providing the company has invested in its own activity or reinvested in other oil companies a minimum of $20 million. The tax credit must be taken during the fiscal year in which the investment is made or during the three immediately following fiscal years. PETROPERÚ no longer has exclusive rights to secondary recovery programs. Private Peruvian and foreign contractors may now, "in exceptional circumstances," sign operation and service contracts with PETROPERÚ concerning secondary and tertiary recovery operations with the approval of the Council of Ministers.

The tax incentive measures are intended to remain in force until 1999. Implementing regulations are expected in 1981. These changes were expected to stimulate the growing interest foreign oil companies have shown in initiating exploration in Peru.

PRODUCTION

The value of Peru's five most important mineral products—copper, lead, silver, zinc, and iron ore—decreased nearly 5% compared with their 1979 value. The major reason was an 8% drop in copper production due to strikes and a severe drought in northern Peru, which affected mining operations in that region. CENTROMÍN operated six mines in central Peru and remained the major producer of metals and sub-products at its La Oroya metallurgical complex located west of Lima. CENTROMÍN's production is shown in table 2. In addition, CENTROMÍN produced 239,248 tons of zinc concentrates for export and 294 tons of tungsten concentrates for export. A significant proportion of the metals produced at La Oroya come from custom concentrates purchased from smaller mining and concentrating operations—30% to 40% of the copper, 50% to 60% of the silver, and 32% to 47% of the lead. In 1980, an annual record high was set by CENTROMÍN in the recovery of selenium, copper sulfate, and zinc sulfate. Overall, CENTROMÍN failed to meet 1980 programed production goals because of labor problems and drought.

Crude oil production increased marginally, primarily owing to improved secondary recovery operations. Domestic consumption rose almost 8% in 1980, compared with the 5% consumption increase experienced in 1979.

Peru does not have a central statistical gathering agency. Except for information available from Banco Minero, MINPECO, and the various producing companies, there is no other source of data. The last published information on nonmetallic mineral production was for 1976. There is a possibility that in the near future—1 to 3 years—MINPECO will assume the responsibility for gathering nonmetallic mineral information.

TRADE

The Central Reserve Bank preliminary statistics on the value of nonfuel mineral exports in 1980 indicated a record $1.86 billion, more than 19% above the $1.56 billion exported in 1979. Exports were subject to erratic and somewhat declining international mineral prices during the second half of 1980. The United States and Japan continued to be the major markets for Peruvian mineral exports, with silver, copper, and lead accounting for the largest values in the case of the United States, and copper, zinc, iron, and lead for Japan.

In 1980, mineral exports accounted for 48% of the total value of exports. Copper and silver were the major nonfuel mineral foreign exchange earners, together accounting for 72% of the value of nonfuel mineral exports.

In 1980, the value of petroleum exports reached $810 million and surpassed that of copper. Crude oil exports averaged about 48,000 barrels per day, compared with 1979 exports of about 52,000 barrels per day and 1978 exports of 29,300 barrels per day.

Preliminary 1980 mineral exports through MINPECO, the state agency in charge of marketing all Peruvian minerals, are shown in the following tabulation:

Product	Quantity (metric tons)		Percent change	F.o.b. value (thousands of U.S. dollars)		Percent change
	1979	1980		1979	1980

COMMODITY REVIEW

METALS

Copper.—The following tabulation shows the principal producers of copper ores and concentrates, in metric tons of copper:

Company	1979	1980	Percent change
Southern Peru Copper Corp.:			
Toquepala Mine	107,552	108,491	1
Cuajone Mine	183,521	150,829	-18
CENTROMÍN	27,669	26,978	-3
MINERO PERÚ (Cerro Verde Mine)	33,100	33,279	0.5
Minas Aguila, S.A	5,410	6,900	28
Cía. Minera Pativilca, S.A	4,920	4,600	-7
Northern Peru Mining Corp	3,095	3,515	14
Cía. Minera Condoroma, S.A	3,585	3,250	-9
Cía. Mineral del Madrigal	2,595	2,945	13
Minas de Cobre de Chapi, S.A	2,300	2,360	3

Total 1980 copper production decreased about 8% from 1979, mainly resulting from a 28-day strike at SPCC's Cuajone Mine and a 33-day strike at the concentrator. The Toquepala Mine lost 18 days of production owing to strike activity. SPCC was negotiating with the Government relative to a $220 million expansion program. Plans included a $150 million investment at Toquepala to increase ore reserves and to expand concentrator production from 110,000 to about 145,000 tons per year, and a $70 million investment at the Cuajone Mine operation to increase the capacity of the concentrator to accommodate a lower grade ore and, therefore, enable the plant to maintain present copper output.

CENTROMÍN, the third largest copper producer, completed the basic engineering study for modernizing the copper refinery at La Oroya. Work is to begin during the last half of 1981 with completion expected to take 4 years in order to maintain the plant in an operating status during construction. At the Cobriza Mine, infrastructural and development work was initiated for expansion and a new concentrator. It was estimated that construction would be concluded by mid-1982.

A CENTROMÍN subsidiary, Cía. Minera Los Montes S.A., received loans to begin construction on the $13.7 million Monterro-

sas copper mine and concentrator to be located in Ica Department. Initial output is scheduled for 1982. Capacity production was set at about 17,000 tons per year of copper concentrate averaging 25% copper, and 70 tons per year of molybdenum concentrate averaging 53% molybdenum. Ore reserves at Monterrosas were estimated at 1 million tons grading 8% copper.

CENTROMÍN awarded a feasibility study contract on the Toromocho polymetallic deposit located in Morococha district, about 142 kilometers east of Lima. Studies were first initiated on this deposit in 1963. The present study has a completion date of late 1981 and includes the possibility of a separate mining and metallurgical complex. Under consideration are an opencast mine and crusher, transport to a 32,000-ton-per-day flotation concentrator, and a dump leaching area for metal recovery from marginal ore. Later stages of development could locate a metallurgical complex in the Pucara Valley east of the Toromocho concentrator. The metallurgical complex envisioned consists of a smelter and refinery to produce 83,000 tons per year of refined copper, molybdenum and tungsten separation plants, an anode slimes plant to recover silver and other metals, and a sulfuric acid plant. Another possible addition to the metallurgical complex would be the incorporation of a 180,000-ton-per-year lead smelter to accommodate concentrates from other mines in the area. The metals of economic interest contained in the Toromocho ore deposit were described as follows, calculated on proven ore reserves of 354 million tons averaging 0.75% copper and using a cutoff grade of 0.5% copper:

Metal	Average grade, percent	Estimated metal content
Copper ____ metric tons__	0.75	2,655,000
Lead ____ do____	.031	109,700
Zinc ____ do____	.145	513,300
Silver ____ ounces__	[1].2711	95,970,000
Gold ____ do____	[1] .00007	24,780
Molybdenum __ metric tons__	.013	46,000
Bismuth ____ do____	.005	17,700
Tungsten ____ do____	.024	85,000
Arsenic ____ do____	.045	159,300
Antimony ____ do____	.0082	28,300

[1]Troy ounces per metric ton.

Using a cutoff grade of 0.4% copper, Toromocho ore reserves were estimated at 500 million tons. In addition, 530 million tons of leachable ore has been identified where the average grade is 0.39% copper with a 0.2% cutoff.

The magnitude of the Toromocho project was believed to be beyond the resources available to CENTROMÍN and that one or more private Peruvian or foreign partners would be required to realize the project.

MINERO PERÚ, the second largest copper producer, continued to operate the Cerro Verde Mine and Ilo copper refinery with no significant changes during 1980. Potential investors have been contacted for the first phase of expansion at the Cerro Verde Stage II deposit, but negotiations were not held during 1980. Cerro Verde is a wholly MINERO PERÚ operation, and the company must decide whether this second stage should be independent of the first stage or whether a new company should be formed, perhaps using the "Tintaya model" to take over the operations of both stages.

The magnitude of the Cerro Verde Stage II project will probably require a three-phase development program. Under the proposed first phase of Stage II, copper production would be increased to 20,000 tons per day of ore yielding 200,000 tons per year of 28% to 30% copper concentrate containing about 50,000 tons per year of copper. The first phase of the second stage plan was given a cost estimate of $290 million. The project ultimately involves the development of about 1.2 billion tons of copper sulfide, averaging 0.65% copper, underlying the 61 million tons of oxide ores which have been under production since 1977.

MINERO PERÚ's first priority, however, has been the development of the Tintaya copper deposit located in the Province of Espinar in southern Peru. In March 1980, the Government established the Empresa Estatal Minera Asociada Tintaya S.A. (EMATINSA) to develop this deposit. The new company is owned by three Government agencies: MINERO PERÚ (45%), CENTROMÍN (45%), and the Financial Development Corp. (COFIDE) (10%). Initial capitalization was $100 million. A Canadian company, Nenninger and Chennevert, was awarded the contract to undertake project management and provide technical assistance.

In accordance with Government policy, projects such as Tintaya should be self-

financed with private national and foreign capital to reduce Peru's risk and financial obligation. EMATINSA has held negotiations with several foreign companies interested in the project. Equity would be divided between MINERO PERÚ (minimum of 25%), Peruvian investors (30%), and foreign investors (40% to 45%). Any remaining equity would be covered by the International Finance Corp. with the provision that these shares will eventually be sold preferentially to Peruvian investors. Total cost of the project has been estimated at almost $300 million. EMATINSA has negotiated a $250 million loan from Canada's Export Development Corp. and a banking group.

EMATINSA has initiated infrastructual and development work and tentatively planned that the operation will be onstream by 1984 at a projected mining rate of 8,000 tons per day, yielding 160,000 tons per year of 33% copper concentrate. Ore reserves at Tintaya have been placed at 10 million tons of oxides containing an average of 2.2% copper, and 41 million tons of sulfide averaging 2% copper. The mine life has been estimated at between 16 and 25 years, depending on the rate of extraction.

Empresa Minera Especial Asociada Antamina S.R.L., owned by MINERO PERÚ (51%) and the Romanian state mining agency Geomin (49%), has rejected a third feasibility study but agreed to modify the original plans to reduce costs. Changes included a shift from a 20,000-ton-per-day operation costing $530 million to a two-stage plant of 10,000 tons per day, costing $326 million for the first stage. Financing was not secured during 1980, and some organizational changes could be advanced that would modify the company structure. The Antamina copper-zinc deposit, located in the Province of Huari, Department of Ancash, some 50 miles east of Huarás, has proven ore reserves of about 166 million tons containing 1.3% copper, 1.1% zinc, 0.04% molybdenum, and 0.48 ounce of silver per ton.

MINERO PERÚ's copper refinery, located 3 miles from both the Port of Ilo and SPCC's smelter, was scheduled for expansion. The company was evaluating several proposals for increasing capacity from 150,000 tons per year to 225,000 tons per year. Production from this refinery declined slightly in 1980 owing to a decrease in the supply of blister copper from SPCC's smelter.

A severe drought in northern Peru seriously affected operations at Minas Aguila S.A.'s new copper mine in the Province of Sihuas, Department of Ancash. The mine operated at one-half of its planned 60,000-ton-per-year production but was still the largest copper producer in the medium sector. In order to avoid similar water problems in the future, the company extended its water canal by 12 kilometers into the lakes of the Cordillera Blanca.

The 150,000-ton-per-year flash smelter planned for construction at Chimbote by Fundiciones del Norte, S.A., has been temporarily postponed pending a favorable decision from COFIDE on financing arrangements. The $15 million smelter was planned to accommodate production from the Aguila Mine and from other private mines in the area.

Amax Exploration, Inc., has been conducting exploration studies at the Pashpap copper-molybdenum deposit located 380 kilometers north of Lima in the Department of Ancash. This deposit was formerly owned by Homestake Mining Co. By the end of 1980, drilling had indicated 60 million tons of ore containing 0.8% copper and 0.053% molybdenum. Amax planned to reevaluate data so far gathered on Pashpap and also identify additional areas of mineralization that would justify development.

Gold.—The largest gold production continued to come from placer mining in the southeastern jungle region, with Puerto Maldonado, Department of Madre de Dios, as the center of activity. Mining in this area has been primarily by individual miners using elementary methods, although there are a few medium-sized operations owned by Peruvian and foreign interests that employ more sophisticated mining techniques. In 1980, gold production from the Madre de Dios area, in ounces, was as follows:

Puerto Maldonado	15,487
Laberinto	12,974
Huaypetue	7,315
Mazuco	4,984
Colorado	3,455

CENTROMÍN has two gold concessions of 15,000 hectares each, located on the Madre de Dios and Inambari Rivers, 80 and 110 kilometers, respectively, west of Puerto Maldonado. CENTROMÍN has done exploratory drilling in the Bijahual area where auriferous gravel layers have reportedly

averaged 0.0096 ounce per cubic meter. Information gathered so far indicates the existence of widely distributed auriferous gravels that have a thickness of 50 meters overlying the bedrock. A pilot plant has been purchased to treat the gravel at a rate of 12 cubic meters per hour. It was expected to be located on the Madre de Dios River concession to enhance gold recovery and also to extract other minerals such as titanium, zircon, tin, and magnetite. CENTROMÍN may join with an interested foreign company to develop this prospect.

MINERO PERÚ conducted preliminary studies on its San Antonio de Poto concession in the Department of Puno. The company obtained credit financing to install equipment to treat 1,500 cubic meters of gravel per day to produce about 4,730 ounces of gold annually. During 1980, the concession produced 155 ounces of gold using incomplete equipment. Several foreign and national companies have expressed an interest to participate in this project and MINERO PERÚ was expected to render a decision in 1981 regarding possible partners.

In the northern jungle, important placer gold areas are Santa María del Nieva, Bagua, and Saramiriza. Several northern mining groups were also milling from gold vein deposits. Cía. Minera Poderosa was developing the La Lima deposit, located in the Province of Pataz, Department of La Libertad. Here, a 200-ton-per-day mill was installed to treat ore grading 0.29 ounce of gold per ton. The mine was expected to become operational in 1982. In the southern coastal region the largest gold producers were Minas Ocoña S.A., Oro Arequipa S.A., Explotora S.A., and Santa Clarita S.A., all new companies with the exception of Ocoña.

The increased market value of gold continued to lure miners and investors to Peru. In 1980, the average price of gold was over $612 per ounce as opposed to the average $306 per ounce received in 1979.

Recoverable gold production by sources is shown, in ounces, in the following table:

	1979[p]	1980[p]	Percent change
In ores and concentrates	15,143	11,028	-27
In blister	13,921	12,957	-7
Refined	42,857	45,043	5
In placer gravels[1]	69,735	79,862	15
Total	141,656	148,890	5

[p]Preliminary
[1]As reported by Banco Minero del Peru, Memoria 1980.

The Banco Minero purchased 73,754 ounces of gold in 1980, a 13% increase over the 65,266 ounces purchased in 1979. The bank exported 64,591 ounces of gold in 1980, mainly to the United States.

The principal producers of gold in ores and concentrates are shown in table 4.

Table 4.—Peru: Principal producers of gold in ores and concentrates

Company	1979 (ounces)	1980 (ounces)	Percent change
Minas Ocoña S.A	13,447	11,402	-15
CENTROMÍN	8,084	5,982	-26
Cía. Minera Castrovirreyna S.A	6,401	5,725	-11
Minas de Arcata S.A	4,232	4,791	+13
Cía. Minera Milpos, S.A	3,957	4,218	+7
Cía. Minera Atacocha S.A	3,892	3,854	-1
Cía. Minera Millotingo S.A	2,931	3,151	+8
Northern Peru Mining Co	2,952	2,776	-6

Iron Ore.—State-owned HIERRO PERÚ and the West German company, Klöckner-Humboldt-Deutz Aktiengesellschaft signed an agreement for a prefeasibility study on the recovery of copper, nickel, and cobalt from tailings of the San Nicolás plant. The study was to include the installation of a sulfuric acid plant. HIERRO PERÚ wants to diversify its production rather than rely solely on iron ore, which has suffered from a depressed market for several years. HIERRO PERÚ's 1979-80 production, by categories, is shown in the following table, in thousand metric tons:

Production	1979	1980	Projected 1981
Pellets	1,784	1,564	2,235
High-grade sinter feed	1,953	2,800	3,048
Pellet feed in slurry form	530	265	--
Pellet feed in cake form	1,177	1,076	1,422
Total	5,444	5,705	6,705

Iron exports in 1980 amounted to 5,586,500 tons, of which Japan purchased 44% and Korea, 31%. Smaller shipments were sent to Romania, Yugoslavia, the United States, Argentina, and Czechoslovakia.

Lead and Zinc.—CENTROMÍN remained Peru's largest lead and zinc producer by a wide margin. Improved metal recovery of the concentrates were obtained at its Cerro de Pasco and Morococha units. Lower production from the medium mining sector reduced the overall positive effects of gains made by CENTROMÍN and some privately held companies, as shown in table 5. Labor problems and an emphasis on silver recovery on the part of several companies were responsible for decreases in production from the private sector.

Table 5.—Peru: Mine output of principal lead and zinc producers

NA Not available.

Cía. Minera Milpo, S.A. benefited from the increased ore treating capacity completed in mid-1979. Mine efficiency was also increased to accommodate the new concentrator, which has improved metal recovery and the fine metal content of the concentrates. The company continued work on infrastructural projects. Milpo has a 71% interest in Cía. Promotora de Negocios Mineros "Perú" S.A., which has had encouraging results from exploration at the Colladre polymetallic prospect in Cajamarca. Milpo acquired a 65% interest in the Japanese-owned Cía. Minera Hilarion S.A. An aggressive exploration program has been planned for this lead-zinc-silver deposit located in Huallanca, Department of Huánuco, where ore reserves are estimated at 9 million tons, grading 3% lead, 7% zinc, and 2.5 ounces of silver per ton.

MINERO PERÚ's Cajamarquilla zinc refinery was expected to initiate operations in March 1981. The 101,500-ton-per-year plant is expected to produce about 54,000 tons of high-grade zinc in 1981 and will require at least 200,000 tons of concentrate per year for full capacity production. The bulk of the concentrate will come from small- and medium-sized operators in the central region as well as from CENTROMÍN, whose La Oroya refinery can produce about 75,000 tons of zinc per year. In addition to zinc, the new Cajamarquilla refinery should produce about 350 tons of refined cadmium, 1,650 tons of copper cement, 14,900 tons of lead-silver residues, and 176,000 tons of sulfuric acid per year. This latter product has caused some negative public reaction because of environmental dangers resulting from transport of sulfuric acid to end users. MINERO PERÚ expects to ship about 110,000 tons per year to its Cerro Verde Mine operation in southern Peru, using truck transport as far as Pisco, where it would then go by sea to the Port of Matarani. Sulfuric acid production is also expected to be sold to other mining companies and the export market.

Manganese.—Peru has not reported manganese production since the closure of the Minas de Gran Bretaña operation in 1976. In the near future, Cía. de Minas Buenaventura, S.A., expects to recover manganese compounds from its Uchucchacua silver-lead mine where a lixiviation plant has been planned. Manganese will be recovered as manganese dioxide, ferromanganese, and manganese sulfate. The company anticipated it may take 3 years to complete the metallurgical studies involved. The new

plant is also expected to enhance silver recovery to about 90%.

Molybdenum.—In mid-1980, SPCC completed the installation of its new molybdenum concentrator at Caujone. The immediate visible effect was a doubling of SPCC's molybdenum production to 2,658 tons from 1,182 tons in 1979. Additional tonnage came from small operators such as Cía. Minera Turmalina in northern Peru and Cía. Minera San Diego in the Department of Apurímac, southeast of Lima. Development work planned for 1981 at the San Diego Mine could halve its output that year.

Taminsa, S.A., was exploring the Aries molybdenum deposit located in the District of Chacas, Province of Huari, Department of Ancash. Preliminary work indicated that ore reserves could amount to 220 million tons containing 0.4% to 0.5% molybdenite and some tungsten. A foreign partner may join Taminsa to develop this property, which was estimated to require about $7 million for preliminary development studies.

In northern Peru, another potentially large deposit containing molybdenum along with copper and silver was under study by a Hochschild Group company, Mina de Tamboras, S.A. Reserves were estimated at 100 million tons of ore averaging about 0.16% molybdenite and 20 million tons of combined molybdenum-copper-silver ore.

Silver.—A lower silver content in CENTROMÍN's copper and lead concentrates and labor problems at the La Oroya metallurgical complex reduced the production of silver. This reduction was balanced by a generally increased output from the medium mining section, as shown in table 6.

Table 6.—Peru: Principal producers of silver in ores and concentrates

(Recoverable content in thousands of ounces)

Company	1979	1980	Percent change
CENTROMÍN	10,465	10,235	-2

Cía. Minera Caylloma, S.A	606	1,135	87
Cía. Minera Millotingo, S.A	1,033	1,120	8
Cía. Minera Atacocha, S.A	1,039	1,026	-1

Cía. de Minas Buenaventura, S.A., remained the largest private producer of silver from its four units: Julcani and Huachocolpa in the Department of Huancavelica; Orcopampa in Arequipa; and Uchucchacua, located 120 kilometers northeast of Lima. Buenaventura also has an interest in Cía. Minera Colquirrumi (52.5%), Cía. Minera Condesa (92.4%), and Sociedad Minera El Brocal, S.A. (11%), and Cía. Minera Toachi S.A. (33%).

The Hochschild Group, an international enterprise, has long been an active participant in Peruvian mining. The group mines silver from Minas de Arcata, Cía. Minera Pativilca, Cía. Minera Condoroma, Cía. Minera Caylloma, and Cía. Minera Locumba. An aggressive exploration program has been initiated for expanding activities, preferably with Peruvian capital participation.

Hochschild's Arcata Mine is under an expansion program to increase milling capacity to 600 tons per day along with the construction of a 3.8-megawatt hydroelectric plant. At the San Cristóbal Mine, owned by Cía. Minera Caylloma and located in the Department of Arequipa, expansion is planned to increase capacity from 300 to 500 tons per day. Reserves have been estimated at over 4 million tons averaging 8 ounces of silver and 0.016 ounce of gold per ton.

Colquiminas, S.A., which operates the silver-lead-zinc Cacachara Mine between Tacna and Puno in the District of Santa Rosa, Department of Puno, produced 380,000 ounces of silver in 1980. Reserves have been estimated at 1 million tons averaging 12 ounces of silver per ton. The company has been exploring lower levels of this underground mine in an attempt to increase reserves.

The Salpo Mine, located near Quiruvilca in the Department of La Libertad and owned by the Arias Group, was reactivated. A new 200-ton-per-day plant was under

construction to service the Salpo Mine and the new Urumalqui Mine when it starts production in 1982. Urumalqui is located about 15 kilometers east of the Salpo Mine.

The Farallón Mine, owned by Unidad Minera (Arias Group) opened in 1980. Production was about 180 tons of concentrates per month, averaging 26 ounces of silver per ton. A new mill is planned to increase capacity from 80 to 180 tons per day. Improvements toward the recovery of concentrates are also planned.

Cía. Minera Los Andes, S.A., reopened the Sucuitambo Mine, formerly owned by the Hochschild Group and shut down in 1962. The Sucuitambo operation consists of two units, the Nora and the Maria. A 120-ton-per-day mill has been installed. The ore averages 8 to 10 ounces of silver per ton with traces of gold. In 1980, the mine produced 36,000 ounces of silver, but production is expected to increase to 120,000 ounces in 1981.

Tungsten.—In 1980, production from the Pasto Bueno Mine of Fermin Malaga Santolalla e Hijos Negoc. Minera rose above that of CENTROMÍN's San Cristóbal Mine, which continued its downward trend. Pasto Bueno is located in the District of Pampas, Department of Ancash, and has been in operation since 1910. New exploration, high ore grades, plant expansion, the installation of more modern equipment, and a worker incentive program contributed to the company's 54% increase in production over that of 1979 and made it Peru's largest tungsten producer in 1980. Reserves were believed to be sufficient for about 20 years of operation.

Minera Regina, S.A., the third largest tungsten producer, also increased production during 1980. Its concentrate production was almost equal to CENTROMÍN's, although the WO_3 content was lower than CENTROMÍN's.

Production by company in 1979 and 1980 was as follows, in metric tons of WO_3 content:

Company	1979	1980	Percent change
Malaga Santolalla	192	296	+54
CENTROMÍN	403	209	-48
Minera Regina, S.A.	102	145	+42
Small producers	58	50	-14
Total	755	700	-7

NONMETALS

Barite.—Through a loan of $1.5 million from NL Industries Inc.'s Baroid Div., Cesibar, S.A., opened a new barite mine in 1980. The mine, the Santa Cesilia, is located near the Graciela Mine in Huarochirí Province east of Lima. Graciela is owned by Baroid's subsidiary company, Perubar, S.A., and was Peru's major barite producer.

Cement.—The Government reached a financial settlement with Cemento Andino, S.A., over its expropriation of 49% of the 500,000-ton-per-year cement plant at Tarma. The Government was also expected to increase its interest to 49% in the 1-million-ton-per-year Cementos Norte Pacasmayo, S.A., plant. At Cemento Yura, S.A.'s plant in Arequipa, a 1,000-ton-per-day dry process kiln was added with startup scheduled for 1980.

Phosphate.—A new company, Empresa Promotora Bayóvar (PROBAYOVAR), owned by MINERO PERÚ (70%) and two other state agencies, COFIDE and the Empresa Nacional de Comercialización de Insumos, was created in 1980 to study the development of the Bayóvar phosphate deposits in northern Peru. In July, the company received a $7.5 million loan from the World Bank to further study the technology and economic viability of exploiting the deposit, which has ore reserves of 600 million tons and potential resources of up to 10 billion tons. A pilot plant has been constructed as part of the study. The study is also expected to include a determination of whether uranium can be economically extracted from the phosphoric acid. Another study will determine the extent of potash reserves near Bayóvar, which have tentatively been estimated at 8.3 million tons of potassium chloride.

The 1980 production of phosphoric rock decreased at the Bayóvar concentrator because of a 33% decrease in employee working hours. Personnel were diverted to storage yard construction work and also to work for PROBAYOVAR.

MINERAL FUELS

Coal.—MINERO PERÚ was considering new plans for the development of the Alto Chicama coal deposit. Three alternative plans were proposed using production levels of 1, 2, or 3 million tons per year. The proposals included the possibility of pro-

ducing coal for export. The need for market studies added to the factors responsible for delaying the implementation of the project.

At the Jatunhuasi coal deposit, located 45 kilometers northeast of Huancayo, CENTROMÍN has identified 80,000 tons of proven and probable semi-bituminous coking reserves, and inferred reserves of 10 million to 15 million tons. Exploration was to continue in an attempt to locate proven reserves of between 750,000 tons and 1 million tons. CENTROMÍN requested a credit from the United Nations Rotary Fund to finance the exploration and feasibility study. It was reported that CENTROMÍN planned to open up one of the three coal layers so far identified.

Petroleum and Natural Gas.—In July 1980, the Government concluded contract renegotiations with Occidental Petroleum Corp. and Belco Petroleum Corp. in accordance with the December 1979 guidelines governing oil contracts with foreign contractors.

Under the Occidental contract, PETROPERÚ will be the supervisor, title-holder, and owner of all the production in the contract area. Occidental will receive in kind a share of production as compensation for its services. This share will be based on the daily volume and can range from 42% to 50%. The price paid to Occidental for crude, which will be sold domestically in Peru, will vary according to fluctuations in the value of Middle Eastern crudes, while the price of crudes sold to PETROPERÚ for their export market will be set at world prices. Occidental will receive 50% of the total volume of natural gas produced in the contract area. In addition, Occidental agreed to provide training for PETROPERÚ's personnel and to pay PETROPERÚ annually the sum of 1.9 billion soles (about $5 million) for a period of 20 years in order to help the state company in its development of the oil industry.

The new Belco contract provided them with 50% of the total oil produced in the contract area, Block Z-2A. Out of this production share, the company will be responsible for the payment of income taxes directly to the Peruvian Government. Other terms are similar to those agreed by Occidental. Belco also signed an agreement for the sale of natural gas, whereby Belco will receive $1.50 per thousand cubic feet for the first 15 million cubic feet per day, escalating to $3.00 per thousand cubic feet for deliveries exceeding 20 million cubic feet per day. Contract terms for the currently nonproducing Block Z-1A area are similar to those for Block Z-2A, and the Belco Group will share equally with PETROPERÚ in case there is any production in the future. In 1980, Tenneco Oil Co. and Champlin Petroleum Co. withdrew their association with Block Z-2A, leaving Belco as the operator holding 75% and Union Oil Co. with 25%.

Similar negotiations were held with the Occidental-Bridas Exploraciones y Producción of Argentina Group, and an agreement was reached that generally conformed to the Occidental and Belco contracts. In addition, the Occidental-Bridas contract included the agreement to form a new company, Petrolera Latinomericana (PETROLATINA), to exploit the partnership's recovery program in the Talara north coastal block. Ownership of PETROLATINA was defined as Occidental 49%, Bridas 25%, and PETROPERÚ 26%. The Occidental Group became a service contractor, receiving a fee on all petroleum produced instead of sharing 49% of the increased output resulting from the program. The group will pay Peruvian income taxes on the fees earned. The fee can escalate in line with a formula involving Middle Eastern oil prices. However, by the end of 1980, no action had been taken to form the new company, and the project continued as before with Occidental holding 84% of the equity and Bridas 16%, and 51% of production sold to PETROPERÚ.

Waterflooding operations began in August 1980 in the Talara area. Occidental drilled more than 288 wells in this area during 1980. Since the project began in 1978, Occidental has drilled more than 600 wells at Talara. During this period, no secondary recovery crude has been lifted, but new primary output has increased production from 6,000 barrels per day to 17,700 barrels per day.

Occidental's northeastern jungle fields continued to produce at near the capacities of the spur line, the Trans-Andean Pipeline, and the river barge fleet. In 1980, 12 jungle fields in which Occidental held a 50% interest produced about 106,000 barrels per day. Occidental has drilled a total of 210 wells in this area since 1977, and exploration efforts in 1980 resulted in extensions to the San Jacino and Dorissa Fields. A wildcat was also drilled in the Tigre prospect.

Peru's total estimated 1980 crude oil production, in barrels per day, by company, was as follows:

Company	1979	1980
PETROPERÚ	51,184	43,960
Occidental	106,180	105,885
Belco	28,329	27,984
Occidental-Bridas	5,957	17,702
Total	191,650	195,531

In 1980, a $32.5 million loan was received from the World Bank to finance the major part of a 3-year program to improve production capabilities of PETROPERÚ's jungle and northwest coastal operations. Improvements included the installation of 35 pumps in the northern jungle fields, pumping systems to reactivate primary production from the coastal fields; a study on a secondary recovery project for the Brea-Pariñas coastal area; seismic surveys; and consultant services.

PETROPERÚ opened new areas in the jungle for exploration and several agreements were under negotiation during 1980. The first contract basis agreement—considered a preliminary step for the later signing of an operations contract—was signed in October with Royal Dutch/Shell. This agreement covered Blocks 38 and 42 in the southeastern jungle region in the Alto Ucayali and Madre de Dios Basins below latitude 7° S. It was reported that Shell has planned to initially invest $100 million in the project. Final agreement remained dependent on negotiations regarding production split, taxes, and other matters.

The Superior Oil Co. and Petrolera General S.A., a subsidiary of Phoenix Canada Oil Co., Ltd., were negotiating for exploration rights to Block 2, which consists of about 2.5 million acres in the northeastern jungle south of Occidental's Block 1-A and east of the Río Santiago. Final agreements with both the Shell and Superior groups were expected early in 1981.

At least 14 other companies have expressed an interest in initiating negotiations with PETROPERÚ for exploration or secondary recovery projects. Among those mentioned were Husky Oil Co., Mapco, Allied Chemical Corp., C and K Petroleum, Conoco, Mobile, Gulf, Elf-Aquitaine, Petroleos Brazileira S.A., Cities Service, Sun Oil Co., Phillips Petroleum Co., Coastal State, Marathon Oil Co., British Petroleum Co., and two local companies, Petroinca and Petroleos del Norte S.A.

The late 1980 changes in the petroleum law and the forthcoming implementing regulations are expected to influence final investment decisions by Shell and other interested companies.

Uranium.—The Instituto Peruano de Energía Nuclear announced that rich uranium deposits were located north of Lake Titicaca near the Bolivian frontier. Geological indications of uranium were also reported near Oxapampa in Pasco Department.

Decree Law 23112 of 1980 governs investment in the mining of radioactive minerals. It provides guarantees concerning the remittance of profits abroad, tax exemptions, and stability until the year 2010. Foreign participation in the exploration and exploitation of uranium was indicated as being acceptable with the restriction that those areas of highest potential are reserved for the Government.

The Mineral Industry of the Philippines

By John C. Wu[1]

The Philippines economic performance as measured by the growth of real gross national product (GNP) in 1980 was not so remarkable as that of other resource-rich Southeast Asian countries, such as Malaysia, and Indonesia. Its 4.7% increase in real GNP was considered better than advanced industrial nations in the Western World affected by world inflation, recession, and a series of oil price increases. The country's output performance as measured by real gross domestic product (GDP) managed to advance a modest growth of 5.2% in 1980. However, by industry sector, real gross value added by mining and quarrying increased 10.1% in 1980, second only to the smallest but fast-growing electricity, gas, and water sector, which registered a 16.4% in real growth.

In 1980, the mining and quarrying sector contributed US$315 million[2] in 1972 constant dollars to the country's GDP of US$12,325 million in 1972 constant dollars.

Despite its relatively small contribution to the country's GDP, the mining industry remained an important sector of the Philippines economy. In 1980, the Philippines remained 1 of the top 10 world producers of copper and gold. Other important metallic mineral commodities produced by the country were nickel, cobalt, chromium, and silver. The industry's output of copper, gold, and nickel were among the top 10 foreign exchange earners, which have generated a substantial amount of foreign exchange compensating for the growing import bills of crude petroleum and capital goods. The mining and quarrying industry was also one of the fast-growing sectors among the Philippines major industry sectors in terms of the real gross-value-added for the past years.

Five major industrial projects related to the mining sector were started in 1980. A joint venture agreement between the Government of the Philippines and Reynolds Aluminum Co. of the United States was signed in February 1980 to build a $460 million aluminum smelter with an annual capacity of 140,000 tons in Misamis Oriental, on the Island of Mindanao, to be completed in 1985. Construction of the Philippines first $250 million copper smelter started at Isabel of southern Leyte in August 1980. The owner and operator of the smelter chose a Japanese consortium composed of Marubeni Corp., Sumitomo Corp., and C. Itoh & Co., as its major foreign partner. The project is expected to be completed in 1983 with an initial output of 138,000 tons per year of refined copper, 195,000 ounces of gold, 850,000 ounces of silver, and other byproducts such as selenium and sulfuric acid. A joint venture agreement between the Philippines and West German concerns was finally approved by the Philippines Board of Investment to start a $40.2 million iron ore mining and milling project in Antipolo Rizal by yearend 1980. The proposed plant would have an annual capacity of 1.5 million tons of iron ore concentrate for export by 1984. Under the Philippines cement industry rationalization program, the first of five 1-million-ton-per-year, coal-fired cement plants was started by Negros Cement Corp. at Basay, Negros Oriental, in June 1980, and a $33.3 million contract was awarded to Krupp Polysius A.G. of the Federal Republic of Germany to convert nine oil-fired cement plants to coal in the Philippines in November 1980. The Philippines has selected Isabel of Leyte Island as its first phosphatic fertilizer plant site and invitation-to-bid papers were sent

to four consortiums in August 1980. The estimated $370 million fertilizer project was expected to start in the spring of 1981 and be completed by February 1983. Upon completion of the project, the complex would have a sulfuric acid plant, a phosphoric acid plant, a granulation plant, and an ammonium sulfate plant. The planned output capacity of phosphatic fertilizer is 350,000 tons per year. A joint venture agreement between the Government of the Philippines and Billiton International Metals B.V., a wholly owned subsidiary of Royal Dutch/Shell, was signed in September 1980 to create an investment firm. The $100 million joint venture investment company will be involved in various domestic mining projects, which include mining of copper, zinc, lead, nickel, tin, tungsten, molybdenum, chromium, and associated nonferrous metals. Under the agreement, the National Development Co. (NDC) would hold 60% equity of NDC-Shell Mineral Investment Co., and the remaining 40% would be held by Billiton B.V.[3]

The Philippines has made significant progress in coal production as well as in exploration. However, the country suffered a major setback in 1980 when the output of the offshore Nido Oilfield, the country's only active oilfield, northwest of Palawan Island, dropped drastically from the peak level of 40,000 barrels per day in September 1979 to 10,000 barrels per day in mid-1980 and down to 3,500 to 4,500 barrels per day by yearend 1980.

During 1980, the Government of the Philippines issued four new laws related to the country's mining sector. On February 19, 1980, the President of the Philippines issued a new decree No. 1677, which states that "in case the foreign service contractor or another foreign company holds equity in the local mining corporations involved in the service contract, the equity participation including the service fee shall in no case exceed 40% of the net proceeds of the operations before tax."[4] These are among the terms and conditions set forth by new regulations for the approval of service contracts for the exploration, development, exploitation, and utilization of mineral resources. On March 11, 1980, the President issued Executive Order No. 581, to reimpose a 4% basic export tax and a 40% premium duty (up from 10%) on gold, silver, copper ore and concentrate, and refractory chromite. But the President suspended the order on March 27, 1980, until a mutually acceptable formula was worked out by the Government and industry. On August 1, 1980, Executive Order No. 609 was issued by the President. The executive order, effective January 1, 1981, provides the latest modification of the Philippines tariff schedule, to be implemented in up to five stages over the next 5 years, which will reduce the tariff on many imports. The minimum tariff rate in general is 10% for producer goods not available locally, and 5% for certain critical raw materials needed by the country's various manufacturing industries.[5] On September 18, 1980, a new decree called Batas Pumbansa No. 84 and Presidential Decree 1924, were signed by President Marcos. Under Batas Pumbansa No. 84, the royalty taxes (ad valorem) on minerals and mineral products will raise from 1.5% to 2% on the actual market value of gross output to 5% on such products as gold, silver, and copper. The accompanying Presidential Decree No. 1924 gave the President the power to revise the rates of taxes and classifications of mineral products, as well as to prescribe the rates to tax in the case of marginal mines, which require protection, assistance, and incentives.[6]

PRODUCTION

The Philippines overall mineral production, in terms of the value of preliminary estimated output, increased 33.3% in 1980 over that of 1979. Of the total minerals produced in the Philippines, the following commodities registered a gain in the output value of 1980: Gold increased 42%; silver, 83%; cobalt, 2.7%; copper, 42%; nickel, 46.9%; bentonite, 30.3%; cement, 27.1%; coal, 15%; silica sand, 24.2%; and sand and gravel, 20.0%. The commodities that registered a drop in the output in 1980 were lead, decreased 28% in value; molybdenum, 59.9%; zinc, 30.6%; metallurgical chromium ore, 53.9%; and unwashed manganese ore, 40.2%. The main reasons for increased minerals output were various new mines came onstream in 1980, some old mines were rehabilitated, and various mining and milling capacities were expanded as a result of higher world commodity prices. Those commodities that suffered a decline in output mainly resulted from declining ore grade, breakdown of machinery and equipment, as

well as depressed market prices. The Philippines only oil output was from its Nido Oilfield. The oil flow dropped sharply from 40,000 barrels per day in September of 1979 to 3,500 to 4,500 barrels per day by yearend 1980. According to Cities Service, the operator of the Nido Oilfield, and the Ministry of Energy, the Nido Oilfield is approaching exhaustion.

Table 1.—Philippines: Production of mineral commodities[1]

(Metric tons unless otherwise specified)

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.

[1]Table includes data available through July 10, 1981.

[2]In addition to the commodities listed, the Philippines produces platinum-group metals as byproducts of other metals, but output is not reported quantitatively and no basis is available to make reliable estimates of output levels.

[3]Reported figure.

[4]Includes "pebbles" and "soil," not further described.

[5]Excludes limestone for road construction, reported in cubic meters, which totaled 9,687 cubic meters in 1978 and 2,932 cubic meters in 1979 (other years not available).

[6]Includes materials described as "rock, crushed or broken," "stones, cobbles, and boulders," "rock aggregates," and "broken adobe."

TRADE

In 1980, the Philippines total export earnings were valued at $4.64 billion, a 22.8% increase from $3.78 billion for 1979. Total imports were valued at $6.39 billion, a 15.3% increase from $5.54 billion for 1979. The resulting negative balance of $1.75 billion for 1980, however, represents only a slight improvement from the $1.76 billion merchandise trade deficit recorded in 1979. This was due mainly to larger import bills that arose from the higher prices of crude oil and capital goods.

Copper, gold, and nickel were among the Philippines top 10 foreign exchange earners along with sugar, coconut oil, garments, lumber, bananas, and electric and electronic equipment and parts. In 1979, copper exports, valued at $481.2 million, accounted for 12.7% of total export earnings; gold exports, valued at $104.6 million, accounted for 2.8%; nickel exports, valued at $99.6 million, accounted for 2.6%; cobalt exports, valued at $51.2 million, accounted for 1.4%; and refractory chromite ore exports, valued at $22.3 million, accounted for 0.6%. The main copper importing countries were Japan, which accounted for 75%; South Korea, 10%; and the United States, 6%. The main purchasers of gold were Japan, accounting for 69%; the United States, 16%; and South Korea, 9%. The major buyers of nickel were the United States, accounting for 31%; Japan, 30%; and the Netherlands, 28%. Of the total cobalt exported, 98% was shipped to Japan. In 1980, the configuration of export destination for the major metallic minerals remained substantially the same as in 1979.

Mineral fuels, machinery other than electric, base metal (iron and steel) transport equipment, materials for the manufacture of electrical and electronic machinery, and chemical elements and compounds were among the top 10 principal imports of the Philippines in 1979. The imports of these six major items were valued at $4.0 billion, and accounted for over 70% of the value of overall merchandise imported by the Philippines in 1979. The main suppliers of principal imports in 1979-80 were Japan, the United States, the European Economic Communities, and the Middle East countries.

During 1979-80, the major trading partners of the Philippines, based on the value of two-way trade, were the United States, Japan, the European Economic Communities, and Middle East countries (mainly Saudi Arabia and Kuwait).

Table 2.—Philippines: Exports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1978	1979	Destinations, 1979	
			United States	Other (principal)
METALS				
Aluminum metal including alloys:				
Unwrought	--	1,050	--	Hong Kong 850; Taiwan 200.
Semimanufactures	1,894	924	--	Hong Kong 652; Indonesia 76; Malaysia 76.
Chromium:				
Chromite	402,247	304,952	123,849	Japan 91,922; Netherlands 16,000; China, mainland 15,525.
Concentrate	53,434	191,818	29,098	Japan 112,040; China, mainland 18,880; Brazil 11,800.
Copper:				
Ore and concentrate thousand tons	895	1,048	58	Japan 797; Republic of Korea 111; Taiwan 39; U.S.S.R. 20.
Metal including alloys:				
Scrap	1,270	792	--	Japan 498; Taiwan 198; India 66; Belgium 19.
Matte	8	10	--	All to Japan.
Unwrought and semimanufactures kilograms	--	845	--	All to Hong Kong.
Gold:				
Metal in copper ore and concentrate troy ounces	411,169	367,211	62,738	Japan 258,597; Republic of Korea 21,158; Taiwan 15,305.
Bullion do	1,227	--		
Iron and steel:				
Ore and concentrate thousand tons	3,280	4,100	--	Japan 4,018; Taiwan 82.
Roasted pyrite	54,992	33,079	--	All to Taiwan.
Metal including alloys:				
Scrap	2,749	2,530	--	Taiwan 1,315; Japan 1,157.
Pig iron and similar materials	4	23	--	All to Republic of Korea.
Ferroalloys:				
Ferrosilicon	11,398	10,117	--	Japan 8,222; Indonesia 1,232; Thailand 522.
Other	756	1,021	--	Japan 1,011; Australia 10.
Semimanufactures:				
Bars, rods, angles, shapes, sections	227	283	--	Guam 282.
Universals, plates, sheets	51,414	78,195	3,788	Taiwan 39,127; Thailand 22,574; Indonesia 8,636.
Hoop and strip	396	2,950	--	All to Malaysia.
Wire	--	25	--	All to Japan.
Tubes, pipes, fittings	151	2,808	--	Australia 1,998; Singapore 404; France 339.
Castings and forgings, rough	517	905	746	Australia 156; Singapore 3.
Lead, ore and concentrate	2,268	5,574	--	All to Japan.
Manganese ore and concentrate	7,715	7,383	--	Taiwan 5,396; Japan 1,987.
Molybdenum ore and concentrate	41	210	44	West Germany 152; Netherlands 14.
Nickel:				
Ore and concentrate	578,034	704,299	--	All to Japan.
Metal including alloys:				
Scrap	85	--		
Unwrought	12,016	14,791	5,332	Netherlands 5,470; Japan 1,742; Romania 1,556.
Semimanufactures	1,166	2,416	1,005	Japan 900; Canada 332; Netherlands 179.
Silver metal including alloys, unworked and partly worked:				
Silver, including silver gilt and platinum-plated silver troy ounces	16,464	168,195	--	Hong Kong 166,196; Switzerland 1,999.
Rolled do	--	5,370	--	All to Hong Kong.
Tin metal including alloys, waste and scrap	21	403	33	Indonesia 294; Japan 70; Hong Kong 6.
Tungsten metal including alloys, waste and scrap kilograms	--	393	393	
Zinc:				
Ore and concentrate	16,126	22,295	3,277	Japan 19,018.
Metal including alloys:				
Scrap	--	305	--	Japan 270; Taiwan 20; Singapore 15.
Blue powder	40	--		
Semimanufactures	--	15	--	All to Hong Kong.
Other: Ash and residue containing nonferrous metals	2,291	1,949	11	Japan 982; Taiwan 784; Singapore 93.
NONMETALS				
Abrasives:				
Emery, pumice, natural corundum, etc	17	--		
Grinding and polishing wheels and stones kilograms	--	6	--	All to Indonesia.
Asbestos do	250	--		

See footnotes at end of table.

Table 2.—Philippines: Exports of mineral commodities —Continued

COMMODITY REVIEW

METALS

Aluminum.—NDC, the investment arm of the Philippines Government, and Reynolds Aluminum Co. of the United States, signed a 50-50 joint venture agreement in February 1980 to build the country's first aluminum smelter on Mindanao Island. The 140,000-ton smelter was expected to be operational in 1985 at a cost of $460 million. A decision was finally made in October 1980 to build the smelter at Claveria near Cagayan de Oro, Misamis Oriental Province, on the Island of Mindanao. Mindanao Island reportedly is not only capable of supplying the proposed smelter with an adequate, reliable, and cheap hydroelectric power but also offers better harbor facilities with a deepwater port capable of serving bulk carriers of up to 250,000 deadweight tons.

In July 1980, the United Nations Development Program granted the Philippine Government a $2 million loan for the survey of the bauxite deposits on Samar Island, central Philippines. The survey would be undertaken by the Philippines Bureau of Mines and Geo-Sciences. The initial exploration indicated the bauxite deposits on the Samar Island were medium grade, containing between 40% to 50% Al_2O_3. The initial estimate of ore reserves was 63 million tons of bauxite with a possible total reserve of about 100 million tons.[7] The development of this bauxite deposit was expected to proceed according to the time schedule of the aluminum smelter project on Mindanao Island, which was expected to use locally mined bauxite mainly from Samar Island.

Chromium.—The Philippines is an important world producer of refractory- and metallurgical-grade chromite. In 1979, its share in the total chromite production of the world was 6%. The overall production of chromite in 1980 declined from that of 1979. Consolidated Mines Inc. contributed 94% of the total refractory chromite ore produced in the first half of 1980, followed by Amer-Asia Mining and Development Corp., 3%; Pulsar Mineral Resources, Inc., and Capital Mineral Resources and Development Co., Inc., 3%. Production of metallurgical chromite ore was by 11 companies. Based on the output of the first half of 1980, the leading six producers were: Velore Mining Corp. accounting for 15.4%; Chrome Ore Minerals Exponents Inc., 14.7%; Palawan Consolidated Mining Co., Inc., 11%; San Grace Mining Corp., 10.3%; Antonio Roa, Jr., 10.3%; and Davao Timber Corp., 10%. The remaining output was by Lino Duhaylungsod, Apollo Talampas, Misamis Exploration Corp., Loyalty Mining and Development Corp., and Santiago Mining Corp. Production of metallurgical chromite concentrate by three companies in the first half of 1980 was as follows: Acoje Mining Co., 71% of total output; and Trident Mining and Industrial Corp., 29%. The other metallurgical chromite concentrate producer, Golden Arrow Mining Co., Inc., stopped operation on January 17, 1980.

Ferrochrome Philippines, Inc., a joint venture of the Herdis Group of Manila and Vöest Alpine AG of Austria, began construction of a P450 million ferrochrome plant at Tagaloan, near Cagayan de Oro, Misamis Oriental, on Mindanao Island in December 1980. The ferrochrome plant would have an annual capacity of 52,000 tons of ferrochrome. Acoje Mining Co., a major producer of metallurgical chromite concentrate as well as another Herdis-Vöest Alpine joint venture company, will supply the metallurgical chromite concentrate to the plant. Vöest Alpine will finance not only the entire project, but will also provide the necessary technology and the marketing of ferrochrome in Japan, the United States, and Australia.

Alamag Corp., a wholly owned subsidiary of Bayer AG of the Federal Republic of Germany, will build a P87.5 million chemical-grade chromium processing plant at Isabela on Samar Island. The chromite deposits were discovered by Island Mining and Industrial Corp., and the chromite deposits in the Isabela area were estimated at 1.93 million tons. Plans call for the chrome processing plant to be operational by 1983 with an initial annual chrome ore processing capacity of 100,000 tons.

In 1980, Golden Arrow Mining Co. expanded its metallurgical chromite milling capacity from 400 to 600 tons per day by installing additional vibrating tables and other equipment at its Silanguin project in Zambales. The company also decided to operate its second chromite project at Bacungan, Palawan, with a planned capacity of 1,000 tons per day, expected to be operational by yearend 1980. Acoje Mining Co. began an expansion and modernization

program at its chromite property at Santa Cruz, Zamabales, to assure a continuous supply of chromite ore and concentrate to the company's overseas consumers, mainly Japan.

According to the Philippines Bureau of Mines, the principal chromite ore reserves of the Philippines were estimated in 1979, as follows:

Owner and/or operator	Mine location	Estimated reserves (tons)	Cr_2O_3 (percent)
Metallurgical chromite:			
Island Mining and Industrial Corp	Divilacan, Isabela	50,700,000	48.00
Acoje Mining Co., Inc	Sta. Crux, Zambales	4,367,470	21.00
Golden Arrow Mining Co., Inc	Puerto Princesa, Bacungan, Palawan.	3,841,290	17.50
Trident Mining and Industrial Corp	Nara, Lapu-Lapu, Palawan.	2,448,782	26.93
Palawan Consolidated Mining Co., Inc	Irahuan, Palawan	1,880,497	35.25
Masinloc Chromite Mining Co., Inc	Masinloc, Agop-op, Candelaria, Zambales.	950,000	32.00
Refractory chromite:			
Consolidated Mines, Inc	Masinloc, Coto, Zambales.	4,811,830	30.45
Armon Mining and Development Corp	Sta. Cruz, Zambales	720,000	20.00

Cobalt.—Cobalt production in the Philippines was by Marinduque Mining and Industrial Corp. (MMIC), the only cobalt producer in the country. Cobalt was extracted and recovered as a byproduct from the company's Nonoc nickel project at Surigao nickel mine and refinery on Nonoc Island. MMIC finalized the plant engineering to increase cobalt recovery at its Nonoc nickel project, which will cost $13 million. The project was expected to be operational by 1981, and a net savings of $8 million per year was anticipated based on prevailing cobalt prices.

Copper.—The Philippines was the world's ninth largest copper producer, accounting for about 4% in 1979. Copper mining remained the major industry of the Philippines mining and quarrying sector as well as the top foreign exchange earners of the Philippines export sector. Based on the value of mineral production, copper accounted for 42.5% of an estimated $1.6 billion worth of minerals produced in the Philippines for 1980.[8]

While total mine output of copper in 1980 increased only moderately from that of 1979, a remarkable 41.4% increase in value of mine output was recorded (from $494.6 million in 1979 to $699.3 million in 1980) owing to higher world copper prices.

Copper production was mainly by 13 primary copper producers, which accounted for 99% of the country's total output, and the remainder was by other producers. The major primary copper producers were: Atlas Consolidated, which operated three open pit mines and one underground mine at Toledo in Midwestern Cebu, accounting for 42% of total mine production; Marcopper at Santa Cruz on Marinduque Island, 11%; Benguet Corp. (formerly Benguet Consolidated) at San Marcelino in Zambales, 8%; Philex at Tuba in Benguet, 7%; CDCP Mining at Basay in Negros, 6%; MMIC at Bagacay on Samar Island and at Sipalay in Negros, 6%; Lepanto at Mankayan in Benguet, 5%; Western Minolco at Atokim in Benguet, 4.7%; Sahena at New Bataan in Davao del Norte, 3%; Consolidated Mines at Mogpog in Marinduque (suspended copper operation in August 1980 to ease mounting cash problems), 2.3%; Baguio Gold at Tublay in Benguet, 2%; and the remaining 2% was by Black Mountain at Tuba in Benquet and Acoje at Mabini in Pangasinan.

During 1980, two copper mines came onstream. Dizon copper-gold project of Benguet Corp., located near San Marcelino in Zambales Province, began operation on January 7, 1980. The total cost of the project was $90 million plus $16 million in financing charges. The complex includes an open pit mine, a 17,000-ton-per-day copper flotation concentrator, and a port. Annual output was expected to be 27,200 tons of copper, 100,000 ounces of gold, and 220,000 ounces of silver. Ore reserves of the area were

estimated at 90 million tons with 0.45% to 0.60% of copper and 0.02 to 0.03 ounce of gold per ton of ore. Azure Mining started up a 500-ton-per-day copper mill in Pilar, Capiz, on October 30, 1980, the first on the Island of Panay. The company plans to expand its mill capacity to 2,000 tons per day of ore by 1982.

Expansion projects expected to be completed in 1981 were: CDCP Mining was to expand its milling capacity from 15,000 to 22,000 tons per day at Basay in Negros Oriental Province by yearend 1981; and MMIC was to complete its plant expansion at Sipalay in Negros Occidental Province from 18,000 to 30,000 tons per day by the first quarter of 1981.

Other expansion programs to be completed after 1981 were: Black Mountain, which planned to expand production capacity from 3,200 to 10,000 tons per day at a cost of $18.5 million; and Sabena Mining, which planned to expand its Davao copper project on Mindanao Island from 10,000 to 17,000 tons per day at a cost of $20.8 million.

Additionally, new copper mines were expected to come onstream in the next 5 years: Bully Bueno project of Hercules and Oils, Inc., located in Cacapian, Marcos, Ilocos Norte, to be operational by the second quarter of 1981; and the Mancayan project in Bulalacao, Mancayan in Benguet, scheduled to open in 1982. The Bully Bueno project has a planned initial capacity of 3,000 tons per day of ore yielding 70 to 75 tons of copper concentrate per day. Amacan project of North Davao Mining Corp. awarded a $76 million turnkey project of a mining plant to a Finnish consortium (Outokumpo Oy, Kone Oy, and Rauma-Repola Oy). The consortium will supply the equipment and technology as well as the installation of the copper mining and ore concentrating complex. The San Antonio copper project of Marcopper, near Tapian, was expected to commence early in 1984. The Hinobaan Copper project in Negros Occidental Province, which is a joint venture project between NDC-Shell Mineral Investment Co. and Billiton International Metals B.V. of Royal Dutch/Shell, was to invest $100 million and own 60% of the project. The remaining 40% was to be owned by a group of companies: Lepanto Consolidated Mines Corp., Delta Mining and Industrial Development Corp., and three property claimants: Colet Mining Co., Sta., Barbara Development Co., and South Mining and Exploration Co. Ore reserves of the Hinobaan deposit were estimated at 90 million tons with an average of 0.5% copper.

Based on forecasts made by the Philippines Bureau of Mines and Geo-Sciences, the new copper mines would have an average milling capacity of 10,000 tons per day each. This would increase the Philippines copper concentrate production to about 200,000 tons per year by 1985.

According to the latest company annual reports, estimated reserves of the principal deposits in the Philippines, by owner and/or operator and grade, as of December 1979, were:

Owner and/or operator	Estimated reserves (tons)	Copper (percent)
Atlas Consolidated Mining and Development Corp	900,441,000	0.45
Marcopper Mining Corp	101,200,000	.43
Marinduque Mining & Industrial Corp	651,000,000	.49
CDCP Mining Corp	111,789,000	.45
Philex Mining Corp	154,153,000	.38
Consolidated Mines, Inc	101,767,000	.50
Benguet Corp. (formerly Benguet Consolidated, Inc.)	84,341,000	.45
Lepanto Consolidated Mining Co	5,567,400	.25

The Philippines Associated Smelting and Refining Corp. (PASAR), the owner of the Philippines first copper smelter project, has chosen a Japanese consortium as its major foreign partner of the copper smelter project and the exclusive distributor of 76% or 105,000 tons per year of the smelter's 138,000-ton-per-year output. The Japanese consortium (50% owned by Marubeni Corp., 30% by Sumitomo Corp., and 20% by C. Iton and Co.), will invest $32 million in the project's $100 million equity or a 32% equity position in PASAR. International Finance Corp., a World Bank subsidiary, was offered 5%. The remaining 63% equity will be held by the Philippines Government through NDC (34.3%), and the remainder (28.7%) to be shared by nine local copper producers. The equity contribution of the participating nine mining companies were Atlas, $10 million; Lepanto, $4.65 million; Marcopper, $4.13 million; MMIC, $2.52 million; Sabena, $2.17 million; Philex, $1.81 million; CPCD Mining, $1.81 million; Western Minolco, $1.02 million; and Black Moun-

tain, $0.29 million.[9]

Construction of the $250 million smelter at Isabel in southern Leyete started in August 1980. The support structure was 50% completed as of early October (expected completion to be by the end of 1980). Roadways were 15% completed and plant-site grading was 30% completed. Marubeni Corp. won the turnkey contract for the smelter construction and was expected to ship materials and equipment from Japan to the smelter site in early November. The entire project was scheduled for completion in 1983. During the first year of operation, the smelter was expected to process 480,000 tons of concentrate, produce 138,000 tons of copper, 195,000 ounces of gold, 850,000 ounces of silver, 161 pounds of selenium, and about 480,000 tons of sulfuric acid.

Gold.—The Philippines continued to be one of the top 10 world gold producers. Its share in the world total gold production was about 2% in 1979 and the Philippines was the world's sixth largest producing country. Gold mining remained the second most important industry of the Philippines mining sector. It accounted for about 14% of the value of the Philippines mineral production in 1980. Despite three newly opened gold mines in 1980, gold production increased only moderately over that of 1979. However, the value of gold output rose 42% from $158.2 million in 1979 to $224.6 million in 1980, owing to higher prices of gold, which averaged about $612 per ounce in 1980 compared to $303 per ounce in 1979.

About 30% of total gold produced in 1980 was by 7 primary producers, and 70% was by 12 copper producers, which operated copper and gold mines. The top seven gold producers were: Benguet Corp.—formerly Benguet Consolidated—(both primary and byproduct output), accounting for 28.8% of total gold production; Atlas (primary and byproduct), 23.2%; Philex (byproduct), 18.0%; Lepanto (byproduct), 9.5%; Marcopper (byproduct), 4.0%; Western Minolco (byproduct), 3.9%; and Apex (primary), 3.6%. The remaining 9% of total gold production was by Benguet Exploration, Itogon, Vulcan, and Manila (all primary producers); and Baguio Gold, MMIC, Sabena, CDCP Mining, Black Mountain, and Consolidated Mines (all byproduct producers).

Three new gold mining projects that came onstream during 1980 were: (1) Dizon copper-gold project of Benguet Corp. (see copper section). (2) Masbate gold project of Atlas in Aroroy on Masbate Island (a rehabilitation of an old project at a cost of US$23 million). The site is an open pit mine with a capacity of 3,500 tons per day of ore, capable of producing 90,000 ounces of gold and 100,000 ounces of silver annually. The estimated ore reserves could last 8 years of operation (but further exploration was expected to extend the economic life of the mine). (3) Surigao mining project of Manila Mining Corp. at Placer in Surigao del Norte commenced operation in January 1980. (This is a $6 million gold mill with a capacity of 200 tons of ore per day, capable of producing 1,800 ounces of gold per month. Lepanto acted as general manager of the project for Manila Mining.)

Four other important new gold projects that were expected to come onstream in 1981 or later as a result of higher gold prices were: (1) Surigao Consolidated Mining Co. The old La Suerte gold mining operations at Jose Panganiban, Camarines Norte in Southern Luzon, was to be reactivated at a cost of $6.6 million. The gold mill was expected to be operational in January 1981 with a capacity of 1,000 tons per day. The main source of ore is the Luna Pelang vein with an estimated reserve of 302,000 tons, averaging 0.286 ounce of gold per ton of ore. Surigao Consolidated Mining Co. will also start an open pit mine at Barrio Siana, Mainit, Surigao del Norte, on Mindano Island, during the fourth quarter of 1981. The mill capacity was rated at 1,000 tons per day with an estimated reserve of 3.7 to 4.5 million tons, ranging from 0.5 to 0.17 ounce of gold per ton of ore. The project costs were $7.2 million with an estimated economic life of 10 to 14 years. (2) Philippines Eagle Mines, Inc. (formerly Metal Exploration Asia, Inc.), which took over the property from Marsman and Co. at Panacale in Camarines Norte, will start its Longos gold production operation during the first quarter of 1981. The initial milling capacity would be 500 tons per day. The ore reserves at Panacale were estimated at 1.5 million tons, averaging 0.5 ounce of gold per ton of ore. The project costs were $29 million including a $20 million mill plant. (3) Gold Arrow Mining Co., an important metallurgical-grade chrome ore and concentrate producer, will start operation of its Labo gold project in Camarines Norte in January 1981 with a capacity of 1,000 tons per

day. The proven ore reserve of the area was expected to last 5 years. The company was reportedly planning to operate a $26 million gold project in Run-runo, Quezon, Nueva Vizcaya, in 1981. The plan calls for a gold mill with a capacity of 2,500 tons per day. The proven reserves of the area were estimated at 9 million tons, with an overall grade of 0.054 ounce of gold per ton of ore. (4) Batony Buhay Gold Mines Inc., a new gold producer, was expected to start its 9,000-ton-per-day Batong Buhay copper-gold mill in Kalinga-Apayao of northern Luzon. The project, currently managed by Philex Mining Corp., reportedly has spent about $200 million for equipment and for mine development costs, and an additional $40 million would be needed to bring the mine into production. Ore reserves of the area were estimated at 54.3 million tons, averaging 0.599% copper and 0.12 to 0.373 gram of gold per ton of ore.

Iron and Steel.—In 1980, there was no production or export of iron ore. San Pio Guinto Mining Corp., the only producer of lump ore in 1979, reportedly has stopped operation.[10]

Sta. Ines Mining and Steel Corp., a joint venture between the Seguera family and Nihon Metallgesellschaft, an affiliate of Lurgi Chemi und Huttentechnik GmbH of the Federal Republic of Germany, has secured all the financing needed to start its P300 million iron ore mining and milling project in Antipolo, Rizal. The project would be financed 70% by stockholders of the company, 20% by Nihon Metallgesellschaft, and the remaining 10% by other foreign investors. The project would put up an iron ore processing plant in Antipolo, Rizal, to process the iron ore produced from its mine in Mount Masarat near the Quezon and Camarines Norte boundary by 1984. The proposed plant would have an annual capacity of 1.5 million tons of iron ore concentrate. Lurgi will conduct the project's engineering work and supply the mining and milling equipment on a turnkey basis. Nihon Metallgesellschaft will handle the marketing of Sta. Ines iron ore concentrate in the world market during the first 3 to 5 years of operation.

The viability of an integrated steel mill development project at the Phividec Industrial Estate in Villanueva of Misamis Oriental Province, originally scheduled to be completed by 1985, was still under review in 1980. The Government has commissioned Vöest Alpine AG of Austria to conduct a study to find out the suitability of domestic raw materials for several small plants, each with an annual capacity of 200,000 tons per year, instead of a giant steel mill at 1.5 to 2 million tons per year as proposed by a Japanese study. Two likely domestic raw material sources cited by the Philippines Board of Investments were the tailings of nickel mining and refining operations of MMIC in Nonoc, Surigao del Norte; and iron cinders, a byproduct of the forthcoming phosphatic fertilizer operation of Philippine Phosphate Fertilizer Corp. in Isabel. United States Steel Corp. of the United States, Nippon Steel of Japan, and Thyssen Steel of the Federal Republic of Germany have expressed interest in supplying the equipment and/or minority equity participation.

Nickel.—The Philippines nickel mine output accounted for 5% of the world's total mine production. Value of nickel output was 11% of the Philippines total mineral production in 1980, and was the third most important industry in the country's hard mineral sector.

MMIC, a major nickel ore producer and the only refined nickel producer of the Philippines, produced about 75% of the country's total nickel output in 1980. MMIC operated a Surigao nickel refinery at Nonoc, Surigao del Norte, with an annual capacity of 34,000 tons of refined nickel. After a 23-day plant turnaround in July 1979, the capacity utilization reached 81.4% in October 1979 for the first time, and reached another new high at 84.5% in May 1980. The average capacity utilization in 1980 was 73.7%, about 17% higher than that of 1979. MMIC nickel production is expected to continue to increase in 1981 if the world market prices of nickel remain at the current levels of about $3 per pound. In an effort to reduce the energy costs of its Nonoc nickel refinery, MMIC obtained a $70 million loan from the Banco Exterior de Espana and a $25 million loan from the Development Bank of the Philippines to finance converting the power source from oil to coal. The coal-fired plant, that will replace an oil-driven power kiln at its Nonoc nickel refinery, would result in a savings of about $33 million per year for the company.

The other important nickel ore producer in the Philippines was Rio Tuba, which operated a nickel mine at Bataraza on Palawan Island.

MMIC shipments in 1979 were as follows: 45.7% went to Europe, 37.7% to the United

States, 10.9% to Japan, 2.7% to other Asian countries, 2.1% to Canada, and the remaining 0.9% to domestic consumers. All of Rio Tuba's shipments went to Japan.

Based on the previous estimate by the Bureau of Mines and Geo-Sciences in 1976, the country has 3,822 million tons of nickel reserves averaging 0.96% nickel. However, the most recent figures released by the Mineral Economics and Information Division of the Bureau of Mines and Geo-Sciences indicated that as of December 31, 1979, the total nickel ore reserves of the country were estimated at 1,479,462,378 tons, with ore grades ranging from 0.23% to 2.4% nickel.[11]

Uranium.—The Australian Government and the Philippines have agreed in principle to a 5-year joint project to find and define prospective uranium mining areas in the Philippines. The project was expected to spend a total of P34 million for uranium exploration and training. The Australian Government will contribute $2.5 million for technical expertise and technology to conduct airborne radiometric surveys, which would pinpoint targets for groundwork. The Australian team will also train Philippine scientists in uranium exploration. The initial exploration will start in the first quarter of 1981 and the target areas are to be in the Ilocos region, Mindoro, Polillo Island, Cataduanes, Masbate, Isabela, and Nueva Vizcaya.

Other Metals.—Production of unwashed manganese ore was by Black Rock Mining Corp. at Dimapique, Isabela, and Associated Mining and Industrial Corp. at Cabadbaran, Agusan del Norte. Lead was produced by Zambales Base Metals, Inc., from its lead-zinc-copper operation at Ayala district, Zamboanga City in Zamboanga del Sur. Zinc production by Zambales Base Metals, Inc., accounted for 54% of total zinc output in 1980, and the remainder was by Benguet Exploration, Inc., from its gold-silver-zinc-copper operation at Tuba, Benguet. Production of molybdenum was mainly by MMIC from its Sipalay copper-gold operation as a byproduct at Cartagena, Negros Occidental. Other producers of molybdenum were Black Mountain, Atlas, and CDPC Mining.

NONMETALS

Cement.—Under the country's cement industry rationalization program, five 1-million-ton-per-year-capacity cement plants were to be constructed over the 1980-85 period. Under the program, new cement plants must be coal fired; plant sites must be located at a place where the raw material reserves are adequate, and good harbor facilities must be available for receiving the coal and distributing the cement; and 70% of plant output must be exported. In June 1980, the Philippine Cement Industry Authority (PCIA), selected Negros Cement Corp. (NCC) to build the first of the five cement plants at Basay, Negros Oriental, adjacent to the shipping facility of CDCP Mining, the largest construction company in the country as well as the major copper and gold producer. NCC was formed by the CDCP Group in 1980. NCC reportedly has a marketing contract with Phillips Bros. of the United States, which has been committed to a 30% equity participation in the cement plant. Lone Star Cement of the United States reportedly was also interested in investing in the project. The project cost was estimated at more than $100 million, and was expected to be operational in 1984.[12]

The cement industry rationalization program also calls for the cement industry to rehabilitate equipment and to modernize existing plants. The Government will assist companies that convert their fuel systems from bunker to coal-fired kilns. It was reported that the Northern Cement Corp., one of the leading cement producers of the Philippines, would be the first cement plant in Luzon to convert from bunker oil to wholly coal-fired kilns. The company would also install new equipment and expand its capacity to 1 million tons per year by 1981.

Krupp Polysius AG of the Federal Republic of Germany was awarded a $33.3 million contract in November 1980 to convert nine oil-fired cement plants to coal in the Philippines. According to the contract, Krupp would supply and install the coal-fired cement kiln and other equipment at the plants by 1982.

In 1980, the Philippines had 17 cement plants, which operated at about 70% of total industry capacity of 7.4 million tons. Low capacity utilization was due to outmoded equipment, inefficient plant size (no plants have an annual capacity of 500,000 tons), inadequate working capital, and lack of the required electrical supply.

Cement manufacturing is the most important industry in the Philippines nonmetallic mineral production sector. In 1980, the Philippines production of cement was valued at $230 million, which was about 27% higher than that of 1979, and accounted for 63% of nonmetallic and 14% of the Philip-

pines total mineral production.

Dolomite.—Philippine Mining Service Corp., a joint venture company between Kawasaki Steel Corp. and Kawatetsu Mining Co. of Japan, and Dolomite Mining Corp. of the Philippines, was formed in July 1980. Kawasaki reportedly has a 40% interest in Philippine Mining Service Corp., which would mine the dolomite deposits of Dolomite Mining Corp. under a service contract at Alcoy in Cebu, about 60 miles from Cebu City. The mining area involves 52 hectares with a proven minable ore reserve of 15 million tons. The total cost of the project was estimated at $8 million. Construction of the facilities started in July 1980, and they were expected to be operational by October 1981. The company plans to produce 360,000 tons of dolomite per year during the first 2 years of operation and gradually increase to 500,000 tons per year in later years. Kawasaki Steel Corp. was expected to purchase most or all of the dolomite produced from the dolomite mine in Cebu Island.[13]

Fertilizer.—As one of the Philippines 11 industrial projects announced in 1976, plans for a phosphatic fertilizer plant finally started in 1980. The Philippines Phosphatic Fertilizer Corp. (Philphos), the owner and operator of the country's $370 million fertilizer project, has decided to build the plant at Isabel on Leyte Island in central Philippines. In August 1980, the company sent invitation-to-bid papers and other documents to four consortiums. The successful bidder would build the complex on a turnkey, fixed-price basis. Construction was to start in the spring of 1981, and be completed by February 1983. The whole complex would have four plants: A sulfuric acid plant, a phosphoric acid plant, a granulation plant, and an ammonium sulfate plant. The planned annual capacity is 350,000 tons of phosphatic fertilizer. After negotiations with several candidates, the Government of the Philippines finally accepted the investment offer made by Nauro Phosphatic Corp. (NPC) of the Central Pacific Republic of Nauro in a 40% equity participation or with $40 million in a form of raw material (phosphatic rock) to be supplied by NPC for the fertilizers plant. The other raw material—sulfuric acid, would come from the neighboring copper smelter, which was scheduled to be operational in 1983. However, some pyrites would have to be imported.[14] The Philippines Bureau of Mines and Geo-Sciences also identified several phosphate rock reserves in seven Provinces for the raw material sources of the fertilizer plant. Phosphate rock reserves in Leyte were estimated at 1.23 million tons; Negros Occidental, 219,344 tons; and Davao del Norte in Cebu, 185,728 tons. The total reserves of the seven Provinces were estimated at 2.08 million tons of phosphate rock.

Silicon.—Maria Cristina Chemical Industries (MCCI) planned the construction of a P80 million silicon plant at Ayungon, Negros Oriental. The company has already invested P10 million in the silicon plant at the mine site set up 2 years ago in a 400-hectare lot in Barangay Maaslm, Negros Oriental. The silica produced from the mine was shipped to MCCI's plant in Iligan City to make ferrosilicon. The ferrosilicon produced by the company was exported to Romania, Japan, Australia, and Southeast Asian countries. The silica ore deposits at Ayungon was estimated at 500 million tons.[15]

MINERAL FUELS

Coal.—For the first time, the production of coal increased 20% from that of 1979, and passed the 300,000-ton level in 1980. In 1979, coal production was produced mainly from three coal mining areas in Cebu Island by about 50 small privately owned coal mine operations, accounting for 85% of total production. The remaining 15% of the production was from Gigaquit in northeastern Mindanao and from Burdeos on Polillo Island. In 1980, a new open pit coal mine, operated by Vulcan Industrial and Mining Corp. on Semirara Island off the southern coast of Mindoro Island, started production at 300 tons of coal per day. The projected production of coal was to reach 150,000 tons in 1981 and 250,000 tons in 1982, with an additional investment of P14 million for acquiring necessary equipment. The characteristics of Semirara coal has been specified as low ash and sulphur contents, fixed carbon content of 31% to 52%, and a heating value ranging from 9,000 to 10,000 Btu's per pound.

Presently, almost all of the coal produced in the Philippines is consumed by various domestic cement plants and some utility companies. According to the Philippines Ministry of Energy, coal contributed only 1% of the country's total energy requirements in 1979. In line with a long-term strategy of accelerating the development of indigenous energy resources, coal's share of

the Philippines total energy requirements would be increased to 13.5% in 1985 by increasing annual coal production to 2.3 million tons, and importing the remaining 3.1 million tons possibly from mainland China, the United States, and Australia.

During the past decade, the Philippines has been actively engaged in coal exploration and development. As of early 1980, there were 13 coal mines under various stages of active exploration. Six were along the northeastern coast of Mindanao, one on Cebu Island, two on Catanduanaes Island, two on Mindoro Island, and two in Luzon. According to the Philippines Bureau of Energy Development, the Philippines has a proven coal reserve of 186 million tons as of 1980. The most promising coal areas reportedly were in Cebu, Zamboanga del Sur, Semirara Islands, Bataan Island, and Polillo Islands.

The Government of the Philippines planned to set up six coal depots in the coming years to supply the fuel needs of mines and cement plants, which were to shift from bunker-oil to coal-power generation. The depots will also serve as blending stations. The feasibility studies on the depots were completed, but the financing has yet to be lined up. According to the Ministry of Energy, the depots would be located at the North Harbor in Manila; Poro Point in La Union; Naga cement plant in Cebu; Pacific cement plant in Surigao del Norte; MMIC plant on Nonoc Island; and Iligan City, where Iligan Cement, Floro Cement, and Mindanao Cement have plants.

The Government of the Philippines also created the National Coal Authority in September 1979 to handle the marketing, importation, blending, storage, and distribution of coal in the country.

Petroleum and Natural Gas.—In 1980, the only oil-producing field was Nido, which went into full production in February 1979, and reached a peak of 40,000 barrels per day in September 1979 with five productive wells. Average daily output of Nido Oilfield dropped to about 14,000 barrels per day in January of 1980. By February, Nido A-1, the biggest well, was shut down after water seeped into the oil flow. On March 20, Nido A-2, B-1, B-2, and B-3A were also shut down for 5 days to allow repairs on the single-buoy mooring system. All four wells, except A-1, which has shut down permanently, resumed production later, but the average daily output declined from 11,000 barrels per day in July to 9,000 barrels per day in October, and declined further to 3,500 barrels per day at the end of 1980.

The operator of Nido Oilfield, Cities Service has revised the original estimate of the Nido Oilfield's oil reserves of 45 million barrels to between 11.5 and 17.1 million barrels. In late 1980, Oildeco, a Norwegian company was hired by Cities Service to review its initial studies and data. At the same time, the Philippines Ministry of Energy, in cooperation with the Indonesian Pertamina, also conducted its own reassessment. According to Cities Service, by the end of 1980 a total of 12.2 million barrels has been pumped out since the Nido Oilfield went into production in February of 1979.

During the 1977-80 period, the Philippines discovered four new oilfields near the existing Nido Oilfield, offshore northwest of Palawan Island: Cadlao Oilfields, discovered by Amoco about 20 miles north of Nido Oilfields in 1977, (Cadlao-1 and Cadlao-3 wells were scheduled to produce at an initial rate of 9,000 barrels per day in June 1981); Matinloc Oilfield, discovered during the 1979-80 period by Cities Service about 12.5 miles northeast of Cadloa Oilfield, was to start production in late 1981 at an initial rate of about 11,000 barrels per day. Two other oil discoveries also made by Cities Service are the Pandan Oilfield and Libro Oilfield. The former is located about 33 miles northeast of the Nido Oilfield and the latter about 4.3 miles east of Pandan Oilfield. Based on data released by the operators, the quality of crude oil from these newly discovered oilfields is of low-sulfur crude oil with an API gravity of 43° to 44°.

Domestic crude oil production accounted for 10% of the country's annual consumption of about 85 million barrels in 1979, and for only about 2% in 1980. Combined output of Nido and Cadlao was estimated to produce about 5% of the Philippines oil consumption of 89 million barrels in 1981.

In mid-1980, the State-owned PNOC Exploration Corp. (PNOC-EC) discovered a natural gas well, San Antonio-1, located in Barrio San Antonio in Echague of Isabela Province, onshore of the Cagayan Valley Basin. This is the only productive gas well found so far out of five wells drilled. Reportedly, the initially estimated flow rate of 6 million cubic feet per day was revised to 12 million cubic feet per day.

The Philippines reportedly will build a $141 million 100,000-barrel-capacity refinery in Limay, Bataan Island, by 1983. A new $10-million crude oil import terminal of the

Bataan Refining Corp. in Limay was completed in June 1980. A $60 million gas terminal next to its refinery in Tabangao reportedly will built by NDC-Shell Mineral Investment Co. in 1983.

The Mineral Industry of Poland

By Tatiana Karpinsky[1]

In 1980, the production plan in Poland was not fulfilled in many sectors of industry. The economic situation of the country was extremely difficult, and Poland was in deep political and economic crises. A huge wave of strikes along the Baltic coast and Silesia Coalfields in August and early September 1980 was followed by a rash of smaller stoppages throughout the country. Strikes hit many industries, labor productivity dropped, and discipline deteriorated. The results were particularly visible in the coal, steel, copper, sulfur, fertilizer, and cement industries, where production was short of the planned targets for 1980.[2]

On September 14, Poland's Council of State issued a decree on legal procedures for the registration of new trade unions to be formed outside the jurisdiction of the existing Central Council of Trade Unions. The decree came exactly 2 weeks after the strike settlement in Gdansk had provided the workers with the right to form their own independent and self-governing organizations. On November 10, 1980, Poland's Supreme Court legally registered the Solidarity labor union, and this move defused political tension in the country.

According to an agreement between the Government commission and the Interfactory Strike Committee concluded on September 3, 1980, at the July Manifesto coal mine, the new system of free Saturdays is to be introduced in coal mines, as of January 1, 1981.

According to the Ministry of Mining, output of coal in the first three quarters of 1980 was 4 million tons less than planned. At yearend, the country was short 13 million tons of coal against the planned 206 million tons. The shortage in coal production affected coal exports. Deliveries of coal to the ports for export were greatly reduced, and stocks at Szczecin and Swinoujscie Ports were already exhausted at the end of September.

In 1980, the production of steel fell short of the plan by about 2.7 million tons; the output of rolled products by 716,000 tons; production of copper by about 33,000 tons; and production of electrical energy by 3 billion kilowatt-hours.

According to Polish sources, national income in 1980 decreased 4% compared with the 1979 level and decreased 6% compared with the 1978 level; the total output of industry fell by approximately 4%. Capital investments decreased from 23.2% of the national income in 1979 to 19.7% in 1980. While there was an overall reduction in the value of output, wages increased and amounted in zlotys (Z) to Z359 billion, an increase of 14% over that of 1979.[3]

The total number of industrial workers and employees in State enterprises in Poland was 4,754,000 in 1979 and 4,758,000 in the first half of 1980. The number of workers and employees in State mineral and energy enterprises by branch is given in the following tabulation for 1979:[4]

Branch	Total workers and employees (thousands)	Workers (thousands)	Percent of total employment in industry
Coal	402	323	8.5
Other fuel	51	37	1.1
Power	85	53	1.8
Ferrous metals	187	143	3.9
Nonferrous metals	74	53	1.5
Building materials	186	139	3.9

In 1980, Poland was involved in the construction of nine raw material projects within the CMEA countries.[5] In exchange, in addition to the quantities provided for by a longstanding agreement, Poland received from the U.S.S.R. about 1 million tons of crude oil, 2.8 billion cubic meters of natural gas, 2.5 million tons of iron ore, 61.8 thousand tons of ferroalloys, and 25,000 tons of asbestos.[6]

With a new large coal mining and power complex at Belchatow and several other power projects underway, Poland was still facing an energy shortage. Therefore, Poles have taken an active part in building three nuclear power stations in the Soviet Union to receive in return 1,200 million kilowatt-hours of electric energy in 1984 and 6,000 million kilowatt-hours annually in the years 1988-2003. In Khmielno, Kursk, and Smolensk, 1,600 Polish workers were engaged in construction worth 200 million rubles. The number of Poles working there is to rise to 5,000. In addition, Poland is to supply equipment for these nuclear power projects worth about 200 million rubles.

The targets of the seventh 5-year plan (1981-85) were initially outlined at the Eighth Congress of the Polish United Workers Party which met in Warsaw in February 1980.[7] The program outlined at the Congress foresees further economic growth and improvement of working and living conditions. The seventh 5-year plan envisages an increase of 14% to 18% in the national income and 20% to 24% in gross industrial output.

In the 1981-85 period, Poland will concentrate its investment in the energy, transport, and agricultural sectors. Capital investment is planned to fall from about 26% of national income in 1978 to under 20% in 1981-85.

Poland is planning to accelerate modernization of many branches of industry, increase its exports, and increase housing construction. Priority is to be given to food production.

According to the plan outlined at the Eighth Party Congress, the mineral commodity production for 1985, in million tons, is as follows:

Copper	0.5
Zinc	.2
Lead	.1
Crude steel	24.0
Rolled steel products	17.0
Fertilizer materials:	
Nitrogen	1.7
Phosphorus	1.2
Bituminous coal	235.0
Lignite	80.0-90.0

In the 1980's, the primary area of cooperation within the CMEA will be participation in the implementation of long-term directional programs of cooperation, which were prepared following the resolutions adopted at the 30th CMEA Session in 1976. The programs concern cooperation in five branches of material production until 1990, including fuel, energy, and raw materials.

On December 3, 1980, the Central Committee put the Government under obligation to work out, within the framework of the 5-year plan, a 3-year plan for restoring economic equilibrium and economic stabilization to the country. This plan is to determine the direction for concentrating the means and structural changes indispensable for improving the financial and market situation; expanding agriculture; meeting the material, raw material, and energy needs; developing the economy's export capacity; and improving the State's balance of payments.

The plan for 1981 is to be the first stage of the 3-year program of economic stabilization and for solving existing difficulties. The Polish economic plan for 1981 is modest, but was not fully elaborated in 1980. The Government planning commission expects the level of industrial output in 1981 to be close to that of 1980. Some sectors should have even lower production. Investment outlays will be lower by at least Z100 billion, that is, by about 20% compared with 1980 levels. The volume of mining production compared with that of 1980 will probably be lower. This concerns hard coal, copper, zinc, lead, and sulfur.[8]

In connection with the introduction of an economic reform starting January 1, 1981, enterprises are determining their annual plans on their own. The tasks determined

by industrial unions, ministries, and the State Planning Commission of the Council of Ministers concern only some issues. Therefore, economic results of 1981 will depend to a considerable extent upon independent initiatives of the basic economic organization.

Poland's debts to developed economy countries amounted to about $23 billion in 1980. Poland counted on a surplus of $600 million in trade in 1980, but instead had a foreign trade deficit of about $700 million.

At the end of 1980, Poland's population totaled 35.7 million, an increase of 322,000 over the 1979 total.

PRODUCTION

Poland has large reserves of coal, lignite, sulfur, copper ore, salt, and lead and zinc ores. However, the country must import crude oil, gas, iron ore, magnesite, kaolin, phosphate, chromium, molybdenum, manganese, and a few other materials.

In 1980, only 40% of the projects envisioned for completion were actually completed. By the end of 1980, capital tied up in incompleted investments had grown to Z800 billion, compared with Z665 billion at the end of 1979. Industry was badly affected by shortages of raw and semifinished materials, fuel, and energy, as well as by work stoppages and strikes. According to official results, output of the majority of "basic articles" fell in 1980, compared with that of 1979. Decline was even greater compared with the 1980 plan.

In 1980, production dropped for coal, rolled steel products, primary aluminum, fertilizers, and cement. Increases were reported in some products, including pig iron and electrolytic copper. Economic results for the first 6 months of 1980 were respectable, with both national income and industrial production; however, the industrial picture deteriorated during the second half of 1980. Economic results of the first and second half of 1980, compared with the same periods in 1979 follow, in percent:

1980	First half	Second half
Hard coal	106.6	89.5
Crude steel	106.2	96.9
Rolled products	105.0	95.5
Cement	111.5	82.3

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.

[1]Table includes data available through July 10, 1981.

[2]In addition to the commodities listed, antimony, cobalt, germanium, gold, a variety of crude nonmetallic construction materials, and carbon black are also produced, but available information is inadequate to make reliable estimates of output levels. Poland may also produce alumina in small quantities, but details of such an operation, if it exists, are not available.

[3]Reported figure.

[4]Includes building gypsum, as well as an estimate for gypsum used in production of cement.

[5]Total of listed commodities only; excludes products not reported individually as well as refinery fuel and losses.

TRADE

In 1980, the value of exports increased by 3.4% over 1979 value and reached Z51.9 billion; the value of imports increased 6.1% and reached Z57.6 billion. The deficit of the balance of payments went up to Z5.7 billion in 1980, or 39% over the 1979 total. The poor trade results were due to the unsettled situation prevailing in Poland during the second half of the year. While foreign trade increased during the first 6 months of 1980, the trade results deteriorated substantially during July through December.

The trade deficit, with the centrally planned countries, amounted to Z3 billion in contrast to a surplus of over Z1 billion in 1979. The balance of payments deficit with market economy countries was reduced to Z2.7 billion compared with the 1979 deficit of Z5.2 billion. The decline in the deficit resulted by increasing exports, while holding imports approximately to their 1979 level. Exports to market economy countries were valued at Z22.9 billion, about 10% below the planned target, and imports at Z25.6 billion.[9]

Among branches of the Polish industry, the most important in external trade was electrical and manufacturing industries. In 1980, exports by the electrical and manufacturing industries contributed about 48% of Poland's total export value; fuel and electric power, 14%; ferrous and nonferrous industry, 9%; chemical industry, 8.5%; and products of other industries, about 20.5%. The import value of manufacturing and electrical industries accounted for 35%; fuel and electrical power, 18%; ferrous and nonferrous industry, 11%; chemical industry, 12%; and products of other industries, about 24%.[10] In 1980, coal exports amounted to 31 million tons.

The value of coal export in 1980 decreased by Z1 billion (about $332 million) compared with 1979 values. There were decreases also in exports of lignite, coke, cement, copper, fertilizers, caustic soda, and sulfur.

In the second half of 1980, in comparison with the same period of 1979, exports dropped as follows: Coke—312,000 tons, copper—7,500 tons, sulfur—312,000 tons, and cement—314,000 tons.

Prices paid by Poland for raw materials imported from the U.S.S.R. (per metric ton unless otherwise specified) were as follows:

Raw material	Prices paid by Poles to Soviets		World prices	
	Zlotys	Dollars	Zlotys	Dollars
Crude oil	318	106	735	244
Iron ore	46	15	52	17
Apatite	201	67	212	70
Natural gas (per 1,000 cubic meters)	253	85	340	113
Aluminum	3,484	1,157	3,605	1,197

The prices paid by the Soviets for raw materials imported from Poland (per metric ton) follow:

Raw material	Prices paid by Soviets to Poles		World prices	
	Zlotys	Dollars	Zlotys	Dollars
Coal	170	56	--	--
Sulfur	213	71	375	125
Copper	5,291	1,758	6,306	2,095
Zinc	2,650	883	2,123	705

During 1975-80, Polish-Soviet total trade turnover reached Z147 billion (about $48.8 billion). It was approximately twice that of the 1971-75 turnover.[11]

The U.S.S.R. is the main trade partner of Poland. Poland's turnover with the Soviet Union in 1980 amounted to about Z35 billion. It comprised about 32% of Poland's total foreign turnover and about 58% of the turnover with centrally planned economy countries.[12] Soviet Union supplies constituted 38% of total Polish imports of all raw materials. Besides raw materials, Poland imported from the Soviet Union about 53,000 tons of aluminum and about 3 million tons of petroleum products in 1980. Poland balances imports from the U.S.S.R. with exports of coal, machinery and equipment, and complete industrial plants. In 1980, more than 13 million tons of Soviet oil, over 5 billion cubic meters of natural gas, and 9 million tons of iron ore were delivered to Poland. Supplies from the Soviet Union accounted for 100% of all imports of natural gas, 76% of crude oil imports, and 72% of iron ore imports. The U.S.S.R. has guaranteed to maintain the supply of crude oil, natural gas, iron ore, and other raw materials at the level of 1980 for the next 5-year period (1981-85).

In 1980, about 12% of raw materials supplied by the Soviet Union comprised materials received in exchange for Poland's participation in joint investment projects in the Soviet Union for many years. These projects included development of potassium salt in Belorussia, construction of an asbestos plant in Kiembayevsk, construction of the Orenburg gas pipeline, and building of the atomic energy power stations.

In 1980, the U.S.S.R. agreed to supply Poland with additional commodities worth $150 million and to grant Poland a 10-year low-interest credit worth $260 million. The Soviet Government has also rescheduled the repayments of the credits worth $280 million granted to Poland for the purchase of intermediate and raw materials from market economy countries.[13]

The Swedish Government has granted Poland credit guarantees to the value of 200 million crowns ($47.6 million) to enable Swedish enterprises to continue exports to Poland of industrial commodities, iron ore, and other products.

In 1980, Brazil and Poland signed a long-term contract for sulfur supplies from Poland to Brazil and supplies of Brazilian intermediate and raw materials to Poland.

The Polish Construction of Mining Projects Abroad Co. and the British Castle Brylling Rigs signed a contract under which Poland is to supply Britain with 3,500 drilling bits made by the factory of mining and drilling machines, in Garlice (Poland), in 1981. New credits for Poland were fixed by the Federal Republic of Germany. The Government is to guarantee credits totaling 300

million deutsche marks to finance exports of semifinished goods and food to Poland. Poland's debts, in deutsche marks, which mature in the first half of 1981, are put at about 500 million. In 1980, a cooperation agreement was signed in Frankfurt on the Main between the Polish Commercial Bank and a consortium of the Federal Republic of Germany. The credit worth DM400 million was granted to Poland for the development of the Lublin coal basin.

In 1980, the Energoinvest Corp. of Sarajevo (Yugoslavia) and Impexmetal of Poland signed a contract for delivery of alumina worth $31 million for the Polish aluminum industry in 1981. The major commodities that Centrozap of Poland imported from France in 1980 were spare parts for the machines and equipment installed in the Lubin copper basin, as well as spare parts to metallurgical installations imported from France.

In 1980, an agreement was signed between Impexmetal of Poland and Société Generale de Mines of Belgium for deliveries of copper to Belgium.

Table 2.—Poland: Apparent exports of selected mineral commodities[1 2]

(Metric tons unless otherwise specified)

Commodity	1978	1979	Principal destinations, 1979
METALS

[7]Partial figure; tonnage not available for all trading partners.

[8]Statistical Yearbook of the Member States of the Council for Mutual Economic Assistance, Moscow.

[9]Official trade statistics of Poland report imports of 14,267 tons of limestone and dolomite, and official trade statistics of individual trading partners report exports of 201 tons of dolomite to Poland.

COMMODITY REVIEW

METALS

Aluminum.—The production of aluminum in Poland is based on alumina imported mainly from Hungary and Yugoslavia. In 1980, production of aluminum was 3,000 to 4,000 tons short of what was originally planned. The smelters of Skawina and Konin each have an annual capacity of 50,000 tons per year. The shortfall was entirely due to a shortage of coal to produce the huge amount of power needed to produce aluminum. Reportedly, the Skawina plant, near Krakow, is to be closed down because of its pollution and deleterious effects on the environment and because of its high consumption of energy. Output of aluminum is expected to fall considerably in 1981, and imports of aluminum metal are expected to increase. Two new methods for aluminum extraction from non-alumina raw materials, such as fly ash from the Turow power station and overburden clays from Turoszow brown coal open pit mine, continued to be under research in 1980.

Copper.—It was originally planned that in 1980 the copper plants would deliver 425,000 tons of refined copper, and in 1983 about 500,000 tons. According to Polish reports, the new copper production target for 1980 was set at 390,000 tons.

However, the new production plant was not fulfilled because of strikes which started in August and continued in September 1980. The miners of the Legnica-Glogow Copper Basin demanded an immediate return to the traditional three-shift working day, and a reduction of the working week to 5 days in the coming years. Meeting the demands of the miners would mean a decrease in the extraction of copper ore by over 6.5 million tons per year and in the production of electrolytic copper by about 90,000 tons. However, the Polish Government announced on October 1, 1980, a return to the three-shift system for the copper miners in the Legnica-Glogow Copper Basin. The agreement also provided for a 5-day week.

According to Polish sources, the downward trend in copper production is expected to continue in 1981. In 1980, due to labor strikes, Poland could not fulfill all the copper export contracts.

In 1980, copper ore was mainly extracted from the Lubin, Polkowice, and Rudna Mines, located in the Legnica-Glogow Copper Basin. Development of the Sieroszowice copper mine, located in the same area, continued in 1980.

The first shaft of the mine was completed at the depth of 750 meters in August 1979;

when the first stage of development of the Sieroszowice Mine is completed in 1983, the mine is to produce 5.5 million tons of ore per year.[14] Projected mine capacity is 15 million tons of ore per year. The Rudna Mine, which started operating in June 1974, with a planned capacity of 12 million tons, produced 2.2 million tons of copper ore in the first 3 months of 1980. The copper ore deposits in the Legnica-Glogow Copper Basin lie at depths 600 to 1,200 meters below the surface and consist of sulfide ores. The average copper content was estimated at 1.4% to 1.5% in 1980. According to the Central Geological Office, it is believed that the deposits of copper ore will last about 35 to 40 years at the planned rate of production.

Poland's Orsk plant has produced only 7,500 tons of rolled copper since it came onstream in May 1979. The Orsk plant has a capacity of 100,000 tons per year of rolled copper wire.

In 1980, the Polish Impexmetal of Warsaw and the Belgian Société Generale de Mines signed a contract for the delivery of 42,000 tons of copper to Belgium between 1981 and 1984.[15]

In the same year, the Federal Republic of Germany's consortium had agreed to take 480,000 tons refined copper for 1979-90, in addition to the 40,000 tons per year agreed for 1977-88.

Gold.—The Geological Institute of Warsaw has begun a study of the possibilities of producing gold in Poland from old mines. Prospecting for new deposits of gold-bearing material is planned to be concentrated in Lower Silesia.[16] A concentration of 100 milligrams of gold per cubic meter of material is the minimum economic amount for a start-up of mining operations in Poland. Polish industry uses about 2.5 tons of gold per year. The use of gold in industry has been increasing sharply in recent years. Reportedly, it is possible to recover 1.5 tons of gold per year from waste. The copper ore of the Lubin-Glogow deposit contains gold, and it is estimated that it could yield annually (in addition to 400,000 tons of copper) about 40 tons of gold, currently worth about $800 million. Production of gold, however, would require great investment.

Iron and Steel.—Poland's steel production for 1980 was well below the planned 22.2 million tons. Ferrous metallurgy was hard hit by power interruption due to a shortage of coal at powerplants.[17] There had been 58 days of power restriction during the 98 working days between September 1 and December 6. Production losses during this period amounted to 1 million tons of crude steel and 611,000 tons of rolled products.

In 1980, Z30,100 million was allocated for the development of metallurgy. One of the biggest metallurgical plants in Krakow, the Lenin Metallurgical plant, which produces over 6.5 million tons per year, produced the 100 millionth ton of steel at yearend 1980.

The major overhaul of the No. 1 blast furnace of the Lenin iron and steel enterprise was completed in 1980. The Lenin plant employs about 40,000 people. In 1980, the second stage of construction at the Katowice metallurgical plant continued. In 1981, however, there will be limitation in the volume of investment for expansion of Katowice Steel complex and for several other steel industry projects. Only Z8,300 million is earmarked in the steel industry for 1981. The plan for 1981 foresaw a steel output of 17.7 million tons.

In 1980, Poland's Nowotko plant was building an 800,000-ton-per-year mill to produce cold-formed sections. The Polish steel industry is almost entirely dependent upon imported iron ore. Imports of iron ore and concentrate from the U.S.S.R. were about 9 million tons in 1980. Under agreement signed in 1975, Poland has to deliver to Brazil 33 to 36 million tons of hard coal between 1975 and 1990, and Brazil is to supply Poland with 33 million tons of iron ore during the same period.[18]

In 1980, exploration of the magnetite iron ore deposits continued in northeast Poland. Development of an underground mine, with an initial annual capacity of 8 million tons of iron per year, is to begin at Krzemionka, near Suwalki. The iron ore deposits are at a depth of 2,000 meters. The ore contains some quantities of titanium and vanadium of industrial value, as well as containing 27% iron.[19]

Lead and Zinc.—Poland has long been one of the largest zinc-producing countries in the world. As a result of strikes, production of refined zinc and lead was 4,000 to 5,000 tons short of the planned amount for each metal in 1980.

In 1980, there were three major lead-zinc mines in operation—Boleslaw, Olkusz, and Pomorzany—all located in the Katowice area.

To increase zinc production, Poland hopes to start using slag with a content of about

5% to 6% zinc. Poland imports about 15% of its zinc requirements in the form of 50% zinc concentrate from Peru, Canada, Mexico, and Norway.

It is also planned to increase lead-zinc production in the future from deposits discovered in the Olkusz-Chrzanow and Zawiercie regions. In the Zawiercie region, Poland plans to develop one mine with a capacity of 2.5 million tons of ore per year and another mine with a capacity of 1 million tons after 1980.

Poland's second Imperial Smelting Furnace at Miasteczko Slaskie was completed in the beginning of 1980. The furnace is to produce 52,000 tons per year of zinc and 23,000 tons per year of lead, using local concentrates.

In 1978, a decision was made to close the shaft furnace in the lead production at Szopience because of its pollution of the environment. However, the shaft furnace continued to be in operation and produced 140 tons of lead compounds in 1980.

Nickel.—In 1980, Poland continued to produce nickel ore at Zabkowice Slaskie from weathered peridotite. The ore contained 0.7% to 1% nickel metal. Domestic production of nickel metal meets about 30% of the national requirements.

Silver.—Production of silver is becoming one of Poland's major hard currency earners.[20] In 1980, production of silver did not increase considerably compared with the 1979 level. Practically all of Poland's silver was obtained as a byproduct of copper production. It is not known what proportion of the silver produced is put aside for currency purposes. In 1979, the income from exporting silver was 45% of income obtained from the sale of copper. Export of silver amounted to Z327 million in 1979.[21] Export of silver in 1980 was estimated at Z515 million. The silver is sold mainly in Western Europe.

Tin.—In 1979, some tin deposits of economic value were discovered in the Krobnica region near Swieradow-Zdroj (Lower Silesia). The probable resources were estimated at about 25 million tons of tin ore. Further prospecting of the deposits continued in 1980.

NONMETALS

Cement.—In December 1980, the shortages of fuel and other materials caused 70 of the 91 available furnaces for the cement industry to be put out of operation. Production of cement was less than planned by 2.6 million tons. It was expected that the January 1981 supplies would barely meet half the cement industry's need. At the end of 1980, the cement factories in Kielce Province substantially reduced output of cement because of a shortage of coal, heavy oil, and because of power cuts. The plant Nowiny-1 was shut, the Novini-2 was working at 50% capacity, and the Malogoszcz was working at 25% capacity. At the Lublin cement combine in Chelm, production was also decreased due to the coal shortages.

Poland's total cement production capacity in 1980 was estimated at 25 million tons. However, internal conditions permit utilization at only 84% to 88% of production capacity.[22]

Polish cement demand is expected to be 277 million tons in 1985.

Fertilizers.—The revised 1980 plan provided, in terms of nutrient content, 1.28 million tons of nitrogenous fertilizers and 845,000 tons of phosphoric fertilizers. The original goals for 1980 were 2.2 and 1.3 million tons, respectively. The revised 1980 plan for nitrogenous fertilizer was fulfilled; however, production level was lower than that of 1979. The shortage in nitrogenous fertilizer production was due to a breakdown at the Wloclowek nitrogen plant, one of the three main fertilizer plants. The production section of this plant was shut down for extensive repairs. Operating rates at the Pulawy nitrogen complex were reduced by 30% due to a shortage in gas supplies. Production of phosphoric fertilizer was below the revised planned target by approximately 2.5 thousand tons.

The plants in Police and Gdansk, located in the neighborhood of seaports, underwent stoppages because of strikes, while the plants in Libon, Ubocz, and Banarka had shortfalls owing to a lack of phosphoric raw materials, which stayed on board ships.[23]

In 1980, consumption of fertilizers per hectare of area was reported as 192 kilograms; this was much less than planned. Plans are to increase fertilizer consumption to 230 kilograms per hectare in 1985.

In 1980, the U.S.S.R. delivered about 1 million tons of potash fertilizer to Poland, with the remainder from the German Democratic Republic and Belgium. Potash consumption in Poland fell considerably in 1980. Apatite concentrate and phosphorites were imported mainly from the U.S.S.R. and Morocco.

The Police 11 ammonia/urea and ammo-

nium phosphates complex continued under construction in 1980 (due for completion in 1983). Occidental Petroleum has agreed to supply fertilizers, chemicals, and other agricultural products to Poland, following a visit by the Occidental Petroleum Chairman.

Salt.—Poland possesses some of the world's richest deposits of rock salt. The oldest salt mines are located in Wieliczka and Bochnia; however, the salt mine in Wieliczka is not an economically important center. Of greater economic importance in 1980 were the salt mines in Inowroclaw, Klodawa, and Wapno.

In 1980, there were 12 salt mines and plants in operation in Poland, with average employment of about 5,000 people. The Klodawa Mine in Konin Province, the biggest salt mine in the country, was to produce 1.5 million tons of rock salt in 1980, about 23,000 tons more than in 1979. However, the plan was not fulfilled as the expansion and modernization of the enterprise were delayed.

Sulfur.—Polish sulfur production is concentrated in the Tarnobrzeg region. In 1980, sulfur was surface mined at the Machov-Piaseczno Mine, while the Frasch process was used at the Grzybow and Jezierko Mines. Sulfur was obtained by the Frasch process at the depth of 40 to 180 meters. In 1980, it was reported that the experimental Baszina Mine in the Preusl region produced 70,000 tons of sulfur during the trial operation and that preparations for exploitation of the second working area of this mine were to start in 1981. Tarnobrzeg ore contained 16% to 35% sulfur; ore reserves were estimated at 100 million tons.[24]

According to a report from Warsaw, plans were announced to double the production of sulfur in the Tarnobrzeg Basin in the near future.

Sulfur production in 1980 was below the target. Approximately 2,000 workers at the open pit mines and processing plant at Machow went on strike September 3, 1980, and a week later, the Polish sulfur industry was reported to be paralyzed. The workers wanted all the benefits of coal miners plus a 15% supplement for unhealthy work with sulfur. Total exports of sulfur from Poland in 1979 dropped by 10% compared with that of 1978, as a result of production problems experienced during the year. The drop in Polish sulfur exports during 1979 occurred completely with the developed market economy countries; exports to the centrally planned countries increased by 5%. Sulfur exports from Poland during the first half of 1980 showed an improvement on 1979's half-year deliveries of sulfur. However, September's labor strikes lowered the total sulfur production and exports in 1980. Sulfur exports fell by 312,000 tons in 1980, compared with the 1979 level.

In the beginning of 1980, the first stage of a new railway was completed between the iron ore producing region of Vladimir Volynski in the U.S.S.R. and the Polish metallurgical complex at Katowice. The line was used to transport Soviet iron ore to Poland in exchange for Polish coal and sulfur from the Slask and Tarnobrzeg regions.[25]

In September 1980, Brazil signed a $150 million loan for deliveries of sulfur from Poland. Poland will supply Brazil with 4 million tons of sulfur during the next 10 years. Deliveries are scheduled to start in 1981, with 220,000 tons per year to increase gradually to 350,000 tons annually by 1991. The loan from the Government of Brazil has been granted to finance the development of Poland's new sulfur mine at Baranow. This mine is scheduled to come onstream in 1983.[26]

It is expected that Occidental will provide credit for additional sulfur development in Poland. Occidental agreed that annual production of the mine will be reduced from the proposed 1.5 million tons to 1 million tons. It is expected that an agreement on this transaction will be concluded in March 1981. With a 10-year contract, Occidental would extend to Poland credit worth about $750 million and would consider the credit as a direct investment in developing new Polish sulfur deposits, stressing that 30% to 50% of the extracted sulfur is to be delivered to Occidental at production cost. However, Poland claims the credits represent only an advance payment for sulfur deliveries.

MINERAL FUELS AND RELATED MATERIALS

Coal is the principal source of energy in Poland. In 1980, the total primary energy production was 216.3 million tons in standard coal equivalent (SCE). This represents a decrease in total primary energy production by 4.3%, compared with the 1979 level. Coal (lignite and bituminous) contributed 94.4%; crude oil, 0.2%; natural gas, 3.9%; and others (peat, wood, and hydropower), 1.5%. Total consumption of all types of primary energy reached 219.6 tons SCE, with coal providing 78.4%; petroleum, 13.1%; nat-

ural gas, 7%; and about 1.5% for others. In 1980, the total apparent consumption of primary energy increased 1.6% over consumption of 1979; however, exports decreased by 23.7%. The energy balance for 1980 and 1979 is shown in table 4.

Table 4.—Poland: Total primary energy balance for 1980 and 1979

(Million tons of standard coal equivalent)[1]

	Total primary energy	Coal (lignite, bituminous) and coke	Crude oil and petroleum products	Natural gas	Others
1980:					
Production	216.3	204.2	0.5	8.4	3.2
Imports	38.8	1.0	30.7	7.1	--
Exports	35.5	33.1	2.4	--	--
Apparent consumption	219.6	172.1	28.8	15.5	3.2
1979:					
Production	226.1	212.4	.5	9.8	3.4
Imports	36.6	.9	30.4	5.3	--
Exports	46.5	44.2	2.3	--	--
Apparent consumption	216.2	169.1	28.6	15.1	3.4

[1]One ton of standard coal equivalent (SCE)=7,000,000 kilocalories. Conversion factors used are from the United Nations as follows: Hard coal, 1.0; brown coal, 0.3; coke, 0.9; crude oil, 1.47; petroleum products, 1.54; natural gas (1,000 cubic meters), 1.33.

Source: Biuletyn Statystyczny (Statistical Bulletin), Warsaw. No. 1, 1981, pp. 14, 30, and 32. Rocznik Statystyczny (Statistical Yearbook), Warsaw, 1980, p. 142.

Coal.—As a result of the strike, extraction of bituminous coal in 1980 was about 13 million tons short of total planned. However, supplies of coal to the population increased by 1.8 million tons compared with the provisions of the plan. In 1980, supplies of coal to the power industry amounted to 60 million tons, which was 600,000 tons more than planned, and 4.8 million tons more than supplied for 1979.

In 1981, output of bituminous coal is planned to be 170 to 172 million tons, with Saturday output considered above plan.[27] Saturday output is estimated to be 16 to 18 million tons of coal. Total output of bituminous coal was originally planned at 210 to 212 million tons for 1981.

In 1980, Poland failed to fulfill foreign contracts for 12.2 million tons of coal. Poland's coal exports in 1980 totaled 31 million tons, 10.4 million tons less than in 1979. Because coal amounts to about 12% of Polish total exports, the shortfall caused a serious deficit in Poland's hard currency earnings.

In 1979, Poland exported 14.9 million tons of coal to centrally planned economy countries; 9.5 million tons went to the U.S.S.R., and 26.5 million tons went to developed countries. In 1980, Polish coal exports to the Soviet Union amounted to about 5 million tons. Finland, Denmark, France, Italy, and the Federal Republic of Germany are the largest West European recipients of Polish coal. Finland is most dependent; about 91% of its imports of coal comes from Poland. Denmark is second with over 41%. In 1981, export of coal is planned to be about 21 million tons.[28]

In 1980, Poland operated 66 coal mines. There were 320 completely mechanized longwall faces in operation. Average mining depth was estimated at 550 meters. Extraction of coal started at the Halemba Gleboka Mine in Ruda Slaske at a depth of 1,030 meters. The first longwall in operation is to supply 2,000 tons per day. The development of new mines continued in 1980. Among the new mines under development are the Suszec, Kaczyce, Czeczot, and Orantovice Mines. The Suszec Mine is to have four shafts. The first shaft reached the planned depth in 1980. The Kaczyce Mine is planned to be 1,100 meters in depth. In 1980, three shafts were under sinking at the mine. The second shaft reached a depth of 560 meters, and the first shaft reached 800 meters in July 1980. The first coal is to be produced in 1983, and by 1987 the mine is to produce 6,000 tons per day. Development of the Orantovice Mine started in 1978. In 1980, four shafts were under construction, each of which was 9 meters in diameter. It is expected to yield 20,000 tons per day from seams 1,000 and 1,500 meters deep in the 1990's.

Eight miners were killed and 18 injured—

4 seriously—in an accident which occurred at the Halemba coal mine in Ruda Slaska on September 1.

Work was continuing in the new Lublin Hard Coal Basin in 1980. The Lublin Basin in the east of Poland covers over 4,000 square kilometers and its development started in 1975. The mines will be over 800 meters deep. The first to be developed is the central coal region with recoverable reserves of 2.6 billion tons, covering the area of 240 square kilometers.[29]

Geological and preparatory work in the Lublin Basin were completed in 1980. More than Z7.5 billion was invested in the development at the Bogdanka and Stefanow Mines in the Lublin central coal region. With the completion of the first stage of the project scheduled for 1990, the annual output is to reach 20 million tons. In 1980, the development plan for the Lublin Coal Basin was cut back; only three mines are to be developed at the Basin in the near future. Plans are to continue development of the Bogdanka Mine, to resume development of the K-2 Mine in 1983, and to begin development of the K-3 Mine in 1985.[30] The coal seams in the Lublin Basin are about 1.0 to 2.0 meters thick and are comparatively flat. The coal is of steam quality.

In 1980, Poland signed an agreement with the Federal Republic of Germany's Krupp-Kopper to build a small $140 million coal gasification plant near a coal mine outside of Katowice. The facility will use the Federal Republic of Germany's technology and equipment. The plant is to produce 950 million cubic meters of gas per year for home and industrial heating. Construction is to begin in 1982, with startup planned for 1984.

Poland is one of the world's largest producers of lignite, which is used mainly by local electric power stations. Lignite production was planned to reach 42 million tons in 1980, but the extraction of lignite was much below the planned target. The shortfall in production was aided by the strikes in Poland.

The Turnow Basin's surface-mined output accounted for about 60% of the total lignite production in 1980. On November 20, 1980, miners reached the first lignite seam at a depth of 93 meters at Belchatow Basin. The Belchatow project includes two power stations, each with a generation capacity of 4,300 megawatts. Belchatow is to have an annual capacity of 40 million tons per year when it is fully developed. The Basin's lignite reserves are said to total 1,250 million tons.

Natural Gas.—In 1980, production of indigenous gas declined slightly; about 5.3 billion cubic meters of natural gas was imported from the U.S.S.R.[31] Under a 20-year agreement, Poland is to receive 2.8 billion cubic meters of natural gas per year in return for the investment made in constructing the Soyuz pipeline from the U.S.S.R. Poland expects to participate in construction of U.S.S.R., Polish, and German Democratic Republic sections of the proposed new Northern gas pipeline to receive additional deliveries of gas. For the coming years, it is expected that a further decrease will take place in the supply of natural gas from indigenous fields with large amounts of methane, while supplies of gas containing nitrogen will increase. A new field supplying natural gas containing nitrogen was opened for exploitation in 1979. A future rise in gas imported from the U.S.S.R. is expected.

Nuclear Energy.—The first nuclear power station in Poland is to be put into service at Zarnowice, Gdansk Province. It is to have two 440-megawatt units and one 1,000-megawatt unit. The first 440-megawatt unit is to start operations in 1986, but owing to delays in preparatory work which was planned to start in the first quarter of 1980, this target date will not be met. The second nuclear power station project will be the Kujawy station, near Wloclawek, on the Vistula. The station will consist of four 1,000-megawatt units. Under a cooperation agreement with the CMEA countries, deliveries of equipment for the station should begin in 1986 and be completed in 1990. In the years 1986-90, construction is to begin of two nuclear power stations, which should go into operation between 1991 and 2000. The nuclear fuel for the Polish power stations is to be imported from the U.S.S.R. Poland is participating in the construction of three nuclear powerplants in the U.S.S.R.

Petroleum.—Production of crude oil in Poland is relatively insignificant. In 1980, oil imports from the U.S.S.R. were planned to be about 15.9 million tons, including 2.8 million tons of products and 1.1 million tons of crude oil as payment for Polish construction of an oil pipeline in the U.S.S.R. However, there was a delay in supply of crude oil due to strikes in Poland. Imports from the U.S.S.R. account for about 76% of crude

oil used by Polish industry.

In recent years, imports of oil from the Organization of Petroleum Exporting Countries have been increasing, and this trend will continue in the coming years. In 1979, the Nigerian and Polish Governments signed an agreement under which Nigeria is to deliver to Poland 0.5 million tons per year of crude oil at current world prices. It is expected that Poland will use about 30 million tons of crude oil in 1985. For the first time in the 5 years of its existence, Gdansk refinery failed to meet its annual crude oil processing and sales targets. In 1980, the sale of petroleum products by the refinery was 6% less than planned. This was due to a shortfall in the supplies of oil for processing. Modernization of the Gdansk refinery continued in 1980. This will include change in production structure. The variety of petroleum products at the Gdansk refinery is planned to be increased. The Plock refinery processed about 13 million tons of crude oil and fulfilled the 1980 plan.

Poland planned to explore its Baltic seabed for oil and gas. The first stage of drilling for oil and gas started at the northern Port of Gdansk in 1980. The first borehole is to be 3,000 meters deep. The Petrobaltic Enterprise's platform was equipped for drilling down to a depth of 6,000 meters, with a water depth of 90 meters.[32]

In 1980, intensified exploration has resulted in the discovery of new oilfields near Karlin in the Koszalin region, northwest Poland. The fields were estimated to contain about 1.5 to 2 million tons of oil.

Poland's most productive deposits of oil are located near Kamien Pomorski, where oil is extracted from a depth of 2,300 meters. Wysoka Kamienska is another major source of oil. There are also smaller deposits of oil in Western Pomerania. In 1980, exploration for oil and gas continued in the Polish lowlands.

The Mineral Industry of Portugal

By Roman V. Sondermayer[1]

As in the rest of Europe, economic growth in Portugal slowed significantly from 5.7% in 1977 to an estimated 2% in 1980. Inflation decreased from 20% in 1979 to 18% in 1980 and unemployment was close to 9%. The extractive sector of the mineral industry accounted for about 1% of the gross domestic product of $20 billion.[2] The mineral industry of Portugal was modest by world standards, except for the production of tungsten which contributed about 4% to the world total in 1980. Output of other minerals was of domestic significance only, and production of stone was the most important.

After many years of political instability, elections held in October 1980 increased the majority of the governing coalition. The new Government planned to revise the Constitution and take Portugal into the European Communities.

During 1980, the major events of the country's mineral industry were the preparation for production from the mixed sulfate ore deposit at Castro Verde, the beginning of modernization at the Seixal steel plant, and the modernization of a coal mine in northern Portugal.

PRODUCTION

Latest trends in minerals production of Portugal are shown in table 1.

Table 1.—Portugal: Production of mineral commodities[1]

TRADE

Trade in Portugal's minerals for 1978 and 1979 are shown in tables 2 and 3.

Table 2.—Portugal: Exports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1978	1979	Destinations, 1979	
			United States	Other (principal)
METALS				
Aluminum metal including alloys, all forms	2,921	9,812	--	Spain 3,701; France 1,536; India 513.
Chromium oxides kilograms	800	700	--	All to Angola.
Cobalt oxide and hydroxides	9	--		
Columbium and tantalum: Tantalum ore and concentrate	9	--		
Copper:				
Ore and concentrate	100	1,004	--	Sweden 1,000.
Sulfate value	--	$41	--	All to São Tomé and Principe.
Metal including alloys, all forms	1,711	5,046	626	France 1,769; Italy 1,077; Belgium-Luxembourg 549.
Iron and steel:				
Roasted pyrite	14,689	27,514	--	West Germany 27,120; Spain 385.
Metal:				
Scrap	9,716	4,796	(1)	Netherlands 2,554; Spain 2,016.
Pig iron, ferroalloys, similar materials	103,716	92,773	37,634	Italy 11,105; Canada 8,905; Romania 8,000.
Semimanufactures:				
Bars, rods, angles, shapes, sections	3,797	69,387	--	Syria 33,516; Egypt 12,608; Switzerland 10,462.
Universals, plates, sheets	10,690	35,833	--	Romania 12,125; Switzerland 10,673; Egypt 5,454.
Hoop and strip	312	1,018	--	Angola 693; Morocco 290.
Rails and accessories	264	320	--	Pakistan 262.
Wire	172	155	NA	NA.
Tubes, pipes, fittings	5,215	5,408	--	Spain 1,172; Italy 776; France 523; Angola 492.
Castings and forgings, rough	7,105	12,562	3,851	United Kingdom 4,478; Sweden 1,183; France 981.

See footnotes at end of table.

Table 2.—Portugal: Exports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1978	1979	Destinations, 1979	
			United States	Other (principal)
METALS —Continued				
Lead:				
Ore and concentrate	740	1,635	--	Mainly to Belgium-Luxembourg.
Oxides	5	113	--	Belgium-Luxembourg 100.
Metal including alloys, all forms	621	100	--	Angola 86.
Magnesium metal including alloys, waste and scrap	--	8	--	All to West Germany.
Manganese:				
Ore and concentrate	4,000	2,050	1,400	France 650.
Oxides	70	(1)	--	All to Guinea-Bissau.
Molybdenum metal including alloys, all forms, value	--	$470	$470	
Nickel metal including alloys, all forms	69	84	--	Netherlands 34; United Kingdom 34; India 14.
Platinum-group metals including alloys, unwrought and partly wrought, troy ounces	r1,736	3,312	--	France 1,704; United Kingdom 1,061.
Silver metal including alloys, unwrought and partly wrought, do.	354	488,878	--	West Germany 379,387; France 109,345.
Tin metal including alloys, all forms	5	9	--	Angola 5; United Kingdom 3.
Tungsten:				
Ore and concentrate	1,617	1,704	216	United Kingdom 700; West Germany 219; Netherlands 202.
Metal including alloys, all forms, kilograms	100	--		
Zinc:				
Oxides	3,270	2,087	--	West Germany 1,601; Netherlands 311.
Metal including alloys, all forms	133	129	--	Netherlands 100.
Other:				
Ores and concentrates	463	315	--	Belgium-Luxembourg 200; West Germany 104.
Ash and residue containing nonferrous metals	r46,708	11,339	--	West Germany 10,226.
Oxides, hydroxides, peroxides	10	4	--	United Kingdom 2; Spain 2.
Metals:				
Metalloids	18,530	21,066	--	Japan 9,600; West Germany 6,151; Romania 2,200.
Precious metals including alloys, waste and sweepings, value	$288,780	$319,802	--	Belgium-Luxembourg $131,633; United Kingdom $126,175; France $44,702.
Base metals including alloys, all forms	1,336	6	--	Mainly to Angola.
NONMETALS				
Abrasives, n.e.s.:				
Natural: Pumice, emery, corundum, etc	70,239	85,646	--	United Kingdom 80,207.
Artificial corundum	--	6	--	Spain 4.
Grinding and polishing wheels and stones	57	69	21	West Germany 20; Angola 11.
Asbestos	118	--		
Barite and witherite	3	283	--	Mainly to Tunisia.
Boron materials: Boric acid	--	2	--	Mainly to Mozambique.
Cement	5,174	13,288	(1)	Cape Verde 4,978; Gibraltar 4,272; Guinea-Bissau 3,955.
Chalk	91	22	--	Cape Verde 17.
Clays and clay products:				
Crude clays:				
Kaolin	36	--		
Other	2,007	906	--	Spain 568; Mozambique 259.
Products:				
Refractory including nonclay brick	664	429	NA	Angola 264; France 81.
Nonrefractory	8,467	16,873	369	Spain 2,848; France 2,539; United Kingdom 2,108; West Germany 1,805.
Diamond:				
Gem, not set or strung, thousand carats	58	6,081	--	All to Switzerland.
Industrial, do.	--	29,602	--	Switzerland 29,596.
Diatomite and other infusorial earth	1,213	16	--	Venezuela 10; Guinea-Bissau 6.
Feldspar, leucite, nepheline, etc	2,148	9,099	--	France 4,900; East Germany 3,520; United Kingdom 675.
Fertilizer materials:				
Natural and manufactured:				
Nitrogenous	148,833	181,894	--	Netherlands 40,940; West Germany 36,907; Belgium-Luxembourg 23,002.
Phosphatic	71,840	108,968	--	Brazil 65,814; United Kingdom 13,563; U.S.S.R. 9,960.
Potassic	1,315	100	--	All to Cyprus.
Other including mixed	61,365	89,220	--	Belgium-Luxembourg 58,750; Nigeria 9,960; Netherlands 6,200.

See footnotes at end of table.

Table 2.—Portugal: Exports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1978	1979	Destinations, 1979	
			United States	Other (principal)
NONMETALS —Continued				
Fertilizer materials —Continued				
Ammonia	14,091	8,648	--	Greece 8,644.
Graphite, natural	90	106	--	Spain 104.
Gypsum and plasters	64	145	--	Mozambique 75; Angola 52.
Lime	389	66	--	Cape Verde 39; Angola 27.
Mica, all forms	414	232	--	Mainly to United Kingdom.
Pigments, mineral:				
Natural, crude	r69	23	--	São Tomé and Principe 7; Mozambique 5.
Iron oxides, processed	51	21	--	Angola 8; Cape Verde 6.
Pyrite, gross weight	135	133	--	Sweden 122.
Salt	4,083	15,024	--	United Kingdom 13,891.
Sodium and potassium compounds, n.e.s.:				
Caustic soda	70	105	--	São Tomé and Principe 80; Guinea-Bissau 11.
Caustic potash kilograms	100	300	--	All to Cape Verde.
Soda ash	295	4,837	--	Argentina 3,000; Spain 1,790.
Stone, sand and gravel:				
Dimension stone:				
Crude and partly worked:				
Marble and other calcareous	111,246	108,444	42	Italy 37,399; Spain 29,011; Belgium-Luxembourg 12,345.
Slate	8,037	3,634	36	Denmark 1,348; West Germany 1,194; Netherlands 662.
Granite and other	21,311	23,660	242	Japan 16,740; Italy 6,440.
Worked:				
Slate	6,745	8,690	38	West Germany 2,940; Belgium-Luxembourg 2,433; Netherlands 2,147.
Paving and flagstone	102,868	138,230	80	West Germany 92,074; Denmark 15,582; United Kingdom 9,087.
Marble and other	40,978	46,593	1,730	West Germany 18,652; France 7,339; United Kingdom 5,972.
Dolomite, chiefly refractory grade	--	3	--	All to Angola.
Gravel and crushed rock	600	4,660	(1)	Gibraltar 4,450.
Limestone, except dimension	233	215	--	Mozambique 68; Guinea-Bissau 63.
Quartz and quartzite	7,938	3,812	--	Norway 2,000; United Kingdom 788; West Germany 703.
Sand excluding metal-bearing	13,862	14,112	--	Gibraltar 12,200.
Sulfur:				
Elemental, all forms	92	205	--	Cyprus 199.
Sulfuric acid	335	28,649	6,204	Spain 8,934; Italy 7,325; Canada 5,996.
Talc, steatite, soapstone, pyrophyllite	127	18	--	Angola 10; Mozambique 7.
Other:				
Crude	r139	111	--	Spain 110.
Slag, dross, similar waste, not metal-bearing:				
From iron and steel manufacture	2,140	1,226	--	France 1,200.
Other kilograms	--	200	--	All to United Kingdom.
Oxides, hydroxides of magnesium, strontium, barium value	--	$20	--	All to Cape Verde.
Building materials of asphalt, asbestos and fiber cements, and unfired nonmetals	1,765	1,742	--	Guinea-Bissau 833; Cape Verde 777.
MINERAL FUELS AND RELATED MATERIALS				
Asphalt and bitumen, natural kilograms	9,100	300	300	
Carbon black do	3,200	300	--	Mozambique 200; Angola 100.
Coal, all grades including briquets	18	11	--	France 10; Cape Verde 1.
Coke and semicoke	24	15	--	Cape Verde 8; West Germany 5.
Hydrogen and rare gases	20	(1)	--	All to Cape Verde.
Petroleum refinery products:				
Bunker deliveries:				
Gasoline, aviation thousand 42-gallon barrels	(1)	(1)		
Kerosine do	(1)	(1)		NA.
Jet fuel do	1,217	1,121		NA.
Distillate fuel oil do	8	27		NA.
Residual fuel oil do	1,171	1,136		NA.
Lubricants do	65	142		NA.
Unspecified do	234	405		NA.
Nonbunker deliveries:				
Gasoline, motor do	78	768	207	Netherlands 320; United Kingdom 161.
Kerosine do	22	(1)	--	All to Republic of South Africa.
Jet fuel do	--	167	(1)	Iraq 103; Spain 64.
Residual fuel oil do	--	510	360	United Kingdom 150.
Lubricants do	54	36	(1)	Spain 11; United Kingdom 7.

See footnotes at end of table.

Table 3.—Portugal: Imports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1978	1979	Sources, 1979	
			United States	Other (principal)
METALS				
Aluminum:				
Bauxite and concentrate	2,191	550	--	Spain 308; Suriname 140; Denmark 102.
Oxides and hydroxides	6,808	6,285	62	West Germany 2,630; United Kingdom 2,098; France 1,234.
Scrap	91	503	1	Norway 393; Denmark 40.
Unwrought	20,222	21,803	200	Canada 7,951; France 4,199; Spain 4,160.
Semimanufactures	15,855	14,177	286	Belgium-Luxembourg 3,217; Spain 2,002; Austria 1,998.
Arsenic	8	--		
Beryllium: Beryl ore and concentrate	10,788	762	8	Spain 576; Netherlands 60.
Chromium:				
Chromite	692	733	--	Republic of South Africa 294; Netherlands 180; Finland 131.
Oxides and hydroxides	237	254	--	West Germany 227.
Cobalt oxides and hydroxides	6	9	1	Belgium-Luxembourg 6.
Columbium and tantalum: Columbium ore and concentrate	14,999	NA	NA	NA.
Copper:				
Ore and concentrate	6,248	62	--	Spain 44; United Kingdom 18.
Oxides	246	296	(1)	United Kingdom 142; Norway 104; West Germany 31.
Sulfate solution	(1)	10	--	Mainly from United Kingdom.
Metal including alloys:				
Scrap	826	269	24	United Kingdom 100.
Unwrought:				
Blister	985	643	--	All from Chile.
Refined, unalloyed	13,525	10,933	--	Belgium-Luxembourg 2,900; France 2,475; Zambia 1,302; Canada 1,156.
Other	2,538	1,345	(1)	United Kingdom 642; Spain 628.
Semimanufactures	10,427	12,556	28	United Kingdom 3,715; France 2,224; Italy 1,911; Spain 1,503.
Gold:				
Ore and concentrate value	--	$143	--	All from France.
Metal including alloys, unworked or partly worked troy ounces	6,230	8,982	81	Belgium-Luxembourg 6,653; Switzerland 1,903.
Iron and steel:				
Ore and concentrate including sinters, pellets, briquets, etc	386,182	619,650	--	Brazil 143,915; Venezuela 129,926; Mauritania 128,590.
Roasted pyrites	NA	37	--	Netherlands 20; Australia 17.
Metal:				
Scrap	663,603	145,809	75,392	Netherlands 30,633; U.S.S.R. 14,931; United Kingdom 8,440.
Pig iron, ferroalloys, similar materials	37,127	58,204	(1)	Spain 48,180; Canada 4,034; Republic of South Africa 3,179.

See footnotes at end of table.

METALS —Continued				
Iron and steel —Continued				
Metal —Continued				
Steel, primary forms	232,305	147,824	--	Japan 59,333; West Germany 37,941; Netherlands 16,916.
Semimanufactures:				
Bars, rods, angles, shapes, sections	139,032	105,048	52	West Germany 27,459; Spain 18,810; Belgium-Luxembourg 13,500.
Universals, plates, sheets	223,923	178,020	772	West Germany 54,821; Czechoslovakia 20,272; Belgium-Luxembourg 19,982.
Hoop and strip	73,229	65,225	72	West Germany 28,522; Belgium-Luxembourg 23,345; France 8,795.
Rails and accessories	13,107	3,847	--	West Germany 1,288; United Kingdom 1,227; Austria 886.
Wire	27,830	17,184	35	Spain 3,860; United Kingdom 2,619; Republic of South Africa 2,392.
Tubes, pipes, fittings	37,276	26,077	--	West Germany 11,066; France 5,361; United Kingdom 3,359.
Castings and forgings, rough	35,091	728	62	France 218; West Germany 124.
Total	549,488	396,129		
Lead:				
Oxides	114	60	--	West Germany 40; Spain 20.
Metal including alloys:				
Scrap	82	91	14	United Kingdom 77.
Unwrought	16,622	28,044	NA	United Kingdom 12,143; Switzerland 1,001.
Semimanufactures	49	5	(1)	Spain 2.
Magnesium metal including alloys, all forms	8	33	25	France 2; Norway 2.
Manganese:				
Ore and concentrate	144,616	235,709	--	Gabon 109,700; Republic of South Africa 53,019; Brazil 44,620.
Metal including alloys, all forms	1,001	846	NA	Belgium-Luxembourg 241; Ireland 221; Spain 138.
Mercury 76-pound flasks	1,007	815	(1)	Spain 705.
Molybdenum metal including alloys, all forms kilograms	4,400	2,000	(1)	France 1,000.
Nickel:				
Matte and speiss	118	104	(1)	Canada 70; Norway 20; Finland 8.
Metal including alloys:				
Scrap	11	18	NA	NA.
Unwrought	233	206	--	Canada 71; West Germany 48; Finland 44.
Semimanufactures	468	452	2	West Germany 142; Finland 66.
Platinum-group metals including alloys, unworked or partly worked troy ounces	5,985	8,753	10	France 3,646; Switzerland 2,211; United Kingdom 2,095.
Rare-earth metals, oxides	18	18	--	France 12; United Kingdom 4.
Silver metal including alloys, unworked or partly worked thousand troy ounces	r1,253	1,422	--	West Germany 1,200; France 90.
Tantalum metal including alloys, all forms value	$319	$818	--	All from Austria.
Tin:				
Ore and concentrate	332	256	--	Indonesia 206; Malaysia 50.
Oxides	r81	61	36	West Germany 18; United Kingdom 7.
Metal including alloys:				
Scrap	10	20	18	Sweden 1.
Unwrought	464	529	--	Thailand 200; Malaysia 140; Spain 60.
Semimanufactures	39	52	(1)	Netherlands 24; United Kingdom 20.
Titanium:				
Ore and concentrate: Rutile	476	NA	NA	NA.
Oxides	7,794	8,231	2	Spain 2,157; Finland 1,373; West Germany 1,317.
Tungsten:				
Ore concentrate including residues	--	100	--	All from Spain.
Metal including alloys, all forms kilograms	400	600	100	Netherlands 200; United Kingdom 100.
Zinc:				
Ore and concentrate	22	22	--	All from Spain.
Oxides	100	166	--	West Germany 65; Netherlands 47; United Kingdom 38.

Zinc —Continued				
Metal including alloys:				
Scrap	98	781	39	Spain 306; Canada 145; United Kingdom 118.
Blue powder	545	815	--	United Kingdom 376; Norway 306; Belgium-Luxembourg 76.
Unwrought	17,139	14,524	18	Canada 3,242; Spain 3,169; France 2,990; Belgium-Luxembourg 2,139.
Semimanufactures	1,228	2,094	21	West Germany 1,159; Belgium-Luxembourg 633; United Kingdom 212.
Other:				
Ores and concentrates:				
Of titanium, vanadium, zirconium	886	1,126	--	Spain 637; Australia 190; Republic of South Africa 176.
Of base metals, n.e.s	20	386	--	Spain 335.
Ash and slag containing nonferrous metals	174	95	--	Chile 70; India 25.
Oxides, hydroxides, peroxides	r1,611	1,703	42	United Kingdom 967; Spain 424; West Germany 141.
Metals:				
Metalloids	44	258	1	Spain 254.
Alkali, alkaline earth, rare-earth metals kilograms	600	3,700	--	United Kingdom 3,400.
Pyrophoric alloys	r39	45	--	Netherlands 18; United Kingdom 12; France 6.
Base metals including alloys, all forms	147	115	(1)	Belgium-Luxembourg 59; Spain 16.
NONMETALS				
Abrasives, n.e.s.:				
Natural: Pumice, emery, corundum, etc	372	300	6	Netherlands 123; Italy 74.
Dust and powder of precious and semiprecious stones, including diamond kilograms	286	51	--	United Kingdom 34; Ireland 13.
Artificial corundum	1,384	1,753	4	West Germany 867; Brazil 343; France 268.
Grinding and polishing wheels and stones	563	530	6	Italy 205; United Kingdom 84; Spain 58; Austria 55.
Asbestos	17,111	11,213	16	Republic of South Africa 6,350; Canada 3,889; Australia 431.
Barite and witherite	458	645	--	West Germany 234; France 206; Spain 145.
Boron materials:				
Crude natural borates	2,450	4,570	--	Turkey 3,700; Netherlands 467.
Oxide and acid	451	553	--	France 364; U.S.S.R. 126; Turkey 33.
Borates and perborates	3,517	3,924	1,906	France 992; Netherlands 926.
Cement	64,281	95,800	36	Spain 83,814; United Kingdom 11,645.
Chalk	7,805	10,319	--	Spain 4,770; France 3,390; Belgium-Luxembourg 1,009.
Clays and clay products:				
Crude clays:				
Bentonite	22,991	22,477	229	Spain 21,050.
Kaolin	10,354	12,413	373	United Kingdom 9,916; France 1,240.
Other	10,450	8,038	80	Spain 4,480; France 1,953; United Kingdom 1,155.
Products:				
Refractory including nonclay brick	10,872	10,282	16	West Germany 3,918; Austria 2,083; France 1,279.
Nonrefractory	402	482	--	Spain 272; Italy 182.

COMMODITY REVIEW

METALS

Copper.—Exploration continued on a deposit of complex copper-lead-zinc ore near Castro Verde in southern Portugal. The mineralized area contains several ore bodies, of which Neves and Corvo were the most significant.

According to preliminary reports, the Corvo deposit contained 20 million tons of high-grade ore (5% to 6% copper), and the Neves deposit contained about 40 to 50 million tons of ore, with a copper content of between 1% and 1.5%. Chemical analysis of Neves-Corvo ores showed the following composition: Sulfur, 4%; iron, 4%; zinc, 2% to 4.5%; copper, 1% to 6%; arsenic, 0.5%; silver, 45 grams per ton; and gold, 0.3 grams per ton.

During 1980, the Government of Portugal requested French shareholders to transfer 11% of their shares to Portuguese interests to give Portugal majority ownership in the company at Neves-Corvo. A new firm Sociedade Mineira Neves Corvo S.A.R.L., in which a Portuguese Government-owned company holds 51% of the capital, was created to implement the agreement and develop and operate the future mine. The rest is equally divided between the private company Peñarroya (French) and the French Government-owned Bureau de Recherches Géologiques et Minières. Reportedly, mining should start sometime after the beginning of 1983.

Iron and Steel.—Exploration and preliminary development work continued on the Moncorvo iron deposit, located east of Torre

Moncorvo in northeast Portugal. The ore reserves at Moncorvo were reported at 500 million tons, with an average content of 37% iron and 0.58% phosphorus.

During 1980, plans for expanding the Seixal steelworks started to be implemented. The Siderurgia Nacional S.A.R.L. negotiated purchase of continuous caster from an unnamed firm from the Federal Republic of Germany. Vöest-Alpine of Austria received the order for supplying two 120-ton Linz-Donawitz (LD) converters. The Seixal works expansion was planned to increase capacity by 1 million tons of steel and 800,000 tons of rolled products. In addition to two LD converters, the Seixal plant will include one 1.5-million-ton-per-year pelletizing plant, one 1-million-ton-per-year blast furnace (9 meters in diameter), three 6-strand continuous casters, one 400,000-ton wire rod mill, and one 400,000-ton-per-year light section mill.

Pyrite.—After the Council of Ministers authorized implementation of a plan for the total utilization of pyrite in 1979, preparatory works for expansion started in the Aljustrel Mine during 1980. Plans call for production of 1.2 million tons of pyrite annually by 1982 and 2.7 million tons by 1985. The average grade of Aljustrel ore was reported as follows: Zinc, 2.2% to 3%; lead, 0.9% to 1.2%; sulfur, 41% to 46%; and iron, 36%. Recovery of nonferrous metals, pelletization of iron cinder and its use in steel plants were part of the plan. Outokumpu Oy of Finland, and the Swedish Government through LKAB International AB, were the principal contractors for the project.

Tungsten.—During 1980, Sociedade Portuguesa de Empreendimentos acquired a controlling interest in the Vale de Gatos (Vila Real) tungsten mine. After several years of exploration, Union Carbide relinquished its tungsten interests in the Covas area. Reportedly, the small tungsten deposits discovered will be operated by local companies.

Modernization and modification of the mill at Borralha, operated by Mines de Borralha S.A.R.L., started during 1980. Details of the program were not made public.

Joint exploration by Geomines of Belgium and local companies continued for tungsten deposits at Tabução. During 1980, the largest producer of tungsten was the mine of Panasqueira, operated by Beralt Tin & Wolfram (Portugal) S.A.R.L., a subsidiary of Beralt Tin & Wolfram, Ltd., of the United Kingdom. Tungsten remained the only mineral produced in Portugal which had significance for the world mineral economy.

Zinc.—According to reports, an 11,000-ton-per-year zinc electrolytic plant started production at a site near the town of Barreiro, southeast of Lisbon in the second half of 1980. The owner and the operator of the new plant was the Goverment-owned concern Quimigal E.P.

NONMETALS

Beryl.—Commercial deposits of beryl are found in the pegmatites of northern Portugal, in Braga and Vila Real Districts. Beryl was produced as a byproduct of quartz-feldspar output. Of quartz-feldspar producers in operation in Portugal, the largest producers of beryl were Companhia Portuguesa de Fornos Electricos S.A.R.L. (F. Electricos) and Sociedade de Exploração de Rochas Lda. (Quarfel) a wholly owned subsidiary of Metalurgica do Norte S.A.R.L. (Milnorte), an important producer of silicon metal in Portugal.

Diatomite.—The largest producer of diatomite, with about 90% of country's output, was Sociedade Anglo Portuguesa de Diatomite Lda., which operated two mines near Couto Mineiro do Jordim in the southern part of the Leiria District. In addition, a second producer, Sociedade Quisselgur Lda., operated a small mine at Amieira in the region of Obidos, east of Caldas de Rainha, Leiria District.

Feldspar-Quartz.—Quartz production was associated with feldspar in Portugal. During 1980, the averge number of companies that produced both quartz and feldspar was 13; 8 reported production of quartz alone, and 3 registered output of feldspar only. As in the past, during 1980 producers of silicon and ferrosilicon owned and operated their own sources of quartz. Fornos Electricos owned and operated mines at Senhora da Assunção Varzea e Valdeireiras, near Satão, and at Santa Luzia near Viseu, both in Viseu District. The mined ore was processed in a washing plant at Canas do Senhorim, also in Viseu District. Average yearly output from Fornos Electricos' quartz mines was about 50,000 tons of quartz and about 1,000 tons of feldspar. Quartz was used in the metallurgical facilities of Fornos Electricos, and feldspar was sold to the domestic ceramic industry. Milnorte obtained quartz supply from its mining subsidiary Quarfel. Principal mines

were at Mata da Lapeira, near Celorico de Basto in Braga District; Corga do Cavacao in Guarda District; and Medronheiro, near Satão, in Viseu District. Quarfel produces about 20,000 tons of quartz per year.

The most important producer of quartz-feldspar in Portugal during 1980 was Unimil Minerais Lda., which operated the Arreigada and Vilela Mines in the Pôrto District and the Celorico de Basta Mine in Braga District. The ore is processed in a grinding plant at Formiga, approximately 20 kilometers from the Arreigada Mine. A new mill was under construction at Seixoso near Amarante. The project was financed jointly by Unimil and Minas do Zezere S.A.R.L. In addition to ore, tailings from tin operations of Zezere will be processed in the new mill.

The A. J. da Fonseca was the largest feldspar producer in Portugal during 1980. In addition, the company produced some quartz. Most of the operations of Fonseca were in the Braga District, at Viana do Castelo and in the Vila Real District. About 75% of the company's feldspar output came from ore operations near Chaves. Fonseca produced about 10,000 tons in 1978, the latest year for which data were reported. In addition to Unimil, Fonseca, Quarfel, and Fornos Electricos, there were a number of other feldspar-quartz producing companies operating in Portugal. The more important of these were: Minas do Baranco Lda., at Gouveia, Guarda District; Graliminas-Mineiro da Gralheira Lda., at Villa Longa, Viseu District; and Joao Cergueira Antones, with a number of mines at Ponte de Barea, Viana do Castelo, and Montealegre, Vila Real District.

Lithium.—During 1980, lepidolite was produced in one mine near Seixo Amarelo in the Guarda District. The operator was Sociedade Mineira Carolinos Lda. The average content of lithium oxide (Li_2O) in ore was reported at 1.5%. A deposit of lithium minerals at Goncalo, Guarda District, owned by Societa Mineira Pegmatites (Pegmatica), was not in operation.

Salt.—Salt solution mining by Segema-Sociedade Mineira Lda. at Torres Vedras, north of Lisbon, remained the largest source of salt in Portugal and accounted for about two-thirds of the country's output. A 25-kilometer-long pipeline brings the solution to the soda ash plant of Soda Povoa at Povoa de Santa Ira. Soda Povoa was a subsidiary of Solvay et Cie. of Belgium. Mineira de Sais Alcalinos S.A.R.L. (Clona) was also a salt producer in 1980, from a rock salt deposit near Loulé in the Algarve District, in southern Portugal.

Silica Sand.—Silica sand for use in glass, foundry, and ceramics was produced from two regions, Figuera da Foz in the Coimbra District and Rio Maior in the Santarem District. Sarel-Sociedade de Arieas Reunidas Lda, the largest producer, had active operations in both areas. In the Maioz area of the Santarém District, silica sand was produced by the smaller producers Maoril-Aries Industriais, Lda., and Sifucel-Silicas Lda.

Stone.—Production of stone was the most important segment of the mineral industry of Portugal during 1980 in terms of both value and number of personnel employed. About one-half of the value of minerals produced in the country can be attributed to the production of stone. About 1,000 companies were estimated to be producers, with sizes ranging from small family-run quarries to large companies producing from several deposits. Marble was the most valuable product, and limestone was the largest by volume. Marble was produced mostly around the cities of Vila Vicos, Borba, and Estremos, and this region accounted for about 85% of Portugal's marble production. During 1979-80, the major producers in the area were: Marmores e Materias de Construcao Lda. (Marmetal); Marmores do Condado S.A.R.L.; Companhia Industrial de Marmores de Estremor Lda. (Marmor); and Sociedade Lusco-Belga de Marmores, S.A.R.L. (Solubema).

The major limestone producing areas were found in the area between Leiria, Lisbon, and the Tagus River. Cement companies own their limestone quarries and were the largest producers of limestone, about 50% of the total. Siderurgia Nacional purchases limestone from independent producers operating at Arrabida, located about 30 kilometers north of Lisbon. Granite was produced by a large number of small companies in the north in the Districts of Braga, Viana do Castelo, Pôrto, Vila Real, and Viseu.

Slate production came from the area around Valongo in the Pôrto District. Seven companies produced slate during 1980: Empresa das Losuas de Valongo, S.A.R.L.; Pereira Gomez e Carvalho Lda.; Fonseca, Costa e Ca Lda.; Companhia Portuguesa de Ardosia Lda.; Exportadora de Ardosias Lda.; Balterejo, Sampaio e Ca. Lda.; and Exploracao Mineira de Valongo Lda. (Emir-

al).

MINERAL FUELS

The energy demand of Portugal was almost completely met by imports of crude oil, high-rank coals, and coke. Portugal did not produce natural gas or crude oil, and coal, mostly anthacite, remained the principal fuel produced in the country.

Coal.—West German mining experts, working under terms of a Technical Cooperation Agreement between the Governments of Portugal and the Federal Republic of Germany, assisted in expanding capacity of the only Portuguese coal mine, Germunde, also known as the Pejão Mine, located in northern Portugal and operated by the Empresa Carbonifera do Douro S.A.R.L. During 1980, mining equipment made in the Federal Republic of Germany and valued at 1.1 million German marks, or about $500,000 was delivered to the mine site. A nearby powerplant, which in the past used almost all coal produced at Pejao, will remain the major consumer.

Petroleum and Natural Gas.—Portugal did not produce crude oil and natural gas during 1980. Geophysical exploration was carried out near the townships of Seixal, Barreiro, and Palmela in cooperation with specialists from Spain. At yearend, results of the exploration were studied, but no decision was made to start drilling.

The first onshore well drilled since 1962, Campelos No. 1, was spudded in by Sceptre Resources of Portugal near Caldas Rainha, 55 kilometers north of Lisbon. The drilling contractor was Bawden Drilling of the United Kingdom, using a National 80-UE rig. Partners with Sceptre were Boe Valley Exploration of Portugal and Siebens Oil and Gas of Portugal.

In addition, the Goverment of Portugal, through its Gabinet e para e Pesquisa e Exploração de Petroleo, concluded contracts for petroleum exploration with Exxon Inc. and Union Texas Inc. According to terms of the later contract, Union Texas is obliged to invest about $1.6 million during a 2-year period for seismic exploration. If the results of seismic work warrant, Union Texas was to drill two wells at a total cost of $46 million. The onshore concession covers 2,571 square kilometers near the township of Leiria, north of Lisbon. The earlier contract with Exxon had awarded three concessions (total area, 2,554 square kilometers) in deep waters off the southern coast (Algarve coast).

Portugal had the following petroleum storage capacities in use at the beginning of 1980, in cubic meters: Crude petroleum, 2,290,000; liquefied petroleum gases, 130,000; gasoline, 529,000; kerosine, 157,000; aviation gasoline, 7,000; jet fuel, 212,000; gas oil, 681,000; and fuel oil, 1,089,000.

The Mineral Industry of Romania

By Richard Levine[1]

In 1980, economic growth in Romania often fell short of the planned target. Increases in many economic areas have been rapid compared with other East European countries, and margins between planned and actual performance at times reflect deviations from self-set ambitious goals.

In 1980, national income grew by 2.5% against a projected 8.8% growth, and gross industrial production grew by 6.5% against a projected 11.4% growth. Investment as a percentage of national income continued to average approximately 40%, and this high rate of investment has fueled Romania's economic growth.

Economic shortcomings in 1980 were attributed to poor weather for agriculture, large price increases for imported oil and raw materials, and the world economic state. Labor shortages in mining were experienced as soldiers, students, and workers from other parts of the country were mobilized to help during critical periods.

1981 plans call for smaller increases. National income and gross industrial product are each to rise by 7%. Investment is to continue at a lesser but still high percentage of the national income during the 1981-85 planning period.

Romania is not rich in mineral resources although it had been a net petroleum exporter. It is now a net petroleum importer and a net importer of other energy raw materials including coke, coking coal, and natural gas.

To reduce material costs, Romania is implementing its "new economic mechanism." The new economic mechanism stresses the use of net output instead of gross output to eliminate inputs purchased outside the enterprise, including energy and materials, being counted as production, and it stresses profit from sales to reduce production cost and eliminate the production of unwanted goods. To provide a more realistic assessment of production costs, it was decided in 1980 to raise the domestic price of raw materials to conform to their world market price. This measure went into effect on January 1, 1981. Also, as of January 1, 1981, it was decided to switch to a new single commercial rate of exchange for exports, imports, and internal exchange of 15lei=US$1.00[2] Other programs to reduce costs include recycling and reducing imports.

The 12th Romanian Communist Party Congress, which met in December 1979, approved a program to make Romania self-sufficient in energy and fuels in the 1990's. Plans call for intensified geological explorations to tap new petroleum and gas deposits including deep drilling and drilling on the Black Sea shelf. At the same time, greater use is to be made of coal as well as nuclear and hydroelectric power.

The State is also promoting research in the use of solar, wind, biogas, geothermal, and other potential sources of energy. These efforts will be conducted along with a concerted effort to promote savings in the use of energy and minerals.

PRODUCTION

In 1980, the production of several important mineral commodities fell far below planned goals. Production of crude oil again declined, and coal production fell far short of the 1980 goal of 54.1 million tons. The production of natural gas, however, exceed-

ed the plan. Steel production increased slightly, but was far below the planned target.

For many commodities, the production goals set for 1981 are lower than the unattained 1980 goals. For example, in 1981 coal production is planned to be 50.8 million tons compared with the 54.1-million-ton goal set in 1980; steel production, 14.665 million tons compared with 15.6 million tons; cement production, 15.86 million tons compared with 18.3 million tons; and crude oil production, 12.6 million tons compared with 15 million tons. Still, to achieve many of these goals it will require production increases much greater than occurred in 1980.

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.

[1]Includes data available through Aug. 4, 1981.

[2]In addition to the commodities listed, antimony, asbestos, gypsum, and a variety of crude construction materials are produced, but output is not reported quantitatively, and available information is inadequate to make reliable estimates of output levels.

[3]Reported figure.

[4]Romanian sources do not indicate whether refinery fuel is reported as a part of the listed product yields. Moreover, additional minor products may be produced, but are not listed in official sources.

TRADE

In 1980, Romania's foreign trade turnover reached 340.3 billion lei.[3] Imports accounted for approximately 90% of the iron ore, 70% of the bauxite and crude oil, and 50% of the coking coal requirements. Although the Soviet Union is Romania's largest single trading partner, the country is not dependent upon it for the majority of its mineral imports. For example, in 1980 approximately 10% of Romania's imported crude oil (1,496,000 tons), 45% of its imported iron ore (7,230,000 tons), and 20% of its imported phosphates (197,000 tons) came from the Soviet Union.

Approximately three-fourths of fuel and raw materials imports came from market economy countries. Romania is a net importer of copper, lead, zinc, sulfur, and many other minerals. It exports large amounts of petroleum products along with metals, nonmetals, and precious and semiprecious metals and stones. Because of the increased price of raw material on the world market, Romania intends to increase its share of trade with the CMEA[4] countries to reduce its hard currency payments, and is seeking cooperative agreements with all countries. However, in 1980, despite its membership in CMEA, all petroleum imported from the Soviet Union was paid for in hard currency at Organization of Petroleum Exporting Countries (OPEC) level prices.

In 1980, Romania was engaged in cooperative ventures with the CMEA countries. It is one of the CMEA countries participating in the development of the Kiyembay Asbestos complex in the Soviet Union, and was scheduled to receive 15,000 tons of asbestos in 1980, increasing to 25,500 tons in 1981, and eventually to 30,000 tons by 1991. In 1980, Romania was scheduled to receive shipments of 1.5 billion cubic meters of natural gas from the Soviet Union through the Orenburg pipeline in conjunction with Romania's participation in the pipeline's construction.

Success has been achieved in arranging cooperative ventures for minerals with non-CMEA countries. Many of these ventures, however, are described in terms of their future potential, and it is not certain if and when deliveries are to begin. A number of cooperative venture agreements have been made with African states. The Romanian-Zambian joint enterprise "Mokambo" is to cooperate in the exploration and development of coal, nickel, lead, phosphate, molybdenum, uranium, and hydrocarbon deposits. In Kenya, the K.M.I.L. joint company is conducting geological surveys of nickel deposits. In Burundi, the Somiburom joint company is to participate in the exploration and mining of nickel deposits; in Tanzania, the Besaminco joint company is to explore and mine mineral resources; and in Mozambique, geological surveying is being conducted for coal and iron ore. Other cooperative ventures are either underway or being initiated with Guinea, Zaire, the Congo, Liberia, and Angola.

In North Africa and the Mideast, there is joint oil drilling and mineral exploration with Algeria, exploration with Morocco of copper deposits, and a cooperative venture for mining and concentrating phosphates in Egypt. Iraq, which supplied Romania with oil in 1980, signed an agreement to cooperate in oil prospecting, drilling, and refining operations. In 1980, an agreement was announced whereby Iran is to supply Romania with a large quantity of oil for hard currency, although it is uncertain whether this agreement will actually be put into effect. This agreement would result in a marked increase in deliveries from Iran, and would be comparable in quantity to the agreement negotiated with the former Shah's Government.

In the Far East in September 1979, the Romanian and Chinese Governments signed a cooperative agreement to mine coking coal in mainland China. Collaboration is to occur in the construction of mines, dressing plants, and other facilities. The Romanians are to receive one-half of the coking coal output. Initial design work for this project began in December 1979. Romania is also obtaining oil from China and imported approximately 770,000 tons in 1980.

In the Balkans, Romania is trying to increase trade and promote good relations. Romania imports minerals, including chromium ore and concentrate, from Albania; has established joint companies with Greece to market petroleum products; is cooperating with Turkey in the construction of a petroleum refinery; and is engaged in joint hydroelectric projects with Yugoslavia and Bulgaria.

Romania is also trying to increase trade with the developed market economy countries. In 1980, it entered into a separate trade agreement with the European Communities (EC) although the CMEA position is to negotiate with the EC as a block. This separate agreement was the first of its kind

between a CMEA country and the EC although Romania's official position is still to support joint EC-CMEA negotiations. Under the terms of this agreement, a range of 94 industrial products and raw materials is allowed to enter the EC countries.

The United States is one of Romania's important trading partners. During the first half of 1980, petroleum products, which had traditionally dominated U.S. imports, remained at their 1979 low of 16% of U.S. imports. Romanian imports of U.S. coal increased greatly in 1980 as shipments began in accordance with a contract with the Island Creek Coal Co., a subsidiary of the Occidental Petroleum Corp. According to this contract, Romania is to receive 2 million tons of coal annually for 20 years from a large coal mine being developed in Upshur County, W. Va.

Romania is giving much attention to reducing its hard currency indebtedness, which was estimated at $6.7 billion as of yearend 1979, with a debt-servicing ratio of 22%. Romania's debt-servicing ratio is the lowest among the East European countries.[5] Romania is also the only CMEA country belonging to the World Bank and the International Monetary Fund; and it has Most-Favored-Nation trading status with the United States.

Table 2.—Romania: Apparent exports of mineral commodities[1 2]

(Metric tons unless otherwise specified)

Commodity	1978	1979	Principal destinations, 1979
METALS			
Aluminum:			
Bauxite	--	8,295	All to Austria.
Metal including alloys:			
Scrap	7,160	2,016	Italy 1,627; France 192.
Unwrought	[3]70,300	[3]65,000	Japan 10,330; France 8,131; Italy 5,127.
Semimanufactures	27,562	28,584	United States 6,856; Poland 6,718; Japan 6,679.
Arsenic trioxide, pentoxide, acid	80	150	All to Greece.
Chromium:			
Chromite	10	--	
Oxides and hydroxides	47	199	United States 114; Japan 85.
Copper:			
Sulfate	--	20	All to Greece.
Metal including alloys:			
Scrap	3,561	844	Italy 764.
Unwrought	5,423	5,350	All to West Germany.
Semimanufactures	260	242	Pakistan 200.
Iron and steel:			
Pyrite, roasted thousand tons	147	126	All to Hungary.
Metal:			
Scrap	3,412	1,142	Yugoslavia 764; Italy 369.
Pig iron thousand tons	114	51	Austria 32; Italy 10.
Ferroalloys do	4	20	West Germany 10; United Kingdom 3; Netherlands 2.
Steel, primary forms do	[4]641	[4]541	Yugoslavia 216; Italy 107; Japan 80.
Semimanufactures:			
Bars, rods, angles, shapes, sections do	[4]324	[4]295	West Germany 40; Poland 23; Yugoslavia 14.
Universals, plates, sheets do	[4]757	[4]575	West Germany 35; United States 21; Japan 16.
Hoop and strip	231	309	Yugoslavia 288.
Wire thousand tons	[4]117	[4]147	West Germany 15; Pakistan 3.
Tubes, pipes, fittings do	[3]420	[3]389	West Germany 35; Poland 34; United States 14.
Castings and forgings, rough do	4	3	West Germany 3.
Lead:			
Oxides	5	3	All to Spain.
Metal including alloys, scrap	58	--	
Molybdenum metal including alloys, all forms	3	--	
Nickel metal including alloys, scrap	--	2	All to West Germany.
Platinum and platinum-group metals including alloys, unworked or partly worked value, thousands	$12	--	
Silver metal including alloys:			
Unworked or partly worked do	$1,037	$4	All to Italy.
Waste and sweepings[5] do	$10,400	--	

See footnotes at end of table.

(Metric tons unless otherwise specified)

Commodity	1978	1979	Principal destinations, 1979
METALS —Continued			
Tungsten metal including alloys, all forms	11	11	All to France.
Zinc metal including alloys:			
Unwrought	--	[6]100	Belgium-Luxembourg 49.
Semimanufactures	--	19	All to Morocco.
Other:			
Ash and residue, nonferrous	603	542	West Germany 530.
Oxides, hydroxides, peroxides	--	2,667	Pakistan 2,666.
Metalloids	199	16	All to Switzerland.
Nonferrous metals including alloys:[3]			
Unwrought	563	439	NA.
Semimanufactures	13,478	--	
NONMETALS			
Abrasives: Grinding and polishing wheels and stones	1	11	West Germany 9.
Asbestos	100	20	All to United States.
Barite and witherite	598	2,478	France 1,199; Italy 1,030.
Boron oxide and acid	529	370	Italy 160; Singapore 100.
Cement thousand tons	[3]2,934	[3]2,738	Egypt 903; Saudi Arabia 229; Pakistan 169.
Clays and clay products:			
Crude	650	3	All to Austria.
Products:			
Refractory	133	1,476	Yugoslavia 1,437.
Nonrefractory	5,218	5,922	Nigeria 3,711; Yugoslavia 1,208.
Diamond:			
Gem, not set or strung value, thousands	$106	--	
Industrial do	$39	$1,050	All to Belgium-Luxembourg.
Fertilizer materials:			
Crude, nitrogenous	1,600	5,044	All to Turkey.
Manufactured:			
Nitrogenous: Urea thousand tons	[3]1,043	[3]1,023	Turkey 188; Egypt 65; Morocco 46.
Phosphatic do	18	148	Turkey 96; Indonesia 47.
Other including mixed do	[3]1,205	[3]1,315	Thailand 133; Yugoslavia 44; Turkey 36.
Ammonia do	5	35	Yugoslavia 29.
Gypsum and plasters	28,203	27,989	All to Hungary.
Lime	7,633	9,489	Do.
Pigments, mineral: Iron oxides, processed	139	53	All to Greece.
Precious and semiprecious stones excluding diamond, natural value, thousands	$1	$3	All to France.
Salt thousand tons	[3]781	[3]841	Hungary 445; Yugoslavia 131.
Sodium and potassium compounds, n.e.s.:			
Caustic soda	[3]303,500	[3]238,600	Hungary 24,573; Egypt 16,827; Yugoslavia 15,718.
Caustic potash	317	515	Italy 407; Tunisia 50; West Germany 38.
Soda ash	[3]518,300	[3]457,400	Czechoslovakia 53,000; Thailand 24,753.
Stone, sand and gravel:			
Dimension stone:			
Crude and partly worked	172	547	Japan 463; Belgium-Luxembourg 50.
Worked	15,920	23,351	West Germany 16,179; Austria 3,593.
Gravel and crushed rock	120,946	121,428	Hungary 121,354.
Limestone	687	932	All to West Germany.
Sand, not metal-bearing	1,081	20	All to United Kingdom.
Sulfur:			
Elemental, other than colloidal	1	--	
Sulfuric acid	--	5,322	All to Yugoslavia.
Talc and steatite	22	88	West Germany 72.
Other:			
Crude	1,677	1,896	Hungary 1,538; West Germany 358.
Slag, dross, and similar waste	[r]98,195	119,199	All to Yugoslavia.
Oxides and hydroxides of magnesium, strontium, barium	25	--	
MINERAL FUELS AND RELATED MATERIALS			
Asphalt and bitumen, natural	5,906	996	All to Yugoslavia.
Carbon black	[3]45,400	[3]30,200	Sri Lanka 1,378; Thailand 579.
Coal and briquets:			
Anthracite and bituminous coal including briquets	300	--	
Lignite and lignite briquets	11	--	
Gas, natural million cubic feet	[3]7,063	[3]7,063	All to Hungary.
Peat and peat briquets	2,501	2,006	Austria 1,595; Italy 411.
Petroleum refinery products:			
Gasoline thousand 42-gallon barrels	[3]20,502	[3]20,226	Netherlands 5,743; West Germany 5,321.
Kerosine do	2,906	([7])	NA.
Distillate fuel oil do	[3]18,016	[3]15,092	Turkey 4,469; West Germany 2,357; Netherlands 1,667.
Residual fuel oil do	[3]15,218	[3]17,005	Italy 4,542; Netherlands 1,249; Sweden 1,195.

rRevised. NA Not available.

[1]Owing to the lack of official trade data published by Romania, this table should not be taken as a complete presentation of Romania's mineral imports. These data have been compiled from various sources which include United Nations information, data published by the partner trade countries, and partial official trade sources of Romania.

[2]Unless otherwise specified, all data are derived from official trade statistics of individual trading partners.

[3]Official Romanian trade statistics.

[4]Quarterly Bulletin of Steel Statistics for Europe, United Nations, New York.

[5]Silicomanganese ferroalloy only; total import from the U.S.S.R. not available.

[6]Presumably largely bituminous coal; of total officially reported coal imports in 1979, 2,840,000 tons was described as washed pit coal for coke manufacture, while 1,005,000 tons was not further described.

COMMODITY REVIEW

METALS

Ferrous mining and metallurgy employs approximately 107,700 workers and accounts for 7.7% of the country's industrial output, and nonferrous mining and metallurgy employs approximately 70,800 workers and accounts for 3.4% of the country's industrial output.[6] Romania is not rich in metals and is largely dependent upon imports to supply sufficient raw materials for metal production. The country is exporting precious metals, but there is a lack of reliable information regarding production of these metals.

The 1981 plan calls for geological exploration to locate new reserves of iron ore, nonferrous metals, and rare and precious metals. Also, greater use is to be made of rare and precious-metal deposits with poor and dispersed contents. Local industries as well as individuals are being encouraged to mine gold, silver, and other precious metals.

Plans call for expanded secondary recovery of iron, pig iron, iron and steel alloys, copper, aluminum, and other nonferrous metals. By 1985, Romania plans to supply through recycling 40% of its iron, 41% of its copper, and 40% of its lead requirements.

Aluminum.—Production of bauxite remained at its 1979 level, and production of alumina and primary aluminum ingots increased. In 1980, a second aluminum foil rolling mill began operations at Slatina. This mill was designed and built in Romania. Beginning in 1981, Slatina is to provide the country's entire supply of aluminum foil from 5 to 750 micrometers thick.

Copper.—Total copper production continued to increase, and future increases are planned based in part on the expansion of enterprises in the Moldova Noua and Rosia Poieni areas. Research has been conducted on copper preparation to make better use of the low-grade ores from these areas. In addition, the flotation installation at Moldova Noua is to be enlarged. Projected annual capacities for the Rosia Poieni and Moldova Noua Mines are given as 15 million tons and 9 million tons of ore, respectively, and production of copper ore is projected to increase by four times.

Gold.—President Ceausecu claimed that gold is still being mined from regions where it was mined 2,000 years ago and stated that substantial amounts of alluvial gold are contained in other areas. It was claimed that new prospecting areas for gold-bearing ores were discovered during the 1976-80 planning period. Individuals are being encouraged to mine gold from alluvial deposits. The unemployed and pensioners are to receive 150lei for every gram of fine gold obtained. Local industry is also being encouraged to engage in gold production. In October 1980, Romania was the world's second largest exporter of gold for sale in Switzerland with a reported 10 tons.

Iron and Steel.—In 1980, production of crude steel increased although falling short of the plan. Production of pig iron also rose, but that of iron ore declined.

Some problems in steel production were experienced in 1980. Shortages were reported in the delivery of widely used rolled products. These included shortfalls in the supply of billets from the Hunedoara and Resita complexes, which resulted in decreased pipe production. In addition, the steel industry exceeded its consumption level for coke, and this was blamed on the poor quality of coke and coking coal provided. Poor-quality electrodes and nonenforcement of provisions regarding the quality of scrap were faulted for the steel industry exceeding its norm for electrode consumption.[7]

A number of measures were stressed for eliminating problems. The use of alloy steel, especially in the machine building industry, is said to be unjustifiably high and an effort is being made to replace alloy steel with an improved carbon steel. Production of alloy steel in 1981 is to be directed toward those types of steel that reduce imports. Shortages of certain special alloy steels are forecasted for 1981 due to planning delays.[8] The importance of attaining the projected parameters for the new heavy plate rolling mill at the Galati complex was stressed for ensuring the necessary amount of metal for the machine building industry. Production of stainless and refractory steel plates is required to double in 1981 compared with 1980 production.

In 1980, production facilities that came into operation included a 100-ton electric furnace at the Calarasi complex, two 100-ton electric furnaces at the Tirgoviste complex, the first oxygen converter with a 160-ton capacity at plant No. 3 at the Galati complex, continuous casting machines for blooms at the Galati and Calarasi complexes, a 1,000-cubic-meter blast furnace at the Calan "Victoria" enterprise, a medium section rolling mill at the Braila "Laminor-

ul" enterprise, a wire rolling mill at the Zalau Tube enterprise, a hard steel wire drawing mill No. 3 at the Cimpia Turzii Metallurgical enterprise, and a stainless steel sheet and strip facility at the Otelinox enterprise of Tirgoviste.

Lead and Zinc.—The production of lead and zinc has declined from the production level at the beginning of the 5-year plan in 1976. Plans are to increase the production of both commodities during the next plan period. In 1981, lead production is projected to increase by 13.9% and zinc production by 8.9% over that of 1980. By 1985, plans are to obtain 40% of lead production from secondary materials. Construction is being completed of a metallurgical facility for electrolytic lead at the Copsa Mica nonferrous metallurgical enterprise.

Silver.—During the 1976-80 planning period, Romania claims to have discovered new prospecting areas for silver-bearing ores. As with gold, individuals are being encouraged to mine silver from alluvial deposits. Unemployed persons and pensioners are to receive 7.5 lei per gram of silver obtained.

NONMETALS

Romania produces a variety of nonmetallic mineral commodities. It is a net exporter of products such as sodium compounds, nitrogenous fertilizers, cement, stone, gravel, lime, and salt, and is a net importer of other products such as asbestos, pyrite, and magnesite. During the 1981-85 planning period, production increases are projected for many nonmetallic minerals including kaolin, bentonite, graphite, sulfur, limestone, pyrite, etc. To better exploit nonmetallic mineral deposits, local industry is being encouraged to mine building materials. In an effort to reduce energy and material costs, plans are to change production methods and to use less expensive materials in the production of cement and concrete.

Cement.—Cement production has been steadily increasing. However, because of the energy-intensive nature of cement production and the cost of raw materials, an effort is underway to alter current production methods. Production plans call for the share of dry processing to rise to 95% of total production by 1985. Dry processing is said to result in a 30% energy savings. The use of secondary materials is also planned to increase. In 1981, there is to be an increase in the use of ash from thermal and electric powerplants by five times over use in 1979 and in the use of blast furnace slag as additives.

In 1981, emphasis is to be placed on the modernization of existing enterprises to achieve fuel and materials savings. Only 5.6% of production increases in the Ministry of Forestry Administration and Construction Materials is to be based on new capacities being activated or attaining their planned parameters. Regarding increasing capacities, the expansion of the Alesd Binder and Asbestos Cement complex, scheduled for 1980, will make it the largest enterprise of its kind in Romania.

Clays.—Production figures for clays are generally not published and must be estimated. It was stated that in 1980 there was a failure to meet the extraction plan for certain clays. Shortages were cited in the supply of refractory materials including furnace linings, which caused negative repercussions at the Galati, Hunedoara, and Resita steel complexes.[9] In 1981, plans call for the production of refractory clay to increase by 10.9%. A refractory clay washing installation is under construction at Suncuius.

By 1985, production of kaolin is planned to increase by 40% and in 1981, by 12.5% over its 1980 level. A kaolin preparation unit at Parva is scheduled for completion in 1981.

Fertilizers.—In 1980, problems occurred in agriculture partly because of a lack of timely deliveries of fertilizers; and total fertilizer production in 1980 was reported to have declined.[10] Although Romania is an importer of fertilizer raw materials, it is an exporter of fertilizers and is one of Europe's leading exporters of nitrogenous fertilizers. Less than 50% of fertilizer production has been used for domestic agriculture. The issue has been raised as to whether it would be preferable to make a greater percentage of fertilizer production available for domestic agriculture because of the need for agricultural products. Also the expense of fertilizer production, caused by the rise in energy prices, coupled with the rise in price of agricultural products on the world market, indicates that it might be more advantageous to apply fertilizers to obtain increased yields rather than to simply export them.

Projections for 1985 call for urea to comprise the greatest proportion of nitrogenous fertilizer production, followed by ammonium nitrate and nitrochalk. For phosphate fertilizers, superphosphate concentrate is to replace simple superphosphate as the domi-

nant type. The greatest growth is to be in the production of complex fertilizers, which is to triple.

In 1980, it was reported that urea plants were under construction at the Bacau, Arad, and Slobozia fertilizer enterprises with a capacity of 1,300 tons per day for each plant. France's Coppee-Rust S.A. is the contractor for the three urea plants.

Sulfur.—Although Romania has been mining pyrite for its sulfur production, it also depends on imported raw materials. In 1980, work was described as being in the advanced stage for starting operations at the sulfur-bearing ore deposit in the Caliman Mountains, and production is scheduled to begin in 1981. This deposit is stated to have an annual capacity of 60,000 tons. During the 1981-85 planning period, sulfur production is projected to increase sixfold.

MINERAL FUELS

Romania's energy policy is directed toward diverting its limited oil and gas supplies from fuel uses wherever more economic substitutes exist in order to produce the more valuable hydrocarbon products. In electric power generation, it is intended to substitute lignite and oil shale and to develop hydroelectric and nuclear power.

For the 1981-85 planning period, energy consumption is expected to increase while the production of oil and natural gas is to be below their peak levels in the 1970's. Oil production has been stagnating despite the fact that a large percentage of the geological research budget is designated for the discovery of oil reserves. To compensate for the shortage of oil, coal production is planned to increase sharply until nuclear powerplants come onstream in the late 1980's. Emphasis is also being placed on the development of hydroelectric power. Along with hydroelectric and nuclear power, Romania intends to increase its share of solar and other nonconventional power sources.

Table 4 shows the planned changes in the sources of electric power generation. The total energy balance for 1979 and 1980 is shown in table 5.

Table 4.—Production of electricity, by source

(Percent)

Source	1979	1980[1]	1985[1]	1990[1]
Hydrocarbons	53.49	39.7	20	4-5
Coal and oil shale	26.66	40.0	55	44
Hydroelectric	17.46	17.6	20	24
Nuclear	--	--	--	17-18
Nonconventional (wind, solar, etc.)	2.39	2.7	5	10
Total	100.00	100.0	100	100

[1]Figures for these years are estimated Romanian plan figures.

Table 5.—Romania: Primary energy balance

(Million tons of standard coal equivalent)[1]

	Total primary energy	Coal (lignite, anthracite, bituminous) coke	Crude oil and petroleum products	Natural and associated gas	Hydropower
1979:					
Production[2]	80.8	16.0	18.1	45.3	1.4
Exports	11.6	--	10.9	.3	.4
Imports	27.4	6.2	21.0	--	.2
Apparent consumption	96.6	22.2	28.2	45.0	1.2
1980:					
Production[2]	82.3	17.0	16.9	46.9	1.5
Exports	11.7	--	11.0	.3	.4
Imports	31.9	6.2	23.5	2.0	.2
Apparent consumption	102.5	23.2	29.4	48.6	1.3

[1]One ton of standard coal equivalent (SCE)=7,000,000 kilocalories. Conversion factors used are hard coal, 1.0; lignite and brown coal, 0.33; coke, 0.9; crude oil, 1.47; natural gas, 1.33 (per 1,000 cubic meters); and hydroelectric power, 0.123 (per thousand kilowatt-hours).

[2]Production from production table and from Anuarul Statistic al Republicii Socialiste Romania, 1980 (Annual Statistics of the Socialist Republic of Romania, 1980), Bucharest, 1980.

Coal.—Coal production, which was planned to reach 54.1 million tons in 1980, fell far short of this goal. Romania has tended to set unrealistically high goals for coal production, which it fails to achieve, even though production increases.

In 1980, the coalfields in the Oltenia region were to produce 32 million tons of lignite, but by July 1980, output had already fallen 6 million tons short of the plan. Failures to meet targets were blamed in part on lack of delivery of equipment and inadequate use of existing equipment. Inability to meet production targets in the Oltenia region resulted in thermal powerplants not being adequately supplied.[11]

In an effort to aid production, workers from all parts of the country, as well as soldiers and students, were tasked to work in coal mines during critical periods. Along with production problems, on December 1, 1980, Agerpres reported one of the worst coal mining disasters which occurred in the Jiu River Valley and resulted in 49 deaths and 26 persons injured.

In 1981, efforts will be made to complete ontime the new lignite production facilities at the Tismana II, Jilt-South, Pesteana-North, Rosia de Jiu, and Moii Mines. Also in 1981, exploitation of lignite deposits is scheduled to commence at the Prunisor-Izvoru Anestilor and Husnicioara locales in Mehedinti County, with projected capacities of 150,000 tons per year and 490,000 tons per year, respectively.

Natural Gas.—While Romania's oil production fell in 1980, its production of natural gas exceeded the plan and was the only mineral fuel produced above the planned goal. Still, natural gas production has declined from the start of the 1976-80 planning period. By 1985, natural gas production is projected to increase from its 1980 level to 31 billion cubic meters, as natural gas is to be substituted for other fuels. In 1980, Romania was an importer of natural gas and is scheduled, for the period 1980-85, to receive 1.5 billion cubic meters annually from the Soviet Union through the Orenburg pipeline.

Nuclear Power.—In 1980, Romania had no nuclear powerplants in operation, but is planning by 1990 to supply about 18% of its electric energy through nuclear power. Canada had in 1978 extended Romania a $1 billion credit for the purchase of four Candu-type reactors, the first of which is to be commissioned at Cernovoda. In 1980, Romania negotiated a $320 million contract with an Italian-United States consortium composed of the Italian firm Ansaldo Societa Generale Elettromeccanica (ASGEN), a subsidiary of the State-owned conglomerate I.R.I. Finmeccanica, and the General Electric Co. According to this agreement, Romania is to receive two turbine generators for use with its nuclear reactors.

By using the Candu technology, Romania is able to use domestic nonenriched uranium. There has been a call for greater attention to exploration for new domestic uranium deposits. Furthermore, Romania has concluded agreements concerning uranium with Gabon and Zambia. Gabon, according to a 1979 3-year contract, is to deliver 100 to 150 tons of uranium annually starting in 1986. Details of the agreement with Zambia are not yet known, although the joint Romanian-Zambian mining company Mokambo is to extend its work to uranium mining.

Oil Shale.—In 1981, mining is scheduled to commence at an oil shale deposit, which is part of the Anina oil shale mining enterprise. This shale deposit has a projected annual capacity of 500,000 tons. By 1985, total oil shale production is projected to be 15 to 16.5 million tons and is to be a significant fuel for thermal electric power generation. The Anina thermal electric powerplant located in Caras-Severin County is to be the first to operate on oil shale and is scheduled to begin operations in 1981.

Petroleum.—The 1980 crude oil production of approximately 11.5 million tons was below the official target and the previous year's production. Gheorghe Vlad, Deputy Minister of Mines, Petroleum and Geology, attributed failure to meet planned production to a number of factors including delays in the supply of equipment, overly long periods between the drilling of wells and their exploitation, inadequate recovery procedures from older wells, and deficiencies in securing personnel. The major problem, the Minister stated, is that the volume of oil deposits discovered and exploited is below the amount of oil being extracted, leading to depletion of the oil supply.[12]

Projected output for 1985 is 12.5 million tons, which is below the peak amounts produced in the 1970's. Consideration was taken in setting this goal on maintaining an adequate level of reserves. Plans for the 1981-85 period call for intensified geological research and for improving recovery from existing wells. Large sums are to be expended for the expansion of geological exploration, including deep drilling and offshore

drilling on the Black Sea shelf. Romania commissioned an offshore drilling platform in 1976, the Gloria I, which has not yet produced significant quantities of oil. In 1980, a second offshore drilling platform, the Orizont, was launched with equipment still to be installed on it. It is the first of four Orizont platforms to be built.

According to Vasile Patilinet, former Minister of Mines, Petroleum, and Geology, during the 1981-85 period, increased recovery is to create 70% to 71% of the increase in resources and is to account for 20% to 22% of oil production compared with 55% to 57% and 14% to 16%, respectively, during the 1976-80 period.[13] The rate of recovery is to go from 31.5% in 1979 to approximately 40% by 1985.

Romania has developed an export trade in refined petroleum products and relies on crude oil imports to achieve its refining capacity. Increasingly high-priced imported oil makes refining less lucrative and more dependent on uncertain supplies. In 1980, approximately 70% of the crude oil supply was imported, and, in addition, there was underutilization of refining capacity. Crude oil imports in 1980 were approximately 16 million tons, of which 1,496,000 tons came from the Soviet Union and were paid for in hard currency. Crude oil deliveries from two other major suppliers, Iran and Iraq, were interrupted due to their war, and this was reported to have adversely affected the Romanian economy. Another major supplier in 1980 was China, which provided approximately 770,000 tons. 1981 plans call for a reduction in total imports of crude oil to 12.5 million tons.

Other.—*Hydroelectric Power.*—In 1980, hydroelectric power accounted for approximately 18% of electric power generation and is projected to increase to 20% in 1985 and 24% in 1990. Along with the construction of large hydroelectric powerplants, a major emphasis is to be placed on the construction of numerous small hydroelectric powerplants supplying between 5 and 5,000 kilowatts.

A significant increase in hydroelectric power is to be achieved through cooperative ventures. Upon the completion of the joint Romanian-Yugoslav Iron Gates II, and the joint Romanian-Bulgarian Turnu Magurele-Nikopol hydroelectric powerplants, Romania is to receive annually 1.2 billion and 2 billion kilowatt-hours, respectively. An agreement with Bulgaria was reached in 1980 to build a joint hydroelectric powerplant in the Cernavoda region entirely on Romanian territory.

Nonconventional Energy Sources.—In 1980, approximately 2.7% of electric power generation was from nonconventional energy sources (solar, wind, geothermal, biogas, etc.), and this percentage is planned to rise to 5% by 1985, 10% by 1990, and 20% by the year 2000.

Production of solar energy equipment is in progress. For example, the Sadu mechanical enterprise is organizing the production of solar panels. In 1980, it produced 2,400 solar panels; in 1981, it is targeted to produce 70,000, and in 1985, more than 250,000. Efforts to harness wind-power are underway. Construction was reported of a wind-powered electric plant in the Semenicului Mountains in the Banat region. Although its capacity is only about 5 kilowatts, it is to be the first of a number of such plants with higher output in that area. Research is also progressing on the construction of wind turbines. To discover and make greater use of geothermal waters, a research unit has been established in Oradea. Using geothermal waters, it is envisaged by 1985 to supply energy with the caloric equivalence of 500,000 tons of conventional fuel. As part of the program to utilize nonconventional sources, local industry is being encouraged to utilize and to produce components for these sources.

---

[1]Foreign mineral specialist, Branch of Foreign Data.

[2]In addition to establishing a new single commercial rate for the leu of 15lei = US$1.00 = 1.00 convertible ruble, as of February, 1981, a new tourist exchange rate for the leu was established of 11lei = US$1.

[3]In 1980, for the first time, Romania began reporting its foreign trade figures in lei rather than foreign trade (valuta) lei. However, the replacement of the foreign trade leu with an exchange rate of 4.47lei = US$1.00 by a single commercial rate of 15lei = US$1.00 was only to take effect in January 1981. Using the new single commercial rate instead of the foreign trade rate, foreign trade would have grown by approximately 10% in dollar value in 1980 instead of the reported 23.2%.

The Mineral Industry of Saudi Arabia

By Peter J. Clarke[1]

Substantial increases in petroleum revenues continued to fuel the development of the Saudi economy in 1980. Petroleum revenues topped $100 billion[2] for the first time in 1980, and comprised over 60% of the total gross national product. Petroleum, both crude and refined, and natural gas liquids (NGL) were the major exports. Emphasis continued, however, on diversification of the economy and on adding value to Saudi Arabia's hydrocarbon resources. Construction of downstream processing facilities was given top priority in the country's third 5-year development plan (1980-84), and large investments were made in nonpetroleum heavy industries such as iron and steel, cement, and fertilizers. The nonoil sector achieved a nominal growth rate of about 20% for 1980, compared with a 9% growth rate for the economy overall.

Nonfuel mineral development received greater emphasis under the new 5-year plan. Exploration for copper-lead-zinc and gold deposits was being conducted by the U.S. Geological Survey, the French Bureau de Recherches Géologiques et Minières (BRGM), Hunting Survey's Ltd. (United Kingdom), and Shell Minerals Exploration Saudi Arabia. Development continued on the Red Sea minerals mining project, and a pilot program was to begin operation at the end of 1981. Mineral exploration was carried out under the auspices of the Directorate General of Mineral Resources (DGMR), and hydrocarbon development was under the control of the General Petroleum and Mineral Organization (Petromin), both of which were Government owned and sponsored.

Basic infrastructure development for Saudi Arabia's two major industrial centers, at Jubail on the Persian Gulf and Yanbu on the Red Sea, was nearly completed by the end of 1980. Jubail was to be the site for two major export refineries, five petrochemical projects, an iron and steel mill, and an aluminum fabrication plant, as well as secondary support industries and a residential community to house 300,000 people.

Industrial development in Yanbu, which began as little more than a sideshow to Jubail, took on much greater significance in the wake of the Iran-Iraq war. Yanbu was to become a major crude oil and NGL export terminal, giving the Kingdom its first outlet on the Red Sea, and avoiding the vulnerable Strait of Hormuz. Yanbu was to house a gas fractionation center, an export and lubricating oil refinery, and a petrochemical plant. The harbor at Yanbu has been expanded from two berths to nine, with five special-purpose, artificially created harbors alongside each industrial plant, and separate terminals for crude oil and NGL export.

Saudi Arabia's third 5-year Economic Development Plan reflected the progress the Kingdom has already made toward industrial development and diversification. Government spending shifted away from basic infrastructure and into "productive" investments, such as heavy industry, agriculture, and mining. Saudi Arabia's goal was to become an industrial processor of its own resources, thereby increasing the value added to its raw materials. Combined with this emphasis on resource development, the Government gave high priority to increasing the number of Saudi nationals owning and operating major industries. New limits were placed on the growth of expatriate labor, whose numbers reached over 2 million in 1980, and greater attention was paid to increasing Saudi participation in joint ventures. The Saudi Government completed

its full takeover of the Arabian American Oil Co. (Aramco) late in 1980. The company, originally a partnership of American oil companies, was gradually bought out by the Saudi Government, and the remaining 40% share was purchased in March for $1.5 billion, thereby ending 47 years of foreign ownership of Saudi Arabia's oil concessions.

The Saudi Government, through its expenditures, was the engine of economic growth. The runaway inflation of 40%, brought on by free spending from 1974 to 1977, was under tight control by 1980. In 1977 and 1978, expenditures and revenues were kept in balance, and budget allocations were kept constant in real terms. Tight controls on spending managed to reduce inflation to around 8% in 1980, despite a 27% increase in budget allocations in fiscal year (FY) 1980-81 budget. Even with this increased spending, the Government was expected to run a substantial surplus in its current accounts. The Saudi Arabian Monetary Agency (SAMA) was in charge of investing these surpluses to receive a maximum return. SAMA has traditionally invested in Government bonds or in quasi-governmental organizations with official guarantees, and more recently has moved into private bond issues, mostly of top U.S. corporations. Estimates place nearly 80% of Saudi investments in dollars, equally divided between deposits and securities, but with less than 50% in the United States itself. SAMA's total assets in 1980 were estimated at $75 billion.[3]

PRODUCTION

Crude oil production in Saudi Arabia reached its highest level ever in 1980, as production ceilings were raised from 9.5 to 10.5 million barrels per day to accommodate countries affected by the Iran-Iraq war. The 10.5-million-barrel-per-day production level continued through the end of the year, creating an oversupply condition in the world market. The Saudi's attempted to use their dominant position in the Organization of Petroleum Exporting Countries (OPEC) to stabilize prices by keeping a downward pressure on the spot market price. Saudi Arabia's Arabian light (34° API) marker crude began the year at $26 per barrel, and was raised to $28 in April, $30 in August, and $32 in November, which was consistently the lowest price charged by any OPEC country.

Saudi Arabia was in the process of building the largest single gas-gathering and processing project in the history of the oil industry in 1980. By the close of 1980, the NGL gas-gathering center in Shedgum and the fractionation plant in Ju'aymah were completed, and the third center at Uthmaniyah was to be completed by the end of 1981. Total capacity of the gas complex after completion of this phase was to be 700,000 barrels of NGL per day, to be used both for export and production of liquefied petroleum gas (LPG) and ethane. In 1980, 96 million barrels of LPG were produced, and 92 million barrels were exported, a 20% increase over 1979 levels. Plans were made to nearly double this output by 1983.

Production of refined products in the Kingdom continued to grow to 323.8 million barrels, a 6% increase from that of 1979. Expansion plans were underway at the Riyadh and Jeddah refineries, and six new refineries were to be constructed by the middle of the decade, bringing total refining capacity to over 900 million barrels per year.

Saudi Arabia's nonfuel mineral production was also scheduled for large-scale expansion. Nitrogenous fertilizer production rose to 330,000 tons of urea, the highest level ever, and a new ammonia-urea plant at Jubail was to come onstream early in 1981. The Saudi Iron and Steel Co. planned to construct an 800,000-ton-per-year direct-reduction steel plant in Jubail, and capacity at the Jeddah steel rolling mill was upgraded to 140,000 tons per year. The cement industry, already operating near capacity, commissioned two new cement plants during the year and was scheduled to add five more by 1982. The Kingdom also produced small quantities of other nonmetallic minerals, mostly for use in local construction. Saudi Arabia's mineral production is shown in table 1.

Table 1.—Saudi Arabia: Production of mineral commodities[1]

Commodity and unit of measure	1976	1977	1978	1979[p]	1980[e]
METALS					
Iron and steel: Crude steel thousand metric tons	5	5	5	45	50
NONMETALS

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.
[1]Table includes data available through July 13, 1981.
[2]Data are for the Hejira calendar year, which corresponds closely to the Gregorian calendar year.
[3]Includes Saudi Arabia's 1/2 share of production in the Kuwait-Saudi Arabia Partitioned Zone.

TRADE

Saudi Arabia's balance of trade surplus continued its rapid growth in FY 1979-80, fueled by higher oil prices and high production levels. The surplus in the current account balance was nearly $40 billion, up over 300% from that of 1979. Exports of crude petroleum accounted for virtually all export earnings, but the Kingdom also exported refined products, and was the world's largest exporter of NGL. The major recipients of Saudi crude oil were Western Europe, Japan, and the United States. Most of the NGL exported was destined for Japan and Western Europe.

Total Saudi Arabian imports for 1980 were estimated at $32 billion and were increasing at an average rate of 28% per year. The United States supplied approximately $6 billion of the total, which was up 20% from the previous year, making Saudi Arabia the seventh largest market for American technology and products. Although total imports from the United States were up in FY 1980, the overall U.S. share of Saudi imports declined from 20% to 18%, and the U.S. share of construction contract awards dropped to 3%.

COMMODITY REVIEW

METALS

Exploration for metallic minerals continued in 1980, primarily in the Arabian Shield, where a total of 95 metalliferous prospects have been identified. Most of the deposits were located in volcanic rocks which hosted copper, lead, zinc, and iron minerals, but seven prospects have been drilled into basic plutonic rocks where chromite, nickel, platinum, and copper have been identified. A project was initiated by DGMR of Saudi Arabia to investigate sedimentary rocks underlying 1.5 million square kilometers of the Kingdom for deposits of lead and zinc.

Rio Tinto Finance and Exploration Ltd. (Riofinex), a subsidiary of Rio Tinto Zinc Corp. Ltd. (United Kingdom), concluded a preliminary review of mineral deposits in the Kingdom during 1977. Slated for further investigation were stratiform copper-lead-zinc deposits in the Ad Dawadimi-Jebal Sakhen Basin, metallic sulfides in the Wadi Wassat-Wadi Qatan district, iron ore at Wadi Sawawin, columbium and tantalum at Ghurayyah, and several other metallic mineral deposits.

The U.S. Geological Survey and BRGM of France were also investigating mineral deposits in central and western Saudi Arabia, while Hunting Surveys Ltd. (United Kingdom) continued surveying and mapping the Eastern Province. Shell Minerals Exploration Saudi Arabia, a subsidiary of the Royal Dutch/Shell Group, also began an exploration program in the Western Province. Shell was mainly prospecting for copper and zinc.

Feasibility studies were continuing in 1980 on mining the metalliferous muds of the Red Sea Atlantis II Deep Basin. The Saudi Sudanese Red Sea Commission (RSC) had spent over $300 million on research and development of seabed mining technology. Of the 17 minerals identified in the muds, lead, zinc, copper, silver, and cadmium were thought to be commerically minable. The Saudi Sudanese Authority for the Exploitation of Red Sea Resources was constructing a pilot program scheduled for completion by the end of 1981, and precommercial exploitation was to continue until 1988. Zinc and copper were to become the first commercially exploited minerals, starting in 1988. The mining process, developed by Orenstein and Koppel AG of the Federal Republic of Germany, involved agitating the muds free of the seabed, mixing with seawater, and then pumping to a processing ship—most likely a refitted ore carrier. The ore was to be concentrated on the carrier and then shipped by barge to a smelter-refinery, possibly located at the Yanbu Industrial Complex. The residual slurry was to be pumped back into the sea to a depth of 500 feet where tests have shown it will settle back to the seabed without an unacceptable amount of dispersion. The estimated value of ores in the Atlantis II Basin was around $3.5 billion, and the return from the mining operation was to equal that of the most efficient land mining operations.

Aluminum.—Saudi Arabia canceled its plans to build a 200,000-ton-per-year aluminum smelter in the Jubail industrial zone. The Government had drawn up plans to build the smelter in 1975 and commissioned Southwire Ltd. (United Kingdom) to perform a feasibility study in 1978. The decision to cancel the project was a result of both Bahrain's decision to expand capacity of its smelter from 126,000 to 170,000 tons per year and the commissioning of a new smelter in Dubai, with a 135,000-ton-per-year capacity. The Government of Saudi Arabia acquired a 20% interest in Aluminum Bahrain (Alba) in 1978.

Saudi Arabia joined six other Persian Gulf nations in a tentative agreement to establish the Gulf Aluminum Rolling Mill Co., at a cost of about $100 million. The plant, to be located in Bahrain, was to be integrated with the Alba smelter. Annual capacity of the plant, which was expected to come onstream in 1983, was expected to be 40,000 tons of semifabricated aluminum products. Saudi Arabia owned a 20% share, as did Bahrain, Kuwait, and Iraq; Oman and Qatar owned 10% shares.

Aluminum Products Co. (Alupco) brought an aluminum extrusion plant into production in 1978. The plant, located in Damman, was to produce 5,000 tons per year of aluminum products for the domestic market. There were approximately 45 aluminum fabricating plants operating in the Kingdom in 1980, with a combined capacity of 40,000 tons per year, most of which produced aluminum doors and windows and household manufactures. The Alupco plant in Damman was the first extrusion plant in

Saudi Arabia.

Copper.—The Arabian Shield Development Co. continued its exploration and development program in the Al Masani area. Drilling tests indicated significant amounts of copper, zinc, lead, silver, and gold in a north-south trending shear zone 30 meters wide and over 5 kilometers long. Copper and associated minerals were found along the strike of the zone in lenses and stringers. Watts, Griffis, and McQuat Ltd. (United Kingdom) was manager of the underground development project, and National Mining Co. was the Saudi partner.

Granges AB (Sweden) was continuing the search in 1980 for copper and precious metals in the Al Nagra and Al Safra regions, 250 kilometers northwest of Medina. Petromin reserved the right to enter into a joint venture with Granges in the event of a commercial discovery. Granges was awarded the exploration contract in 1978, but no development plans had been discussed by 1980.

Many other copper deposits of varying grades were located by the Riofinex mission, most of which were in the shield volcanic rocks. Copper deposits at Kutan and Jebel Sayid, under investigation by Noranda Mines Ltd. (Canada) and BRGM, respectively, were found to be uncommercial.

Gold.—Consolidated Gold Fields (United Kingdom) and Petromin continued their development plans for the Mahd-ad-Dhahab gold deposit, 280 kilometers northeast of Jeddah. Consolidated Gold Fields began exploration in the area in 1976, and Petromin took a 50% share in 1979. Exploration in the area revealed evidence of an open pit mine worked over 3,000 years ago, possibly the location of King Solomon's legendary mines of Ophir. Feasibility studies conducted by Gold Fields-Petromin established the existence of 1.2 million tons of ore containing 1.1 ounces per ton of gold, 4.3 ounces per ton of silver, and 0.8% copper. Gold Fields planned to start commercial production in 1981, with an expected annual output of 3 tons of gold and 10 tons of silver.

Iron and Steel.—The British Steel Corp. (BSC) continued its investigation of the Wadi Sawawin iron ore deposits located in northwest Saudi Arabia near the Gulf of Aqaba. BSC was awarded a $15 million contract to determine the tonnage and grade of the reserves at Wadi Sawawin. Initial estimates were 350 million tons of about 42% iron, with a high-silica (30%) and high-phosphorus (0.2% to 4%) content. Reserves appeared sufficient to establish a large-scale mining operation, but the ore grade was too low for use in commercial direct-reduction processes. The BSC, in conjunction with the London School of Mines, was investigating ways to upgrade the ore for use in Saudi Arabia's planned steel industry. A final report was due in 1981.

The Saudi Iron and Steel Co. (HADEED) was finalizing plans in 1980 for a major iron and steel complex to be located in Jubail. In December of 1979, the Saudi Iron and Steel Co., a joint venture owned 80% by the Saudi Arabian Basic Industries Corp. (SABIC) and 20% by Korf Stahl of the Federal Republic of Germany, signed a $208 million contract with Lurgi Chemie and Huettentechnik (Federal Republic of Germany) for the supply of two direct-reduction plants for the Jubail complex. The plants had a combined capacity of 800,000 tons per year, and utilize the Midrex direct-reduction process. In May 1980, a $236 million contract was awarded to Voest Alpine (Austria) for overall construction of the complex. The contract included installation of three electric hearth furnaces, each with 120-ton capacity, three six-stranded continuous casting machines, building infrastructure, and offices. The work was scheduled for completion early in 1983.

In October 1980, Saudi Iron and Steel Co. signed a $225 million contract with an international consortium headed by Mannesmann-Damag (Federal Republic of Germany) and including Schloemann-Seimag (Federal Republic of Germany), Redec Daelim Saudi Arabia, and Compagnie d'Enterprises Metalliques (France), to supply on a turnkey basis, two steel rolling mills and associated ancillary facilities for the Jubail complex. The first mill was to produce 6- to 32-millimeter reinforcing bars, and the other mill was to produce 6- to 12-millimeter wire rod coils. The combined production capacity of both mills was 800,000 tons per year. The output from the Jubail complex was to supply the domestic market, to reduce Saudi Arabia's heavy dependence on imported steel.

Iron ore to supply the plant was to be imported, pending the possible development of the Wadi Sawawin iron ore deposits. During the year, Saudi Arabia was negotiating with Brazil about importation of iron ore from the Carajas Mine, and technical assistance from the Rio Doce Staff. In re-

turn for a possible source of iron ore, Brazil was interested in Saudi financing for the Carajas mining project.

Modernization and expansion of the Steel Casting Co. of Jeddah (formerly Jeddah Steel Rolling Mill) was nearing completion at the end of 1980. The company, owned by SABIC, contracted Korf Stahl to upgrade capacity from 80,000 to 140,000 tons per year of reinforcing bars. The plant was to use imported billets until the Jubail complex begins operation early in 1983.

Construction was continuing on the National Pipe Co.'s plant in Damman. The company, owned 60% by Saudi interests and 40% by Sumitomo Metal Industries (Japan), was expected to produce 80,000 tons per year of spiral welded pipe. The plant was scheduled for completion early in 1981.

Uranium.—Exploration was continuing during the year for radioactive minerals. In 1978, DGMR signed an agreement with Minatome (France) for a 3-year survey of radioactive mineral occurrences throughout the Kingdom. Several deposits had been located by previous aerial surveys, in Jebel Said, Al Ahrayyat, Wadi Sawawin, and Yanbu, but none have proved commercially attractive. After general surveying and mapping, Minatome was expected to undertake more detailed prospecting in promising areas.

NONMETALS

Cement.—Cement consumption in Saudi Arabia increased from 1 million tons in 1973 to 10.4 million tons in 1978, nearly 80% of which was imported. The Kingdom's third 5-year plan called for an increase in productive capacity, from the current 3.5 million tons per year to 10 million tons per year by 1985. Companies from the Federal Republic of Germany, the United States, Japan, and the United Kingdom were supplying technology and training for the expansion. Saudi Arabia's planned and operating cement plants are listed in the following table.

Operating company	Location	Planned capacity (metric tons per year)	Startup date	Contractor	Value (million dollars)
Saudi Cement Corp	Hoffuf	1,000,000	1981	Polysius AG (Federal Republic of Germany) (FRG).	84
Yamama Saudi Cement.	Riyadh	1,000,000	1978	do	150
Yanbu Cement Co	Ra's Baridi	2,000,000	1980	KHD Industrialagen AG (FRG)	100
El Kasseim Cement	Buraydah	700,000	1980	do	--
Southern Province Cement Co.	Gizan	1,000,000	1981	Fuller Co. (United States)	--
Saudi Bahraini Cement Co.	Ain Dar	1,800,000	1981	Ishikawajima Harima Heavy Industries Co. (Japan).	--
Saudi-Kuwait Cement Manufacturing Co.	Kuwait-Saudi Arabia Partitioned Zone.	2,500,000	1982	Prospective Engineering Gestion (United Kingdom).	--
Arab Cement Co	Rabigh	2,500,000	1982	Unavailable	--

Fertilizer Materials.—Production from the Saudi Arabian Fertilizer Co. (SAFCO) rose to a record high 330,000 tons of urea in 1980, or over 10% more than the 1979 level. Of the 330,000 tons produced, 318,000 tons were exported, and the remainder was sold on the local market and used to replenish the company's inventory. Local consumption of urea has increased from 10,000 tons in 1977 to 32,000 tons in 1980, and was expected to reach 35,000 tons in 1981.

In February 1980, SAFCO inaugurated its new sulfuric acid plant at Damman. The plant was designed to produce 300 tons per day of sulfuric acid for domestic consumption, but operated at about 40% of capacity throughout the year. The plant, which was designed to utilize the large quantities of sulfur byproduct produced by SAFCO, was built by Sim Chem (Korea) at a cost of $10 million.

In January, Petromin announced its decision to sell 100,000 shares of its stock in SAFCO to the company's Saudi employees. Petromin formerly held 51% of the equity in the company, with the remaining 49% already in private hands.

The Jubail Fertilizer Co. (SAMAD), a 50:50 joint venture of SABIC and the Taiwan Fertilizer Co. (TFC), was scheduled to begin construction of its $361 million fertilizer complex at Jubail early in 1981. Pullman-Kellogg (United States) was contracted to design and supervise construction

of the complex. The plant was expected to produce 1,000 tons per day of ammonia and 1,600 tons per day of prilled urea. TFC was to purchase 60% of the output, for use in Taiwan and marketing to other Southeast Asian countries. About 40% of the cost of the project was to be financed by a loan from the Saudi Public Investment Fund. The complex was scheduled to come on-stream in mid-1982.

Phosphate.—Granges Engineering Ltd. (Sweden) was continuing its investigation of phosphate deposits in Turayf-Thaniyat and Turayf areas in northwest Saudi Arabia in 1980. Reserves were estimated at about 190 million tons of ore, with an average P_2O_5 content of 23%, and another 772 million tons at 18% P_2O_5. Direct shipping of the ore has proved impossible, but tests indicated that beneficiation and upgrading was possible to provide a commercially acceptable product. In the event of exploitation, the Government reserved the right to enter into a 50:50 joint venture with Granges. Petromin was studying transportation, water, harbor facilities, and associated infrastructure requirements to aid in determining if an economically viable project was possible. Riofinex was also studying the phosphate potential of the Turayf Basin, but no recommendations had been made by the end of 1980.

Magnesite.—DGMR, in cooperation with the French Societé d'Etudes de Recherches at d'Explorations Minières (SEREM), continued its investigation of magnesite deposits at Zarghat for Saudi Arabia Magnesite Ltd. Reserves at Zarghat, located south of Jebel Sayid, were estimated at about 1 million tons of 95% magnesium carbonate, with less than 2% silica. The Government and SEREM were studying the economic feasibility of mining and calcining magnesite at Zarghat.

Stone (Industrial-Ornamental).—The second 5-year plan initiated a program to inventory the country's reserves of nonmetallic industrial and construction materials. Several major deposits of limestone, clay, basalt, dolomite, and glass sand were located during this effort. DGMR opened a model quarry in 1980 to demonstrate modern quarrying techniques, and it also commissioned a modern stone cutting and polishing plant in Jeddah.

MINERAL FUELS

Natural Gas.—Portions of the first phase of Saudi Arabia's massive gas-gathering scheme began operating in the latter half of 1980. Aramco began in the early 1970's to design a gas-treatment center for the Berri Field. Shortly thereafter, the Government decided to expand the project to a large gas-gathering scheme, designed to process 220 billion cubic feet of associated gas per year. Construction and management of the scheme was awarded to Aramco, under the supervision of Petromin.

Aramco modified the construction of the Berri gas-gathering center to be integrated with the rest of the project. Berri reached full capacity in 1979. The remainder of the program involves several gas-gathering centers and secondary fractionation centers. Four NGL centers (Abqaiq, Berri, Shedgum, and Uthmaniyah) receive associated natural gas from the various oilfields, where it is sweetened and the first fractionation takes place. The output of these centers is sulfur, methane, and NGL. NGL is then piped to the secondary fractionation centers (Ras Tanura, Ju'aymah, and Yanbu) where further treatment produces ethane and LPG.

The various units of the project, their capacities, products, and startup dates were as follows:

Center	Design feed capacity	Product	Volume	Startup date
Gas-gathering (million cubic feet per day):				
Abqaiq	600	Sulfur-methane	400 tons per day sulfur, 2 billion cubic meters per year methane.	1973
Berri	600	do		1977
Shedgum	1,400	do		1980
Uthmaniyah	1,400	do		1981
Natural gas liquids (barrels per day):				
Ras Tanura	360,000	Ethane-LPG	370 million cubic meters per year ethane, 370,000 barrels per day LPG.	1973
Ju'aymah	270,000	do		1981
Yanbu	270,000	do		1984

The sulfur output from the project was to be utilized domestically in the production of sulfuric acid. The methane-fuel gas was for use by industrial plants in the eastern region, mostly at Jubail, by desalinization and power generating stations, and as feedstock for the Jubail Fertilizer Co.'s ammonia-urea plant and the Jubail Methanol project. The ethane produced from the secondary fractionation centers was to provide feedstock and fuel for the ethylene petrochemical complexes to be established at Jubail and Yanbu. LPG was for export or to provide feedstock for other future petrochemical projects.

All LPG output of the gas project was already sold under contract up to 1985. Among the buyers of Saudi LPG were Tokyo Gas-Shell International Gas (250,000 tons); British Petroleum (200,000 tons per year); Mitsubishi, Mitsui, C. Itoh, and Nippon Oil (250,000 tons per year each); and Dow Chemical (250,000 tons per year). The price of Saudi LPG in 1980 averaged about $310 per ton for butane and $315 per ton of propane. Butane prices dropped from a high of $330 per ton on January 1, 1980, to $300 per ton late in the year. LPG sales were about 3 million tons in 1980 and were expected to rise to 8.8 million tons per year by 1983, when all the facilities come onstream.

A project to store surplus NGL and ethane underground was nearing completion in 1980. Early in 1981, Aramco planned to begin pumping surplus ethane and NGL from the Ju'aymah fractionation plant into the underground reservoir in the Qatif Field. NGL was to be pumped into the north dome of the field, and ethane was to be pumped into the south dome.

The Saudi Government announced late in 1980, that as of January 1, 1981, it would take over all facilities for the production and export of NGL. The NGL system had been operating on a 50:50 joint venture basis between Aramco (Exxon, Socal, Texaco, and Mobil) and the Saudi Government. Aramco staff would continue to operate the facilities, and little disruption from the takeover was expected.

Petroleum.—*Production.*—Saudi Arabia produced approximately 3.53 billion barrels of crude oil in 1980, making it the largest producer of crude oil in the market economy countries, and second only to the Soviet Union. It was, however, the largest exporter of crude oil, with 1980 exports totaling over 3.2 billion barrels.

The Saudi Government completed the 100% takeover of all Aramco production facilities and oil concession rights in 1980. The Government bought out the remaining 40% share of Aramco's producing assets for an estimated $1.5 billion. The move came 7 years after the Government acquired its first 25% share in Aramco, which was established after World War II by Exxon (30%), Standard Oil of California (30%), Texaco (30%), and Mobil (10%). All facilities continued to be operated by Aramco personnel, but Petromin became full owner of all Aramco stock. The Arabian Oil Co. Ltd., owned 60% by Saudi Arabia and Kuwait and 40% by Japan, and the Getty Oil Co. owned and operated facilities in the Kuwait-Saudi Arabia Partitioned Zone.

There was a sharp increase in drilling during 1980, when 224 additional wells were drilled, a 55% increase over new wells in 1979. Cumulative oil production in Saudi Arabia, up to the end of 1980, was 40.6 billion barrels, and oil reserves were down only slightly from the 1979 level of 168.39 billion barrels to 167.46 billion barrels. Oil production from the Kuwait-Saudi Arabia Partitioned Zone amounted to 56.6 million barrels. Onshore oilfields in the Partitioned Zone were operated by Getty on behalf of Saudi Arabia, and Kuwait Oil Co. on behalf of Kuwait. The Arabian Oil Co. Ltd. operated the Partitioned Zone offshore fields on behalf of both Governments. Saudi Arabia's share from the Partitioned Zone was 50% of total production and reserves. Remaining crude oil reserves in the Partitioned Zone were 904 million barrels.

The Government became fully responsible in 1980 for setting production ceilings for all oilfields. The overall production ceiling was raised from 8.5 to 9.5 million barrels per day in the third quarter of 1979. Production remained steady at this level throughout most of the year, until a 10.5-million-barrel-per-day provisional increase was agreed upon in October of 1980 to offset the loss of supplies from Iran and Iraq. The 10.5-million-barrel production level remained in effect until the end of the year. These "incremental" crude supplies were allocated to countries most affected by the cutoff from Iran and Iraq. Included in the list were Brazil, Turkey, France, Japan, Italy, Spain, Greece, Yugoslavia, India, Pakistan, Morocco, and Somalia. As exports from Iran and Iraq slowly increased, the Saudis maintained the higher level of production in order to stabilize world oil prices and prevent

another round of rapid increases. At year-end 1980, the price of Arabian light crude oil was $32 per barrel.

Refining.—The Government of Saudi Arabia, through joint ventures with various major oil companies, planned a major increase in refining capacity to be completed about the middle of the 1980's. Of the five operating refineries in the Kingdom, two were undergoing multifold expansion, and six new refineries were being constructed or planned. Total output of refined products in 1980 was 323.8 million barrels, while domestic consumption during the year was about 200 million barrels, the balance of which was exported. Of the six new refineries in the planning or construction stage, four were to produce products mainly for export. By the mid-1980's, Saudi Arabia's refining capacity was estimated to approach 2.5 million barrels per day.

Aramco planned to construct a 250,000-barrel-per-day domestic refinery at Ju'aymah, which was intended to process high-sulfur 27° API crude oil from the Manifa Oilfield. Chevron Research, a subsidiary of Standard Oil Co. of California, was awarded a $2.5 billion contract for the process design of the refinery. Completion was scheduled for 1980.

Tenders were requested at the end of 1980 for construction of a 250,000-barrel-per-day export refinery at Jubail. Petromin and Shell Saudi Arabia Refining Ltd., a subsidiary of Royal Dutch/Shell (Netherlands), agreed to set up the refinery in April of 1979. No completion date was available.

Another major refinery, at Yanbu, was entering the construction stage at the end of the year. Petromin and Mobil Oil Corp. agreed in March 1979 to build a 250,000-barrel-per-day export refinery at Yanbu. Chiyoda Chemical Engineering and Construction Co. (Japan) was providing engineering, material and equipment procurement, and field supervision services for the 50:50 Petromin-Mobil venture. The project was to go onstream in 1984. Crude oil supplies were to be delivered via the East-West Transpeninsular Pipeline, due to be operational by mid-1981.

A third export refinery, a Petromin-Petrola International Saudi Arabia (Greece) joint venture, was to be constructed at Rabigh on the Red Sea coast. Output from the 325,000-barrel-per-day refinery was to be mainly for export. Construction was being carried out by Petrola, under a $2.6 billion contract, and engineering services were provided by Lummus Co. Ltd. (United Kingdom). The first phase of the project was to be completed by 1982.

Two large lube oil complexes were also in the design stage in 1980. The Jubail Lube Oil Refinery, jointly owned by Petromin (50%), Socal (25%), and Texaco (25%), was to produce 12,000 barrels per day of premium lubricating base stocks. C. E. Lummus, a British subsidiary of Combustion Engineering (United States), was preparing design specifications and cost estimates for the plant. Petromin also planned to construct a 5,000-barrel-per-day lube oil refinery in conjunction with Ashland Oil Co. (United States). The plant, which was to be located at Yanbu, was to cost $500 million. Petromin was studying the possibility of constructing a third lube oil complex, as a joint venture with the Arab Petroleum Investment Corp. (Apicorp). The plant, to be located somewhere on the Red Sea coast, would produce 4,000 barrels per day of lubricating oil, at an initial cost of $300 million.

Saudi Arabia's operating and planned refineries are listed in the following table.

Location	Ownership	Capacity (barrels per day)	Market	Startup date	Contractors
Ras Tanura	Aramco	750,000	Export-domestic	1945	--
Ras al-Kahafji	Arabian Oil Co	30,000	Domestic	1966	--
Mina Saud	Getty Oil Co	100,000	Export-domestic	1958	--
Riyadh	Petromin	20,000-120,000	Domestic	1974-1981	Chiyoda.
Jeddah	do	98,000-240,000	do	1968-1981	--
Ju'aymah	Aramco	250,000	do	1986	Bechtel-Chevron.
Jubail	Petromin-Shell	250,000	Export	--	Tenders requested.
Yanbu	Petromin-Mobil	250,000	do	1984	Chiyoda.
Rabigh	Petromin-Petrola	325,000	do	1982	Lummus-Petrola.
	Lube oil refineries:				
Jubail	Petromin-Socal-Texaco	12,000	Export-domestic	1985	C. E. Lummus.
Yanbu	Petromin-Ashland Oil Co.	5,000	do	--	--
Red Sea	Petromin-Apicorp	4,000	Tentative study	--	--

Petrochemicals.—The Saudi Arabian Government, through the state-controlled SABIC was planning to construct six major petrochemical complexes, all of which were to be completed about the middle of the decade. Methane and ethane from the Kingdom's huge gas-gathering project was to provide low-cost feedstock for the nearly $9 billion petrochemical industry. Output from all the plants could account for about 8% of the total world petrochemical output. Original plans were for seven petrochemical plants, but analysis showed that all the plants created more petrochemical capacity than the world needed. Two of the major projects, with Dow Chemical (United States) and the Saudi Petrochemical Development Corp. (SPDC) (Japan) consortium, were merged in order to reduce excess ethylene capacity.

Most of the remaining projects remained committed to construction. Many of the major U.S. oil companies were persuaded to enter joint ventures with SABIC on these plants in order to be eligible for incentive crude oil allotments offered by the Saudi Government. Crude oil entitlements were based on the formula of 500 barrels per day of additional crude oil supply per $1 million current dollars invested by the foreign partner. Fifteen-year agreements for incentive crude were signed by Petromin with U.S. Shell (Pecten), Mobil Oil Corp., SPDC, and Exxon. Saudi Arabia's planned petrochemical industry is shown in table 2.

Multimillion dollar subcontracts were signed by many U.S. and international firms for construction of the complexes. For the Yanbu complex, SABIC and Mobil signed agreements for use of patented technology with Scientific Design Co., Combustion Engineering, and Union Carbide, all U.S. companies. The plants were to utilize monoethylene glycol, ethylene, and polyethylene process technology. Bechtel Corp., C. F. Braun, and Fluor Corp. (all U.S. companies) were major contractors for construction of petrochemical plants. The SABIC-Shell plant at Jubail and the SABIC-Celanese Arabia Inc.-Texas Eastern Arabic methanol plant were already nearing the construction stage in 1980. Output from all the plants was primarily for export, although some production was to provide raw materials for petrochemical plants further downstream.

Pipelines.—Two separate but parallel pipeline projects were nearing completion at the end of 1980. Mobil Overseas Pipeline Co., a subsidiary of Mobil Oil Corp. (United States), and Petromin signed an agreement in 1977 for construction of a transpeninsular East-West pipeline, to transport crude oil from the Eastern Province (Abqaiq) to Yanbu on the Red Sea. Crude oil was to be used in the Petromin-Mobil and Petromin-Petrola refineries in Yanbu and Rabigh, respectively, as well as providing a new crude oil export terminal to avoid the unstable Persian Gulf. Southeast Engineering and Drilling Co. (Sedco) (United States) and Contracting and Trading Co. (Lebanon) built the 530-kilometer western section, through the mountains, under a $112 million contract, and Italy's Saipem (ENI) constructed the eastern portion. Total capacity of the 1,200-kilometer, 48-inch crude oil line was 1.85 million barrels per day, but expansion to 2.35 million barrels per day was likely, according to the management of Petroline, the Mobil-Petromin operating company. The pipeline was to be completed early in 1981.

Running parallel to the crude oil line was an East-West NGL pipeline. NGL was to be carried from the Shedgum gas plant in the Eastern Province, to Yanbu. The line's capacity was 270,000 barrels per day of NGL to be delivered to the Yanbu fractionation plant. Propane and butane were to be exported, while ethane was to be used in the SABIC-Mobil petrochemical complex in Yanbu. The $2 billion pipeline was built by Aramco and was scheduled to start operating in the first quarter of 1981.

Also nearing completion at the end of the year was a 140-kilometer pipeline linking the Riyadh refinery to the Khurais Oilfield in the east. The 300,000-barrel-per-day crude oil pipeline was built by Niigata Engineering Co. (Japan) under a $51.3 million contract awarded in 1978. The pipeline will supply feedstock to the Riyadh refinery, which was undergoing expansion from 20,000 to 120,000 barrels per day. Output from the Khurais Field was also being raised from 50,000 to 165,000 barrels per day to supply the refinery.

In December 1980, Petromin commissioned an international firm to perform a feasibility study for the construction of about 2,600 kilometers of product distribution pipelines. Areas under study were Riyadh-al Qasim (450 kilometers), Diba-Tobuk (250 kilometers), Mecca-Jeddah-al Tarf, Yanbu-al Madinah, Dhahran-al Hafur, Ras Tanura-Jubail-al Qaisumah, and Riyadh-al Kharg.

The Mineral Industry of Sierra Leone

By William F. Keyes[1]

Sierra Leone experienced slow rates of growth during the 1970's because of the decline in its mining sector and the consequent erosion of the country's export base. Some improvement in export earnings occurred in 1979 and 1980 because of continued high prices for diamonds, and because of an increase in the quantity of cocoa sold on the international market. A sizable trade deficit, in the range of $50 million[2] each year in recent years, contrasted with a gross domestic product of about $900 million. The balance of trade deficit is a result of heavy reliance on imported goods and worldwide inflation, particularly in the price of imported crude oil.

The economy of Sierra Leone is based primarily on agriculture, but diamond mining, bauxite production, petroleum refining, and, recently, rutile production, are important. During the year, an agreement to expand bauxite mining was reached; iron ore mining was to be revived; kimberlite diamond mining was to be undertaken (production has been virtually all alluvial hitherto); and a seismic survey led to a decision to drill for oil offshore.

PRODUCTION AND TRADE

Sierra Leone depends on mineral exports for over one-half of its foreign exchange earnings, despite the fact that over 70% of its population derives its living from agriculture. The future outlook was uncertain, however, because the country depends on the extent of its mineral resources, which have not been fully explored, and on world demand for its mineral products, chiefly bauxite and diamonds.

Diamond production continued to decline in 1980, but this may be reversed if underground mining is successful. Bauxite production, the other large money earner, was up, with prospects for a further increase to 1 million tons annually. Bauxite is sold principally to the Federal Republic of Germany.

Table 1 gives production for the years 1976 to 1980.

Table 1.—Sierra Leone: Production of mineral commodities[1]

Commodity[2] and unit of measure	1976	1977	1978	1979	1980[p]
Aluminum: Bauxite, gross weight thousand metric tons	651	745	716	672	831
Diamond:					
Gem thousand carats	433	423	353	419	291
Industrial do	650	538	426	436	303
Total do	1,083	961	779	855	594
Petroleum refinery products:					
Gasoline thousand 42-gallon barrels	231	331	394	421	e430
Jet fuel do	109	101	102	277	e300
Kerosine do	185	199	213	105	e100
Distillate fuel oil do	407	464	501	586	e600
Residual fuel oil do	423	824	412	434	e400
Liquefied petroleum gas do	3	10	10	7	e10
Other do	--	--	--	2	e5
Refinery fuel and losses do	29	6	43	55	e55
Total do	1,387	1,935	1,675	1,887	e1,900
Salt thousand metric tons	180	180	180	200	200
Titanium: Rutile ore and concentrate, gross weight metric tons	--	--	--	10,000	50,000

eEstimated. pPreliminary.

[1]Table includes data available through Sept. 1, 1981.

[2]In addition to the commodities listed, a variety of crude construction materials (clays, sand and gravel, and stone) is produced, but output is not reported and available general information is inadequate to make reliable estimates of output levels. Gold may occur, but data are not available for estimating production. Sierra Leone annually refines 4,000 to 10,000 metric tons of salt from imported crude marine salt, but this is not included in the body of the table because it would represent double counting of materials credited to the country where the salt was originally collected. This output would be in addition to that reported in this table.

COMMODITY REVIEW

METALS

Bauxite.—An agreement for exploration of the Port Loko bauxite deposit, northeast of Freetown, was signed between the Government and Swiss Aluminium Ltd. (Alusuisse) in May 1980. Conditions of exploitation remained as reported last year; the Government was to have a 50% share and would grant Alusuisse a 5-year tax holiday. One million tons of bauxite would be mined per year and converted to alumina at a plant to be built at Pepel, near Freetown.

Alusuisse's subsidiary, Sierra Leone Ore and Metal Co. (SIEROMCO), sole current producer of bauxite, planned to construct a washing plant near the Mokanji mining area in Southern Province and a drying plant at the Port of Nitti to handle up to 1 million tons per year of bauxite, which will allow for some expansion of output.

Gold.—In addition to the efforts of Eurocan Ventures Ltd. (Canada) in the Baomahun area, described last year, which were carried on in conjunction with Diamond Distributors Explorations Ltd. (a subsidiary of Harry Winston Inc. of New York), two other moderately sized companies were granted special exploration and prospecting licenses (SEPL's). In the Nimini hills area in eastern Sierra Leone, Eurocan (referred to as the Atlanta Co.) and Sierra Leone Diamonds Ltd., owned by Leon Templesman and Sons, were carrying out deep drilling near an area where National Diamond Mining Co. (Sierra Leone) Ltd. (DIMINCO) recovers some byproduct alluvial gold. In addition to these two groups interested in lode mining, Big Bent Spoon Ltd. (BBS), a private Sierra Leone and American company, obtained an SEPL for an alluvial area near Lake Sonfon, formerly a producing area.

Reported production in 1980 was a byproduct of DIMINCO's alluvial diamond mining operations; illicit production and exports were also considered to be significant.

Iron Ore.—Austromineral KG, a subsidiary of Vöest-Alpine AG of Austria, after carrying out a feasibility study, agreed to rehabilitate the mine at Marampa, closed since 1975. Austromineral was the latest in a series of foreign iron mining companies that had been approached by the Sierra Leone Government for that purpose. Exports over the refurbished railroad to the Port of Pepel would start in 1982. An Austrian Government-sponsored loan of $16 million and Sierra Leone Government equity capital of $6 million were reportedly to be provided.

Titanium.—Sierra Rutile Ltd. (SRL), a joint venture of Bethlehem Steel Corp.

(85%) and Nord Resources Corp. of Ohio (15%), which started production in 1979, recovered rutile by dredging alluvial sands at Mogbwemo, about 270 kilometers by road southeast of Freetown. A technical description of the operation was published.[3] A number of potentially exploitable deposits have been identified within the lease area, which was formerly worked by Sherbro Minerals Ltd., from 1966 to 1971. Rutile grades are high in the topsoil (averaging 2.5% TiO_2), and in the basal sands and gravels (up to 3.5% TiO_2); the entire stratigraphic column has an average content of 2.2% TiO_2 as rutile. Average depth of the column was not reported, but the dredge had a maximum digging depth of 15.25 meters below, or 6.1 meters above the waterline. Hydrocyclone desliming and Reichert concentrators on the dredge deliver a preconcentrate to a table plant on shore. Final magnetic separation produces a product containing 96% TiO_2, less than 1% ZrO_2, and less than 1% Fe_2O_3 at a rate of 13.2 tons per hour. Operating a planned 7,700 hours per year, the plant should reach an output of 100,000 tons of rutile per year; other heavy minerals are not recovered.

NONMETALS

Diamond.—Alluvial mining continued as virtually the sole source of diamonds, but development of a number of kimberlite pipes in the Yengema-Tongo region was planned. These are part of the diamond fields, presently yielding alluvial stones, which occupy an area of 20,000 square kilometers in the southeast around Kenema. Diamond production has been seriously declining since 1969 when it reached 2 million carats. DIMINCO, in addition to its alluvial production (about 170,000 carats in 1980, or about one-third of reported production), also produced some kimberlite ore from one pipe, but this output was limited to depths of 150 feet or less with the only available equipment (front-end loaders). A massive capital investment, probably about $100 million, would be required, to be undertaken by DIMINCO's parent organizations, the Sierra Leone Government (51%) and Sierra Leone Selection Trust, now a subsidiary of British Petroleum Ltd. (49%).

MINERAL FUELS

Coal.—Deposits of lignite of Pleistocene age were described.[4] Proven reserves, in the Koya area south of the Rokel River, about 25 kilometers east of Freetown, are about 2 million tons, although perhaps 20 million tons were considered probable. Washed samples gave proximate analyses of about 46% volatile matter, 34% fixed carbon, and 5% ash. The seams average 1.25 meters in thickness and lie beneath about 15 meters of overburden. The deposits were exploited sporadically in the past, but may also provide fuel for a newly established brick manufacturing industry 5 kilometers southeast of Freetown.

Petroleum.—A seismic survey was conducted in August by the *T. W. Nelson*, for Mobil Oil Corp., offshore near Turner's Peninsula, in the central coast. Promising signs of oil were revealed, and the vessel returned to Sierra Leone again at yearend to assist in locating the best drilling area. About 85% of a 73,000-square-mile concession belonging to the Aracca Petroleum Co., Oxoco Petroleum Co., and Sundance Petroleum Co. was farmed out to Mobil. Early in 1981, it was decided to drill a $6 million well in the concession by May 1981.

The 10,000-barrel-per-day capacity refinery of Sierra Leone Petroleum Refining Co. (SLPRC), owned by the Government and five foreign oil companies, was the only refinery in the country. During the year, SLPRC found the cost of imported crude increasingly onerous, and shortly after yearend, the Government announced an increase in the pump price of gasoline from Le3.00 to Le3.40 per imperial gallon ($2.35 to $2.66 per U.S. gallon).

The Mineral Industry of the Republic of South Africa

By Miller W. Ellis[1]

For the third straight year, the mineral industry continued to dominate the economy of the Republic of South Africa and to be dominated by the gold industry, which contributed nearly 70% of its value. The country's mineral products had a new record value of $19.27 billion in a gross domestic product of $80.21[2] billion in 1980. The price of gold soared to a record $850 per troy ounce in January 1980 and remained at $600 to $700 during most of the latter half of the year, maintaining an annual average sales value of $616 per troy ounce, more than twice the average dollar price of $307 realized in 1979. Similarly, the state realized $4.87 billion in the form of tax and state's share of the profits in 1980, more than double the $2.19 billion realized in 1979. Although most of the increase in dollar value of its mineral products was due to gold, the country's coal industry was a major contributor also with a 31% increase in total sales value including a 35% increase in export sales.

The Republic's construction industry had a banner year with major projects at the South African Coal, Oil and Gas Corp. Ltd. (Sasol) plants, the Drakensburg diversion dam and irrigation scheme, the Koeberg power station near Cape Town, and a multitude of new mine plant or mine expansion projects. The new township in the near-desert country near the new Black Mountain Mine operated by Gold Fields of South Africa Ltd. (GFSA) in northwestern Cape Province was one example. The Government continued to control some of the mining industry through the Industrial Development Corp. of South Africa Ltd. (IDC), which indirectly controlled such companies as the South African Iron and Steel Industrial Corp. Ltd. (ISCOR), Phosphate Development Corp. Ltd. (Foskor), and the Alluvial Diamond Diggings of Alexander Bay, near the mouth of the Orange River. Sasol's operations included the company's original pilot plant, Sasol I, and its captive 6-million-ton-per-year Sigma Colliery at Sasolburg in the Orange Free State, the almost completed, partly commissioned Sasol II plant, and its mirror image Sasol III, under construction near the new Bosjesspruit Colliery at Secunda in southern Transvaal Province. Bosjesspruit also produced 6 million tons of coal in 1980 and was scheduled for 14 million tons in 1982 and 30 million tons in 1985, when Sasol III was to reach full capacity. A substantial portion of the capital for Sasol II and III was raised by public sale of stock in the enterprise.

In June 1980, the minimum starting wage for unskilled mine employees was increased by 14.3%. This was in addition to an "average minimum living level for an urban family of five" that has been established from time to time by the University of South Africa as a measure of the amount and quality of the housing, food, clothing, medicine, and social services provided free to employees. Throughout the mining industry, the total amount of wages paid to the employees in 1980 was more than 20% higher than that of 1979.

In May 1980, the chairman of the Uranium Enrichment Corp. of South Africa Ltd. (UCOR) was also appointed as chairman of a Committee of Inquiry into the Restructuring of Nuclear Activities in the Republic of South Africa. The committee was newly created by the Cabinet to monitor nuclear activities carried out with state funds and to recommend steps to ensure that the state's activities in this field were efficient.

PRODUCTION AND TRADE

In 1980, the Republic of South Africa produced and exported more chromite, gem diamonds, gold, platinum, and vanadium than any other country in the world and was one of its three top producers or exporters of antimony, asbestos, coal, industrial diamond, fluorspar, manganese, uranium, and vermiculite. Details of its 1980 mineral production are listed in table 1.

The manufacturing industries of the United States, Japan, and Western Europe continued to be highly dependent on many of the country's mineral commodities, and certain East European countries were also customers in 1980. With the changed Government in Iran, the Republic lost its trade ties with the Middle East but was able to find sources for decreasing amounts of crude oil elsewhere. Both the demand and the prices for many industrial commodities remained stable or weakened only slightly during most of the year, with coal prices showing increases for both domestic and export sales. More than 8 million tons of coal was exported to France in both 1979 and 1980. There was a 12% increase in the average price of diamonds by De Beers Central Selling Organization in February 1980 and a 1% increase in total sales value in terms of local currency. Major mineral imports continued to include crude oil and alumina. Details of exports from the Republic of South Africa are shown in table 2, and its imports are listed in table 3. Table 4 shows comparisons of the values of commodities exported and sold locally for the period 1978-80.

Table 1.—Republic of South Africa: Production of mineral commodities[1]

(Metric tons unless otherwise specified)

Commodity	1978	1979	Destinations, 1979	
			United States	Other (principal)
METALS —Continued				
Silver —Continued				
Waste and sweepings[3] value, thousands	$796	$1,268	$476	Italy $280; West Germany $271; Belgium-Luxembourg $137.
Metal including alloys, unwrought and partly wrought ____do____	$12,267	$26,772	$39	United Kingdom $19,688; Italy $5,200; West Germany $1,509.
Tin:				
Ore and concentrate	5,684	3,727	31	West Germany 1,703; United Kingdom 917; Netherlands 828.
Metal including alloys:				
Scrap	368	114	--	Malawi 110.
Unwrought	216	1,108	253	Belgium-Luxembourg 379; France 360; Netherlands 71.
Semimanufactures	36	37	--	All to Sri Lanka.
Titanium:				
Ore and concentrate	7,321	42,845	9,815	Belgium-Luxembourg 21,764; West Germany 6,436.
Slag	--	27,144	27,144	
Oxides	--	892	543	Reunion 178; Taiwan 153.
Metal including alloys, all forms	--	155	155	
Tungsten ore and concentrate	59	80	3	West Germany 35; Sweden 24; Austria 17.
Zinc:				
Ore and concentrate	[2]41,600	[2]37,367	--	West Germany 29,672.
Oxides and peroxides	--	38	--	All to Sri Lanka.
Metal including alloys:				
Scrap	--	17	--	All to Italy.
Unwrought	8,160	33	--	All to Malawi.
Semimanufactures	10	98	46	Portugal 52.
Zirconium ore and concentrate	15,719	48,108	6,588	Japan 15,723; West Germany 10,970; Spain 7,406.
Other:				
Ores and concentrates	26,004	10,905	38	Switzerland 3,648; Australia 2,711; Canada 1,927.
Ash and residue containing nonferrous metals	36,193	70,784	10,790	France 23,014; Italy 18,255; Austria 9,870.
Oxides, hydroxides, peroxides	7,613	9,941	7,610	Canada 998; Belgium-Luxembourg 732; France 333.
Metals:				
Metalloids	16,289	17,442	1,520	West Germany 5,215; Australia 4,665; Netherlands 3,247.
Base metals including alloys, all forms	10,322	17,434	5,845	West Germany 3,088; Japan 2,965; United Kingdom 2,606.
NONMETALS				
Abrasives, n.e.s.:				
Natural: Pumice, emery, corundum, etc	23	4,570	4,092	Taiwan 420; Australia 58.
Dust and powder of precious and semiprecious stones value, thousands	$13,372	$14,678	$9,744	France $3,669; West Germany $799; Sweden $230.
Grinding and polishing wheels and stones	47	138	--	Australia 99; Malawi 31.
Asbestos, crude	287,237	389,470	16,538	Japan 104,095; Republic of Korea; 40,133; Italy 38,935; West Germany 31,611.
Barite and witherite	--	25	--	All to Netherlands.
Boron materials: Crude natural borates	--	24	--	All to France.
Cement	42,720	19,457	206	Reunion 14,348; Malawi 4,775.
Clays and clay products:				
Crude clays:				
Bentonite	[2]722	[2]1,067	--	Taiwan 278.
Kaolin	[2]988	[2]1,263	--	West Germany 76.
Other	[2]91,856	[2]108,316	--	Switzerland 73,260; United Kingdom 25,002.
Products:				
Refractory including nonclay brick	2,704	3,717	--	Italy 1,963; Belgium-Luxembourg 612; United Kingdom 569.
Nonrefractory	292	2,077	16	Belgium-Luxembourg 1,284; Malawi 350; Seychelles 180.
Diamond:				
Gem, not set or strung value, thousands	$785,633	$981,453	$708,843	Belgium-Luxembourg $163,318; Hong Kong $73,618.

See footnotes at end of table.

Industrial ____ value, thousands__	$49,656	$68,610	$50,913	West Germany $6,824; Japan $5,406; Spain $1,641.
Feldspar and fluorspar:				
Feldspar _____	[2]2,712	[2]3,266	NA	NA.
Fluorspar _____	[2]384,387	[2]471,498	NA	NA.
Total _____	387,099	474,764	221,066	Japan 117,509; West Germany 55,287; Canada 25,471.
Fertilizer materials:				
Crude:				
Nitrogenous _____	443	15	--	All to Italy.
Phosphatic _____	--	65,511	--	Venezuela 65,260.
Manufactured:				
Nitrogenous _____	29,086	71,072	--	Malawi 38,629; Sri Lanka 30,900.
Phosphatic _____	7,278	18,811	--	Malawi 11,828; West Germany 6,536.
Potassic _____	200	1,929	--	All to Malawi.
Other including mixed _____	596	6,526	--	All to Sri Lanka.
Graphite, natural _____	842	359	--	United Kingdom 181; Taiwan 106; France 72.
Gypsum _____	[2]3,654	[2]3,237	NA	NA.
Kyanite and related materials _____	[2]54,457	[2]69,810	--	West Germany 16,872; Japan 13,040.
Lime _____	[2]25,215	[2]77,071	NA	NA.
Magnesite _____	501	13	--	Canada 8; New Zealand 5.
Mica, crude including splittings and waste _____	3,049	2,414	--	United Kingdom 1,460; West Germany 444.
Pigments, mineral: Processed iron oxides	[2]736	[2]696	NA	NA.
Precious and semiprecious stones except diamond:				
Natural ____ value, thousands__	$8,295	$29,424	$4,579	Switzerland $17,707; West Germany $2,526; Spain $1,788.
Synthetic _____ do____	$58	$48	--	West Germany $32; Philippines $10.
Pyrite, unroasted (sulfur content) ____	[2]17,236	[2]2,463	NA	NA.
Salt _____	[2]38,260	[2]53,612	--	Malawi 10,199; Seychelles 233.
Sodium and potassium compounds, n.e.s.:				
Caustic soda _____	12	102	--	Sri Lanka 99.
Caustic potash _____	--	21	--	Sudan 11; Spain 10.
Soda ash _____	NA	1,949	--	All to Israel.
Stone, sand and gravel:				
Dimension stone:				
Crude and partly worked ____	[2]198,513	[2]191,530	3,491	Japan 75,704; France 72,284; Italy 68,235.
Worked _____	[2]6,705	[2]10,172	--	United Kingdom 1,216; Belgium-Luxembourg 960.
Gravel and crushed rock _____	1,767	1,225	280	United Kingdom 734; Italy 211.
Limestone except dimension _____	[2]19,073	[2]11,681	NA	NA.
Quartz and quartzite _____	[2]1,321	[2]1,540	NA	NA.
Sand:				
Silica _____	[2]685	[2]757	NA	NA.
Other _____	37,257	32,353	102	Netherlands 28,162; Belgium-Luxembourg 3,308.
Sulfur, elemental, colloidal _____	5	361	--	All to Malawi.
Talc and related materials: Pyrophyllite (wonderstone) _____	[2]6,837	[2]6,353	NA	NA.
Vermiculite _____	[2]186,665	[2]171,991	NA	NA.
Other: Slag, dross, and similar waste, not metal-bearing _____	36,904	71,244	--	France 26,056; Japan 23,416; United Kingdom 21,772.
MINERAL FUELS AND RELATED MATERIALS				
Carbon black _____	2,643	2,329	--	United Kingdom 2,185.
Coal and briquets:				
Anthracite and bituminous coal thousand tons__	[2]15,389	[2]23,341	999	France 8,117; Italy 2,325; Japan 2,265.
Briquets of anthracite and bituminous coal _____	--	106,515	--	Republic of Korea 105,465.
Lignite including briquets _____	--	25,591	--	All to West Germany.
Peat including briquets and litter ____	29	15	15	
Petroleum refinery products:				
Gasoline thousand 42-gallon barrels__	972	840	--	Australia 397; Malawi 351; New Zealand 92.

See footnotes at end of table.

Bituminous mixtures ---do---	--	1	--	Mainly to Seychelles.
Mineral tar and other coal-, petroleum-, or gas-derived crude chemicals	6,851	5,926	10	United Kingdom 4,018; Brazil 1,753.

NA Not available.

[1]Because official South African trade statistics provide data only on the value of total exports of each commodity class (with no data on destinations) and not on quantity of material exported, this table has been compiled from a variety of sources including the quarterly publication "Minerals" issued by the Department of Mines (issues for 1978 and 1979) as well as official trade returns of trading partner countries. Data from the "Minerals" is footnoted; other figures are compiled from a variety of sources with specifics on destination obtained from the import statistics of the countries listed.

[2]Source: "Minerals" quarterly of the South African Department of Mines. Figures represent shipments by producers for export and not actual exports.

[3]May include platinum-group metals.

COMMODITY REVIEW

METALS

Aluminum.—Alusaf (Pty.) Ltd. continued to import alumina from the Alusuisse operation in Gove, Australia, to its refinery at Richards Bay, and produced 82,500 tons of liquid metal and ingots in 1980 for its affiliated fabricators. Alusaf was owned 66% by the IDC, 22% by Alusuisse, 8% by Barlow Rand Ltd., 3% by Huletts Aluminum Ltd. (Hulamin), and 1% by Alcan Aluminum Ltd. The adjacent Alustang (Pty.) Ltd. factory produced redraw rods and solid sector aluminum for electrical cable, and Hulamin produced flat and coil sheet, extrusions, cable, and aluminum paste for the paint industry at its four plants. Hulamin announced it was adding a third foil mill to its holdings. The mill was to cost $11.5 million and was scheduled to be on-stream in 1982. Alusaf announced that it was to purchase another 86,000-ton-per-year smelter from Nippon Light Metal Co. of Japan and was to install it at Richards Bay at a total cost of $296 million. The South African Marine Corp. (Pty.) Ltd., also a Government enterprise, was awarded the $9.6 million contract to transport the relatively new plant starting early in 1981. Commissioning at its Richards Bay site was scheduled to start early in 1982, and full production was to be achieved the following year. Alusaf was also investigating the local production of carbon anodes utilizing coal and waste gases from the Triomf fertilizer complex also at Richards Bay.

Antimony.—All of the Republic's antimony came from a series of mines along the "antimony line" of the Murchison Range west and northwest of the Palabora copper mine. The mines were owned and managed by Consolidated Murchison Ltd. (CML), reportedly the world's largest antimony producer, owned 25% by Johannesburg Consolidated Investment Co. Ltd. (JCI). Production of cobbed ore and concentrate totaled about 22,000 tons in 1980, 11% more than that of 1979. CML exported 3,000 tons of the product at an average value of $1,360 per ton. Local sales of 12,000 tons at an average price of $1,127 per ton were made to Antimony Products (Pty.) Ltd. (APL), which was jointly owned by CML, JCI, and the McGean Chemical Corp. of Cleveland, Ohio, successor to Chemetron Corp. of Chicago. APL manufactured an antimony oxide fire retardant at its factory built on CML property at Gravelotte in Transvaal. The factory was recently expanded to treat about 80% of CML's annual production of concentrate. CML has improved its concentrating facilities and has installed a plant to treat and recover byproduct gold from the slag discharged by the APL factory.

Chromium and Chromite.—There was a 4% volume increase in the country's production of the chromium-iron oxide mineral chromite in 1980. Coincidentally, both the volume and the domestic value of chromite exports diminished by 4% each, but the value of local sales increased 8% in terms of domestic currency and 17% in U.S. dollar equivalents. Total sales value declined but sales value equivalent increased 10% to $116 million. As in previous years, slightly less than half of the total sales was exported, and most of the domestic consumption was by the ferrochromium industry, although refractory and chemical uses accounted for a significant share of the output. All of the country's chromite came from some 17 mines operating along parallel seams in noritic rock of the Bushveld Igneous Complex of central Transvaal Province. Except for the Grasvally and nearby mines in the northern part of the complex, the chrome-to-iron ratio was low, less than 2.3 to 1, and an increasing amount of high-carbon, high-iron ferrochromium was produced for export sales. Much of the export ore was shipped through the port of Matola, near Maputo in Mozambique.

The country's largest producer of chromite was the General Mining and Finance Corp. Ltd., which was merged to form the General Mining Union Corp. Group (Gencor). Gencor's Montrose and Groothoek Mines in eastern Transvaal and the Zwartkop and Kroondal Mines in the Rustenburg district of western Transvaal produced more than 1 million tons of chromite and were not operating at full capacity because of the oversupply of chromite during the past 3 years.

Barlow Rand announced the installation of load-haul-dump machines, operating between the working face and the underground conveyor belts, to replace scraper and hand loading at its Millsell Mine near Rustenburg. A heavy-medium separation plant was being installed at Millsell's concentrator. A similar plant was scheduled for the Elandsdrift section of Barlow Rand's

Henry Gould Chrome Mine, 30 kilometers east of Millsell, and improvements were also in progress in the concentrator at the Buffelsfontein section.

One of the country's smaller chromite producers was the Bantu Mining Corp., which exported some 15,000 tons of chromite from its Dilokong Mine in the Lebowa Homeland north of Steelport.

Texasgulf Inc. was considering the investment of some $350 million to establish a mining complex near Brits in Transvaal on the UG2 chromatite unit of the Bushveld Igneous Complex, which contains both chromite and platinum but very little nickel. Texasgulf's Expanded Precessive Plasma (EPP) process was expected to achieve good recoveries of both chromium and platinum.

Copper.—Production of copper in the Republic of South Africa increased more than 5% in 1980 but the volume of exports declined 15% and their value dropped 22% in terms of domestic currency, reflecting the depressed state of the world's copper industry and price. Most of the increase in copper production was due to the startup by GFSA and Phelps-Dodge Corp. of the Black Mountain lead-zinc-copper-silver mine in northwestern Cape Province in mid-1980. The Black Mountain Mine near Aggeneys, 200 kilometers northeast of Springbok, was reported to have operated at nearly full capacity for half of 1980. This indicated the production of some 8,000 tons of concentrate containing about 22.5% copper and a substantial quantity of silver plus minor amounts of lead and zinc impurities. The copper concentrate was exported from the new base-metal terminal at Saldanha Bay.

Rio Tinto-Zinc Corp. Ltd.'s (RTZ) Palabora Mining Co. Ltd. (PMC) initiated plans to expand its open pit and to maintain its production rate at more than 30 million tons of ore and 125,000 tons of finished copper per year. PMC installed trolley lines over the main haulage ramps out of the pit and equipped the trucks with dual diesel-electric power sources and pantograph-type trolley pickups. This arrangement was designed to conserve scarce diesel fuel but it also saved time as well as vehicle maintenance because the electric drive allowed greater truck speeds, and the diesel motors were never driven under heavy-load top-speed conditions. PMC also was to install a 2,700-ton-per-hour crusher, equipped with a walking mechanism for mobility, to crush low-grade foskorite for subsequent treatment by Foskor. PMC was also the world's largest producer and exporter of vermiculite, and its other byproducts included uranium oxide, zirconia (baddeleyite), precious metals, and magnetite.

The O'okiep Copper Co. Ltd., owned 57.5% by Newmont Mining Corp. and 14.4% by AMAX Inc., ended 1980 by closing the small Brandkloof, Koperberg, and Rietberg Mines near Springbok in northwest Cape Province because of low copper prices and depleted ore reserves. Its Spektakel Mine, 30 miles west of Nababeep, was started up in November 1980 in order to avoid a shortfall of ore to the mills. The old O'okiep mill, idle since 1975, was previously dismantled and rebuilt at the Spektakel Mine site for this purpose. O'okiep's Carolusberg mill was still functioning as were the mill and smelter at Nababeep. The latter produced 32,000 tons of blister copper from O'okiep's concentrate and from concentrate from the Prieska copper mine at Copperton, 425 kilometers to the east. O'okiep was planning to mine deep mineralization at Carolusberg where shaft-sinking started late in 1979. Diamond drilling indicated that the upper part of the Carolusberg Deep ore body contained 15.7 million tons of 2.05% copper ore and continued downdip. Production from this section was expected to commence in 1983. Anglo Transvaal Consolidated Investment Co. Ltd.'s (Anglovaal) Prieska Copper Mines (Pty.) Ltd. reported that encouraging mineralization had been located, but not delineated on the south limb of the main ore body. The Messina Transvaal Development Co. Ltd. operation in northern Transvaal continued to struggle with the problems of low copper prices and diminishing ore reserves.

Gold.—The gold industry of the Republic of South Africa set new records in terms of ore produced (90 million tons) and sales value of gold (R10.369 billion=US$13.3 billion), although gold production declined more than 4% to 21.67 million troy ounces, the lowest since 1960 when production was 21.38 million troy ounces. The average sales price rose from $307 to $616 per troy ounce, and an alltime high of $850 per troy ounce was recorded in January 1980. Details of production of the major mines or companies and their ore reserves are shown in table 5. Two of these mines produced more than the 1.552 million troy ounces produced by Canada, the world's third largest producer of gold. Five others produced more than the 1.3 million troy ounces from fourth place Brazil, and four others outproduced fifth

place United States with 951,384 troy ounces.

The Republic's 36 larger gold mines produced 89.92 million tons of ore in 1980 at an average grade of 0.234 troy ounce per ton. These 36 mines and 2 major tailings retreatment plants were responsible for most of the country's gold output. All but one were controlled or managed by seven large corporations, reduced to six during 1980 by the merger of two of them to form the Gencor Group. The others were Anglo American Corp. of South Africa, Ltd. (AAC), Anglovaal, Barlow Rand, GFSA, and JCI. Each of the major mines continued to produce its own gold bullion containing about 88% gold, 10% silver, and 2% base metals in bars weighing about 835 troy ounces. The bars were delivered to the Rand Refinery Ltd. at Germiston where they were assayed and purchased on behalf of the South African Government's Reserve Bank. The Rand Refinery continued to be the world's largest gold refinery with a capacity of 100 tons of silver and 1,000 tons of gold per year.

Approximately 107 tons of the country's gold production was minted into coins at the South African Mint in Pretoria and sold throughout the world by the International Gold Corp. (Intergold) on behalf of the Chamber of Mines of South Africa. In September 1980, Intergold introduced three smaller coins of the Krugerrand family exactly like the 1-ounce parent coin except for the denominations 1/2, 1/4, and 1/10 troy ounce. At yearend, Intergold reported sales of 2,845,872 of the 1-ounce Krugerrands, 245,096 of the 1/2-ounce, 353,916 of the 1/4-ounce, and 856,011 of the 1/10-ounce coins, as well as 168,000 2-Rand and 92,600 1-Rand gold coins during 1980.

Most of the more recent plans for expansion of the country's gold mines were formulated as extensions of successful operations in order to offset the capital expenditure involved against their profits for tax purposes. This was only possible where the new properties involved were contiguous, but in such cases the state effectively contributed 60% of the cost. Such a proposed merger involved two of GFSA's richest mines. The West Driefontein, which produced 2.7 million tons of ore at a grade of 0.521 troy ounce per ton in 1980, and the East Driefontein with 2.6 million tons of 0.486 troy ounce per ton of ore, had a total output of 2.67 million troy ounces or more than 83 tons of gold worth nearly $1.7 billion in 1980. In the North Driefontein area between the two mines, reserves of 27 million tons of ore with 0.46 troy ounce per ton were to be extracted with the expenditure of minimal capital on two service shafts and a moderate amount of underground development to facilitate access and ore handling, and to provide ventilation. The combined operation was to qualify as the world's largest gold mine on the basis of gold output.

The new GFSA Deelkraal concentrator commenced operations at an initial rate of 60,000 tons per month of ore in January 1980, following trial operations the preceeding month. Underground development was accomplished from twin production shafts 142 meters apart on the surface. The project was started in 1974 entirely on the evidence of drillhole information and was under budget after an expenditure of $174 million by the first of the year. Substantial savings were realized by the purchase of all basic equipment for mine and infrastructure early and storing it until needed. Both reduction works and housing were erected well ahead of the date required. The No. 2 shaft and its subvertical extension were continued to a depth of 2,419 meters and plans involved a tertiary shaft system to 3,403 meters. Ventilation was provided by two 2,610-kilowatt fans on the 58.1-square-meter downcast area of the No. 1 shaft. Two similar fans operated on the 42-square-meter upcast area of the No. 2 shaft. Two 3,300-kilovolt refrigeration units at the surface provided service water at 6° C, but their capacity was only 25% of that required when more extensive underground development had been achieved.

The primary crusher was a slipper-bearing autogenous mill 4.85 meters in diameter and 11.15 meters long. The grinding capacity for autogenous operation had been rated as 75,000 tons per month, but this was not achieved because of an excessive number of large rocks in the ore feed. As a temporary measure, these were extracted and stockpiled pending installation of a jaw crusher in mid-1981.

In mid-1980, GFSA's Doornfontein Mine was reclassified as an "other deep level gold mine," which entitled it to a 10% allowance on capital expenditure for a 10-year period. It was also granted a new, less onerous, lease from the Government. Both arrangements were retrospective to July 1, 1979. Doornfontein applied for and was granted a mining lease over ground held by GFSA which contained the downdip extensions of

the Doornfontein ore body. GFSA received the rand equivalent of $1.25 million as option consideration and agreed to subscribe for 172,000 new Doornfontein shares. Development work on two subshafts was started prior to the granting of the new lease and subsequently a new No. 2 shaft was started from surface. Erection of the headgear was nearly completed and construction of the shaft buildings and installation of the man hoist were in progress at yearend.

Barlow Rand's East Rand Proprietary Mine was planning to expand its scale of operations by August 1980. After a year of record-breaking profits ($197.7 million in 1980), it announced plans to expend some $385 million during the next 5 years to achieve a major extension in the life of the mine. About $300 million was to be spent on additional surface, subvertical, and tertiary shafts that would allow mining to progress below the present depth of 3,458 meters to approximately 4,250 meters. The necessary refrigeration system for mining at this depth was estimated to consume 85 megawatts of power. Approximately $75 million was scheduled for housing and facilities for additional staff and $10 million for surface plant, including an administration building.

During 1980, Union Corp. Ltd. became a wholly owned subsidiary of Gencor. The new Unisel Mine, brought into production in 1979 by Union Corp., continued to have its 920,000 tons of gold ore treated in St. Helena's concentrator on a toll-fee basis, and reported a working profit of more than $80 per ton. At the new Beisa uranium-gold mine, excessive water hampered shaft sinking but construction of surface buildings was proceeding satisfactorily, including both the uranium and gold extraction plants. The latter was the first Witwatersrand plant to use the carbon-in-pulp gold extraction process on a large scale. The gold was collected on small fragments of charcoal made from coconut shells. The cost of the 75,000-ton-per-month plant was estimated at $2.6 million. Gencor was also commencing the expenditure of about $412 million for commissioning by 1985 the Beatrix gold mine south of Unisel, near Welkom in Orange Free State.

AAC's Vaal Reefs Mine earned the title of the world's largest underground gold mine because it hoisted and milled 8.4 million tons of ore and produced therefrom nearly 2.25 million troy ounces of gold worth more than $1.4 billion. It also became the first mine to earn more than $1.0 billion in gold revenue in 1 year. Its working profit was $122 per ton of ore, but this was surpassed by 10 mines including AAC's Western Deep Levels Mine, which earned $225 per ton, and by GFSA's Kloof, East Driefontein, and West Driefontein Mines, which earned $234, $260, and $275 per ton of ore, respectively. Vaal Reefs' achievements were attributed to improved safety and working conditions resulting from increased refrigeration capacity, better training, and more efficient use of computers in personnel work, administration, and plant management.

AAC proposed to combine their Free State Saaiplaas, Welkom, and Western Holdings operations with the low-grade mineralization underlying the adjacent Erfdeel and Dankbaarheid properties immediately north of Saaiplaas. The capital cost of the independent project was estimated at $514 million, but by merging and offsetting costs against profits, the after-tax cost would be about $129 million. Initial mining operations were expected to generate a portion of the necessary cash flow. The new ore deposit was expected to operate at 200,000 tons per month from an ore body of 62 million tons containing an average of 0.145 troy ounce per ton. The other partners produced nearly 1.44 million troy ounces of gold worth $883 million from 7.6 million tons of ore at an average grade of 0.190 troy ounce per ton in 1980.

AAC was also planning to expand its operations at Western Deep Levels to include adjacent territory with reserves of 63 million tons of ore containing 0.31 ounce per ton of gold plus indicated reserves of an additional 74.3 million tons with 0.195 ounce per ton. The costs of the contemplated twin-shaft system to a depth of 3,760 meters with new surface treatment and refrigeration plants, were estimated to total some $600 million by the commissioning date of early 1986. Nearly $400 million was estimated as the extra cost of a later subshaft system to bottom at 3,800 meters in 1992. It was also planned that a number of facilities such as a 23-kilowatt emergency power generator would be installed at both the Western Deep Levels plants and at the nearby Elandsrand Mine.

Table 5.—Republic of South Africa: Gold production and ore reserves, by producer

Iron Ore and Concentrate.—Production of iron ore decreased 17% in 1980, largely because of reduced demand for the export of hematite, but the value of local sales increased slightly in terms of domestic currency and was reflected as a 9% increase in terms of U.S. dollars. The value of iron ore exports decreased 14% in local terms and 7% in terms of dollars. Japan and the Federal Republic of Germany continued as the principal customers of the country's iron ore with imports of 6.3 and 4.9 million tons, respectively, in 1980. The chief producer and exporter was the Sishen Mine in the arid northern Cape Province, operated by the Government-owned ISCOR. The highly automated Sishen-Saldanha Railway and the Saldanha Bay iron ore loading port with an export capacity of 18 million tons of hematite per year were operated by South African Railways and Harbours (SARAH). Sishen also produced the majority of the ore consumed in ISCOR's steel-producing plants at Vanderbijlpark in Transvaal and Newcastle in Natal Province. Sishen supplied 7,040,700 tons of hematite ore to ISCOR, 12,295,000 tons for export, and 196,000 tons to other local consumers in 1980. ISCOR's Thabazimbi Mine in Transvaal supplied 2,110,000 tons of hematite ore to its third steel plant at Pretoria.

At the Sishen Mine, 1,200-volt direct-current trolley lines were installed over the ramps leading from the pit, and the ore hauling trucks were equipped with pantograph trolley pickups in order to minimize consumption of scarce diesel fuel. The measure also saved time because the up-

grade speed of electrically driven trucks was 20 kilometers per hour instead of the 12-kilometer-per-hour speeds achieved under diesel power. Maintenance benefits also occurred because the diesel engines ran for shorter periods, at lower speeds, and never under full uphill load. Portable crusher units for overburden to be removed by shiftable conveyor bridges and belts were also installed as diesel fuel saving measures. The approximately 200 trucks of Sishen's ore trains were loaded at a rate of 4,000 tons per hour. The trains were 2.3 kilometers long, weighed some 20,000 tons, and traveled the 861 kilometers from Sishen to Saldanha Bay in about 19 hours at average speeds of 45 to 50 kilometers per hour.

Magnetite ore production continued as a byproduct of the carbonatite copper deposit mined by PMC in eastern Transvaal. AAC's Highveld Steel and Vanadium Corp. Ltd. produced 2.2 million tons of titaniferous, vanadiferous, magnetite ore from its Mapochs Mine near Roossenekal on the eastern limit of the Bushveld Igneous Complex.

Iron and Steel.—1980 was a banner year for ISCOR, which reported a profit of $197 million compared with a $45 million loss in 1979. The completion of costly technical improvements to all three of ISCOR's steel plants coincided with a 25% increase in the local demand for steel and produced a profit in a year when most of the world's steel industries experienced recession. Construction of the Sasol II and III oil-from-coal plants, the Koeberg nuclear power station, the Drakensburg dam and water diversion scheme, and a number of new mining and metallurgical plants contributed to the demand for steel, as did the extensive rehabilitation of the railway system throughout the Republic and in neighboring Mozambique. ISCOR's furnaces consumed 9.3 million tons of iron ore, 6.4 million tons of coking coal, and 1.4 million tons of dolomite in 1980, and the company sold 5.5 million tons of steel and nearly 200,000 tons of pig iron. Profits were enhanced by the sale of byproduct tar, creosote, benzole, and ammonium sulfate, the latter supplied to the fertilizer and explosives producing companies.

The Cape Town Iron and Steel Works (Pty.) Ltd., a subsidiary of ISCOR, authorized an Italian company, Danieli Engineering S.p.A., to plan a new electric steelworks near its 52,000-ton-per-year plant. The new plant was to have an initial capacity of 75,000 tons per year of billets, centered around a 25-ton electric arc furnace and a two-strand continuous billet caster.

Middelburg Steel and Alloys Ltd., a 71% subsidiary of Barlow Rand (18% AAC and 11% IDC and others), was spending $193 million to expand its Southern Cross Steel Co. (Pty.) Ltd. plant at Middelburg in Transvaal, from 23,000 to 63,000 tons per year of stainless steel by the end of 1981. Imported equipment included continuous casting facilities from Austria, a Steckel hot-strip mill from the United States, and a Zindzimer cold-strip mill from the United Kingdom. The capacity of the meltshop was to be increased to 200,000 tons per year. In late March 1980, the company announced the development of a new low-cost, corrosion-resistant steel named 3CR12. Consumption was expected to double the demand for chromium within a decade.

Specialty steels, stainless steel sheet, and steel products continued to be produced by AAC's Highveld Steel and Vanadium Corp. Its Vantra Div. at Witbank in Transvaal reported that a one-third increase in capacity was expected to come onstream in 1983.

Ferroalloys.—South African Manganese Amcor Ltd. (Samancor) continued as the country's and the world's first ranking producer of ferroalloys, as well as of manganese. Its ferromanganese capacity increased 300% in a decade to 580,000 tons per year and its ferrochromium capacity increased to 250,000 tons per year in 1980 from about 30,000 tons per year in the late 1960's. Samancor's Kookfontein ferromanganese plant, 30 kilometers south of Johannesburg, operated submerged arc electric furnaces, while its Newcastle plant in Natal was a blast furnace operation. Associated Manganese Mines of South Africa Ltd. (AMMOSAL) operated a submerged arc furnace at Cato Ridge, 50 kilometers from Durban in Natal. AAC had a similar operation at its Transalloy plant at Witbank in Transvaal and was the country's sole producer of medium-carbon ferromanganese.

Lead and Silver.—Until 1980, most of the Republic's silver (70 tons per year) was produced as a byproduct of the gold industry at the Rand Refinery at Germiston and at the refineries of the copper, zinc, and other industries. Most of its lead was imported from mining operations in neighboring countries, such as ISCOR's Rosh Pinah Mine in Namibia. At the end of 1979, the Nation's first predominantly lead-silver mine in the remote near-desert country of northwest Cape Province commenced a 6-

month period of commissioning and became fully operational by mid-1980. The Black Mountain Development Co. Ltd. (BMD), managed and 51% owned by GFSA with Phelps-Dodge holding 49%, commenced mining and milling the upper high-grade lens of its Broken Hill ore body. The approximate grades of the metals and their values in dollars per ton of ore were 9.6% lead ($80), 2.6% zinc ($20), 0.6% copper ($12), and 5.4 troy ounces of silver per ton ($80).

The computer-controlled concentrator was started in late 1979, and throughput was increased until full mining and milling capacity was achieved at the rate of 1,125,000 tons of ore per year. Recovery of the metal constituents was by selective flotation. The lead concentrate contained 72% lead representing a recovery of about 92% of the lead in the ore and 71% of its total silver. The copper concentrate was 22.5% copper and included approximately 75% of the ore's copper content and 18% of the ore's silver. The zinc concentrate averaged 52% zinc and included 65% of the zinc from the ore and less than 1% of its silver.

All three concentrates were trucked over a 166-kilometer road built by the Provincial administration to connect the mine with its storage and loading facility on the Sishen-Saldanha Railroad. Zinc concentrate was railed directly to the GFSA zinc refinery at Springs in Transvaal, operated by the Zinc Corp. of South Africa Ltd. (ZINCOR). Both lead and copper concentrates were railed to the new outloading quay in Saldanha Bay for shipment to overseas smelters. The first consignment of some 11,000 tons of lead concentrate arrived at Saldanha in March 1980, before the new quay's 15-ton cranes were installed, and was stored in a shed where it was loaded into 12-ton skips. The skips were loaded, two on each of several trailers, which were pulled by tractors the 2-kilometer distance to the ship's side on the quay. The 38,542-deadweight-ton bulk carrier La Costa used her two gantry cranes to lift the skips from the trailers and empty them into her holds.

The reserves of the Broken Hill ore body included 38 million tons of ore containing 6.35% lead, 2.87% zinc, 0.45% copper, and 2.7 troy ounces of silver per ton. BMD's long-range planning included future mining of its adjacent Black Mountain deposit, where provisional ore reserves of 80 million tons contained 2.7% lead, 0.6% zinc, and 0.7% copper, and its Big Syncline deposit, where 100 million tons of ore containing 1.0% lead and 2.5% zinc were delineated by drilling. BMD's infrastructure requirements included the provision of a self-sufficient township, which was located midway between Black Mountain and Gamsberg Mountain several kilometers to the northeast. The Gamsberg Zinc Corp. Ltd., owned jointly by Newmont South Africa Ltd., O'okiep Copper, and AAC, have partly developed a deposit of 152 million tons of predominantly zinc mineralization near Gamsberg.

Manganese.—Both the manganese ore mining and the ferromanganese industries had a poor year in 1980. Despite a 10% increase in the volume of ore produced, the volume of ore exported declined 18%, and its domestic value decreased 16% to the equivalent of $140 million, a drop of 9% in terms of U.S. dollars. Declining exports reflected the continued recession in the world's steel industry and the competitive nature of the manganese ore market. By yearend, only some 65% of the domestic production capacity was being utilized. Ten mines were responsible for most of the 5.7 million tons of manganese ore produced in 1980. They were all controlled by three large companies: Samancor (45% Government-owned), AMMOSAL, and AAC. All these operations were in the Postmasburg or Kalahari manganese fields in the northern part of Cape Province, and all shipped their ore some 950 kilometers to the old 6.5-million-ton-capacity iron ore outloading facilities at Port Elizabeth for export by freighter. The ore trains usually comprised 100 trucks and were as much as 1.7 kilometers in length.

Samancor was the world's largest producer of manganese ore and of ferroalloys, with enormous reserves of manganese estimated to last 600 years and sufficient chromite reserves to last a century. It established Samancor Metals and Minerals Inc. in the United States to handle sales in the Northern Hemisphere where it owned the European metal sales company Auvernier Ltd. as well as U.S. ferromanganese producer Roane Ltd. of Rockwood, Tenn.

Both Samancor and AMMOSAL were well established as manganese ore producers in the Postmasburg-Kalahari Field with three large underground room-and-pillar operations and six opencast mines that produced a total of nearly 4.5 million tons in 1980 at individual production rates ranging from 20,000 to 140,000 tons per month. The ore grades ranged from 28% to more than

50% manganese and the iron content ranged from 4.5% to 26%. Calcium and magnesium carbonates were the major impurities, and the ore was nearly free of deleterious contaminants with less than 0.05% phosphorous and 0.03% sulfur.

AAC's Middelplaats underground mine was one of the most highly mechanized base-metal mines in southern Africa but was operated at about 75% of its 1.1-million-ton-per-year planned capacity. Its low-phosphorus, calcareous manganese ores were a self-fluxing type suitable for blast or electric furnace operation and were largely exported to Japan and Western Europe.

Rand London Manganese Mines (Pty.) Ltd. operated eight small mines in Transvaal Province; its Ryedale Mine and its sister operation, the Brandvlei Mine, opened in March and July 1980, respectively, in the Ventersdorp district. The new mines had a capacity of 3,000 to 4,000 tons per month each of 35% to 40% MnO_2 (uranium-grade) ore. The company was the major supplier of manganese ore to the Republic's uranium industry. Rand's Gopane Mine produced 4,000 tons per year of battery-grade ore (more than 65% MnO_2) consumed by the dry-cell industry as well as lower grade ore. Rand's total production included about 400,000 tons per year of uranium-grade ore and 50,000 tons per year of chemical ores other than uranium-grade.

A $320,000 spray drying plant was under construction by Delta Manganese (Pty.) Ltd. of Nelspruit, part of Delta Metal Holdings Ltd., to speed up the production of manganese sulfate, which is used in numerous industrial applications, as a trace element additive to fertilizer, and in the chemical industry. Delta Metal also announced plans to install a $19 million plant to produce 20,000 tons per year of electrolytic manganese dioxide adjacent to its manganese metal facility at Nelspruit in eastern Transvaal. Delta Manganese was reportedly the world's largest producer of electrolytic manganese metal. Its capacity, combined with that of Electrolytic Manganese Corp., was reported as 42,000 tons of metal at yearend 1980.

Nickel, Platinum-Group Metals, and Cobalt.—Official figures regarding the volume of production, local consumption, and export sales of nickel, and all data about platinum-group metals were restricted from publication by the Government of South Africa. The values of nickel sold locally and exported were reported as the rand equivalents of nearly $15 million and $69 million, respectively. These represent increases of 33% and 63% over 1979 sales in terms of local currency. The total value of platinum-group metals imported by worldwide consumers was $792.7 million in 1979 and $887.3 million in 1980. Most of the country's output of these metals continued to come from the Merensky Reef in the Bushveld Igneous Complex. JCI's Rustenburg Platinum Holdings Ltd., the world's largest producer of platinum metal, was increasing the capacity of its associated Matthey Nickel's new $15.9 million refinery to 19,000 tons per year of electrolytic nickel as well as 400 tons per year of refined cobalt metal instead of the 500 tons per year of cobalt sulfate produced by the old plant in 1980. The platinum-group metals refinery at Wadesville was owned jointly with Johnson Matthey and Co., which was also sole marketing agents for the company. Rustenburg operated four mines near and northwest of the town of that name. Portions of the mines were in the Bophuthatswana Homeland.

Impala Platinum Mines (Pty.) Ltd. continued as the country's second largest producer, with the capacity for 750,000 troy ounces of platinum-group metals and 10,000 tons per year of nickel. Construction of a pilot plant for the recovery of cobalt was under consideration, but market trends toward the yearend were considered unfavorable. All four of Impala's mines were in the Bophuthatswana Homeland, as were the concentrator and smelter. Matte from the smelter was transported to Impala's nickel-copper and precious metal refineries at Springs in Transvaal Province for separation and purification.

Western Platinum Ltd., a subsidiary of Lonhro Ltd. of the United Kingdom, with Superior Oil Co. of the United States and Falconbridge Nickel Mines Ltd. of Canada, continued production of platiniferous matte at its mine and plant near Brits in Transvaal. The matte was shipped to the Falconbridge refinery in Norway where the precious metal fraction was separated and returned to Brakpan in Transvaal for refining. The base-metal matte was refined in Norway by Falconbridge, which recovered nickel and copper as well as some 10 tons of refined cobalt metal. Western Platinum launched a $33 million project to mine the UG2 reef, 100 to 350 meters below the Merensky Reef in the Rustenburg vicinity, and to recover some 50,000 troy ounces of platinum-group metals per year, as well as

byproduct chromite by flotation and a new, but orthodox, smelting technique.

The following table shows the percentage of the constituents in the precious metal fractions of South African and worldwide platinum deposits, adapted from D. L. Buchanan, "Platinum Group Metal Production from Bushveld Complex and Its Relationship to World Markets," University of Witwatersrand, Johannesburg, Republic of South Africa. Also shown are the average grades of the deposits as fractions of a troy ounce per ton and their resources in millions of troy ounces.

Country and deposit	Percentages of total platium-group metals						Ore grade	Reserves[1]
	Platinum	Palladium	Ruthenium	Rhodium	Iridium	Osmium	Troy ounce per ton	Million troy ounces
Republic of South Africa:								
Merensky Reef	61	26	8	3	1	1	0.252	547
UG2 chromite	43	35	12	8	2	--	.278	1,034
Platreef	43	48	4	3	1	1	.257	367
Canada: Sudbury	44	46	3.4	3.8	1.4	1.4	.025	8
U.S.S.R.: Norilsk	25	71	1	3	--	--	.122	200

United States: Stillwater[2]	20.1	78.7	--	.7	.3	.2	.713	[3]225

[1]Calculated to 1,200 meters vertical depth.
[2]Percentages calculated from analysis reported in Preparation of Platinum-Palladium Flotation Concentrate from Stillwater Complex Ore, table 7, p. 12, by J. Bennetts, E. Morrice, and M. M. Wong. U.S. Department of the Interior, Bureau of Mines, Report of Investigations, 8500, 1981.
[3]Classed as a resource potential by National Materials Advisory Council.

Texasgulf financed smelting research in the United Kingdom and further developed its Expanded Precessive Plasma (EPP) technique to recover both platinum-group metal and chromium from the UG2 chromatite, but the method has not yet shown clear economic potential. South Africa's National Institute of Metallurgy (NIM) has done some research for Western Platinum showing that flotation recovered much of the chromite in marketable form from the UG2 layer ores and that subsequent hotter-than-normal smelting of platinum-group metal concentrate produced a slag containing more platinum and rhodium than those from normal smelting of Merensky reef concentrates. Although the nickel-copper sulfide concentrates still contained enough chromite that normal electric furnace smelting produced deposits on the furnace walls, the problem was overcome by blending chromite-bearing sulfide concentrate with normal platinum-group metal concentrates. These developing techniques could have far-reaching consequences for the platinum and chromium industries of South Africa and of the world.

Tin.—All three of the Nation's tin producers contributed to the slightly reduced output of tin during 1980 as continuing high prices provided the incentive for finding and treating lower grade ores. The Rooiberg Minerals Development Co. Ltd., managed by GFSA, continued its extensive prospecting program and finally discovered additional new ore sufficient to provide for 20 years' operations. The firm's new smelter supplied most of the country's demand for tin metal and the resulting doubling of the volume and the value of tin metal sold domestically caused a corresponding decrease in the volume and value of cassiterite (tin concentrate) available for export. ISCOR's Uis tin mine in neighboring Namibia was the source of cassiterite imported for smelting in ISCOR's Vanderbijlpark facility. GFSA's Union Tin Mines Ltd. found another 3 years' underground reserves late in 1980, while continuing its program of dump retreatment. The third producer, Zaaiplaats Tin Mining Co. Ltd., lost the toll smelting of Rooiberg's concentrates when the latter's smelter was completed. It was able to maintain smelter availability for the reduced amount of cassiterite recovered from its underground mine by the marginally profitable expedient of resmelting old slag.

Titanium Slag, Rutile, and Zircon.—From 1955 to 1963, moderately large-scale beach sand dredging operations used gravity, magnetic, and electrostatic separations to produce ilmenite, rutile, and zircon concentrates at Umgababa, 40 kilometers south of Durban on Natal Province's Indian Ocean coast. In July 1977, operations commenced at the $300 million Richards Bay minerals project, 160 kilometers north

of Durban, and in 1980, output reached near-capacity levels for both Tisand (Pty.) Ltd. and Richards Bay Iron and Titanium Ltd. (RBIT). Both operations were 40% owned by, and the second was managed by, Kennecott Copper Co.'s Quebec Iron and Titanium Inc. of Canada. Other shareholders included Gencor Ltd., 30%; IDC, 20%; and 10% was jointly owned by the South African Mutual Life Assurance Society and the Southern Association. The 1980 production of 85% titania slag by RBIT from Tisand's ilmenite concentrate was 360,000 tons, and 195,300 tons of low-manganese pig iron was its coproduct. Rutile concentrate output was 50,400 tons and 103,500 tons of zircon sand was also produced. The Richards Bay ancient dune sand deposit was parallel to and some 3 to 6 kilometers west of the present beach and has been explored over a width of 2,000 meters for a north-south distance of 17 kilometers. The deposit included some 700 million tons of sand with about 6% ilmenite, 0.3% rutile, 0.6% zircon, and small amounts of garnet and monazite.

Tisand operated two dredges in a self-made pond. Dune sand was pumped from the pond sides and bottom to a floating concentrator (wet mill) equipped with 54 Reichert cone stacks that made an 85% heavy mineral concentrate that was pumped to an onshore stockpile. The rough concentrate was trucked 8 kilometers to a permanent concentrator (dry mill) site at RBIT's main facility, where magnetite was removed by low-intensity drum magnets and stockpiled. High-intensity wet-magnetic separators then removed the ilmenite, and electrostatic separators made a rutile and a nonmagnetic heavy concentrate composed chiefly of zircon. High-tension roll separators and high-intensity dry magnets were used to purify the zircon concentrate. The ilmenite concentrate was smelted in RBIT's electric furnace where Natal anthracite reduced the iron to molten metal and left the titania in the slag. Most of the slag and other products were exported to consumers in the Northern Hemisphere. Prior to mining, timber was harvested from the land adjacent to the pond and half a meter of topsoil was removed to be replaced after the tailings had refilled a mined-out segment of the pit. Casuarina windbreaks were planted to control wind erosion on the reclaimed land, which was planted with grasses and used for grazing.

Uranium.—Production of uranium oxide (U_3O_8) in concentrate increased 29% to an alltime record of 7,295 tons in 1980, bringing the country's aggregate output to 110,497 tons since the first production by West Rand Consolidated Mine in September 1952. Table 6 shows the output of 10 major producing mines and 2 tailings treatment plants during the past 4 years. Most of the U_3O_8 production was derived from uraninite and other radioactive minerals associated with the gold-bearing conglomerates (reefs) of the Witwatersrand fossil placers. A minor amount was recovered as byproducts of copper and phosphate mining in the Palabora carbonatite deposit in northeastern Transvaal. The largest producers, AAC's Vaal Reefs, improved production by 38% over that of 1979 partly because operations commenced at their Afrikander Lease Area where uranium mineralization was more important than the gold. The JCI Randfontein operations increased output by 57% as the snags were gradually worked out of their Cooke Section and Millsite treatment plants. Sinking of a third shaft at Cooke Section was approved in March, and production was scheduled to be started in 1985 from high-grade uranium ore at the relatively shallow depth of 1,000 meters. The estimated cost, reported at $257 million, did not include a separate ventilation shaft to be sunk later if required.

In January 1980, the Nuclear Fuels Corp. (Nufcor), through which all South African uranium producers except Palabora market their product, announced its negotiation of a sales contract on behalf of JCI's Western Areas. Terms included an interest-free loan of $38.6 million with repayment to start with deliveries of concentrate in 1983. Initial production of uranium-rich ore was scheduled at 80,000 tons per month and was to supplant a similar tonnage of ore from the gold reefs.

AAC's Joint Metallurgical Scheme reported a 44% increase in uranium production in 1980 to maintain its position as the country's second largest U_3O_8 producer. However, its plant was treating current tailings (and some U_3O_8 concentrate) as well as a small amount of reclaimed old tailings from six of AAC's gold-mining subsidiaries in Orange Free State. AAC's East Rand Gold and Uranium Co. Ltd. (Ergo) increased uranium recovery by 24% at its tailings retreatment plant 35 kilometers southeast of Johannesburg. The Ergo plant continued to treat tailings from nearly 20 old slimes dams. The final product of the uranium

section was a precipitate of ammonium diuranate (yellow cake) in slurry form shipped in tank trucks to Nufcor.

NIM, one of the Republic's statutory research organizations, developed a new resin-in-pulp uranium recovery circuit, and during 1980, the first commercial-scale resin-in-pulp plant outside South Africa was ordered for installation in New Mexico. NIM's research installation at Randburg was reportedly one of the world's largest mineral-processing research complexes, with a staff of more than 700 employees, and an annual budget of $14 million. The capacity of UCOR's uranium enrichment plant was expanded to 50 tons per year of enriched uranium in mid-1980. It was claimed that this was sufficient to fuel the country's first nuclear power station at Koeberg in the Cape Province after it was commissioned in 1982.

Table 6.—Republic of South Africa: Production of U_3O_8, by producer

(Kilograms)

Company or mine	1977	1978	1979	1980
AAC Joint Metallurgical Scheme[1]	312,750	653,059	676,262	977,116

Miscellaneous	--	--	218,345	743,250
Total	3,962,456	4,672,017	5,637,000	7,295,375

[1]Includes recovery of U_3O_8 from concentrates and tailings produced by the Free State Geduld, Free State Saaiplaas, President Brand, President Steyn, Welkom, and Western Holdings Mines, all subsidiaries of Anglo-American Corp. in the Orange Free State Province.

Vanadium.—The largest reserves of exploitable vanadium in the world were in the titaniferous magnetites of the Bushveld Igneous Complex in the Republic of South Africa. The country's and the world's leading vanadium producer continued to be AAC's Highveld Steel and Vanadium Corp. Ltd. Ore from the Steelport-Roossenekal area of Transvaal was treated in Highveld's Witbank plant, which had the capacity to produce 12,000 tons per year of vanadium pentoxide (V_2O_5). Ucar Minerals Corp. Ltd., a subsidiary of Union Carbide S.A. Ltd., operated plants at Brits and Bon Accord near Pretoria with a combined capacity of 2,000 tons of V_2O_5 per year. The Bon Accord plant was shut down in October 1980. Otavi Mining Co. Ltd. operated a 1,500-ton-per-year V_2O_5 plant near Wapadskloof in Transvaal. Both Samancor and RTZ were reported to control unexploited sources of vanadiferous magnetite ore. All statistics about the production and sales of vanadium ores or products were classified by the Government in 1980.

Zinc.—ISCOR's galvanizing plant at Vanderbijlpark has used zinc metal derived from concentrates imported from Namibia's Rosh Pinah Mine and milling operation for a number of years. In 1972, the Prieska Copper Mines commenced the production of sphalerite (zinc sulfide) concentrate from its four-product mine at Copperton, 65 kilometers southwest of Prieska. Production has continued at a rate of 100,000 to 150,000 tons of zinc concentrate per year. Part of the zinc concentrate was sold to GFSA's ZINCOR smelter-refinery at Springs in Transvaal, which also imported zinc concentrate from overseas. In 1980, BMD reportedly produced some 15,000 tons of zinc concentrate from its Broken Hill ore body in northwest Cape Province, and shipped it to the ZINCOR refinery. Future production was envisaged at the rate of 18,000 tons per year of contained zinc. ZINCOR installed new hot-acid leach equipment at its hydrometallurgical plant at Springs and reported a subsequent improvement in the recovery of zinc metal.

NONMETALS

Asbestos.—Both production and export sales of asbestos declined in 1980 for the third straight year. The Republic of South

Africa produced some chrysotile asbestos, but most of the output was of the crocidolite and amosite varieties for which the country remained the major world source. Cape Blue crocidolite was the most important variety economically and has usually accounted for more than one-half the total value of annual asbestos sales. Three major companies accounted for most of the Republic's asbestos production in 1980. Gencor Ltd. owned two asbestos-producing subsidiaries, Griqualand Exploration and Finance Co. Ltd. and Msauli Asbes Beperk. Griqualand's operations in the Kuruman district of Cape Province produced about 50,000 tons per year of Cape Blue crocidolite fiber. The country's largest producer of crysotile asbestos was the 85,000-ton-per-year Msauli property at Barberton in Transvaal.

Cape Blue Mines (Pty.) Ltd. and Egnep (Pty.) Ltd. were administered by Cape Asbestos South Africa (Pty.) Ltd. Cape Blue produced blue crocidolite from its Pomfret and other mines in northern Cape Province. Egnep's Penge Mine in Lydenberg district, Transvaal, continued to be the world's largest producer of amosite asbestos, with the capacity to produce 100,000 tons per year.

Cape Blue crocidolite fiber was also produced by Kuruman Cape Blue Asbestos (Pty.) Ltd. and Danielskuil Cape Blue Asbestos (Pty.) Ltd., subsidiaries of Asbestos Investment (Pty.) Ltd. and owned by the European Eternit Group. Kuruman's mines had a total capacity of 48,000 tons per year and Danielskuil's mine could produce 15,000 tons per year, all from Cape Province.

Cement.—Despite the loss of more than 50% of its export cement sales due to the overthrow of the Iranian Government and unrest in the Middle East, the Republic of South Africa had a record year for its cement industry because of the countrywide boom in the construction industry. A 21% increase over that of 1979 in volume of cement sales was reported for 1980 when total sales reached a new record of 7.4 million tons. Production facilities were reportedly more than 85% utilized, and transport facilities were claimed to be the bottleneck restricting higher sales. The chief construction projects included the new Sasol II and III oil-from-coal plants and ancillary buildings, the Drakensburg dam, water diversion system and irrigation scheme, and the Koeberg powerplant near Cape Town. There was a general expansion of the mining and other industries throughout the country, which included provision of housing and facilities for employees.

Blue Circle Ltd. was adding a 1,430-ton-per-day kiln plant, 207 feet in length, to its Lichtenburg operation and reported plans to double its output at a later date. Cape Portland Cement Co. Ltd. put a 1,600-ton-per-day preheater kiln onstream at its De Hoek plant in 1980. A 45,000-ton-per-year plant was to be built at Port Shepstone on the Natal south coast. The plant was scheduled to supply the Durban vicinity and reduce the transport of clinker from western Transvaal.

Diamond.—There was an increase of nearly 2% in the overall production of diamond (gem and industrial) in the Republic of South Africa during 1980 and a 3.3% increase in the number of carats sold. The total sales value of the marketed diamonds increased marginally but did not reflect a reduction of world market prices, but rather a diminution in the average size or quality of the diamonds marketed. The output of low unit value mine diamonds increased by 10%, while production of the more highly valued alluvial diamonds decreased by 17% in 1980.

The marketed output of diamonds in carats and the average prices in U.S. dollars per carat realized for diamonds from various sources in the Republic of South Africa are shown in table 7.

The world's largest diamond-producing company continued to be De Beers Consolidated Mines Ltd. with headquarters at Kimberley in northeastern Cape Province. De Beers' largest producer since 1979 was the Finsch open pit in a kimberlite pipe 150 kilometers northwest of Kimberley in Cape Province. Underground extraction of ore started from an inclined ramp on February 18, 1980. Total ore production during 1980 was 3,864,900 tons and came mostly from the 160- to 220-meter benches of the open pit, while overburden extraction continued from the 112- to 136-meter levels. The ore grade averaged 75.21 carats per 100 tons yielding 2,906,961 carats, a 12% increase over the 1979 production.

Of the four kimberlite mines within 6 kilometers southeast of the town of Kimberley in Cape Province, the Wesselton underground mine had the largest output with 329,861 carats produced from 1,397,100 tons of ore at a grade of 23.61 carats per 100 tons. The Bultfontein pipe, also mined underground, produced 681,400 tons of ore with 38.83 carats per 100 tons, or 264,611 carats of diamond from the 580- and 700-meter levels. Drainage tunnels excavated south-

west of the pipe yielded substantial quantities of water. The return airway to the joint ventilation shaft and fan chamber was completed during the year. The 1,157,200 tons of ore recovered from Bultfontein floors dumps yielded 319,313 carats at a grade of 27.59 carats per 100 tons. Sampling of other dumps in the area continued, and the hydraulic excavator was converted from diesel to electric power during the year.

At the nearby Dutoitspan underground mine, 603,800 tons of ore from the 760-meter level block cave area yielded 123,264 carats of diamond at a grade of 20.41 carats per 100 tons. The system of water tunnels around the pipe was nearly completed and was draining substantial quantities of water from the surrounding strata. Production from the De Beers underground kimberlite mine yielded 135,993 carats from 665,800 tons of ore from the 620- and 745-meter levels at a grade of 20.43 carats per 100 tons. At the Kamfersdam kimberlite some 5 kilometers to the north, an access ramp was advanced 689 meters to within 206 meters of the pipe. Completion of the ramp and sampling of the 225-meter level of the pipe were scheduled for 1981.

At the Koffiefontein kimberlite mine in Orange Free State Province, nearly 80 kilometers southeast of Kimberley, some 3,645,700 tons of ore was treated and the grade improved from 11.24 to 11.84 carats per 100 tons, resulting in a 5% increase to 431,480 carats of diamond recovered in 1980. Development of the 522-meter level haulages, main tip, crusher, and conveyor installations were completed by yearend. Open pit mining was scheduled to end and underground mining was to start by March 1981.

The Premier kimberlite mine in Transvaal Province, about 10 kilometers northeast of Pretoria, was for many years the Nation's largest producing diamond mine and was still first in ore production in 1980 when 7,597,700 tons of ore was treated to recover 2,039,186 carats of diamond at a rate of 26.84 carats per 100 tons. Of this, the underground mine produced 5,239,400 tons of ore with a grade of 29.36 carats per 100 tons for 1,538,193 carats of diamond, while dump retreatment involved 2,358,300 tons of ore with 21.24 carats per 100 tons for 500,993 carats of diamond. Development below the gabbro still was generally behind schedule because of poor ground conditions that required the installation of additional support in the crusher area. A new heavy media plant for treating fine ore was commissioned at yearend and was expected to recover more small diamonds than had been possible with the jig plant.

Virtually all of South Africa's alluvial diamonds were recovered by the various units of De Beers' Namaqualand Div. along the western coast of Cape Province. De Beers' alluvial output totaled 1,434,262 carats while production from the State Alluvial Diggings at Alexander Bay was 139,114 carats, and a smaller company operating offshore produced nearly 50,000 carats. De Beers' largest alluvial operation was the Koingnass Complex where 22.4 million tons of overburden was excavated and 1,842,100 tons of ore (diamondiferous gravel) was treated, including 341,500 tons mined at Mitchells Bay, 26 kilometers to the south. Washed gravels were transported to the Koingnass diamond recovery plant, where they were treated, along with the recovery from 1.5 million tons of Koingnass gravel. The overall yield of 635,321 carats indicated an average grade of 34.49 carats per 100 tons. At Dreyers Pan, mining was halted in midyear after 755,300 tons of gravel yielded 87,425 carats of diamond at a grade of 11.58 carats per 100 tons. In the latter part of 1980, the bulk sampling plant resumed operations near Dreyers Pan and treated 470,600 tons of gravel to recover 61,951 carats of diamond at a grade of 13.16 carats per 100 tons.

In May 1980, a new recovery plant was commissioned at Tweepad and was staffed with personnel from Dreyers Pan. During the latter half of the year, 1,309,000 tons of gravel yielded 144,348 carats at an average grade of 11.03 carats per ton. At Annex Kleinzee, 3,068,200 tons of gravel was treated at an average grade of 14.98 carats per 100 tons and yielded 459,573 carats of diamond. Some of the Annex Kleinzee gravels came from adjacent farms including the southern part of the Dreyers Pan lease. Overburden stripping in these areas totaled 33,715,600 tons and was expected to increase in 1981 when delivery of a new 46-cubic-meter-capacity dragline was expected. At the Langhoogte Mine, 35 kilometers to the east, gravel production was 339,800 tons at 13.43 carats per 100 tons for a yield of 45,644 carats. An 86-kilometer pipeline was completed during 1980 to bring potable water fron Nababeep to Kleinzee. Pressure testing and commissioning were in progress at yearend.

Table 7.—Republic of South Africa: Marketed diamond output, by province

Province	1978		1979		1980	
	Output (carats)	Price per carat	Output (carats)	Price per carat	Output (carats)	Price per carat
Mine diamond:						
Transvaal	1,940,755	$31.95	2,033,993	$39.60	2,342,714	$39.92
Cape Province	3,593,972	44.38	3,680,787	45.58	3,902,256	52.04
Orange Free State	408,802	113.97	441,050	117.34	531,708	167.92
Total	5,943,529	45.10	6,155,830	48.75	6,776,678	56.94
Alluvial diamond:						
Transvaal	16,274	294.18	22,268	325.21	26,882	506.93

Grand total	7,390,099	69.37	8,173,151	79.70	8,450,245	84.13

Source: Republic of South Africa Department of Mineral and Energy Affairs, Quarterly Information Circular, Minerals, October-December 1980, p. 2. 1 Rand = US$1.2854 for 1980.

Fluorspar.—Production of fluorspar increased nearly 15% to a new record of 523,000 tons maintaining the country as the second largest producer in the world after Mexico. Export sales also increased more than 20% to 443,000 tons with a sales value of $43.8 million. Most of the production consisted of acid-grade fluorspar, with 97% or more CaF_2. Early in 1980, Derby Metals and Minerals S.A. Ltd. announced that it had acquired Marico Fluorspar (Pty.) Ltd., formerly a subsidiary of United States Steel Corp. and the country's largest producer. Derby's affiliate, Rand Mines Ltd., was to become technical manager of the operation. Marico's annual capacity was 120,000 tons per year of acid-grade fluorspar and 40,000 tons per year of metallurgical-grade fluorspar from their mine near Zeerust, in northwestern Transvaal. Gencor's Buffalo Fluorspar (Pty.) Ltd. was reported as operating the world's largest acid-grade fluorspar mine with a capacity of 150,000 tons per year at its mine near Naboomspruit in Transvaal. Buffalo's better ore contained abnormal amounts (0.25%) of P_2O_5 and its mining was discontinued in favor of lower grade (12% to 15% CaF_2) ores with 0.03% P_2O_5. Chemspar Ltd., a subsidiary of Phelps-Dodge and Vergenoeg Mining Co. Pty. Ltd., owned by Bayer A.G., each had a 90,000-ton-per-year capacity, and Ruigtepoort Fluorspar Mines (Pty.) Ltd. had a reported annual output of 25,000 tons.

Phosphate.—The Government-controlled Foskor continued to produce most of the Republic's phosphate from the Palabora carbonatite complex in northeastern Transvaal Province. Like the neighboring PMC copper mine, Foskor installed mobile crushing units feeding shiftable conveyor bridges and belts in order to reduce truck haulage of its foskorite ore and PMC's phosphate-rich waste rock and thus to conserve diesel fuel. After diamond drilling had outlined larger and deeper extensions to the phosphate enriched carbonatite, Foskor was assessing a possible plant expansion that could double the production of phosphate concentrate. In 1980, nearly 20 million tons of ore was treated to produce nearly 3.5 million tons of concentrate. Triomf Fertilizers (Pty.) Ltd. at Richards Bay, and the smaller Federale Kunsmis Ltd. (Fedmis), near the PMC plant, purchased most of Foskor's concentrate, and their combined output was more than 500,000 tons of phosphoric acid in 1980, mostly for export. Fedmis operated its own phosphoric acid plant, which consisted of a 72,000-ton-per-year No. 1 unit, plus No. 2 and No. 3 units with a combined capacity of 221,000 tons per year of phosphoric acid. Simon Carves Pty. Ltd. (Africa) had contracted to enlarge the No. 2 and No. 3 units by 30%. The No. 3 sulfuric acid plant was also enlarged, and a new 200,000-ton-per-year sulfur-burning plant was completed by yearend.

MINERAL FUELS

Coal.—For the third straight year, the value of the country's coal production has exceeded $1 billion, and the value of coal exports reached the equivalent of $884 million in foreign exchange, an increase of 35% over that of 1979 in terms of domestic currency. An increasing amount of coal was

used to generate electrical energy as both coal and ore transport vehicles were converted from diesel consumption to part electric drive. The country's 78 producing collieries supplied 72% of the country's energy requirements. The coal consumption at the Sasol II oil-from-coal plant also increased as additional units commenced functioning.

ISCOR commissioned its $300 million Grootegeluk opencast coal mine near Ellisras in northwestern Transvaal for opening on April 15, 1980, as its major source of 1.8 million tons per year of mixed coking coal for its metallurgical requirements. Grootegeluk's middlings were scheduled to supply a planned Electricity Supply Commission (ESCOM) power station. In order to reduce diesel-powered truck haulage, ISCOR was installing 22-cubic-meter Parkinson and Howard electric shovels that loaded overburden through 3,000-ton-per-hour mobile gyratory crushers and fed shiftable 110-meter-long bridge conveyors linked to crawler-mounted spreaders at the dumps.

On January 25, 1980, Rand Mines opened its new opencast Duvha coal mine designed to supply ESCOM's Duvha power station under construction nearby. The power station had a capacity of six 600-megawatt units and the Duvha Colliery was to provide its fuel for 35 years. Mining was to utilize three 53-cubic-meter draglines and two smaller draglines when full production was achieved in 1986.

GFSA installed a $1.5 million beneficiation unit for fine coal at its Greensides Colliery near Witbank to produce 4,000 tons per month of low-ash fine coal for export to European power stations. The new plant was integrated with GFSA's No. 2 seam plant, which treated 160,000 tons per month of raw coal.

The facilities of the Richards Bay Coal Terminal Co. (RBCT) were established in 1970 to supply Japanese steelmakers with 27 million tons of coal from the Transvaal Coal Owners Association and to relieve the port of Durban. The port capacity was 12 million tons per year in 1976 and had expanded to 20 million tons per year by April 1979. In 1978, the Government authorized further expansion to 44 million tons per year at a cost to RBCT of $296 million. Upgrading of the railroad was handled by SARAH, which also was planning construction of additional harbor facilities including two new quays. The two original quays were 360 meters in length and could load 150,000-deadweight-ton bulk carriers at the rate of 6,500 tons per hour. Some $60 million was to be spent for dredging the harbor to handle 250,000-ton bulk carriers during the next 2 years. Bituminous coal from Transvaal was brought to the port in trains of 84 trucks with a total capacity of 4,900 tons, while Natal anthracite was carried in smaller block trains of 2,500-ton capacity.

Petroleum.—The Republic of South Africa continued to import crude oil, but an increasing amount of its refineries' requirements were met by the combined output of synthetic crude (syncrude) from its Sasol I and II plants. The full-scale Sasol II plant at Secunda was reportedly producing at 40% of its total capacity and was consuming about 135,000 tons per week of coal from the nearby Bosjesspruit Colliery. At the adjacent Sasol III plant, construction was about 35% complete and commissioning for full production was scheduled for 1984. Security around the construction site was intensified following explosions that destroyed liquid fuels worth approximately $5.5 million at Sasolburg and Secunda early in 1980.

The Government-owned Southern Oil Exploration Corp. (Pty.) Ltd. (Soekor) continued offshore exploration throughout 1980. In December, its FA2 well, 90 kilometers south of Mossel Bay, intersected a 70-meter section of rock including three layers of hydrocarbon-bearing sandstone at depths slightly in excess of 2,700 meters. Initial testing of the upper layer indicated a flow of 11 million cubic feet of gas per day accompanied by some 200 barrels of gas condensate or very light oil. The second layer produced a test of 8 million cubic feet of gas and 100 barrels of condensate per day. Soekor was planning additional seismic surveys to determine the extent of the field and additional drilling to explore the extent and uniformity of the reservoir.

[2]Where necessary, values have been converted from South African rand (R) to U.S. dollars at the rate of R1=US$1.19 for 1979, and at R1=US$1.2854 for 1980, as shown in International Financial Statistics, v. 34, No. 7, pp. 348-350.

The Mineral Industry of Spain

By Roman V. Sondermayer[1]

Spain continued to make efforts to increase domestic production of minerals, with an aim to lower imports of raw materials for its fast growing industry and to cut the trade deficit, which was largely caused by imported liquid fuels.

During 1980, Spain remained an important producer and processor of minerals in Europe, with output of several minerals that were significant to the world economy. Spain's approximate share of world output of these minerals was mercury (17%), pyrite (11%), fluorspar (7.3%), and potash (2.8%).

The Spanish mineral industry contributed about 11% of the gross national product. The share of petroleum refining was 10%, and the extractive segment was only about 1%. Total employment in the mineral sector was close to 600,000 persons, of which mining employed about one-third.

The overall economic situation in the country was similar to that in other European countries. Unemployment was near 12%, and inflation was just over 15%. Except for the mineral industry, all activities were depressed, including the energy sector.

In 1980, major events of the mineral industry included completion of an alumina plant at San Ciprian in northern Spain; Rio Tinto Zinc of the United Kingdom (RTZ) increased its holding in Rio Tinto Minera (RTM), the largest producer of copper in Spain, from 25% to 49%; exploration for iron ore in southern Spain; the startup of a new opencast mercury mine near Almaden; and the construction of a strontium compound plant and modernization of a strontium mine near Granada.

PRODUCTION

The mineral industry of Spain is owned by the Government and by private capital. Government manages most of its companies through Instituto Nacional de Industria (INI). A following tabulation shows the structure of the industry.

Table 1.—Spain: Production of mineral commodities[1]

(Metric tons unless otherwise specified)

Commodity	1976	1977	1978	1979[p]	1980[e]

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.
[1]Table includes data available through Sept. 1, 1981.
[2]Reported figure.
[3]In previous editions, reported as "Earths, industrial, n.e.s."
[4]Includes sand obtained as a byproduct of feldspar and kaolin production.

Commodity	Major companies	Location of principal facilities
Alumina	Alumina de Espana S.A	Plant of San Ciprian.
Aluminum	do	Do.
Do	Endasa S.A	Plant at Aviles and Valladolid.
Do	Aluminio de Galicia S.A	Plant at La Coruna and Sabinanigo.
Bituminous coal	Hunosa S.A	Mines in Asturia.
Cement	Cía. General de Asfaltos y Portland S.A	7 plants.
Copper ore	Rio Tinto Minero S.A	Mines at Rio Tinto.
Copper, refined	do	Refinery at Huelva.
Ferroalloys	Soc. Espanola de Carburos Metalicos S.A	Plant at Berga.
	Hidro Nitro Espanolas S.A	Plant at Monzon.
	Ferroaleaciones Espanolas S.A	Plant at Medina del Campo.
Iron ore	Cía. Andalusa de Minas S.A	Mine at Marquesado.
Lead ores	Sociedad Minera y Metallurgica de Penarroya de Espana.	Mines at Mantas des Los Azules, Union.
Lead smelter	do	Smelter at Santa Lucia.
Mercury	Cousejo de Administration de Minas de Almaden.	Mines and smelter at Almaden.
Petroleum, refined	Empresa Nacional del Petroleo S.A	Refineries at Valle de Escombreras and Puertolano.
Do	Cía. Esp. de Petroleos S.A	Refineries at St. Cruz de Tenerife, Algeciras.
Potash	Potasas de Navarra S.A	Mine near Pamplona.
Do	Minas de Potasas se Suria S.A	Mine near Suria.
Do	Union Explosivos Rio Tinto S.A	Mines at Balsarney-Sallent and Cardon.
Pyrite	Tharsis Sulfur and Copper Co. Ltd	Mines at Tharsis and La Zarza.
Steel	Empresa Nacional Siderurgica S.A	Work at Aviles, Felguera, Gijon-Moreda, Gijon-Verina.
Do	Altos Hornos de Vizcaya S.A	Work at Baracaldo-Sestao.
Zinc ore	Real Cía. Asturiana de Minas S.A	Mines at Reocin and Rubialres.
Zinc, smelter	do	Electrolytic zinc plant at San Juna de Neuva.

TRADE

During the last several years, Spanish imports of minerals heavily taxed the country's balance of payments; during 1980, this situation remained. Tables 2 and 3 show details of foreign trade of Spain in minerals as reported in Foreign Trade Statistics published by the Spanish Government.

Table 2.—Spain: Exports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1978	1979	Destinations, 1979	
			United States	Other (principal)
METALS				
Aluminum:				
Ore and concentrate	19	1,106	--	All to Portugal.
Oxides and hydroxides	47	69	--	Portugal 43; United Kingdom 11.
Metal including alloys:				
Scrap	219	684	15	Italy 589; Pakistan 40; West Germany 20.
Unwrought	5,838	42,870	499	Japan 24,777; Portugal 4,185; Netherlands 3,499.
Semimanufactures	10,790	21,755	3,627	France 7,442; Portugal 2,207; Finland 770.
Antimony metal including alloys, all forms	r464	593	18	Netherlands 294; France 127; Japan 69.
Bismuth metal including alloys, all forms	2	4	--	Mainly to Netherlands.
Cadmium metal including alloys, all forms	143	194	88	Belgium-Luxembourg 47; Netherlands 32.
Chromium:				
Chromite	14	4,099	--	Mainly to East Germany.
Oxide and hydroxide	20	72	--	United Kingdom 40; Colombia 18.
Copper:				
Ore and concentrate	36	98	--	All to West Germany.
Matte	689	325	--	Do.
Sulfate	736	297	279	Morocco 15.
Metal including alloys:				
Scrap	705	704	--	West Germany 405; Japan 101; United Kingdom 73.
Unwrought	52,375	35,856	(1)	Belgium-Luxembourg 12,799; France 6,258; West Germany 5,774.
Semimanufactures	17,629	20,065	1,071	Italy 4,457; Morocco 3,124; Portugal 2,008.
Gold:				
Waste and sweepings value	--	$20,318	--	All to West Germany.
Metal including alloys, unwrought and partly wrought -- thousand troy ounces	482	194	--	Switzerland 96; United Kingdom 64.
Iron and steel:				
Ore and concentrate except roasted pyrite thousand tons	r2,025	1,995	--	West Germany 641; Netherlands 576; Romania 391.
Roasted pyrite do	r320	330	--	West Germany 307; France 13.
Metal:				
Scrap	727	172	--	West Germany 75; Belgium-Luxembourg 60; Netherlands 22.
Sponge iron, powder, shot	11,737	13,397	1	Italy 5,263; West Germany 1,995; France 1,874.
Ferroalloys:				
Ferromanganese	47,242	53,481	9,401	Romania 14,795; West Germany 11,194; China, mainland 5,000.
Other	74,403	120,350	3,835	West Germany 43,745; United Kingdom 13,189; Japan 12,924.
Steel, primary forms	r264,605	248,421	1,790	Venezuela 57,995; Turkey 36,305; Syria 20,063.
Semimanufactures:				
Bars, rods, angles, shapes, sections thousand tons	2,391	2,742	156	U.S.S.R. 307; Saudi Arabia 281; West Germany 244.
Universals, plates, sheets	r933,077	802,304	156,088	West Germany 97,351; Greece 74,387; U.S.S.R. 58,786.
Hoop and strip	17,772	27,172	--	West Germany 11,134; France 4,722; Belgium-Luxembourg 2,599.
Rails and accessories	546	11,502	--	Mainly to Saudi Arabia.
Wire	43,228	39,114	850	China, mainland 12,724; Algeria 9,331; Portugal 4,010.
Tubes, pipes, fittings	406,927	364,364	40,275	West Germany 57,450; France 41,406; China, mainland 40,022.
Castings and forgings, rough	22,407	28,143	3,786	France 7,042; Canada 2,521; West Germany 2,358.

See footnotes at end of table.

Oxides and acid	2,986	781	632	Canada 126; Portugal 15.
Cement, thousand tons	9,830	9,592	453	Saudi Arabia 2,928; Nigeria 1,046; Venezuela 974.
Chalk	18,753	23,877	1	Algeria 6,836; Portugal 4,606; Libya 4,400.
Clays and clay products (including all refractory brick):				
Crude:				
Bentonite	37,881	39,876	--	Portugal 16,602; United Arab Emirates 8,500; Egypt 3,000.
Kaolin (china clay)	59,802	71,794	--	Poland 15,939; West Germany 15,303; Algeria 11,049.
Other	24,623	42,612	1,034	Portugal 6,707; United Arab Emirates 6,500; United Kingdom 4,759.
Products:				
Refractory (including nonclay brick)	r28,187	23,411	--	Egypt 6,769; Cuba 3,050; France 2,673.
Nonrefractory	308,085	335,265	18,711	France 86,374; Andorra 26,966; Saudi Arabia 25,026.
Cryolite and chiolite, kilograms	(1)	16	16	
Diamond:				
Gem, not set or strung, value, thousands	--	$139,978	$12,320	Belgium-Luxembourg $74,294; Switzerland $53,348.
Industrial, do	$82,047	$142,436	$223	Belgium-Luxembourg $59,665; Mexico $54,823; Ireland $27,680.
Diatomite and other infusorial earth	1,658	1,453	--	United Kingdom 391; Italy 385; France 180.
Feldspar, leucite, nepheline, nepheline syenite	6,989	1,901	--	United Kingdom 1,050; France 716.
Fertilizer materials:				
Crude and manufactured:				
Nitrogenous	311,253	77,752	--	Belgium-Luxembourg 22,503; United Kingdom 19,094; Ireland 14,220.
Phosphatic	17,133	4,107	--	United Kingdom 2,420; Ireland 1,650.
Potassic	404,741	677,503	29,200	Portugal 98,530; Norway 82,103; Brazil 71,400.
Other including mixed	191,892	176,100	--	Venezuela 52,500; Turkey 36,911; Mexico 21,103.
Ammonia	53	39	--	Ghana 18; Mauritania 16.
Fluorspar	193,485	101,546	25,883	Italy 45,398; West Germany 16,311; Netherlands 5,603.
Graphite:				
Natural	1	3	--	Mainly to Pakistan.
Artificial	768	778	--	Portugal 299; Sweden 245; France 203.
Gypsum and plasters	r776	1,111	137	Sweden 262; Denmark 211; Norway 138.
Iodine	2	1	--	Mainly to Cuba.
Lime	6,999	7,776	--	Guinea 3,506; Algeria 2,138.
Magnesite	79,029	93,459	--	West Germany 43,652; United Kingdom 24,209; Netherlands 7,931.

See footnotes at end of table.

Table 2.—Spain: Exports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1978	1979	Destinations, 1979	
			United States	Other (principal)
NONMETALS —Continued				
Mica, all forms	3,048	4,173	--	Mainly to United Kingdom.
Pigments, mineral: Iron oxides, processed	9,652	11,246	846	United Kingdom 1,974; Australia 736; Canada 707.
Precious and semiprecious stones, except diamond:				
Natural ---value	$140,655	$173,810	--	Switzerland $103,553; United Kingdom $50,994.
Synthetic ---do	$479,984	$722,592	$40,328	Switzerland $646,838; France $16,730.
Pyrite (gross weight)	242,302	126,963	(1)	Belgium-Luxembourg 116,930; West Germany 8,007.
Salt and brines	816,357	782,353	229,160	Italy 124,995; Portugal 64,188; Norway 56,151.
Sodium and potassium compounds, n.e.s	90,033	121,373	694	India 24,785; Portugal 15,802; China, mainland 14,987.
Stone, sand and gravel:				
Dimension stone:				
Crude or partly worked:				
Calcareous	26,457	37,239	226	Italy 26,005; France 3,322; Nigeria 3,096.
Slate	1,648	4	--	All to Andorra.
Other	79,765	101,901	--	Italy 75,511; France 18,708; Japan 3,225.
Worked:				
Slate	147,677	172,093	17	France 146,758; West Germany 11,629.
Paving stone and flagstone	48	177	--	France 70; Italy 43; Saudi Arabia 40.
Other	20,133	21,864	278	Saudi Arabia 5,170; France 2,345; Andorra 1,196.
Dolomite	110,304	105,399	--	United Kingdom 64,804; West Germany 31,700.
Gravel and crushed rock	58,085	33,992	--	Morocco 18,124; Andorra 9,487; Liberia 3,399.
Limestone excluding dimension	--	99,434	--	Belgium-Luxembourg 82,312; Benin 17,121.
Quartz and quartzite	224,408	333,698	--	Norway 315,221; Sweden 17,603.
Sand excluding metal-bearing	174,217	385,786	--	Mainly to Andorra.
Sulfur:				
Elemental, all forms	25,953	17,733	--	Turkey 8,964; Algeria 5,901; France 1,891.
Sulfuric acid	112	175	--	France 65; Libya 32; Portugal 28.
Talc, steatite, soapstone, pyrophyllite	6,128	15,030	2,175	West Germany 4,099; Cuba 3,532; United Kingdom 1,887.
Other:				
Crude	508,142	535,133	906	France 185,417; Belgium-Luxembourg 157,232; West Germany 77,087.
Slag, dross, and similar waste, not metal-bearing	74,367	102,208	--	Portugal 48,425; West Germany 32,678; France 10,105.
Oxides and hydroxides of magnesium, strontium, barium	181	394	--	Tunisia 308; Italy 44; Republic of South Africa 22.
Building materials of asphalt, asbestos and fiber cements, and unfired nonmetals	82,630	38,717	1	France 22,547; Iraq 3,538; Nigeria 2,864.
MINERAL FUELS AND RELATED MATERIALS				
Asphalt and bitumen, natural	26	35	--	United Arab Emirates 25; Guinea 10.
Carbon black and gas carbon	5,081	11,577	--	Portugal 3,442; Italy 3,100; France 2,819.
Coal and briquets:				
Anthracite and bituminous coal	r16,238	14,475	--	Belgium-Luxembourg 13,240; France 1,048.
Briquets of anthracite and bituminous coal	157	60	--	Andorra 36; Italy 24.
Lignite and lignite briquets	31	436	--	All to Andorra.
Coke and semicoke	2,048	3,378	--	Italy 2,339; Mexico 1,000.
Hydrogen, helium, rare gases	530	1,418	--	Belgium-Luxembourg 763; Italy 592.
Peat including peat briquets and litter	4	163	--	Libya 121; Portugal 42.

See footnotes at end of table.

Table 2.—Spain: Exports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1978	1979	Destinations, 1979	
			United States	Other (principal)
MINERAL FUELS AND RELATED MATERIALS —Continued				
Petroleum and refinery products:				
Crude and partly refined--42-gallon barrels--	--	3	--	Mainly to Italy.
Refinery products:				
Gasoline, including natural thousand 42-gallon barrels--	628	895	--	United Kingdom 314; Argentina 237; Netherlands 182.
Kerosine and jet fuel---------do----	r1,720	530	193	Portugal 213; Netherlands 90; Morocco 33.
Distillate fuel oil ----------do----	4,853	2,087	--	Netherlands 596; Italy 283; Portugal 195.
Residual fuel oil ----------do----	7,177	6,847	478	Netherlands 2,213; Italy 709; Sweden 270.
Lubricants----------do----	r100	51	(1)	Portugal 8; Lebanon 2.
Other:				
Liquefied petroleum gas----do----	30	29	--	Algeria 25; Morocco 3.
Mineral jelly and wax -----do----	6	7	--	France 2; India 2; Morocco 1.
Bitumen and other residues--do----	2,808	3,125	--	Italy 1,479; Libya 624; France 215.
Bituminous mixtures, n.e.s --do----	319	405	--	Libya 154; Nigeria 87; Guinea 46.
Pitch and pitch coke ------do----	78	94	--	France 74; Portugal 10; India 9.
Unspecified ----------do----	r3,516	1,294	21	Taiwan 169; Netherlands 152; Ivory Coast 136.
Mineral tar and other coal-, petroleum-, or gas-derived crude chemicals ----------	19,239	163,272	31,763	Netherlands 54,672; France 35,900; Italy 34,730.

r Revised.
[1]Less than 1/2 unit.
[2]May include waste and sweepings of platinum-group metals.

Table 3.—Spain: Imports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1978	1979	Sources, 1979	
			United States	Other (principal)
METALS				
Aluminum:				
Bauxite and concentrate ----------	117,952	142,818	--	Guyana 57,046; Greece 30,560; Suriname 27,000.
Oxides and hydroxides ----------	432,225	559,226	348	Guinea 267,881; Jamaica 195,958; France 73,624.
Metal including alloys:				
Scrap ----------	3,108	4,080	328	Portugal 3,566.
Unwrought ----------	37,972	7,152	1	France 6,715; United Kingdom 274.
Semimanufactures----------	12,121	14,617	2,810	France 2,590; Belgium-Luxembourg 2,479; United Kingdom 1,345.
Antimony:				
Ore and concentrate----------	564	664	--	Morocco 217; China, mainland 206; Thailand 195.
Metal including alloys, all forms ----------	r127	199	--	Czechoslovakia 105; Belgium-Luxembourg 90.
Arsenic metal including alloys, all forms ------	14	19	1	Sweden 18.
Beryllium metal including alloys, all forms kilograms--	1	10	4	France 3; Japan 2.
Bismuth metal including alloys, all forms------	96	102	--	Mexico 34; Belgium-Luxembourg 20; West Germany 19.
Chromium:				
Chromite ----------	95,597	117,977	--	Albania 53,721; Republic of South Africa 30,218; Turkey 26,333.
Oxides and hydroxides ----------	247	135	1	West Germany 110; U.S.S.R. 13.
Metal including alloys, all forms ----------	r5	6	(1)	United Kingdom 4; West Germany 2.

See footnotes at end of table.

Table 3.—Spain: Imports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1978	1979	Sources, 1979	
			United States	Other (principal)
METALS —Continued				
Cobalt oxides and hydroxides	143	75	1	Belgium-Luxembourg 48; Canada 16.
Copper:				
Ore and concentrate	222,248	191,109	--	Papua-New Guinea 58,963; Peru 46,061; Canada 33,707.
Sulfate	1,130	1,517	--	France 930; Czechoslovakia 300; Israel 198.
Metal including alloys:				
Scrap	11,466	18,951	8,361	France 5,949; Switzerland 1,072; Canada 526.
Unwrought	63,709	64,396	4,718	Chile 24,659; Belgium-Luxembourg 11,654; Republic of South Africa 8,201.
Semimanufactures	17,088	28,146	545	United Kingdom 5,819; France 4,986; West Germany 4,463.
Gold:				
Ore and concentrate kilograms	1,014	350	NA	Papua-New Guinea 244; Canada 55; Republic of South Africa 21.
Waste and sweepings value, thousands	$145,633	$250,768	$8,042	United Kingdom $101,738; Switzerland $87,501; France $52,707.
Metal including alloys, unwrought and partly wrought thousand troy ounces	r353	80	(1)	West Germany 72; France 4.
Iron and steel:				
Ore and concentrate except roasted pyrite thousand tons	r4,628	5,195	1	Brazil 1,359; Venezuela 1,026; Canada 921.
Metal:				
Scrap do	1,950	2,927	1,307	United Kingdom 649; France 414; Netherlands 163.
Pig iron including cast iron	33,785	44,312	--	Canada 18,825; Finland 8,102; Republic of South Africa 7,154.
Sponge iron, powder, shot	6,526	136,600	16	Canada 129,090; Sweden 4,187; France 2,657.
Ferroalloys	34,587	46,557	1,704	Republic of South Africa 26,235; Sweden 6,195; France 5,593.
Steel, primary forms	r295,040	509,314	28	West Germany 136,343; France 77,153; Romania 55,746.
Semimanufactures:				
Bars, rods, angles, shapes, sections	139,525	172,056	1,925	United Kingdom 31,575; France 26,514; Republic of South Africa 22,592.
Universals, plates, sheets	213,489	266,890	1,949	West Germany 88,670; France 52,664; Netherlands 42,581.
Hoop and strip	65,201	66,036	236	France 27,276; West Germany 19,324; Italy 3,922.
Rails and accessories	1,559	2,218	(1)	United Kingdon 1,425; France 500; West Germany 133.
Wire	15,860	19,111	146	France 4,439; Japan 4,362; West Germany 3,305.
Tubes, pipes, fittings	31,130	37,561	2,485	West Germany 14,509; France 8,374; Japan 2,304.
Castings and forgings, rough	3,926	6,274	442	France 2,248; Italy 863; West Germany 839.
Lead:				
Ore and concentrate	33,344	15,155	--	Morocco 13,729; Ireland 1,425.
Oxides	24	109	--	Mainly from Bulgaria.
Metal including alloys:				
Scrap	4,024	286	112	Canada 130; West Germany 15; Andorra 15.
Unwrought	r3,653	1,168	132	France 619; Netherlands 299.
Semimanufactures	141	69	2	West Germany 54; France 9.

See footnotes at end of table.

Manganese:				
Ore and concentrate	369,679	487,333	--	Republic of South Africa 194,273; Ghana 92,564; Australia 77,187.
Oxides	670	1,310	15	Belgium-Luxembourg 617; Ireland 560.
Metal including alloys, all forms	r262	351	6	Republic of South Africa 299; West Germany 19.
Mercury 76-pound flasks	23	16	1	Austria 7; West Germany 3; United Kingdom 3.
Molybdenum metal including alloys, all forms	28	32	10	Austria 10; Netherlands 5.
Nickel:				
Matte, speiss, similar materials	r2,654	2,074	10	Canada 1,005; Cuba 859; Norway 99.
Metal including alloys:				
Scrap	--	32	--	All from Netherlands.
Unwrought	6,708	6,500	283	Canada 1,838; Australia 981; Cuba 908.
Semimanufactures	r1,079	721	40	West Germany 256; France 150; United Kingdom 100.
Platinum-group metals including alloys, unwrought and partly wrought troy ounces	43,146	600,672	354	Canada 482,261; Switzerland 87,836.
Rare-earth metals including alloys	29	29	--	Brazil 14; Austria 8; United Kingdom 5.
Selenium, elemental	24	42	1	Japan 10; Canada 10; West Germany 7.
Silicon, elemental	7	45	(1)	Mainly from France.
Silver:				
Ore and concentrate[2]	26	33	10	Morocco 9; Republic of South Africa 8.
Waste and sweepings[2] value, thousands	$24,210	$23,636	$2,104	France $14,645; Switzerland $3,978; United Kingdom $2,281.
Metals including alloys, unwrought and partly wrought thousand troy ounces	2,347	1,993	68	West Germany 699; Belgium-Luxembourg 625; United Kingdom 307.
Tantalum ore and concentrate	31	168	24	Australia 44; West Germany 35; Republic of South Africa 35.
Tellurium, elemental	6	2	--	Peru 1; U.S.S.R. 1.
Tin:				
Ore and concentrate	5,083	3,263	--	United Kingdom 1,345; Thailand 940; Indonesia 576.
Oxides	r368	301	--	West Germany 152; United Kingdom 102; Italy 45.
Metal including alloys, all forms	79	167	2	United Kingdom 72; Malaysia 40.
Titanium:				
Ore and concentrate	106,200	162,977	--	Australia 93,986; Norway 68,986.
Oxides	1,921	2,151	242	Belgium-Luxembourg 679; France 516; West Germany 496.
Tungsten metal including alloys, all forms	17	21	1	France 4; Netherlands 4; Austria 3.
Uranium and thorium metals including alloys, all forms kilograms	431	485	375	France 110.
Vanadium oxides	113	73	--	Finland 70; Republic of South Africa 2.
Zinc:				
Ore and concentrate	89,251	111,703	--	Peru 60,668; Ireland 33,761; Sweden 8,522.
Oxides	526	650	40	West Germany 324; Italy 154; France 121.
Metal including alloys, all forms	1,360	3,265	(1)	West Germany 1,187; Belgium-Luxembourg 841; Mexico 552.
Zirconium:				
Ore and concentrate	20,991	26,526	(1)	Australia 19,119; Republic of South Africa 7,406.
Metal including alloys, all forms	r4	2	(1)	Mainly from France.

See footnotes at end of table.

COMMODITY REVIEW

METALS

Aluminum.—Although almost completely dependent on imported bauxite, Spain continued to develop its aluminum industry. During 1980, completion of the first alumina plant in Spain at San Ciprian, Province of Lugo, ended construction of the alumina-aluminum complex there, which is the largest aluminum producing installation in Spain. In addition to the 800,000-ton-per-year alumina plant owned by Alumina Espanola S.A., the new complex incorporated a 180,000-ton-per-year aluminum plant owned by Alumino Espanol S.A., all necessary ancillary installations, and a seaport capable of handling vessels up to 60,000 tons. The alumina plant at San Ciprian used the traditional Bayer process, and produced anhydrous alumina. Alumina is stored in two 25,000-ton silos. The red mud is treated by the dry process developed by Giulini Krauss Maffei. This process was in use at the alumina plant near Ludwigshafen in the Federal Republic of Germany. Capacity of the plant can be expanded to 2.4 million tons of alumina per year without difficulties.

The smelter capacity of San Ciprian was derived from two 90,000-ton-per-year potlines, each having 265 cells. The smelter process is computer controlled, with technology by Aluminium Pechiney S.A. Provisions have been made to expand capacity by adding a third 90,000-ton-per-year potline. Power comes from a lignite-burning powerplant at Puentes de Garcia Rodriguez, about 40 kilometers southwest of San Ciprian.

The smelter was designed to protect the environment as much as possible. Gases from the smelter are treated before release into the atmosphere. The collected "rich gas" is circulated in a gas treatment installation countercurrent with an alumina stream. Alumina absorbs fluoride from gases and is fed to the pots. The air from the pot room is treated in 64 wet scrubbing towers and is exchanged 18 times per hour.

The startup of the smelter was delayed because of strong objections by environmentalists fearing damage from fluoride emissions. However, an investigation carried out by the Spanish authorities found the emissions from the San Ciprian aluminum smelter to be within permissible limits.

Total employment, at both installations, was reported at 2,000 persons. With completion of the San Ciprian facilities, Spain became self-sufficient in alumina and aluminum, and the size of aluminum-producing capacities placed Spain among the leading aluminum producers in Europe. During 1980, the following aluminum smelting installations were in operation:

Name	Company	Capacity in thousand tons per year
La Coruna	Aluminio de Galicia S.A.	78
Aviles	Endasa S.A. (Government).	101
Valladolid	do	25
Sabinanigo	Aluminio de Galicia S.A.	14
San Ciprian	Aluminio Espanol S.A	180
Total		398

Copper.—RTZ, which holds 25% of capital in RTM, acquired an additional 24%, at a cost of 2,850 million pesetas, equivalent to US$41 million.[2]

After this latest financial transaction the Union Explosivos Rio Tinto S.A.'s (UERT) share of RTZ was 51% and that of RTM was 49%. During 1980, RTM was near completion of a program that should bring company copper output to the level of 50,000 tons per year by the end of 1981. At the Huelva copper smelter, owned by RTM, the largest copper smelter and refinery in Spain, new pollution control equipment has been added to the existing facilities.

Two major producers of secondary copper, Cobre Electrico Metales, S.A., and Industries Reunidas Minero Metalurgicas S.A., were preparing to merge during 1980, but final agreement was not announced during the year.

Gold.—During 1980, the Rodalquilar (Almeria) gold mine was the site of stepped-up exploration. Higher gold prices made future production from Rodalquilar, closed since 1966, far more attractive than in the past. In addition, a number of prospecting permits for precious metals were requested for exploration in the Rioja area in northern Spain, mostly in abandoned mines.

Most of the production of gold in Spain, about 90% of the country's total, comes from copper mining operations of Rio Tinto Minera S.A. in Huelva Province, southern Spain. In addition, some gold was recovered by Metal Química del Nervion S.A. from pyrite cinder at its installations at Axpe-Erandio, Bilbao, in northern Spain.

Iron and Steel.—Exploration for iron ore by the Instituto Geologico Minero de Espana (IGME) at the localities of Cala Teulera (Huelva), San Guillermo-Colmenar, Santa Justa, and La Berrona, all in Badajoz Province, located significant reserves of iron ore. Reserves of all categories in the area were estimated at 150 million tons of ore, mostly magnetite with an average metal content of 30% to 40% iron.

Based on preliminary results, the largest reserves were at the deposits shown in the following tabulation, in million metric tons:

Deposits	Reserves	
	Proven	Others
Cala-Teuler-San Guillermo	27	51
Justa	21	NA
La Berrona	22	NA

NA Not available.

The IGME's experts believe more iron can be found by further exploration.

Based on these new reserves, a project for construction of a pelletizing plant located at Fregenal de la Sierra and one for a direct-reduction (DR) plant at Huelva, were prepared, but the actual construction awaited the approval of the Government. Both plants were planned to use recently discovered natural gas from the Gulf of Cadiz.

Prereducidos del Suroeste de Espana S.A. (Presursa) was formally constituted in Madrid, to own and operate Spain's first DR plant. Presursa announced plans to construct a two-module DR plant, but selection of technology to be used was not announced by yearend. Empresa Nacional Siderurgica S.A. (Ensidesa), the major steel producer in Spain, started to test its new wire-rod mill at Verina Works. The mill was rated at 450,000 tons of wire rods (diameter 5.5 to 12.5 millimeters). The mill is computer controlled, and there is a Stelmore-controlled cooling system.

Ensidesa announced plans to close its 150,000-ton-per-year plate mill at La Felgriera Works in Austurias by the end of June 1980.

A new program of revitalization of the Spanish steel industry prepared by the Ministry of Industry provided for 3-year financial aid, ending in 1981, of 139,000 million pesetas (US$1,985 million). The social pact, part of the program between the workers of steel companies, included the renunciation of strikes, reduction of absenteeism, and a freeze of wages in 1981, with a rise of 3% and 4% in 1982 and 1983, respectively.

The Spanish steel industry had heavy losses during 1980. A report published by the Spanish Government states that facilities of the industry are, in general, in a satisfactory competitive position except for the sinter plants at Aviles, open-hearth

shop at Aviles, the plate mill at Meres, and the integrated works at Sagunto.

In general, productivity figures for Spanish integrated steel plants are about 82% of the average figure achieved in the steel plant of the European Communities (EC).

The nonintegrated steel sector in Spain had about 33 companies in operation at the beginning of 1980. Roughly 34% of the total country steel capacity, 51% of total rolling capacity, and 76% of round bar capacity was operated by the nonintegrated steel sector. Raw materials supply was a problem. Scrap was imported from EC countries, Eastern Europe, and the United States. Imports from the EC and Eastern Europe are limited to some extent by Government control and from the United States by the limited number of suppliers.

It was suggested that the use of direct reduction be studied as a solution for scrap shortages; centralized purchasing of scrap was mentioned as another possibility for alleviating scrap shortages. In general, the nonintegrated sector, highly dispersed, could improve its economic position by coordinating development of new capacities and by avoiding expansion of already existing facilities, and by switching from investments in rolled steel to investments in production of steel ingots.

Lead.—Exploracion Minera International, Espana S.A., continued to develop its property at La Troya, near Rubiales in northern Spain. Mine production was planned for 1981, and output should reach 6,000 tons of metal in ore. During 1980, Andalusa de Piritas S.A. produced about 21,000 tons of lead in ore at its mine in Aznalcollar, about 40 kilometers by road, northwest of Seville.

According to a report prepared by Centro National de Investigaciones Metalurgicas, Madrid, and Associacion Nacional del Plomo, a new lead smelter may be constructed before the end of 1985. With this new smelter, domestic capacity would reach 120,000 tons of lead per year. The location was not mentioned, but it appeared that it may be in the general area of Seville because the new smelter would treat lead concentrates from mines producing and treating complex sulfide ores in southern Spain. At yearend 1980, the total lead smelter capacity of two smelter operations in Spain was 105,000 tons. The largest was Penarroya's Santa Lucia smelter at Cartagena, capacity of 65,000 tons of refined lead and 5,000 tons of lead alloys; the second smelter was at Lineares, Jaéen Province, with a capacity of 40,000 tons of lead and 10,000 of lead alloys owned by the Cía. La Cruz. During past years, Spain was about 25% dependent on imported lead concentrates to meet its lead smelter demand.

Mercury.—In late 1980, the Spanish parliament passed a bill which transformed the Consejo de Administration de Minas de Almaden Arrayanes from a department of the Ministry of Finance to a Government-owned company. The new company will administer the Almaden mining complex and supervise the general development of the Almaden region. The new law also stipulated that the Government approve a contract regulating relations between the state and the new company.

The El Entredicho mercury opencast mine, located about 5 kilometers southwest of Almaden, went onstream during 1980. Reportedly the El Entredicho Mine was the cheapest mercury producer in the world, and it contained the largest reserves and highest metal content of any mercury deposit in the world.

Pyrite.—The development of Sotiel Mine, Province of Huelva, southern Spain, and construction of a 600,000-ton-per-year complex ore flotation plant nearby, continued during 1980. Management of the Government-owned Minas de Almagrera S.A., which owns the facilities, expected production to start sometime late in 1981 or in 1982.

The Aprovechiamento Integral de Pyritas S.A., a company which was organized by UERT, Compañía de Azufre Cobre Tharsis S.A., and Metal Química del Nervion S.A. for recovery of lead, zinc, copper, and silver from pyrite cinders, underwent a financial rearrangement. UERT increased its holdings in the venture, Compañía de Azufre Cobre Tharsis S.A. lost some holdings, and Fosforica Espanola S.A. joined the venture.

Strontium.—A new strontium compound plant, with an annual capacity of about 1,500 to 2,000 tons of strontium carbonate, was under construction during 1980 near the Port of Motril in Granada, in southern Spain. The plant, operated by Promisura S.A., was supplied principally by the Montevive Mine near Granada, about 70 kilometers away. The mine was modernized recently to produce about 40,000 tons per year of ore. Most of the output was 2- to 4-inch lump material containing about 94% Sr SO_4. Reportedly, reserves are between 2 and

3 million tons of celestite.

Tin.—During 1980, the refurbishing of the washing plant at the tin mine at Serradilla in Cáceres Province increased the plant's throughput capacity from 350 to 1,000 tons of ore per day. During the year, the owner, Astruminera S.A., was evaluating the economics of the operation.

Tin in Spain was produced from tin operations and from tungsten-tin operations. Tin alone was produced by 14 producers; the Province of Salamanca, with 4 producers, produced about 55% of the total.

Two tin smelter companies merged during 1980, when MESAG S.A. acquired all the shares in Electrometalurgica del Agueda, a company owned by Portugese interests. MESAG S.A. had a tin smelter and ferroalloy-producing facilities at Villa Irabo, Province of Zamora.

NONMETALS

Barite.—The barite mines in Cordoba Province owned by Coto Minero Nacional Carbonell were taken over by Minas de Baritina S.A. Details of the financial arrangements were not made public.

Kaolin.—A plant for the treatment of kaolin was planned based on the deposit at Molina de Aragon (Gudalajara). The new plant should produce good-quality kaolin, which in the past was imported. The size of the plant and ore reserves were not published.

Potash.—Potasas de Navarra S.A., a member of the state-owned INI group, announced its intention to slow down and close the mine to cut losses unless labor union demands become more reasonable, but negotiations apparently resolved some of the problems.

Salt.—During exploratory drillings for oil in the Province of Huelva, three wells—Almonte, Asperillo, and Moguer—encountered a 400-meter thick salt formation starting at 800 meters. The Triassic formation dips west and extends into Portugal, where salt is produced by underground mining at Olhao. The Government of Spain has rented one block to each of the following companies: UERT, Dow Chemical Iberica S.A., and Energia y Industria Aragonesas S.A. Apparently, salt will be produced by hydrofracturing and controlled dissolution. Cía Andaluz de Sal proposed to exploit the Adelina and Martre concession in Huelva by solution mining.

MINERAL FUELS

During 1980, Spain remained heavily dependent on energy imports (about 70%) and was particularly dependent on oil, which accounted for about two-thirds of primary energy demand. The only sizable domestic energy resources were solid fuels and hydropower, which provided about 87% of the total domestic production.

Coal.—As in the past, coal remained the principal fuel produced in the country. Production of coal and lignite increased significantly during 1980, and coal imports followed the production with an upward trend, indicating that efforts of the Government to reduce dependence on liquid hydrocarbons and to switch to coal started to produce results.

During 1980, exploration for coal conducted by the Empresa Nacional Adaro near Granada resulted in discovery of one lignite deposit at Arenas del Rey and a peat deposit at Padul.

At Arenas del Rey, proven reserves were reported at 53.9 million tons of lignite, with a calorific value of 2,060 kilocalories per kilogram with humidity 40%. Of the total, 39 million may be mined by opencast mining (with a ratio of 10 cubic meters of overburden to 1 ton of lignite). Future employment at this mine should be 375 persons.

The peat deposit at Padul has proven reserves of 41 million tons of peat, with a calorific value of 1,400 kilocalories per kilogram. A future peat operation could provide employment for 106 persons. By yearend, no decision had been made in regard to the future of these two deposits.

The largest coal producer in the country was Empresa Nacional Hulleras del Norte S.A. (Hunosa). Hunosa was created to encompass various private coal-producing companies in Asturias, and assure control of the operation to the Government through the INI. Hunosa produced about 4.5 million tons of coal annually from underground mines and 0.5 million from opencast mines. During 1980, its production was concentrated in nine large mining operations and five large coal washeries, with a total capacity of 10 million tons of run-of-mine coal. Three deposits—Coto Belo, San Victor, and Nicolosa—were mined by opencast methods. Equipment at these mines had the capacity to move 12 million tons of material per year.

Natural Gas and Petroleum.—Onshore and offshore exploration continued, but no major discoveries were made public during 1980. Production tests run on the well, Serrablo-3, in the Serrablo Field, Province of Huesca, indicated the existence of a gas

deposit at depths between 1,600 and 2,000 meters. According to a representative of the Compañía Arrendataria del Monopolio de Petroleos S.A., reserves of natural gas in the Gulf of Cadiz are equivalent to 6 million tons of crude oil, and six out of eight wells were ready for production.

At the beginning of 1980, 10 refineries were operational in Spain, having a total capacity of 76 million tons of crude per year. About 48 million tons of crude were processed during 1980 and refineries employed around 9,000 persons. Petrleos Mexicanos (Pemex), the Mexican Government petroleum company, acquired from Campsa 15% of the capital of Refineria de Petroleos del Norte (Petronor), with an option to buy another 19% within 1 year. Petronor operated a 10-million-ton-per-year refinery at Somorrostro, near Bilbao.

Uranium.—According to reports published in the local press, a substantial uranium deposit was discovered in the area of Tavertet and Vilanova de Sau (Barcelona Province). No details were given on quality and size of reserves.

The Mineral Industry of Sudan

By E. Shekarchi[1]

Efforts have been made over a 50-year period to discover major ore deposits in Sudan; however, the mining industry remained practically primitive. In 1980, as in previous years, essentially the only activity consisted of small-scale exploitation of a few ancient gold mines and production of chromite, manganese ore, salt, and mica. Since 1949, cement has been manufactured in the country. The most significant event of 1980 was the discovery of petroleum 170 kilometers southeast of Gabra at a depth of 9,000 feet, with a total flow of 11,000 barrels per day. Exploration programs to confirm the configuration of the new discoveries were underway, and a plan for active petroleum exploration by 1982 was discussed by Government officials. A committee was set up to study the consumption of petroleum fuels in the country, with the aim of attaining self-sufficiency in energy. In 1980, the cost of oil imports to Sudan exceeded $300 million. Total export during 1980 amounted to $750 million, whereas the imports were at about $1.8 billion. Contribution of the mining industry, with exports of about 23,000 tons of chromite, remained negligible.

Completed in the latter half of 1980, the Port Sudan—Khartoum road was carrying half of the port's cargo. Vitally important and politically sensitive imports of wheat, flour, sugar, and general cargo were transported mainly by this road. The Port Sudan operation, managed by the Sea Ports Corp. (SPC) of the Ministry of Transportation, was improved substantially a year or 2 ago. The improvements were part of World Bank Part 1 project, which was scheduled for completion in October 1981. New cargo handling equipment and 42 new forklifts were already in use in 1980, and new berthing facilities for container and roll-on and roll-off cargo was expected to be completed in 1981. SPC was pushing plans to build a new port in Suakin, 40 kilometers south of Port Sudan. The first stage of construction of a breakwater and four berths, two for container vessels and two for ships, with roll-on and roll-off capabilities, was scheduled to start in 1982. Saudi sources were to provide $200 million for major facilities, while the Federal Republic of Germany was to supply $80 million for associated infrastructure. Work being considered for the latter stages included the construction of tanker and bulk terminals. Should Sudan develop an oil export capability, Suakin would be the terminus of a pipeline from the oilfields.

Even though Sudan's overseas workers provided $350 million as a net foreign exchange income, the flow of skilled workers and managers to nearby labor-hungry Persian Gulf Oil producing nations remained a critical work force problem for the country. It was expected that with development of oilfields, refinery construction, and pipeline building, many of the expatriates may be persuaded to return to Sudan and help restore the economy of the country. A radical new financial and currency exchange control measure was introduced in early 1980 to boost the general economy and to handle export-import currencies. The main consequences of the measure were to lift a battery of controls on the import and export of foreign currency; to establish a two-tier exchange system with an official rate of 50 piasters per dollar (for essential commodities), and a parallel rate of 80 piasters for all other transactions (including repatriation of Sudanese expatriate's earnings and all foreign business persons and tourist's currency dealings); and finally, to

abolish the much-abused nil value import license system, whereby Sudanese nationals working abroad could obtain permission to finance imports or finance international barter trade.

The conflict between Iran and Iraq indirectly affected Sudan's petroleum supply. Iraq suddenly suspended its 5-year crude supply agreement with Sudan in the latter part of 1979. However, Sudan was able to conclude an agreement with Saudi Arabia for importing an additional 1.2 million tons of crude oil. Moreover, Kuwait agreed to increase its exports of refined products to Sudan by 300,000 tons per year over and above the 400,000 tons per year, which it had been supplying in the past.

Table 1.—Sudan: Production of mineral commodities[1]

(Metric tons unless otherwise specified)

[e]Estimated. [p]Preliminary.

[1]Table includes data available through July 10, 1981.

[2]In addition to the commodities listed, modest quantities of a variety of crude construction materials (including clays, stone, and sand and gravel) presumably were produced, but output is not reported quantitatively and available information is inadequate to make reliable estimates of output levels. Crude oil was produced from several wells on a testing basis but was not being produced for domestic use or export through yearend 1980.

[3]Reported figure.

COMMODITY REVIEW

METALS

Chromite.—Chromite production from the Ingessana Hills in the southeast of the Blue Nile Province was reported at 25,000 tons in 1980. The deposits were mined by the Government-owned Ingessana Hills Mine Corp. and the privately owned Blue Nile Chromium Ltd. A feasibility study by Mitsubishi, in partnership with Japanese Metals and Chemical Co., on the erection of a ferrochrome plant with a 50,000-ton-per-year capacity was completed in 1980, but final discussions on the construction were postponed. The original plan called for construction of the ferrochrome plant on the mine site at a cost of $50 million, and export of ferrochrome to Japan in a prearranged barter agreement. No firm date for construction was given by the end of 1980. The lack of proven chromite reserves in the entire country seemed to be the main reason that outside investors were uninterested. The Geological and Mineral Resources Department (GMRD) of Sudan identified two new chromite occurrences during the year—in Sol Hamed, 35 kilometers northwest of Halaib village, and in the western part of the Devaheib area. Exports of chromite were mostly to Japan and Western European nations in 1980.

Gold.—Because of the high prices for gold on the international market, local small operators, mostly family-type operations,

flourished during 1980. Official figures of these operators were not available by yearend. Most of the gold mineralization occurred along the Nile River and the northern parts of the Red Sea Hills. In a publication entitled "The Geology and Mineral Occurrences of the Red Sea Hills" prepared in 1979, GMRD of Sudan has shown the location of seven gold-producing mines in this area. No firm decision on a joint venture between a British firm, Robertson International, and Sudan Government to mine gold along the Red Sea Hills was reached during the year.

Iron Ore.—The iron ore occurrences previously known, and those located during the regional aeromagnetic survey of the Red Sea Hill area (1971-77) were listed at 20 in a published report by GMRD during 1980. Total reserves of these deposits and occurrences were given at 500 million tons. Those estimates and calculations were provided by various geological teams working in the country, including Japanese and Soviet teams. Discussions between the Sudanese Government and Arab Mining Co., concerning funding for iron ore mining and beneficiation, continued during the year. Even though preliminary agreements were reached, the size of the investment and production ceiling was not made public by yearend.

Manganese.—Detailed systematic investigations, including a geological and geophysical survey and drilling to find the extent and occurrence of manganese mineralization in Sudan, was completed by 1979, and reportedly 37 manganese occurrences and deposits have been found. Twenty-three of the occurrences were located in the coastal sediments, while the other 14 occurred in the rocks of the basement complex. None of the reported deposits was evaluated for contained reserves, although some were chemically analyzed. The manganese grade ranged from 23% to 53% Mn. Mining of manganese remained on a local level, and primarily hand sorting was used to upgrade the ore.

Uranium.—According to directives from GMRD, the exploration effort to map uranium-bearing rocks in the country by various private overseas companies has been successful. The Ministry of Energy and Mining began negotiations with several foreign firms for evaluating the ores and for more detailed geological work. Apparently more exploration permits were issued during the year, but no exploitation agreements were in sight.

NONMETALS

Asbestos.—Development work on the asbestos mining by a company jointly owned by Johns-Manville of Canada, Gulf International Group of Kuwait, and the Goverment of Sudan, continued during 1979. Most of the development work was on the mill and infrastructure section. When in operation, the mining would be underground, and the material would be processed in a plant with 100,000 tons of fiber capacity.

Cement.—The second renovation phase of Nile Cement Co.'s Rahak plant was completed during 1980. Installation of a 150-ton-per-hour crusher, which replaced the old 40-ton-per-hour crusher, resulted in a new record high production, about 80,000 tons, for the cement plant. Also the purchase of 12 new haulage vehicles made transportation of feed material, about 60 kilometers from quarry to plant, a reality in 1980. This plant was able to supply the cement requirements of most of the east Nile area and was operational during the entire year, rather than being closed the usual 4 months due to road conditions and lack of feed material.

MINERAL FUELS

Petroleum.—Encouraging petroleum discoveries were made by the U.S. company, Chevron Overseas Petroleum Inc., a Standard Oil of California subsidiary, during 1979. By the end of 1980, Chevron, concessionaire of about a 280,000-square-kilometer area in the southern part of Sudan, had drilled 17 wells—3 were rated as discoveries, 1 had a small oil flow, 5 were successful confirmation holes, and 8 were dry. The first discovery was made in the spring of 1979, when well 1 Abu Gabra flowed 560 barrels per day at a depth of 9,000 feet. The second discovery, Unity wells, completed in the spring of 1980, about 175 kilometers southeast of the first discovery well, flowed 8,000 barrels per day from seven zones. The third discovery, completed early in the summer of 1980, about 60 kilometers northwest of Abu Gabra, was 1 Sharaf, which flowed 2,500 barrels per day from one zone at 9,000 feet. The fourth wildcat well which produced oil, but was not rated as a discovery, was well 1 Tabaldi, about 25 kilometers northwest of Abu Gabra. Four successful wells have been drilled in the Unity area, but Chevron was not certain by yearend whether they all tap the same reservoir. No

additional drilling had taken place near well 1 Sharaf discovery by end of 1980.

Concerning development priorities, Chevron would not indicate which reservoir was to be developed first, but confirmed that development programs were under discussion with Sudan's officials on production levels for export, as well as the production for refinery fuels.

A new exploration area was to be opened in the Sudd region, where Chevron was the sole concessionaire, operating under a production-sharing agreement with the Sudanese Government. By the end of 1980, Chevron's expenditure on oil exploration had reached over $160 million, and the sum of $70 million was budgeted for exploration in 1981.

Other companies active in exploration in Sudan were Texas Eastern, Union of Texas, and Total Exploration, a wholly State-owned subsidiary of France's Compagnie Francaise des Petroles (CFP-Total). A 10-year accord for the exploration of an area of 145,000 square kilometers in the south was signed in November 1980 by Sudan's Energy Minister and representatives of Total Exploration. Total Exploration was to hold a 65% interest, the Geneva-based International Energy Development Corp. was to hold 25%, and the State-owned Sudanese Public Petroleum Corp. was to hold the remaining 10%. Total Exploration was also due to begin drilling in a 6,400-square-kilometer area offshore Port Sudan as a part of a 3-year agreement with an optional 2-year extension. CFP-Total was to pay for all exploration and development as part of the offshore deal.

Refining.—The Ministry of Energy announced a project for construction of a new 10,000-barrel-per-day oil refinery to be built by Chevron over a 20-month period, scheduled to begin in early 1981. The refinery, capable of expansion to 25,000 barrels per day, was to be located at Kosti, 275 kilometers south of Khartoum, and was expected to go onstream in 1983 at an initial capacity of 15,000 barrels per day. The cost of the refinery with the pipeline, which will transport the crude from the Unity, Abu Gabra, and Sharaf oilfields and which is reportedly capable of producing between 11,000 and 15,000 barrels per day, was estimated at $200 million. The 500-kilometer, 10-inch pipeline will be capable of moving an initial 5,000 to 10,000 barrels per day. Funding for this project was discussed between Chevron, Sudan's Government, and the World Bank in 1980. The World Bank's soft loan affiliate, the International Development Association, has expressed its readiness to provide a loan for the project. The question of project equity was yet to be settled, but the Sudan Government had expressed a desire to have a share of between 60% and 70%.

Sudan's other refinery at Port Sudan on the Red Sea Coast, with a 2,600-barrel-per-day capacity, operated at full-rated capacity during 1980. This refinery, which processed Saudi Arabian crude in 1980, was owned by Shell-British Petroleum and the Sudan Government. The refinery supplied products to Khartoum through a 12,000-barrel-per-day pipeline, which was constructed and financed in 1977 by the Kuwait Metal Pipe Industries Co.

Consumption of Refinery Products.—Sudan consumed about 1.3 million tons of petroleum products in 1978, mostly produced in the Port Sudan refinery. In addition, Sudan imported 280,000 tons of product from the Kuwait National Petroleum Co.'s refinery. The following table shows product consumption in metric tons in Sudan for 1976 and forecasts by the Ministry of Energy for the years 1985 and 1990.

[1]Supervisory physical scientist, Branch of Foreign Data.

	1976	1985	1990
Liquefied petroleum gas	3,491	10,000	15,000

The Mineral Industry of Sweden

By Joseph B. Huvos[1]

In 1980, the mineral industry of Sweden remained small but technologically advanced. Sweden was potentially one of the world's largest iron ore producers and exporters and a significant producer of nonferrous metals and hydroelectric power. Fossil fuels and many important industrial minerals were imported.

In 1980, Sweden's gross national product was about $123 billion.[2] The consumer price index increased by 13.7%, and unemployment was, by yearend, 2%. The real growth rate of Sweden's economy decelerated to 2.2%. Among the industries that fared better-than-average were some of the important engineering sectors. Slow progress was made towards trimming and rationalizing the major industries that had been heavily subsidized, such as shipyards and the Svenskt Staal AB (SSAB). Forecasts for 1981 were even less favorable.

Indices of Swedish mineral industry production in 1979 and 1980 are shown in the following tabulation (1968=100):

Industry sector	1979[r]	1980[p]
Iron ore mining	80	90
Nonmetallic mineral products	89	89
Metal industries	114	107
Mining, quarrying, manufacturing	129	130

[r]Revised. [p]Preliminary.

Source: Monthly Digest of Swedish Statistics, No. 4, 1981, p. 13.

Significant events in Sweden's mineral industry in 1980 included startup of the apatite plant of Luossavaara Kiirunavaara AB (LKAB) in Kiruna, commissioning of three nuclear powerplants, and beginning of commercial oil production on Gotland Island. Construction continued to expand the Aitik copper mines and construction continued on three nuclear powerplants. Gränges AB allocated $100 million to modernize its aluminum industry. A contract was concluded by LKAB and Outokumpu Oy (Finland) to develop the Viscaria copper deposit. Significant silver and gold deposits were discovered by Boliden AB, and kaolin deposits, by Höganas AB. The decision was made by SSAB to cut back steel production and close some iron ore mines, and by Supra AB, to close an ammonia plant.

PRODUCTION

In 1980, iron ore mining gained; nonmetallics as a group were unchanged; metal industries declined; and industry as a whole gained little. Production of mineral commodities in 1980 and the 4 previous years is shown in table 1.

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.

[1]Includes data available through Oct. 5, 1981.

[2]In addition to the commodities listed, cobalt, nickel (as nickel sulfate), and metallic titanium are also produced, but output is not reported and available information is inadequate to make reliable estimates of output levels.

[3]Production of sponge iron is as follows, in thousand tons: 1976—188; 1977—161; 1978—117; 1979—136; and 1980—not available.

[4]Includes clinker as follows, in thousand tons: 1976—111; 1977—43; 1978—15; 1979—not available; and 1980—not available.

[5]Represents material for sale, not that produced.

[6]Includes strontium minerals, unspecified minerals, and fragments of ceramic materials.

TRADE

Exports of goods in 1980 declined almost 3% in real terms, due mainly to the sluggishness of European markets, Sweden's principal trading partners. Imports rose 0.3% in real terms due to increased oil prices. The trade deficit was $2.7 billion. Sweden's total mineral trade in 1978 and 1979 is shown in tables 2 and 3.

COMMODITY REVIEW

METALS

Aluminum.—As in the previous year, production of aluminum ran near capacity. Gränges Aluminium, Sweden's only aluminum producer, with its 82,000-ton-per-year plant located at Kubikenborg near Sundsvall on the Baltic Sea, decided on an investment program that exceeded $100 million. One of the items under consideration was to increase the capacity of the Sundsvall smelter to 100,000 tons per year. Final decision was delayed until after the Swedish referendum on nuclear power, which would assure availability of sufficient electric power. There were also negotiations between Gränges and Aardal og Sunndal Verk of Norway for cooperation by the two companies in the field of production of aluminum.

Copper, Lead, and Zinc.—Expansion of Boliden's Aitik copper mine, located in north Sweden, from 8 to 11.3 million tons of ore per year was proceeding according to the original plans, and the higher rate of production was to be reached during 1981.

In 1980, Boliden announced its plans to buy all shares of Elektrokoppar AB, with plants located in Helsingborg on the Öresund. Elektrokoppar, the largest manufacturer of copper wire rod in Nordic countries, is currently owned by ASEA AB (75%) and LM Ericsson (25%). It produces, among other products, 60,000 tons of copper wire rod per year, with Boliden supplying one-third of the company's raw material requirements.

Starting with 1983, for a 10-year period, copper concentrates produced at LKAB's Viscaria Mine in northern Sweden are to be delivered to Outokumpu's Harjavalta smelter, located near Pori in Finland. The deal was valued at $250 million.

The agreement has helped to revitalize the faltering project and will create new employment in the Kiruna area, offsetting a decline in iron mining. For Outokumpu, the deal secures about 15% of the company's copper concentrate requirements. The Finnish company had been seeking to invest in mining projects abroad to secure feed for its smelter as local output declined. Viscaria ore reserves were valued at 30 million tons, bearing 1.1% copper. There was to be open pit and underground mining at 1 million tons per year, resulting in 50,000 tons per year of 25% copper concentrates.

Gold and Silver.—In 1980, Boliden's extended mineral prospecting in various areas of Sweden has resulted in discoveries of significant gold and silver deposits. In the Garpenberg District of central Sweden, a complex sulfide ore deposit was discovered with reserves of over 5 million tons, and possible reserves of up to 10 to 15 million tons of ore, assaying over 200 grams per ton of silver and containing various other nonferrous metals, making it the largest silver mine of Europe. Construction costs at the deposit, named Damsjö Mine, are estimated at about $30 million, and production is expected to start in 1984.

Boliden had well-advanced plans to open a gold mine at Enaasen in the municipality of Ljusdal, Gävleborg County. Here, an ore body of 1 to 2 million tons was discovered containing 3 to 4 grams per ton of gold. The deposit is in an opencast mine situated in old diggings. The mine is expected to begin production in 1982.

Another complex sulfide ore body was

discovered about 100 kilometers west of Skellefteaa in northern Sweden. The find was expected to yield between 5 and 6 grams of gold per ton.

Boliden Mineral AB, a Boliden subsidiary, discovered ore deposits containing gold, silver, and other metals at the central Swedish mine of Saxberget, believed previously to be worked out. Two grams per ton of gold and 20 grams per ton of silver were found in the ore.

Iron Ore.—Vigorous marketing efforts combined with cost-cutting schemes were the main features of an action plan adopted by LKAB, Sweden's Government-owned iron ore mining company. The company's aim was to produce at least 25 million tons of iron ore from its three northern mines, of which at least 20 million tons was to be sold in Western Europe, although the market for this phosphorus ore was particularly unfavorable. The principal cost-cutting target was the freight charged by the State railways for transporting ore from the mines to the Swedish and Norwegian loading ports, which LKAB wished to cut by at least 50%. A Government proposal to cut freight cost was expected in 1981. Rationalization underway was to be pursued by combining the entire iron ore operation under a single division. The Government granted about $70 million to LKAB to cover 1980 losses and about $150 million for expected losses in 1981.

An additional cutback was SSAB's Straassa iron ore mine in central Sweden, to be closed permanently. This mine was supplying the Spännarhytten blast furnace at Surahammar, west of Stockholm, which was also to close. Closure of some other SSAB mines in central Sweden was also under consideration, where mining was said to be much more costly than at the LKAB mines in the north of the country.

Iron and Steel.—SSAB, a half Government, half privately-owned steelmaker, announced a series of production cutbacks as a result of slumping home and export demand. Affected were a small blast furnace at Luleaa that was being closed temporarily, until demand improves, and the smaller of two blast furnaces at Oxelösund.

At Domnarvets, the output of the electric shop was to be restricted to a rate of 275,000 tons per year, rather than 420,000 tons per year as previously planned. SSAB was already in the process of reducing operating capacity from 4 to 3 million tons per year, and the new cuts will further lower it by 500,000 tons. On the export side, sales of semimanufactures were weak, with very little market for slabs. Part of the reason was the European Economic Community's (EEC) 15% cutbacks in imports of steel in 1981. The EEC was SSAB's major export market. The only SSAB division doing well was the plate operation at Oxelösund where orders were up and sales were 10% above expected levels.

In 1980, SSAB's losses increased, despite large state aid, mainly due to changes in world steel market conditions. In 1980, the company lost about $120 million and about $315 million since its establishment in 1978.

The Swedish bar producer, Hallstahammars AB, announced plans to stop steel production. The company is part of Sweden's small independent carbon steel sector. Since 1973, demand has fallen about 50%, while pressure from imports remained intense. Hallstahammars' works in central Sweden has a 107- to 10,000-ton-per-year open-hearth furnace, a 200,000-ton-per-year blooming mill, and a 75,000-ton-per-year finishing mill. Fagersta AB, a major world producer of high-speed steel, has approved an investment of $5 million to rebuild a wire rodmill at its Laangshyttan works near Falun, north of Stockholm. This move is to consolidate the company's world position.

NONMETALS

Ammonia.—Escalating feedstock costs and weak ammonia prices have prompted Supra AB, a subsidiary of Boliden AB, to decide to close its ammonia plant at Kvantorp, central Sweden. The plant, commissioned in 1952, was rated at 54,000 tons per year of nitrogen and supplied ammonia for processing into fertilizers at Supra's Köping and Lanskrona fertilizer plants. As a consequence, Supra is to rely more heavily on imported ammonia for processing into fertilizers. Requirements are scheduled to increase to 220,000 tons per year in 1982, following the commissioning of a new nitric acid unit at Köping. About three-quarters of these were estimated to have to be imported to supplement the output of the company's only remaining ammonia unit, located at Köping.

Apatite.—A major producer of iron ore, Government-owned LKAB, made its first delivery of apatite concentrate (35% P_2O_5 content) from its new production plant at Kiruna, Swedish Lappland. The apatite is recovered from the phosphorus-rich tailings of LKAB's iron ore activities at Kiruna.

LKAB began dephosphorising of its iron ore in response to increasing demand for ore with a low phosphorus content. After the initial delivery was made to Norsk Hydro in Norway, commercial production was to begin in September 1981 at a rate of 50,000 tons per year. In the fertilizer year of 1982-83, full-scale production is scheduled to reach 200,000 tons per year. In addition to production from Kiruna, LKAB is planning to produce apatite at its Malmberget Mine, also in northern Sweden. Apatite concentrate from this mine has a P_2O_5 content of 39%, and if the decision is taken to go ahead, production should begin in 1983; capacity is 200,000 tons per year.

Feldspar.—In 1979, Sweden produced 50,000 tons of feldspar. The country's only producer was AB Forshammars Bergverk. Main production of the company was from the Limberget quarry in Örebro, about 40 kilometers north of Köping. The pegmatite rock in Limberget is white in color, with proven reserves of 700,000 tons of pegmatite, and indicated reserves of up to 100 meters depth are 4 million tons.

Graphite.—In 1980, a bulk furnace and a new ring furnace were commissioned for the production of graphite by Härnösands Grafit AB at its Härnösand plant, 250 miles north of Stockholm on the Gulf of Bothnia. The company is owned by the SIGRI Group, a West German corporation, and produces graphite electrodes and graphite powder. A second graphite manufacturer in Sweden was Union Carbide Norden AB, wholly owned by the Union Carbide Corp. of the United States, producing graphite electrodes at Trollhättan, south of Lake Vänern.

Kaolin.—A large kaolin find that could sharply reduce Swedish imports was announced by Höganäs, which already mines about 30,000 tons of ceramic-grade kaolin at Axeltorp. The deposit underlies presently worked deposits; a 1-ton-per-day pilot plant is in operation on the deposit. It is planned to start up a 100,000-ton-per-year operation in 1984. Total expenditure on the project is expected to be about $20 million. At present, most kaolin imports come from the United Kingdom, which exported in 1980 about 240,000 tons to Sweden.

Lime.—Total lime produced in Sweden in 1980 was approximately 800,000 tons, of which about 425,000 tons was sold in the open market while the balance was produced for internal consumption, mostly by companies that use burnt lime in the production of steel. However, approximately 45% of the marketed production was sold to the steel industry in 1979: 25% for pulp and chemical production, 15% for the manufacture of building materials, and 15% for water treatment and other minor uses. It was expected that by 1982, the overall open market demand will be less than 300,000 tons per year. Cementa AB, Sweden's only cement producer, is also the largest producer of burnt lime for the open market, with a production of about 210,000 tons in 1980. Lime production was centered on two plants: Köping to the west of Stockholm in central Sweden and Limhamn near Malmö in southern Sweden. Sweden's other major producer of lime for the open market was Strabrücken AB, which operates two plants in the Province of Dalecarlia: Boda on the north of Öland Island, off the southeast coast of Sweden, and at Rättvik in central Sweden. One other significant producer and user of burnt lime is Ytong AB, with a plant at Hällabrottet in central Sweden.

Magnetite.—From March 1980 onwards, AB Forshammars Bergverk, which is part of the Forshammar Group of Göteborg, an LKAB subsidiary, is to handle the marketing of a magnetite concentrate produced at LKAB's Malmberget Mine. The dried concentrate has an iron content of 71.5%, corresponding to a 99% pure magnetite, and a silica content of less than 0.2%. The company can supply a wide range of different particle sizes to meet specific requirements for use in heavy media separation, as a chemical catalyst, as an iron oxide pigment, and for electronic components, battery and welding electrodes, and small electric motors.

Olivine.—Sweden's only olivine producer in 1980 was Handöls Täljtens AB, which had a small output near the town of Handöl in northern Sweden. In former years, the company produced about 10,000 to 20,000 tons per year of lump, crushed, or graded olivine, and a large proportion of its production went to the parent company, Höganäs, for the production of forsterite bricks and other olivine-based refractories. However, refractory use of olivine has decreased to 5,000 to 7,000 tons per year and olivine is now used largely for the manufacture of bricks for night storage heaters.

MINERAL FUELS

In 1980, over one-fifth of Sweden's energy was supplied by domestic hydroelectric power, fuel wood, and waste heat. The remainder was imported oil, coal, and enriched

nuclear fuel. A report prepared by the Swedish Government shows the country's energy supply, in billions of kilowatt-hours, in 1980, as follows:

Oil	300
Water power	60
Nuclear power	22
Woodbark, etc	36
Coal	16
Timber	7
Waste heat	2
Total	443

Coal.—Plans were made for the construction of two new coal-fired powerplants, one at Oxelösund on the eastern shore and the other at Karlshamn in the south. Completion is planned for the end of the decade at a total cost of $1.5 billion. The Oxelösund plant alone was to produce 7 billion kilowatt-hours per year, about 5% of Sweden's electric supply. In 1980, no coal was produced in Sweden, and all coal was imported.

Nuclear Power.—In 1980, Sweden had the following nuclear powerplants in operation:

	Capacity (megawatts)
Oskarshamn-1	460
Ringhals-2	860
Oskarshamn-2	590
Ringhals-1	792
Barsebeck-1	590
Barsebeck-2	590

After a referendum in favor of nuclear power, the following nuclear powerplants were commissioned in 1980:

	Capacity (megawatts)
Ringhals-3	900
Fosmark-1	900
Fosmark-2	900

Futhermore there were three nuclear powerplants under construction:

	Capacity (megawatts)
Ringhals-4	900
Fosmark-3	1,060
Oskarshamn-3	1,100

Based on the current legislative situation, no further nuclear powerplants were planned.

In 1980, total nuclear-generated electricity was 26,727 gigawatt hours or 27% of total Swedish electric power production.

Peat.—It was reported that a large deposit of peat was discovered by the district government near Kiruna in northern Sweden. No plans were released for the utilization of the deposit.

The municipality of Umeaa was planning to build a peat-fired powerplant, to use 1.5 million cubic meters of peat per year. It was expected that the peat would be imported from Finland.

Petroleum.—In 1980, a decision was made to start commercial production of oil on Gotland Island. Production was expected to be only 20,000 tons per year. Greater hopes were attached by the Svenska Petroleum AB's Oil Prospecting Inc., the operator, to finding oil in the Hanö Bay area of southern Sweden.

A 20-year agreement was signed between Norway and Sweden for the supply of at least 2 million tons of Norwegian oil to Sweden in exchange for electric power, both at prevailing market prices. The agreement provided also for an industrial cooperation fund of about $50 million to help finance joint projects.

In 1980, Swedish refining capacity remained about 21 million tons per year, as shown in table 4.

[1]Physical scientist, Branch of Foreign Data.
[2]Where necessary, values have been converted from Swedish kroner (SKr) to U.S. dollars at the rate of SKr4.22=US$1.00 for 1980.

The Mineral Industry of Switzerland

By Roman V. Sondermayer[1]

As in the past, the operations of the mineral industry of Switzerland were modest by world standards during 1980. Cement, lime, gypsum, salt, and sand and gravel were produced from domestic raw materials. In addition, the industry processed imported crude oil, alumina, and raw materials for the steel industry. Imported fuels were essential for an adequate supply of energy; hydropower and fuelwood supplied only about 16% of domestic energy consumption.

In general, the economy of Switzerland had a relatively good year. The country enjoyed a high level of employment, and private investment and foreign markets were the mainstays of the business cycle.

In the second half of 1980, signs of weakening began to show. Incoming orders started to decline, investment activity diminished, and the volume of imports and exports receded after the third quarter.

The real gross national product (GNP) rose about 2% in 1980 over that in 1979. Consumer prices rose on an average of 4%, which according to Swiss sources was still the lowest rate of inflation in the world.

The announcement of plans to modernize two aluminum plants and to build a new combination bar and rod mill were the principal events of the mineral industry during 1980.

PRODUCTION

In Switzerland, the mineral industry was privately owned, with no Government involvement. Table 1 shows the latest trends in production of minerals during the 1976-80 time period.

Table 1.—Switzerland: Production of mineral commodities[1]

[e]Estimated. [p]Preliminary. [r]Revised.

[1]Table includes data available through July 10, 1981.

[2]In addition to the commodities listed, a variety of crude construction materials (common clay, sand and gravel, and stone) is undoubtedly produced, but output is not reported and available general information is inadequate to make reliable estimates of output levels.

TRADE

Latest trends in Switzerland's foreign mineral trade are shown in tables 2 and 3. As the tables show, Switzerland had a brisk minerals trade, but many transactions were for reexport.

COMMODITY REVIEW

METALS

Aluminum.—Swiss Aluminium Ltd. announced plans to invest about 250 million Swiss francs in new technology in its Chippis (30,000 tons per year) and Steg (48,000 tons per year) plants. Modifications will enable both plants to meet environmental standards, and in addition, the investment at Chippis will cover, in part, replacement of some electrolytic cells by an experimental installation that should have a capacity of 5,700 tons per year of aluminum. No details on the kind of technology used were available.

During 1980, three aluminum plants were in operation in Switzerland with an aggregated capacity of 88,000 tons of aluminum per year. In addition to the two plants mentioned above, a third one, at Martigny (10,000 tons per year) was operated by Usine d'Aluminium Martigny S.A. All plants processed imported alumina.

Iron and Steel.—One of the four steel producers in Switzerland, S.A. Von Moos, announced plans to invest about 120 million Swiss francs in a new combination bar and rod mill to be located at Littau, Lucern Canton. The new mill, to be built by West Germany's Schloemann-Siemag, was planned to replace an existing one that is reportedly outdated. Plans called for beginning production in 1981 at an annual capacity of 265,000 tons of products per year or 65,000 tons more than the existing plant.

In addition to S.A. Von Moos, Monteforno Acciaierie e Laminatoi S.A., Von Roll Ltd., and Ferrowohlen AG produced steel during 1980. Total steel capacity of all four companies was 700,000 tons per year.

NONMETALS

During 1980, the nonmetals sector of the mineral industry in Switzerland had an uneventful year. Table 1 shows the most recent trends in production of nonmetals.

MINERAL FUELS

Again, as in the past, imported primary energy carriers were the major sources of energy in Switzerland during 1980. Domestic output was limited to hydropower and noncommercial fuels, including waste products. During 1979, the last year for which complete data were available, petroleum remained by far the major source followed by hydropower (18% of total consumption), nuclear power (15%), imported natural gas (4%), and coal, wood, and industrial waste (each 1%).

Petroleum and Natural Gas.—Switzerland did not produce oil and gas during

1980. Some exploration, mostly geophysical, was conducted in the pre-Alpine and Jura regions.

Three petroleum refineries, La Raffinerie du Sud-Ouest S.A., at Collombey, La Raffinerie de Cressier S.A. at Cressier, and La Raffinerie Rheintal AG, were operating and processed about 4.5 million tons of crude petroleum. Output of petroleum refinery products covered about 34% of the total demand.

Uranium.—Construction of four nuclear powerplants continued during 1980 in Switzerland. A local referendum was held in September in Zurich Canton. As a result, completion of the Kaiseraugust nuclear plant was approved. Although the vote was close, it was taken as a sign that anti-nuclear sentiment in Switzerland has peaked.

Total capacity of nuclear plants, both operational and under construction, was 4,500 megawatts electric.

The Mineral Industry of Taiwan

By Edmond Chin[1]

Taiwan's gross national product (GNP) for 1980 was estimated at $39,570 million[2] at current market prices and at $27,800 million at 1976 prices, compared with $32,346 million and $26,138 million, respectively, for 1979.[3] During 1978-80, GNP grew at about 20.6% annually at current prices; real growth during the period was, however, 9.5% annually. Per capita, GNP at current prices reached $2,246 in 1980, a growth of 21.1% over that of 1979. Estimated total trade in 1980 was valued at $40 billion, comprised of $19.6 billion for exports and $20.4 billion for imports. The value of exports as share of GNP continued to rise from 53.5% in 1978, to 53.9% in 1979, and to 56.0% in 1980. Taiwan's median family income, one of the highest in Asia, was $5,753 in 1980, compared with $4,574 in 1979.

Despite its dependency on foreign raw materials, i.e., minerals and fuels, Taiwan's industrial production index grew by about 11.4% in 1980, compared with 12.4% in 1979. Manufacturing, the largest component of industrial production, grew by 10.1% in 1980. The most vigorous growth was by public utilities (electricity, gas, and water), which grew by 21.6%. Growth in the construction sector registered 10.4%. The index of industrial production for mineral-related components of the economy (1976=100) are given in the following table.

Sector	1977	1978	1979	1980
Mining:				
Coal	91.4	89.2	84.1	78.9
Petroleum and natural gas	102.9	100.3	93.8	91.9
Metal	88.9	107.8	106.6	127.9
Miscellaneous mining and quarrying	120.1	123.3	137.6	168.8
Chemicals:				
Basic chemicals	109.6	126.1	148.5	149.1
Petrochemicals	139.8	194.1	242.0	250.8
Fertilizers	105.0	125.9	127.9	133.9
Nonmetallic mineral products:				
Cement	118.2	131.1	136.0	158.5
Cement products	103.5	104.2	112.8	130.5
Structural clay products	108.4	118.8	107.8	112.7
Basic metals:				
Iron and steel, primary	142.6	192.0	231.4	205.6
Aluminum, primary	111.2	159.3	169.3	169.9
Overall industrial index	112.9	141.0	153.4	164.8

Except for construction raw materials, Taiwan is deficient in many minerals. Additionally, domestic mine output is insignificant in terms of the world market. While the value of mine output has increased annually since 1976, this was a result of higher world prices rather than an increase in the quantity of mine output. In 1980, the mineral-processing sector outweighed the domestic mining sector 21-to-1 in output value compared with a 25-to-1 ratio in 1979, as shown in the following tabulation:

Sector	1976	1977	1978	1979	1980
Mining:					
Coal	4,388	4,043	4,072	4,311	5,700
Crude petroleum and natural gas	4,420	4,472	4,331	6,055	10,100
Metal mining	1,022	912	1,032	1,323	1,900
Miscellaneous mining and quarrying	1,566	1,825	1,962	2,337	3,300
Total	11,396	11,252	11,397	14,026	21,000
Manufacturing:					
Chemical materials and products	63,068	77,050	95,744	136,652	146,900
Petroleum and coal products	47,732	57,132	68,560	87,560	148,800
Nonmetallic mineral products	22,322	26,128	31,078	36,095	48,600
Basic metals	29,030	39,340	62,288	83,185	90,700
Metal products	5,066	6,036	8,013	9,676	13,300
Total	167,218	205,686	265,683	353,168	448,300

In 1979, employment in the mining and quarrying sector was 54,631, working a monthly average of 182 hours. Average monthly earnings in the mining sector was NT$9,243 in 1979, compared with NT$7,872 in 1978. Earnings by miners in 1979 has increased by 46.7% compared with 1976.

In early September 1980, the Council for Economic Planning and Development adopted a 4-year period as a cycle for implementing Taiwan's 10-year development plan (1980-89). The 4-year cycle was adopted because a shorter period was expected to have better flexibility to cope with a changing situation in the international market. A shorter period to carry out an intermediate plan in the long-term economic plan would be easier, and State enterprises preferred the 4-year period for an intermediate program.

Under the 10-year development plan,[3] the output value of the mining sector was projected to increase $350 million in 1979 to $439 million in 1984, and to $539 million in 1989. However, the mining input to the gross domestic product was to decrease from 1.1% in 1979 to 0.9% in 1984, and to 0.7% in 1989. The structure of the manufacturing sector was designed as follows, in percent:

Component	1979	1984	1989
High technology products	23.9	28.6	34.0
Metals and minerals	13.5	15.2	16.8
Iron and steel	3.6	4.2	4.7
Other metals	5.7	6.9	8.1
Other minerals	4.2	4.1	4.0
Chemical and petrochemical	26.1	24.1	21.5
Petroleum products	4.8	4.1	3.7
Petrochemical feedstocks	1.9	2.0	1.8
Other chemicals	19.4	18.0	16.0
Other industries	36.6	32.1	27.7
Value of total manufacturing, millions	$13,801.3	$22,844.8	$36,802.6

Total fixed investment in the mining sector was estimated at $0.4 billion in 1980-84 and $0.7 billion in 1985-90, compared with $20.2 billion and $30.8 billion, respectively, for manufacturing. Employment in the mining sector was projected to decrease from 63,000 in 1979 to 55,000 in 1984, and to 48,000 in 1989.

Of the 120 major investment projects planned by the Government at a total cost of $86 billion, only 2 involved mining—offshore oil exploration ($428 million) and cement ($94 million)—constituting about 0.6% of total investment funds. A total of $5,580 million was to be allocated for second-stage construction of China Steel Corp. (CSC) and $106 million for a zinc smelter. Investment for 18 chemical and petroleum projects totaled $3,347 million.

PRODUCTION

Coal was the most important mineral commodity mined in Taiwan. However, output of bituminous coal has decreased annually since 1976, declining to about 2.5 million tons in 1980. Domestic production of crude petroleum and natural gas is negligi-

ble. The only minerals domestically mined of significant quantity include china clay, dolomite, feldspar, fire clay, limestone, marble, salt, and serpentine. Only small amounts of metal ores are produced domestically, notably copper, gold, and silver. The mining index (1976=100) for 1980 was estimated at 101.0 compared with 96.2 for 1979 and 97.3 for 1978.

[6]Includes liquefied petroleum gas and jet fuel among "not reported."

TRADE

Taiwan's two-way trade in 1980 was estimated to total $29.5 billion. Exports increased 22.7%, reaching $19.8 billion in 1980 while imports increased 33.5% to $19.7 billion. Industrial products accounted for 90.6% or $17.95 billion of the total value of exports followed by agricultural products, $1.81 billion. Imports of agricultural and industrial raw materials during the year were valued at $13.96 billion or 70.8% of the total value of imports; followed by capital goods, $4.62 billion; and consumer goods, $1.14 billion.

The value of total shipments to the United States totaled $6.75 billion; followed by Japan, $2.16 billion; and Hong Kong, $1.55 billion. Japan was Taiwan's major supplier of imports, providing $5.35 billion. Receipts from the United States were $4.67 billion, and from Kuwait, $2.24 billion. Taiwan's oil import bill in 1980 was $4.1 billion.

[3]Excludes quantity valued at $162,860.

COMMODITY REVIEW

METALS

Metal mining in Taiwan is insignificant and output is limited to only minor quantities of magnetite and pyrite, copper, and gold.

Iron and Steel.—In July 1978, CSC began construction of its second-stage expansion whereby the capacity of its integrated steelworks at Kaohsiung would be increased from 1.5 million tons of steel per year to 3.25 million tons per year in June 1982. Cost of the second-stage expansion program was estimated at NT$51.34 billion ($1.4 billion). On October 6, 1979, CSC concluded an $80 million loan agreement with a U.S. banking consortium headed by the Bank of America. Additionally, on January 14, 1980, CSC concluded two separate loan agreements; one with the U.S. Export-Import Bank for $212.5 million, and the other with a U.S. banking consortium headed by the National Bank of Pittsburgh for $40 million. The loan from the Export-Import Bank was to be repayable in 12.5 years,

and the loan from the consortium in 6.5 years. In November 1980, the Council for Economic Planning and Development approved a proposed investment increase of NT$4,466 million for CSC. Additional funds necessitated by cost overruns were caused by higher oil prices, inflation, upgrading of equipment and product specifications, and the purchase of 127 hectares of land needed for construction. Facilities to be added in the second-stage expansion included a material handling system; two batteries of coke ovens; a sintering plant; a 5,000-ton-per-day blast furnace; a basic oxygen furnace; two continuous casters; a hot strip mill; a cold strip mill; an oxygen plant; powerplant equipment, and a research center.

Other Metals.—Aluminum production was by Taiwan Aluminum Corp. (Talco), a wholly Government-owned company, integrated from alumina production through the metal-fabricating stage. Annual metal capacity is 75,000 tons per year.

Taiwan Metal Mining Corp. (TMMC), also a Government-owned company, operated an 18,000-ton-per-year copper smelter-refinery near its copper mine at Chinkuashih. TMMC started commercial operation of its 50,000-ton-per-year smelter-refinery at Keelung in August 1980.

NONMETALS

Cement.—Expansion programs completed in 1979-80 increased the country's cement production capacity to close to 14 million tons per year. Fuller Co. of the United States was providing all machinery and equipment for the 1,000-ton-per-day plant expansion of Ching Tai Cement. Fuller was also supplying equipment for the 3,000-ton-per-day expansion of the Kangsan plant of Chia Hsin Cement Corp. Polysius reportedly received a contract for major equipment for the new 2,200-ton-per-day plant of Hsin Hsin Cement Corp. of Taipei. KHD Humboldt Wedag of the Federal Republic of Germany completed the expansion to increase the output of the Huaben plant of Asia Cement Corp. to 5,200 tons per day. Also, F. L. Smidth completed the expansion of the 3,200-ton-per-day Suao plant of Taiwan Cement Co.

Other Nonmetals.—The major nonmetallic minerals produced in Taiwan include: China clay, dolomite, feldspar, fire clay, limestone, salt, serpentine, and talc. Small quantities of asbestos, gem stones, gypsum, and mica are also produced. Decorative marble was mined in eastern Taiwan. Marble deposits extend from Hualien County in a long, narrow vein that extends 20 kilometers from Suao in Ilan to Chihpen in Tantung. Maximum width of the vein is 10 meters and, in places, reaches a depth of 1,000 meters.

MINERAL FUELS

Taiwan produces only small quantities of coal, petroleum, and natural gas, and domestic energy output from all sources provides about 13.5% of the country's total energy supplies. In 1979, Taiwan energy supply-demand configuration was as follows, in 1,000 kiloliters of oil equivalence:

Domestic production:	
Coal	1,964.2
Natural gas	1,893.3
Hydropower	1,222.2
Crude oil	230.6
Imports:	
Crude oil	17,891.9
Petroleum products	3,647.3
Nuclear	1,693.7
Coal	1,653.0
Total	30,196.2
Domestic consumption:	
Petroleum products	15,144.8
Electric power:	
Thermal	7,666.8
Hydropower	1,222.2
Coal and coal products	2,348.0
Natural gas	1,828.5
Nuclear	1,693.7
Exports:	
Petroleum products	1,100.7
Coal and coal products	5.1
Inventory adjustment	(813.7)
Total	30,196.1

Energy consumed by the mining industry in 1979 was estimated at 1,598,200 kiloliters of oil equivalent; nonmetallic mineral products, 3,117,600 kiloliters; metallic products, 1,810,000 kiloliters; chemicals, 2,703,500 kiloliters; and for the energy sector, 3,251,700 kiloliters.

The Mineral Industry of Tanzania

By Suzann C. Ambrosio[1]

Diamonds continued to be the most important mineral commodity produced in Tanzania during 1980. The mineral industry contributed approximately 1.3% to the country's real gross domestic product (GDP), estimated at $4.6 billion in 1980.[2] Nearly 90% of the value of mineral production and 50% of mineral export revenues were attributed to diamond sales.[3] Minerals produced on a small-scale basis, including cement, salt, kaolin, gypsum, and coal were of domestic significance only. Precious stones, mica, gold, and tin comprised the majority of mineral exports during the year.

The Tanzanian Government continued to play a large role in the mineral industry sector of the economy. A new ministry, solely responsible for developing the minerals sector was proposed, and the following strategies were being implemented: 1) gather geologic information, 2) propose mining legislation, 3) organize and coordinate the mining sector into several related institutions, and 4) actively pursue mine development programs. The Geology and Mineral Exploration Div. of the Ministry of Water, Energy, and Minerals was expected to carry out geological surveying, mapping, and sophisticated mineral exploration efforts. Petroleum exploration, development, and marketing were to continue to be carried out by the Tanzania Petroleum Development Corp. (TPDC) under joint venture agreements with foreign investment companies. The State Mining Corp. (STAMICO) was responsible for exploring new mineral deposits and developing and operating new mines and mineral-related activities. Government policy continued to stress majority shareholding in major mining operations.

Inadequate investment capital has consistently been a major factor adversely affecting mineral development activities in Tanzania. During the last decade, less than 2% of the country's budgeted development funds have been allocated to mineral projects. Proposed 1980-81 outlays for the Ministry of Water, Energy, and Minerals were divided among training programs, 2%; STAMICO, 3%; river basin authorities, 4%; mineral investigations, 6%; operating expenditures, 7%; water plans and investigations, 7%; TPDC, 15%; water supplies, 27%; and electricity supplies, 29%, of the total $115 million budget. The new Ministry of Mines budget was expected to receive increased funding, and the role of the private sector was expected to be enlarged with regard to mineral development activities. The Government planned to attract foreign investors through reorganization of mineral agencies, updating mining and investment legislation, and developing infrastructure and a trained labor force to support the mineral industries.

New mining legislation was passed in 1979 and became effective January 1, 1980. The law was divided into small-scale mining provisions and large-scale mining operations. Mineral rights were delineated for reconnaissance, prospecting, and mining. Mineral licensing provisions included 1 year for exploration activities (with renewals allowed for a maximum of 3 years); 3 years' exclusive rights for prospecting, upon approval of submitted minimum budget expenditures and work and training programs (with an optional renewal for two more periods of 2 years); and a 25-year (maximum life) mining license which would incorporate government participation.

Mineral investigations conducted during 1976 through 1980 focused on the explora-

tion of Tanzania's mineral deposits. Regional airborne geophysical surveys covered in excess of 1 million line kilometers. Data processing, interpretation, and final maps were being prepared during 1980. Airborne magnetic and ground follow-up surveys have identified possible kimberlitic intrusives. A number of greenstone belts in western Tanzania show encouraging potentials for gold and base metal deposits. Geosurvey International (Federal Republic of Germany) conducted the airborne survey and was expected to organize and train approximately 60 Tanzanians in mineral exploration methods for future ground follow-up studies.

The United Nations Development Program (UNDP) agreed to make available professionals to prepare a 20-year mineral development plan. UNDP has also provided financial assistance to the Eastern and Southern African Mineral Resource Development Center (ESAMRDC), including member countries Tanzania, Ethiopia, Mozambique, the Comoros, and Uganda. Professionals were being recruited in 1980 to construct and staff the headquarters, which was to be located in central Tanzania at Dodoma.

Tanzania received $625 million in bilateral and multilateral aid for 1980-81.[4] Nearly 60% of the assistance was in outright gifts, and approximately 75% of the aid was donated by the World Bank and Scandanavian countries. Foreign aid was expected to finance 70% of the country's development budget. In August 1980, the Government signed a 2-year, $235 International Monetary Fund (IMF) credit guarantee. By November 1980, nearly 20% of the credits were drawn for balance of payments assistance. The overall balance of payments deficit was estimated to have worsened by $40 million in 1980.

The trade deficit at yearend 1980 was estimated to have increased 32% over the previous year to $739 million. The value of imports increased because of high petroleum prices, despite a decrease in the volume of imports. The increased value of exports were primarily because of higher agricultural product prices, despite a decline in the volume of agricultural exports.

The national budget deficit was estimated at $230 million, and approximately 16% of the national income was consumed by the Government in 1980. Economic growth was hindered by corruption and inefficiencies within the 300 parastatal organizations and ministries. The World Bank reported in 1980 that Tanzania owed 25% of its gross national product for outstanding public debt. The Government's total indebtedness to the banking system increased by 73% in 1979 and continued to drive up inflation, running at approximately 20% in mid-1980. The breakup of the East African Community in 1977, the 1978-79 Ugandan war, and rapidly increasing oil import bills continued to adversely affect the Tanzanian economy in 1980. The war was estimated to have cost Tanzania $500 million.

PRODUCTION AND TRADE

The small-scale production of diamonds, gold, tin, tungsten, lead, mica, and a variety of gem stones continued to be the predominant mineral foreign exchange earners. Cement, salt, coal, kaolin, and meerschaum production continued to supply a significant portion of domestic industries' needs. STAMICO was investigating prospects for iron, coal, gold, fertilizer raw materials, kaolin, magnetite, beach sands, soda ash, and gypsum in 1980. Plans were made to expand production of these minerals over the next 5 years. Projects were undertaken in 1980 to develop medium-sized mines at Buck Reef and Lupa for gold, Minjingu for fertilizer raw materials, and large-scale mining at Songwe-Kiwira for coal, Pugu for kaolin, and Kilwa for gypsum.

The Tanzanian Government's 1980 production and trade statistics were not published, therefore, table 1 was based on projected production trends and available export data. The value of mineral exports increased by 43% between 1978 and 1979 to approximately $44.3 million. A 64.8% increase was recorded for petroleum product exports during the same period, equivalent to $16.7 million. Mineral exports represented approximately 8% and petroleum products comprised 3% of Tanzania's total exports in 1979. Diamonds contributed approximately one-half of the value of mineral exports during 1979.

Tanzania's relatively small export trade with the United States in 1979 was divided among agriculture and livestock (90%), unmanufactured minerals (3%), and other materials (7%). Nonferrous metals comprised the bulk or 67% of the Tanzanian-U.S. mineral trade by value. Diamond and gem stone exports to the United States declined by over 50% in value between 1979 and

1980. Exports of nonferrous metals also fell by over 10%.

Tanzania continued to import ferrous and nonferrous metals, fertilizer, and refractory materials for domestic industries. Imports of crude oil increased 43% between 1978 and 1979. A larger import bill was expected for 1980-81 because 60% of the country's oil, previously provided by Iraq, had to be purchased on the higher priced spot market. The total bill for crude oil, refined products, and other petroleum products for 1980 was projected to increase 80% to $360 million. Reexports of approximately 128,650 tons of residual fuel oil, 21,165 tons of bunker fuel oil, and small quantities of other refined products were expected to earn nearly $22 million in foreign exchange.

Crude oil imports accounted for over 50% of Tanzania's foreign exchange earnings in 1979-80. Import restrictions and cutbacks, imposed during 1979, continued in 1980 because of a lack of foreign exchange. Consequently, the vicious cycle of declining imports, especially of raw materials, was expected to continue to adversely affect the potential values of Tanzania's mineral production and trade.

COMMODITY REVIEW

METALS

Gold.—The reopening of the Buck Reef and Lupa gold mines was projected to produce a total of 25,700 thousand troy ounces per year, at a cost of $88 million. Small-scale operations commenced at the Lupa mines in the Mbeya region, resulting in 322 troy ounces of refined gold exports during 1979. Machinery installation and construction work on the Buck Reef Mine, at Geita within the Mwanza region, was expected to commence early in 1981.

Iron and Steel.—Iron and steel products continued to be produced in small quantities during 1980. Large titaniferous and vanadiferous iron ore deposits, grading 48% Fe, 12.8% TiO_2, and 0.7% V_2O_5, were known to exist in southern Tanzania. Inadequate infrastructure and market constraints hindered their development. The completion of the Uhuru Railway between Zambia and Tanzania improved the potential for domestic development of the known reserves. The National Development Corp. (NDC) was considering extending existing steel rolling mills and galvanizing capacity by establishing a second iron and steel plant. The United Nations Industrial Development Organization (UNIDO) was assisting NDC in planning the $1.2 billion facility. The plant is to be located in the southwestern Njombe district and would utilize domestic iron ore and coal reserves. Plant capacity was projected to be capable of producing 10,000 tons of iron and 300,000 tons of steel annually.

NONMETALS

Cement.—Tanzania's Saruji Corp. nearly doubled the Nation's annual cement capacity to approximately 1.1 million tons during 1980. The new Tanga plant, rated at 1,600 tons per day, consisted of a kiln with a four-stage cyclone preheater and Unax planetary cooler, a raw mill, and a finish mill. Another 800-ton-per-day plant was under construction at Mbeya and was expected to come online in 1981. The equipment contract for the Mbeya plant was awarded to the same company that supplied the equipment for the Tanga Plant, F.L. Smidth (Denmark). Saruji Corp. planned to upgrade the country's first cement facility located at Wazo Hills. Another 800-ton-per-day dry-process plant was to be installed, with Kulijan Corp. handling the engineering design and initial commissioning of the facility. Feasibility studies were under way for two more cement plants which were projected to add 2,100 tons per day to capacity.

Diamond.—Diamond output increased in 1979 due to greater recoveries from the Mwadui and New Almasi Mines. Approximately 314,000 carats were produced at the two kimberlite mines in 1979, registering an 11.3% increase over 1978 levels. Diamond continued to be the most important mineral foreign exchange earner during 1980, despite depressed world market conditions. Roughly $12.5 million in foreign exchange earnings were attributed to Tanzania's diamond industry in 1980.

Fertilizer Materials.—*Phosphate.*—Plans were under way to develop the Minjingu phosphate deposit in the Arusha region of Tanzania. The deposit was discovered 20 years ago and was estimated to contain 10 million tons of phosphate. STAMICO was negotiating technical and financial assistance for the construction of the $180 million mine and processing plant. Approxi-

mately 170,000 tons of phosphate ore per year was expected to be processed into 100,000 tons of phosphate concentrate by 1983. The phosphate was expected to replace Middle East phosphate imports, which were used at the Tanzania Fertiliser Co. (TFC) plant in Tanga. Reserves at the Minjingu deposits were expected to last for more than 15 years and save about $8.5 million per year in foreign exchange.

Nitrogenous.—Toward the end of 1980, an Agrico subsidiary, Agrico Overseas Investment Corp. (U.S.), provisionally agreed to form a joint venture called Kilwa Ammonia Co. with Tanzania. Plans to construct a large-scale fertilizer complex at Kilwa Maseko were discussed. The proposed 345,000-ton-per-year plant was projected to cost $450 million. The expected products, ammonia and urea, were projected to exceed domestic requirements; therefore, the majority of the urea produced was to be exported. Natural gas from Tanzania's offshore gasfields were expected to be used as plant feedstock, and operations were expected to commence during 1984.

Mica.—Small-scale mining of mica continued at Morogoro, the Pare Mountain area, and within the Karagwe district. Although mica output declined by 3.5% in 1979, rising prices in the world market continued to compensate for production losses projected through 1980. U.S. trade data indicated that imports of Tanzanian unmanufactured mica increased by 25% to 705.5 kilograms between 1979 and 1980.

Mica was Tanzania's only industrial mineral mined in sufficient quantities for export during 1980. Part of the work program, outlined by ESAMRDC in 1980, included evaluating the uses and specifications of Tanzania's available industrial raw materials. The investigations were to assess mica, graphite, magnesite, bentonite, kaolin, and soda ash development potentials. In addition, ESAMRDC was planning to organize and advise small-scale cooperative mining societies for mica, gem stones, gold, and gypsum.

MINERAL FUELS

Coal.—Plans were made to develop large-scale mining at the Songwe-Kiwira coal deposits in southwest Tanzania. Proven reserves of bituminous coal were estimated at 300 million tons. The Tanzanian Government was encouraging joint venture participation schemes to generate investment capital and technical assistance. In the near term, the focus was expected to be on expanding production at known deposits. High transportation costs and the lack of adequate local markets have prevented large-scale development of the existing coal deposits. These constraints were expected to become less significant as the iron and steel and infrastructure projects in southern Tanzania were completed.

Natural Gas.—Huge natural gas deposits were discovered in 1978, offshore southern Tanzania's Songo Songo Islands. Two test wells drilled during 1979 revealed approximately 100 billion cubic feet of proven gas reserves. Two more wells, on and offshore, were drilled by TPDC in 1980. The last well showed traces of light crude, which encouraged further exploration. The International Development Agency of the World Bank provided, for the first time, direct funding, worth $30 million for drilling operations.

Petroleum.—The completion of seismographic surveys have confirmed "reasonable petroleum prospects" in Ruri, Kimbiji and Mafia (Coast region), Bigwa (Morogow region), and certain parts of the Zanzibar Channel.[5] Numerous international oil companies were interested in obtaining exploration rights, despite the fact that no commercial quantities of oil were found by yearend 1980. Algeria's SONATRACH signed a new agreement with TPDC in September 1980. A previously signed technical cooperation accord was expanded to include exploration and pilot drilling.

At least one exploratory well was expected to be drilled in the northern part of the Songo Songo Field. Algeria was expected to supply the oil experts and drilling equipment. In addition, if oil is found the drilling operation will be carried out by Algeria in accordance with Tanzania's new petroleum law.

Tanzania's major oil supplier, Iraq, was expected to continue to provide financial and technical assistance for various energy-related projects. Iraq was considering financing the major portion of the expansion of Tanzania's refinery capacity. The proposed $256 million plan would raise the Dar es Salaam refinery capacity from 17,000 barrels per day to approximately 36,250 barrels per day. A feasibility study for the project was completed in August 1980.

The Mineral Industry of Thailand

By Gordon L. Kinney[1]

The Thai economy continued a moderate uptrend during the early part of 1980, but strong inflationary pressure and a growing balance of trade deficit were powerful restraints on the national economy. Real growth in gross national product (GNP) was 5.8% in 1979 and 5.5% in 1980, and the agricultural sector expanded perhaps by 10% in the 1980 crop year.

GNP for 1979 was $26.8 billion[2] in current prices and $13.2 billion at constant 1972 prices. The 1980 GNP estimate was $32.3 billion, or $13.9 billion in 1972 prices.[3]

The cost of living index increased by 15% during 1979. As Thai inflation rates have been relatively low among the less developed countries, this unprecedented increase caused problems in the economy. Businesses seeking to maintain their profit margins were partly responsible for a cost-push inflationary spiral that climbed to an estimated 20% per annum rate in 1980.[4] The Government sought ways to lessen the cost of living increase on the lower income workers, in part by not passing on increased utility and transport costs to the public, and also by tightening price controls on certain basic products. The result of these policies has been spreading shortages of sugar, milk, cement, steel rods, and other consumer items, and the emergence of a black market in retail trade.

The farming sector employed about 70% of the labor force in Thailand. However, the relative importance of agriculture to the economy has gradually decreased from 34% of gross domestic product (GDP) in 1973 to less than 26% in 1979. Mining and quarrying on the other hand have continued a slow increase in relative importance from 1.3% of GDP in 1975 to 2.4% in 1979.

Much of the Thai mining industry was highly labor intensive and frequently showed large changes in the number of persons employed. In addition, some sectors show strong seasonal employment as well. The overall mining work force dropped from 84,000 in December 1978 to 68,000 in December 1979. By mid-1980, the total was 54,000, a small decline from the same period of 1979. In November 1980, the labor force had returned to 73,000 reflecting the return of the seasonal tin workers. The tin and combined tin-tungsten operators employed over 60,000 people or 83% of all Thai miners in November 1980. This was an increase from 76% in November 1979.

In June 1980, the Thai cabinet issued new regulations directed toward the offshore tin mining industry. Foreign companies that had operated in Thailand for 25 years and that wanted to be given a new concession to the same area must form a new company in which Thai citizens hold at least 70% of all shares. Foreign countries requesting concessions in new areas must have 51% of the shares held by Thais. Five years from start of operations, the shares must be distributed so that Thais have at least 70% ownership. Foreign companies that have registered as Thai companies and had binding offshore mining contracts prior to June 1980 can continue under the old 60-40 proportion.

The new regulations concern operations in water less than 61 meters deep. In deeper water, which requires high-level technology, companies will continue as before except that the Government mining company and Thai citizens must also be allowed to invest. Sixty percent of the shares must be owned by Thais within 10 years of the start of operation. The Government was determined that as much of the mining profits as possible should stay in the country without jeopardizing future foreign investment.

In other mining developments, the Offshore Mining Organization (OMO) took delivery of its new 16-cubic-foot bucket-ladder dredge *Bodan* built in Singapore. This will be OMO's first attempt at operating a tin dredge on its own rather than leasing or contracting the operation to private companies.

The Thai Pioneer Enterprise Co. tin smelter at Pathum Thani was being completed at yearend. The 3,600-ton-per-year plant was Thailand's second tin smelter. The Board of Investment (BOI) granted promotional privileges for the country's first tantalum refinery. The plant would use tantalum-columbium-rich tin smelter slags, which are currently exported.

Possibly of more economic significance to the country than any other mineral development during 1980 was the start of construction on the offshore natural gas pipeline. The pipeline will be a major factor in stabilizing the rapidly rising fuel import costs by substituting domestic gas for most of the imported fuel oil.

The electric power situation in the first half of 1980 was critical as the water level in reservoirs became so low after the drought that hydroelectric power production was barely possible. In addition, the need for irrigation water for the second rice crop and the desire to conserve high-price fuel oil used in thermal power generation prompted the Government to introduce various measures to cut down electric consumption.

Output from mostly oil-fired steam turbine generators increased by 33% and accounted for 84% of total output in the first half of 1980. Hydropower production dropped sharply from a total of 1,473 million kilowatt hours in the first half of 1979 to 587 million kilowatt hours in the same period of 1980. Hydropower normally accounts for 25% of total electricity generation but dropped to only 9.4% because of the water shortage.

As the cost of fuel oil increased, the deficit between the heavily subsidized price of electricity and the actual cost of generating it grew to an unmanageable level. As a result, the Government increased the price of electricity to the consumer by an average of 38% in February 1980. Even with the price increase, the Government subsidy was still substantial.

PRODUCTION

Tin mining in Thailand is a significant local industry and supplies about 13% of the total world output. Tin metal production capacity is around 33,000 tons per year; all production is virtually by the Thaisarco smelter. In addition, significant amounts of columbium and tantalum are recovered and shipped in the form of slag from the tin smelting operations. Other valued byproducts of Thailand's tin mining sector include ilmenite, monazite, xenotime, and zircon. Close to 3,000 tons of elemental antimony contained in ore and about 1,600 tons of tungsten in concentrates are produced annually. Minor quantities of iron ore, lead, and manganese are also mined locally.

Thailand's mine output of fluorspar—both acid and metallurgical grades—are solely for export. In addition to other aggregates and gypsum, dolomite and limestone are quarried and consumed principally by the cement industry. Output of other nonmetallics of significance to the local economy included asbestos, china clay, feldspar, talc, and pyrophyllite.

Domestic production of crude petroleum is negligible, and all of Thailand's refinery output is essentially derived from imported crude. As a result of the high price of energy, use of indigenous resources of lignite have increased. Lignite production has increased from 0.4 million tons in 1977 to around 1.4 million tons in 1980. Likewise, development and use of offshore natural gas was expected to increase rapidly after 1980.

The mineral industry as a whole contributed $676 million to the Thai economy in 1979, or about 2.4% of GNP.

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.

[1]Includes data available through July 30, 1981.

[2]Excludes columbium- and tantalum-bearing tin slags, which make Thailand the world's largest source of newly mined tantalum.

[3]Exports.

TRADE

Thailand exported minerals and metals worth over $735 million in 1980, a 28% increase over 1979. Tin accounted for $550 million or about 75% of the total. Other major mineral exports were tungsten, gem stones, barite, fluorite, antimony, tantalum-bearing tin slag, and lead concentrate. The value of lead concentrate exports continued to rise, but at a slower rate, as the new processing facility was brought up to near its design capacity. Cement continued the swing from a major export item to a significant import commodity. Value of cement imports totaled over $58 million in the first 9 months of 1980. Minerals ranked as one of the four most valuable exports with rice, tapioca products, and natural rubber. The export of tin slag constitutes the major source of new tantalum on the world market.

The value of total trade was $12.5 billion in 1979 and climbed to $15.8 billion for 1980. Exports rose from $5.3 billion in 1979 to $6.5 billion in 1980.[5] The export target for 1981 was placed at $8.4 billion. Imports have been rising at an even faster rate than the exports. The trade gap widened during 1980 when total imports climbed to $9.8 billion. The resulting deficit of over $2.8 billion was the largest ever experienced by Thailand. Petroleum and petroleum products were again the high-cost import items. Compared with 22% of the total 1979 import bill, petroleum accounted for 31% of the total imports in 1980, as the price of crude oil increased 74% over the 1979 price.

Japan was the major trading partner for both exports and imports, but its share of Thailand's total imports dropped from 31% in 1978 to 26% in 1979 and continued the

relative decline to 22% in early 1980.[6] The United States, the Netherlands, and Singapore were the other major importers of Thai goods, while the United States, Saudi Arabia, and the Federal Republic of Germany were major suppliers of Thailand's imports in 1980. Thailand's major imports after fuels were machinery, manufactured goods, and chemicals.

COMMODITY REVIEW

METALS

Iron and Steel.—Plans for a natural-gas fueled direct-reduction plant and electric furnace steel mill were being discussed during the year but no firm decisions were made. Projected location of the plant would be on the Gulf of Thailand near Rayong. Thailand has small, rather low-grade iron ore deposits and unless future exploration confirms more suitable iron ore, the proposed plant would have to use a blend of imported and domestic ores. Thai scrap supplies were expensive and unreliable. The direct-reduction plant would insure dependable supplies of sponge iron that could be substituted for scrap in the electric arc furnaces.

Thailand's raw steel capacity was about 570,000 tons per year in 1980. Most production comes from scrap-based electric furnace steelmakers, utilizing their own rolling mills. The Siam Iron and Steel Co., Ltd., has a 100,000-ton-per-year blast furnace that uses local raw materials. Current rolling capacity was about 1 million tons per year. Reinforcing bars were in short supply because of increased building activity, and much of the industry's demand for rebar and other semifinished steel was met by imports or rolled from imported billets.

Expansion of domestic rebar production was underway by several of the rolling mills. Capacity of the Siam Iron and Steel Co., Ltd., plant in Saraburi Province, was being increased by 120,000 tons per year with completion scheduled for late 1981. Bangkok Steel Industry Co., Ltd., in Samut Prakan Province, Bangkok Iron and Steel Co., Ltd., and Bangkok Iron and Steel Works, Ltd., planned to raise their capacities by 110,000 tons per year, 60,000 tons per year, and 50,000 tons per year, respectively.

Tantalum and Columbium.—For several years Thailand has been the world's largest supplier of tantalum, mainly in the form of exported tin smelter slags. In 1979-80, Thailand supplied more than one-third of the market economy countries' output.

Rather than continuing the export of slag, the second most valuable mineral export, the Thai Government decided to have the tantalum extracted within the country. As a result, the Thai BOI reportedly awarded the recently formed Thailand Tantalum Industries Co. (TTIC) full promotional privileges for a proposed tantalum refinery project (TTIC is 90% Thai share-

holders, 10% S.A. Minerals Co., Malaysia). BOI ruled that TTIC should have sole rights to produce tantalum pentoxide in Thailand for a period of 8 years. Of critical importance to the TTIC proposal was the additional stipulation by BOI that there will be a ban on all tin slag exports to begin 1 year before TTIC's planned start of operations. If the plant was built, the 100% Billiton Thailand Ltd.-owned Thaisarco tin smelter would apparently have to supply all of its slag to TTIC. Billiton had also submitted a proposal for a tantalum processing facility to BOI but this was reportedly rejected late in 1980.

The TTIC project was to consist of a refinery in Phuket to be built in two phases and completed in 1983. The first phase was a plant to produce 2,000 tons per year of ferrotantalum-columbium alloy. The second phase, at the same site, was to produce 300 tons per year each of tantalum pentoxide and columbium pentoxide. Hermann C. Starck Co. of the Federal Republic of Germany has agreed to furnish process technology for the plant in return for at least one-half of its total output.

The new plant would also be able to process Thai tantalite and columbite concentrates and the much lower grade Malaysian tin smelter slags. In connection with the new project, the Thai Department of Mineral Resources has apparently drawn up new royalty regulations for the tantalum content of the tin slag produced at the Thaisarco smelter. If plans and construction proceed as scheduled, Thailand could be producing 40% of the world's tantalum by yearend 1983 (which includes imported Malaysia slag).[7]

Tin.—As in past years, tin was by all measures Thailand's most valuable mineral commodity and by far the largest employer, both directly and indirectly in the mineral sector. In 1979, more than 80% of the earnings from mineral exports came from tin, and the tin industry contributed 94% of the Thai Government's revenue from mineral royalties.[8]

Despite the increases in production over the last few years, the tin industry was facing some serious problems.

Energy costs more than doubled in the last 2 years, increasing costs at all stages of the mining and refining cycle. A drought at the end of 1979 and continuing into early 1980, cut into the water supply needed for onshore dredging and gravel pump mining operations.

At the beginning of 1980, roughly one-half of Thailand's tin was produced from quasi-illegal operations. These consisted mainly of small suction-dredge boats poaching in areas reserved for the OMO. Realizing the potential loss of revenue if this tin did not enter legal channels, the Government authorized various agents to buy tin from illegal operations and then to pay royalties when it is resold to the Thaisarco smelter. Attempts to stop or control the illegal suction boats have met with little success and have resulted in a great deal of political sensitivity.

At the current production rate, the small suction boats will have degraded or depleted most of the deposits in water up to 20 meters deep by the end of 1983. Conversely, the large dredges will also have worked a great deal of the better grade shallower areas. If new shallow water deposits are not found, it appears that the small boats could be out of business in a few years and Thai tin production would drop substantially.

Another problem was security in some of the most promising areas for new tin exploitation. These were the highlands in Nakkon Si Thammarat (08°N, 100°E) and Surat (Thani, 09°N, 99°E) Provinces where insurgents were powerful enough to deny effective control of mining operations to the Government.

Smuggling had been a serious problem in recent years. Since the Government began buying the illicit tin concentrate, and the Malaysia Government banned purchase of smuggled concentrate, the problem has diminished to a tolerable level. Thai industry experts believed that no more than 2,500 tons were smuggled out of the country in 1979.

Delivery of OMO's new $18 million bucket ladder dredge was delayed in early 1980 by construction problems. OMO finally took delivery late in the summer. The 330,000-cubic-meter-per-month capacity dredge was then leased to Aokham Thai Co., Ltd., to dredge for 4 months in its concession area off Phuket. This furnished a shakedown period for the dredge and also a training period for OMO's mining staff to acquire experience in its operation. After this break-in period, the dredge was to be returned to the OMO concession area at Baan Bor Daan off Phangnga Province.

Southern Kinta Consolidated Ltd. ceased tin dredging at its Takuapa concession in southern Thailand because of losses incurred during its offshore operation. The losses were attributed to a depletion of the reserves in its concession area by illegal suction boat operations. The company decided to limit its loss and was moving the

dredge to Phuket Bay where it will be kept under maintenance. Proposals to modify the dredge to increase throughput and enable it to mine thicker alluvium were being considered.[9]

The Thai Natural Resources Department extended the concession of Tongkah Harbor Tin Co. for 25 years. The concession was renewed after Tongkah Harbor changed its equity structure to conform to new Government regulations. The concession area covers 7,000 acres in the southern Provinces of Phuket and Phangnga.

Plans for a new offshore dredging operation in southern Thailand were being delayed by land-use conflicts. The deposit, with 20,000 tons of tin metal content, was located in Patong Bay and was the last known major shallow water deposit that has not been worked previously by either dredge or small suction boats. Sethasap Mining Co., Ltd. (formerly Sethasap Karn Rae Co., Ltd.), the concession holder, planned to work the deposit with a large bucket ladder dredge but individuals and groups supporting tourism and environmental concerns claim the work would despoil the beauty of the area. The deposit could make a significant contribution to Thailand's tin production at a time when output from other offshore areas was expected to begin declining.[10]

Aokham Tin was to form a new company to explore and evaluate tin-bearing reserves several miles off the Takuapa coast in southern Thailand. The company will have Thai and Malaysian participation in accordance with new Thai regulations. A previous seismic survey and scout borings indicated promising reserves at depths below the normal limits of dredging.

Several small new onshore operations or expansions were applied for or granted by BOI during the year. Siam Mineral Products Co., Ltd., applied for promotional privileges to mine tin and process up to 400 tons of concentrate per year at Tambol Suan Phueng in Ratchaburi Province. Sierra Mining Co., Ltd., had a dry mining system and a jig table ore recovery plant under construction at its property in southern Thailand. The expansion would provide data for development of the main ore body, which could be mined at a rate of over 300 tons per year of concentrate. Thai Watana Mining Co., Ltd., applied for permission to produce 2,000 tons per year of concentrate at Thai Muang (8°30'N, 98°15'E), Phangnga Province. In April 1980, Chinteik Brothers Co., Ltd., began operating a mine and a 240-ton-per-year ore dressing plant at Thai Muang in Phangnga Province. This operation reportedly would also produce byproduct tantalite concentrate. A foreign investor and a local Thai company formed International Tantilite Co., Ltd., to develop and expand a local operation. Capacity was to be 1,500 tons per year of tin concentrate and 50 to 70 tons per year of tantalite concentrate.

The Thai Pioneer Enterprise Co.'s smelter at Pathum Thani was ready for commissioning at yearend 1980. The new facility, Thailand's second tin smelter, will have a startup capacity of 3,600 tons per year and refine concentrates from northern and central Thailand.

The Thai Present Co. smelter was erroneously reported in the press to be under construction at Nakhon Pathom in 1979. Construction actually never began at the site and plans were changed for both capacity and location during 1980. The company now reportedly has plans for a 10,000-ton-per-year operation at Phuket with completion scheduled for 1983.

Tungsten.—The Government has approved a proposal by Siam Tungsten International Corp., Ltd., to build the country's first ammonium paratungstate plant. The 3,000-ton-per-year plant would be located at Ayutthaya near Bangkok and cost over $11 million. The company was owned 60% by local Thai shareholders and 40% by unnamed European and U.S. interests. The Thai Government has been advocating more domestic processing and refining of crude minerals wherever feasible to realize a higher value for its nonrenewable natural resources. Export of the ammonium paratungstate would bring a much higher price than the crude tungsten concentrate.

Wolframite production continued a decline started in 1979, while scheelite production showed a small increase for the third consecutive year. The wolframite decline was attributed to the gradual depletion of the high-grade sections of the Khao Soon Mine, which had supplied up to 75% of Thailand's wolframite output during the last few years.

Zinc.—The proposed 60,000-ton-per-year Mae Sot zinc refinery project in Tak Province had another year of trouble in 1980. Early in the year there was a problem of financing the $120 million to $150 million project as the question of its economic viability was studied once again. Moreover, a question of the availability and price of

electricity in the remote area of the mine and plant was brought up. This critical power problem was apparently worked out later in the year. Just as events began to look promising for the start of construction, press reports stated that the prime contractor and 30% owner of Thai Zinc Co., Ltd., Whashin Industrial Co. of South Korea, was having financial troubles at home and might withdraw from the project. Early in November, Whashin Co. informed the Thai Government that it was indeed withdrawing from the project. As a result, on December 5, 1980, the Thai zinc consortium missed the Government's fifth and final deadline for arranging financing and starting construction on the project. Thai Zinc Co. thereby forfeited its mining leases and authorization to construct the attendant refinery.

The Government wants the refinery built and reportedly was considering putting up the leases and construction permit for competitive bidding. If so, the Thai Zinc Co. shareholders, less Whashin Co., could bid. It was rumored, however, that the old Thai Zinc Co. participants would form a new syndicate with Vielle-Montagne S.A. of Belgium heading up the new company.

NONMETALS

Cement.—The cement industry continued to produce at its maximum sustainable production for the third straight year. Production was not sufficient to meet demand, which continued to increase steadily despite efforts to cut consumption. To meet demand, $58 million worth of cement was imported in the first 9 months of 1980. South Korea supplied more than 55% of the total, followed by Japan, Indonesia, and Malaysia.

The Thai BOI announced it would accept applications for new or expanded cement plants in late 1977. At least 10 companies submitted applications and by mid-1978, 5 applications were granted promotional privileges. Work started on some of the projects during 1978-79, but some were postponed or dropped for various reasons and some new proposals were tentatively approved.

In March 1980, the first of the new facilities was completed by the Siam Cement Co. at its Thung Song plant in Nakhon Si Thammarat Province; capacity of the new section was 410,000 tons per year. A 1.6-million-ton-per-year expansion of Siam Cement Co.'s Tha Luang plant was nearing completion. Also underway, was a 1.5-million-ton-per-year expansion of the Siam City Cement Co. plant in Saraburi, scheduled for completion in 1981.

Current and planned capacity of the cement industry in Thailand is as follows in metric tons:

	1979	1980	1981	1982	1983
Siam Cement Co	3,730,000	4,140,000	5,780,000	5,780,000	5,780,000
Siam City Cement Co	660,000	660,000	2,160,000	2,160,000	2,160,000
Jalaprathan Cement Co	907,500	907,500	907,500	907,500	2,587,500
Thanabhumi Cement Co	--	--	--	--	1,249,000
Total	5,297,500	5,707,500	8,847,500	8,847,500	11,776,500

Completion of this ambitious construction program would alleviate the current shortage.

Fluorite.—Fluorite was one of Thailand's more important mineral industries employing over 3,400 persons in 52 active mines in mid-1980. Mining activity increased during the first half of 1980 as did production. Output of low-grade ore, in particular, showed a substantial increase. This ore was generally beneficiated into an acid-grade fluorite and exported. Japan was Thailand's best customer for the acid-grade material, taking over 78% of the 1979 production.

BOI was considering the possibility of establishing downstream fluorite-based industries in Thailand. Development of these industries would increase overall value of domestic fluorite output, create new job opportunities, and considerably increase foreign exchange earnings.

Salt and Potash.—Discussions continued about the planned soda ash factory which was to be Thailand's Association of Southeast Asian Nations (ASEAN) development project. Soda ash was a major Thai import, and development of the soda ash industry and its related chemical plants would be beneficial to the Thai economy by reducing the balance of trade deficit and employing a considerable work force.

An agreement was reached during 1980 on the equity ratio between Thailand and the other ASEAN countries involved in the development of the mines and industrial facilities. Under the final agreement, Thai-

land will hold 60% of the equity, Malaysia, Indonesia, and the Philippines will hold 13% each, and Singapore, which had doubts about the projects commercial viability, will hold 1%. Thailand set up the Rock Salt and Soda Ash Holding Co., Ltd., to manage its interests. The Thai ownership was 34% by the Government and 66% by 10 private Thai companies who are soda ash consumers.

Plans call for a rock salt mine to be opened at Bamnet Narong (15°30'N, 101°42'E) in Chaiyaphum Province, with the limestone mine to be located in Saraburi Province. Reserves at the mine sites were good for many decades of production. The final site for the soda ash plant was to be either Sattahip, Laem Chabang, or Rayong, all of which are on the coast and along the alinement of the natural gas pipeline.

The Department of Mineral Resources has reportedly rejected a proposal from Amax Exploration, Inc., for exploring and developing a promising potash deposit at Wanon Niwat (17°40'N, 103°45'E) in Sakon Nakhon Province. The Government was asking for one bid for the exploration work and a separate bid for the development work, with the exploration company having no priority claim to the later work. Amax would like developmental rights before making a large investment in a detailed exploration of the deposit. Amax remained interested despite the impasse, and the Thai Government will continue negotiating with the company, which remained the sole applicant for the potash concession.[11]

The Thai potash occurrence was the only large high-grade deposit known in the Southeast Asia area, but its development will require a great deal of capital investment because of the remoteness of the deposit.

MINERAL FUELS

Lignite.—With respect to the world's rapidly rising energy costs, Thailand's once economically marginal lignite deposits have taken on considerable new importance. Most of the Thai lignite production was used for electric power generation at the mine sites. The Thai Government has embarked on an extremely ambitious expansion program of the Mae Moh (18°16'N, 99°43'E) lignite mining and power generation complex. Currently two units of 75 megawatts each were operating in 1980. A third 75-megawatt unit was due online in early 1981, and a fourth unit of similar size was due online by the end of 1981. Two 150-megawatt units were scheduled for mid-1980 operation and three 300-megawatt units are scheduled to be built by 1987. The Electricity Generating Authority of Thailand (EGAT) has been studying the possibility of using a fluidized bed combustion technology for units 6 through 9. A mining expansion program was planned to keep the mine's production capacity in line with future increase in demand.

A detailed evaluation of the lignite reserves in the Mae Moh Basin was being undertaken by an Australian engineering team. A high-resolution seismic survey will delineate the basin structure and seam thickness. A large number of noncored holes will be drilled and wireline logged to determine lignite occurrence and quality.

EGAT has not ignored the search for additional lignite reserves. A new deposit was discovered in the Mae Ramat district (17°10'N, 98°30'E) of Tak Province, while drilling for oil shale. EGAT has applied for a $1.5 million loan to finance a detailed survey of this deposit which was believed to be several times the size of the Mae Moh deposit.

Drilling confirmed two small coal deposits in Lampang Province. The coal had the same heat value as the Mae Moh lignite and total reserves were estimated at 58 million tons.

Natural Gas and Petroleum.—During 1980, a 425-kilometer-long natural gas pipeline was being laid in the Gulf of Thailand from the Union Oil Co.'s gas discovery to emerge onshore near Rayong. Concurrently, a 160-kilometer-long onshore segment was being laid from Rayong to the Bangkok metropolitan area. The 86-centimeter pipeline was currently the longest submarine pipeline under construction in the world and would cost over $500 million when completed. The line, and supporting offshore and onshore facilities, were scheduled for completion in late 1981. The line is projected to begin operating at a rate of 250 million cubic feet per day, with all of the initial output going to the generation of electric power. The pipeline was designed for a 500-million-cubic-foot-per-day capacity. This will be reached when a planned 110-kilometer extension is completed to the Texas-Pacific Co.'s gasfield southeast of Union Oil Co.'s present development.

This energy development project was designed to reduce Thailand's dependence on foreign oil imports and lower the balance of trade deficit. In 1980, Thailand spent nearly

$3 billion for crude oil and refined product imports, exceeding the trade deficit for the year.

As more development drilling was done in the Gulf of Thailand, total gas reserves increased to over 9 trillion cubic feet. In addition to its primary use in electric power generation, the increased reserve situation would allow development of natural resources, which are high energy consumers.

In particular, the gas could be used to fuel the proposed soda ash and sponge iron plants or any of several petrochemical projects. At yearend 1980, there was still no price agreement with the Government for the development of the discoveries in the Texas-Pacific Co. concession area or for Union Oil Co.'s Block 10 discovery.

According to Petroleum Authority of Thailand (PAT), plans were going ahead for the expansion of the Thai Oil Refining Co. (TORC) refinery from 65,000 to 165,000 barrels per day despite political pressure to revise the agreement. By the terms of the agreement, PAT and the Crown Property Bureau will own 49% and 2%, respectively, while TORC and Royal Dutch/Shell Corp. would own the remaining 49%. The expansion would cost around $580 million. If there were no delays, a contractor would be chosen in 1981. There was no progress in 1980 concerning the often discussed plans to expand the capacity of the ESSO and Summit Industrial Corp., Ltd., oil refineries. Prospects for the construction of a new fourth refinery were also uncertain at yearend 1980. Although all parties agreed that new refining capacity was urgently needed, the subject was politically sensitive. Ownership, financing, and distribution of profits were the points of contention rather than technical or engineering problems.

The country's three large refineries operated entirely on imported crude oil, mostly from the Persian Gulf countries. In 1979, Saudi Arabia, Qatar, the United Arab Emirates, and Kuwait together supplied 82% of Thailand's crude requirements. Thai crude oil import volume fell 3.6% in 1980, while the value rose 66%. The Persian Gulf countries still supplied 81% of the total.

The import situation will change somewhat when the natural gas begins flowing in 1981. The main change will be a drop in demand for heavy fuel oil as the thermal powerplants switch over to natural gas. In addition, several thousand barrels per day of light-end gas condensates will also be available as a natural gas byproduct.

The Mineral Industry of Tunisia

By E. Shekarchi[1]

While petroleum and phosphate rock exports earned $560 and $61 million in foreign exchange, respectively, for Tunisia in 1980, activities in other areas such as iron ore shipments, steel output, lead, zinc, and cement production were not insignificant. Cement production continued to be a national priority as Tunisia strived to become self-sufficient in this area. Toward this end, the Government allocated $75 million, half of which went to the Jebel Oust cement project. During 1980, cement production reached a new high of 1.4 million tons, necessitating imports of cement from Spain, the U.S.S.R., and Turkey.

Total production of phosphate rock in 1980 reached 4.2 million tons, an improvement over 1979 production but still well below the goals of the Fifth Development Plan (1977-81). Failure to reach planned levels can be traced to a number of factors. First and foremost, the plan to double annual phosphate production from 3.5 to 7 million tons in 5 years proved unrealistic. Rather than implement their expansion program in stages, the Tunisians tried to do everything at once, and the personnel and infrastructure were insufficient for the task. In 1980, the management of Cie des Phosphates de Gafsa (CPG) announced that it would soon transfer its headquarters from Tunis to Metlaoui, site of one of the largest phosphate mines, in order to communicate better with all the operating mines. One-third of all phosphate production was exported and the remainder was used in the domestic chemical industries to produce phosphoric acid and its derivatives. Phosphoric acid exports earned $80 million during 1980.

The Tunisian economy continued its vigorous growth of previous years with about a 5% increase in 1980. This increase brought the per capita gross national product (GNP) to about $1,120, which was an achievement for a developing country. However, one of the most important problems facing the Tunisian economy, open and hidden unemployment, remained unchecked. In 1980, an estimated 250,000 people were unemployed. In addition, there was considerable hidden unemployment in the agricultural sector. The Government was aware of this serious situation and gave high priority to creating new jobs and educating and training workers to qualify for job openings in the future.

In the latter part of 1979, after some construction tenders had been announced, the Government suspended further consideration of the Miskar offshore gas project. The main reason for the cancellation of the project was the lack of proven reserves. The proven reserves of the field were found, after the drilling of two additional confirming wells, to be less than expected. As a result, Miskar offshore gasfield has been put in the bank to wait for the higher internal rate of return that future energy price rises will bring. The gasfield will also serve as a useful hedge against the failure to find new commercial petroleum fields.

The proposed expansion of the Bizerte refinery capacity from 1.5 million tons to 4 million tons per year, another major 5-year plan (1977-81) energy sector project, was delayed but will probably be started late in 1981. During 1980, a consulting engineer was selected, and construction tenders were to be issued in the late 1980's.

PRODUCTION AND TRADE

Continuation of the improvement in Tunisia's balance of payments in 1980 depended in large measure on exogenous factors, such as the price of petroleum and the price of phosphate rock and new chemical fertilizer exports from Gabes facilities on the international market. By the end of the year, the overall trade balance was reported at $1.1 billion, with a surplus in the service account of about $500 million. Production of minerals as well as exports and imports of mineral and some semimanufactured-related materials are presented in tables 1, 2, and 3.

COMMODITY REVIEW

METALS

Iron and Steel.—Since Douaria and Tamera Mines were exhausted, all production of iron ore was from the Djebel Djerissa Mine located approximately 40 miles west of Bizerte. The ore, with a 52% iron content, was consumed in domestic industry. Tunisia operated a small but fully integrated steel mill, El Fouladh, at Menzel Bourgba, near Bizerte. Total capacity of the mill was reported to be about 180,000 tons. Downstream products of the El Fouladh consisting of bars and rods of various diameters, were down to one-half millimeter in diameter, and a limited range of steel structures were primarily consumed locally.

The expansion plans for El Fouladh by adding two electric furnaces, which have been under discussion for years, remained undecided. Whether or not this project is ever implemented, Tunisia soon will have to turn to the international market to meet its iron ore demand. The iron ore reserves estimated in 1980 ranged from 2 to 4 million tons, and all efforts of exploration to find new ore bodies had failed.

Lead and Zinc.—Tunisia continued to mine lead and zinc in 1980, but owing to exhaustion of the mine and generally antiquated equipment, mine production remained about 15,000 tons for both metals. Exploration activities by the Société Tunisianne d'Expansion Minére, the only lead-zinc producer in the country, remained low key. An American firm, Golder Associates, was selected in 1980 to do a feasibility study for the upgrading of the Fedj Hassene lead-zinc mine, where a low grade of lead-zinc in substantial quantities has been reported in the past. Most of the lead production of Tunisia was consumed domestically, while a significant portion of zinc concentrates were shipped to European markets.

Other Minerals.—Tunisia produced a limited amount of silver as a byproduct from lead-zinc mining and mercury for cosmetic markets. A small amount of arsenic was produced from the Tabett ben Ksouri deposit to satisfy domestic consumption.

NONMETALS

Cement.—Tunisia produced $1.4 million tons of cement in 1980, about one-half million tons short of domestic consumption. The Société Les Ciments Tunisians, a Government-organized company, continued to administer the building of a cement plant near Jebel Oust. This plant was expected to come into production in 1984. The plant would cost close to $200 million and have a capacity of 1 million tons. The asbestos cement products plant, with a capacity of 26,000 meters of pipe per year, went into full operation in 1980. Most of the product was used domestically, primarily for irrigation and sanitation purposes.

Fertilizer Materials.—Phosphate rock production by the State-owned CPG reached a new high of 4.2 million tons of concentrate in 1980. One-third of this was exported to European markets, and the remainder was processed in the domestic chemical industries. Domestic chemical industries produced phosphoric acid, triple superphosphate, phosphate animal feed, and other phosphate derivatives, mostly for export. In 1979, phosphoric acid exports earned $78 million and total superphosphate fertilizer exports were worth $80 million. In sum, phosphate and phosphate derivatives represented 11% of total merchandise export earnings, to rank third in importance behind crude oil and textiles.

Eight major phosphate mines were operating in 1980. All but one, the new Kef Echfaier Mine near Metlaoui, were underground. The five older mines at Metlaoui, Kaiaa Khasha, Moulares, Redeyef, and M'Dilla underwent various forms of modernization, ranging from construction of new washeries to application of recent technologies in ore extraction. The three new centers at M'Rata, Kef Echfaier, and Sehib were expected to provide at least half of Tunisia's total phosphate rock production within the next few years.

As mentioned, two-thirds of Tunisian phosphate production was used domestically to produce chemicals and fertilizers. The older plants were located in Sfax and Tunis, and the new centers of industry were located in Gabes, where several huge new plants—the largest of which were the Industries Chimiques Maghrebines (ICM) and Société Arabe des Engrais Phosphates et Azotes (SAEPA) complexes—began operation in the late 1970's.

ICM produced 250,000 tons per year of phosphoric acid, of which 190,000 were exported and the rest was used to make 100,000 tons of triple superphosphate and 60,000 tons of phosphate animal feed per year, mostly for export. In 1979, Hitachi of

Japan won a contract to expand ICM's production base to produce an additional 190,000 tons per year of phosphoric acid by 1982.

SAEPA, so titled because of a 40% equity share by the Abu Dhabi Development Fund, began production in late 1979. SAEPA produced 330,000 tons per year of phosphoric acid, of which 270,000 tons were exported and the rest was used to manufacture 330,000 tons of diammonium phosphate fertilizer per year.

Gabes Chimie Transport, an affiliate of ICM, owned three phosphoric acid tankers with a total capacity of over 25,000 tons that were used to deliver fertilizer products to Tunisia's customers around the world. Planned investment in the phosphate mining sector for 1980 totaled $41 million, which was a significant decrease from 1979 levels of almost $90 million. A major reason for the decrease was the financial situation of CPG. Another reason was the gap between the production costs of CPG and selling prices. Losses totaled about $46 million in 1979 and resulted in drastic changes in the top management of the company and a strict control on its capital expenditures. Even with the reforms and higher world phosphate prices, however, CPG faced large losses in 1980. Investment in the chemical and fertilizer industries in 1980 was also decreased substantially, from $107 million to $44 million.

Other Nonmetals.—Production of fluorite and barite remained at the same level of 1979 output. Most of the fluorite was consumed by the Industries Chemiques de Fluor in producing aluminum fluoride. Since the market for barite was limited by demand for drilling in the petroleum industry, barite was stockpiled at the mining site. Production of gypsum and lime, which were used mostly in the housing industry, remained at the same level as in 1979.

MINERAL FUELS

Between 1977 and 1980, exploration efforts in Tunisia identified about 50,000 barrels per day of new petroleum that could be commercialized by 1985. This amount probably would not meet Tunisia's net export requirement of 2.5 million tons per year projected in the last 5-year plan. Tunisia, with a declining petroleum production and increasing domestic consumption, eagerly expected production from Isis Oilfields. However, Isis Oilfield was in the disputed offshore area between Tunisia and Libya. Although the two countries have asked the International Court of Justice to advise them on a formula that could be used to draw mutually accepted boundaries, the court will not render its opinion until 1982. It seemed that by mid-1980, Tunisia would have to rely on imports of refinery products while exporting its petroleum to the international market at premium prices.

Crude petroleum production in 1980 totaled 5.6 million tons, compared with 5.3 million tons in 1979. About 93% of 1980 petroleum production was from two fields: El Borma and Ashtart. No new concession was brought onstream in 1980. A slight production increase in 1980 allowed Tunisia to maintain a petroleum export surplus of 2.5 million tons, which earned about $550 million in foreign exchange in 1980. The El Borma Field was utilizing secondary recovery techniques in 1980, and although production there was projected to rise still further in 1981 and 1982, it could drop off very sharply thereafter.

Although the expansion of Tunisia's only petroleum refinery at Bizerte was postponed until 1981, the refinery produced 1.5 million tons of products in 1980 (mainly using imported Saudi Arabian and Iraqi crude). In addition, Tunisia imported 700,000 tons of refined petroleum products, mainly from refineries in Italy.

By the end of 1980, about 21 permits for petroleum exploration, covering an area of approximately 155,000 square kilometers, was still valid. There were 14 expansion and development wells completed. In most of the exploration permits, the oil company or companies formed a 50% partnership with the Tunisian State oil company, Enterprise Tunisienne des Activites Petroliers (ETAP). ETAP was to reimburse its share of exploration expenses only in the case of a commercial find, otherwise the companies were to absorb all of the exploration expenses. By the end of 1980, new permit holders were required to commit a specific number of wells and/or investment figures during the life of the permit.

The Mineral Industry of Turkey

By Peter J. Clarke[1]

The Turkish economy and Government underwent major structural reforms in 1980 in an attempt to solve the problems of economic stagnation and eliminate the political infighting that had paralyzed the country. Several years of restrained economic growth, rapidly rising rates of inflation, high unemployment, and massive balance-of-payment deficits had combined to erode the confidence of international creditors and placed the country in a nearly irretractable economic slump. Partly to blame for the condition of the economy was the soaring oil import bill, which exceeded total foreign exchange receipts for commodity exports in 1980. In January 1980, a major economic reform package was instituted to restore the health of the economy. The first half of the year showed little improvement, but in the second half the inflation rate began to slow, and imports and exports began to pick up. The overall rate of economic growth, as reflected in the country's gross national product, declined in 1980, as it has every year since 1974. Industrial production was down 4% in 1979, and dropped another 0.5% in 1980, which indicated the partial recovery of the manufacturing sector during the year. International loans for investment and balance-of-payments assistance were necessary to keep the economy stabilized while the reform program began to take effect.

Despite its large reserves of various minerals, the mining sector contributed approximately 3.7% of Turkey's gross domestic product. Total mineral production decreased 5.4% from that of 1979. The decline in production was due, in part, to the Government's nationalization of major mines, which was authorized by Law No. 2172 of October 19, 1978 (Mines Expropriation Law). The Government took control throughout 1978 and 1979 of major iron ore, lignite, boron, and magnesite mines. Once in control of the major deposits, Etibank, the State Economic Enterprise (SEE) responsible for mineral production, did not possess sufficient funds for the necessary capital investments to get the mines operating. Production in all sectors, except lignite, declined.

Recognizing that Etibank was unable to increase the productivity of the nation's mines, the Council of Ministers, in June 1980, published a decree authorizing the return of nationalized mines to their original owners, under several conditions. Before the Ministry of Energy could begin returning the mines, the Supreme Administrative Court issued a restraining order at the request of Maden-Is, the mineworkers' trade union, questioning the authority of the Council of Ministers to rescind a law enacted by the Parliament. At the end of the year, the Government was preparing a bill to submit to the Parliament to authorize the return of the mines.

These changes in the ownership of the nation's mines were part of a sweeping reform program, instituted in January 1980, to strengthen the economy and allow market forces to operate more independently. These measures were to coincide with a nearly $2 billion[2] loan agreement provided by the Organization for Economic Cooperation and Development (OECD) members and the International Monetary Fund for balance-of-payments assistance. In addition, OECD members agreed to reschedule about $5 billion in official and officially guaranteed debts owed by Turkey.

Among the reforms instituted under the Government of Prime Minister Suleyman

Demirel were a 35% devaluation of the lira against the dollar, raising interest rates on bank advances, and partial decontrol of oil and coal prices. The main objectives of the plan were to boost exports, open the economy to foreign investment, and slow the annual rate of inflation, which had been running at nearly 100%. Many sectors of the economy, including mining, which had been allowed little access to foreign capital, were to be opened. Investments could be made in any area not nationalized by the Council of Ministers. Passage of the return of expropriated mine bills would make accessible many profitable mining ventures to multinational companies. Metal and nonmetallic processing industries were also opened to foreigners. Non-Turks were allowed to own between 10% and 49% of most companies' equities. However, in some industries, mainly export oriented where there is no competition with Turkish companies, foreigners were allowed 100% ownership.

The petroleum industry, which was much in need of foreign expertise and money, was also liberalized. Foreign companies were allowed to export 35% of their oil production, and exploration licenses were granted for many regions, including those under the control of the state-owned Turkiye Petrolleri Anonim Ortakliki (TPAO).

In addition to economic problems, Turkey suffered from political instability as well during 1980. Citing the inability of the elected Government to effectively govern the country, the Turkish Armed Forces took power on September 12, 1980, as they did in 1960 and 1971. The military Government pledged to continue the economic reforms initiated under the previous Government, and to return the country to parliamentary democracy as soon as was practically possible.

PRODUCTION

Total production from the mineral sector in 1980 declined 5.4% from the 1979 level. Still, Turkey remained a major producer of several minerals, notably chromite and boron, in which Turkey ranked fifth and second, respectively, in terms of world output. Production of most commodities remained low, however, for several reasons. Demand was low, owing to a nearly stagnant economy, and the lack of foreign exchange crippled most of the SEE's capital replacement and development plans. Labor unrest and frequent power cuts from electricity shortages contributed to the low production level.

The reaction to the nationalization decree that went into effect in October 1978 was an almost universal decline in output. Lignite production, which declined 4% in 1979, was the exception, showing nearly a 10% increase in production in 1980, as many older mines were brought back into production after being nationalized, and some of the newer mines were managed more efficiently. However, hard coal production continued its decline. The hard coal industry was hard hit by the lack of foreign currency to purchase equipment and machines.

Output of iron ore remained relatively stable in 1980, following the dramatic drop in production in 1979. Problems in this industry included energy shortages and lack of diesel fuel for transporting ore to the steel mill.

On the brighter side, tungsten output remained high at Etibank's Uludag tungsten operation in Bursa. Operating difficulties had been curtailing mine and mill output since the plant opened in 1977. Barite also showed a significant increase in production from 1979, owing mainly to increasing world demand for drilling muds. Petroleum production continued the long decline from the peak level of the late 1960's. Production dropped nearly 20% from the high level in 1979. Turkey began to implement secondary recovery programs to boost domestic production. A slightly improved foreign exchange situation in 1980 allowed crude oil imports to rise, and as a result, consumption increased over 7%, after the 14% drop in 1979, when funds for imports were at their lowest. Mineral production in Turkey is shown in table 1.

[4]Includes Zn content of zinc and lead-zinc ores but excludes Zn content of lead ore.

TRADE

Reflecting the overall decline in production and a slight improvement in foreign currency availability, mineral imports increased 32% in 1980 over that of 1979. Because of the significant increases in the price of imported oil, Turkey's total import bill rose to over $6 billion and mineral imports represented 51% of total Turkish imports in value terms. Minerals, including oil, represented only 25% of total imports in 1979.

Mineral exports, on the other hand, declined 19% from the 1979 level, after showing a 16% increase from 1978 to 1979. Minerals composed 4.2% of total Turkish exports. The major exported minerals were aluminum, barite, boron, chromite, magnesite, and tungsten. Total mineral exports were valued at around $140 million.

Turkey showed an overall trade deficit of nearly $4 billion in 1980, a major increase over the $2.8 billion deficit in 1979. The increased price of petroleum imports was largely to blame for the increase. The trade balance began to improve slightly at the end of the year, following the coup and liberalization of some of the free market barriers, and continued improvement was expected as more foreign capital entered the country under the military Government's revised regulations.

Barite and witherite	124,123	95,844	--	U.S.S.R. 86,620; Romania 7,350; United Kingdom 1,016.
Boron materials:				
Crude natural borates	690,123	621,915	63,000	Italy 125,640; France 118,210; Japan 60,950.
Oxide and acid	14,377	13,933	2,860	West Germany 4,700; United Kingdom 2,200.
Cement, thousand tons	1,240	(2)		
Chalk	2,112	5,972	--	Iraq 3,135; Libya 1,150; Lebanon 1,130.
Clays and clay products:				
Crude clays	3,482	8,119	--	Lebanon 2,750; Italy 2,635; Iraq 2,625.
Products:				
Refractory including nonclay brick	492	246	--	Pakistan 226.
Nonrefractory	3,856	9,502	--	U.S.S.R. 2,098; Iraq 2,024; Jordan 1,287.
Diatomite and other infusorial earth	5	--		
Feldspar and fluorspar	--	30	--	All to Lebanon.
Gypsum and plaster	5,000	--		
Lime	356	104	--	All to Saudi Arabia.
Magnesite	68,986	41,506	1,520	Austria 33,920; Netherlands 3,560; East Germany 2,006.
Pigments, mineral: Natural, crude	54	32	--	All to Syria.
Sodium and potassium compounds, n.e.s.:				
Soda ash	5,072	--		
Stone, sand and gravel:				
Dimension stone:				
Crude and partly worked	18,128	19,352	--	Syria 10,735; Italy 3,603; Switzerland 1,615.
Worked	4	28	--	West Germany 24; Saudi Arabia 3; Austria 1.
Quartz and quartzite	3	10	--	All to Mexico.
Gravel and crushed rock	16	1	--	Mainly to West Germany.
Sand excluding metal-bearing	--	400	--	All to Yugoslavia.
Sulfur: Sulfuric acid, oleum	120	--		
Talc and natural steatite	42	615	--	Libya 265; Iraq 220; Lebanon 65.
Other:				
Crude: Meerschaum, amber, jet	9	8	--	West Germany 4; Italy 3; Austria 1.
Building materials of asphalt, asbestos and fiber cements, unfired nonmetals	--	370	--	All to Libya.
Unspecified	43,990	42,200	--	West Germany 18,100; Italy 10,400; France 5,475.
MINERAL FUELS AND RELATED MATERIALS				
Coal, anthracite and bituminous	520	1,485	--	All to Iraq.
Hydrogen, helium, rare gases, value	$3,000	--		
Lignite including briquets	244,617	130,885	--	All to Romania.
Petroleum refinery products:				
Kerosine and white spirit, 42-gallon barrels	76	--		
Lubricants, do.	140	700	--	All to West Germany.
Mineral tar and other coal-, petroleum-, or gas-derived crude chemicals	1,073	532	--	All to Italy.

[1] Quantity not reported; exports valued at $26,570,000, mainly to Czechoslovakia, Italy, and the United States.
[2] Quantity not reported; exports valued at $44,893,000, mainly to Egypt and Syria.

COMMODITY REVIEW

METALS

Aluminum.—Disruptions in fuel supply and bauxite shipments kept the Seydisehir Aluminum Complex operating at half capacity for the third consecutive year. Bauxite for the complex was mined at Etibank's Seydisehir Mortas Mine, where reserves were estimated at 13 million tons with an Al_2O_3-SiO_2 ratio of 6.77. Some bauxite was also mined in western Anatolia, on the Aegean coast, near Mugla. Total throughput capacity of the integrated Seydisehir works was 460,000 tons per year of bauxite (boehmite and gibbsite) to produce 200,000 tons per year of alumina and 60,000 tons per year of aluminum. A fourth potline was to be put into production in 1981, increasing alumina production to 400,000 tons per year and aluminum production to about 120,000 tons per year. The Soviet Union, who provided the technology for the original plant, was considering funding the expansion project.

From 1977 to 1980 shortages of fuel had curtailed bauxite shipments, and production was held to about 30,000 tons per year of aluminum. Etibank announced in April 1980 that production was to reach full capacity by June because of increasingly available energy, but the fuel supply bottlenecks continued and production remained low throughout the year.

Antimony.—Antimony was produced principally by Ozdemir Antimuan Madenleri Ltd. Sti., at Tokat in central Anatolia. The mine produced 43,000 tons of ore, about 60% of capacity, to produce 2,000 tons of concentrate (65% antimony and 0.57% arsenic). Total reserves at Tokat were estimated at 350,000 tons containing about 12% to 13% antimony ore.

Other small antimony producers were Usak Mermer Sanayi ve Madencilik A.S., which produced about 1,000 tons of ore from its mine located in Kutahya Province, and Ahmet UZ, which operated a small mine in the Balikesir area. Reserves at Balikesir were estimated at 300,000 tons of ore containing 5% to 6% antimony. Etibank's plans to build a 2,600-ton-per-year antimony smelter at Balikesir were postponed owing to monetary shortages. The Italian firm, Tectomin, was to construct the facility, but Etibank lacked the necessary financing.

Chromite.—Turkey slipped to the fifth position in world chromite output, behind South Africa, the Soviet Union, the Philippines, and Zimbabwe. Chromite deposits occur in 40 of the country's 67 Provinces, along two major ore-bearing belts. Ore was mined by open pit, small-scale underground, and large-scale underground methods, depending on the type of deposit.

By far the largest producer of chrome ore was Etibank, which was responsible for approximately one-half of the country's output. Etibank mined chromite from the Guleman area near Elazig, from the Uckopru region near Mugla, and also near Bursa. Total capacity of Etibank's mining operations were around 300,000 tons per year of ore. Etibank operated three concentrators to process the ore. The Karagedik concentrator was located in Mugla, and the Sori and Kefdag concentrators were located near Elazig. The Karagedik concentrator had an annual capacity of 50,000 tons of ore and the Sori concentrator had an annual capacity of 30,000 tons; both of which produced 44% to 48% Cr_2O_3. The Kefdag concentrator treated low-grade disseminated ores from the Mount Kef region, and the maximum concentrate grade was 42% Cr_2O_3.

Ferrochrome.—Etibank also produced both high- and low-carbon ferrochrome from its two plants in Antalya and Elazig. At the Antalya Ferrochrome Works, approximately 10,000 tons of low-carbon ferrochrome ore was produced annually. Approximately 5,000 tons per year of ferrosilicon was also to be produced at Antalya in the near future. Etibank's Elazig Ferrochrome Works produced around 22,000 tons of high-carbon ferrochrome in 1980. The Elazig works was scheduled to add two additional electric furnaces to raise capacity from 50,000 tons per year to 100,000 tons per year, but installation was delayed until the plant reached current capacity.

In addition to Etibank, chromite ore was mined by several private Turkish operators, and also two foreign-owned companies. Turk Maadin Sirketi, owned by Metallurg of New York, operated mines in Denizli and Eskisehir with an annual capacity of 75,000 tons of chromite. Egemetal Madencilik A.S., an associate company of Metallgesellschaft (Federal Republic of Germany), was also an important producer of chrome ore. Egemetal also acted as a clearinghouse for the many small producers in the country. Met-

allgesellschaft handled the overseas sales for Egemetal.

Copper.—Production of blister and refined copper remained low in 1980, owing mostly to operating inefficiency and technical problems. Copper was produced mainly by two companies, Etibank and Karadeniz Bakir Isletmeleri (KBI), which is owned 49% by Etibank. Both companies operated mining, milling, or smelting facilities at the three major mining districts: Murgul, Ergani, and Kure.

At Murgul, Etibank operated one open pit mine with an annual capacity of 1 million tons of ore and KBI operated two open pits, with a combined capacity of 1.8 million tons per year. About 1 million tons of ore was mined from KBI's pits in 1980. Reserves at Murgul were estimated at 150 million tons. Both Etibank and KBI operated concentrators at Murgul, where the ore was upgraded to 18% copper. In 1980, the Etibank concentrator produced 200,000 tons of copper concentrates and KBI produced 60,000 tons. Etibank operated the only smelter at Murgul, with a 12,000-ton-per-year blister copper capacity, which produced around 500 tons of 90% copper in 1980. Modernization efforts were underway in 1980 at the smelter to increase production. Associated pyrite ore from Murgul was trucked to Hopa, about 60 kilometers north, where the pyrite ore was concentrated.

Etibank also operated a mine-mill-smelter complex at Ergani in eastern Turkey. Annual production capacity of the Ergani smelter was 16,000 tons of blister copper from 70,000 tons of 14% copper concentrates and 1 million tons of ore. Etibank was also modernizing the Ergani smelter, which was to increase production by 1982. Total reserves at Ergani were estimated at 1 million tons.

In the Kure District in northern Turkey, both Etibank and KBI operated mines. Etibank's Kure Cuprous Pyrite Works consisted of a 1-million-ton-per-year open pit mine and concentrator. KBI, at its Black Sea Copper Works, operated an underground mine, a concentrator, and a smelter located at Samsun, with a total capacity of 40,000 tons per year of blister copper. The KBI smelter continued to operate at about 20% to 40% of capacity, owing to mechanical problems and the difficulty in obtaining spare parts. The Samsun smelter came onstream in 1977, and has never reached its designed capacity.

Turkey continued to examine the possibility of developing the Rize-Cayeli copper deposit in northwestern Turkey, also on the Black Sea coast. Reserves at Cayeli were a confirmed 34 million tons of ore and another 200 million tons of probable reserves. Etibank owned the concession, but the mine was to be operated by Fenni-Gamma Inc., the former Turkish private owner. Fenni-Gamma was, in 1980, seeking a foreign partner to initiate development. The U.S. Agency for International Development was also considering providing some financing.

Iron Ore.—Despite planned increases in output, Turkey remained a large importer of iron and steel. The state-owned Turkish Iron and Steel Works (Turkiye Demir ve Celik Isletmeleri) supplied most of Turkey's iron ore output, from the Divrigi Mine, located in Sivas-Malataya Province. Total capacity at Divrigi was 2.8 million tons per year of 52% to 58% iron. Other iron ore mines that were nationalized in 1978 were to be returned to their former private owners in an attempt to increase iron ore production, which dropped 35% after nationalization. Despite plans to increase capacity at Divrigi to 5.2 million tons per year, output remained at under 2 million tons.

The Government continued to study the development of the Hasancelebi iron ore deposit, located southwest of Divrigi. Hasancelebi possessed large reserves (300 million tons) of relatively low-grade (15% to 30%) magnetite ore. The ore grade was too low for direct charging, and would require substantial concentrating before conversion into sinter or pellet feed. No development plans were made for the deposit in 1980, owing to a lack of development capital and the questionable economic benefit of the project.

Iron and Steel.—The Turkish Government owned or participated in all three of Turkey's operating steel mills, at Karabuk, Iskenderen, and Eregli. Crude steel production for the year totaled around 2 million tons, which was down slightly from the 1979 level, and was far below the targeted output. The shortage of locally available iron ore, the lack of foreign exchange for imported iron ore and coking coal, and insufficient production of electricity to keep the mills operating all contributed to the low productivity of the plants.

The state-owned Turkish Iron and Steel Works (Turkiye Demir ve Celik Isletmeleri) operated two steel plants; in Karabuk, 175 kilometers north of Ankara, and Iskenderun, on the Mediterranean coast near the

Syrian border. Production capacity at Karabuk was 600,000 tons per year of crude steel. Karabuk received imported iron ore and coking coal from the U.S.S.R. The plant at Iskenderun continued to experience major operating problems. The work force at the plant, originally intended to be about 10,000 people, mushroomed to over 18,000 as the plant managers, under Government pressure, attempted to alleviate some of the local unemployment and in turn win support for the Government. The plant has not operated above 25% of its design capacity since it opened. The Soviet-built plant utilized domestic iron ore, but imported most of its coke. Design capacity of the plant was 1 million tons per year of raw steel. The plant was expected to run at a loss of about $30 million in 1980.

The sole example of high productivity and operating efficiency in the industry was the Eregli Iron and Steel Works Association. (Eregli Demir ve Celik Febrikalari T.A.S.), which was owned partly by the Government and partly by private shareholders. Initial capacity at the steelworks was 800,000 tons per year when it opened. In 1973, a contract was awarded to Nippon Kokan of Japan to expand capacity to 1.8 million tons per year through the addition of a new blast furnace. The furnace began operation in 1977, and by 1980 output had reached 3,000 tons per day, exceeding its design capacity and setting a Middle East production record. The Eregli works utilized iron ore from Divrigi as well as domestically produced coal and coke. To further expand its output, Eregli ordered a second single-strand slab caster in March 1980.

Plans to build Turkey's fourth integrated steelworks were postponed owing to problems existing at the plants already in operation. The Turkish Iron and Steelworks Inc. originally planned to build another plant located at Sivas in eastern Anatolia. The $1 billion complex was to produce 1.8 million tons of steel annually, utilizing domestic iron ore and coal. Izmir Metalurji Fabrikasi T.A.S., a privately owned company in Izmir, also planned to construct a direct-reduction steel mill 12 miles east of Izmir, with a total capacity of 600,000 tons per year. Insufficient quantities of high-grade ore, as well as the high-capital costs of direct-reduction technology curtailed these plans as well.

Lead-Zinc.—Etibank and Cinko-Kursun Metal Sanayii A.S. (CINKUR) were responsible for most of the lead-zinc ore and refined metal produced in Turkey. At Etibank's Keban Lead and Zinc Works, approximately 40,000 tons of ore was mined, containing an average of 4% lead and 4.5% zinc. Both lead and zinc concentrates were produced, with output averaging 3,000 tons of 50% zinc and 41% lead.

CINKUR, owned 47% by Etibank, mined lead-zinc ores from the Zamanti Mine where reserves were estimated at 3.5 million tons of high-grade lead-zinc ore. The CINKUR smelter, which was completed in 1976, processed around 80,000 tons of ore in the production of 3,600 tons of lead, 8,000 tons of zinc, and a small amount of silver.

Other producers of lead and zinc ore were Beril Maden ve Sanayi Ltd. Sti. from mines in the Nigde-Kayseri region, M. Kemal Dedeman, also in the Nigde Kayseri area, and Menka Sanayi ve Ticaret A.S. from Sivas.

Mercury.—The production of mercury is one of Turkey's oldest industries. Cinnabar ore has been mined from three main areas (Konya, Karaburun, and Aydin) for nearly 8,000 years. Production has declined steadily from a high of over 10,000 76-pound flasks in 1971 to an average of 5,000 flasks per year, owing mostly to declining world demand. Many occurrences of mercury have been reported, with considerable reserves, mostly in western and central Anatolia. MTA, the Mineral Research and Exploration Institute of Turkey, reported that mercury production could be greatly expanded should world demand increase.

Etibank was the only producer of mercury in 1980, from its two smelters at Halikoy, near the Aydin mines, and in Konya. The Halikoy smelter could produce 120 tons per year of 99% pure mercury, while capacity at the Konya smelter was 100 tons per year. Some of the smelting facilities at Halikoy were converted to antimony production in 1978 because of the low demand for mercury.

Tungsten.—Etibank's Uludag tungsten mine began operating in 1977, after nearly 25 years of planning, development, and problems. The mine is situated near the summit of Uludag Mountain, in eastern Bursa Province, 42 kilometers from the town of Bursa. The deposit was discovered in 1950 by Maden Tetkik ve Arama Enstitusu (MTA), who had carried out the exploration, feasibility studies, and a preliminary plan for production by 1954. In 1961, Etibank took over all rights to the ore body, while MTA continued to evaluate possible

mineral dressing techniques. The decision to go ahead with the project was made in 1968, and underground development work was begun. Austro Mineral (Austria) was contracted to prepare a development plan for the mine, and Salzgitter Industriebau GmbH of the Federal Republic of Germany was contracted for process designing of the concentration plant. A consulting firm, Bergbau Sachtleben of the Federal Republic of Germany was called in 1977 when problems were encountered during commissioning of the mine and concentrator. Since 1978, Etibank has carried out all work under short-term supervision by United Nations experts.

The ore at Uludag consists of both granitic and skarn types. The granitic ore contains wolframite, while the skarn ore contains scheelite. The scheelite is mostly in finely disseminated form.

The Uludag deposit contains 9.4 million tons of proven reserves, and another 4.9 million tons of probable reserves. The average estimated grade of ore is 0.5% WO_3. The ore is extracted by both underground and open pit mining, although the open pit is closed from fall to late spring because of severe winter snowfalls. Total ore production in 1980 was nearly 290,000 tons, 190,000 tons of which came from underground. Underground mining techniques switched from long-wall stoping to sublevel stoping, with the ore being broken out by ring drilling and blasting. At the open pit, visible reserves were about 2.1 million tons, with a stripping ratio of 1 cubic meter per ton of ore. All open pit mining was carried out by private firms under seasonal contracts, but Etibank planned to take over all production in the near future.

The concentrator at Uludag was designed to treat 550,000 tons per year of both granitic and skarn ores. Originally two separate processes for concentration were envisioned for the two types of ore, but because of equipment failure, the skarn ores' dry grinding and magnetic separators have not come into operation. Both types of ore were wet ground, using the granitic separator at 30% over its capacity for both types. Various grades of concentrate are achieved, ranging from 20% to over 50% WO_3. In 1980, a flotation scheme to complement the current processing technique was being tested, which was to provide a 60% WO_3 concentrate in the near future.

Etibank also planned to replace timbering in the mine with roof bolting and renew the underground haulage network by 1981. Plans for the mill included commissioning a new automated hydroclassifier by 1981, purchasing two high-capacity wet-magnetic separators, installing a tertiary crusher, and recovering scheelite from the process slime by flotation by 1981.

NONMETALS

Asbestos.—Production of asbestos rose to approximately 16,000 tons, owing mainly to increased output from the 10,000-ton-per-year processing plant built by Amyant Sanayi A.S. in 1976. The company was the largest producer of asbestos in Turkey, operating a 30,000- to 40,000-ton-per-year tremolite deposit at Mihaliceik, near Eskisehir. Despite the higher level of production, Turkey was expected to import 5,000 to 10,000 tons of asbestos for domestic use. Approximately five other manufacturers were mining deposits in the country, mainly for their own use. All of the other deposits were of the amphibole type. Among the producers were Bilfer Maden Ltd. Sirketi (5,000 tons per year), Ozgur Atermit Sanayi ve Ticaret A.S., Sark Amyant Isletmeri, and Erton Bulgurlu Ithracat Ithalat ve Dahili Ticaret.

Barite.—The barite industry in Turkey has expanded rapidly since 1974, when the Government banned the export of raw barite, in an attempt to increase the export value by forcing producers to install grinding equipment. Grinding capacity increased by 500,000 tons per year in just over 5 years. Most of Turkey's ground barites were exported to the U.S.S.R., and some to Iraq, but with new capacity onstream in 1980, producers were searching for new Western and Middle Eastern markets. Turkey's barite producers were as follows:

Company	Location, mine(s), mill(s)	Mine capacity (tons per year)	Grinding capacity (tons per year)
Bastas Barytes Industry and Trading Co. Inc.	Alanya-Sarikaraagac, Trabzon, Antalya.	150,000	120,000
Barit Maden Turk A.S	Marash, Adana	50,000	70,000
Polbar Baryte Industries A.S	Alanya	40,000	50,000
Baser Maden Sanayii ve Ticaret A.S	Sarikaraagac	60,000	80,000
Kimya Tesisleri Sanayi ve Ticaret A.S	Silifke-Kutahya, Yarimca-Kocaeli.	30,000	100,000
Emas Industrial Minerals A.S	Mas	60,000	60,000
Dolsan Dolgu Maddeleri Sanayi Kollektif Sirketi	Antalya, Eskisehir	40,000	10,000
Durmus Yaser ve Ogullari	Isparta, Izmir	10,000	10,000
Etibank	Beysehir	1,000	--
Kale Madencilik	Icel	1,000	--
Egemetal Madencilik	Mersin	1,000	--

Bastas Barytes Industry and Trading Co. was Turkey's largest producer of ground barite. Despite the large capacity of its mines in Alanya and Sarikaraagac, most of the raw material for its mill in Antalya was purchased from other producers. Bastas formerly ground barite for Polbar Baryte Industries until Polbar brought its own mill online in 1980.

Polbar also has part of its raw output ground by Kimya Tesisleri (Kimtes) in Istanbul. Baser Maden Sanayii ve Ticaret A.S. was in the process of installing an extension to its grinding plant in 1980 to produce 80,000 tons per year of micronized material down to 5 micrometers. Kimtes also recently completed an expansion project raising grinding capacity from 30,000 tons per year to 100,000 tons per year in 1979. Emas Industrial Minerals was another newcomer to the industry, opening its integrated mine and mill in 1978. Production remained low in 1980 because of electricity shortages. Emas planned to export most of its output to the Middle East. Other smaller producers, including Etibank, sold their mine output to the large grading companies. Etibank, however, planned to enter the industry by installing a grinding plant at Beysehir.

Boron.—In March 1979, the Government of Turkey issued a decree nationalizing all boron mines, as well as iron ore and lignite, in the country. Contrary to the Government's intentions of increasing output of the private mines, no boron was produced for 10 months following nationalization, and then only 20% of the amount of boron was produced as when the mines were in private hands. To rectify the production problem, the Government was considering returning the mines to their former private owners. Three of the four former operators were willing to accept the offer, but no action was taken by the Government during the year and boron output remained low.

Boron was mined by Etibank from three major deposits located in Bigadic, Kirka, and Emet, all in northwest Turkey. In Bigadic, Etibank operated a 150,000-ton-per-year open pit colemanite and ulexite mine. Some output of the mine was exported in raw form and the remainder was shipped to Etibank's Bandirma facility for processing. Etibank was in the process of constructing a 150,000-ton-per-year concentrator at Bigadic. No completion date was available. Reserves at Bigadic were estimated at 30 million tons containing 25% B_2O_3. In Emet, Etibank operated both underground and open cast mines. The colemanite ore was concentrated to obtain 40% to 47% B_2O_3 at the 500,000-ton-per-year Emet Colemanite Works.

At Kirka, Etibank took control of an integrated tincal mining and processing operation. The Kirka Mine had a total capacity of 400,000 tons per year of tincal, most of which was trucked to Bandirma for processing. A chemical complex was completed at Kirka in 1980, but low output of the mine delayed startup of the plant. The complex was designed to produce 180,000 tons per year of crude borax pentahydrate, 60,000 tons per year of refined anhydrous borax, and 6,000 tons per year of refined borax decahydrate.

Etibank's Bandirma borax and acid plant was opened in 1969 to refine borax from the Emet mines. In 1980, ores from Kirka, Emet, and Bigadic were processed at Bandirma, located on the Sea of Marmara in northwest Turkey. Annual capacity of the complex was 55,000 tons of borax decahydrate, 25,000 tons of boric acid, 20,000 tons of sodium perborate, 120,000 tons of sulfuric acid, and 55,000 tons of borax pentahydrate (if required). Etibank was in the process of

expanding the facility through the addition of a 100,000-ton-per-year boric acid plant and a 100,000-ton-per-year borax plant to be completed in 1982, and a 20,000-ton-per-year hydrogen peroxide plant to be completed in 1985.

Cement.—The capacity of the Turkish cement industry was nearly 20 million tons per year in 1980, while demand stood at approximately 12 million tons annually. Exports of cement were hindered by inadequate loading facilities at Turkish ports, and noncompetitive prices set by the Ministry of Trade. Actual production of cement in 1980 was 14 million tons, reflecting lower productivity caused by the shortage of fuel oil and electricity. Lower production was accompanied, however, by a general slackening in demand, thus maintaining a small surplus available for export.

Contracts for expanding cement production capacity were awarded to Fuller Co. (United States) by Cankkale Cimento Sanayii T.A.S. of Istanbul to raise capacity to 5,000 tons per day, and to KHD Industrieanlagen of the Federal Republic of Germany for construction of seven 1,750-metric-ton-per-day cement plants. The seven new plants were ordered by the state-owned Turkiye Cimento Sanayii T.A.S., which already owned and operated 15 of the country's 34 cement plants. Most of the units and raw materials for the plants were to be provided by Turkish companies, with only the main structural elements being imported from the Federal Republic of Germany.

Emery.—Turkey produced approximately 80% of the world's output of fine-grained emery. Etibank was the major producer, from its Milas Mine in western Anatolia. Production capacity at the mine was 30,000 tons per year of raw emery. The only other producer of any significance was L. Kitapci Mineral Co. Ltd., which operated several small mines in the Mugla area. Most of Turkey's emery was exported in raw form, for use in abrasives. Very little processing was carried out in the country. Only about 20 to 25 tons of emery powder and 10,000 tons of abrasives were exported, compared with approximately 25,000 tons of run-of-mine exported in 1980. Most of the output was exported to France, the United Kingdom, the Netherlands, and the Federal Republic of Germany.

Fertilizer Materials.—Production capacity of Turkey's fertilizer industry increased approximately 12% in 1980, through the addition of several units at the Bandirma fertilizer complex. Other planned expansions of the industry were tentatively shelved owing to the shortage of foreign currency to purchase equipment. Turkey produced approximately 7.6 million tons of fertilizers in 1980, well below the nearly 10 million tons required in the country. Most of Turkey's fertilizer plants operated at or below 60% of their capacity.

Despite the increases in overall capacity, production of fertilizers remained low, especially for phosphate fertilizers. At Bandirma, Bandirma Gubre Fabrikalari (Bagfas) operated a triple superphosphate plant, which was built in 1973. The plant originally produced single superphosphate from sulfuric acid, but was later converted to produce triple superphosphate from phosphoric acid. Two additional plants were added to the complex late in 1979 and in March 1980. The first was a 495,000-ton-per-year sulfuric acid unit and the second was a 40,000-ton-per-year nitrogen ammonium sulfate plant. Three additional units were to be commissioned by 1981. These were: A 145,000-ton-per-year phosphoric acid unit, a 15,000-ton-per-year diammonium phosphate plant, and a 150,000-ton-per-year complex fertilizer unit. Uhde of the Federal Republic of Germany was responsible for construction of the project, except for the sulfuric acid plant, which was constructed by Polimex-Cekop of Poland. The fertilizer unit was to be operated by Bagfas, while the acid units were to be operated by Isci Isadami Kimya Sanayii Kuruluslari (Iskur). Included in the expansion project were additional fertilizer loading and unloading facilities.

Phosphate.—Despite Turkey's large reserves of middle- to low-grade phosphate rock, the country continued to import over one-half million tons of phosphate rock per year, making it the country's largest mineral import. Turkey spent over $28 million on imports of phosphate in 1980.

Etibank was the only producer of phosphate rock from the southern Anatolian Phosphate Project at Mardin in southeast Turkey. Operating capacity at the Mazidag deposit was 250,000 tons per year of phosphate rock. Etibank contracted Beker Industries (United States) in 1978 to aid in developing the deposit, which has operated at only about 10% of rated capacity for the past 2 years. Total reserves at Mazidag were estimated at 410 million tons of phosphate rock, containing 10% to 25% P_2O_5.

Sulfur.—Etibank was a direct producer of sulfur from its underground and opencast

mine at the Keciborlu Works, where production capacity was 20,000 tons per year of pure sulfur. The rest of the country's sulfur output came from fertilizer plants and sulfide ores used for manufacturing copper, from which a pyrite concentrate was obtained. All of the concentrate was consumed in acid production. Acid production from the country's copper works and fertilizer plants was 495,000 tons per year of sulfuric acid from the new plant at Bandirma, 365,000 tons per year of technical-grade acid from the Black Sea Copper Works, and a small amount of acid from the Ergani Copper Plant. Pyrite ores from Murgul were trucked to Hopa where they were concentrated. About 20,000 tons per year of pyrite was concentrated at Hopa in 1980.

Magnesite.—Turkey produced approximately 500,000 tons of magnesite in 1980, 90% of which came from four major producers operating in the Kutahya, Eskisehir, and Konya Districts. The magnesite industry has experienced major problems in recent years, mainly caused by lack of financing, poor conditions in the world market, and labor problems. Labor unrest forced one magnesite plant to close late in 1979.

Dead-burned magnesite was produced by Kutahya Manyezit Isletmeleri A.S. (Kumas), Manyezite A.S., and Sumerbank. Kumas was by far the largest producer operating three deposits in Kutahya, with a total capacity of 250,000 tons per year, and a calcining plant, also in Kutahya, with a 180,000-ton-per-year capacity. Kumas was considering building a brick manufacturing plant at Kutahya, instead of selling some of its output to the brick plant operated by Sumerbank at Konya.

Manyezit A.S. also operated its mines in the Kutahya-Eskisehir region. Production capacity of the Manyezit Mine was 120,000 tons per year of crude ore and 60,000 tons per year of calcined magnesite. The company was originally a subsidiary of Veitscher (Austria), but was in the process of changing ownership, possibly to Continental Madencilik Sanayi ve Ticaret A.S. (Comag), or the Government.

Sumerbank, the last major producer of dead-burned magnesite, was also the only producer of refractory bricks. The sinter magnesite capacity of the plant, located in Konya, was 40,000 tons per year. Brick capacity was 26,000 tons per year. Magnesite ore from the Konya area was generally of lower quality and higher in silica and lime content than ore from the Kutahya-Eskisehir District. Sumerbank supplemented its mining operation with high-grade ore produced by Kumas.

Comag was the country's largest producer of caustic calcined magnesite. Magnesite ore was mined in two areas, Tavsanli and Kumbet, and calcining plants were located adjacent to both mines. The plant at Tavsanli was operating at about one-third of its capacity, while the Kumbet plant operated quite profitably in 1980. Raw material for the Kumbet plant was high-grade magnesite, very low in silica and iron. Output of the calcining plant was suitable for use in electrofused magnesia products, the price for which was nearly double that of agricultural-grade products.

Other producers of magnesite in Turkey were Bozuyuk Kimya Sanayi in Eskisehir, Ismail Sahin and Koycegiz Kromlari Isletmeri A.S., also in Eskisehir, and Mittas Metalurji Ticaret A.S. in Erzurum. Output from the other producers was below 40,000 tons of ore per year.

Perlite.—Perlite production rose 15% in 1980 as a result of increasing world demand. Several mines were operating in the country, with the two major operations located in Cumaovasi, Izmir. Etibank developed the integrated Cumaovasi Mine and processing plant in 1975. Annual production capacity from the operation was 140,000 tons of processed perlite and 50,000 to 60,000 cubic meters of expanded perlite. Raw material for the Etibank grinding and processing plant was supplied by two mines, one several hundred meters from the plant, reserves at which were 4.5 million tons proven and another 5.6 million tons probable. Raw material was also available from the Minassa deposit, several kilometers away. Perlite from Minassa had significantly better expansion characteristics than the perlite from the plant area. Reserves at Minassa were estimated at about 7 million tons, of which 2.5 million tons were proven.

The other major producer of perlite in Turkey was Zihni International Trade and Marketing, whose mine was also located in Izmir. Annual production capacity of the mine was 50,000 tons. The company was considering setting up a grinding plant with a capacity of 75,000 to 100,000 tons per year. Other smaller perlite producers were Izmir Perlit Madencilik Ltd. Sti. at Bergama (3,000 tons per year) and Pabalk Ticaret ve Perlit Sanayi A.S. near Istanbul.

MINERAL FUELS

Total electric power generating capacity in Turkey in 1980 was 4,600 megawatt hours. Of the total electricity produced, approximately 45% is from hydroelectric plants, with the remaining 55% from thermal generating stations. Approximately 34% of electricity produced by thermal plants was from oil-fired furnaces, and 66% was from coal; mostly lignite and a small amount of hard coal. Annual increases in demand for electricity have averaged 500 to 600 megawatts. Because of the difficulty in expanding coal mining operations, the lack of foreign currency to purchase new coal-fired thermal stations, and the antiquated nature of the coal transportation network, increases in electricity demand have been met almost solely by increasing imports of oil, for which the Turkish economy has paid a stiff price. Because of the oil import bill and the rising demand for electricity, energy projects were receiving top priority by the new Government of Turkey. The emphasis was placed on expanding coal production and increasing the capacity of coal-generated electricity.

Coal.—Turkey has pinned most of its hopes for energy independence on coal and lignite. The state-owned Turkish Coal Authority (TKI) was the sole producer of hard coal, and also produced from 70% to 80% of all lignite. TKI operates in conjunction with the Turkish Electricity Authority (TEK) who installs the thermal power stations in lignite mining areas. Despite the emphasis on coal production and coal-fired power stations, most coal mines operated below capacity, owing mostly to bottlenecks in transporting coal from the mining areas to the power stations. Even with its ample reserves of both hard coal and lignite, Turkey imported around 20% of its total domestic requirements.

Hard coal was produced by TKI from the Zonguldak District. Annual production was about 4 million tons per year from several mines, including Kandili, Kozlu, Uzulmez, and Gelik. The mines were operated by Ergeli Komuleri Isletmeri under the authority of TKI. Production of privately held mines in the same area accounted for less than 1% of total hard coal production. Reserves of hard coal in the country were estimated at 1.2 billion tons. Turkey still had to import metallurgical coal for use in the Iskenderun and Eregli steel mills.

In October 1978, the Turkish Government nationalized nearly all lignite mines in the country in an attempt to increase their productivity. With production under the authority of TKI, annual lignite output declined over 30%, owing to poor management of the mines, labor disputes, and a shortage of diesel oil to run the machinery. Production in 1980 rebounded somewhat, but remained below the annual output from when the mines were privately owned.

Lignite was produced in several areas around the country. Major mines were located in Tunebilek, Soma, Beypazari, and Seyitomer. Production capacity at all of TKI's lignite operations was nearly 20 million tons per year. Production or transportation problems existed at nearly every location, holding production to around 60% of total capacity. Total lignite reserves in the country were estimated at about 6 billion tons.

TKI planned expansion projects for several of the major lignite mines. Production capacity at Beypazari was to be upgraded to 3 million tons per year at a cost of over $85 million. Production at Tunebilek was to reach 2 million tons per year by 1981 at a cost of about $24 million. The mines at Seyitomer were to increase capacity to 1.2 million tons per year also by 1981 for about $18 million. The mines at Soma were also scheduled to undergo expansion to produce 7.8 million tons per year of lignite in two separate projects, Soma-Isiklar and Soma-Denis. The Soma-Isiklar project was to be integrated with a thermal power station. The project was scheduled for completion in 1981.

By far the largest and most ambitious project in TKI's expansion program was for the Afsin-Elbistan region, where construction had already begun on an integrated 20-million-ton-per-year lignite mining operation and a 2,400-megawatt thermal power station. The powerplant was to be the largest lignite-fueled powerplant in the world. Construction began in 1977 on the power station, and in 1979, 4.2 million cubic meters of overburden were stripped off the coal deposit on which the plant sits. Reserves at Elbistan were estimated at around 2 billion tons of lignite. Cost of the project was estimated at over $3 billion, 60% of which required foreign financing. The first phase of the integrated operation was to come onstream sometime in 1982. The second phase of the project, still in the planning stage, was to produce another 20 million tons per year of lignite to fuel four addi-

tional generators. The first phase alone was to burn 60,000 tons of lignite per day, and employ over 6,000 people.

TKI and TEK planned to construct several other integrated coal mine power stations, although Afsin-Elbistan was preempting most of the investment funds. Other plants were planned for Bursa-Orhaneli, Bursa-Keles, Mugla-Yatagan, Sivas-Kangal, and Tekindag-Saray. Because of the economic situation in Turkey, the initiation of any new projects during the construction of the Afsin-Elbistan plant appeared unlikely.

Petroleum.—Turkey was one of the countries most seriously affected by the oil price increases in 1979. The Government spent more than its income from exports on imported oil, leaving little for manufactured goods and development projects. The annual oil import bill was expected to exceed $3 billion in 1980. Combined with the increasing price of imported oil, domestic crude oil production has been declining since 1969. The need to purchase imported oil and the resulting divergence of foreign currency away from the productive sectors has fueled runaway inflation and left the economy with serious difficulties. New exploration and production agreements with foreign firms may be able to reverse the decline in domestic production, but it is unlikely that the country's oil problem will disappear in the near future.

Production.—Domestic production of crude oil in Turkey was at its maximum in 1969, at about 70,000 barrels per day. It has declined unevenly since then to about 46,000 barrels per day in 1980. Production rose unexpectedly in 1979 to 56,000 barrels per day in response to the severe shortage during that year, but dropped again in 1980. The declining production was due to the fact that most of Turkey's wells were 10 to 20 years old and now facing water problems.

The major oil producer in Turkey was the state-owned Turkiye Petrolleri Anonim Ortakliki (TPAO), which produced approximately 35% of all crude oil in the country. N.V. Turkse Shell, a subsidiary of U.S. Shell, produced about the same amount, and Mobil Exploration Mediterranean Inc. (a Mobil Oil Corp. subsidiary) and Erson Petrol Sanayii both produced about 15% of the total. Domestic production accounted for about 14% of the country's petroleum requirements.

The International Bank for Reconstruction and Development (IBRD) (United States) was considering loaning Turkey $50 million for an enhanced secondary recovery program for the Bati Raman Oilfield. Bati Raman, located in southeastern Turkey near the Syrian-Iraq border, was the country's most productive field, producing slightly less than 10,000 barrels per day. Enhanced recovery programs at other fields were not expected to yield significant results until 1982 or later. Turkey's oil reserves were estimated at about 400 million barrels.

As part of the economic recovery program initiated in 1979, and endorsed by the military Government, new decree's were issued to encourage foreign investment in the oil sector and an Office of Foreign Investments was established in 1980 to promote these investments.

The new decrees abolished most of the disincentives of the 1973 decrees as well as promoting the use of foreign expertise, reopening processing industries to foreign companies, and permitting companies to export 35% of production and to use these proceeds for the repatriation of their capital and profit. The TPAO became entitled to enter joint ventures with foreign firms, and was permitted to accept international arbitration in its joint venture agreements. An exploration fund was also established for both state and private companies to facilitate oil exploration.

Exploration.—The new decrees have attracted some international attention. Shell, already operating in Turkey, picked up two additional exploration permits in the Agachan site in the Siverek District of Urfa. Other foreign firms to express an interest were Veba, of the Deminex group (Federal Republic of Germany), CFP Total (France), and three United States companies; Phillips 66, Occidential Petroleum, and Sunmark of California.

Under TPAO's own exploration program, approximately 75 test wells were drilled in 1980, 17 of which encountered hydrocarbons. Results of the tests were not conclusive enough to determine the size of additional reserves. TPAO made a potentially sizable discovery at Nusaybin, 20 kilometers from Camurlu, near the Syrian border. Initial estimates put the potential production from one well at 1,000 barrels per day. TPAO also encountered significant quantities of natural gas at Thrace. Initial production from the wells was 3 million cubic feet per day, which has since risen to 5.2 million cubic feet per day with six wells producing from the field. New discoveries were not

expected to have an impact on Turkey's domestic production until 1982.

Pipelines.—1980 was a difficult year for Turkey in terms of assured supplies of imported oil. Two of Turkey's major suppliers, Iran and Iraq, almost completely dried up in September 1980 at the start of the Iran-Iraq war. Turkey had just completed an agreement with Iran to purchase 60,000 barrels of oil per day, making Turkey Iran's fourth largest customer. Oil sales from Iraq, which were transited mainly through the Kirkuk to Yumurtalik (Botas) pipeline, were to reach 35 million barrels in 1980, only 24.5 million barrels of which had been delivered when the pipeline was bombed in September. Iraq and Turkey had also agreed to increase the capacity of the pipeline from 700,000 barrels per day to about 1 million barrels per day. Included in the agreement were plans to construct a joint refinery and petrochemical complex in Yumutalik, near Ceyhan, to build a natural gas pipeline to carry Iraqi natural gas to Turkey, and to build another pipeline from Yumurtalik to a projected 10,000-barrel-per-day oil refinery near Ankara. The war temporarily or permanently shelved most of these plans. Late in September, Turkey's oil stocks dwindled to below 1 month's supply.

In an effort to make up some of the shortfall caused by the war, several Persian Gulf nations agreed to increase their output and aid Turkey's supply situation. Turkey was in the process of negotiating a long-term contract with Saudi Arabia late in 1980. Turkey also concluded an agreement with the U.S.S.R. for delivery of an unspecified amount of oil. As Turkey's foreign exchange crunch eases and oil from Iraq resumes flowing through the pipeline, Turkey's chronic shortage of supplies is expected to improve.

Refining.—All four refineries in Turkey were owned by the state organization, TPAO. The Anandolu Tasfiyehanesi A.S. refinery, originally owned by Mobil Oil Corp. (United States), Royal Dutch/Shell (Netherlands), British Petroleum, and Marmara Refining, was nationalized because it was operating below capacity. TPAO, once in control, was unable to increase its output, the problem being a shortage of crude oil input. In April 1980, TPAO allowed Mobil to use the refinery for a nominal fee if Mobil would bring in the necessary crude oil to be paid for by the Government. The refinery was able to operate near capacity for the rest of the year. TPAO's other refineries, at Izmir, Batman, and Aliaga operated near capacity, with only temporary interruptions in crude oil supply.

The Istanbul Petrol Refineri A.S. (IPRAS) refinery at Izmir was owned 99% by TPAO, but operated autonomously from the state. Originally built by the California-Texas Petroleum Co. (United States), the refinery was the most efficient in the country. Expansion was underway at IPRAS to bring capacity to 250,000 barrels per day from the current 150,000 barrels per day. The lack of foreign exchange has delayed startup of the new capacity.

Turkey and Iraq signed an agreement in December 1980 to set up a joint venture refinery and petrochemical complex near the terminus of the Kirkuk-Yumurtalik pipeline. Whether Iraq plans to go ahead with the project despite its loss of output from the Iran-Iraq war was unclear.

Petrochemicals.—Turkey's petrochemical industry was founded in 1956 with the opening of the Batman refinery. A state-owned organization, Petkim Petrochemicals Corp. was formed in 1965 to operate Turkey's first petrochemical complex, which opened in Yarimca in 1970. Increasing demand for petrochemical products in the 1970's led to the decision to expand the Yarimca complex and establish a second plant at Aliaga. The state organization produced petrochemical raw materials that were used mostly by the private sector in producing semimanufactured items, such as synthetic fibers and chemical compounds.

The Yarimca plant, currently the only producer of raw petrochemicals in Turkey, was to complete its expansion program by 1982. The second petrochemical complex, at Aliaga, was under construction, and the estimated completion date was sometime in 1984. Most of the financing for the $1.5 billion Aliaga plant has been obtained, and contracts for construction of all units were signed.

Petkim was preparing to establish a third petrochemical complex, at Yumurtalik, in a joint venture with Iraq. The complex was to be located near the terminus of the Kirkuk-Yumurtalik pipeline, and operate on Iraqi crude oil or natural gas. The plant was to be composed of 19 units and was to cost an estimated $2 billion. No tenders were called for as of the end of 1980, and Iraq's participation in the project was called into question since the start of the war. The products and capacities of Turkey's petrochemical

plants are given in the following tabulations.

Petkim-Yarimca

Product	Current capacity (tons per year)	Expanded capacity (1982) (tons per year)
Ethylene	30,000	55,000
LD polyethylene	12,000	27,000
Vinyl chloride monomer (VCM)	27,000	54,000
Polyvinyl chloride	26,000	52,000
Styrene	25,000	25,000
Polystyrene	15,000	15,000
Chlor alkali	18,000	36,000
Carbon black	15,000	30,000
Dodecylbenzene	10,000	20,000
Coprolactum	25,000	25,000

Petkim-Aliaga (1984)

Product	Capacity (tons per year)
HD polyethylene	40,000
LD polyethylene	150,000
Polypropylene	60,000
Chlor alkali:	
Chlorine	65,000
Caustic soda	73,000
Vinyl chloride monomer (VCM)	105,000
Polyvinyl chloride (PVC)	100,000
Naphtha cracking:	
Ethylene	300,000
Propylene	150,000
C_4	80,000
Prolysis gasoline	215,000
Aromatics:	
Benzene	115,000
P-xylene	110,000
O-xylene	65,000
Pure terephthalic acid	70,000
Ethylene oxide	54,000
Ethylene glycol	68,000
Phthalic anhydride	30,000
Acrylonitrite	70,000

Uranium.—The findings of the uranium study conducted by the Woods Hole Oceanographic Institute and the Institute of Paleontology at Hamburg University were called into question by a subsequent investigation by MTA. The original study speculated that around 6.7 million tons of uranium oxide was present in deepwater basins in the Black Sea. The new study indicated that little uranium was present on the sea floor near the Turkish coast, but the uranium level increased slightly at depths of 2,000 meters or more. The estimated reserves on the sea floor were reduced to 2.2 million tons of ore. The study reported that uranium deposits on land in the eastern Black Sea region were more economic from an extraction and processing standpoint.

The Mineral Industry of the U.S.S.R.[1]

By V. V. Strishkov[2]

The U.S.S.R.'s completely nationalized economy maintained its position as the world's second largest producer of industrial products in 1980. In the Soviet Union, 1980 marked the end of the 10th 5-year plan for 1976-80. The following production increases, compared with that of 1979, have been reported in million tons: Oil (including condensate), 17.4; natural gas (billion cubic meters), 28.4; iron ore, 3.3; mineral fertilizers, 9.5 (Soviet standard); and cement, 2. Electric power output increased 57 billion kilowatt-hours. Output of many nonferrous, rare, and precious metals, oil refinery and petroleum products, and nonmetallic minerals was slightly higher than in 1979. Production of the following mineral commodities decreased, compared with that of 1979, in million tons: Raw coal, 2.7; crude steel, 1.0; and finished rolled ferrous metals, 0.2.

The U.S.S.R. is the leading world producer of iron ore, manganese ore, platinum-group metals, petroleum, steel, potassium salts, asbestos, and cement. The U.S.S.R. occupies second place, following the United States, in world output of aluminum, lead, natural gas, coal, and phosphate rock; it ranks second, after Canada, in the production of nickel and follows South Africa in gold and chromium ore output.

In 1980, official industrial production rose only 3.6% (4.5% planned), national income increased by 3.7% (4% planned), and the Soviet Union has confirmed that its economy had suffered its second worst year since World War II. Heavy industry grew 3.7% (4.5% planned) and consumer goods production rose 3.5% (4.5% planned). Industrial labor productivity grew only 2.6% (3.8% planned).

Soviet mineral production statistics released by the Central Statistical Administration ("Pravda," January 24, 1981) show that production goals contained in the 1976-80 5-year plan were not met. The revised goals for 1980, which were approved in December 1979, were also not met except for natural gas production. The 1980 annual plan was not fulfilled for the extraction of crude oil, coal, the production of pig iron, crude steel, finished ferrous rolled metals, iron ore, mineral fertilizers, cement, and many nonferrous and precious metals. The coal and ferrous industries enterprises not only failed to cope with the target but actually reduced their output in comparison with that of 1979.

On the whole, the Soviet mineral industry is lagging in respect to planned targets. Despite the fact the U.S.S.R. is the world's leading producer of steel, pig iron, mineral fertilizers, and cement, the mineral industry has failed to deliver to the economy its requirement of iron, steel, rolled metal, cement, mineral fertilizers, and other products. The shortage of metals and cement is holding back the development of allied industries, especially machine building and construction. This is because the performance of the Soviet industry is measured by units of gross production rather than units efficiently consumed in the economy.

Table 1 gives planned and reported figures for 1979 and 1980.

Table 1.—U.S.S.R.: Soviet industrial production

(Million tons)

Commodity	1979		1980		
			Planned		
	Planned	Reported	Originally (low-range)	Revised goal	Reported
Iron ore (usable)	NA	NA	276	NA	245
Pig iron	114	NA	NA	115	NA
Steel, raw	156	149	169	157	148
Coal, raw (bituminous, anthracite, lignite)	752	719	800	745	716
Crude oil (including condensate)	593	586	620	606	603
Natural gas (billion cubic meters)	404	407	400	435	435
Mineral fertilizers (Soviet standard)	111	95	143	115	104
Cement	NA	123	143	NA	125
Power, electric (billion kilowatt-hours)	1,265	1,239	1,340	1,295	1,295

NA Not available.

The U.S.S.R.'s reported mineral commodity consumption per capita approaches that of Western Europe, although there is still a significant difference in the living standards. One reason for the apparent difference is that the Soviet growth is measured in terms of energy and minerals produced, not in terms of energy and minerals usefully consumed. In addition, fuel and mineral shortages often bring with them substandard commodities that are marketed as standard items.

Although comparisons of minerals data between the Soviet Union and those of Western countries are often made, they are rarely valid unless qualified in great detail. The relative size or the relative growth of the Soviet mineral industry can be determined from a careful and exhaustive study of all pertinent Soviet publications. Soviet self-criticism, although sometimes reported in an obscure fashion, shows an acute awareness of their problems.

The central economic problem is the slowdown in the growth of industrial production. The economy grew at an annual rate of 6% in the 1950's, 5% in the 1960's, 3.5% by the mid-1970's, and probably will only grow by 2% to 2.5% in the 1980's.

Mineral Industry Labor.—With a total population of 266.6 million in January 1981 (a growth of 2.1 million in 1980), the Soviet economy employed 112.5 million industrial workers and 13.5 million farmers. In 1979, women accounted for more than 51% of the labor force. In the U.S.S.R., 9 out of every 10 women of working age (i.e. 16 to 55 years old) work in the Soviet economy. Only 1 woman out of 10 does not work, chiefly in families with many children, or cares for a very young child. The employment of both spouses is characteristic of the Soviet family. Until recently, women represented a major labor reserve but the main sources for labor force growth have been practically exhausted and the use of other CMEA[3] member nations' labor is growing in the Soviet Union. For example, Polish workers are constructing the Surgut-Polotsk oil pipeline, extending 153 kilometers, and Bulgarian workers are working on construction in the Turkmen S.S.R. The CMEA member countries are assisting in developing the Soviet mineral industry with a view toward obtaining crude oil, natural gas, metals, and other raw materials.

Practically all sectors of the mineral industry maintained a greater number of production personnel than called for by plan targets. This is done for a number of reasons, including unforeseen breakdowns in production, demands to send industrial workers to do agricultural work, and the transfer of workers to perform community service.

The Soviet ferrous and nonferrous industries employed over 3 million workers,[4] including 130,000 persons in the transportation sector of the nonferrous industry alone,[5] and the coal industry employed 2.2 million workers.[6] The oil, gas, and petrochemical industries employed 2.6 million workers, including over 250,000 in the development of oilfields and gasfields.[7] The crude oil extraction industry employed about 740,000 persons.[8] There were about 155,000 graduate mining engineers in the Soviet economy in 1980, who were trained at 38 Soviet institutes.

The work week in the U.S.S.R. is 41 hours for standard workers and 36 hours for underground miners. Soviet statistical agencies do not publish data on the actual earnings of mineral industry workers. The average official monthly earnings of all Soviet workers and employees in 1980 was

168.5 rubles[9] compared with 163.5 rubles in 1979, an increase of 3%. In 1980, the monthly minimum wage was 70 rubles.

Because of the falling increment of the able-bodied population, labor shortages have become a major problem for the Soviet economy. During the period 1981-90, the labor growth rate will not rise above 4% compared with 18% during the past 10 years. The main cause of this is the decline of the birth rate, as a result of remote consequences of World War II. More than 94% of the able-bodied population are already drawn into the economy. Nearly 2 million jobs are vacant in the economy of the U.S.S.R., with an economic demand growing by 0.8 million workers annually. However, it must also be stressed that in the early 1990's the situation in the labor resources will improve.

With the approval of the Soviet trade union, thousands of coal mines are being forced to work 7 days a week, including Sundays, while thousands more have to work double shifts during the week. The free days, usually Sundays, have been gradually made into workdays in some mines of the Donets Coal Basin. According to "Labor,"[10] throughout the Ministry of the Coal Industry of the Ukrainian S.S.R., the whole period from March to July 1980, inclusive, were working days. Despite this, 74 of the 92 mines of the Voroshilovgrad Oblast' did not fulfill their planned targets. The weekly repairs on the mines used to be done on Sundays, but mining on Sundays does not permit machinery to be kept in repair.

Government Policies and Programs.—Soviet mineral policy is predicated on the principle of maximum self-sufficiency at all costs. With state-owned and state-operated enterprises, low-wage labor, and low consumption, the U.S.S.R. has become the most self-sufficient of the world's leading industrial nations. In the Soviet economy, the price mechanism is set to yield desired results (often political) other than profitability; thus some mineral ventures in the Soviet Union might well be uneconomic by Western standards. Mineral development, as the basis of industrial growth, holds a key place in the Soviet economic policy. Very large sums are spent on mineral exploration and production, and the funds are distributed over a dozen specialized ministries.

Balance in the Soviet economy is achieved by Government intervention through subsidies, controls, and similar measures. The Soviet mineral economy has been a totally planned economy since 1929. Production goals are established at a very senior level and are approved by the Supreme Soviet of the U.S.S.R. One of the most striking contrasts between Soviet and Western mineral economies is the clear direction given to the development of Soviet mineral policy. In most market-orientated economies, national mineral policy is largely an accommodation of often divergent and conflicting sectors of the economy. In contrast, the Soviet Union's 5-year plan and year-to-year plans set a definite policy for all mineral commodities. In addition to expressing national priorities within which each industry must operate and individual industry goals, the plan is also law and carries mandatory obligations.

The measures for reorganizing the Soviet planning system approved by the CPSU Central Committee and the U.S.S.R. Council of Ministers on July 29, 1979, do not signify any basic reorientation of Soviet economic policy. A reorganization within the planning and bonus system is designed to promote the intensive factors in economic growth, particularly such matters as increases in productivity and expansion of contractual relations, which are simultaneously supposed to improve horizontal coordination within the economic process.

The current operating gross cost indices show the fulfillment of the plan in tonnage and rubles. Society is interested in the reduction of production costs, but the enterprises, seeking to fulfill their planned targets in gross tonnage and ruble value, find it more expedient and profitable to produce heavier and expensive products. For example, in 1980 certain metallurgical enterprises failed to deliver a substantial volume of valuable products to consumers. At the same time, they successfully fulfilled their plans for marketing. Until now the basic evaluation index has been gross production, but according to the new decree, results are to be evaluated by the index of net production. Soviet planners believe that the net output index will remove the incentive to use the more expensive raw materials and semifinished goods, thus decreasing the cost of an enterprise's gross output.

The new standard net output indicators (introduced in the reform decree of July 29, 1979) possess some advantages in comparison with quantitative indicators of production. However, the comparison is extremely

complex and, to a certain extent, artificial in practical application. The main difficulty will be the evaluation of the final results of economic performance. In this instance, enterprises would not simply fulfill quotas but would also strive for more complete satisfaction of national economic requirements.

Consequently, there is some doubt about the effectiveness of the new measures, because of (1) shortages of practically all goods and (2) the continued use of the quantitative index "production of tons." Better coordination between the individual sectors of the economy and a steady rise in efficiency could probably be achieved only if the Soviet leadership could permit a greater measure of market-oriented regulation and sanctions imposed by the market and if functioning mechanisms for this were to be established.

New wholesale prices are to be introduced in the U.S.S.R. on January 1, 1982. An estimated 12 million different prices will be involved. The last comprehensive reform of wholesale prices occurred in 1967. Retail prices will, in general, not be affected. An increase in the wholesale prices of fuel and raw materials will lead to higher costs not only in industry, but also in other sectors of the Soviet economy.

In the past 4 years there have been three official increases in prices. On January 5, 1977, prices were raised for certain consumer goods and travel. On March 1, 1978, gasoline prices were approximately doubled and coffee prices were approximately tripled. At the same time, the cost of gold and platinum increased by 60% and that of chocolate products increased by 30%. Prices on a number of goods in the U.S.S.R. went up on July 1, 1979; for example, automobiles increased by 18%; imported furniture increased by 30%; and articles made of precious metals increased by an average of 50%.

Much attention is now being paid to economic "integration" and industrial "cooperation" within the CMEA group of countries, and this tends to make East Europe, Mongolia, Cuba, and Vietnam more dependent upon the Soviet mineral industry. The East European countries are uniformly interested in the widening of economic contacts with the Western countries. The CMEA countries have adopted special programs for long-term cooperation until 1990 in energy, fuel, raw materials, the agricultural food industry, and machine building.

The Plan for Multilateral Integration Measures for the CMEA countries (1976-80), included among other Soviet projects, the joint construction and financing of the Kiyembay asbestos complex (both stages completed), the development of the Orenburg gasfield and gas pipeline from Orenburg to the Soviet western border (completed), the 750 kilovolt transmission line from Vinnitsa to the Hungarian border (completed), and new facilities for iron ore mining, ferroalloys production, and petroleum refining elsewhere in the U.S.S.R. (under construction). Reportedly, the total investment in joint projects involves about 9 billion transferable rubles by participating CMEA countries with provisions for repayment to be made in raw material produced (asbestos, iron ore, ferroalloys, natural gas, petroleum, and electrical power).

CMEA joint construction of nuclear powerplants, with a total capacity of 37,000 megawatts, is to start in the 1980's. The Khmelnitskiy nuclear powerplant in the Ukraine, with a capacity of 4,000 megawatts, is to be completed by 1984. The total investment in the project is expected to be 1,500 million transferable rubles, half of which will be contributed by the Soviet Union. Of the remainder, Poland is committed to deliver goods and services, including equipment and labor, to the value of 400 million transferable rubles; Czechoslovakia will supply the four reactors for the project, "technological" equipment, transport vehicles (including Tatra trucks), machine tools, and other machinery to the value of 240 million transferable rubles; and Hungary will supply communications equipment, buses, construction equipment, and building materials to the value of 110 million transferable rubles.

In return for their investment in the project, the three East European contributors will recieve, as full payment, electricity produced by the powerplant over the period 1984-2003; the amount of electricity each country will receive will be proportional to its investment. The Soviet Union will retain exclusive legal ownership of the powerplant.

The second nuclear powerplant has the same capacity of 4,000 megawatts, consisting of four 1,000-megawatt VVER-type reactors. It is apparently to be located in Konstantinovka in the Ukraine. It remains unclear which countries will participate and what their commitment to the project will be. Apparently, the three contributors to the Khmelnitskiy project (Czechoslova-

kia, Hungary, and Poland) will also contribute to the new scheme. According to "Economic Gazette," Romania will participate in this project and also in the installation of the Soviet-Romania-Bulgaria powerline.

In addition to its commitments under multilateral agreements with the Soviet Union, Poland has contracted to participate in the construction of more nuclear powerplants in the U.S.S.R. Under this bilateral agreement, Poland will take part in the construction of the Kursk and Smolensk nuclear powerplants. During 1980, 1,300 to 1,600 Polish workers were employed in the construction of various Soviet nuclear powerplants. Between 1982 and 1983 this number is planned to increase to about 4,500.

The Soviet Union is turning to its CMEA partners for assistance in improving the low level of recovery in its oilfields. Romania is the only other important oil producer in East Europe and it may be called upon to provide equipment and technology to increase oil recovery in return for Soviet oil deliveries. The U.S.S.R. has undertaken an extensive minerals development project in Romania in an attempt to further secure nonferrous metals.

Czechoslovakia has signed a contract to supply to the U.S.S.R. 300 locomotives of the CME-3 type and 600 trams of the T-3 and KP-4 types. The Grimme chemical engineering complex in Leipzig, the German Democratic Republic (GDR), will supply the U.S.S.R. with 26 oil-processing plants. The first has gone into trial operation at Surgut in Western Siberia.

A long-term program of economic, scientific, and technical cooperation between the U.S.S.R. and Yugoslavia was signed in September. The value of goods exchanged in the 1981-85 period is expected to total $26 billion, compared with about $16 billion in 1976-80.

Because of the limited availabilities of good-quality machinery, the U.S.S.R., in an attempt to accelerate the development of its mineral resources, is showing increasing interest in joint development ventures and in the exchange of scientific and technical services with foreign (mainly western) countries and firms. While the law prohibits any direct foreign capital investment in the U.S.S.R., the Soviet Union is anxious to attract West European, U.S., and Japanese firms to participate in joint production and marketing. Foreign investors are invited to develop deposits and to construct plants in the U.S.S.R., and repayment is promised in the form of commodities produced by these operations. The joint ventures should give the Soviets help with one of their biggest problems, the efficient introduction and application of new technology.

The barter-type arrangements fall into two broad categories. The cost of a plant purchased from the West is repaid by goods produced by the plant or by other Soviet goods.

According to Soviet sources, the value of buy-back agreements and contracts is estimated at several thousand million rubles for many projects in the chemical, petrochemical, petroleum, gas, and coal industries as well as in ferrous and nonferrous metallurgy. Some of the arrangements with the West have also involved CMEA joint investment projects. This category includes the agreement with Austrian, French, Italian, and West German firms for the delivery of large-diameter steel pipes, fittings, equipment, and materials for developing the gasfields and building gas pipelines. Deliveries of natural gas will pay for the credits.

This type of transaction fits well with the Soviet planning system. The foreign trade organizations do not have to worry about the lack of hard currency, and the Soviets do not need to search for markets to earn the much-needed hard currencies.

In the 1976-80 period, compensation agreements were covered by 60 large-scale industrial projects with two-thirds of the projects in the chemical and petrochemical industries. Large amounts of imported equipment were supplied to enterprises in the coal and ferrous and nonferrous metal industries. Most compensation agreements do not fix prices on Soviet-produced commodities; they just formulate the principle of their adjustment to current world competitive prices. Many compensation projects are being constructed in the remote Eastern and Northern parts of the U.S.S.R.

Some metallurgical complexes under construction in the U.S.S.R., with imported equipment under compensation deals are: An electrometallurgical complex (direct reduction of iron ore) in Staryy Oskol, Belgorod Oblast', supplied with equipment by West German firms; the Nadezhda nickel-copper-platinum-group metals dressing and smelting complex in Norilsk, equipment is supplied by Finnish firms; a large alumina plant in Nikolayev, Ukraine, and a primary aluminum plant in Sayansk, Siberia, equip-

ment supplied by French firms; and a mining and iron ore concentration complex in Kostomuksha, the Karel Autonomous Republic, with the participation of Finnish firms.

Reportedly, in December 1980, the Japanese Export-Import Bank signed a contract providing the U.S.S.R. with loans totaling $1,000 million (208,800 million yen). The loans, which will carry an annual interest of close to 7.25%, will help finance the Neryunga coal and forestry development projects in Siberia.

U.S.S.R. and West Germany are expanding their long-term economic and industrial cooperation, as outlined in the Soviet-West German 25-year agreement signed on May 6, 1978. The agreement foresees joint exploration for oil and natural gas in coastal regions of the Soviet Union, and joint projects to exploit and process raw materials and metals. A long-term program for the development of economic, scientific, technical, and industrial cooperation between the U.S.S.R. and Austria in the period 1981-90 was signed on January 19, 1980.

A U.S.-Soviet-Japanese project for developing natural gas reserves in Yakutia has been indefinitely postponed.

The U.S.S.R. Ministry for Production of Mineral Fertilizers was setup in October 1980. It was signed out from the U.S.S.R. Ministry of Chemical Industry to accelerate development of the mineral fertilizers industry.

The Soviet Union encourages state control over mineral resources in developing countries. The U.S.S.R. sends out technical advisors and makes loans to countries willing to promote state development and distribution of fuels and minerals. Soviet technical assistance and economic aid programs include several hundred projects at a cost of over 5 billion rubles. The CMEA International Investment Bank has setup a special fund of 1 billion rubles to grant credits for economic and technical assistance to developing countries. The fund started functioning in January 1974. During 1980, the number of CMEA technicians rose to 90,000.

Soviet influence in developing countries is based on substantial armament deliveries and economic aid which, in recent years, has reached record proportions. The U.S.S.R. grants economic, scientific, and technological aid to 90 Asian, African, and Latin American countries. Soviet aid in mineral extraction, particularly in bauxite, is geared to sustaining the huge requirements of the Soviet domestic economy. These requirements, apart from political considerations, have brought about a large-scale effort to develop foreign mineral sources of supply. Thus, in many instances, the assistance to developing countries is linked with mineral supplies to the U.S.S.R.

The Soviets have been racing to develop foreign mineral sources of supply. The U.S.S.R. has negotiated many technical and economic assistance agreements with mineral-rich developing countries. In many instances, the assistance to developing countries is linked with mineral supplies to the U.S.S.R.

The U.S.S.R. and Morocco have started implementation of a large-scale, long-term (20 years) agreement on economic and technical cooperation in the sphere of phosphates. The project is the development of the Meskala phosphate deposit and is estimated to cost $2,000 million.

In Asia, the Soviet Union and other CMEA members are helping Iraq develop its mining, oil processing, and power engineering. More than 100 projects have been built or are under construction with Soviet aid. The U.S.S.R. has provided vast sums of money for the development of India's steel industry and construction of powerplants. It has aided India in coal mining and in exploration for oil. Soviet-Turkish discussions on the expansion of economic and technological cooperation in energy, ferrous and nonferrous metallurgy, oil refining, and other fields continued in 1980. An agreement on coordinating the 1981-85 Soviet and Laos state plans was signed on September 12, 1980.

In Africa, the first Nigerian metallurgical works is to be built with Soviet assistance. The capacity of this plant is to be 1.3 million tons per year of steel. It will be built near a deposit of iron ore discovered and proved by Soviet geologists. Under an agreement, the U.S.S.R. will help Ethiopia in the construction of cement works and in prospecting for oil and gas. Reportedly, Brazilian officials are in favor of the formation of a Soviet-Brazilian metallurgy cooperative, proposed in November by a Soviet delegation visting there.

Mineral Industry Technology.—The Soviet Union employs over 3 million scientists and technicians in research and development, and spends over 20 billion rubles annually for scientific work. It has long occupied first place in the world in the number of engineering graduates employed

in its economy and also in the number of students graduating from higher technical schools. In nonferrous metallurgy alone, there were over 40 scientific-designing institutes, which employed over 12,500 professionals including 100 Doctors of Sciences and 2,600 Kandidates of Sciences.[11] There are more than 3.5 million engineering graduates at work, compared with about 1 million in the United States. This fact is frequently cited in Soviet publications, apparently as evidence of the country's advanced state of technical development. However, a straight comparison of the numbers of engineering graduates ignores the quality and effectiveness of their preparation. This view is borne out by numerous references in the Soviet press concerning the poor qualifications of technical personnel.

Soviet technology for reducing alumina to aluminum is about 10 to 12 years behind Western technology. Pechiney Ugine Kuhlmann Corp. of France is helping the Soviets build the U.S.S.R. aluminum industry. The U.S.S.R.'s steel industry relies heavily on open-hearth furnace production. The Soviets lag in powder metallurgy electric steel and stainless steel production.

The mechanization of labor intensive manual work in the Soviet economy is proceeding very slowly. In the past several years, the number of manual workers has increased substantially and at many mines and plants up to one-half of the production workers were employed in manual labor, including surface loading and unloading. According to *Problems of Economics*,[12] there were about 45 million manual workers in the Soviet economy in 1974. The work performed manually without machines is indicated by the following figures: 55.7% at coal mines, 60% at longwalls, 57% in development, and 100% on repair of workings. At nonferrous mines and plants in Kazakhstan, manual labor comprises 54% and planned production goals are met by increasing the level of manual operations. More than 50% of the heavy and labor-intensive operations at ferrous-metallurgical enterprises have to be done manually. Over 67% of the workers in blast furnace production perform manual operations. The situation is somewhat better in steel-smelting production, where 55.8% of the workers perform manual labor.[13]

The equipment currently used in mining is not large by Western standards. Excavators with scoop capacities of 4 to 8 cubic meters and dump-trucks of 20- to 40-ton capacity are mainly used instead of 12- to 20-cubic-meter shovels in combination with trucks of 110- to 180-ton capacity that are actually required. The use of the 500-horsepower bulldozer to replace four of the T-100s now in use makes it possible to release 12 workers.[14] The main trouble, however, is that the machine builders have been failing to manufacture new equipment for many years. Over the past 10 years, only one-third of the equipment ordered for nonferrous metallurgy has been supplied.[15]

Equipment used in the Soviet mineral industry is standardized and of types made earlier in Western Europe and the United States.The production of mining equipment has grown substantially, but the technical standards and the quality is poor. Production facilities are enlarged chiefly by quantitative expansion of the equipment with very inadequate replacement of obsolete and worn-out machinery, and replacement frequently does not affect the technical level of production. As a result of this extensive growth in the production facilities, the number of jobs rises much faster than the number of workers that can fill them.[16]

The reserves in the thin coal seams of the Donets Basin account for 83% of the total. But the equipment for mining thin seams is not available, and they are mined by old, wide-cut equipment. Chokotka, like the rest of the north, is experiencing a shortage of equipment specifically designed for northern use.

The tunneling machines, manufactured by the Yasinovatskiy machine-building plant and the new excavators type "EKG-8u" are of very poor quality and tend to breakdown after a few days of operation.[17] The lack of pilot and experimental facilities is only one of the reasons for the delays encountered by the implementation of technical innovations.

Because of the poor quality of equipment and shortage of spare parts, many excavators, dump trucks, and other equipment stand idle for long periods of time. For example, half of the 27- and 40-ton dump trucks at the Dneprovsk iron ore mining and concentration complex in the Ukraine are badly in need of repair. Because of shortages of spare parts and materials, in the first half of 1979 alone, the shovels stood idle waiting for repair for more than 37,000 machine-hours and the dump trucks waited 75,000 machine-hours. The peletizing plant

at this complex is not operating consistently.[18] The repair shop has not been constructed at the Mikhaylovsk iron ore mining and concentration complex in the Kursk Magnetic Anomaly area. This resulted in unsatisfactory conditions of mechanization at this complex.[19]

Almost 30% of the concentration plants in the nonferrous industry continued to underfulfill the planned targets for the extraction of metals into concentrate. The greatest number of plants that do not meet their extraction quotas are in Kazakhstan, Uzbekistan, and in the Urals. Among them are the Tekeli, Kentau, Almalyk, Kirovgrad, and Sredneuralsk concentration plants. Above-quota losses of metals are the result of poorly organized technological sampling of deposits, an uneven-paced delivery of ore to concentrators, and deviations from the planned composition of ore to be treated.[20]

The majority of nonferrous metallurgical plants and especially Norilsk (Cu-Ni-Co-Pt), Pechenga (Cu-Ni-Co-Pt), Severonikel (Cu-Ni-Co-Pt), Yuzhuralnikel (Ni), Krasnoural'sk (Cu-Au-Ag), Ufaleysk (Ni), Sredneuralsk (Cu-Au-Ag), Chimkent (Pb), and the Elektrotsink (Zn), have not met their planned targets for the recovery of metals.[21]

Recovery of copper from copper-zinc ores in the Urals ranges from 70% (Sibay) to 87% (Kirovograd), average 82.9%, and that of zinc ranges from 47% (Gay) to 74% (Sibay), an average 60%.

Processing of ores at the nonferrous concentration plants in Kazakhstan increased in 1980 by 13% compared with that of 1972, but the content of lead decreased by 24.5%, and that of zinc decreased by 38.9% (relatively) during that period.

Many projects have operated over a long period with lower capacities than originally planned. For example, in January 1980, only 6 of Kazakhstan's 23 nonferrous industry complexes attained designed capacity. At the Madneulskiy mining and concentration complex, designed capacity for mining of ore was attained by only 26% and that at the Urupskiy mining and concentration complex by only 50%. At the Achinsk alumina plant designed capacity was attained by 73% and that at the Krasnoyarsk primary aluminum plant by 75%.[22] Unattained designed capacities could have produced 11 million tons of cement in 1980.[23]

At many Soviet mineral industry enterprises, the number of workers greatly exceeded the design parameter. For example, the Zodskiy gold ore mine in Armenia employed 220 persons above the planned quota and at the Karamken gold ore mine in the Soviet Far East almost 400 employees were above the planned quota in 1980.[24]

The Soviet economy is going through one of its worst periods since the end of World War II, and a rapid increase in productivity is needed. The planned average annual increase of productivity for the period 1976-80 was 6.1%, but the actual official increases have been 3.3% in 1976, 4.0% in 1977, 3.6% in 1978, 2.4% in 1979, and 2.6% in 1980. The 1981 plan calls for an increase of 3.6%, much too high a figure. As there can be little hope of an increased total labor force, the growth of production can only come from increased productivity. However, the yearly average labor productivity growth has been decreasing.

Transfer of Technology.—Scientific and technological cooperation with developed Western countries holds an important place in the system of foreign economic relations of the U.S.S.R. Recently, these programs have become longer term and larger in scale. Western technology is a key factor that can favorably influence Soviet economic performance. The transfer of technology and licensed manufacture of products is largely one-sided, with the U.S.S.R. usually on the receiving end. The import of Western technology does not resolve many of the contradictions in the Soviet economy, but it does accelerate industrialization.

The rate of growth in Soviet trade with the West will slow substantially during the next few years. In the 1973-78 period, Western companies completed more than 60 compensation agreements. In the next 5-year period (1981-85), Soviet planners expect that only 15 new compensation projects will be completed. According to Soviet sources, projects for the chemical industry will receive less attention in the future. Demand for Western technology by the U.S.S.R. is unlikely to diminish and the gap between Eastern and Western technology will continue.

In the past decade, the Soviet Union has made a major effort to catchup with Western technology. Some progress has been made, but import of Western technology does not resolve many of the contradictions in the Soviet economy. Imports of Western technology and equipment have not given a sharp boost to Soviet productivity.

The Soviet Union has technical cooperation with Austria, Belgium, Britain, Denmark, Spain, Italy, Canada, the Nether-

lands, Norway, Portugal, Federal Republic of Germany (FRG), Finland, France, Switzerland, Sweden, and Japan. U.S. exports of high technology items to the U.S.S.R. will continue to be banned for the foreseeable future. The Soviets' scientific and technical ties with the industrially developed Western countries are an important element in the development of Soviet industry.

West Germany was the largest Western exporter of equipment and machinery to the U.S.S.R. in 1980. Its involvement includes deliveries of trucks for the construction of the Baykal-Amur Main Railway (BAR), the Kama automobile works, the Oskol metallurgical complex, and a number of large chemical complexes. Daimler Benz has received Soviet orders worth Deutsche marks (DM)15 million for 150- to 320-horsepower trucks. Krupp of Essen is to build an electrosmelting plant at the Soviet iron and steel complex in Staryy Oskol, near Kursk, which is to start operating in 1982. Under the contract, signed in Moscow in March 1979, four electric furnaces are to be installed, mainly for the production of high-grade steel (1.45 million tons per year). The contract is worth about DM350 million to Krupp, and the total cost of the electric steel plant is estimated at DM600 million. The project is largely being undertaken by Krupp and four other German companies. Within the framework of an agreement worth DM50 million, the Schiess AG Group will supply a mill capable of working pieces weighing up to 800 tons.

Reportedly, a Klockner-led consortium has signed a contract with the Soviet Metallurgimport for the supply of a carbon-anode plant for the Sayansk aluminum complex in southern Siberia. The contract, worth DM555 million, includes the supply of equipment worth F 420 million from the French Klockner subsidiary. The anode plant will have a capacity of 350,000 tons per year and will be installed in the 400,000- to 500,000-ton-per-year Sayansk aluminum complex. The first of five potlines at the smelter is scheduled to begin operation early 1984.

In June 1980, the U.S.S.R. State Committee for Science and Technology and the West German company Hoesch signed an agreement on the technology for making pipes for oil and gas pipelines. Under the agreement, the FRG is to receive considerable quantities of Soviet natural gas. In June, Soviet Mashinoimport and the West German firm Borsig signed a contract for the delivery to the U.S.S.R. of valves for gas pipelines and compressor installations for the chemical industry. Carl Schenek of the FRG has announced that its group of companies has won a Soviet order for vibroscreens for a large coal preparation plant. The total order is for 33 screens, each 9.5 meters by 2.9 meters of the latest design.

The large crane ship Azerbaydzhan, which had been built by Blom and Voss in Hamburg on Soviet order, was put into operation in Baku. The giant crane is able to lift steel structures weighing thousands of tons to a height of 32 meters and install them in offshore areas at depths of as much as 300 meters. This is more than three times the depth at which Caspian engineers have worked before.

The Soviet Union and France have signed agreements on scientific industrial and technical cooperation for 1980-90 and an economic cooperation for 1980-85. In 1980, French companies concluded a number of large new contracts for supplying the U.S.S.R. with plants and equipment for various branches of industry amounting to over F 3,000 million. These include in particular: Creusot Loire SA was given the $350 million order from the U.S.S.R. for the construction of an electrical steel plant, with a capacity of 480,000 tons per year. In April, French Pont-a-Mousson signed a contract to build a plant in Lipetsk to produce 180,000 tons per year of 100- to 300-millimeter diameter steel pipe. A new rolling mill has been commissioned at the Moscow pipe plant, the second mill to be delivered by the French firm Wean-Damiron. There is also a joint large-scale project under way—the construction of a gas trunk line, which may secure a supply of 10,000 to 13,000 million cubic meters per year of natural gas to France from the U.S.S.R.

The Soviet Union depends on Western, in particular United States, oil and gas technology. Reportedly, the U.S. Department of Commerce has approved 75 applications for the export of petroleum equipment to the U.S.S.R. The value of equipment and machinery to be delivered is understood to be about $280 million. Dresser Industries has sold a $144 million plant to manufacture oil drilling bits. The Soviet Mashinoimport has awarded a $15 million contract to International Enterprise Inc. of Oklahoma City, Okla. (United States), for 10 combination drilling rigs. The company exported six similar drilling rigs in 1977. The Caterpillar

Tractor Co. has sold to the U.S.S.R. some $1 billion worth of equipment for laying a natural gas pipeline from Siberia to Western Europe. Fiat-Allis Construction Machinery Inc. will sell 300 large bulldozers (model 31S with 425-horsepower) to the U.S.S.R. for about $90 million. The machinery has been designed to operate in temperatures as low as 40° below zero. The Soviet Union has been using Fiat-Allis model 41Bc, the company's largest with 500-horsepower, since 1974 in gold mining.

Reportedly, Montedison SpA of Italy and the Soviet Union signed a 10-year commercial and industrial cooperation agreement valued at $1,500 million. Montedison will supply equipment and technical assistance valued at $800 million for the construction of seven chemical plants in the U.S.S.R. The construction of these plants is to be completed by 1987. Montedison will purchase Soviet ammonia, crude oil, and other goods valued at $700 million. In 1931, Montedison built the first ammonia plant in the U.S.S.R. Between 1973 and 1979, Montedison built six Soviet chemical plants. Soviet Sudoimport has placed an order for three cargo ships with the Viana do Castelo shipyard of Portugal. The vessels are to be delivered to the U.S.S.R. by January 1983.

The 5-year extension of the Finland-U.S.S.R. 15-year agreement (to 1995) and the agreement for cooperation in stages II and III of the Kostamus project was signed in November. According to the agreement, the production capacity of the Kostamus complex under construction will be raised from 3 million tons per year to 9 million tons per year of iron pellets. The value of this agreement is about $750 million. It is planned to complete stage I by 1982.

The semisubmersible offshore drilling rig, constructed in Finland on Soviet order, has arrived. Wells can be drilled up to 6,000 meters deep through water up to 200 meters deep. Three floating Arctic drilling ships are being built for the U.S.S.R. in Finland. The ships are designed to work in waters as deep as 300 meters and drill to 6,000 meters. The first such ship is due in 1981. The shipbuilding firm of Waertsilae has contracted to supply the U.S.S.R. with seven river icebreakers in 1983-84. The value of the order is about FM700 million. Soviet Sudoimport has signed a contract with the Finnish firm Laivateollisuus for five research ships. The Rauma Repola of Finland has received a 500 million Finnish marks order for the construction of 12 cargo vessels and drilling ships. The Valmet Engineering Co. of Finland has received an order worth nearly $50 million from the U.S.S.R. for the construction of five Arctic cargo vessels to be used on the rivers of northern Siberia. Discussion on Soviet-Finnish cooperation on the construction in Finland of a nuclear powerplant continued in 1980.

The Soviet Union and Austria have signed an agreement on cooperation in the manufacture and marketing of nuclear energy equipment. This will cover the construction of a turbine plant in Leningrad and the supply of Austrian equipment for a nuclear research center being built with Soviet assistance in Libya. Reportedly, Denver Equipment (United States) has completed delivery of the first stage of an order valued at L500,000 for a large iron ore project in the U.S.S.R. The complete order involves the supply of two thickeners (30 meters and 55 meters in diameter), four agitators (18.3 meters by 13.7 meters), together with a number of slurry pumps and auxiliary equipment. The Export-Import Bank of Japan has granted the U.S.S.R. credits of more than $200,000 million for the development of timber and coal resources of Siberia and the Soviet Far East. Most of the money will be spent on buying Japanese equipment for these projects. A long-term agreement providing for the further expansion of Soviet-Japanese cooperative trade was signed in December 1980.

Over 90% of the natural gas supplied by the U.S.S.R. to Western Europe is exported under compensation agreements signed between 1968 and 1974. Discussions with West German energy companies on the construction of a 4,500-kilometer natural gas pipeline, from Western Siberia to Europe at a cost of $11,600 million, continued in 1980. It could be in operation by 1986 with a 40,000-million-cubic-meter-per-year capacity.

A 3,000-millimeter rolling mill for the Il'ich plant in Zhdanov has been imported from Czechoslovakia. The mill will produce special high-quality steel sheet 5 to 25 millimeters thick for oil and gas pipelines. Equipment for the third stage of Cuba's only steelworks is to be supplied by the U.S.S.R. and Czechoslovakia in 1981-88. The total capacity of the plant (three stages) is to be 680,000 tons per year. The Soviet Union will supply equipment for the third stage of the Bruno Leuschner nuclear powerplant in the GDR, which has a capacity of 880 megawatts. A 400,000-ton-per-year

continuous slab caster for Bulgaria is under construction at the Uralmash plant in Sverdlovsk, U.S.S.R. The design of the third stage of the Kozloduy nuclear powerplant in Bulgaria is to be done by the U.S.S.R. The basic equipment for this stage is to be supplied by the Soviet Union in 1983.

The U.S.S.R. and Yugoslavia have concluded a second contract for the export to the Soviet Union of 20 steam separators for 1,000-megawatt nuclear powerplants. The value of the contract is about $170 million; the first consignment is to be sent in the second half of 1981. The first contract also provided for export to the U.S.S.R. of 20 separators, 13 of which have been supplied. The second stage of the Novi Sad oil refinery is being built with Soviet help. The basic materials and equipment have already been delivered from the U.S.S.R. The Soviet Union is also assisting in building the Skopje oil refinery in Yugoslavia.

The U.S.S.R. has officially confirmed that it is to continue to provide assistance to India in expanding the steel industry along with plans for the development of India's coal, oil, and aluminum industries. According to an Indian-U.S.S.R. agreement for 1980-82, Soviet know-how will be available for improving Indian steel plant technology. Construction of Sail's Vizag steel plant, with a capacity of 3.4 million tons per year to be completed by 1988. Under an Indian-Soviet agreement concluded in October 1980, the U.S.S.R. is to provide India with the latest know-how on coal mining and to help redesign its coal washers.

The Soviet Union plans to assist Iran with construction of an 800-megawatt thermal powerplant. Reportedly, the U.S.S.R. has offered to supply badly needed spare parts for Iran's oil and gas production equipment. The Soviet Union is assisting Pakistan with construction of a 1.1-million-ton-per-year steel works project at Birr Oasim near Karachi. The majority of the cost of the project is to be met by credit from the U.S.S.R. Soviet experts are working with the Vietnamese to put the offshore drilling project for oil and gas into commercial operation in 1982. The U.S.S.R. is assisting Mongolia in the construction of the Hotd cement and lime complex.

In April, Algeria and the Soviet Union signed an agreement to extend scientific and technical cooperation. The U.S.S.R. is to assist in construction of a 630-megawatt thermal powerplant. In Ethiopia, the Soviet Union is renovating the 600,000-ton-per-year Assab oil refinery. The U.S.S.R. and Nigeria have resolved differences arising from delays in the construction of the Ajaokuta steel project. The first stage, with a capacity of 400,000 tons per year of slab, is now set to come onstream in the first half of 1981. Construction of a mining and concentration complex was completed at Mfouati in the People's Republic of the Congo with Soviet technical and financial assistance. The enterprise is to produce 30,000 tons per year of lead and zinc concentrate. Part of the concentrate is to be sent to the U.S.S.R. The Soviet Union and Mozambique have signed a major economic agreement that covers mining, industrial, agricultural, and shipping areas.

A joint commission to exchange technological information has been established by the U.S.S.R. and Bolivia. Faster construction of the Lia Palca low-grade tin volatilization plant in Potoci and the start of construction for a similar plant at Machacamarca, in Oruro, have been discussed. According to Bolivian sources, the U.S.S.R. is interested in cooperation with Bolivia in the search for the exploitation of hydrocarbons. The second hydroelectric powerplant is being built in Brazil with Soviet technical and financial assistance. Reportedly, after studying the power-generating potential of the country's rivers, a group of Soviet experts have prepared a report on the feasibility of building a hydroelectric powerplant in Nicaragua. In 1981-85, the U.S.S.R. is to provide Cuba with assistance in the construction of an 880-megawatt nuclear powerplant and a metallurgical works with a capacity of 1.3 million tons per year of steel.

Indian, Algerian, and Turkish blast furnace, steel, smelter, and rolling mill operators are being trained at the Soviet Azov plant in Zhdanov. More than 100 technicians from Asia, Africa, and Latin America have been trained at the plant's school for improving the qualifications of production leaders from developing countries over the past 10 years.

The 11th 5-Year Plan (1981-85).—The 5-year plan for 1981-85 was ratified by the 26th Congress of CPSS on March 2, 1981. The targets of the 10th plan (1976-80) were to be high in most of the important economic areas, but the 11th plan (1981-85) is characterized by reduced ambitions. Industrial output in the 5-year period is to be increased by 26% to 28%, including means of production (Group A) by 26% to 28%

and consumer goods (Group B) by 27% to 29%. Labor productivity in industry is to be increased by 23% to 25%. More than 90% of the increase in production must be derived from this plan. The number of workers involved in manual labor in all branches is to be steadily reduced, especially in auxiliary work. The quality of all products is to be improved.

Capital investments are to be concentrated on the most important projects that were due for startup during previous years, and, above all, on the reconstruction and technical reequipping of existing enterprises. Construction of new production projects is to be restricted in the European part of the country.

Over the 5-year period, a saving of fuel and energy resources amounting to 160 to 170 million tons of standard fuel is to be secured, including 70 to 80 million tons resulting from reduced consumption. There is to be a reduction in consumption of ferrous rolled metal by no less than 18% to 20%, of steel pipe by 10% to 12%, and nonferrous rolled metals by 9% to 11% in machine building and metal processing. There is also to be a saving of ferrous rolled metal and timber materials by 7% to 9% and of cement by 5% to 7% in the construction sector.

Utilization of fuel and energy resources must be improved. Consumption of oil and petroleum products, such as boiler and furnace fuel, must be reduced. The nuclear power industry must be developed at an accelerated rate. Extensive use must be made of comprehensive processing of raw materials, resource-saving technology, and technological processes that produce little or no waste. Utilization of production facilities and basic assets must be improved.

The unit capacities of machinery and equipment are to be raised to an optimum with a simultaneous reduction of their dimensions, metal input, and power consumption, and lowering the cost of production per unit.

The following data show the principal goals for individual mineral commodities in the new 5-year plan:

1. The generation of 1,500 billion to 1,600 billion kilowatt-hours of electricity in 1985 is planned, including up to 220 billion to 225 billion kilowatt-hours at nuclear powerplants and up to 230 million to 235 million kilowatt-hours at hydroelectric powerplants. The increase in electricity generation in the European part of the U.S.S.R. must be ensured, mainly, by nuclear and hydroelectric powerplants. New facilities of 24 million to 25 million kilowatts of nuclear powerplants must be put into operation. Construction of thermal powerplants using coal from the Ekibastuz and Kansk-Achinsk Basins, as well as natural and associated gas from West Siberian fields, must be carried out at an accelerated pace.

Construction of the Smolenskaya, Kalininskaya, Kurskaya, Balakovskaya, and Rostovskaya nuclear powerplants must be completed by 1985. The capacity of the Chernobyl, Yuzhno-Ukrainskaya, and Rovno nuclear powerplants in the Ukraine are to be increased and construction of the Khmelnitskiy, Zaporozhye, and Crimean nuclear powerplants and the Odessa thermocentral powerplant will start and the first stages are to be commissioned.

2. In 1981-85, crude oil and gas condensate output is to be increased 620 million to 645 million tons. The oil-extracting industry in West Siberia, Kazakhstan, and in the north of the country's European part must be developed at a faster pace. The application of new methods of treating oilfields must be expanded thus increasing recovery of oil from the strata. A progressive method of gas lift working of the wells and highly productive submersible electric pumps must be introduced. In 1985, the proportion of oil extraction at comprehensively automated oilfields must be increased 85% to 90%. Labor expenditures on drilling wells must be reduced by 15% to 18%. The production of oil and gas condensate in Siberia is to be increased in 1985 to 385 million to 395 million tons. Pipeline networks are to be expanded, mainly to bring oil from Siberia to the European part of the U.S.S.R.

It is planned to raise the volume of primary oil processing. In the Soviet Far East the development of the oil refining industry will expand. Construction of the Chimkent and the second stage of the Pavlodar refineries are to be completed by 1985. Efficiency of utilization of oil in the petroleum-refining industry is to be raised. A further deepening of its refining and reduction of losses of oil and petroleum products must be ensured. Large-tonnage production of aromatic hydrocarbons, liquid fuel, ethylene, petroleum, and eletrode coke must be attained. Production of highly effective additives to fuels and lubricants must be increased; and the quality of petroleum products produced must be raised.

3. Natural gas production is to be increas-

ed to 600 billion to 640 billion cubic meters in 1985. The production of gas in Siberia is to be increased to 330 billion to 370 billion cubic meters. Construction of powerful gas trunk pipelines must be implemented. There is to be a special effort to increase construction of underground gas storage units near large cities.

4. Raw coal (bituminous, anthracite, and lignite) production in 1985 is to be increased 7% to 12% over the 1980 level. This would bring production from 716 million tons in 1980 to 770 million to 800 million tons in 1985. Coal extraction is to be increased at a rapid rate by the surface method in the Kuznetsk, Kansk-Achinsk, and Ekibastuz Basins. Development of open pit coal, the construction of a coal concentrator, and the first stage of the thermal powerplant at Neryunga in Yakutia must be completed by 1985. There is to be development of underground coal mining, particularly for coking requirements, and mining by hydraulic method. The quality of coal supplied to the national economy is to be improved. Conditions of labor and accident prevention are to be improved. The increase in coal production is to be brought about mainly by increasing labor productivity.

According to Soviet sources, over 7 million people work in the energy sector of the economy and over one-third of the capital investment in industry is used in the development of the energy complex.

5. Raw steel production is to be increased and output of finished rolled steel products is to reach 117 million to 120 million tons in 1985. In the iron and steel industry, special attention is to be devoted to improving quality and expanding the range of products. Increase in raw steel output is to be obtained by developing the oxygen converter and electric steel smelting methods. Electric steel production is to be increased by 60%. The amount of continuous-casting steel is to be raised to 35 to 37 million tons.

Expansion of the steel industry remains high on the list of priorities of the U.S.S.R., although the emphasis is swinging away from tonnage output toward improvement of quality and more efficient shapes of products. The production of cold-rolled sheet, rolled metal subjected to hardening by heat treatment and made from low-alloy steel, thin sheet metal including extremely thin sheet with protective coatings, cold-rolled strip, dynamo steel, special-section and high-precision rolled metal, and thick steel plate is to be increased 50% to 150%. The production of threaded pipes for the oil industry with new types of thread connection and anticorrrosive coatings, high-strength pipes for high-pressure boilers, pipes for bearings, and pipes for nuclear power engineering is to be developed at an accelerated rate. The production of multilayer pipes for a gas pipeline is to be attained.

There is to be rapid development of the raw material base of ferrous metallurgy. The metal content in iron, manganese, and chromium concentrates is to be raised. It is planned to put into operation the Stoylenskiy iron ore mining and concentration complex in the Kursk Magnetic Anomaly area, with a capacity of 9 million tons per year of concentrate and facilities for extraction of iron ore at the Kacharskiy mining and concentration complex in Kazakhstan in 1985.

6. In nonferrous metals, production of aluminum is to be raised 15% to 20%; copper production is to increase 20% to 25%; and nickel and cobalt production is to be increased by no less than 30%. There will be an increase in the production of zinc, lead, titanium, magnesium, precious metals, tungsten and molybdenum concentrates, columbium, and other alloying elements. The construction of mining and concentration complexes at new deposits is to be accelerated. Output of nonferrous metals is to be increased chiefly by raising labor productivity.

Kazakhstan will continue to be one of the largest producers of nonferrous metals. It is planned to complete construction of the second stage of the Zharmsk and the first stage of the Boshchekul mining and concentration complexes in Kazakhstan. Development of the Annensk and Spassk mines of the Dzhezkazgan complex, and new mining facilities at the Mirgamaliysk and Shalkinsk deposits in this Republic are to be completed by 1985.

The plan calls for construction of additional production facilities at the Pavlodar alumina plant and at the Ust'-Kamenogorsk lead-zinc complex (70 million rubles investment) in Kazakhstan. New potlines are to be commissioned at the Regar aluminum plant in Tadzhikistan, and production of aluminum is to start at the Sayansk plant in Siberia.

There will be a renovation of nonferrous enterprises in Armenia, as well as a major expansion of the Norilsk copper-nickel and platinum-group metals complex, which is to

be completed by 1985. It is planned to complete construction of the Orlovsk mining and concentration complex and the development of the Orlovsk and Spokoynensk polymetallic deposits in the Chita Oblast' by 1985. Output of copper and production of lead-zinc ore at the Almalyk complex in Uzbekistan are to be increased during the 1981-85 period. The 5-year plan also calls for the beginning of construction of a tin mining and concentration complex and completion of a gold complex in Tadzhikistan. Design work on the Udokan copper deposit in East Siberia is to be completed by 1985.

However, development of the Soviet nonferrous industry will face problems with mine depletion, declining metal content in the ore, and lagging development of new mining, concentration, and smelting facilities.

7. Output of mineral fertilizer is programed to grow by almost 50% to 150 to 155 million tons per year in Soviet standard units or 36 to 37 million tons in terms of 100% nutrient content. The most rapid rate of growth is to be in the production of phosphorous fertilizers. It is planned to increase output of apatite concentrate in the Kola Peninsula and expand the production of phosphate rock at Karatau in Kazakhstan by 50%. Output of potassium fertilizers in Belorussia is to be increased by 40%, and the output of concentrated and compound fertilizers is to be extended. From 1985, potassium fertilizers are to be supplied to agriculture only in granulated form. Labor productivity in this industry is to be increased by 28% to 30%. In 1985, the supply of mineral fertilizers to agriculture is to be not less than 115 million tons in Soviet standard units or 26.7 million tons in 100% nutrient content. Chemical feed additives are to amount to 5 million tons.

8. Geological prospecting activities are given special attention in the new 5-year plan, largely for exploration for oil, natural gas, and condensate fields in Tyumen Oblast, in Eastern Siberia, the European part of the U.S.S.R., Central Asia, and Kazakhstan, and on the continental shelfs. Prospecting for deposits of coking coal, energy coal, and lignites (particularly in the European part of the U.S.S.R.), for easily concentrated ores for ferrous and nonferrous industries, for precious metals and diamonds, for bauxite and raw materials, for the nuclear energy industry, and for the production of mineral fertilizers will continue in 1981-85.

9. The increase in output of machine building is to be no less than 40%. Labor productivity is to increase by 31% to 35%. Cement production is to reach 140 to 142 million tons in 1985.

10. About 3,500 kilometers of new railway lines were built in the 1976-80 period. The total length of Soviet railways is now more than 141,000 kilometers. In the new 5-year plan, no less than 3,600 kilometers of new railway lines are to be commissioned, over 6,000 kilometers are to be electrified, and more than 5,000 kilometers of double tracks are to be built. The entire length of the BAR is to be opened to rail traffic. The turnover of cargo by railway transportation is to be increased by 14% to 15% and passenger turnover is to increase by 9%. Labor productivity is to be raised by 10% to 12%.

In maritime transportation, the cargo turnover is to be increased by 8% to 9%. Construction of the second stage of the Vostochnyy deepwater port near Vladivostok in the Soviet Far East is to start during the new 5-year plan period. Pipeline transportation is to receive accelerated development, particularly for oil, natural gas, and petroleum products. The quality of construction of pipelines is to be raised. In air transportation, the network of airports will be developed, particularly in areas of the North Siberia and the Far East.

11. To carry out this plan, large resources will be required. Capital investment in the U.S.S.R. for the next 5 years has been set at a level of over 700 billion rubles, an increase of 12% to 15% over the preceeding 5-year period. Capital investment must be channeled first into reconstruction and technical reequipment of enterprises and into completion of construction projects started earlier. One of the most important developments under the new plan is the geographical shift in new projects.

In the European part of the country, and in the Urals, the further development of industry is to be implemented mainly by means of the better use of the production potential, which has already been created by reconstruction and technical reequipment of existing enterprises without increasing the number of workers. Nuclear power generation is to be extensively developed. The putting into use of hydropower resources of the North Caucasus and Transcaucasia is to be continued. In Siberia, the accelerated growth of fuel industry, electricity generation, nonferrous metallurgy, chemical, petrochemical, and construction industries is to be provided. The production

of crude oil, including gas condensate and natural gas, is to be increased considerably. In the Soviet Far East, there will be a further development of the nonferrous and the oil refining industries.

The average monthly wages of manual and office workers are to be raised by 13% to 16% and their level should be brought up to 190 to 195 rubles a month by the end of the 5-year period. The income of collective farmers is to be raised by 20% to 22%.

The level of Soviet industrial production in 1980 and as planned for 1985 is given in table 2.

Table 2.—U.S.S.R.: Soviet industrial production in 1980 and planned 1985

(Million tons unless otherwise specified)

Commodity	Production		Increase	
	1980 reported	1985 planned	Quantity	Percent
Coal, raw (bituminous, anthracite, lignite)	716	770-800	54-84	7-12
Petroleum, crude, including condensate	603	620-645	17-42	3-7
Natural gas (billion cubic meters)	435	600-640	165-205	38-47
Steel, raw	148	NA	NA	NA
Rolled finished ferrous metal	103	117-120	14-17	14-17
Mineral fertilizers (Soviet standard)	104	150-155	46-51	44-49
Mineral fertilizers (100% nutrient content)	25	36-37	11-12	45-49
Cement	124	140-142	16-18	13-15
Power, electric (billion kilowatt-hours)	1,295	1,550-1,600	255-305	20-24

NA Not available.

It has been estimated that in the 1981-85 period, a growth of fuel output of all types of primary energy will amount to 16% to 17% or 300 million to 320 million tons of standard fuel. There will be definite changes in the structure of fuel and power production. These changes will include a reduction of the share of oil, a sizable growth of the share of natural gas, and a growth of hydraulic and nuclear power generation. The existing large losses of fuel and energy will continue in the 1981-85 period.

The output of crude oil including gas condensate, will grow over the next 5 years by 25 million to 35 million tons, which means the total production in 1985 will be between 625 million and 640 million tons. The slowdown of the growth rate of oil production in the Soviet Union stems mainly from low labor productivity and shortages of labor, equipment, and materials.

Soviet natural gas output increased by 140,000 million cubic meters over the last 5 years. This growth will probably continue in the next 5 years, which will bring the Soviet natural gas production up to 580,000 million cubic meters in 1985. A reduction of the share of coal in the total production of primary energy toward 1985 is going to be accomplished by not more than 7%, which will amount to 770 million tons of raw coal and lignite in 1985. But the quality of coal (ash content and other impurities) will decrease over the next 5 years by at least 8%.

The overall volume of fuel and power exports from the U.S.S.R. amounted to over 300 million tons and imports were about 26 million tons of standard fuel in 1980. More or less the same amount of fuel and power will be available for export in 1985. The greater number of exports will be shipped to CMEA countries. It is expected that exports of fuel and power to CMEA nations will be raised by about 20% compared with that of the previous 5 years. The U.S.S.R. will keep exporting fuel to Western and developing countries. The amount of this export will depend on world prices of oil, gold, platinum-group and nonferrous metals, and other mineral industry commodities, which are the main earners of hard currency to pay for imports.

The years covered by the 1981-85 5-year plan are to be difficult for the U.S.S.R. and a slower pace for economic activity is expected in the future (after 1985).

The Plan for 1981.—The state plan for 1981, set as part of the 1981-85 plan, was ratified by the Supreme Soviet on October 23, 1980. A significant cutback in the industrial growth target confirms that the economy will suffer its third worst year since the Second World War. The growth of national

income planned for 1981 at 3.4% represents the lowest planned target in the last 10 years. It is also lower than all the figures for growth of national income actually achieved under the 9th and 10th 5-year plans, except that of 1979. More or less, the same can be said of the 4% increase in industrial production projected for 1981, the only difference being that this figure is a little higher than the actual level achieved in 1980.

It is evident that the Soviet leadership is expecting a further slowdown in economic development in 1981, is not regarding current difficulties as being of a temporary nature, and is entertaining no hopes of any real improvement in the economic situation.

It is worth noting that the Soviet leadership has once again demonstrated a desire to give somewhat more priority to the production of consumer goods in 1981. Admittedly, the margin is very slight, a 4.2% increase for consumer goods compared with a 4.1% increase for capital goods. Similar attempts have been made in the past but have been quickly forgotten, with preference once again being given to heavy industry. Nevertheless, the possibility cannot be ruled out that this slight margin in favor of consumer goods will be achieved, as was the case in 1971 when consumer goods showed an increase 0.2% higher than capital goods.

The Soviet leadership does not seem to be expecting any substantial improvement in agriculture where planned gross output at 7.5% is lower than the average of 9% annual growth achieved under the 10th 5-year plan.

Capital investment is to total 140 billion rubles, a 4.9 billion increase over that planned for 1980. State capital investment is planned at 124.1 billion rubles in 1980, a 5.2% growth over the 1980 planned level. Investment will be significantly increased in the "basic branches of industry" and consumer goods. Compared with that of 1980, higher rates of growth in investment will be for electrical generation, fuels, chemicals, ferrous and nonferrous metallurgy, machine building, the electrotechnical industry, light industry, transport, and others. The capital investment in the fuel and power sector will be increased by 9.4% compared with that of 1980.

In 1980, crude oil and condensate output increased by 112 million tons compared with that of 1975. Production of crude and condensate in 1980 was 17.4 million tons over the 1979 level. The 1981 plan calls for production of 610 million tons of crude and condensate, only 7 million tons more than the 1980 level. Pipeline networks are to be expanded, mainly to bring oil from Siberia to the European part of the U.S.S.R. It is planned to put into operation the Tyumen-Yurgamysh, Perm-Almatyevsk, and the Krasnoleninskiy Svod-Shaim oil pipelines in 1981. The aggregate capacity of oil refineries is to increase by 6 million tons, including the first stage of the Achinsk oil refinery in Krasnoyarsk Kray.

The brightest spot in the energy picture is natural gas. About 435 billion cubic meters were produced in 1980 and the goal for 1981 is up 5.3% to 458 billion cubic meters. All of the growth in gas production is to come from Western Siberia, which is to supply 42% of the total produced, and more than half of Soviet oil output is to come from that area. A 5,600-kilometer addition to trunk and branch gas pipelines is also planned. The 1,273-kilometer Urengoy-Nizhnyaya-Turna-Petrovsk pipeline and the 2,000-kilometer Urengoy-Nadym-Punga-Ukhta-Gryazovets-Torzhok pipeline are to be commissioned in 1981. Raw coal and lignite mining in 1981 is planned at 738 million tons. Production was 719 million and 716 million tons in 1979 and 1980 compared with planned output at 752 million and 745 million tons in 1981. The main increase is to be from open pit lignite operations in Kazakhstan and Siberia. Increased coal production is to be from the Kuznetsk, Karaganda, Ekibastuz, and Kansk-Achinsk basins.

The plan does not mention the 1981 quotas for production of pig iron, raw steel, and iron ore. Finished rolled output is planned at 109.2 million tons and that of steel pipe at 18.5 million tons. It is planned to attain an output of 140 new shapes of ferrous rolled products. Completion of the renovation of blast furnace No. 2 with a capacity of 420,000 tons per year at the Rustavi works in Georgia and the "2,000" rolling mill at the Cherepovets works were rescheduled for 1981. Renovation of the "2,500" rolling mill at Magnitka and the "900-750" mill at the Dzerzhinsk plant in Dnepropetrovsk are also to be completed in 1981. The oxygen-converter shop No. 2 at the Novolipetsk complex is to be put on-stream. It is also planned to commission additional facilities for iron ore production at the Mikhaylovsk (Kursk region) mining and concentration complex and the Shere-

goshsk Mine in Western Siberia with a capacity of 2 million tons per year of crude ore each. In 1981, iron ore production facilities are to be increased by 14 million tons of crude ore per year.

According to 1981 targets, the country's fertilizer production will be 113.8 million tons (Soviet standard), an increase of 9.8 million tons over that of 1980. The generation of electric power is to be increased by 3.5% to 1,335 billion kilowatt-hours. In 1981, nuclear power generation is to be developed in the European part of the U.S.S.R. Two 500,000-kilowatt units are to go onstream at the Kursk nuclear powerplant. New facilities are to be commissioned at Chernobylsk, Rovensk, Smolensk, and other nuclear powerplants. Cement production is to be increased by 4.5 million to 128.5 million tons in 1981.

Railway capital investment is planned at 8.8% over the 3,700 million rubles planned for 1980 (excluding expenditures on the BAR). About 760 kilometers of new track, 860 kilometers of double track, and 1,000 kilometers of electrified track are to be completed in 1981.

Soviet priorities for the 1980's will continue to be the vital oil, gas, and machine-building industries. Oil and gas production are so important (as energy and hard currency sources) that adjustments will be made elsewhere to ensure fulfillment of the planned targets. There will be continued exports of petroleum and natural gas and imports of steel pipe, pipelining, and petroleum and natural gas extraction equipment.

Table 3.—U.S.S.R.: Soviet industrial production

(Million tons)

Commodity	1980		1981
	Planned	Reported	Planned
Pig iron	115	NA	NA
Steel, raw	157	NA	156.8
Rolled finished ferrous metal	109	103	109.2
Coal, raw (bituminous, anthracite, lignite)	745	716	738
Petroleum, crude including condensate	606	603	610
Natural gas (billion cubic meters)	435	435	458
Mineral fertilizers (Soviet standard)	115.5	104	113.8
Steel pipe	18.5	18.2	18.5
Cement	NA	124	128.5
Power, electric (billion kilowatt-hours)	1,295	1,295	1,335

NA Not available.

Exploration.—There are more than 20,000 explored mineral deposits in the country. Over 5,000 deposits of various minerals were being exploited in 1980. According to Soviet sources, the U.S.S.R. accounted for 28% of world mining output and for one-quarter of the world mineral production in 1980. Up to 40% of capital investment in industry is spent on exploration and mining of minerals. Expenditures on geological prospecting for the years 1950-80 increased by a factor of 8, and in 1980 they amounted to about 5 billion rubles. They will continue to increase annually by 5% to 8%. Extensive prospecting and exploration for practically all commodities was carried out on a large scale. There were over 500,000 employees in the geological and prospecting organizations in 1980, including over 120,000 graduate specialists with university and technical education. The Ministry of Geology had 36 research institutes and 2 design establishments with a total staff of over 40,000 persons. Every year geologists of the Ministry of Geology alone complete more than 20 million meters of core well drilling, over 3 million meters of petroleum and gas wells, and about 300,000 meters of various underground mining excavations. The geologists have at their disposal more than 10,000 drilling rigs.

The main purpose of recent Soviet mineral exploration has been to improve the regional distribution of resources for the production of major metals, all fuels, and many nonmetallic minerals. However, during the past 15 years, no increment in tin reserves has been achieved even in the Soviet Far East. Poor results were also reported in the growth of reserves of bauxite, lead, zinc, mercury, tungsten, molybdenum, antimony, and nickel (Kola Peninsula). According to the Ministry of Geology of the U.S.S.R., the quota for exploration of additional mineral reserves in the first half of 1980 was met by 117.4% for oil and gas condensate, 116.6% for iron ore, 143.7% for lead, 200% for zinc and tungsten, and 152% for phosphate.

In recent years, the effectiveness of prospecting and exploration has been reduced and the number of deposits transferred for mining has been reduced. Effectiveness has been especially low at Rudnyy Altay, Dzhungariya, Karatau, and Balkhash. The raw material base is especially poor at the Achisay, Balkhash, Tekeli, Belogorsk, and Kargayly polymetallic complexes, and all

gold mining enterprises of Kazakhstan. An improvement in geological prospecting in the Soviet Far East is expected as a result of the creation of the Soviet's Dalgeologiya Production Geological Association established in May in Khabarovsk on the base of the Far Eastern Territorial Geological Administration. The new organization is directly responsible to the Ministry of Geology of the U.S.S.R. Another production association, Yakutgeologiya, was also setup in May in the Far North. It will prospect for minerals in a vast region of the country adjacent to the Arctic Ocean. Exploration in Yakutia has been entrusted to 13 large prospecting expeditions.

There are shortages of bauxite, copper (Urals), nickel (Kola Peninsula), mercury (Ukraine), and lead (Rudnyy Altay and Kazakhstan). While there have been problems in improving the distribution of reserves, production has been increased from existing deposits. Good results were obtained in increasing the quantity and quality (by 50%) of copper-nickel reserves in the Norilsk area, where over 20 teams of geologists were employed in 1980.

Over 2,500 geological and geophysical teams are permanently employed in oil and gas exploration and about 2,200 exploration wells are completed each year, using 2,500 drilling rigs. In 1980, the target for oil and gas exploratory drilling by the Ministry of Geology was not met. The speed of drilling remained essentially at the 1976 level (387 meters per rig month). In 1980, Western Siberia continued to be the main target for Soviet oil and gas exploration, but the speed of drilling was low. The main causes of the low performance of drilling operations in West Siberia are the complex transport system for delivery of the basic materials, pipes and tools, and organizational deficiencies, and also the severe climatic conditions influencing the duration of all forms of operations. There is no incentive for deep drilling because quota fulfillment in the U.S.S.R. is calculated on the basis of the number of meters drilled, independent of depth. Exploration of oil and natural gas is to be extended in the next 5 years. There is to be intensive exploration in the European part of the country, in Siberia, and on the eastern coast of the Caspian Sea.

The search for oil at great depths of the Caspian Sea yielded its first result in January. A well drilled 84 meters deep yielded 200 tons of oil. It is planned to drill wells in water depths exceeding 150 meters. This is possible with new West European drilling rigs. Reportedly, the $110 million contract for assistance in oil exploration in the Caspian Sea went to a French consortium in March. A number of self-propelled platforms for geological prospecting in the Black Sea are to be constructed at the Kiev shipbuilding yard. The construction of the first vessel was almost finished in 1980. The first stage of drilling for oil and natural gas off Gdansk in the Baltic Sea, with the U.S.S.R., Poland, and the GDR participating (Petrobaltic), started in August and the first well was to be 3,000 meters deep. Soviet and Finnish specialists have discussed the possibility of Finnish firms taking part in the exploration of oilfields and gasfields in the northern continental shelf off the U.S.S.R.

Approximately 35,000 meters of exploratory wells have been drilled on the Sakhalin Island shelf with encouraging results. The Soviet Union has pledged to sell half of the oil produced to Japan in return for the Japanese assistance in drilling. With the signing of the Soviet-Vietnam agreement on cooperation in geological prospecting and extraction of oil and gas on the continental shelf off Southern Vietnam in July, the U.S.S.R. gained access to Vietnam's promising offshore oil and gas reserves. Under a Soviet-Brazilian agreement, Soviet geologists will be sent to Brazil to search for oil.

Soviet geologists are not well equipped with geophysical instrumentation, particularly with automated data acquisition and processing equipment. The main method of contouring deposits is still the preferred mechanical method, i.e., drilling wells and drifting mine workings. Expenditures on geophysical surveying of oil and gas accounted for 25% of the total exploration cost for these commodities. The U.S.S.R. is purchasing large quantities of oil equipment from Western suppliers as exploration of its "vast" oil and gas reserves continues. Offshore prospecting needs specialized geological and geophysical ships and floating drilling rigs, but domestic production of these is proceeding slowly.

Surveying of the Aktogaysk copper deposit in Kazakhstan and the Kholodnenskoye lead and zinc deposit in East Siberia was completed in 1980. The latter deposit is situated 50 kilometers from the BAR. Pre-

liminary exploration of the Betyuninsk iron ore deposit at the Urals was completed. The Soviet Union has reported the discovery of its third largest phosphate deposit in Estonia. Completion of detailed exploration of the Podal'skoye copper deposit in the Urals, and the Karabinskoye tungsten and Shalkiya lead-zinc deposits in Kazakhstan, as well as surveying of the Udokan copper deposit in East Siberia, were rescheduled for 1981. Completion of exploration of the Severogor-Blagodatskoye in the Urals, Belanovskoye in the Kremenchug region of the Ukraine, and Aleshinskoye (Kazakhstan) iron ore deposits were also rescheduled for 1981.

Prospecting was intensified for copper in the Urals, at the Udokan deposit in Chita Oblast', and in Central and Southern Kazakhstan. Prospecting for lead and zinc in the Rudnyy Altay region was conducted on areas adjacent to the Leninogorsk and Zyryanovsk complexes and at the Uchkulachsk deposit in Uzbek S.S.R. Tin prospecting was increased in the Yakut A.S.S.R., in the Khabarovsk Kray, in the Pamirs, and in other promising regions. Prospecting was also undertaken on the northern side of the Talnakh ore deposit at Norilsk, and the Trudovoye tin deposit in Kirgiziya. According to "Communist Tadzhikistana," the geological prospecting in Tadzhik S.S.R. will undoubtedly lead to the discovery of new commercial deposits of nonferrous and precious metals. The development of gold mining in the Republic supports this contention. Reorganization of the prospecting and development firm "Tadzhikzoloto" (Tadzhik gold) into production and development of a new mine and construction of new concentration plants has recently become necessary as a result of prospecting successes and the increased price of gold.

Exploration for oil and natural gas in the Anadyr area (Soviet Far East) is expected to increase sharply during the 1981-85 plan period. Also, according to an agreement, the U.S.S.R. will help Turkey in oil exploration and drilling.

Table 4.—Soviet mineral reserves in place in the A+B+C$_1$ categories [1]

(Thousand metric tons unless otherwise noted)

Commodity	A+B+C$_1$
METALS	
Bauxite, 26% to 62% alumina	65,000
Antimony, metal content	150
Arsenic, white (As_2O_3)	40
Beryllium, beryl, cobbed, 10% to 12% BeO	50
Bismuth, metal content	2.5
Cadmium, metal content	50
Chromium, chromite ore, 30% to 56% Cr_2O_3	60,000
Cobalt, metal content	100
Copper, metal content	40,000
Gold, metal content, thousand troy ounces	200,000
Iron ore, 38% iron [2]	60,200,000
Lead, metal content	16,000
Magnesium, metal content	2,800
Manganese ore, 23% to 26% Mn [2]	250,000
Mercury, metal content, 76 pound flasks	1,100,000
Molybdenum, metal content	200
Nickel, metal content	5,000
Platinum-group metals, content, thousand troy ounces	90,000
Silver, metal content, do	1,000,000
Tin, metal content	600
Titanium, TiO_2 content	10,000
Tungsten, metal content	150
Zinc, metal content	20,000
NONMETALS	
Asbestos	100,000
Barite	10,000
Cement [2]	27,720,000
Clays: Kaolin (including china clay)	80,000
Corundum, natural	150
Diamond:	
Gem, thousand carats	30,000
Industrial, do	120,000
Diatomite	10,000
Feldspar	8,000
Fluorspar	10,000
Phosphate rock: [2]	
Apatite; 16% P_2O_5	2,750,000
Sedimentary rock, 13% P_2O_5	2,700,000

[1]Estimated except where otherwise noted.
[2]Reported in Soviet sources.

Construction.—The U.S.S.R. continues to experience difficulty in completing mineral industry projects on schedule owing to deficiencies in planning, inadequate coordination, and equipment and material shortages. The construction of new projects remained slow and expensive and material and labor force resources were frequently dispersed over a large number of projects, so that leadtimes were two to three times as long as specified by the U.S.S.R. State Construction Committee. The 10- to 15-year period required to develop a mine with a capacity of 1 million to 2 million tons per year contributed to disparities between the capacities of mines, concentration mills, and metallurgical plants in the iron and steel industry of Kazakhstan and many other projects. The practice of resorting to expedients resulted in great inefficiencies and prolonged delays in reaching design capacity. For example, in the majority of mines developed in the Donets Coal Basin during the 1971-75 period, the planned capacity goals had not yet been reached by a total of 12 million tons of coal per year.[25]

Construction of stainless steel production facilities at the Bekabad Plant in Uzbekistan started in 1974. By 1978, the facility was to have achieved 70% of total capacity, but actually it reached only 40% by the end of 1979. The first and second stages of the project cost 90 million rubles. The production cost of steel is 284 rubles per ton, while the price is set at 82 rubles per ton. There is great overuse of ore, energy, and material.[26] The volume of unused equipment at the ferrous industry construction projects is very large. Unused equipment increased by 70% in 1980 compared with that of 1975.[27] In the chemical industry, there is an enormous backlog of unfinished chemical plants purchased abroad, which are to form the backbone of Soviet fertilizer production. The idle time of construction equipment and trucks at practically all construction projects is considerable and chronic.[28] The attainment of designed capacity of rotary kilns in the cement industry takes from 5 to 12 years.[29]

New enterprises that became operational in the iron and steel industry included the first section of the first stage of the cold rolling mill with a capacity of 1 million tons per year of cold rolling sheet at Novolipetsk. Completion of the second section of the first stage at this plant was rescheduled for 1981. Construction of the "150" rolling mill, with an annual capacity of 0.4 million tons of wire at the Beloretsk complex in the Urals was completed in December. The No. 1 350-ton oxygen converter with a capacity of 2 million tons per year at the Cherepovets Plant was put into operation on December 31, 1980. About 16,000 workers were employed in the construction of the converter and oxygen plant in 1980, and the cost of construction for the year amounted to 206 million rubles.[30]

The 2-strand, 8-million-ton-per-year pelletizing plant at Krivoy Rog was commissioned in June. The plant was built by FRG's Lurgi Chemie and Huttentechnik GmbH. There are now three Lurgi pellet plants, with a total capacity of 14.3 million

tons per year, in operation or under construction in the U.S.S.R. At the Mikhaylov iron mining and concentration complex in Kursk Oblast', the No. 13 section of the concentrator, with a capacity of 0.8 million tons per year of concentrate (1.5 million tons of ore), was put into operation in December. New facilities for production of 1.7 million tons per year of iron concentrate at the Lebedi complex in the Belgorod Oblast' went onstream in August. The second stage of the No. 2 pelletizer plant, with an annual capacity of 3 million tons of iron pellets, at the Dneprovsk complex, was commissioned in November. The first stage of the Yubileynaya Mine at Krivoy Rog, with a total capacity of 4 million tons per year of crude iron, was commissioned on December 26, 1980. The fifth section of the Olenogorsk mining and concentration complex in Murmansk Oblast', with an annual capacity of 1,275,000 tons of iron concentrate, was commissioned in July. The total capacity of five sections is about 6 million tons of concentrate per year.

The sinking of the 620-meter-deep shaft at the Yakovlevo Mine in Belgorodsk Oblast' was completed in April and new facilities for the production of 2 million tons per year of iron sinter at the Cherepovets Plant went onstream in December.

In the nonferrous industry field , the following facilities were put into operation in 1980: The fourth (March) and fifth (December) potlines at the Regar (Tadzhik) aluminum plant, the first stage of the Nikolayev alumina plant, a new facility for production of anode copper at the Severonikel complex in Monchegorsk (Kola Peninsula), and a rolling mill at the Balkhash copper complex in Kazakhstan. New facilities also were put onstream at the Ust'-Kamenogorsk lead and zinc and the Irtysh chemical metallurgical complexes in Kazakhstan, and at the Dukat gold mining and concentration complex in the Soviet Far East. The Nadezhda tin mine at the Solnechnyy complex in Khabarovsk Kray was opened in May and the Glubokaya mercury mine at the Khaydarkan complex in Kirgiziya became operational in December. The first stage of the Molodezhnaya chromite mine, with a capacity of 0.8 million tons per year of crude ore, in Aktyubinsk Oblast', Kazakhstan, and a new manganese mine, with an annual capacity of 0.3 million tons of crude ore, at Chiautura Basin, Georgia, went into operation in 1980.

The second stage of the Kiyembay asbestos mining and concentration complex in the Orenburg Oblast' was put into operation in December. The design capacity of this stage is 250,000 tons per year, raising the complex's total capacity to 0.5 million tons per year. New facilities for production of sulfuric acid at the Kokhtla-Yarva mineral fertilizers plant (0.5 million tons per year) in Estonia and at the Gomel chemical plant in Belorussia went into operation; the equipment was manufactured in Poland.

The 1980 plan called for development of new and renovated underground and open pit mines for the production of about 16 million tons per year of raw coal and construction of new and the renovation of four coal washers of 16.3 million tons per year of raw coal. A State Commission accepted for operation in 1980 the following new coal production facilities in the Donets Basin: The first stages of the Zhadovskaya-Kapital'naya Mine with an annual capacity of 2.1 million tons of anthracite, the Sukhodol'skaya-Vostochnaya Mine with capacity of 1.2 million tons per year, and the Nagol'chanskaya Mine with designed capacity of 0.75 million tons per year. The No. 2 coal washer in the Karaganda Basin, with an annual capacity of 7.5 million tons of marketable coal, which has been under construction for 10 years, went onstream in April 1980. In Estonia, a new section at the October open pit mine, with a capacity of 0.9 million tons per year of oil shale, was put into production in December.

Several articles in the Soviet press[31] sharply criticized the pace of development of the Nerunga coal production complex in South Yakutia, from which exports of coking coal to Japan (on compensation basis) are to begin in 1983. There is a shortage of 4,000 workers (50% of the labor requirements) and the construction plan for 1979 was met by only 50%.

In 1980, 4,100 kilometers of pipelines were to be laid, but only part of the planned quota was constructed. The 192-kilometer Priobskaya crude oil pipeline in Siberia was completed in May and the 425-kilometer Samgori-Batumi in Transcaucasia was put into operation in November. The oil pipeline in the Caspian Sea, which connects the Neftyanyye Kamni offshore oilfield with the continent, has reached Zhiloy Island. The Soviet Union is having difficulties building petroleum refining and petrochemical industry projects. Construction of the

Tomsk petrochemical complex has been behind schedule for several years. In 1980, only the first stage of the Mazheykskiy primary oil refinery in the Lithuanian S.S.R. was put onstream in September.

The 1980 planned capital investment for development of the Soviet gas industry was set at 45 billion rubles. It was planned to construct 5,000 kilometers of gas pipelines and 29 compressor stations. The following gas pipelines were put into operation in 1980: The 200-kilometer Maykop-Sochi (January), 180-kilometer Vozey-Usinsk-Pechora (February), 70-kilometer Andizhan-Mayli-Say (July), 403-kilometer Shurtan-Syr Darya (November), Yevlakh-Nakhichevan in Azerbaydzhan (December), and a 150-kilometer stretch of the fourth string of the Siyaniye Severa gas pipeline between Urengoy, Ukhta, and Gayazovets (December).

During the 1976-80 period, about 50,000 kilometers of oil and gas pipelines, over 300 compressors, pumping stations, and gas-processing plants with an aggregate capacity of 15,600 million cubic meters per year were put into operation. Compared with the preceding 5-year period, the volume of building and assembly work for the construction of enterprises of the oil and gas industry has increased by 36%, while in Western Siberia it has risen by 130%.

The 1980 plan called for construction of 17 billion kilowatts of electrical generating capacities. The 600-megawatt Beloyarsk prototype fast breeder reactor went into operation in April. The reactor is the third unit in the plant, which also includes two pressure tube reactors with generating capacities of 100 megawatts and 200 megawatts.

The fifth reactor-VVER-1000, with a capacity of 1 million kilowatts, at the Voronezh nuclear powerplant was commissioned in June. The total capacity of the five reactors at this plant is 2.5 million kilowatts. The VVER-440 reactor with a capacity of 440 megawatts at the Rovenskaya nuclear powerplant was put into operation in 1980.

In 1979, the Soviet Union sank 200 shafts with a total length of 27,560 meters, of which 82 were coal shafts, 97 shafts were metallic, and 21 shafts were for the chemical and mineral fertilizer industries. Of the total length, 19,380 meters were vertical and 8,180 meters were inclined shafts. Construction of the BAR is 1.5 years behind schedule. The largest problem is a lack of labor. Labor turnover is 50% per annum.

The number of uncompleted projects in the construction industry has risen considerably in the last 10 years. The total volume of unfinished construction at the beginning of 1979 reached 85% of the annual level of capital investment instead of the 65% average according to established regulations. The above norm unfinished construction projects are valued at 23 billion rubles.[32] Many mines and plants are costing two to three times more than had been originally estimated.[33]

Additional production facilities, including new or expanded plants and renovation of existing units, are given in table 5.

PRODUCTION

A Soviet decree of April 1956 classifies all data on production capacity and production plans of nonferrous, precious, and rare metals and some nonmetallic enterprises as State secrets. Although the U.S.S.R. does not publish official statistics on many mineral commodities, information is available on most minerals. Published information on industrial development, however, provides some basis for estimating output of many other commodities. The increase in Soviet mineral production in 1980 was largely due

to additional capacity and labor rather than to productivity gains. The U.S.S.R. devotes one-fourth of its gross national product (GNP) to investment, compared with one-sixth in the United States. Total Soviet industrial production remains about one-half of that of the United States.

Reportedly, 70 elements were recovered in the U.S.S.R. In 1979, one-third of the total crude steel and 20% of nonferrous metals were produced from scrap. The maximum depth of underground coal production reached 1,150 meters in 1979, while the average depth was 430 meters. Many new plants and mines that were put into operation in the 1971-75 period produced at only 50% to 60% of their design capacity.[34] During the 1977-80 period, the Asian part of the country (east of the Urals) provided an increase of almost 100% of oil, natural gas, and aluminum, over 90% of raw coal and lignite, and about 80% of copper.

In 1980, the Russian Soviet Federated Socialist Republic (RSFSR) continued to rank first among the 15 Soviet Republics in mineral production and produced about 80% of the gold and silver, practically 100% of platinum-group metals, 90% of the petroleum, over 50% of the natural gas, more than half of the coal and steel, and about two-thirds of the electric power. While having only 3% of the territory of the U.S.S.R., the Urals produced a considerable portion of the industrial output of the Soviet Union. Steel and rolled ferrous metal products, pipe and metallurgical equipment, aluminum, copper, zinc, nickel, cobalt, gold, platinum, minor metals, asbestos, potassium, and various construction materials are produced in the Urals. The Urals are providing the Soviet economy with modern machinery and equipment, which currently extracts more than 70% of the oil and gas, produces 80% of the sinter, over 90% of the pig iron, 80% of the continuous cast slabs, 30% of the hot-rolled metal, all of the cold-rolled steel bars, and all of the freight car wheels.

The Ukraine occupied first place in output of coking coal, manganese and iron ore, and second place in natural gas. This Republic continued to provide about one-third of the total Soviet coal output, over 50% of iron ore, about 50% of the pig iron, 39% of the steel and rolled metal, over 75% of the manganese ores, about 20% of the natural gas, and nearly 50% of the metallurgical and electric engineering products. The Republic also produces a considerable share of the country's output of titanium, mercury, sulfur, and graphite. In 1980, this Republic had over 6,000 deposits of different minerals. Kazakhstan occupied third place in Soviet mineral production and was the leader both in reserves and in production of lead, zinc, copper, chromium, and cadmium. There was also considerable production of alumina, titanium, magnesium, gold, and silver. This Republic produced 30% of the total Soviet copper, 50% of the zinc, and over 70% of the lead.

The Soviet mineral industry is facing a number of technological problems, including declining ore grades, insufficient variety of flotation reagents, increasing ash and sulfur content in coal produced, and obsolete equipment. Because of low labor productivity, the labor force shortage is a major problem in the development of mineral industry despite the fact that Soviet miners are relatively well paid.

In 1980, raw steel output in the U.S.S.R. was lower than that in the preceding year. Bottlenecks in raw material, transport, and slowness in the introduction of sophisticated engineering and technology will hold back the development of the Soviet steel industry. During the 1976-80 5-year period, Soviet raw-coal production has fallen considerably behind schedule. In 1980, production fell to 716 million tons, 2.7 million tons less than in 1979, and 29 million tons short of the revised (84 million tons short of original) yearly goal. Daily production of natural gas at the Novyy Urengoy Field, the largest gasfield in the U.S.S.R., is 20 million cubic meters less than the planned target. The four ministries that are responsible for bringing the field onstream have failed to implement a program adopted in 1976 for development of this field. Only two of three gas-processing installations planned for 1978 and only one of three planned for 1979 were brought onstream. The plan for drilling is behind schedule. It was planned to raise the 1975 volume of primary oil processing 25% to 30% by 1980. Actually, during the 4-year period (1976-79), primary oil processing increased only by 15%.

Although about 400 different minerals are mined and processed in the U.S.S.R., insufficient attention is paid to the comprehensive use of mineral resources. For example, at the Zyryan lead and zinc complex only 8 out of 16 main components of the ore are extracted; the remainder go to waste. Generally, only the main metals in a specific ore type are extracted and most of the

byproducts (zinc, cobalt, silver, barium, etc.) are discarded. Losses of byproducts amount to more than half of the total value of the ores. About 31% of all beneficiation and metallurgical plants of the Soviet nonferrous industry did not meet planned targets for recovery of copper, lead, zinc, tin, and tungsten in 1979. The largest losses of metals were permitted by the concentrators of the Almalyk (Uzbekistan) and Balkhash (Kazakhstan) metallurgical complexes, by the Tekely and Achisay (Kazakhstan) mining and concentration complexes, as well as by the Chimkent lead plant, the Ust'-Kamenogorsk (Kazakhstan) lead-zinc metallurgical complex, and by the production association Nikel complex (Kola Peninsula).[35]

The 1979 planned quotas for Soviet production of alumina, aluminum, lead, zinc, nickel, sulfuric acid, and others were not met because of shortages of raw materials, supplies, fuel, power, and transportation problems, as well as nonfulfillment of planned targets for construction of new facilities.[36] Nonferrous metallurgy of East Kazakhstan decreased production of metals during the 1976-80 period.[37] The Dzhezkazgan, Achisay, Irtysh, and Tekel complexes in Kazakhstan did not meet production quotas for 1979.[38] Unsatisfactory performance of the Chimkent lead (Kazakhstan), "Elektrotsink" zinc, Kirovobad (Azerbaydzhan), the Ural'sk aluminum, and Krasnoural'sk (the Urals) copper plants was reported in 1979 and 1980.[39] In 1979, production targets for output of nonferrous ores were not met at the mines of Dzhezkazgan (Kazakhstan), Almalyk (Uzbekistan), Krasnouralsk (the Urals), and the Irtysh (Kazakhstan) metallurgical complexes as well as at Tyrny-Auz (North Caucasus), Achisay, and Karagaylinsk (Kazakhstan) mining and concentration complexes.[40]

The lead-zinc industry in Rudnyy Altay (East Kazakhstan) is facing serious problems as the high-grade polymetallic deposits near depletion. Lower-grade ores were used recently, but industry lacks the capacity to develop and process them. During the 1976-79 period, the Leninogorsk and Zyryanovsk lead-zinc metallurgical complexes processed about 3.5 million tons of polymetallic ores with a total lead and zinc content of 0.5% to 0.6%.[41] The slow development of new mines in Kazakhstan forced the nonferrous enterprises of this Republic to process old slags of lead shaft smelting to recover lead and zinc.[42] The Dzhezkazgan and Balkhash complexes in Kazakhstan have experienced shortages of copper ore for a long time.[43] The old industrial central and southern regions of the Urals were beginning to experience shortages of copper, iron, and other ores in 1980. Some enterprises at these areas began to operate on raw materials transported from other regions.[44]

The quality of Soviet metal is low. Ferrous metallurgy is slowly reorganizing for the production of economical shapes. Of 140 effective rolled products, which according to the 1976-80 5-year plan should be produced for the needs of the machine-building industry, more than one-half were not produced. The consumption of metal for many kinds of machines is up to 50% greater in the Soviet Union than in the West. The main reason for this lag is inferiority of the grades and inadequate strength of the rolled products. When the needed grade is not available, a large piece is used.[45] About 80% of the accidents that occurred in 1979 breaks were caused by pipe breaks during the operation of the main gas pipelines. The main cause of accidents is external corrosion of the gas pipeline metal.[46] The quality of steel produced is low; consequently, protection from corrosion is also poor, resulting in losses of 15 million tons of steel annually.[47] Because of shortages and poor quality of pipe metal, the country is buying large quantities of pipe from Japan, the FRG, and other West European countries.

The official average ash content of coal shipped to consumers increased from 21.6% in 1965 to 23.9% in 1979,[48] but the actual ash content is much greater. For example, the discrepancy between the Shaturskaya thermal powerplant and the Dubrovskaya underground mine in appraisal of the ash content of the very same batch of fuel reached 15% to 17%. The Partizan underground mine shows in its documents an ash content of 39% to 40%, while actually it is often 61% to 62%.[49] Izvestiya[50] said that one of the reasons powerplants were not receiving sufficient coal was the poor quality of fuel. Mine operators were not directly concerned with supplying powerplants with high-quality fuel.

There is a vast labor force at work in full-quality inspection. About 17,000 people are employed in the quality administrations Department of Technical Control and chemical laboratories of the U.S.S.R. Ministry of Coal Industry mines alone. U.S.S.R. Gossnab (State Supply) has more than 800 inspectors who specialized in coal. More than

2,000 laboratory and claim workers stand guard over U.S.S.R. Minenergo (U.S.S.R. Power Ministry) fuel interests, and the share of guardians grows constantly. At one of the Ekibastuz's open pit mines, 227 people for mining coal and 217 people for taking samples and monitoring are employed. There is almost one observer for each miner.[51]

Many cement plants have produced low-quality products for a long period of time, resulting in overconsumption of cement in construction.[52] There is a small amount of good-quality products produced by the enterprises of the U.S.S.R. Ministry of Coal Industry, the Ministry of Ferrous Metallurgy, the Ministry of Nonferrous Industry, the Ministry of Construction Materials, and the Ministries of Machine Building.[53]

Losses of minerals during mining, processing, and extraction are large. Furthermore, the valuable byproducts are not always used and they are dumped as waste, thus depriving the economy of extra raw materials and contributing towards the pollution of the environment. Many enterprises of machine-building ministries are continuing to produce heavy equipment and machinery, a result of which the coefficient of metal utilization is low. The rolled metal is produced in tonnage, not in accordance with its purpose, it is stored badly, and it is squandered.[54] According to Soviet sources,[55] annual losses of metal in the technology of its production, overconsumption in machine-building, and in repair of equipment and machines amounted to 42.2 billion rubles. The losses of cement amounted to 16.5 million tons per year. Transportation of cement alone resulted in losses that are 1,100% to 1,200% higher than permitted by regulations.[56]

There is a shortage of metal in the country, which is becoming more acute each year. Among the main causes of the metal shortage are the inefficient planning (production in tons), shortage of new modern facilities, and poor product quality. Despite the fact that metal output is increasing, the volume of production in the economical categories is not meeting the national economy's requirements. This applies particularly to structural sheet, rolled metal with anticorrosive coatings, a number of types of low-alloy steel, heat-toughened rolled metal, and high-precision sections. Powder metallurgy is developing slowly. The Ministry of Nonferrous Metallurgy is failing to supply industry and construction with sufficient volumes of many types of nonferrous metal products, particularly rolled aluminum, and high-strength and corrosion-resistant alloys which are effective substitutes for ferrous metals.[57]

Builders are constantly complaining of a shortage of material resources. This is true, but at the same time, more than 5 million tons of ferrous rolled products, almost 24 million tons of cement, and more than 12 million cubic meters of timber are frozen above normal at many enterprises.[58]

Citing the chemical industry's importance for the national economy, especially for the production of mineral fertilizers, the Presidium of the U.S.S.R. Supreme Soviet in November divided the All-Union Ministry of the Chemical Industry into two all-union ministries: The Ministry of the Chemical Industry and the Ministry for the Production of Mineral Fertilizers.

[2]Includes data available through Sept 4, 1981.

[3]Reported in Soviet sources.

[4]1976-79 data are from: United Nations Economic Commission for Europe. Annual Bulletin of Steel Statistics for Europe 1979, New York. V. 7, 1980, p. 21.

[5]Produced from semimanufactures listed above and possibly also from similar imported semimanufactures. Therefore, these data are not additive to total semimanufactures listed.

[6]Run-of-mine coal. The average ash content of coal shipped from mines was 20.2%, and the average calorific value was slightly more than 5,000 kilocalories per kilogram (9,000 Btu's per pound) in 1977.

[7]Not distributed by type and therefore not suitable for conversion to volumetric units. Data include all energy products and some nonenergy products as well as refinery fuel and exclude petrochemical feedstocks, paraffin, petroleum coke, white spirit, unspecified minor nonenergy products, and refinery losses.

[8]1976-78 data are from: United Nations. World Energy Supplies 1973-78, New York. Ser. J, No. 22, 1979, p. 148.

Mine Safety and Health.—While the U.S.S.R. does not publish data on injuries in the mineral industry, available Soviet information revealed that there were many fatal injuries in 1980. In 1978, fatal injuries occurred at one-third of the Donets coal mines. The February 22, 1978, Pravda (for the first time) indicated that a major accident occurred at the Sokuskaya coal mine of the Karaganda Basin; resulting in an unspecified number of deaths. The second major coal mine disaster reported by the U.S.S.R. was at the Molodogvardeyskaya coal mine in the Donets Basin that occurred on August 10, 1979. The third reported major coal mine disaster took place at the Gorskaya Mine, also in the Donets Basin, on April 26, 1980. No casualty figures have been disclosed but it is thought that the loss of life was considerable.

In 1978, the number of fatal injuries increased in coal mines at the following coal production associations: Krasnoarmeyskugol', Makeyevugol', Ukrshakhtstroy, Ukrzapadugol', Donetskugol', Shakhtersk, Anthracit in the Ukraine, Gruzugol', Kizelu-

gol', Primorskugol', and Yuzhkuzbassugol'. In 1979, the number of injuries in the nonferrous industry increased at the enterprises of the "Armzoloto" production association, "Svinetsstroy" and Boksitostroy" trusts, at the Tyrny-Auz metallurgical complex, as well as at the Mikhaylovskiy and Lebedinskiy mining and concentration complexes of the ferrous industry. In 1979, a high level of injuries took place at the following oil production associations: Permaneft, Komineft', and Yugansknefteqaz.[59]

During 1980, the greatest level of traumatism was allowed at a number of coal mines controlled by management of the Voroshilovgrad, Kuznetsk, Karaganda, and Sakhalin safety districts. An inadmissible situation has arisen during the operation of hoisting cranes at many construction projects of ferrous and nonferrous metallurgy enterprises. At some mining enterprises work is conducted with a large number of long-standing infractions. Operational startup of units and enterprises with substantial incompletions of safety measures are occurring. The workers are sent for underground work in potentially dangerous areas, where safety violations have not been abolished.[60] The level of fatal injuries at the enterprises of the U.S.S.R. Ministry of Geology continued to be high. There were many violations of safety regulations at many exploration projects.[61] It has been established by an inspection that fuel accidents have been covered up, thus preventing these cases from being investigated by special commissions.[62]

There was a high rate of injury in many mines that resulted from mine management neglect, inadequate safety conditions, and violations of safety regulations and labor laws to increase production. The number of fatal accidents at underground mines continued to be high, especially from roof caving, mainly due to the shortages of props.[63] For example, requirements for prop shipments to the Karaganda coal basin were only 41% in 1979 and 48% in the first quarter of 1980. These resulted in shortages of props in the amount of 100,000 cubic meters in 1979 and 34,700 cubic meters in the first quarter of 1980.[64] The staff of the Makeyevka Safety Institute after a study of the work at 35 production faces (longwalls), established that because of shortages of support material in 29 faces, supporting had been violated. Inspections show that at many coal mines of the Donets Basin, very little attention is paid to full and correct supporting of production and development faces. Inspections also show that many longwalls are insufficiently provided with support material.[65]

The amount of workings at coal mines that are not in accord with safety regulations are large. On January 1, 1979, it was 29.9% at production association Artemugol, 25.5% at Pervomayskugol', and 19.1% at Ordzhenikidze.[66] At a number of coal mines, significant shortcomings of fire-prevention measures are allowed. According to a Soviet source,[67] 84 kilometers of mine workings that are supported with wooden props, and 85.3 kilometers of air pipelines do not correspond with safety regulations and standard requirements. Many coal mines are not equipped with fire extinguishers, fire hoses, etc.[68]

The accumulation of dust at work sites in underground mines in the Soviet Union is high and often exceeds the sanitary standard. The neglect of proper dust control at many mines resulted in unhealthy working conditions. The replacement of old and wornout ventilators have been proceeding slowly. At many coal mines the dust content in the air exceeds the maximum allowable concentration. During the inspection of 100 longwalls at mines of the Ministry of the Coal Industry of the Ukrainian S.S.R., it was determined that in 15% of production faces dust suppression equipment was idle and 55% of the longwalls' water dust suppression was inadequate.[69]

The lighting at the underground haulage of many coal mines is only from 8.6% to 44.5% of the sanitary standard. In 1980, the supply of lamps to Donbass coal miners was more than 60,000 lamps short of the requirement, and this was reason for delaying fulfillment of the annual production quota. At the Abakum Mine, almost a third of the underground miners did not have lamps and had to borrow lamps belonging to miners who worked on other shifts. The mine has 3,500 miners and are short 1,000 lamps. Moreover, the quality of the lamps that are supplied has deteriorated.[70]

According to "Labor,"[71] the real reason why mining in the Soviet Union is very hazardous is that "...production quotas are becoming not just highly demanding, but excessively so." According to the first secretary of the Komi Oblast' Party Committee, I.P. Morozov,[72] "the target for coal output in the Komi A.S.S.R. exceeds the mines potential for production." The miners are unable

to cope with such quotas, even though they are compelled to work on most of their days off.[73]

MINERAL TRANSPORTATION

The railroad accounted for more than half of all the freight turnover in 1980. The changes in the Soviet freight turnover by type of transportation, over the last 20 years is shown in table 7.

Table 7.—U.S.S.R.: Soviet transporation statistics in percent

Type of transportation	1960	1965	1970	1975	1980
Railway	79.4	69.0	63.1	59.2	50.4
River	5.2	4.7	4.4	4.0	3.7
Marine	6.9	13.8	16.6	13.4	12.5
Oil pipeline	2.7	5.2	7.1	12.1	18.0
Gas pipeline	.6	2.2	3.2	5.1	9.1
Automobile	5.2	5.1	5.6	6.2	6.3
Total	100.0	100.0	100.0	100.0	100.0

Source: Ekonomicheskaya gazeta (Economic Gazette), Moscow. No. 48, November 1980, p. 10.

About 90% of 1980 mineral production was shipped by rail. Coal is the most important commodity transported by rail, contributing 20% of the total shipping volume, followed by petroleum with 15%. The performance of the railways, which are essential to the development of all sectors of the Soviet economy, appears to have declined substantially during the past 5-year period. Since 1976, average speeds have dropped by 2.4 kilometers per hour and the average distance covered by a locomotive within a 24-hour period has fallen by 60.5 kilometers. The figures for electrified lines alone are even worse-falls of 4.4 and 97.7 kilometers per hour.[74]

Cross hauling and the irrational transportation of coal, coke, ore, oil, timber, building materials, and other bulk loads have reached gigantic proportions. The Soviet Rail Transportation Research Institute has estimated that elimination of irrational freight movements could reduce transportation costs by between 400 million and 500 million rubles per year and at the same time make it possible to deliver an additional 150 million tons of freight to its destination.[75]

Apart from crosshauling, an enormous amount of useless deadweight is transported around the country. For example, if the coal industry made a better job of washing its output, the railroad would be relieved of conveying between 20 million and 25 million tons of rock. Between 35% and 40% more freight cars are required to transport undressed logs than would be the case with sawed timber. About 11 million tons of mineral fertilizers, with a useful content of only 20%—half the acceptable standard—are also dispatched by rail each year.[76]

Another factor that directly contributes to the burden on the railroad system is the tendency, for economic reasons, to concentrate the manufacture of certain industrial products in one geographic location. Very often, the high costs of transportation that result more than overweigh any savings in the prime cost of production.[77]

The growth of coal mining in the U.S.S.R. is being accompanied by a deterioration of its quality. Some lumps reach the meter size when the permissible standard is 30 centimeters. The moisture, waste rock, sulfur, and ash content in the coal shipped is rising. During the past 10 years, the shipment of such low-quality products to power-generating plants alone increased by 60 million tons per year. Tens of thousands of railroad cars are required daily for coal hauling. Coal trains that travel from the eastern regions to the European part of the country are often loaded with as much as 40% waste rock and moisture. This means that two-fifths of the rolling stock is used irrationally. In the winter, an excessive moisture in coal causes it to freeze during transportation into monolith. It cannot be unloaded, therefore, a crusher is required. Idle time is increased and cars damaged during unloading have to be sent for repair prematurely. The high content in the coal of ash, sulfur, and other impurities accelerates wear on the power-engineering equipment and even leads to breakdowns. The powerplants have to create new equipment to use poor-quality coal and lignite.[78]

During the railroad transportation, each railroad car loses from 5 to 10 tons of coal. The coal sifts through the holes and is blown upward by tachind.[79] Each time a frost occurs hundreds and thousands of railroad cars arrive at coal mines with large

remnants of frozen coal; the latter is thrown outside and turns into debris.[80] More than 40,000 tons of iron pellets produced by the Mikhaylovskiy mining and concentration complex are lost during railroad transportation each year.[81]

There is cross-hauling of coal on Central, Ukraine, West Siberian, and other railroads. Millions of tons are sent each year from Kuzbass (4,000 kilometers) to various parts of the Ukraine. Here it is made into coke and then returned to its native districts. As a result, the railroads on this route are constantly overloaded. Millions of tons of coking coal from the Donets Basin (Ukraine) travels in the opposite direction. During the last 4-year period, the growth in average distance for coal hauling by rail increased by 98 kilometers. During this period, coal transport cost customers 180 million rubles more than for former distances. The amount of work done by the railroads increased 75.5 million ton-kilometers. For the national economy this means the loss of a real possibility for hauling an additional 46.5 million tons of freight.[82] It frequently happens that an empty car arrives at a mine with broken wooden sheathing, bent guard doors, and badly cut hatches. Therefore, coal is lost through these cracks during transportation.[83] Millions of tons of iron ore are transported from the Kursk region to the Urals each year.[84]

During the 1976-80 period, 3,300 kilometers of new railway lines and more than 3,000 kilometers of second track were commissioned. On January 1, 1980, the total length of Soviet railways was 141,000 kilometers; 42,400 kilometers of track were electrified. By the end of 1980, 2,100 kilometers of the planned 3,500 kilometers of track were laid at the BAR. It is planned to put 760 kilometers of new line into operation, to electrify 1,000 kilometers of track, and to equip over 2,000 kilometers with automatic signaling systems in 1981. The plan calls for construction of not less than 3,600 kilometers of new railway lines during the 1981-85 period.

By January 1, 1981, the U.S.S.R. Ministry of the Merchant Marine had 1,748 ships of 18.6 million deadweight tons in aggregate. There were 1,428 dry-cargo vessels (11 million deadweight tons), 310 tankers (6.5 million deadweight tons), and 10 combined dry-cargo ships and tankers (1.1 million deadweight tons). The tanker fleet has six vessels of the "Krym" class (150,000 deadweight tons). A 15,000-ton-capacity tanker, Sovetskaya neft, was constructed in 1980. It is the sixth Soviet tanker with the same capacity, but no more orders for such tankers have been placed. Soviet shipping lines employ mainly tankers of 20,000 to 40,000 deadweight tons. During the 1976-80 period, the fleet was augmented by new ships of 4.26 million deadweight tons in aggregate. In the course of the 5 years, a considerable number of old ships were written off. There was an effective increase of 5% in the deadweight tonnage of the fleet since the beginning of 1976.

The U.S.S.R. has the sixth largest merchant fleet in the world. The Soviet fleet is increasing by about 1 million deadweight tons per year. During the 1981-85 period, Czechoslovakia is to supply the Soviet Union with more than 90 vessels: Dry-cargo river-sea vessels, bucket-ladder dredges, and floating suction dredges.

The first stage of the Vostochnyy port east of Vladivostok, which has been constructed with Japanese assistance, can handle vessels up to 100,000 deadweight tons, although ships of only 20,000 deadweight tons are being used at present. Japanese steel companies received about 2 million tons of coal through this port in 1980. The second stage of the Vostochnyy port is to be built, again with Japanese assistance, in the 1981-85 period and will comprise a group of container terminals, the second stage of a coal-handling section, wharves for general cargo, wharves to handle grains, and various other projects.

TRADE

Soviet foreign trade is a state monopoly and is administered by the Ministry of Foreign Trade, operating through more than 70 foreign trade organizations. Political objectives exert a strong, and often determining, influence on foreign trade. The Soviet Union trades with 130 countries and in 115 cases the trade is based on interstate agreements. The trade continues to be orientated toward imports of large quantities of Western industrial machinery and technology (including complete industrial plants) and substantial grain purchases. The Soviets rely heavily on both foreign Government-backed and commercial credits to finance the increasing foreign

currency deficit. Exports of minerals help pay for these imports.

In 1980, Soviet foreign trade turnover (exports plus imports) increased by 11.7% compared with that of 1979, reaching 94,100 million rubles. The increase in trade turnover resulted from a slight increase in physical volume and a substantial rise in foreign trade prices for a number of export and import goods, particularly oil and other energy sources. Soviet foreign trade by groups of countries is presented in table 8.

Table 8.—U.S.S.R.: Soviet foreign trade in 1975, 1978, 1979, and 1980

(Million rubles)

	1975	1978	1979	1980
Whole world:				
Turnover	50,700	70,200	80,300	94,100
Exports	24,000	35,700	42,400	49,600
Imports	26,700	34,500	37,900	44,500
Socialist countries:				
Total	28,600	42,000	45,100	50,600
Exports	14,600	21,300	23,600	26,900
Imports	14,000	20,700	21,500	23,700
Of which CMEA members:				
Total	26,300	39,100	41,600	45,700
Exports	13,400	19,800	21,700	24,300
Imports	12,900	19,300	19,900	21,400
Western industralized countries:				
Total	15,800	19,700	25,700	31,500
Exports	6,100	8,700	12,500	15,800
Imports	9,700	11,000	13,200	15,700
Less developed countries:				
Total	6,300	8,500	9,500	12,000
Exports	3,300	5,700	6,300	6,900
Imports	3,000	2,800	3,200	5,100

Sources: Vneshnyaya torgovlys S.S.S.R. (Foreign Trade of the U.S.S.R.) 1978, and Ekonomicheskaya Gazeta (Economic Gazette), Moscow. No. 13, March 1981, pp. 21-22.

Soviet trade turnover with Western developed countries increased by 12.3% compared with that of 1979, chiefly owing to the sharp increases in prices. These countries' share of U.S.S.R. foreign trade turnover rose from 31.8% in 1979 to 33.5% in 1980.

During 1980, the volume of total official Soviet trade with leading Western developed countries, in million rubles, is shown in the following tabulation:

Country	1975	1979	1980
Germany, Federal Republic of	2,800	4,200	5,800
Finland	1,800	2,600	3,900
France	1,300	2,600	3,700
Italy	1,400	2,200	3,000
Japan	1,900	2,600	2,700
United Kingdom	1,000	1,900	1,800
United States	1,600	2,800	1,500
Netherlands	500	1,100	1,400
Belgium	500	800	1,200
Austria	400	800	1,000

Soviet trade with other Western developed countries in 1980, in million rubles, was as follows: Canada, 1,000; Australia, 800; Switzerland, 800; Sweden, 700; Greece, 500; Spain, 400; and Denmark, 300.

Soviet trade with CMEA countries increased by 11% in 1980 compared with that of 1979. At the same time, the CMEA countries' share of Soviet foreign trade fell from 55.7% in 1978 and 51.9% in 1979 to 48.6% in 1980.

Soviet trade turnover with CMEA countries is shown, in million rubles, in the following tabulation:

Country	1975	1978	1979	1980
Bulgaria	3,991	6,142	6,486	7,099
Hungary	3,274	4,826	5,155	5,738
Vietnam	206	458	594	612
German Democratic Republic.	5,263	7,693	8,133	9,200
Cuba	2,589	4,169	4,249	4,266
Mongolia	480	743	772	884
Poland	4,853	7,050	7,555	8,002
Romania	1,526	1,950	2,146	2,791
Czechoslovakia	3,911	6,061	6,546	7,184

Trade with Yugoslavia increased by over 46% compared with the 1979 level, reaching 3,800 million rubles in 1980. Trade turnover with North Korea increased by 16%, reaching 572.1 million rubles. Trade with China decreased from 332 million rubles in 1979 to 317 million rubles in 1980. Shipments of Soviet goods to Laos increased by 48%, reaching 37 million rubles.

In 1980, the Soviet Union traded with 97 developing countries and commercial relations with 76 countries were regulated by intergovernment trade or economic treaties and agreement. In 1980, trade agreements were concluded with Gabon, Grenada, and Nicaragua.

Soviet trade turnover with developing countries is presented, in million rubles, in the following tabulation:

Country	1975	1978	1979	1980
India	686	771.4	1,035	1,740
Argentina	304	331.2	313	1,193
Iraq	600	1,084.0	1,182	732
Libya	19	158.6	437	451
Turkey	95	157.7	379	443
Syria	168	205.0	199	321
Afghanistan	132	215.0	324	505
Egypt	710	345.5	325	384
Iran	510	671.1	409	335
Brazil	396	165.1	180	275

In 1980, trade with Ethiopia reached 147 million rubles; with Angola, 95 million rubles; and with Yemen, 61 million rubles.

Soviet foreign trade continues to be oriented toward imports of needed machinery and equipment, including complete industrial plants. Fuels, mineral raw materials, and metals play the largest role in Soviet exports, representing about half of the total official exports during 1980. Soviet exports increased by 11.7% in 1980 over that of 1979, to a considerable extent as a result of the increased price of a number of goods on the world market. There was a particularly sharp rise in the price of energy sources.

During the 1976-80 period, the Soviet Union stepped up its exports of traditional raw materials such as oil and petroleum products, natural gas, coal and coke, precious and nonferrous metals, and some nonmetallic mineral commodities. In 1980, much of the mineral commodity exports were directed to CMEA nations, but there was also a large shipment to the West. Western Europe is a major importer of Soviet petroleum and natural gas. Sales of chromium, titanium, and platinum-group and precious metals have also been significant. Soviet gas is transmitted to the following CMEA countries: Poland, the GDR, Czechoslovakia, Hungary, Romania, and Bulgaria. Soviet gas is also flowing to Austria, the FRG, France, Italy, Finland, and Yugoslavia.

Estimated ferrous metal exports from the U.S.S.R. in 1980 were valued at over 2,000 million rubles, with rolled products accounting for 1,250 million rubles. In addition, in 1980, the Soviet Union exported an estimated 47 million tons of ferrous metal ores, including iron, manganese, and chrome ores, with a total estimate of 600 million rubles. High-quality ferrous metal imports were at 2,575 million rubles, including rolled steel products at 1,337 million and steel pipe at 1,238 million rubles. The U.S.S.R. became a net importer of ferrous products in 1978 and total steel imports are second only to grain in value. Despite being the world's largest steelmaker in tonnage, the Soviet Union needs to import considerable amounts of high-quality products from abroad to cover domestic demand, especially pipe and some rolled products.

The planned amount of foreign exchange was easily achieved in 1980 by a smaller level of gold and other mineral industry commodity sales because of the higher prices for these commodities. The U.S.S.R. traditionally sells most of its gold through Zurich, Switzerland, but a small share of Soviet gold is sold at other European and American gold markets. In recent years very little, if any, gold from the U.S.S.R. has been sent directly to London. In 1979, reportedly, the U.S.S.R. sold 230 tons and in 1978, 400 tons of gold. Soviet gold sales in 1980 dropped back sharply from the 1979 level. The U.S.S.R. transferred 39.76 tons of gold to the Swiss bullion market, and also sold some metal through London and New York. It is estimated that the U.S.S.R. sold only 80 tons of gold in 1980. The sale of gold in previous years were so high that stocks were depleted and what was sold in 1979, in fact, conformed more closely to current production. The Soviet Union normally sells its gold when prices are high and keeps the returns for an emergency. The U.S.S.R. may have ceased selling gold for a period, since its earnings from oil and gold in 1979 have given it enough foreign currency for its planned requirements.

The program for the sale of Soviet platinum, gold, and silver Olympic coins was completed in early 1980, and according to Y. Kuzkin, Deputy Chairman of the Board of the Soviet Bank, $170 million worth of coins have been sold in 20 Western countries. The FRG, the United States, Switzerland, Canada, and Belgium were the main customers.

The Soviet Union is a net exporter of lead and zinc. Lead exports from the U.S.S.R. averaged about 100,000 tons per year in the 1970-80 period, while imports (metal and concentrate) for the same period averaged over 80,000 tons. Zinc exports from the U.S.S.R. averaged over 100,000 tons per year from 1965 through 1980, while imports (metal and concentrate) amounted to over 70,000 tons per year in the 1970's. Unexpected heavy buying of lead and zinc by CMEA countries, headed by the U.S.S.R. in 1979, was caused by considerable decreases in shipments of Iranian lead and zinc ore and concentrate. Soviet imports of Iranian lead

ore and concentrate decreased from 47,695 tons in 1978 to 17,117 tons in 1979, and that of zinc ore and concentrates decreased from 72,241 to 5,914 tons for the same years.

The U.S.S.R. used to be a major exporter of mercury. In 1979-80, it sold an estimated 8,000 to 9,000 flasks to Western free markets. However, it is not expected that mercury will be exported to the West in 1981. The Soviet Union has considerably halted aluminum shipments to the West. As a result of problems in mining of potash in the Urals' mines, Soviet exports of potassium decreased from 5.77 million tons in 1978 to 4.77 million tons in 1979 and to an estimated 5 million tons (Soviet standard) in 1980. It is possible that exports of palladium, titanium, and high-grade chromium to the West may also be decreased in the future.

In 1980, the Soviet Union imported machines and equipment in total value of 15,100 million rubles. Machines and equipment is the largest group of the U.S.S.R.'s imports. Their share in the total Soviet imports amounted to 34%. In 1980, goods worth 15.7 billion rubles were imported from Western developed countries, including machinery, equipment, and transport facilities worth 4.7 billion rubles, rolled steel products worth 1,337 billion rubles, and steel pipe worth 1,238 billion rubles. Between 1976 and 1979 Soviet imports of Western equipment for the chemical industry increased almost threefold over the previous 5 years to reach 6.2 billion rubles. This equipment has been put into operation at ammonia, carbamide, and superphosphate producing plants in the cities of Odessa, Togliatti, Gorlovka, Novgorod, Cherepovets, Dneprodzerzhinsk, and others.

The Soviet Union imports large quantities of bauxite, alumina, rolled steel and pipe, tin, fluorine, barium, and some copper, lead, zinc, cadmium, tungsten, silver, antimony, molybdenum, and mica. In 1978 and 1979, the U.S.S.R. imported about 16 tons of silver each year. In 1980, it purchased over 31 tons. The country increased imports of tungsten and some other commodities in 1980.

Large-scale and long-term cooperation increasingly accounts for the growth in Soviet trade with Western countries, which doubled during the 1976-80 period, showing a rise of 15.5 billion rubles. The U.S.S.R.'s main exports to Western Europe are crude oil, petroleum products, and natural gas. Western Europe has been an importer of Soviet natural gas since 1968 when a branch of the Brotherhood Trunkline, which feeds Eastern Europe, reached Austria. Export contracts have since been signed with the FRG, France, Italy, and Finland guaranteeing shipments of natural gas over a 20-year period. Natural gas exports will soon become the Soviet Union's second main trade commodity (after petroleum). More than half of the hard currency earnings come from oil and gas sales. Shipments to France were scheduled to begin in February 1980 under a 4-billion-cubic-meter annual delivery contract. Soviet deliveries of natural gas to Western Europe were to be increased by 20% in 1980 compared with that of 1979 shipments.

West European banks are negotiating with the U.S.S.R. credits of $10 billion to finance the purchase of steel pipe and pumping equipment for the construction of a 5,000-kilometer gas pipeline to transport gas from Siberia to Western Europe. Under the new proposed gas for steel pipe and pipeline equipment deal, the FRG, France, Italy, Belgium, Austria, the Netherlands, and Luxembourg would receive up to 40 billion cubic meters of Soviet gas annually over 20 years starting in 1985. The FRG is to receive between 10 and 12 billion cubic meters annually. The cost of the entire project has been estimated at $14 billion. Soviet petroleum exports of OEDC countries, chiefly in Western Europe, declined slightly for the first time in 1979.

Trade between the U.S.S.R. and the FRG in 1976-80 more than doubled over the years 1971-75, and in 1980, for the eighth year, the FRG was the Soviet Union's biggest trading partner among the Western countries. The U.S.S.R. supplies the FRG with natural gas, crude oil, and a number of important raw materials. Reportedly, Soviet deliveries of enriched uranium supplied more than one-half of the FRG's requirements. Soviet palladium, titanium, and asbestos accounted for a large share of the FRG's consumption. During the 20 years following the conclusion of the first contract, the Mannesmann Corp. of the FRG has supplied 6 million tons of large-diameter steel pipes to the U.S.S.R. From 450,000 to 715,000 tons of large-diameter pipes were annually supplied to the Soviet Union. In addition, pipes of other types for the oil industry, in particular, had also been delivered to the U.S.S.R. No less than 13% of all West German steel pipe export is absorbed by the U.S.S.R. About 15% of all exported steel plate and over

10% of all machine tools sold abroad are shipped to the U.S.S.R. At the same time, West German imports from the U.S.S.R. advanced at a rate of 50% less than overall West German purchases abroad.

Soviet-Finnish trade turnover in the 1975-80 period exceeded 12 billion rubles compared with the initially planned amount of 9 billion rubles. In 1981, mutual trade is to reach a total value of FM24.4 billion, compared with an estimated 22 billion in 1980. Soviet export of crude oil, which was expected to amount to 7 million tons in 1980, is to increase slightly in 1981. The 1981-85 Soviet-Finnish trade agreement calls for trade valued at more than $23.5 billion. Nearly half of the Finnish exports are metal industry products, mainly ships and ship equipment, machinery, cables, steel products, and others. In return, the U.S.S.R. supplies Finland with crude oil, petroleum products, natural gas, nuclear fuel, coal, coke, and electricity.

The Soviet-French trade increased 23% over the 1979 level and reached 4 billion rubles (F F 10.4 billion) in 1980. In 1980, the U.S.S.R. had to supply France with over 8 million tons of crude and petroleum products and 4 billion cubic meters of natural gas. France is one of the Soviet Union's most preferred Western trading partners. On July 21, 1980, the Finsider Co. of Italy signed a $2.5 billion 5-year exchange agreement in the U.S.S.R. Under the agreement, the Soviet Union will supply Italy coal, nickel, iron ore, and steel scrap in exchange for 500,000 tons per year of large-diameter pipe, steel plates, electrical sheets, and other steel products. Italy has announced that the state holding company, Ente Nazionale Idrocarburi would participate in a $10 billion project to transport Siberian natural gas to Western Europe.

Japanese steelmakers have agreed to supply a huge Soviet order for 1 million tons of large-diameter steel pipe and 360,000 tons of steel plate to be delivered each year for the next 5 years. But the realization of the agreement will depend on whether or not the Export-Import Bank of Japan will approve Government financing for pipe export. Reportedly, Japan's Government has been asked by the U.S.S.R. to provide between $2 billion and $3 billion in loans for promotion of a Siberia-Western Europe gas pipeline project. The U.S.S.R. was interested in importing up to 60,000 tons of Japanese alumina in both 1980 and 1981. About 1,500 tons of copper ingots will be sent by Japanese copper smelters to the Soviet Union in 1981. Soviet aluminum scrap exports to Japan picked up in 1980, but coking coal shipments that same year to Japan were short 840,000 tons. Under the 1974 agreement, the U.S.S.R. was committed to begin shipping between 3.2 million and 5.5 million tons of coking coal from the Neryunga complex, South Yakutia, on an annual basis between 1983 and 1998. However, the Soviet Union notified Japanese coal importers that it cannot start shipments of Neryungian coal in 1983.

Reportedly, in 1980, British exports to the Soviet Union rose by 8% to £452.8 million while British imports fell by 5% to £786.2 million. The Soviet Union exports 40,000 to 60,000 tons per year of aluminum scrap (aluminum content) and also exports zinc slag, titanium solids and turnings, some tin, and occasionally some copper in the form of old radiators. The United Kingdom and the United States take considerable quantities of titanium scrap, while Japan, Austria, and Italy import a lot of aluminum scrap.

The Soviet Union's trade turnover with the United States decreased to $1.5 billion in 1980. The value of U.S. exports to the Soviet Union fell 58% in 1980. American exports to the U.S.S.R. had a value of $1,510 million in 1980 compared with a value of $3,604 million in 1979. The fall was due almost entirely to the decline in U.S. agriculture exports. The U.S. Trade Commission, in October 1979, determined that imports of Soviet ammonia were disrupting domestic markets and recommended a quota of 1 million tons in 1980, 1.1 million tons in 1981, and 1.3 million tons in 1982. In November 1979, the President embargoed the sale of 17 million tons of grain and exports of all phosphate fertilizers to the U.S.S.R. In addition, the President reimposed an emergency quota on Soviet ammonia imports of 1 million tons in 1980.

During the years 1979-80 the U.S.S.R. exported to the United States the following mineral industry commodities, in million U.S. dollars:

Commodity	1979	1980
Anhydrous ammonia	56.5	94.8
Gold bullion, refined	548.3	85.7
Palladium	62.1	54.6
Uranium compounds, fluorides	--	34.6
Nickel, unwrought	28.6	20.7
Metal coins, n.e.s	25.2	18.3
Palladium bars, plates, etc	2.3	11.7
Uranium compounds, n.e.s	--	9.0
Platinum bars, plates, etc	3.5	7.0
Rhodium	9.9	6.3
Crude petroleum, testing under 25° A.P.I. (heavy fuel oils)	6.8	6.3
Platinum-group metals and combinations, n.e.s.	16.0	5.2
Naphthas, derived from petroleum, etc., n.e.s.	--	5.0
Titanium waste and scrap, unwrought	8.0	4.6
Platinum sponge	5.2	4.6
Chrome ore, chromium content not over 40% chromic oxide.	10.7	3.8
Diamonds, over 1/2 carat, cut, not set	1.9	3.0
Titanium sponge, unwrought	2.6	2.7

Sales of Soviet titanium in the United States in 1979 totaled about 300 tons of sponge and over 280 tons of ingot. In 1980, there were sales of only about 100 tons of Soviet sponge. The Soviet Union offered limited quantities of titanium sponge to the U.S. market in 1981 at approximately $10 per pound, down from $25 per pound in 1980. In the first 4 months of 1980, Soviet exports of chromite grading more than 46% Cr_2O_3 to the U.S. were 31,000 tons.

Reportedly, a consortium of Dutch banks has agreed to provide up to $1.2 billion worth of financing to Dutch companies involved in the construction of a 5,000-kilometer gas pipeline from West Siberia to Western Europe. Trade between the U.S.S.R. and the Belgium-Luxembourg Union has increased almost fivefold in the past 10 years. Reportedly, Belgium, aiming to secure gas supplies from the Soviet Union, announced in October 1980 that a credit of about $1,000 million is being negotiated with the Soviet Union by a consortium of Belgian banks to help finance a natural gas pipeline from Siberia to Western Europe. Use á Tubes de la Meuse, a Belgian steelmaker, received a contract worth $480 million to supply the U.S.S.R. with 500,000 tons of seamless pipes over 5 years. The deal forms part of a project to build a gas pipeline from Siberia to Western Europe.

Soviet-Austrian trade in 1980 amounted to 1,000 million rubles, the highest annual figures for bilateral trade in the post-war period. The Soviet Union shipped oil, coal, and other mineral products to Austria. The Soviet Union wants to double trade with Sweden by 1990, especially trade in metal and energy products, including Soviet imports of drilling equipment for oil and gas on continental shelves and offshore. The U.S.S.R. has offered to supply Sweden with natural gas. The supply of gas to Sweden from the Soviet Union would be made possible by the construction of a pipeline across Finland. The quantity is to be a minimum of 1.5 to 2 billion cubic meters of gas per year. Finland has been importing just under 1,000 million cubic meters of gas annually from the U.S.S.R. since 1974.

During the 1978-80 period, the U.S.S.R. imported over 80,000 tons per year of copper concentrate (over 20,000 tons of metal content) from Canada. The Soviet Union has signed an agreement with Spain on exports to Spain of 150,000 tons of ammonia until 1983. Soviet-Swiss trade in 1980 amounted to 800 million rubles. The Swiss authorities are now considering the question of buying natural gas from the U.S.S.R. Soviet-Greek trade in 1980 reached a value of 400 million rubles, nearly double the figure for 1979.

The U.S.S.R. provides nearly 100% of the CMEA countries' imports of crude oil, natural gas, pig iron, and electric power; about two-thirds of their petroleum products, rolled ferrous metals, and phosphorous fertilizers; about 60% of their coal and manganese ore; and up to 90% of their iron ore. Of the six East European members of CMEA, only Romania and Hungary do more business with the West than with the U.S.S.R. In the 1976-80 period, the Soviet Union was to supply its CMEA partners with 370 million tons of crude, 46 million tons of petroleum products, 88 billion cubic meters of natural gas, and 64 million megawatt-hours of electricity. During the 1981-85 period, Soviet energy deliveries to CMEA nations are to be increased by 20% over that of 1976-80, but almost none of it will be in oil. The expected Soviet oil exports to CMEA countries in 1981-85 will be 400 million tons, or the 1980 level of 80 million tons per year. Substantial quantities of iron ore, rolled ferrous metals, nonferrous metals, and chemical products are to be supplied.

According to the CMEA Secretariat, in the last 5 years exports of Soviet natural gas to East European countries increased by 200%, from 13.4 billion cubic meters in 1976 to about 27 billion cubic meters in 1980, and that of oil and electricity increased by 50%. The 1980 planned deliveries of Soviet petroleum to East European CMEA countries were: Bulgaria, 13 million tons of crude oil;

Czechoslovakia, 19.2 million tons of crude and products; the GDR, 19 million tons of crude and products; Hungary, 7.5 million tons of crude oil; Poland, 15.9 million tons of crude (13.1 million) and products (2.8 million); Romania, 1.0 million tons of crude and products.

In 1980, Soviet exports of iron ore, pig iron, copper, zinc, and aluminum to CMEA nations increased over that of 1979. The Soviet Union's exports permit a controlling influence over the economies of its CMEA satellites. In Eastern Europe, this control rests largely on the fuels and energy trade. Romania is the only country producing moderate quantities of oil; all others are heavily dependent upon liquid fuel imports. The U.S.S.R. has a controlling influence over the metallurgical industries of the CMEA nations through exports of coke and ferrous and nonferrous metals.

In 1981-85, Soviet-Bulgarian trade is to exceed 40 billion rubles, an increase of 37% over the 1976-80 level. In 1980, Bulgaria was to receive 4 billion cubic meters of gas from the U.S.S.R. Soviet-Czechoslovakian trade in 1976-80 totaled 29 billion rubles, and an increase of 35% is anticipated in the 1981-85 5-year period. In 1980, the U.S.S.R. was to deliver to Czechoslovakia 19.2 million tons of crude and petroleum products at a cost of 1,125 million rubles, and 8.7 billion cubic meters of natural gas. During the 1981-85 period, Czechoslovakia anticipates annual purchases from the U.S.S.R. of 18 million tons of crude oil, 8 million tons of iron ore in terms of iron content as well as 1 million tons of pig iron, several billion cubic meters of natural gas, and various other deliveries. Soviet-Czechoslovakian trade in 1981 is to amount to 7.7 billion rubles. The U.S.S.R. is to supply 19 million tons of crude oil, nearly 9 billion cubic meters of natural gas, iron ore, and nonferrous metals for the same year. Czechoslovakia is to supply the U.S.S.R. in 1981 with 300,000 tons of steel pipe worth 120 million rubles. The pipes are to be mainly of the seamless variety for use in oil and gas pipelines and in the oil-refining industry.

Reportedly, in 1980 the GDR imported the following mineral commodities from the U.S.S.R.: 19 million tons of crude oil and products, 6.5 billion cubic meters of natural gas, 1.7 million tons of iron ore (iron content), 3.2 million tons of rolled steel, 130,000 tons of aluminum, 42,000 tons of copper, 430,000 tons of apatite concentrate, and other mineral commodities. Soviet-East German trade in 1981 is to reach 10 billion rubles, an increase of about 10% over the 1980 level. During the 1981-85 5-year plan period the GDR is scheduled to import from the Soviet Union 95 million tons of crude oil and petroleum products, 32.5 billion cubic meters of natural gas, 8.5 million tons of iron ore (iron content), 4.5 million tons of pig iron, 650,000 tons of aluminum, 211,500 tons of copper, 6.5 million tons of coke, 21 million tons of hard coal, and other mineral commodities. Although these trade figures are impressive, in reality Soviet deliveries of mineral industry commodities will remain at their 1980 level during the 1981-85 period. The GDR will supply the U.S.S.R. mostly with machinery and equipment.

In 1980, Hungary obtained 76% of its oil requirements (7.5 million tons), 27% of its natural gas, 23% of electric power, and more than half its aluminum (in exchange for alumina) from the U.S.S.R. In 1981, Soviet-Hungarian trade is to reach 6 billion rubles. The U.S.S.R. will continue to supply Hungary with oil, natural gas, iron ore, electricity, etc. In 1981-85, total Soviet-Hungarian trade is to amount to 34 billion rubles. Soviet imports of Mongolian fluorspar increased in 1980. During the 1976-80 period, trade between the U.S.S.R. and Romania grew by 70% in comparison with the 1971-75 period and amounted to 9 billion rubles. The Soviet Union delivered 0.4 million tons of crude oil to Romania in 1979 and agreed to ship about 1 million tons of crude to Romania in 1980.

The U.S.S.R. exports to Poland include iron, manganese and chrome ore, asbestos, apatite concentrate, pig iron, ferroalloys, lead, aluminum, and other products. Poland ships to the Soviet Union sulfur, zinc, copper, cadmium, coal, and other products. In 1980, Poland was to receive from the Soviet Union 13.1 million tons of crude oil, 2.8 million tons of petroleum products, over 5 billion cubic meters of natural gas, about 9 million tons of iron ore, etc. The Soviet Union and Poland signed a long-term agreement that runs to 1990. The U.S.S.R. has agreed to maintain raw material sales to Poland at the 1980 level. Cuba supplies the Soviet Union with nickel-cobalt concentrate. Soviet-Cuban trade is to amount to approximately 30 billion rubles in the 1981-85 period, or about 50% more than in 1976-80. The U.S.S.R. has promised to deliver 61 million tons of oil to Cuba during the 1981-85 period.

The Soviet Union now holds first place

among Yugoslavia's trading partners. In 1981-85, Soviet-Yugoslavia trade is to exceed $26 billion. The U.S.S.R. will continue to supply Yugoslavia with oil and natural gas. Alumina and nonferrous metals will be among the products supplied by Yugoslavia. U.S.S.R.-mainland China trade dropped by about 5% in 1980 from the 1979 level. The U.S.S.R. exports to North Korea coal, coke, crude oil, petroleum products, ferroalloys, chrome and manganese ores, asbestos, sulfur and rolled steel. Soviet mineral imports from North Korea consist of zinc, lead, cadmium, ingot, and rolled zinc.

An important new element in trade treaty relations with developing countries is the conclusion of long-term agreements and programs on economic, scientific, and technical cooperation over a period of 10 to 15 years covering a wide field of commercial relations and creating opportunities for cooperation in the utilization of mineral resources. Soviet exports to developing countries consist mainly of machinery and equipment. From a total of $5.1 billion in imports in 1980, over 20% were mineral industry related commodities.

According to preliminary figures, Soviet trade with African countries in 1980 amounted to $2 billion, an increase of 20% over that of 1979. In the first three quarters of 1980, trade with Guinea increased by almost 20%, with the Congo by 50%, and with Benin by 100%. Soviet trade with Angola, Libya, and Algeria also grew noticeably. Soviet imports of Guinean bauxite will be increased from an estimated 2.3 million tons in 1980 to 3 million tons in the future.

In 1980, India replaced Iraq as the biggest trade partner with the Soviet Union among the developing countries. India received an additional 700,000 tons of Soviet oil and products in 1980, in exchange for rice, above the 1.5 million tons supplied under a long-term agreement. India's request for 5 million to 6 million tons of Soviet oil annually in exchange for 1.5 million tons of grain (oil for grain deal) is to be negotiated. Soviet imports of Indian mica amounted to an estimated 850 tons in 1980 compared with 680 tons in 1979. The U.S.S.R. has supplied about 35,000 tons per year of sulfur to India since 1971, but shipped only 25,000 tons in 1979. The U.S.S.R. is reported to have agreed to take 3 million tons of iron ore from India's Kudremukh project.

Reportedly, Argentina intends to buy enriched uranium from the Soviet Union for medical purposes. Argentina is also buying heavy water from the U.S.S.R. The U.S.S.R. supplied Turkey with oil, fertilizers, ammonia, ferroalloys, ferrous rolled metal, and electricity. Shipments of Afghan gas to the U.S.S.R. totaled 2.5 billion cubic meters in 1980, a 16% increase over that of 1979. Fertilizers and rolled ferrous metals will be provided by the Soviet Union to Afghanistan during the 1981-83 period under an agreement signed in August 1980. Before the revolution in Iran, the U.S.S.R. imported about 10 billion cubic meters of Iranian associated gas. Deliveries dropped to about 2.5 billion cubic meters in 1979. Because of price disagreement, Iran cutoff deliveries of gas in March 1980 and negotiations for resulting gas sales continued in 1980. Exports of Iranian lead and zinc ores and concentrates has decreased considerably during the 1979-80 period.

Reportedly, Brazil has accepted the Soviet order to export petroleum to Brazil. The U.S.S.R. is interested in buying some of the Brazilian columbium production. The U.S.S.R. supplied Morocco with oil, petroleum products, ammonia, and imported superphosphate. An agreement between the Soviet Union and Morocco on trade in 1981-85 was signed in November 1980. The Soviet Union will import from Morocco superphosphate and phosphoric acid. Agreement was also reached on Soviet assistance in prospecting for phosphates in Morocco.

Reportedly, the U.S.S.R., a previous exporter of graphite, has attempted to buy large quantities of graphite from Madagascar. Mozambique shipped tantalite to the U.S.S.R. in 1980. According to an agreement, Kenya shipped to the Soviet Union fluorspar worth £2.09 million. Under another agreement, the U.S.S.R. will purchase 50,000 tons of fluorite from Thailand in 1981.

Recently, there have been changes in Soviet mineral trade patterns. According to some Western experts, the U.S.S.R. has ended most mineral export sales to the West. Moreover, the Soviets have actively been purchasing metals in which that country has been self-sufficient, and the U.S.S.R. has switched from a net exporter to net importer of these commodities. These experts explain that a new pattern in Soviet minerals trading is the beginning of a fundamental shift in mineral trade policy to the "Resource War."

According to these experts, Soviet mines suffer from depletion of reserves and poor recovery rates. The high financial and tech-

nological cost of extracting minerals and the shortage of raw materials on the world market have produced the "shift" in Soviet mineral policy. The liabilities these analysts have in mind concern the potential risk of conflict with the United States over access to strategic raw materials.

After careful examination of all the available facts on Soviet mineral production and trade it was found that:

1. In the Soviet minerals economy, international trade is given high priority. Since the value and volume of trade are both outlined in the national plans, foreign trade reflects national goals and priorities. There is, therefore, an implied commitment to export to achieve a desired trade balance and this can result in sales below world prices. Domestic consumer demand is a less important motivation than exports. Soviet exports are not surplus and almost all exports could easily be consumed domestically.

2. Exports of some mineral commodities have declined and imports of some nonfuel materials have begun, but the U.S.S.R. has not switched from a net exporter to net importer except for tin and in value of rolled steel products.

3. The Soviet Union is a substantial supplier of many mineral commodities to the West. Price increases in petroleum, gold, platinum-group metals, diamonds, and other Soviet-exported mineral commodities led the U.S.S.R. to decrease its sale of some minerals to the West in the 1977-80 period. The increased precious metals and diamond sales and increased return on petroleum sales have allowed that country to keep other critical metal supplies for domestic use. The Soviets export many mineral commodities which they need more than the country to which they are exported. Among those metals now being safeguarded from excessive export are high-quality chromium, manganese, asbestos, titanium, vanadium, and nickel.

During the August-October 1980 period, the Soviet Union reportedly sold more than 1.8 tons of platinum-group metals valued at about 32.6 million Swiss francs. Due to slackening prices, gold sales dropped to 80 tons for the year, from more than 400 tons in 1978, and over 200 tons in 1979.

4. Increases in imports of lead and zinc ingots during the 1978-80 period has resulted from a substantial decrease of Soviet imports of Iranian lead and zinc ore and concentrates. These metals were sent to the GDR and Czechoslovakia on Soviet account.

5. Soviet mineral commodities exports to the West peaked in 1978. In the future, the U.S.S.R. will benefit from the continued increase in world oil and other mineral commodity prices. In regard to exports, a striking change is the considerable increase in the U.S.S.R.'s return from its exports of crude oil and petroleum products. The share of these commodities of the Soviet's Western exports increased by about 7% in 1978. In this respect, the U.S.S.R. profited by the price policy pursued by the Organization of Petroleum Exporting Countries. It reduced the shipments of petroleum to the OECD countries from 60.4 million tons in 1978 to 58.8 million tons in 1979, or by 1.6 million tons.

6. Due to unresolved questions on natural gas price, financing, and equipment supply, the signing of the U.S.S.R.-West German large gas pipeline deal has been postponed until the summer of 1982.

Table 9.—U.S.S.R.: Estimated production, trade, and consumption of mineral commodities in the U.S.S.R., 1980

(Thousand metric tons unless otherwise specified)

Commodity	Production	Imports	Exports	Apparent consumption

Refractory including nonclay brick[3]	129,280	129,812	Cuba 37,096; Romania 22,023; Bulgaria 20,772.
Nonrefractory	5,297	894	Saudi Arabia 496; Ivory Coast 333.
Diamond:			
Gem, not set or strung value, thousands	$380,447	$314,731	Belgium-Luxembourg $211,860; Japan $34,960; West Germany $30,600.
Industrial do	$753	$291	Belium-Luxembourg $160; United States $129.
Diatomite and other infusorial earth	--	114	All to Yugoslavia.

See footnotes at end of table.

Table 11.—U.S.S.R.: Apparent exports of mineral commodities[1] [2] —Continued

(Metric tons unless otherwise specified)

Commodity	1978	1979	Principal destinations, 1979
NONMETALS —Continued			
Fertilizer materials:			
Crude:			
Nitrogenous	293	--	
Phosphatic thousand tons	2,897	3,980	East Germany 1,144; Bulgaria 719; Poland 636.
Potassic	1,998	6,014	New Zealand 5,226.
Manufactured:			
Nitrogenous[3] thousand tons	2,336	2,321	Cuba 510; Czechoslovakia 284; Hungary 249; Turkey 177.
Phosphatic[3] do	703	638	Cuba 262; Bulgaria 182; Hungary 120.
Potassic[3] do	5,771	4,773	Poland 1,538; Hungary 561; Italy 363; Czechoslovakia 344.
Other including mixed do	79	50	Hungary 48.
Ammonia do	547	1,205	United States 705; Italy 249; Netherlands 115.
Graphite, natural	12,180	12,697	Japan 4,734; Poland 3,636; United States 3,306.
Gypsum and plasters	112,484	52,578	Sweden 32,100;[3] Finland 20,340.[3]
Iodine	r35	40	All to Hungary.
Lime	20	56	Do.
Magnesite	17,979	19,383	Hungary 7,163; Netherlands 6,922; Japan 5,095.[3]
Pigments, mineral: Iron oxides, processed	2	24	All to Belgium-Luxembourg.
Precious and semiprecious stones excluding diamond:			
Natural value, thousands	$2,880	$10,321	Switzerland $7,925; Spain $837; Hong Kong $592.
Synthetic do	$1,064	$1,617	Austria $799; Switzerland $290; Hong Kong $201.
Pyrite[3] thousand tons	852	915	Italy 282; West Germany 98; Hungary 83.
Salt[3] do	403	403	Hungary 120; Czechoslovakia 118; Denmark 59.
Sodium and potassium compounds, n.e.s.:			
Caustic soda	849	210	All to Turkey.
Caustic potash	2	--	
Soda ash	45,386	37,293	Italy 28,389; United Kingdom 5,148.
Stone, sand and gravel:			
Dimension stone:			
Crude and partly worked	15,894	19,181	West Germany 9,500; Italy 7,273.
Worked	1,308	1,411	Poland 881; Saudi Arabia 478.
Gravel and crushed rock	46,932	2,394	Hungary 2,200.
Quartz and quartzite	34	--	
Sand not metal-bearing	436	210	All to Hungary.
Sulfur:			
Elemental:			
Other than colloidal	29,606	28,382	Hungary 27,583.
Colloidal	--	2	All to United Kingdom.
Sulfuric acid[3]	162,471	143,676	Czechoslovakia 119,368.
Talc	43	561	All to Japan.
Other:			
Crude	90,690	82,876	Belgium-Luxembourg 27,716; Italy 21,427; Spain 17,720.
Oxides and hydroxides of magnesium, strontium, barium	734	654	United States 214; Belgium-Luxembourg 200.
MINERAL FUELS AND RELATED MATERIALS			
Carbon black[3]	r94,252	102,286	Bulgaria 24,153; East Germany 23,029; Hungary 18,945.
Coal including briquets:			
Anthracite and bituminous thousand tons	17,676	21,730	Bulgaria 4,586; East Germany 4,456; Czechoslovakia 3,246.
Briquets of anthracite and bituminous coal do	888	--	
Lignite and lignite briquets do	48	59	Yugoslavia 47; Japan 8.
Coke and semicoke do	2,661	1,688	East Germany 903; Hungary 522; Bulgaria 262.
Gas, natural million cubic feet	847,662	1,063,760	Italy 292,117; Czechoslovakia 259,385; East Germany 152,919; Poland 140,658.
Peat and peat briquets	167,544	196,118	West Germany 54,086; France 32,001; Austria 22,140.[3]

See footnotes at end of table.

[6] In addition to the total of 757 tons, Australia exported to the U.S.S.R. tungsten ore valued at $2,635,000.

COMMODITY REVIEW

METALS

Aluminum.—The Soviet Union, second only to the United States in aluminum production, operated 14 primary reduction plants, with a total probable annual capacity of 2,185 million tons as of January 1981. Estimated production in 1980 was 1.94 million tons (including 150,000 tons of secondary aluminum), a 2.1% increase over the 1979 output. Production of alumina and aluminum fell short of the planned increase[85] because planned goals were not reached at the Krasnoyarsk, Regar, Kirovobad, and several other plants, and output did not start at the new potline at the Tadzhik plant.

During the 1966-75 period, the output of aluminum grew by 220%. Under the 1976-80 5-year plan, output in 1980 was scheduled to be 20% to 30% above the 1975 level; the regions east of the Urals were to account for the entire increase. To achieve the goals, it was planned to put into operation several potlines at the Tadzhik and Sayansk plants and to complete construction of the Krasnoyarsk plant in Siberia. It was also planned to accelerate construction of additional alumina facilities at the Bogoslovsk and Uralsk plants in the Urals and at the Kirovabad plant in Azerbaydzhan. The Nikolayev alumina plant, with an annual capacity of 1 million tons, was to be completed by 1980. Due to slow construction and delays in the delivery of equipment, construction of the first half of the Regar plant in Tadzhikistan, the first potline at the Sayansk plant, and the Nikolayev alumina plant were not completed in 1980.

According to the 1981-85 5-year plan, output of aluminum in 1985 is scheduled to be 15% to 20% above the 1980 level. The

completion of construction of the Tadzhik aluminum and Nikolayev alumina plants and startup of several potlines at the Sayansk plant in Siberia are planned for this period. It is also planned to put into operation additional alumina facilities at the Bogoslovsk and Uralsk aluminum plants in the Urals.

Expansion of the Soviet aluminum industry has continued over recent years with the assistance of foreign technology and imported bauxite and alumina. During the 1976-79 4-year period, Soviet production of primary aluminum increased by 9.6%. Production of primary aluminum at the Bratsk plant increased by 110% during the 1971-75 5-year period and only by 13.1% during the 1976-79 4-year period. Production capacity of the Krasnoyarsk plant has attained only 75%.[86] In 1979, a big overuse of power took place at all Soviet aluminum and alumina plants, in particular at the Bratsk and Novokuznetsk aluminum plants and at the Achinsk alumina plant.

Table 13.—U.S.S.R.: Estimated capacity and production of primary aluminum plants in the U.S.S.R.

(Thousand metric tons)

Plant	Operations began	Probable output 1980	Probable annual capacity Jan. 1, 1981
Bogoslovsk	1945	120	140
Bratsk	1966	480	540
Dneprovsk	1933	60	70
Irkutsk	1962	200	240
Kanaker	1950	55	70
Kandalaksha	1961	20	30
Krasnoyarsk	1964	300	390
Nadvoitsa	1954	25	35
Novokuznetsk	1943	135	160
Regar (Tadzhik)	1975	100	160
Sumgait	1955	60	70
Uralsk	1939	120	135
Volkhov	1932	15	20
Volgograd	1959	90	125
Total		1,780	2,185

Aluminum is produced more for export than for domestic consumption, and the U.S.S.R. has exported over 500,000 tons in each of the 7 past years. Primary and secondary aluminum is exported to European countries, Japan, and the United States. Exports are expected to increase to CMEA countries.

Construction continued at the Krasnoyarsk, Regar (Tadzhik), and Sayansk primary aluminum plants and at the Nikolayev alumina plant. Construction of the Krasnoyarsk plant, the second largest aluminum plant in the country, is nearing completion. The No. 4 potline at the Regar plant was commissioned in March 1980, 3 months behind schedule. With the commissioning of this potline, the production capacity of the plant will be increased by 25%. The No. 5 potline at this plant went onstream on December 29, 1980, and was officially commissioned in January 1981. The third (final) stage of the plant for production of baked anodes at the Regar aluminum plant was completed in July 1980. Domestic anodes were used here for smelting metal for the first time in October 1978 with the startup of the first stage of the plant. Renovation of potlines at the Bratsk plant started in 1978 and is to be completed during the 1981-85 period. The first potline at this plant was commissioned in 1966 and the last one (No. 18) in 1976.

The first potline of the Irkutsk aluminum plant was brought onstream in 1962 and the last one (No. 8) was put into operation in 1971. The total probable capacity is 240,000 tons per year, and probable output is 200,000 tons in 1980. The planned capacity of this plant is to increase by 20% to 25% during the 1981-85 period. The plant's raw materials come from the Urals; its output consists of aluminum wire and ingots, of which about one-third is exported.

Reportedly, a consortium headed by KHD Humbolt Wedag of Cologne, FRG will build a $292 million aluminum anode plant in conjunction with construction of the Sayansk 400,000- to 500,000-ton-per-year smelter in Siberia. The first of five potlines at the smelter is scheduled to begin operation early in 1984.

Although the Soviet Union is a large producer of low-grade bauxite, supplies are insufficient and it is developing alumina production from nepheline and alunite. The alumina is produced in the U.S.S.R. only at the Volkhov aluminum plant and at the Pikalevo complex in Leningrad Oblast', from the 1.5-million-ton nepheline concentrates of the apatite complex at the Kola Peninsula, and at the Achinsk alumina plant from nepheline rock in Siberia. In 1980, over 82% of primary production was derived from bauxite, 16% from nepheline, and less than 2% from alunite. The amount of alumina produced from nepheline increased 4.7 fold between 1968 and 1978. Flotation nepheline concentrate containing 29% Al_2O_3 originates from the Kola Peninsula. Contruction of the nepheline concentrator No. 2, with a capacity of 4

million tons per year of concentrate (2.5 fold more than the No. 1 concentrator) at Kola Peninsula began several years ago. The Ministry of Chemical Industry built one nepheline concentrate plant with a 1.5-million-ton-per-year nepheline concentrate capacity and spent 23 million rubles on a second 4-million-ton-per-year plant before being told by the Ministry of Nonferrous Metallurgy that the nepheline concentrate was not suitable for making alumina. Further construction of this plant is being converted as an apatite concentrate plant.[87]

The long-range development program provides for a major increase in alumina production by the Nikolayevsk plant and by the expansion of the facilities of the Uralsk, Bogoslovsk and other plants. The first stage (with a capacity of 250,000 tons per year) of the 1-million-ton-per-year Nikolayevsk plant, on the Black Sea, went onstream in September 1980, about 9 months behind schedule. The second stage, with technology from France's Pechiney Ugine Kuhlmann, which was due for completion by December 31, 1980, has been rescheduled for 1981. The plant is being built in four equal stages. The plant has a 500,000-ton bauxite depot in operation. It will use Guinean and Yugoslav bauxite. The stock of imported bauxite at the Dneprobug Seaport is enough for 1 year of production of the No. 1 stage.

The Achinsk alumina from the nepheline plant in Krasnoyarsk Kray has not been operating satisfactorily. The plant has not met its production quota for any of the past 10 years since it went onstream. The main causes of lagging production are technological problems in the production of alumina from nepheline, inefficient repair work, and poor management.

Major reserves of presently minable bauxite are situated in the Turgay in Kazakhstan, on the eastern slopes of the Urals, and in the Tikhvin area of the Leningrad Oblast'. About 75% of the reserves are in the Asian part of the U.S.S.R. Bauxite is the main source of alumina in the U.S.S.R., although there are from 8% to 20% alumina losses during the processing of bauxite. Large quantities of high-grade bauxite and alumina have been imported from Guinea, Greece, Yugoslavia, Hungary, India, and other countries. Because of the depletion of bauxite at Boksitogorsk (Tikhvin area of the Leningrad Oblast'), it is planned to supply the Boksitogorsk alumina plant with bauxite from the Severoonezhsk deposit. Also, the development of the Sredne-Timan bauxite deposit in the Timan-Pechora region is planned during the 1981-85 period.

In 1980, the U.S.S.R. operated 15 secondary aluminum units with a total estimated annual capacity of 190,000 tons and produced an estimated 150,000 tons of secondary aluminum and its alloy.

According to an agreement, the Kindia bauxite complex in Guinea has been financed by the U.S.S.R. and built with Soviet technical assistance. The enterprise, with a capacity of 2.5 million tons per year of bauxite, has been setup on a compensation basis. Reportedly, the agreement has been signed for Soviet participation in the construction of an alumina plant in Jamaica. The U.S.S.R. is to receive 250,000 tons per year of alumina from this plant. It is planned to construct the Andhara alumina plant in India with Soviet assistance. The initial capacity of 600,000 tons per year of alumina is to be expanded later to 1 million tons. Half of the production is destined for the U.S.S.R. as repayment for technology, equipment, and financing. Greece and the U.S.S.R. have reached an agreement in principle on construction of an alumina plant in Greece. The Soviet Union has agreed to purchase at least 50% of the production for a period as repayment for the assistance to Greece in the construction of the plant.

Antimony.—The Kadamzhay complex in the Kirgiz S.S.R. is the principal antimony center, where integrated facilities produce most of the country's refined products. Output at this complex was to increase by 50% in the 1976-80 5-year period.

Construction of the new Aznob mine and mill unit (Dzhidzhikrutskiy complex) in Tadzhikistan continued slowly in 1980. Completion of the first stage was scheduled for 1975, but is now rescheduled for 1981. Deposits of antimony also occur in Kazakhstan and Sarylakh and Tazhdolinsk in Siberia. Production of antimony at the Ust'-Kamenogorsk lead-zinc complex increased slightly in 1980. Detailed exploration of the Novoye antimony-mercury deposit in Kirgiziya continued in 1980. The wholesale price of antimony in the U.S.S.R. is: SUOO-2,350 rubles per ton; SU2-1,850 rubles per ton. It is planned to recover antimony by processing lead scrap.

Arsenic.—Arsenic ore reserves are estimated at 12 million tons, containing 0.2% to 0.5% As_2O_3. Small arsenic deposits are located in Tadzikistan, but all output in 1980 was obtained as a byproduct from the

smelting or roasting of metallic ores. The only plant in the U.S.S.R. to recover arsenic from sulfur has been installed at the Mednogorsk copper and sulfur complex in Orenburg Oblast'. The Ust'-Kamenogorsk lead-zinc complex decreased production of arsenic in 1980.

Beryllium.—The Soviet Union continues to be one of the world's largest producers and consumers of beryl, beryllium alloys, and metal. Beryllium is found in variable quantities in most of the pegmatites all over the U.S.S.R. There are numerous deposits mainly in the Kola Peninsula, Kazakhstan, the Urals, Altay, Transbaykal, the Soviet Far East, and Western Ukraine. Domestic reserves are more than adequate. Production is being expanded and the probable level in 1980 was 1,800 tons of beryl (10% to 12% BeO). It is planned to recover beryllium from the Dzhidinsk tungsten and molybdenum ores in Buryat A.S.S.R.

Bismuth.—Bismuth is recovered as a by-product of lead and zinc smelting in Kazakhstan and other areas in the Soviet Union, from dust and crude metal at the Balkhash, Kirovgrad, and Mednogorsk copper complexes, and from tungsten and molybdenum ores. Estimated production for 1980 was 72 tons, the same as in 1979. Two copper-bismuth deposits (Taryzkan and Kantarkhana) are under exploitation in Tadzhikistan. The Ustarassy Mine in the Chatkal Mountains is the only enterprise to mine bismuth ore. Its concentrates are shipped to the Chimkent lead plant in Kazakhstan for processing.

Renovation and enlargement of bismuth production facilities at the Dalpolimetall lead complex in the Primosk Kray began in 1979. In 1980, the complex was to begin receiving bismuth-bearing ores. Production of bismuth at the Ust'-Kamenogorsk lead-zinc complex declined in 1980.

Cadmium.—Cadmium is produced at various lead and zinc smelters and at some copper complexes as a byproduct. Estimated production in 1980 was 2,850 tons, the same as in 1979. Kazakhstan continues to be the national leader both in reserves and production, and the Leninogorsk polymetallic complex there is one of the largest producers. The Ust'-Kamenogorsk lead-zinc complex decreased output of cadmium in 1980.

Chromium.—With an estimated output of 2.45 million tons, the U.S.S.R. continued to be the world's second producer and exporter of chromite in 1980. Estimated exports totaled 0.75 million tons during the year, with about 75% destined for centrally planned economy countries. Approximately 70% of the output was consumed or stocked in the Soviet Union. Based on 1978 data, Soviet consumption of chromite was distributed as follows: Metal production 45%, refractories 35%, chemical and other products 20%. Soviet-reported production of crude chromium ore was 3.2 million tons in 1979 and 3.4 million tons in 1980.[88]

Chromium ores are situated at Kazakhstan and in the Ural Mountains. The Donskoye operation at Khrom-Tau in Western Kazakhstan, which produces 95% of the Soviet output, is the only supplier of high-quality ore. Deposits in the Ural Mountains have a low chromium oxide content (20% to 40%), as well as a low Cr_2O_3:FeO ratio. These are mostly used in the chemical and refractories industries. It was planned, during the 1976-80 period to put into operation new facilities for production of 2.55 million tons per year of crude ore. However, only the first stage of the underground Molodezhnaya Mine, with a capacity of 0.8 million tons per year of crude ore was put into operation in November 1980. The total planned capacity of the mine is 3 million tons per year of crude ore. Development of the open pit at the "40-years of Kazakh S.S.R." mine is nearing completion. For transportation of overburden, M-120 Unit Rig dump-trucks (109-ton capacity) are used.

Currently, the south Kempirsay chromite deposits are being mined by the Ob'yedinenyy Mine (Millionnyy, Gigant, and Geofizicheskiy open pits), the 20th anniversary of the Kazakh S.S.R. Mine (Yuzhnyy open pit), and the 40th anniversary of the Kazakh S.S.R. Mine (open pit of the same name and the Molodezhnaya underground mine, which is under development). Besides these large deposits, the small shallow Spornoye, No. 16, No. 38, No. 29A, and Geofizicheskoye V deposits are currently being mined or are under development for surface mining. For the mining of deep parts of the "Millionnoye," "Almaz-Zhemchuzhina," "Pervomayskoye," and No. 21 deposits, the Tsentral'naya underground mine will be developed. Mines for the extraction of chromite ore from a maximum depth of 1,200 meters are under development at the Donskoye mining and concentration complex in Aktyubinsk Oblast'. The complex overfulfilled production quotas for the 1976-80 years.

Marketable ores include those with a

chromium oxide content of at least 45%, a maximum silica content of 10%, and a maximum lump size of 300 millimeters. Ore preparation at the Donskoye mining and concentration complex consists of crushing, grading, and handpicking. Rich and lean ores are blended. From 1974 through 1978 (the first stage of the plant began operation in 1974), 1,556,000 tons of feed material with a chromium oxide content of 42.8% was processed and 973,000 tons of concentrate with a chromium oxide content of 50% to 56% was obtained. Design capacity of the gravimetric concentrator is 1 million tons per year of feed.

During the 1976-77 period, the concentrator's marketable output increased by 110%, reaching 435,000 tons, with an average chromium oxide content of 49.8% in 1978. It was planned in 1978 to put into operation additional annual capacities of 700,000 tons of crude ore, to accelerate development of the Molodezhnaya underground mine, and to attain the planned output of the concentration plant by producing 575,000 tons of concentrate (30% over the 1977 level) with an average chromium oxide content of 50.8%. These targets were not met, however. Output of marketable chromite from the Saranov underground operation in the Urals is estimated at about 5% of the total Soviet production or about 140,000 tons.

Cobalt.—Gross cobalt reserves are estimated at about 100,000 tons of metal content, chiefly in nickel-cobalt ores and in cobalt ores of the Khovu-Aksinsk deposit in Tuva Autonomous Republic. Production continues to be concentrated at Norilsk in East Siberia; at Monchegorsk and Pechenga on the Kola Peninsula; in the Urals at the Yuzhuralnikel, Ufaley, and Rezhsk plants; and at a number of copper plants. During the 1976-80 5-Year period, Norilsk became the main supplier of cobalt. Recovery of cobalt remains low, especially from the copper pyrite ores of Bashkiria. The planned production cost of cobalt in concentrate at the Pechenganikel complex was 6,780 rubles per ton.

Cobalt production rose by 16% between 1970 and 1975, and was probably increased by a similiar amount during the 1976-80 period. In 1980, the U.S.S.R. produced an estimated 3,650 tons of cobalt, or about 1.5% over the 1979 level. The planned 5.8% increase of cobalt production at the Norilsk complex was not met in 1979. Since the beginning of 1976, capacity of the Tuva cobalt complex almost doubled as a result of renovation. During the 1981-85 period, cobalt production is to increase by no less than 30%.

Copper.—In 1980, the Soviet Union produced an estimated 1 million tons of blister, including 95,000 tons of secondary copper from 13 smelters with a total probable annual capacity (Janaury 1981) of 1.13 million tons. The secondary blister copper is produced by the Kirovgrad smelter in the Urals, by the Moscow smelting and electrolytic plant, and by several small units of secondary nonferrous plants. There are 11 refineries in operation. Exports of copper increased from 123,000 tons in 1970 to 205,618 tons in 1975. Estimated exports in 1980 were 240,000 tons.

Under the 10th 5-year plan, output of copper in 1980 was scheduled to be 20% to 30% above the 1975 level. The plan provided for 80% of production to come from the Asian part of the U.S.S.R. by 1980. The 1976-80 plan called for a 25% increase in refined copper production in Kazakhstan. However, the planned targets for copper production in this Republic were not met for this period; instead, the increment was only 14%. Under the 11th (1981-85) 5-year plan, output of copper is scheduled to be 20% to 25% over the 1980 level. It is planned to increase production of copper at the Almalyk complex in Uzbekistan, and to complete construction of the second stage of the Zhayremsk mining and concentration complex as well as to start development of the Annenskiy and Akchiy-Spassk Mines of the Dzhezkazgan complex. Production is estimated at a probable 1.15 million tons in 1985 and 1.30 million tons in 1990.

The country operates 40 concentrators with a total probable annual capacity of about 5 million tons of concentrates. Production of concentrates in 1980 has been estimated at 4 million tons with an average copper content of about 20% (from 12% to 36%). Sixty-five underground mines and open pits produced an estimated 126 million tons of ore in 1980. Approximately 80% of all ore was mined by open pit methods. Up to 10% of primary copper is produced as a byproduct.

The main copper ore regions are located in central and eastern Kazakhstan, the eastern slope of the Ural Mountains, Uzbekistan, the Transcaucasus, Eastern Siberia, and Norilsk. Among other regions containing copper deposits of lesser importance are the Northern Caucasus, Western Siberia, and the Kola Peninsula. Kazakhstan

contained about half of the total copper reserves in 1980 and produced 30% of the Soviet total copper output.

Gross copper reserves of the country in 1979 are estimated at 3,600 million tons (average 1.1% Cu). The reserves are chiefly in low-grade cupriferous sandstones and porphyrites but also include several million tons of high-grade pyritic-polymetallic ores, copper-nickel ores, and smaller quantities of copper-molybdenum and other miscellaneous ore types. The gross reserves of the Udokan copper deposit in Eastern Siberia, which has not yet been exploited, amount to over 700 million tons averaging 1.15% Cu (20% oxides, 80% sulfides). It is planned to develop this deposit in 1981-90. The Soviet Union has been negotiating periodically with British, French, and Japanese companies to develop "jointly" the Udokan deposit.

Gold.—Since the early 1930's, little data on Soviet activities in precious metals exploration, production, trade, and stockpiles have been published officially. Available information, however, indicates that in 1980 the U.S.S.R. was probably second among world producers with output estimated at 260 tons, or about 2% above the 1979 level. Over two-thirds of the gold output is from the Soviet Far East and East Siberia (mainly from placers at Kolyma, Aldan, Dzhugdzhur, Indigarka, Yana, and Chukotka); the balance comes mainly from gold and polymetallic ores in the Urals, Kazakhstan, Armenia, Uzbekistan, and West Siberia. However, substantial quantities are also produced as byproducts at nonferrous operations. The biggest sources of byproduct gold in the U.S.S.R. are copper and lead-zinc ores.

Soviet gold production has maintained a steady annual growth rate of about 2%. Prompted by the higher international prices, the U.S.S.R. plans to increase production and has been importing large-scale equipment from West Europe, the United States, South Africa, and Japan. Based on ore reserves, geological and mining conditions in the country's largest gold-producing regions, and fragmentary, indirect reporting, production is estimated at 275 tons in 1985; yet the quota for gold production was not met in 1980. Poor work results were achieved by almost all mining administrations of the Severovostokzoloto association.

Soviet gold holdings are secret, and current production does not automatically reach the world market for gold. Soviet sales are conditioned by both economic and political considerations. Throughout the 1970's, the U.S.S.R. has managed its gold sales to the West carefully, and it is likely that this policy will continue. Official gold sales are declining as prices increase. Also, in the past, gold sales have been occasionally used to finance emergency grain imports.

Dealers estimate Soviet gold sales in 1980 at 80 tons, about 40% of the 1979 figure. Soviet gold enters the markets mainly in Zurich, Frankfurt, and London. Soviet gold and platinum-group metal sales strategy will be critical in shaping world prices of the 1980's.

Potential reserves of gold in ore were estimated at about 6,200 tons in 1979. Although Soviet sources report reserves sufficient for 12 to 15 years at the present rate of production, extensive prospecting continues. Several big mines are suffering from lack of reserves and new mines have been opened in the northeastern parts of the Soviet Far East and the Yakut A.S.S.R. In view of the importance of gold, an intensive search is in progress in the Asian part of the country. It is planned to construct the first stage of the gold mining and concentration complex in Kirgiziya during the 1981-85 period.

Magadan Oblast' is the main producing center with 35 placer mines, 23 dredges, over 500 sand-washing rigs, and about 1,500 bulldozers. Construction of the Dukat complex in the Omsukchansk county of this Oblast' started 12 years ago, and it was put into operation only in January 1980. There was a shortage of earthmoving equipment and some machines were idle for lack of spare parts, while others were undergoing repairs at the Vostokzoloto association plants for a long time. The 1976-80 5-year targets for discovery of gold deposits at the Severovostokzoloto association was not met, but the 1976-80 quotas for gold production in the Chukchi Autonomus Okrug was reportedly overfulfilled.

The development of the Muruntau deposit in Uzbekistan, which was discovered in 1960, continued in 1980. The Muruntau open pit was over 100 meters deep in 1980 and the overburden:ore ratio was 35:1. Estimated output of gold at the Muruntau complex in 1980 was 27 tons. Special attention was paid in 1980 to improving technology of gold recovery at the Ararat plant in Armenia, which is fed by ores from the Zod deposit. In Yakutia, the second largest gold-producing region, the Lenzoloto Trust was

the leading gold-dredging enterprise. The deepest shaft (890 meters) in the Soviet gold mining industry was under development at the Bestube Mine in the Tselinograd Oblast' in Kazakhstan.

Iron Ore.—In 1980, 71 underground mines and 59 open pits, with a total estimated capacity of over 300 million tons of usable iron ore, produced 245 million tons of direct shipping ores plus concentrates (crude ore over 500 million tons), an increase of 3 million tons compared with the 1979 level. Production of usable ore was scheduled to reach 276 million tons (crude ore 560 million tons) in 1980, according to the 5-year plan. There were 92 iron ore concentrators, of which 29 had sinter facilities and 7 had pelletizing facilities in operation (Sokolov-Sarbaysk, Kachkanar, Lebedinsk, Kremenchug, and 3 in Krivoy Rog) with a total estimated annual capacity of 52 million tons. Output of pellets was estimated at 45 million tons in 1980, compared with the original 5-year plan target of 62 million tons.

During the 1976-79 period, new facilities were constructed for an annual production of 108 million tons of crude iron ore, or 60 million tons of usable ore. Of this amount, a 40-million-ton capacity for crude iron ore production replaced depleted facilities. At the Mikhaylovsk mining and concentration complex in Kursk Oblast', the No. 13 section, with 0.8 million tons per year of iron concentrate (1.5 million tons of crude ore), was commissioned in November 1980. New facilities for production of 1.7 million tons of iron concentrate at the Lebedi complex in Belogordskaya Oblast', went into operation in August. This is the second plant at the complex with the same capacity. The complex now has the capacity to process 23 million tons of crude ore annually. The second stage of the No. 2 pelletizing plant at the Dneprovsk complex, with an annual capacity of 3 million tons of iron pellets, was commissioned in November. At the Cherepovets metallurgical plant a new sintering section, with a 2-million-ton-per-year capacity of raw material, was commissioned in November.

The Severnyy mining and concentration complex in Krivoy Rog has become the biggest enterprise in the country for production of iron ore concentrate. The last stage of the new concentration plant was commissioned on April 4, 1980, its annual production capacity is 7.69 million tons of concentrate. The fifth stage of the Olenogorsk mining and concentration complex in Murmansk Oblast', with a capacity of 1,275,000 tons per year of iron concentrate, was commissioned in July. The total annual capacity of five stages is about 6 million tons of concentrate. The first stage of the Yubileynaya Mine in Krivoy Rog was commissioned in December. The design capacity of the mine is 4 million tons per year of crude iron ore. Sinking of the 620-meter-deep first shaft at the Yakovlevo Mine in Belgorodsk Oblast' was completed in April 1980.

Exports of iron ore increased from 36.1 million tons in 1979 to 40 million tons in 1980, principally to CMEA countries. Although a large exporter of iron ore, the U.S.S.R. has continuous problems supplying its own plants, both quantitatively and qualitatively.

The iron content in crude iron ore decreased from 50% in 1950 to 44.5% in 1960, 37.3% in 1970, and 35.1% (planned) in 1980. As a result, the ratio of ores subject to beneficiation increased from 37% in 1950 to about 87% in 1980.

Open pit mining is used in about 74% of the total volume of usable iron ore. In 1980, there were 10 pits, 150 meters or more deep; 16 pits over 200 meters deep (250 to 300 meters at the Sokolovskiy, Sarbayskiy, and other pits). The main underground mining regions are the Krivoy Rog Basin in the Ukraine (60%), the Gornaya Shoriya in Western Siberia (16.7%), and the Tagilo-Kuvshinskiy region in the Urals (16.4%).

The total iron ore reserves in place in the $A+B+C_1+C_2$ categories are 111,000 million tons (as of January 1, 1976), averaging 34.8% iron. These were distributed, as follows: The Ukraine (31%), European Center (24.4%), Urals (15.7%), Kazakhstan (15.0%), Siberia (7.4%), Northwest (3.0%), Soviet Far East (2.5%), and others (1%). Total national reserves in categories $A+B+C_1$ were estimated at 60,200 million tons, averaging 38% iron. This figure included 10,300 million tons of ore, averaging over 55% iron, which does not require dressing, and 34,800 million tons of easily dressed iron ore.

The Ukraine produced over 50% of Soviet iron ore and the Krivoy Rog Basin produced about 89% of the Ukraine's total in 1980. The Kursk region was the second largest producer, followed by the Urals, Kazakhstan, Siberia, and the Kola Peninsula. There were 23 underground mines (10 mining administrations), 9 large and several small open pits in operation in Krivoy Rog in 1980.

Over 40 million tons of crude iron ore were produced in the Kursk region in 1980. It was planned to reach 47 million tons by 1980. There were four iron ore producing enterprises in this region in 1980: The KMAruda complex, the first stages of the Lebedin and Mikhaylov complexes, and the Stoylensk open pit. Development of the Yakovlevsk underground mine, which began in 1974, is proceeding slowly, and the sinking of the second shaft (700 meters deep) started in 1979. The Lebedin complex did not meet production targets for any year of the 1976-80 period.

There are shortages of iron ore in the Urals and over 10 million tons of ore are shipped annually to the Urals from KMA and other regions of the country. Iron ore production in Kazakhstan accounted for 9% of the total, mainly from the Sokolov-Sarbay complex, with an annual capacity of about 30 million tons of crude ore (13.4 million tons of concentrate and pellets).

According to an October 1973 agreement, Finnish companies are building the Kostamush iron ore complex in Soviet Karelia about 30 kilometers from the Finnish border. This project will be built in three stages and will have an annual capacity of 8.9 million tons of pellets (24 million tons of crude ore). Construction of the first stage for the production of about 3 million tons of pellets per year began in 1977 and will continue until 1982. Finland will buy up to 1.2 million tons of pellets per year during the 1983-90 period. The deposit contains an estimated 1,200 million to 1,500 million tons of ore with an average iron content of 31%. Construction will take from 8 to 10 years. When the first stage is completed, production will be 2.96 million tons of pellets annually from 3.25 million tons of concentrate (8 million tons of crude ore). Mining of iron ore on a limited scale started at the Kostamush complex in 1980. For the time being, the ore will be stockpiled.

Iron and Steel.—In 1980, the Soviet iron and steel industry held first place in the world in total quantity of iron ore, coke, refractories, crude steel, ferroalloys, and steel pipe production. However, while the Soviet Union is the largest steel producer in the world, it may also waste more steel than any other country. According to the various published accounts in the Soviet press, the Soviet industry in 1980 used only 73% of the rolled steel that it consumed, with the remaining 27% being wasted. There is also considerable waste in the production of steel. A careful and exhaustive study of Soviet publications show that only about 45% of the total crude steel production is efficiently used in the Soviet economy; 55% is remelted or lost.

Despite the great volume of steel production, the lack of suitable metal limits the development of the economy, and the country became a net importer of efficient rolled steel products in 1978. There are nine main reasons for such a situation:

1. Slow realization of basic qualitative changes in metallurgy itself and a lag in introducing new technological processess into metal-consuming sectors of the economy.
2. Rolled metal products are often turned out with deviations from standards and technical specifications.
3. Rolled metals do not undergo supplementary treatment and do not acquire new qualifications. According to calculations made by Soviet scientists, about 10 to 15 million tons of metal each year are carried away or eaten up by corrosion. Metal needs to be protected.
4. In many construction projects, there have been delays in putting new equipment into operation. The chronic troubles facing the construction work have been project completion delays, a diminishing number of planned projects, higher construction costs, and excessive consumption of labor and materials.
5. The new projects have not achieved design capacities for a long period of time.
6. There is a lack of reserve production equipment. Between 50% and 60% of the main units of metallurgical equipment used in the period from 1966 to 1980 were operated beyond their rated limits.
7. There have been problems in the supply of raw materials. Currently the biggest problem facing the Soviet Union is railway transportation. The iron and steel works in the coal-rich Ukraine area are in need of coking coal. The Donets coal basin can no longer ensure a coking coal supply for the local iron and steel works. The supply has to come from the Kuznetsk in Siberia and Karaganda Basin in Kazakhstan.
8. Negligence is tolerated in the storage and utilization of metal.
9. Significant losses are caused by mismanagement in storing and dispensing metal products.

The 10th 5-year plan called upon the steel industries to increase output both quantita-

tively and qualitatively. Production of crude steel was to increase from 141.3 million tons in 1975 to between 160 million and 170 million tons in 1980. Soviet crude steel output in 1980 was 148 million tons and was 1.1 million tons down from 1979. Production of finished rolled steel was to increase from 98.7 million tons to between 115 million and 120 million tons. Actual production of finished rolled steel in 1980 was 103 million tons, 0.2 million tons below that of 1979. The 11th 5-year plan (1981-85) calls for increased production of finished rolled steel from 103 million tons in 1980 to 117 million to 120 million tons in 1985.

In 1980, 36 enterprises, operating 138 blast furnaces, produced an estimated 108 million tons (revised planned quota 114.2 million tons) of pig iron, 1% less than that of 1979. The average blast furnace capacity increased from 1,135 cubic meters in 1971 to 1,258 cubic meters in 1979. About two-thirds of all blast furnaces use oxygen for enrichment; over 83% of the pig iron was produced by partial use of natural gas, and 75% was produced by use of oxygen.

Crude steel production from 76 metallurgical works decreased by 0.7%, from 149.1 million tons in 1979 to 148 million tons in 1980 (revised planned quota 157 million tons). There were 42 oxygen converters (including 9 with a capacity of 250 to 300 tons) in operation in January 1981.

Soviet finished rolled steel product output in 1980 totaled 103 million tons (planned quota 107 million tons), a decrease of 0.2 million tons compared with that of 1979. It is planned to produce 117 million to 120 million tons in 1985.

In terms of tonnage, the Soviet Union was the largest world producer of steel pipe, with a total of 18.2 million tons in 1980. The gas industry has consumed about 4 million tons of steel pipe (including over 3 million tons of 530- to 1,420-millimeter pipe). Construction of facilities for pipe production continued at the Vyksa metallurgical plant in Gor'kiy Oblast'. Pipe developments in the U.S.S.R. include the construction of a new 15,700-ton-per-year pipe mill at the Azerbaydzhan plant and the 320,000-ton-per-year mill at the Severskiy plant in Sverdlovsk Oblast'.

Lead and Zinc.—With an estimated output of primary lead at 525,000 tons and zinc at 785,000 tons, the U.S.S.R. was probably the world's second largest producer in 1980. Estimated output of secondary metal was 100,000 tons of lead and 80,000 tons of zinc. Estimated primary production in 1985 is 550,000 tons of lead and 820,000 tons of zinc. Lead exports increased from 92,400 tons in 1970 to an estimated 100,000 tons in 1980 and zinc exports from 95,100 to 100,000 tons over the same period. The Soviet Union imported an estimated 80,000 tons of lead and 70,000 tons of zinc in 1980. Reportedly, under the 1979-80 2-year contract, Cyprus Anvil Mining will supply about 15,000 tons each of lead and zinc concentrates.

During the 1966-77 period, output of zinc increased by 80%, but neither lead nor zinc output quotas were reached in 1980 nor in previous years, owing to the slow construction of new facilities, poor supplies, and low metal recoveries.[89] Over 10% of the total lead and zinc production was recovered as a byproduct in 1980. The lead content of mined ores has declined by 0.2% in recent years. Despite of this, however, recovery of lead into concentrate has increased.

The metal content of ore reserves was estimated in 1980 at 16 million tons of lead and 20 million tons of zinc; over two-thirds are located in Kazakhstan, chiefly in the Altay region and in the district of Kara-Tau. There are also large reserves of zinc in the Urals. Exploration of the Uchkulach lead and zinc deposit in Uzbekistan, Chekmar' in Kazakhstan, and Kholodninskoye in Buryat A.S.S.R. continued in 1980. An exploration shaft was being sunk at the Achisay polymetallic complex in Kazakhstan.

Kazakhstan continues to be the leading lead and zinc producer, followed by the Urals, Uzbekistan, Siberia, North Causcasus, and the Ukraine. Production of zinc in Kazakhstan increased by 80% and that of lead by 32% during the 1967-76 period. Kazakhstan produced 50% of zinc and over 70% of the total lead in 1980. The planned quotas for lead and zinc production in Kazakhstan for the 1976-80 period were not met.[90]

The future development of the ore base and Altay region in East Kazakhstan is of serious concern to Soviet officials. The output of polymetallic ores has increased fourfold in the past 10 years, but grades have dropped by 40%. A 20% increase in the output of mined ore was reported at the Zyryanovsk complex with a 25% drop in lead-zinc content.

In the Urals, the second largest zinc producing region, the problem of zinc and gold recovery from the copper-pyrite ores remains unsolved. Slow development of the

mines in the Urals has resulted in shortages at the concentrators. The recovery of zinc in zinc concentrates from copper-zinc ores is on the average only 60%. There are also shortages of lead-zinc reserves at the Sadonsk deposit in North Caucasus. This is the main supplier to the Elektrotsink zinc plant in Ordzhonikidze. Development of the new mining facilities at the Adrasmansk lead-zinc complex in Tadzhikistan are behind schedule.[91] The first stage of the Nikolayevsk lead-zinc mine in the Soviet Far East went into operation in 1980.

Magnesium—Five magnesium plants, with an estimated combined annual capacity of 85,000 tons, produced 74,000 tons in 1980, 3% more than in 1979. Exports of metal increased from 11,380 tons in 1975 to an estimated 15,000 tons in 1980. Production and consumption of rolled metal in the U.S.S.R. is small. Reportedly, over the years of the ninth 5-year plan (1971-75), the output of magnesium and its alloys increased 20.2%. According to the 1976-80 plan, output of magnesium and its alloys was to increase by 23.8% to 74,000 tons compared with an estimated 60,000 tons in 1975.

Manganese.—The Soviet manganese industry remains the largest in the world, with an estimated output of 10.25 million tons (over 23 million tons of crude ore with an average of 23.4% Mn), the same as in 1979. Planned production quotas for 1980 were 10 million tons of marketable ore (23.4 million tons of crude ore), about 80% of the total came from the Nikopol' Basin in the Ukraine, and the rest from the Chiatura Basin in Georgia. About 300,000 tons of crude ore were produced in Kazakhstan. During the 1976-80 period, new facilities for production of 6.36 million tons of crude ore were to be put into operation. Estimated production of marketable ore in 1985 is placed at 12 million tons. During the 1981-85 period, the greatest increase in manganese ore output will be from open pit mining in the Ukraine.

Exports of manganese ore increased from 1.32 million tons in 1979 to an estimated 1.35 million tons in 1980. About 20% of the total was shipped to Western countries and 80% was exported to CMEA countries, which are also helping to increase Ukrainian manganese output.

At yearend 1969, reserves of manganese ore in categories $A+B+C_1+C_2$ were estimated at 2,500 million tons, with an average manganese content of 23% to 26.4%. This included 1,020 million tons in the Nikopol' Basin. Reserves of high-grade ore are located in the Chiatura Basin. Furthermore, detailed exploration of the Ushkatyn III manganese deposit in Kazakhstan and preliminary examination of the Porozhin manganese deposit in Krasnoyarsk Kray continued in 1980. A pilot shaft 106 meters deep was sunk at the Bol'shoy Takmak manganese deposit in the Ukraine in 1980.

The principal Soviet manganese basin, the Nikopol' in the Ukraine, has reserves many times greater than the Chiatura, but the ore (average grade 26.4% Mn) is little more than 2 meters thick and is under 80 meters of overburden. Two concerns, the Ordzhonikidze and Marganets, operate in the Nikopol' Basin, containing 19 underground mines, 10 open pits, and 9 concentrators in operation in 1980. More than 75% of the Nikopol' ore comes from open pit operations. Of the concentrated ore, about 48% had a manganese content of over 45%; the balance contained 34%. Construction of the Tavricheskiy manganese complex in Zaporozhye Oblast' began in 1979. Development of an underground mine at this complex, with an annual capacity of 2 million tons of crude ore, also began in 1979. Completion of the development of new mining facilities (400,000 tons per year) at the Chkalov No. 1 open pit was rescheduled from 1979 to 1981.

The Chiatura manganese basin in Georgia, the richest in the U.S.S.R., produced about 2.5 million tons of concentrates in 1980 from 24 underground mines and open pits and 8 concentrators. Over 80% was extracted from underground mines. Of the total amount of beneficiated ore, 66% contained 48.7% Mn and the rest contained 25.6% Mn. A mine with an annual capacity of 300,000 tons of crude manganese ore went into operation in 1980, and two other mines, with the same capacities, were under development in the Chiatura Basin in 1980. Small amounts of manganese ore were produced at the Dzezhdy and Atasuy Mines in Kazakhstan. The Dzezhdy manganese ore-dressing plant, which was put into operation in May 1965, processed low-grade ore for the Nikopol' (Ukraine) and Yermak (Kazakhstan) ferroalloys plants. Kazakhstan's manganese ore is sulfur-free and does not contain other impurities. The small Zhaksykotyr manganese open pit became operational in 1978, and the development of the Tsentral'naya Mine of the Dzhedy Ore Administration continued.

Mercury.—Output of mercury was esti-

ated at 62,000 flasks (76 pounds each) and the U.S.S.R. was apparently self-sufficient in 1980. There are numerous deposits mainly in Central Asia, the Soviet Far East, and the Ukraine. The Khaydarkan complex in the south of Kirgiziya, the largest Soviet mercury operation, had four mines and a recovery plant in operation in 1980. At this complex, mercury is mined by both underground and open pit methods. Sinking of the 850-meter Tsentralnaya shaft of the Ulug-Too Mine at this complex continued in 1980. A new shaft at the Chanvay Mine of the Khaydarkan complex was under development in 1980. It is planned to develop the Novoye mercury-antimony deposit at the Khaydarkan complex. The renovation of metallurgical facilities at the Khaydarkan complex continued in 1980 and is scheduled for completion in 1981. Near the Khaydarkan complex, the Glubokaya Mine became operational in December 1980. In the 1981-85 period another mine, Tsentral'naya, is to be developed there. This will increase ore output and mercury production.

The Nikitovskiy complex in the Ukraine, where over 70% of ore is mined by underground and about 30% by open pit methods, is the second major producer of mercury. Two underground mines (2-bis Novaya and Novozavodskaya) and the Polukupol Novyy open pit were in operation here in 1980. The complex overfulfilled the production quota of mercury in 1980. The small Zarkarpatskiy mercury complex processes ores from the Borkutnoye, Shayanskoye, and other small deposits in Zakarpatskaya Oblast', West Ukraine.

Mercury output in the Magadan Oblast' was higher in 1980 than in 1979. Construction of the new Dzidzikrutskiy (Aznob) mercury-antimony complex in Tadzhik S.S.R. continued during the year. Completion of the first stage of this complex has been rescheduled for 1981 from 1976. The development of small deposits is planned in North Caucasus, at Chukotka in the Magadan Oblast', and in other regions of the U.S.S.R. Exploration for new deposits in Kirgizia, the Soviet Far East, and other regions of the country continued in 1980.

Molybdenum—Output of molybdenum concentrates was estimated at 10,400 tons (metal content), 2% above that of 1979. Reserves of molybdenum in ore (molybdenite, copper-molybdenum, and tungsten-molybdenum ores) in the U.S.S.R. may approach 200,000 tons. About 50% of the production is based on copper-molybdenum ores from Armenia, Kazakhstan, Sorskoye, and Siberia; over 30% is from the tungsten-molybdenum ore of Tyrny-Auz (Kabardin A.S.S.R. in the North Caucasus) and Dzhida (Buryat A.S.S.R.). The remainder comes from molybdenite ore mined in Uzbekistan and Siberia. There are more than 100 known deposits of molybdenum, mainly in the Urals, but most are too small to be mined economically.

The deposits now in exploitation are in eight geographic areas. Armenia occupies first place, but concentrates are shipped out of the Republic for further treatment. The Zangezur copper-molybdenum complex (the former Kadzharan and Kafan complexes) supplied over 25% of Soviet molybdenum in 1980. Open pit mining and high metal content in the ores have made Kadzharan molybdenum concentrate among the cheapest in the U.S.S.R. However, there are shortages of ore reserves at the Kafan and Agarak mining and concentration complexes. It is planned to install a molybdenum converter at the Alaverdy metallurgical complex in Armenia.

The Sorsk molybdenum complex in Krasnoyarsk Kray was the largest producer in 1980. Although the ratio of overburden to the ore at the Sorsk open pit increased by 59.3% during the last 6 years, the complex continued the fulfillment of the concentrate production quota. The Tyrny-Auz tungsten-molybdenum complex, which operates the Molibden underground mine and the Mukulanskiy open pit, was undergoing enlargement in 1980. Output of ore at the Mukulanskiy open pit increased, and the output of ore and overburden amounted to about 1 million tons in 1980. The Chorukhdayransk concentrator processes copper-molybdenum ores from the Chorukhdayransk and South-Yashransk deposits in Tadzhikistan. Output of rolled molybdenum in Uzbekistan increased in 1980. Construction of the Zhireken molybdenum complex in Chita Oblast', the completion of which was originally planned for 1975, lagged behind schedule in 1980.

The first stage of the Erdenet copper-molybdenum mining and concentration complex in Mongolia was completed in 1979. Construction of the second stage of the Erdenet complex continued in 1980. Exploration in the 1960's outlined large ore reserves grading 1% copper and 0.02% molybdenum; the concentrates from this complex are shipped to the U.S.S.R.

Nickel.—With an estimated 174,000 tons

of primary production, 1.1% more than in 1979, Soviet nickel output was second to Canada. During the 1966-75 period, output of nickel increased by 94%. There was a plan to increase metal production by 20% to 30% in 1980 compared with that of 1975. But actually, during the 4-year (1976-79) period, production of nickel increased only by 6%.[92] Cuba produced around 37,000 tons of nickel-in-concentrate in 1980. Cuba refines about 18,000 tons of oxides locally in refineries. The remaining cobalt-nickel sulfide concentrate was sent to the U.S.S.R. and Czechoslovakia. About 19,000 tons of nickel cobalt concentrate from Cuba is smelted in the U.S.S.R. The 1981-85 5-year plan calls for increase production of nickel and cobalt by no less than 30% in 1985 over that of 1980.

Known reserves in the Soviet Union are not likely to exceed 5 million tons of contained nickel metal, about half of which consists of low-grade silicate ores. Over 50% of the total reserves is in cupriferous pentlandites, containing commercially recoverable copper, cobalt, platinum-group metals, and some minor metals. Sulfide ores are mined at Norlisk in Krasnoyarsk Kray (East Siberia) and in the Pechenga-Monchegorsk area in the Kola Peninsula. Oxide ores are produced in the Aktyubinsk area of Southern Urals, the Ufaley area of the Central Urals, and the Ukraine. The centers of production, in order of importance, continue to be Norilsk, the Urals, and the Kola Peninsula. Of the seven smelters in operation, Norilsk is the most important; the Ufaley, Rezh, and Khalilovo smelters in the Urals are a close second; the Monchegorsk and Pechenga smelters are third; and the Pobuzhsk ferronickel plant in the Ukraine is fourth. In the future, the Soviet Union will be an important nickel exporter, based on both Soviet and Cuban concentrates.

The Norilsk complex in East Siberia is producing copper, nickel, cobalt, platinum-group metals, gold, silver selenium, and other rare metals. During the 3-year period prior to 1979, production of refined nickel increased by 10.9% compared with a 20% planned target. Construction of new facilities, which were to increase capacities for production of nickel by 80%, copper by 70%, and cobalt by 16% was planned. Capital stocks of the Norilsk complex are valued at over 3,000 million rubles. Annual expenditures for capital repairs amounted to about 100 million rubles and for current repairs in excess of this amount.

Construction of the 1,000-million ruble Nadezhda metallurgical complex at Norilsk, a major project of the 10th 5-year plan (1976-80), continued with the technical assistance of Finnish companies; its capacity is to be 550,000 tons per year of nickel concentrate (100,000 tons of nickel) and 650,000 tons per year of copper concentrate (200,000 tons of copper). The autoclaves of this facility are the first of their kind in the Soviet Union's nonferrous metallurgy. The first stage was put into operation in October 1979, producing sulfide concentrate and sulfur from sulfur concentrate. Planned production of the first copper and nickel at the Nadezhda plant at Norilsk is scheduled for February 23, 1981. A new nickel electrolysis shop is to be brought into service in 1981. When the Nadezhda complex attains full capacity, it is expected that output of nickel will be doubled. The new facility will be fed by a 33-kilometer slurry line from Talnakh.

The ores at Severonikel production association in the Kola Peninsula are mined by both open pit and underground methods. The Zhdanov mining and concentration complex is the largest in this area. The capital stocks of the Pechenganikel metallurgical complex of the Severonikel production association are valued at $500 million. Four small underground mines (Kaula-Kotselvaara, Eastern, Western, and Northern) and one small open pit (Kaula-Kammiki) were in operation at the Pechenganikel complex in 1980. During the 1976-80 period, the production of ore at the Pechenganikel complex increased by 6.7%, output of matte increased by 7.3%, and production of nickel increased by 11.8%. Completion of additional production facilities at the nickel association in Monchegorsk, the Kola Peninsula, is planned for 1981. Production of nickel is to increase by 50% in the future.

The Port of Murmansk continued handling Norlisk ore for the Severonikel complex. During the 7 to 8 months of the navigation season, 200,000 tons were shipped; this figure is to be increased in the future. Oxide ore is mined at Promezhutochnoye, Novo-Burenov, Oktyabr', and at other deposits. The Shcherbakov oxide ore open pit at the Kimpersay region in the Aktyubinsk area of the south Urals in Kazakhstan was put into operation in 1979.

The U.S.S.R. is financing a $600 million expansion of Cuban nickel production, with

output of 20,000 tons per year scheduled for 1985. It was planned to expand production of the Nicaro plant from 18,000 to 22,500 tons per year by 1980; to expand production of nickel at the Moa plant from 18,000 to 24,000 tons per year by 1980; and to construct two 30,000-ton-per-year nickel-cobalt oxide plants within 8 kilometers of the Moa plant. The first new plant (Punta Gorda) is scheduled for completion by 1983-84 and the target for the second is 1985-86.

Platinum.—The Soviet Union remains the largest producer and exporter of platinum-group metals, supplying 20% to 25% of international exports of platinum and more than 50% of world consumption of palladium and rhodium. The U.S.S.R. is steadily expanding its output of platinum-group metals. The estimated output was 3.25 million ounces in 1980, or about 1.5% over that of 1979. Ore reserves are adequate to maintain production and increased exports for many years. In 1975, it was planned to increase production of platinum-group metals at Norilsk by 60% over 1970 levels. The 5-year plan called for Norilsk output to rise by about 80% in 1980 over that of 1975. But slow construction of the Nadezhda plant will limit Soviet primary production increases to an annual rate of 4% to 5%. Production of platinum and platinum-group metals may reach 3.5 million ounces in 1981.

Production of platinum and platinum-group metals comes principally from the Norilsk copper and nickel complex in Krasnoyarsk Kray, the Severonikel and Pechenganikel complexes ("Nikel" association) on the Kola Peninusla, and several smaller placer deposits in the Urals. Virtually all platinum-group metals were produced as byproducts with over 75% coming from Norilsk. The first stage of the Nadezhda plant at the Norilsk complex was put into operation in 1979. The high priority given to the Norilsk development suggests a determination to proceed with increased production despite high costs imposed by the harsh northern climate. Expansion is expected to accelerate in a few years, with completion of the Oktyabr' underground mine, and the attainment of capacity of the Nadezhda complex. The mine, under development since 1969, was scheduled for completion in six stages by 1980; the first four stages are in operation and development of stages 5 and 6 was rescheduled for the 1981-85 period.

Silver.—Output of silver was estimated at 46 million ounces, the same as that of 1979. Almost all silver is produced as a byproduct from nonferrous operations, although 14 gold treatment plants also produced silver in 1980. The Norilsk complex in Krasnoyarsk Kray and some copper-nickel enterprises in the Kola Peninsula are also producing silver. Production continued to be centered in the Urals, Kazakhstan, the Soviet Far East, East Siberia, and Armenia. Complex ores in the Urals contain 6 to 15 grams per ton of silver. By 1985, the U.S.S.R. should produce around 48 million ounces, compared with an estimated production of 46 million ounces in 1980. In 1980, the Soviet Union imported over 31 tons of silver compared with about 15 tons in both 1978 and 1979.

Both the Matrosovo gold ore mine and the Karamken gold mining and concentration complex of the Severovostokzoloto gold production association in the Soviet Far East did not fulfill the silver mining plans in 1980. The Karamken complex produced less silver than planned. The Dukat gold mining and concentration complex, also in the Soviet Far East, started production in 1980. However, the technology for extraction of this metal was not adjusted at this enterprise and the new equipment was not mastered. There was a shortage of drilling rigs at the open pits and pipes, which were needed for assembly of washing machinery.

Tin.—Although the Soviet tin production policy is based on self-sufficiency at any price, output continues to be inadequate and over 20% of requirements had to be imported in 1980. Primary tin production in 1980 was estimated at 36,000 tons, 3% over that of 1979. The Soviet Far East, Yakutia, and Transbaykal were the main tin producers. Output of tin may reach 38,000 tons by 1985. Most of new production will come from existing or currently developing mines in the Soviet Far East and Central Asia. In 1980, over 25% of total output was from placers of which the Soviet northeast accounted for 75%. The U.S.S.R. is buying tin mostly through London traders. Soviet consumption of tin for use in canmaking and other tin-related industrial products will be slightly increased over the next few years.

Soviet gross tin reserves are estimated at about 600,000 tons of contained metal. Nevertheless, there are shortages of explored reserves at many enterprises. The average

content in ores ranges from 0.6% to 1% Sn. Intensive exploration programs have been carried out and new small deposits have been reported.

The Maritime Kray is the largest producer and the Khrustal'nyy complex, which operates both lode and placer deposits, is the largest enterprise there. This complex operated the Khrustal'nyy, Ege-Khaya, Imeni Lazo, Kholodnyi, and Alyaskavityy mines in 1980. The Ternistyy and Arsen'evaskaya mines of this complex, which were scheduled for completion in 1975, were under development in 1980 and have been rescheduled for completion by 1981. The ore grade is 0.18% to 0.91% Sn at the Arsen'evskaya Mine and 0.87% at the Valkumey Mine in Magadan Oblast'.

The Khingan complex at Birobdizhan, Jewish Autonomous Oblast', Khabarovsk Kray, the largest tin producing enterprise in the U.S.S.R., was to produce more tin concentrate in 1980 following renovation of the concentrator in 1979. Development of the Berezovyy Mine at this complex continued and a new mine was built near the Obluchye. The Solnechnyy complex operated the Solnechnyy, Molodezhnyy, and Pereval'nyy mines. Expansion of the Solnechnyy complex at Khaborovsk Kray, Sherlovgor in the Transbaykal area, and the Deputatskiy complex in the Yakut A.S.S.R. continued in 1980. The Nadezhda Mine of the Solnechnyy complex was opened in May 1980. It was developed on the site of the depleted Pridorozhnyy and Perevalnyy open pits. Prospecting disclosed the lower seams still rich in tin. A foundation was being prepared for a grinding unit at a new shop of the central concentration plant of the Solnechnyy complex. The shop is to be put into operation in 1981. The Solnechnyy complex overfilled the production quotas for the 1976-80 5-year period. Sinking of a 220-meter-deep shaft at the Deputatskiy tin mining and concentration complex in Yakutia began in 1980. Ores from both the Svetlyy and Iultin mines are processed at the Iultin complex in the Magadan Oblast'.

The Tagobikul, Kumarkh, Mushiston, and the Kaznor deposits of Tadzhikistan are producing small quantities of tin. Recovery of tin has been organized by processing of tailings at the Ognevskiy concentration plant of the Belogorsk polymetallic complex in Kazakhstan. Recovery of tin has also been started from processing of lead scrap.

The La Palca plant, near Potosi in Bolivia, is being built with technical and financial assistance from the Soviet Union. The extraction of tin from the slag heaps is planned.

Three known tin refineries were operating in the U.S.S.R. in 1980: Novosibirsk, Ryazan', and Podol'sk (near Moscow). Concentrates from Siberia and the Soviet Far East are shipped to the Novosibirsk plant, which is the principal supplier of tin in the U.S.S.R. It was planned to increase output of metal at the Sherlova Gora, Ege-Khaya, Leningrad, Sinancha, and other smelters. Output of secondary tin in 1980 was estimated at 12,000 tons. Construction of a tin processing unit at the Rustavi secondary nonferrous metals plant in Georgia continued in 1980.

Titanium. —Titanium production in 1980 was estimated at 37,000 tons, about 3% over that of 1979. Production of titanium was programed to be raised 40% in the 1976-80 period, but during the years 1976-79 the actual increase was only 19.6%.[93] The Ust'Kamenogorsk titanium-magnesium complex in Kazakhstan experienced a shortage of raw material during the 1976-80 period. The titanium slags have been transported to this complex from the Ukraine.[94] Soviet reserves of TiO_2 have been estimated at about 10 million tons, from a 70-million-ton ore reserve averaging 10% to 20% TiO_2. The industry continued to be based mainly on Ukrainian and Siberian ilmenite and rutile.

The Soviet Union, which was supplying about 35,000 tons per year of titanium sponge to the world market, curtailed shipments in 1979. As a result, prices jumped from under $10 per kilogram to about $40. Reportedly, the U.S.S.R. imported 44,000 tons of titanium ores (ilmenite, rutile, and zircon) from Australia in 1979.

The most important sources of ilmenite are placer deposits on two right-bank tributaries of the Dnieper River in the Ukraine. Major producers continue to be the Samotkanskoye zirconium-titanium alluvial deposit and the Volchanskoye titanium deposit in Dnepropetrovsk Oblast'; the Irshanskoye, Streminogorskoye, and Zelenogorskoye titanium deposits in Zhitomirskaya Oblast'; and the Tarasovskoye deposit in Kiyevskaya Oblast'.

Two complexes, the Irshanskiy using dredges and the Verkhnednepprovskiy, operate these deposits and are the main raw material suppliers for the Soviet titantium industry. Four stages of the Irshansk con-

centrator were in operation in 1980.

Tungsten.—Production of tungsten in concentrates was estimated at 8,700 tons, the same as that of 1979, with North Caucasus, Kazakhstan, Uzbekistan, Transbaykal, and the Soviet Far East continuing as the principal producers. Production of tungsten was insufficient to satisfy growing domestic needs and about 2% of the concentrate requirements were imported. The following deposits were under exploitation in 1980: Tyrny-Auz (North Caucasus),Dzhida(Buryat A.S.S.R.); Chorukh-Dayron, Lyangar, Yubileynoye, and Ingechka (Central Asia); Akchataus, Karaobin, and Verkhne-Kayraktin (Kazakhstan); Iultin (Magadan Oblast'), Vostok, and Lermontov (Maritime Territory), and Kul'gutin in the Altay region. Most of the deposits in the U.S.S.R. are low grade. The largest deposit is in the North Caucasus, the Tyrny-Auz deposit, contains both molybdenum and tungsten. The largest deposits in Kazakhstan are the Verkhne-Kayraktin tungsten and Akchatau molybdenum-tungsten deposits. There are considerable reserves of tungsten at the Ingechke deposit in Uzbekistan and the Jidda deposit in Siberia. Completion of additional mining facilities at the Akchatau complex was rescheduled for 1981.

The main producer of tungsten concentrates is the Tyrny-Auz tungsten and molybdenum complex, where both underground and surface methods are used. The Nal'chik plant, based on Tyrny-Auz concentrates, continued operations with the expected increase in tungsten metal output. The Iultin complex is the only tungsten mining enterprise in the Magadan Oblast' and extensive improvements are being carried out here. During the 1976-80 period, the Vostok tungsten mining and concentration complex in the Soviet Far East was setup. The Chorukh-Dayronsk deposit in Tadzhikistan is almost completely depleted and has been replaced by the Yubileyonye deposit, which was put into operation recently. The exploration of the Bogutin deposit in South Kazakhstan and the Maykhura deposit in Tadzhikistan was completed.

The second stage of the Maritime Kray complex was under construction and scheduled for completion in 1982. Originally the richest tungsten ores were mined by surface methods, but an underground mine is now under development.

Vanadium.—The Soviet Union, with large vanadium resources, is becoming an important producer and exporter. The principal sources in 1980 continued to be vanadium-rich slag, a coproduct with iron from the titaniferrous magnetites of the Kachkanar open pits in the Urals. The Nizhniy Tagil metallurgical complex and the Chusovskoy metallurgical plant in the Urals are the enterprises that produce raw material for the production of vanadium and its alloys. Nizhniy Tagil, where the vanadium slag is produced from 130-ton oxygen converters, is the only modern enterprise. The vanadium content of the pig iron at Chusovoy is 0.54% and that at Nizhniy Tagil is 0.45%. After devanadization of the pig iron, the average V_2O_5 content of the slag at Chusovoy is 17.2% and that at Nizhniy Tagil is 21.2%.

The enlargement of facilities at the Kachkanar complex expanded output from 33 million tons of crude ore to 40 million tons, but slow construction of the facilities for processing of vanadium at the Nizhniy Tagil metallurgical complex has not made it possible to increase the output of vanadium products considerably. The development of the Kachkanar No. 2 and additional facilities at the Nizhniy Tagil complex is planned to increase production of vanadium in the future. It is also planned to construct special units at some alumina plants for the recovery of vanadium pentoxides as a byproduct from bauxite and other raw materials.

Minor Metals.—The Soviet Union possesses commercial deposits of all the rare metals that have assumed importance in modern rocketry, aircraft,and nuclear energy. However, extraction of many of the deposits remains low. The main deposits are in Kazakhstan, the Kola Peninsula, Uzbekistan, Armenia, the Urals, the Ukraine, Norilsk, Transbaykal, and the Soviet Far East. Known resources of rare metals are sufficient to satisfy the needs of the economy but prospecting still lags behind the potential of the main producing regions of the Soviet Union.

The primary sources of rhenium are molybdenite from copper-molybdenum deposits of Armenia, Kazakhstan, and East Siberia. Byproduct rhenium is recovered at the Balkhash and Dzezkazgan complexes in Kazakhstan, at the Kadzharan coppermolybdenum complex in Armenia, and at the hard-alloy plant in Uzbekistan.

The selenium content in the coppermolybdenum ores of Armenia ranges from 3.6 to 10.5 grams per ton and that of tellurium ranges from 1.5 to 6.2 grams per

ton. Copper concentrates of Armenia contain 46 to 110 grams per ton of selenium and 18 to 62 grams per ton of tellurium. There are 110 grams of selenium and 40 grams of tellurium in the charge of the Alaverdy metallurgical complex in Armenia. During the 1976-80 period, recovery of tellurium from lead dust at the Chimkentskiy lead plant in Kazakhstan increased by 1%.

Byproduct gallium is recovered from raw materials used to produce aluminum at Volkhov (Leningrad Oblast') and Pavlodar (Kazakhstan) aluminum plants and at the Tikhvin (Leningrad Oblast') alumina plant. Production of gallium increased at the Pavlodar aluminum plant in Kazakhstan in 1980. The main centers of indium and thallium extraction continued to be the Ust'-Kamenogorsk lead and zinc complex (Kazakhstan) and the Chelyabinsk zinc plant. The Ust'-Kamenogorsk titanium and magnesium complex in Kazakhstan began recovering scandium. In the 1976-80 period, recovery of thallium at the Chimkent lead plant in Kazakhstan increased by 3.4%. During the 1976-80 period, the output of minor metals at the Ust'-Kamenogorsk lead-zinc complex increased as follows: Indium, 80%; gallium, 95%; and selenium, 70%.

During the 1965-75 decade, the production of rhenium began at the Balkhash and Dzhezkazgan complexes and the Chimkent lead plant in Kazakhstan, production of gallium began at the Pavlodar aluminum plant, and production of vanadium and scandium began at the Ust'-Kamenogorsk titanium and magnesium complex. Facilities at the Chimkent lead plant for the production of thallium, cadmium, tellurium, germanium, and other minor metals from slag have been put into operation. At the Ognevsk and Belogosk concentration plants of the Belogorsk complex in Kazakhstan, facilities for the production of tantalum from tailings were put into operation in 1980. The Kirgiz metallurgical complex in Kirgiziya produces rare-earth elements.

Among enterprises exploiting zircon alluvial deposits in 1980 were the Samotkan deposit in Dneprovsk Oblast' in the Ukraine. The Verkhnedneprovskiy complex, brought into operation in 1969, increased output of zircon concentrate in 1980. The Mekhanobr Institute in Leningrad has developed technology for recovery of baddeleyite (ZrO_2) from magnetite iron ore of the Kovdor deposit at the Kola Peninsula.

NONMETALS

The Soviet Union produces a wide variety of nonmetallic minerals. However, the resources position varies from adequacy for many nonmetallic minerals to an apparent shortage of others such as barite, fluorspar, mica, and talc.

Asbestos.—The Soviet asbestos industry remains the largest in the world, with an estimated output of the seven grades at 2.15 million tons, or 130,000 tons more than in 1979. Over 59% of the total production came from the Uralasbest complex, about 30% from Dzhetygara in Kazakhstan, over 5% from the Tuvaasbest complex in Tuva A.S.S.R., and 6% from the Kiembay complex in Orenburg Oblast'. Exports rose from 385,000 tons in 1970 to 613,303 tons in 1,975 and to an estimated 500,000 tons in 1980, with about one-third going to Western markets. Despite the asbestos export expansion in recent years, the domestic deficit was expected to be about 100,000 tons in 1980.

Development in the asbestos industry has been concentrated in the Urals, Kazakhstan, Tuva A.S.S.R., and Orenburg Oblast'. Total output of the seven grades of asbestos at the Uralsasbest complex was estimated at 1.27 million tons. Reported production was 1,256,000 tons in 1979 and 1,240,000 tons in 1978.[95] Three open pits at this complex produced 41 million tons of crude ore and dumped 103 million tons of overburden in 1980. It is estimated that mining of crude ore and overburden will be increased from 144 million tons in 1980 to about 150 million tons in 1981, but production of marketable asbestos is expected to remain unchanged at about 1.27 million tons because of reduced grades. It is planned to construct the No. 7 concentrator at Uralasbest with an annual capacity of 340,000 tons of asbestos.

In Kazakhstan, a large complex has been developed for the Dzhetygara deposit in Kustanay Oblast', the second largest in the Soviet Union. The first mill (annual capacity 200,000 tons) was commissioned in 1965. During the 1971-75 period this mill was renovated and production increased from 259,000 tons in 1970 to an estimated 350,000 tons in 1980. The Dzetygara No. 2 mill (annual capacity 400,000 tons) was completed in 1975 and produced an estimated 290,000 tons in 1980. Total output at the Dzhetygara complex was estimated at 640,000 tons in 1980.

The first mill of the Tuvaasbest complex (commissioned in 1964) produced 50,000 tons in 1980. A second mill was commissioned in April 1976. Total output at this complex was estimated at 110,000 tons in 1980.

Construction of the Kiembay asbestos complex in Orenburg Oblast' (Southern Urals) was started in 1968 and continued in 1980. Seven CMEA members are assisting with this project. It calls for a total contribution of 106.2 million transferable rubles from the six East European member countries. The total cost of the project is 300 million rubles.

The design capacity of the Kiembay project is 500,000 tons per year of grades III through VI from 24 million tons of ore with an average grade of 4.4%. The first 250,000-ton stage was completed in November 1979, and 130,000 tons were produced in 1980. The output will be shared among the CMEA members in proportion to their contribution. Equipment was supplied by Bulgaria, Hungary, the GDR, Poland, and Romania; Czechoslovakia shipped machinery for ore transport. From 1981, 170,000 tons of asbestos will be supplied annually to the participating countries for 12 years and afterwards they will be able to extend the agreement for another 10 years. The second stage of the Kiembay complex was put into operation in December 1980. It is to produce 250,000 tons of asbestos per year, raising the complex's total capacity to 500,000 tons per year.

Barite.—Barite is mined by both open pit and underground methods at many operations; crude output is concentrated by flotation. Estimated domestic production in 1980 totaled 500,000 tons. In 1980, about 50% of the country's barite consumption was produced domestically; the balance was imported, mainly from North Korea, Yugoslavia, and Bulgaria. The main centers of production continue to be Georgia, West Siberia, and Kazakhstan. Construction of a 45,000-ton-per-year complex in Khaishi in Svanetia, Georgia, and the development of the underground mine at the Zharemsk polymetallic complex in Kazakhstan continued in 1980. Production of barite from old tailings of the Maykansk, Kayraktinsk, and Kentaussk concentration plants in Kazakhstan started in 1980.

Diamonds.—The U.S.S.R. continues to make progress in expanding its diamond industry, which is centered in Yakutia, where about 20 deposits have been discovered. In 1980, output was estimated very roughly at 8.6 million carats of industrial quality and 2.25 million carats of gem quality. Next to fossil fuels and precious metal exports, diamonds account for a large share of the Soviet Union's overall foreign earnings.

Production in Yakut A.S.S.R. started at a small plant in 1957. In January 1980, the industry consisted of the Mirnyy open pit with five concentrators, the Aykhal open pit and concentrator, the Udachnaya placer mine and concentrator, and the Irelyakh placer mine with two dredges. Small quantities of gem and industrial stones are produced from the Vishera River region in Perm Oblast' (Western Urals) where four dredges and two separation plants were operated at two deposits in 1980. The enlargement of the Udachnyy complex was completed, and the second stage of the concentrator was put into operation in August 1978.

A substantial but unkown quantity of synthetic diamond was produced in 1980 by plants in Kiyev, Yerevan, Moscow, Tashkent, and Poltava.

Gem stones are cut at Leningrad, Sverdlovsk, and Smolensk. Sales of cut stones are rising steadily, and substantial increases were expected by 1980. The U.S.S.R. has arranged to market part of its diamond output in Antwerp through a newly formed Soviet-Belgian company in which the Soviet export organization Almazyuvelirexport has the controlling interest.

Mineral Fertilizers.—Estimated production totaled 24.6 million tons in nutrient content or a reported 104 million tons (original planned quotas 143 million tons and revised quotas of 115.3 million tons) in bulk fertilizer content, an increase of 10% over that of 1979. In 1980, plant capacities were to be expanded by about 11 million tons per year of fertilizers (Soviet standard). The Soviet fertilizer industry is beset by serious problems and did not meet even its revised targets for production of fertilizers or for the construction of additional facilities. Fertilizer production was 39 million tons (Soviet standard) below the original planned target and 11.3 million tons below the revised goal for 1980.

It is estimated that nitrogen fertilizers constitute around 42%, potassium fertilizers about 34%, phosphate fertilizers 21%, and phosphate flour 3% of total fertilizer output. In 1985, the Soviet mineral industry plans to produce 150 million to 155 million tons (Soviet standard) of fertilizers, or 36

million to 37 million tons of nutrient content. The mineral fertilizer industry was favored in terms of the import of Western machinery and equipment. Ammonia production was also to benefit from imported technology. About 26 large Western-supplied ammonia plants were planned to be commissioned in 1976-80, representing 11.4 million tons of the 13.5 million tons in planned additional capacity. The results achieved by 1980, however, do not appear to justify the goals set in 1976.

There was an increase in exports of mineral fertilizers. Despite substantial production and large exports, fertilizers did not meet domestic demand.

During the 1976-80 period, equipment for 26 ammonia plants, each with a capacity of 450,000 tons, was to be supplied by Western companies. They were to be constructed with the assistance of Toyo and Mitsui Engineering (18 plants), Chemico (4 plants), and Cruesot-Loire (4 plants). Two ammonia plants near Odessa (Odessa Nos. 1 and 2) have been built on a compensation basis under an agreement with Occidental, calling for the supply of urea to the United States in exchange for superphosphate acid. Under an agreement signed in July 1980, Vietnam was granted a large credit to build a fertilizer plant with Soviet assistance.

The average content (nitrogen, phosphorous, and potash) is expressed in Soviet standard units. Nitrogen is expressed as ammonia sulfate, 20.5% N, phosphate is expressed as 18.7% P_2O_5, potash is expressed as 41.6% K_2O, and ground rock phosphate (phosphatic flour) is expressed as 19% P_2O_5.

Phosphate.—Estimated output of phosphate rock totaled 64 million tons in 1980, including 45 million tons of apatite ore (16.4% P_2O_5) and 19 million tons of sedimentary rock (13% P_2O_5). The main production centers continued to be the Apatit Association on the Kola Peninsula and phosphorite deposits at Karatau in Kazakhstan. The Chilisay phosphorite basin in Aktyubinsk Oblast', Kazakhstan, which is under development, will be the third main center of phosphorite production. Deposits of phosphorites also occur in Upper Kama in the Urals, Egor'evsk, and Lopatino in Moscow Oblast', Kingisepp in Leningrad Oblast' and some other regions, but the grade is rather low. Generally they produce phosphorite flour with about 19% P_2O_5. The apatite concentrate provided over 80% of all raw materials for the production of phosphate fertilizers. Over a number of years the Soviet Union has been progressively reducing its exports of apatite concentrate to Western Europe. In 1980, these exports decreased to an estimated 200,000 tons compared with 300,000 tons in 1978. During the 1981-85 period, the output of Soviet mineral fertilizers is to increase by 50% and be brought up to no less than 150 million tons (Soviet standard) in 1985. The most rapid rate of growth is to be in the production of phosphorous fertilizers. It is planned to increase output of apatite concentrate in the Kola Peninsula and to expand the production of phosphate rock in Kazakhstan.

There are 45 commercial deposits at the Karatau phosphate basin in Kazakhstan. The five largest contain more than half of the total reserves of Karatau. Seven open pits at the Aksay and Zhantas deposits and the Molodezhnyy underground mine at the Chulaktau deposit produced an estimated total of 9.5 million tons in 1980. Surface mining of the Aksay deposit terminated and shaft sinking began in 1978 and continued in 1980. Also, the development of the Tyesay deposit for surface mining continued in 1980. During the 1976-80 period, output of phosphate rock in Kazakhstan increased by 110%, but planned production targets for each of these years were not met. The 1981-85 5-year plan calls for an increase in production of phosphate rock at the Karatau phosphate basin in Kazakhstan in 1985 by 50% over that of 1980.

The development of the Chilisay open pit in the Aktyubinsk Oblast', Kazakhstan, began in 1978 and continued in 1980. Output of 5.9 million tons of ore and the production of 1.77 million tons of phosphorite flour from this deposit was planned for 1980. Construction of the Chilisay complex continued in 1980. The Voskresensk complex in Moscow Oblast' produced over 2 million tons of phosphate flour the same year and the production of ground phosphate rock at the Verkhnekamsk phosphorite area reached about 0.6 million tons in 1980 instead of the planned 0.7 million tons.

The phosphate reserves in place at the Karatau Basin in categories $A+B+C_1$ were estimated in 1978 at about 1,500 million tons and 500 million tons in category C_2 (overall average grade 21% to 26% P_2O_5). The reserves in place at the Chilisay phosphorite basin in category $A+B+C_1$ were estimated at over 1,000 million tons and about 800 million tons in category C_2. Re-

portedly, the third largest phosphorite deposit in the Soviet Union has been discovered in Rakvere, Estonia.

Potassium.—The Soviet Union is one of the world's leading countries in potassium ore reserves, fertilizer output, and exports of potash salts. Estimated output in 1980 was 19.3 million tons (41.6% K_2O) or 8 million tons in nutrient content, about 20% over that of 1979. Under the original 1976-80 plan, output of potash was to increase 35% from 19.1 million tons (41.6% K_2O), or 7.9 million tons in nutrient content in 1975 to 26 million tons (41.6% K_2O), or 10.8 million tons in nutrient content in 1980. It was planned to complete construction of Soligorsk No. 4, Berezniki No. 4, and Novosolikamsk by 1980. It was also planned to enlarge Solikamsk No. 1 and Soligorsk No. 3 by 0.2 million tons per year each and to enlarge No. 3 Berezniki by 0.14 million tons per year during the 1977-80 period. The revised plan called for 22.4 million tons (41.6% K_2O) of potash production in 1980.

The total output of the potassium mines in the U.S.S.R. exceeded 64 million tons of ore in 1980 but was to be increased to 85 to 90 million tons, according to the original 5-year plan target. The level of potassium production rose at the Beloruskaliy Concern but the Uralkaliy Concern was experiencing problems. In 1979, the Uralkaliy Concern produced over 1.5 million tons of potassium less than in 1978. There were 12 underground potassium mines and 1 open pit in operation in the U.S.S.R. in 1980. The depth of underground mining is 400 to 800 meters. The Kalush Mine in the Western Ukraine, which has been under exploitation for more than 100 years, will be depleted in the near future. It was planned to produce potassium fertilizers with 52.4% K_2O in 1980 compared with 49.4% in 1975. The Soviet standard measurement unit is 41.6% K_2O. The U.S.S.R.'s major market for potash remains in the centrally planned countries of East Europe.

Gross potash reserves are reported at 22,900 million tons of 16% to 40% K_2O content (3,800 million tons of K_2O). About two-thirds of the reserves are located at the Upper-Kama Basin in the North Urals. Reserves are principally carnallite and sylvite with 13% K_2O equivalents. The second largest reserve region (4,600 million tons) is Starobinsk (Soligorsk) in Belorussia, which contains sylvite (16% to 20% K_2O). The third important basin is the Livov Oblast' (2,900 million tons) in the Western Ukraine. The reserves of potassium ores in the Karlyuksk deposit in Turkmen S.S.R. were reported in 1975 at 2,000 million tons and those of the Tuva-Gutansk deposit were reported at 400 million tons. The first discovery of potassium salt in the Western U.S.S.R., was recently made at Ladushkin in Kaliningrad Oblast'.

There are four potash-producing centers: Solikamsk and Berezniki on the western side of the Central Urals, Soligorsk in Belorussia, and Stebnikov and Kalush in the Western Ukraine. The following 11 complexes, with a total annual capacity of 23.08 million tons (41.6% K_2O), were in operation in 1980: Berezniki Nos. 1, 2, and 3; Solikamsk Nos. 1 and 2; Soligorsk Nos. 1, 2, and 3; and the first stage of Soligorsk No. 4; and the first stages of the Novostebnikov and Kalush complexes. In 1980, three complexes were under construction: The third stage of the Soligorsk No. 4 in Belorussia, Berezniki No. 4, and Novosolikamsk in the Urals.

Fluorspar.—Despite the Soviet Union's effort to achieve self-sufficiency, it remained a net importer of fluorspar. Imports of fluorspar, mainly from Mongolia, mainland China, and Thailand, increased from 144,700 tons in 1975 to 493,000 tons in 1979 to an estimated 550,000 in 1980. With an estimated production of 520,000 tons, Soviet consumption of fluorspar in 1980 was over 1 million tons. The iron and steel industry consumed more than 85% of the total and consumption is increasing by 8,000 to 10,000 tons each year.

The Maritime Territory (Yaroslavsk deposit), Transbaykal (Kalunguysk, Abagatuysk, Usuglinsk), Uzbekistan, and Kazakhstan, were the main production areas in 1980. Small quantities of fluorspar are also produced in Tadzhikistan and other regions of the country. The mined ore contained from 20% to 45% CaF_2. The central concentrator in Uzbekistan is treating ores with 24.3% to 26.5% CaF_2 content, and, in the Maritime Territory, a mill is treating ore with an average of 40.5% CaF_2 content.

Mica.—Output, estimated at 46,000 tons, was inadequate to meet demand and strategic-grade mica continues to be imported from India for special industrial requirements. Imports of high-grade mica rose from 160 tons in 1968 to an estimated 680 tons in 1979, and 850 tons in 1980. The following four mining and beneficiation complexes were in operation in 1980: Mamslyuda (Irkutsk Oblast'), Karelslyuda

(Karelia), Kovdorslyuda (Murmansk Oblast' on the Kola Peninsula), and Aldansyluda (Yakutia). Mica is mined mostly by an underground method.

Irkutsk Oblast' continued to be the main supplier of muscovite mica; 75% of all muscovite deposits in the country are in the Mamsko-Chuysk County of the Irkutsk Oblast' where nine small underground mines were in operation in 1980.

The Kovdorslyuda (Kovdor mica) complex in Murmansk Oblast' operates the Yena, Pikolatva, and Kovdor underground mines and vermiculite open pit. Mining of vermiculite began here in 1960 and the capacity of the concentrator is 56,000 tons per year of concentrate. The Karelslyuda (Karel mica) complex in Karelia operates the Plotina, Malinovaya Varakka, and Tedino underground mines. Two 400-meter-deep exploratory shafts were sunk at the Malinovaya Varakka Mine in 1979. It is planned to develop the Slyudyanoy Bor deposit in Karelia in the future.

Salt.—The Soviet Union is one of the world's leading countries for salt reserves, production, and exports. Production in 1980 was estimated at 14.5 million tons. It was originally planned to increase salt production from 12.4 million tons in 1970 to 14 million tons in 1975, and to 20 million tons in 1980. However, the revised production level for 1980 was 14.7 million tons. Exports increased from 293,600 tons in 1970 to an estimated 400,000 tons in 1980. Salt development is concentrated in the Donets Basin (40% of output), the Urals, East Siberia, Armenia, and West Ukraine. The Artemsol' (Artem Salt) concern in the Donets Basin, which operates five underground mines, is the main Soviet supplier of salt. Because of mining mistakes and shortage of freight cars, production at this concern is limited to only 8,000 to 10,000 tons per day instead of the 14,000- to 15,000-ton design capacity.[96] More or less the same situation exists at the Aralsol' (Aralsk Salt), Pavlodarsol' (Pavlodar Salt) concerns, Iletsk Mine, and other salt-producing enterprises.[97] Over one-third of total Soviet salt production is coming from Lake Baskunchak.

Sulfur.—Estimated domestic production in terms of sulfur content totaled 10.9 million tons, of which 3.55 million tons was recovered from pyrite, 3.7 million tons from native sulfur, and 3.65 million tons from other elemental sulfur. Sulfur exports, mainly to CMEA countries, decreased from 463,800 tons in 1970 to an estimated 430,000 tons in 1980. Imports of sulfur increased from 216,700 tons in 1970 to an estimated 600,000 tons in 1980. The principal producers of native sulfur continue to be Rozdol (West Ukraine), Gaurdak in Turkmen S.S.R., Yavorov in West Ukraine, and the Volga Group of the Kuybushev sulfur complex, which together produced the bulk of the country's requirements. Production doubled during the past decade as a result of growth both in the elemental sulfur and as byproduct output. Frasch and the Orenburg sour-gas sulfur projects have become important in the last few years and it is expected that these sources will account for most future growth in the Soviet sulfur industry. The U.S.S.R. is currently ranked fourth in the world in terms of brimstone production.

Over 1 million tons of sulfur was recovered from sour gas in 1980. Production of sulfuric acid increased from 22.4 million tons in 1979 to an estimated 23 million tons in 1980.

Talc.—The U.S.S.R. produced 490,000 tons of talc in 1980, 2.1% over that of 1979. Only the Onotsk deposit in the Irkutsk Oblast', with an annual capacity of 45,000 tons, produced high-grade iron-free material. Despite large reserves and the development of new mines, imports of talc from North Korea and Bulgaria increased from 90,900 tons in 1975 to an estimated 120,000 tons in 1980.

The Kirgiteysk deposit in Krasnoyarsk Kray was the major producer of lower quality talc. The Miass and Shabrovsk deposits in the Urals ranked second in output. Some talc is mined from the Tertiy-Mindorskoye and Kvachevskoye deposits in South Osetinsk, Georgia. The raw material at the Onotsk deposit is shipped for processing to the Miass talc mill in the Urals. The Medvedevskoy talc deposit in Chelyabinsk Oblast' was under development in 1980.

MINERAL FUELS

Production of primary energy derived from fossil fuels, fuelwood, and hydroelectric and nuclear generation increased from 1,881 million tons (standard coal equivalent) in 1979 to an estimated 1,936 million tons in 1980. Compared with the 1975 output, the 1980 production of oil rose 23% (planned 30%), natural gas 50% (planned 55%), coal 2% (planned 15%), hydroelectric power 41% (planned 47.9%), and nuclear power 250% (planned 333%). The share of petroleum and natural gas in total Soviet primary

energy production increased from 70.3% in 1979 to 72.9% in 1980, while that of coal (anthracite, bituminous, and lignite) declined from 25.7% to 25%.

Total consumption of all types of primary energy in the Soviet Union increased from 1,594 million tons in 1979 to an estimated 1,638 million tons in 1980. The share of petroleum and natural gas in the total Soviet primary energy consumption increased from 66.2% in 1979 to 67% in 1980, while that of coal declined from 29.1% to 28.2%. Clearly, there will be a trend towards greater use of oil in the future. However, it is expected that the U.S.S.R. will make great efforts to substitute coal and natural gas for petroleum to make the latter available for export.

In 1980, the U.S.S.R. produced 603 million tons of crude oil and gas condensate, 716 million tons of run-of-mine coal and lignite, and 435 billion cubic meters of natural gas. Soviet long-range forecasting places the demand for raw coal and lignite at over 800 million tons in 1985 and 1,000 million tons by 2000.

Estimated total primary energy balance of the U.S.S.R. for 1980 is shown in table 14.

Table 14.—U.S.S.R.: Estimated total primary energy balance, 1980

(Million tons of standard coal equivalent)

	Production	Imports	Exports	Apparent consumption
Total primary energy	1,936	24	322	1,638
Coal (lignite, anthracite, bituminous, coke)	482	10	30	462
Crude oil and petroleum products	860	12	240	632
Natural and associated gas	515	2	50	467
Peat	14	--	--	14
Oil shale	12	--	--	12
Hydropower	22	--	2	20
Nuclear power	7	--	--	7
Fuelwood	24	--	--	24

Coal.—In 1980, the Soviet Union produced an estimated 716 million tons (originally planned 800 million tons, revised goal 745 million tons) of run-of-mine coal as follows: Bituminous, 473 million tons; anthracite, 70 million tons; and lignite, 164 million tons. Estimated according to Western practice, this was equivalent to 411 million tons of "clean coal," placing the U.S.S.R. second among the world's coal producers. Over 33% of the total output was surface mined. Production of run-of-mine coal and lignite in 1980 was 2.7 million tons below that of 1979.

Production of raw coal and lignite in 1980 from the Donets Basin amounted to 31%; Kuznetsk, 19%; Karagnada, 7%; Moscow, 4%; Kansk-Achinsk, 4%; and other areas, 31%. There were about 800 underground mines with an average annual capacity of 600,000 tons of raw coal and 70 open pits with an average annual output of 3.4 million tons of run-of-mine coal and lignite. The annual capacity of coal and lignite mines increased by 15 million tons (raw coal and lignite) in 1980. In 1985, the planned production of raw coal and lignite is to reach 770 million to 800 million tons.

Preparation of coal for the market does not play a great role in the industry and is normally restricted to coking coals and coal for export. The shortage of coal beneficiation facilities forced Soviet planners to place greater emphasis on improvement in quantity as an expedient.

Practically all Soviet coal requires beneficiation, but of the 716 million tons produced in 1979, only an estimated 345 million tons were treated to produce an estimated 182 million tons of clean coal. About 66 preparation plants are treating coking coal, 38 plants are processing anthracite, and 50 preparation plants are treating coal and lignite for powerplants.

The official average ash content of coal shipped to consumers in 1980 was about 20.3%. The average calorific value of coal from the Karaganda, Kuznetsk, and Donets basins fell by 600, 900,and 1,200 kilocalories, respectively, during the last decade. Up to 40 million tons of substandard quality coals and lignite are being delivered to thermal powerplants annually or about 20% of the total requirements of these plants.

Total Soviet economically minable coal and lignite reserves in place in categories $A+B+C_1$ in Janaury 1975 were 420,000 million tons, including 87,000 million tons of coking coal and 190,000 million tons of lignite. Over 70% of the total coal and lignite reserves are located in the eastern (Asian) part of the U.S.S.R.

Natural Gas.—The country produced 435 billion cubic meters of (originally planned

400 billion cubic meters, revised goal 435 billion cubic meters) usable gas, 7% more than in 1979. In 1985, the output of natural gas is expected to reach 600 billion cubic meters. According to Soviet data, gas reserves in place in the $A+B+C_1$ categories as of January 1978 were 29,000 billion cubic meters, of which 15% of the total were in the European part of the U.S.S.R., 72% were located in Siberia and the Soviet Far East, and 13% were in Central Asia and Kazakhstan.

Petroleum.—Crude oil and gas condensate output in 1980 increased by 17.4 million tons (2.5%) to 603 million tons (610 million tons planned). In 1980, over 500 oil and gas condensate fields (including 36 large fields) were in operation with a total of over 80,000 wells. Soviet petroleum policy is based on the principle of maximum production at any price. The production of crude oil and gas condensate in 1985 is planned at 620 to 645 million tons.

The Soviet Union is rich in oil. However, despite the new discoveries, the growth rate of reserves is lagging behind the rate of growth in extraction. According to Soviet sources, crude oil reserves in place in the $A+B+C_1$ categories as of January 1979 were 12,900 million tons. A 30% to 40% recovery of crude oil in place was claimed in 1980. For the seventh year, the U.S.S.R. remained the world's largest oil producer. The country continues to export crude oil and petroleum products even though the quantities available for internal consumption have been inadequate. The Soviet Union became a net exporter of crude oil in 1951 and of petroleum products in 1954 and has gradually strengthened its position since that time. The U.S.S.R. exported over 25% of its production in 1980.

The U.S.S.R. is the world's largest oil producer and it is the second biggest oil exporter (after Saudi Arabia). But the planned target for recovery of crude oil and gas condensate was not met in 1980. Production costs per ton of crude increased in the Soviet Union by 20% for the last 3 years. Cost of drilling wells increased by 6% to 7% each year. Transport distance for crude oil have trebled during the last 15 years. Investments in the oil industry in the years 1976-80 were 50% larger than in the preceding 5 years, and more than doubled what they were in 1966-70. Cost increased much more rapidly than production.

The Soviet Union is experiencing production problems, and some Western experts predict that the U.S.S.R. will be a big net importer of oil by 1985. A 1977 study by the Central Intelligence Agency (CIA) showed that by the mid-1980's the U.S.S.R. and the East European CMEA countries would be net importers of 175 million to 255 million tons per year. In 1980, the CIA reaffirmed its "conservative" estimate that under the best conditions the Soviet Union will shift from the position of large net exporter to that of a large net importer of oil by 1985. According to the CIA, Soviet oil output may peak at around 595 million tons in 1980 and then decline to 450 million tons in 1985. The agency predicted that the Soviet Union will probably have to import 150 million tons of crude in 1985. The actual increase in production at 14.1 million tons in 1979 and 17.4 million tons in 1980 and the planned increase of Soviet oil production in the 1981-85 years contradict recent CIA projections.

In 1980, the U.S.S.R. produced 603 million tons of crude oil and gas condensate, 112 million tons more than in 1975. However, the figures hide serious financial problems, which in the Soviet economy are not so important as they are in the free economies of Western countries. Soviet oil and gas condensate production slowed toward the end of the 1976-80 period and rose to only 603 million tons compared with the original planned quota of 620 million to 640 million tons and the reduced quota of 606 million tons in 1980. During the 1976-80 5-year plan period, the annual increase in crude and condensate production, in million tons, was as follows: 1976, 28.9; 1977, 26.1; 1978, 25.7; 1979, 14.1; and 1980, 17.4. All of the Soviet net oil output gain is coming from Western Siberia. Production in this region has more than doubled since 1975. Gains outside Western Siberia came from several smaller producing regions in the U.S.S.R. Tataria, Azerbaydzhan, and some other older regions are showing production rate decreases that exceed Soviet predictions.

To replace the declining oilfields in the Ural-Volga area and in the Caucasus, the Soviets had hoped for quick development of West Siberian fields. More than 1,200 million tons of oil have been extracted over 5 years in the Tyumen' Oblast'. But due to shortages of labor and supply, progress there has been slower than anticipated in the original 1976-80 5-year plan. The shortage of labor and the low-quality and shortage of drilling equipment, as well as lack of spare parts are the main obstacles for the development of oilfields in extremely cold

conditions. Living conditions in the Siberian oilfields are bad. The shortage of housing in Western Siberia is most acute. Almost 70% of workers have no apartments of their own, and are living instead in dormitories or in trailers. Labor turnover is topping the 26% mark.

The big oil of Siberia is obtained with a great deal of difficulty. The oilfields being worked have complex climatic conditions and are far from production bases or industrial centers. "Flying teams" of drillers and oil workers from Tataria and Bashkiria, Belorussia, the Ukraine, Saratov, and Baku, work for half a month and than go home for 2 weeks. "Labor"[98] gives a figure of 11,000 for these commuters; the productivity of these teams suffers because people have to change climatic zones twice a month and pass through a period of adaptation.

In the 11th 5-year plan (1981-85) period, it is intended to bring into operation a large number of wells and new fields and to sharply increase drilling operations in Siberia. It is planned to drill annually no less than 9 million meters of wells in Tyumen' Oblast'. On April 14, 1980, a conference was held in the Central Committee of the CPSU to discuss stepping up of capital construction in the vitally important oil- and gas-producing area of Western Siberia. The U.S.S.R. has initiated a program for the intensified development of West Siberian oilfields and gasfields. Thousands of workers are to be drawn from many Soviet regions to build housing, roads, schools, and hospitals. It is planned to increase housing construction by 300% in 1983 compared with the 1980 level.

Oil production in the Soviet Union is expected to reach 620 million to 640 million tons in 1985. The U.S.S.R. plans to step-up the rate of exploratory drilling for oil in Siberia, and will be calling on its CMEA partners to assist in this expansion of oil exploration activity. This expansion will be hampered by shortages of geophysical instruments and modern drilling equipment, although the Soviet deep-drilling technology is improving. The volume of capital construction, drilling, and freight haulage is to be increased by 2 to 2.5 times the level during the 1981-85 5-year plan period.

In 1980, Siberia produced 312.6 million tons of oil and condensate. Production in Siberia is planned to reach 385 million to 395 million tons in 1985 with a possible rise of up to 500 million tons in 1990. The Soviet plan calls for the expansion of oil production up to 2000. The oil production increase is to come from both Western and Eastern Siberia and Yakutia. In 10 to 15 years, oil production in Western Siberia is to be stabilized and the amount of drilling and other related work is to decrease.

The transfer of oil extraction to remote areas of difficult accessibility considerably complicates the work and makes it more expensive. Therefore, the increase will not be big. Soviet oil production by itself is not in trouble, but because of shortages of labor, equipment, and spare parts, the whole Soviet economy is in a difficult situation. Due to the priority in extraction and transportation of natural gas, the increase in the production of crude oil and gas condensate will be much less in the 1981-85 period compared with that of 1976-80.

Oil has long been a major export earner for the U.S.S.R. and it is intended to become more important. In recent years, there has been a growing emphasis on Soviet coal and natural gas production, making more gas available for export. In terms of value, the exports of petroleum rose from 24.6% of total Soviet official exports in 1975 to 27.9% in 1976, 28.1% in 1978 to 34.2% in 1979, and to an estimated 35% in 1980. Despite rising Soviet domestic consumption of oil, deliveries to centrally planned economy countries should continue according to obligations entered into, and deliveries to the West should stay at the same level or decrease only slightly.

Soviet oil exports to CMEA member nations between 1975 and 1980 were nearly 400 million tons. During the 1981-85 period, the U.S.S.R.'s oil deliveries to CMEA countries are to be on the same level as in 1980 (about 80 million tons), despite the more difficult conditions for its extraction. Oil deliveries for the 5-year period are to be brought up to nearly 400 million tons.

The Soviet Union cutback on its oil exports to the Western developed countries in 1980; oil exports to the FRG declined by about 15% from 9.4 million tons in 1979; British purchases of Soviet oil fell sharply from 2.9 million tons purchased in 1979, and Italian imports declined from 6.4 million tons in 1979 to 3.2 million in 1980. France purchased 6.25 million tons in 1980, as in 1979, and Yugoslavia bought 4.5 million tons of Soviet oil compared with 5 million tons in 1979. Annual deliveries of petroleum to India are to amount to 4.75 million tons over the next 5 years compared with deliveries of 3.4 million tons of crude and prod-

ucts in 1980. The agreement with Finland, which was signed in November 1980, calls for annual deliveries of more than 10 million tons per year of crude and petroleum products during the 10-year period, slightly higher than in 1980.

The Soviet Union has been exporting around one-quarter of its oil production in recent years, which helped buildup its hard currency reserves for imports of Western technology and partially for grain.

Exports of petroleum to Western countries may fall at some point, because the periodic increases in world prices make it possible for the U.S.S.R. to earn the same amount of hard currency while exporting less. Natural gas will partially replace oil shipments to Western countries, which provide needed hard currency.

The U.S.S.R. will not be forced to become a net importer of petroleum this decade. The conclusion of some experts that in the middle of the eighties the Soviet Union will turn from a large exporter to a large importer of petroleum, does not correspond with facts. At current world oil prices, the Soviet Union can afford to push even further the development of Siberian oilfields and import the foreign technology. The increase in oil production will be slower in the future, but the periodic increases in world prices makes it possible for the Soviet Union to earn the same amount of foreign exchange while exporting less.

The Mineral Industry of the United Arab Emirates

By Peter J. Clarke[1]

The petroleum sector continued to dominate the economy of the United Arab Emirates in 1980. Of the 626 million barrels of crude oil produced during the year, 620 million barrels were exported, bringing in revenues in excess of $19 billion.[2] Oil and gas production accounted for about 85% of the gross domestic product. Despite a decline in oil production of 6% from 1979 levels, revenues from crude oil exports increased 33%. The price of United Arab Emirates crude rose from an average $27.50 per barrel at the end of 1979, to about $34 per barrel by the end of 1980.

Efforts were continuing in 1980 to increase the role of the Federal Government in oil exploitation and marketing policy. The Ministry of Petroleum and Mineral Resources was responsible for general aspects of exploration and development of oil and mineral resources, but each Emirate still determined its own production and marketing policy. In November 1980, the Emirates General Petroleum Corp. (EGPC) was formed. EGPC was a 100% federally owned company that was to take over responsibility for marketing and distribution of petroleum products in the United Arab Emirates. EGPC's initial task was to take over the marketing operations in the six northern Emirates (everywhere except Abu Dhabi, where Abu Dhabi National Oil Co. (ADNOC) has sole marketing authority), currently controlled by the California-Texas Petroleum Co. (Caltex), Shell Oil Co., and British Petroleum (BP).

Consistent with this strengthening of the federal system was the establishment, on December 15, 1980, of a United Arab Emirates Central Bank to replace the Currency Board. The Central Bank was to have much the same authority as the Currency Board: To issue currency, regulate interest rates, and oversee the commercial banks. The Currency Board, however, had little influence because of its continual lack of federal funds or international reserves. In March 1980, the rulers of Abu Dhabi and Dubai agreed to channel 50% of their oil income to the Federal Government to stabilize the dirham and assure adequate liquidity in the local money market. The United Arab Emirates has been plagued by large capital outflows and correspondingly low liquidity levels because of fixed interest rates much lower than on international markets. A stronger reserve position in the Central Bank and the use of monetary policies was to provide greater access to funds within the country.

The fiscal year 1980 budget for the United Arab Emirates marked a reversal of the past 2 years' emphasis on decreased spending. The 1980 budgetary allocation was up 64% over the 1979 level, to $4.3 billion, most of which was to come from Abu Dhabi, although under the March agreement, Dubai's share was to increase significantly. Major allocations in the budget, by sector, were defense (28.2%), education and youth (8.7%), interior (8.6%), health (8.2%), electricity (3.4%), and public works and housing (2.5%). Individual Emirates were devoting increasing amounts of money into other sectors of the economy to diversify and increase their nonoil sources of revenue. Developmental spending for 1980 was up 65% over the previous year in the United Arab Emirates.

The Abu Dhabi Fund for Arab Economic Development continued to support development projects in the Arab and African world. Twelve projects in 10 countries received over $310 million from the fund

in 1980 including a petrochemical complex in Turkey, agriculture development in Mauritania, electricity projects in the People's Democratic Republic of Yemen, and phosphate fertilizers in Jordan.

Infrastructure development continued to be a top priority in the United Arab Emirates. In Abu Dhabi, the industrial complex at Ruweis was still under construction. The complex was to include the Abu Dhabi Gas Co. (Gasco) natural gas liquids (NGL) plant, a 120,000-barrel-per-day oil refinery, and a nitrogenous fertilizer plant, all of which were under construction during the year. Other plans for the complex were additional petrochemical industries and possibly an iron and steel foundry. Associated with these industries was a new deepwater port under construction at Ruweis and an oil export terminal at Zirku Island.

In Dubai, industrial development was centered around the complex at Jebel Ali. Already online in 1980 was the Dubai Aluminum Co. (Dubal) smelter and the Dubai Gas Co. (Dugas) gas-processing plant. Infrastructure for the complex included a planned 66-berth port in Jebel Ali, and an already completed 35-berth port in Port Rashid. The $500 million dry dock, built by Costain-Taylor Woodrow (United Kingdom) was also commissioned during the year, but attracted little business. Another harbor was under construction in Ras al-Khaimah.

The United Arab Emirates' mineral survey entered its third stage late in 1980. The survey was to be conducted by Hunting Geology and Geophysics Ltd. (United Kingdom), as were the first two stages, which involved location and delineation of previously unknown mineral resources. The third stage was to assess whether the mineral deposits that were discovered were commercially exploitable. The mineral survey had located copper deposits in Fujairah and chromite in Sharjah, Ajman, Ras al-Khaimah, and Fujairah, but no information on reserves or grade was available.

PRODUCTION AND TRADE

Abu Dhabi continued to dominate the petroleum sector in the United Arab Emirates, accounting for 79% of all crude oil produced in the country. Abu Dhabi produced 494 million barrels in 1980, Dubai produced 128 million barrels, and Sharjah produced 3.6 million barrels. Production declined about 6% from 1979 levels, owing to the imposition of production ceilings by ADNOC, but was expected to rise considerably as development of the large Upper Zakum Oilfield continued. The field, one of ADNOC's three offshore fields, produced about 50,000 barrels per day in 1980, but was expected to increase output to 500,000 barrels per day by 1984. Also, expansion plans were in progress for ADNOC's onshore Bu Hasa and Asab Oilfields, where additional reserves were discovered. With new fields onstream toward 1984, the United Arab Emirates was expected to have a production capacity of over 2 million barrels per day. Actual production was not a function of capacity, however, but rather a ministerial decision based on world demand, the price of oil on the spot market, and the desire to maintain productive capabilities over many years. Petroleum reserves in Abu Dhabi, Dubai, and Sharjah were estimated at 40 billion barrels.

Both Abu Dhabi and Dubai were to become significant exporters of NGL. Dugas came onstream in 1980, with a capacity of 100,000 barrels per day of NGL and 50,000 barrels per day of condensates. Gasco was due onstream in 1981, with a capacity of 100,000 barrels per day of NGL. The Das Island natural gas processing plant, which also produced NGL, liquefied petroleum gas (LPG), and pelletized sulfur, operated at about 60% of capacity during the year.

Both Dugas and Gasco were to supply Dubal's smelter, which began producing aluminum during 1980. The plant reached rated capacity late in the year. The plant was a significant step in diversifying the United Arab Emirates' economy away from oil dependence.

The only other major commodity produced in the United Arab Emirates was cement. Four cement plants were operating in 1980, in Abu Dhabi, Dubai, Ras al-Khaimah, and Sharjah. Nearly 1.5 million tons of cement was produced in the United Arab Emirates during the year, and capacity was to be upgraded to over 3 million tons by 1982. Mineral production in the United Arab Emirates is shown on table 1.

The United Arab Emirates' balance-of-trade surplus continued its rapid growth in 1980, rising from $4.6 billion in 1978, to $9 billion in 1979, and $12.5 billion in 1980. Even with a substantial rise in the level of imports, which were steady at about $5 billion in 1977-78, then rose to $6.5 billion in 1979, and nearly $8 billion in 1980, the

United Arab Emirates was left with a $9.5 billion current account surplus. Proper management and investment of these massive surpluses remained a major challenge to the United Arab Emirates Government. Partly because of the country's unprofitable interest rate structure, and also because of the need to recycle large sums of money without inflating the local economy, a considerable (but unspecified) portion of petroleum revenues were invested in foreign markets, mainly by the Abu Dhabi Investment Authority. The Central Bank was expected to continue this policy, while also allowing for more profitable investment within the country.

Exports of oil and gas accounted for about 95% of the United Arab Emirates' total exports in 1980. Oil was exported to Japan (30%), the United States (12%), France (11%), Netherlands Antilles (10%), the Netherlands (7.3%), the Federal Republic of Germany (5.4%), Ireland (3%), and India (2.4%). Other recipients of 10 million barrels or less were other Western European countries, and African and Middle Eastern countries, including Tanzania, Kenya, Ivory Coast, Egypt, Mozambique, Ethiopia, Morocco, and the People's Democratic Republic of Yemen.

Aluminum exports also began for the first time in 1980. About 40% of the output of the Dubal smelter was exported to the United States, and 40% went to the United Kingdom, with the remainder being sold within the United Arab Emirates and other Middle Eastern countries.

Besides receiving most of the United Arab Emirates' oil, Japan and the United States were also the major suppliers of imports into the Emirates, with the United Kingdom, the Federal Republic of Germany, and France also important trading partners. The major imported goods were

[1]Table includes data available through June 24, 1981.

[2]In addition to the Emirates listed, Fujairah and Umm al-Qaiwain record no mineral production but presumably produce small quantities of crude construction materials.

[3]In addition to the commodities listed, crude construction materials such as common clays, stone, and sand and gravel presumably are produced, but output is not recorded quantitatively and general information is inadequate to make reliable estimates of output levels.

[4]Reported figure.

[5]No marketed production is reported; there is probably some small field use.

machinery, transportation equipment, manufactured goods, and foodstuffs. The United States received about 14% of the United Arab Emirates' exports, valued at $2.8 billion and supplied 12.2% of its imports, with a value of $922 million for 1980.

COMMODITY REVIEW

METALS

Aluminum.—Production from Dubal's primary smelter began in November 1979. During 1980, all three potlines were brought onstream, and the plant reached rated capacity of 135,000 tons per year in December 1980. The Dubai Government owned 80% of Dubal, and Alusmelter Holdings, a Grand Caymen Co., owned 37.5% by Southwire Co. of Carrollton, Ga. (United States), and Selection Trust Ltd. (United Kingdom) owned the remaining 20%. The Dubai Government announced in March 1980 its intention to take over the minority interests at an unspecified time, providing full and fair compensation.

The Dubal smelter was part of a threefold project which included a 515-megawatt power-generating facility, supplied by Hawker Siddeley Power Engineering Co. (United Kingdom), and a 25-million-gallon-per-day desalinization plant, built by Weir-Westgarth (United Kingdom). Desalinated water was used at the smelter and also by surrounding industries and the population of Dubai. The powerplant was one of the world's largest industrial gas turbine power stations outside North America. The plant provided power for the smelter as well as steam and electricity for the desalinization plant. Average gas input was 3.15 million cubic meters per day. Gas was supplied by Dugas.

The smelter itself was one of the world's most modern facilities. Computers controlled a major part of the operation, from reduction and anode production, to power and desalinization. The management contractor for the plant was British Smelter Constructions. The complex was located in Jebel Ali, 30 kilometers from Dubai center, and took 32 months to complete. The main features were a 135,000-ton-per-year smelter, comprising 3 potlines, 6 pot rooms, a rodding room, pot repair facilities, a cast house, full workshop and warehouse facilities, training and administration facilities, and housing for 4,000 construction personnel. In addition, a port was expanded at Mina Jebel Ali to handle 500,000 tons per year of supplies and raw materials.

Raw materials for the plant were, at full rated capacity, 260,000 tons per year of alumina, 60,790 tons per year of petroleum coke, and 16,725 tons per year of pitch, along with the gas to drive the turbines. Alumina was supplied by Alcoa of Australia, under a contract providing 200,000 tons per year for a 10-year period.

Dubal was under contract to supply 40% of its output to Southwire Co., and 40% to a British unit of Alcan Aluminum Ltd., and the rest was sold by the Government of Dubai. These contracts were being renegotiated during the year, mainly owing to a rise in the price of alumina and aluminum on world markets. A new agreement was to

specify new offtake percentages for Alcan and Southwire, and also provide some definition of marketing areas.

Aluminum fabricating was given a considerable boost by the opening of the Dubal smelter. Gulf Extrusions Ltd. brought Dubai's first aluminum extrusion plant into production in 1978. The plant, built at a cost of $12 million, could produce 3,000 tons per year of anodized architectural sections in polished or etched finishes. The company was owned by the Al-Ghurain group, and was built by British Smelter Constructions. The company had obtained all its billits from Aluminum Bahrain Ltd. before the Dubal smelter began operating in 1979, when it switched to all Dubal feed. Output was marketed by the company and primarily sold to Arabian Aluminum Co., a fabricating associate in which Al-Ghurain had an interest, and other small fabricators around the Middle East.

A plant producing electrical distribution cables made of aluminum and copper came onstream in October 1979. The Dubai Cable Co., or Ducab, began producing building wires in June of 1979 and power cables in October. The company was a joint venture of British Insulated Callender's Cables N.V. (Netherlands) and the Dubai Government. Operations in the factory included wire drawing from copper or aluminum rod, stranding wires into flexible conductors, polyvinyl chloride insulating, and testing procedures. The plant expected to utilize 1,100 tons per year of imported copper rod and 500 tons per year of aluminum from Dubal.

Iron and Steel.—Feasibility studies were undertaken in 1979 for establishing an iron and steel mill in the industrial city of Ruweis in Abu Dhabi. A $200,000 contract for the study was awarded to Eisenbau A.G. (Federal Republic of Germany). The plant was to produce 400,000 tons per year of steel, and use locally produced natural gas. Preliminary agreements were drawn up in 1979 to operate the mill as a joint venture between India and ADNOC, with iron ore and technology being supplied by India. No decisions were made in 1980 to begin construction of the proposed mill.

There were two operating steel mills in the United Arab Emirates in 1980. Abu Dhabi Steel Works operated a 25,000-ton-per-year reroller, which began operating in 1977, and Ahli Steel Co. (formerly Gulf Steel Mills Ltd.) was established in Dubai in 1974. The Ahli works include a 12-ton electric furnace with an annual capacity of 36,000 tons, a 2-strand continuous billet caster, and a 10-ton-per-hour continuous bar mill.

NONMETALS

Asbestos.—An asbestos plant in Umm al-Qaiwain was inaugurated in June 1979. The $22 million plant was the first major industrial project in the Emirate. Construction of the plant began in 1977 and was financed mostly from loans from the Emirates Development Bank. The plant had an annual production capacity of 40,000 tons of asbestos pipes, sheets, and plates, and was capable of expansion at a later stage to 120,000 tons per year to meet export demand.

Cement.—Cement production increased to 1.5 million tons in 1980 from 1.3 million tons in 1979, as production from the Dubai National Cement Co. reached capacity. The plant came onstream early in 1979. There were four operating cement plants in the United Arab Emirates in 1980, in Abu Dhabi, Dubai, Ras al-Khaimah, and Sharjah, all of which operated near capacity. New cement plants were planned for Fujairah and Ras al-Khaimah. Fujairah Cement Industries of Dibba contracted Voest-Alpine A.G. (Austria) for the construction of a 580,000-ton-per-year turnkey plant, due for completion in 1981. The Gulf Cement Co., a joint venture of the United Arab Emirates Government and Kuwait, planned to construct a 1-million- ton-per-year cement plant in Ras al-Khaimah, principally to supply markets in Kuwait. Current and planned production capacity of the Emirates cement plants is as follows:

Location	Operating company	Current capacity (metric tons)	Planned capacity (year) (metric tons)
Al Ain, Abu Dhabi	Al Ain Cement Factory	200,000	200,000
Dubai	Dubai National Cement Co	500,000	500,000
Fujairah	Fujairah Cement Industries	--	580,000 (1981)
Ras al-Khaimah	Union Cement Co	500,000	500,000
Do	Gulf Cement Co. (United Arab Emirates-Kuwait)	--	1,000,000 (1982)
Sharjah	Sharjah Cement Co	300,000	300,000

Fertilizer Materials.—In October 1980, a joint venture company was set up to construct and operate a $300 million nitrogenous fertilizer plant at the Ruweis Industrial Complex in Abu Dhabi. The agreement for the plant was signed in May 1979 between ADNOC and Compagnie Francaise des Petroles (CFP) (France). ADNOC was to own 66% of the equity, and CFP 33%. The company was formed by a law issued by the ruler of Abu Dhabi, following the initial feasibility studies carried out by Snamprogetti (Italy) in 1979. The plant was to have a production capacity of 1,000 tons per day of ammonia and 1,500 tons per day of urea, mostly for export. Startup was scheduled for 1983 or 1984.

In July 1980, Mitsubishi and Chiyoda Chemical Engineering and Construction Co. (Japan) were awarded a $200 million contract for construction of the plant. In addition to the ammonia and urea plants, ancillary facilities were to include an export terminal, a gas pipeline from Habshan, and a desalinization-powerplant. Natural gas from Abu Dhabi's onshore fields was to be used as feedstock for the producing units and as fuel for the power station.

The Sharjah fertilizer plant increased its production capacity from 10,000 to 35,000 tons per year in 1979. The $5 million facility, which came onstream in 1978, produced chemical fertilizer for the local market.

MINERAL FUELS

Natural Gas.—The Ruweis gas project was near completion at the close of 1980. The project was implemented by Gasco, a joint venture between ADNOC (68%), Shell Oil Co. (United States) (15%), CFP (15%), and Participations and Exploration Corp. (Partex) (Portugal) (2%). The Ruweis facility was designed to process 800 million cubic feet per day of associated gas, and to produce 150,000 barrels per day of NGL, with a product split of 60% NGL and 40% condensate. The plant was to treat associated gas from Abu Dhabi's onshore fields; Asab, Bu Hasa, Bab, and Sahil. The plant was scheduled to come onstream in March 1981.

Most of the expected output from the Ruweis plant was already sold to eight Japanese companies under 5-year supply contracts. The contracts required the supply of 1.49 million tons per year of LPG, 75% of which was to be derived from ADNOC's share of total output. The customers were Idemitsu Kosan (250,000 tons per year), Mitsui Bussan and Bridgestone (400,000 to 450,000 tons per year), C. Itoh and Co. (120,000 tons per year), Mitsubishi Shoji (120,000 tons per year), Maruzen Sekiyu (100,000 tons per year), and Showa Sekiyu (100,000 tons per year). CFP and Partex, also shareholders in Gasco, signed contracts with Marubeni (300,000 tons per year) and Idemitsu (50,000 tons per year).

A pipeline linking the onshore fields to the Ruweis facility was completed late in 1980. C-E Crest, a subsidiary of Combustion Engineering (United States), initiated work on the line and associated subsystems in 1978. The cost of the pipeline was $60 million.

The Das Island natural gas processing plant continued to operate below capacity in 1980, owing both to technical difficulties at the facility and decreased output from the offshore fields. The plant was designed to process 550 million cubic feet per day of associated gas from the offshore fields of Umm Shaif and Upper and Lower Zakum, for the annual production of 15 million barrels of liquefied natural gas (LNG), 5.6 million barrels of LPG, 1.5 million barrels of light distillate, and 1.6 million barrels of pelletized sulfur. About 113 billion cubic feet of natural gas was supplied to Das Island during the year, which represents about 60% of capacity. The Das Island plant, which began operating in October of 1977, was operated by the Abu Dhabi Gas Liquefaction Co. Ltd., a joint company composed of ADNOC (51%), BP (16%), CFP (8%), Mitsui and Co. (Japan) (22%), and Bridgestone Liquefied Gas Co. Ltd. (Japan) (3%). Nearly all of the output of the plant was sold to the Tokyo Electric Power Co. under a 20-year contract.

Tenders were being taken during the year for construction of seven storage tanks at Das Island. The work involved building three 80,000-cubic-meter tanks to store LNG, and four other tanks, two for propane and two for butane. Closing date for submission of tenders was December 31, 1980.

In April 1980, Dubai opened its own natural gas processing plant, designed to utilize Dubai's production of about 100 million cubic feet per day of natural gas, from the offshore fields of Rashid, Fateh, and Southwest Fateh. The plant was owned by Dugas, a joint venture of the Dubai Government and Scimitar Oils Ltd. (formerly Sunningdale Oils Ltd.) of Canada. The plant, designed by Hudson Engineering of Hous-

ton, Tex. (United States), was to produce 11,000 barrels per day of propane, 7,000 barrels per day of butane, 7,000 barrels per day of condensates, and 55 million cubic feet per day of residue gas. Most of the propane, butane, and natural gasoline was contracted to Japanese buyers. The residue gas was used to drive the generators producing power for Dubal's aluminum smelter. Residue gas output from Dugas was still insufficient to drive all the turbines at Dubal. Dubai was negotiating with Abu Dhabi during the year for supplies of residue gas from the Ruweis plant once completed.

The Government of the United Arab Emirates announced, for the first time in 1980, that the price of LNG was linked to the price of Abu Dhabi's Murban crude oil. LNG prices jumped from $2.36 per 1 million British thermal unit (Btu) equivalents, to $4.00 per 1 million Btu's, based on a January 1 price of $21.56 per barrel of Murban crude. Any further increase in the price of the Emirates oil was to have an automatic effect on LNG prices.

Several new gas discoveries were made during the year, significantly boosting the United Arab Emirates' total reserves of natural gas. A new field was discovered offshore Abu Dhabi, at Umm Shaif, midway between Abu Dhabi and Qatar, at a depth of 15,000 feet: Umm Shaif was already a significant producer of petroleum and associated gas. The new gasfield contained an estimated 24 trillion cubic feet of natural gas, enough to more than double the Emirates' total reserves. The field was operated under the authority of the Abu Dhabi Marine Areas Operating Co. (ADMA-OPCO), which was owned 60% by ADNOC, 14.6% by BP, 13.3% by CFP, and 12.1% by the Japan Oil Development Co. (JODCO).

Amoco International Oil Co. had a major gas-condensate discovery on its 600,000-acre onshore concession in the Emirate of Sharjah. The well was believed to be capable of producing 50 million cubic feet per day of gas, and 9,650 barrels per day of condensate. The well, located near the Shaikdom's western coast, was drilled to a depth of 16,000 feet. At yearend, Amoco was formulating plans to develop the field.

Petroleum.—*Abu Dhabi.*—Crude oil production in the United Arab Emirates totaled 626 million barrels in 1980. Abu Dhabi supplied over 75% of the total, about 494 million barrels, of which 489 million barrels were exported. Abu Dhabi operated its oilfields under production ceilings, which were determined by the petroleum minister in conjunction with the operating company. Total production in Abu Dhabi declined 7.5% from 1979 levels owing to a lowering of these production ceilings during the year. A temporary increase in production was ordered in October 1980 to help offset the loss of exports from Iran and Iraq. Further production cuts were ordered to take effect in January 1981, to conserve the reserves of the Emirate.

The Abu Dhabi Co. for Onshore Oil Operations (ADCO) produced oil from four onshore fields; Bu Hasa, Bab, Asab, and Sahil. Shares in ADCO were held 60% by ADNOC, 9.5% by BP, 9.5% by CFP, 9.5% by Shell, 4.75% by Exxon, 4.75% by Mobil, and 2% by Partex. Total production from the onshore fields was 267 million barrels in 1980. Production ceilings were lowered for the onshore fields in August 1980. The Bu Hasa Field ceiling was lowered from 365,000 to 295,000 barrels per day as a new gas-lift, water injection scheme became operational, providing a 1-million-barrel- per-day water injection capacity. Ceilings for the other fields remained the same: Bab (50,000 barrels per day), Asab (300,000 barrels per day), and Sahil (25,000 barrels per day). The onshore fields were not affected by the production increase in October, and further production cuts were planned for January 1981, calling for a 600,000-barrel-per-day ceiling for the onshore fields. A development plan was underway during the year for expanding the output of the north Bu Hasa Field. Exploration revealed additional reserves of up to 1 billion barrels, in both the Bu Hasa and Sahil Fields.

Abu Dhabi's offshore fields were administered by ADMA-OPCO, which was owned 60% by ADNOC, 14.67% by BP, 13.33% by CFP, and 12% by JODCO. ADMA-OPCO operated three fields: Umm Shaif, which produced 250,000 barrels per day; Lower Zakum, which produced 200,000 barrels per day; and Upper Zakum, which produced 50,000 barrels per day. The Upper Zakum Field was undergoing further development and was expected to be capable of producing 500,000 barrels per day by 1984. An export terminal was under construction at Zirqu Island to handle the expected output from the Zakum Fields. The Zakum Development Co. (ZADCO), a joint venture of ADNOC and CFP, was constructing the facility, which was due for completion in 1981. The produc-

tion ceiling for Upper Zakum was lowered to 40,000 barrels per day in August 1980, and then the overall ceiling for all offshore fields was raised in October to allow a 50,000-barrel- per-day increase to help offset supplies lost from Iran and Iraq. An increase of 35,000 barrels per day was to come from the ADMA-OPCO fields, and the remaining 15,000-barrel-per-day increase was to come from smaller offshore fields. These fields were the Abu Al Bukhoosh Field, operated by the Total Group (France) which produced 75,000 barrels per day, the Arzanah Field, operated by Amerada-Hess (United States), and the Mubarraz Field, operated by JODCO, both of which produced 20,000 barrels per day. All of the increased output from the ADMA-OPCO fields and the independent fields was sold under special contract to France.

After a year of inactivity, production was scheduled to resume from the offshore Bunduq Field, on the Abu Dhabi-Qatar border. The main operator, the United Petroleum Development Co. of Japan (UDC) agreed to initiate a $230 million water injection recovery scheme, scheduled for completion in 1983. The field was to resume production in 1981 at around 5,000 barrels per day. Output from the field in 1976-77 averaged 20,000 barrels per day.

Plans were made during 1980 for the development of three new offshore fields in Abu Dhabi. ADNOC and JODCO signed an agreement in July to develop the Delma, Satah, and Jarnain offshore fields, and to construct a 40,000-barrel-per-day export terminal at Delma Island. Development plans included construction of an oil-gathering center, several platforms, a pipeline network, a gas-oil separation unit, a powerplant, storage tanks, and worker housing. Total cost of the project was $700 million; $300 million of which was to be provided by JODCO, and the remaining $400 million was to be supplied in a soft loan from ADNOC. The project was to be carried out by the Umm Addalkh Development Co., a 50:50 venture of ADNOC and JODCO. Reserves at the three fields were estimated at 1 billion barrels.

ADNOC had a significant new discovery during 1980. Oil was discovered at an offshore exploratory well at Bu Tinah, 57 kilometers from the Abu Dhabi coast and 26 kilometers south of Zirku Island. Reserves at Bu Tinah were estimated at 1 billion barrels, and further exploration was slated for 1981.

Several new exploration agreements were signed during 1980 with ADNOC and the Abu Dhabi Government. A 7,880-square-kilometer concession was awarded to a consortium headed by Sceptre Resources of Canada. The agreement involved a minimum exploration expenditure of $70 million over 10 years. The area was located southeast of the Abu Dhabi town.

Amoco was awarded a 2,500-square-kilometer concession north of Al Ain. The exploration commitment was $55.5 million over 8 years, with bonuses of $5 million on signature, $2 million for a commercial find, and incremental bonuses of $2 million when exports hit 50,000, 100,000, and 200,000 barrels per day.

Amerada-Hess, Occidental Petroleum Co., and Alpha acquired two exploration blocks totaling 2 million acres. Seismic work was to begin midway through 1981. The drilling commitment was 30,000 feet.

Petroleum refining capacity in Abu Dhabi was undergoing large-scale expansion during 1980. Pullman Kellog (United States) finalized a contract with ADNOC for construction of a second refinery at Umm al-Nar. The new refinery was to have a capacity of 60,000 barrels per day, and was to be located adjacent to the 15,000-barrel-per-day refinery already operating at Umm al-Nar. The 75,000 barrels per day of total output from Umm al-Nar was expected to meet domestic requirements.

Meanwhile, construction was nearing completion on the 120,000-barrel -per-day export refinery in the Ruweis Industrial Complex. The $650 million facility was being constructed by Snamprogetti (Italy) and was scheduled to come onstream in August 1981. The possibility was being studied of expanding the Ruweis refinery to 250,000 barrels per day at some time in the future.

The United Arab Emirates and India agreed to participate in a joint venture refinery to be located on the western coast of India. The 250,000-barrel- per-day refinery, in which the Emirates had a 50% interest, was to receive crude oil feedstock from the Emirates, and in return the Emirates would share the output of refined products with the Indian Government. No date for construction was available.

Abu Dhabi's first lube oil blending plant was completed in mid-1980 at Umm al-Nar. The plant was built by Balmer Laurie Co. of India and had a capacity of 14,000 tons per year of 50 types of lubricants for the local

market. The plant was owned by ADNOC's subsidiary, the Abu Dhabi National Oil Co. for Distribution.

A drilling mud plant was also inaugurated during the year. The plant, which cost $28 million, was built by AODCAP, a joint venture of ADNOC and NL Industries. The plant was located at Sa'diyat Island in Abu Dhabi.

Several pipeline projects were being considered by the Government of Abu Dhabi during the year. A pipeline to transport petroleum products from the Umm al-Nar refinery to Abu Dhabi City was approved in July. Another pipeline between Abu Dhabi City and Al Ain was being considered. Also under review was a 150-mile crude oil pipeline, running from Abu Dhabi, across the Musandam Peninsula, to Fujairah on the Gulf of Oman. The pipeline was to provide an outlet for crude oil exports should the Straits of Hormuz be blocked for any reason. The Abu Dhabi National Oil Co. also decided to build a major gasline between Abu Dhabi and Dubai to provide Dubal with supplemental supplies of natural gas feedstock.

With the approval of the Abu Dhabi Executive Council, ADNOC increased its working capital from $55 million to over $2 billion late in 1980. The Director General of ADNOC stated that the large increase would enable the company to undertake ambitious investment projects in the 1981-86 period, which were estimated at $10 billion. Among these plans were the Umm al-Nar and Ruweis refinery, several petrochemical projects, tanker purchases and port expansions, and natural gas development. The Director General also stated that from 1971 to the end of 1979, ADNOC realized a clear profit of nearly $4.5 billion.

Dubai.—The Dubai Petroleum Co. (DPC) operated four offshore oilfields; Fateh, Southwest Fateh, Falah, and the Rashid condensate field. Total crude oil production in the Emirate in 1980 was about 129 million barrels, of which 128 million barrels were exported. The Falah and Rashid Fields were undergoing further development during 1980, and output from these fields was expected to increase. Companies operating the concessions were DPC (owned by Conoco) (30%), Dubai Marine Areas (DUMA) owned jointly by CFP and Hispanoil (50%), Deutsche Texaco (10%), Dubai-Sun Oil Co. (United States) (5%), and Delfzee, a subsidiary of Wintershall A.G. (Federal Republic of Germany) (5%).

In August 1979, the Dubai Government reached an agreement with Conoco to purchase from the company 100,000 barrels per day of crude oil from August through October and 180,000 barrels per day in November and December, at 93% of the posted price. The operating companies then had the option to buy back the oil at prices set by the Government. For the second half of 1979, Conoco repurchased 33% of the oil it was required to sell to the Emirate.

Dubai struck oil onshore in 1980, at an exploratory well at Jebel Ali. The well was drilled on a concession held by Sedco-Houston Oil and Minerals (United States), and reached a depth of 17,875 feet. The Sedco-Houston oil well was the first onshore well drilled in Dubai in 12 years. Further test wells were underway to determine the size of the field.

Arco-Dubai, a wholly owned subsidiary of Atlantic-Richfield Co. (ARCO) (United States), was awarded a 760,000-acre, 35-year concession for onshore oil exploration and development. The agreement stipulated a $1 million investment on geophysical work, and a $5 million investment for each well drilled. ARCO must drill one well by the third year, and one well every year for 5 years after that, if preliminary tests are encouraging.

Dubai officially inaugurated its $300 million Jebel Ali power generating desalinization complex in June 1980. The plant was capable of producing 300 megawatts and 2.8 million gallons per day of fresh water. The powerplant was expected to supply 90% of Dubai's power needs in 1980.

Sharjah.—Oil production for Sharjah's offshore Mubarek Field averaged about 10,000 barrels per day in 1980. Total production for the year was 3.61 million barrels. Output of the field declined considerably from a high of 40,000 barrels per day in 1975. The production drop was due to both technical difficulties and the start of a new gas-water injection scheme, designed to restore the field's output to previous levels. The Mubarek Field was operated by Buttes Gas and Oil Co., a subsidiary of Crescent Petroleum (United States). Half the revenues of the field go to Iran, following an agreement in 1971 establishing Iranian cosovereignty over the offshore area.

In February 1980, London and Scottish Marine Oil Co. (LASMO) in partnership with Forman Exploration (United States) discovered natural gas in two zones from the first test well in the Hamriyyah region,

32 kilometers off the Sharjah coast. The well was drilled to 14,440 feet and yielded flow rates of 8 and 6.4 million cubic feet per day. The LASMO-Forman lease called for $10 million in exploration expenditure over 35 years.

Amoco Sharjah Oil Co. (a subsidiary of Standard Oil of Indiana) also struck gas and condensate on its 600,000-acre onshore concession in December 1980. The well was drilled to 15,000 feet, and flowed between 5 and 23 million cubic feet per day of natural gas, and 4,650 barrels per day of condensate. Amoco was making plans to develop the field, which was thought capable of becoming a significant producer of light crude and condensate within 3 or 4 years.

Ajman.—Seismic work was completed in 1980 on a 300-square-kilometer offshore concession awarded to Forman Exploration (United States) and London and Scottish Marine Oil Co. in 1978. The agreement called for $10 million in exploration expenditures over a 35-year period. The first test well was due to spud late in 1980 or early in 1981.

Fujairah.—After 4 years of preliminary work, Fujairah began drilling its first exploratory well in August 1980. A consortium of Denison Mines (Canada) (50%), Getty Oil Co. (United States) (15.7%), Mitsubishi Oil Co. (Japan) (10%), and 15 other companies operated a 700,000-acre concession off the coast of Fujairah. The concession was originally awarded to Reserve Oil and Gas in 1975, but was taken over by Getty in January 1979, when the companies merged. Denison financed 75% of the $13 million cost of spudding the first well. Mitsubishi planned to set up a wholly owned subsidiary, the Fujairah Oil Exploration and Development Co., to assist in developing the concession.

Ras al-Khaimah.—Plans to become the fourth oil-producing Emirate evaporated in 1980. Discoveries by Vitol-Deutsche Schachtbau (Federal Republic of Germany) have proved uncommercial. Plans were also canceled for a 150,000-barrel-per-day refinery in Khor, Kuwait. The refinery was to use Kuwait crude oil, but with production cutbacks in that country the plan was ruled out.

Amoco joined Gulf Oil Corp. in a concession covering all onshore areas and territorial waters in Fujairah. The group planned to drill its first exploratory well late in 1980 at Khatt.

Umm al-Qaiwain.—After a promising gas find in 1977, which tested at 41 million cubic feet per day, subsequent wells delineated a minor gasfield, uncommercial either for power generation or export to Dugas. The five-company group, led by Canadian Superior, with Zapata as operator, decided to terminate the concession in 1980. No further exploration activity was underway.

The Mineral Industry of the United Kingdom

By William F. Keyes[1]

The gross domestic product of the United Kingdom in real terms dropped by 1.6% in 1980, although at current prices it reached £191 billion (at factor cost), an increase of 16%.[2] The inflation rate slowed to just under 17%.

Although steel production fell to its lowest postwar level and the British Steel Corp. (BSC) suffered another large operating deficit, production of fuels rose. Coal production, with the customary Government subsidy, rose about 6%, and petroleum from North Sea fields at last made the country independent of imports.

In May, the Government announced that it was to embark on a round of discussions with United Kingdom mining, industry, and financial institutions concerning means to assure availability of essential minerals and metals. A number of papers and comments were contributed during the year by such bodies as the Mining Association of the United Kingdom and the Foreign Affairs Research Institute. The gist of the contributions was that support should be considered for recycling and conservation measures, stimulation of overseas exploration by British interests, technical and financial assistance for development of domestic mines, other financial measures, and stockpiling of strategic minerals.

At yearend, the Government introduced into Parliament a bill to license British companies to explore and exploit undersea nodules until the United Nations Law of the Sea Treaty came into force. The brunt of the proposed law was to prohibit United Kingdom citizens and companies from mining deepsea nodules outside territorial waters without a permit from the Government. It then protects such licenses from interference from whatever source. When such interference is from outside the United Kingdom, or by countries with discriminatory laws against such mining, licensees could be restrained from using ships of that country, and other measures could be applied. Cooperation with other countries with similar legislation, such as the United States and the Federal Republic of Germany, was envisioned.

PRODUCTION

The index of industrial production declined from 112.6 in 1979 to 105.0 in 1980, but the index of mining and quarrying increased from 294.8 to 300.4, largely owing to an increase of the petroleum and natural gas factor from 31,138 to 31,887.

Production of minerals in the United Kingdom for the last 5 years is given in table 1.

Table 1.—United Kingdom: Production of mineral commodities[1]

(Thousand metric tons unless otherwise specified)

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.

[1]Includes data available through Sept. 21, 1981.

[2]Includes wheels, centers, tires, axles, and semimanufactures for immediate sale.

[3]From imported bullion, including Pb content of alloys produced.

[4]From scrap materials. Series revised to comprise all secondary output including Pb content of secondary antimonial lead and to exclude output from domestic ores.

[5]Excludes plasters.

[6]Consists of brick, retorts, molds, and other refractory products made from clays, silica, silicious materials, magnesite, alumina, and chrome materials.

[7]Gas made at gasworks plus purchased coke oven refinery gas.

TRADE

Trade in minerals and metals for the 2 latest years available is given in table 2 and table 3.

Manufactured:				
Nitrogenous	136,054	148,141	NA	Netherlands 15,099; Ireland 10,172.
Phosphatic	58,184	41,757	NA	Ireland 25,708; Bangladesh 12,066.
Potassic	63,274	164,740	NA	Norway 51,035; Netherlands 32,147; Sweden 27,663; Belgium-Luxembourg 23,930.
Other including mixed	520,530	435,267	NA	Ireland 231,273; West Germany 83,120; Pakistan 42,410.
Graphite, natural	2,648	3,158	1,554	NA.
Gypsum and plasters	r16,470	17,588	NA	Ireland 3,354; Saudi Arabia 1,734.
Lime	40,547	42,365	NA	Venezuela 18,252; Nigeria 5,404.
Magnesite	52,736	65,004	NA	West Germany 14,132; Poland 8,717; France 7,502.
Mica:				
Crude including splittings and waste	3,349	4,878	NA	West Germany 749.
Worked including agglomerated splittings	244	417	3	India 53.
Pigments, mineral: Iron oxides, processed	11,721	9,400	1,116	Italy 827; Australia 556; France 541; Netherlands 392.
Precious and semiprecious stone except diamond:				
Natural value, thousands	r$66,689	$90,588	$7,653	Switzerland $40,540; West Germany $10,600; France $9,363.
Manufactured do	r$447	$246	NA	NA.
Salt	r405,086	424,187	NA	Nigeria 142,903; Sweden 106,187; Ireland 59,959.
Sodium and potassium compounds, n.e.s.:				
Caustic soda	r109,651	54,835	NA	China, mainland 8,439; Ireland 5,646; Nigeria 3,952.
Caustic potash including sodic and potassic peroxides	285	1,588	NA	NA.
Stone, sand and gravel:				
Dimension stone:				
Crude and partly worked	10,411	11,077	NA	NA.
Worked	4,015	5,936	NA	Ireland 517.
Dolomite, chiefly refractory grade	12,079	27,267	NA	Sweden 14,330.
Gravel and crushed rock thousand tons	5,835	6,437	NA	Belgium-Luxembourg 2,640; Netherlands 1,608; France 1,293.
Limestone except dimension	356,267	867,742	NA	Belgium-Luxembourg 244,603; West Germany 207,923; Norway 202,711.
Quartz and quartzite	12,876	317	NA	NA.
Sand excluding metal-bearing	78,123	85,525	NA	Ireland 36,198.
Sulfur:				
Elemental:				
Other than colloidal	1,422	1,344	NA	NA.
Colloidal	123	247	NA	NA.
Sulfur dioxide	r136	104	NA	NA.
Sulfuric acid	159,741	172,556	9,263	Ireland 63,297; Spain 31,117; Italy 18,357.
Talc, steatite, soapstone, pyrophyllite	3,978	5,605	--	Ireland 1,428.
Other nonmetals, n.e.s.:				
Crude	501,489	50,480	--	Netherlands 25,099; West Germany 8,146; Sweden 1,988.
Slag, dross, and similar waste, not metal-bearing:				
From iron and steel manufacture	126,826	97,677	--	West Germany 83,243.
Slag and ash, n.e.s	4,674	4,493	--	Sweden 1,165.
Oxides and hydroxides of magnesium, strontium, barium	570	250	NA	NA.
Halogens, other than chlorine	1,958	1,824	NA	France 905; Ireland 264.
Building materials of asphalt, asbestos and fiber cements, and unfired nonmetals, n.e.s	94,345	77,011	602	Ireland 21,482; Belgium-Luxembourg 4,646; Saudi Arabia 4,567.
MINERAL FUELS AND RELATED MATERIALS				
Asphalt and bitumen, natural	4,294	3,815	NA	NA.
Carbon black	35,235	48,527	NA	Ireland 7,282; Nigeria 5,892; West Germany 4,817.
Coal and briquets:				
Anthracite and bituminous coal thousand tons	2,266	2,339	NA	France 750; West Germany 605; Ireland 219.
Briquets of anthracite and bituminous coal do	146	174	NA	Norway 166.
Lignite and lignite briquets	98	5	NA	NA.
Coke and semicoke	r904,248	720,578	NA	Norway 223,837; Sweden 165,324; Netherlands 121,823.

r Revised. NA Not available.

[1]Total does not include an unreported quantity valued at $2,259,500 imported in 1979.

[2]Less than 1/2 unit.

[3]Excludes quantity valued at $28,656 in 1979.

[4]Pyrite is reported as a part of total sulfur and unroasted pyrite and cannot be separated; however, official British sources indicate that the quantity of pyrite included is "very small."

COMMODITY REVIEW

METALS

Aluminum.—British Aluminium, Ltd. (BA), one of the United Kingdom's three largest aluminum producers, continued its expansion in its plant at Lochaber, Scotland, from 28,000 tons to 37,000 tons per year, with the new power to come from "existing resources." However, its major smelter at Invergordon, Scotland (100,000-ton-per-year capacity), which abandoned expansion plans in 1979 because of high electricity costs, was involved in a dispute with the North of Scotland Hydro Electric Board over contract charges; the disputed amounts were £19 million in 1979 and £30 million in 1980, and the dispute was expected to end up in the courts. BA's profit in the same 2 years dropped from £21 million to £12 million.

In common with the whole of British industry, Alcan Aluminium (U.K.) Ltd. suffered from a "grossly overvalued" pound sterling, as well as high interest rates and serious labor disputes, according to the chairman of the parent company, Alcan Aluminium Ltd. of Canada. The chairman also pointed out that another problem for the British aluminum industry was excess capacity at the rolling mill end, as at Alcan's (U.K.) Rogerstone plant, near Cardiff; he said the United Kingdom needed only one sheet mill, not three or four, as at present. Alcan for the time being had no

plans to expand capacity at its 120,000-ton-per-year smelter at Lynemouth, on the northeast coast.

The third British primary aluminum producer, Anglesey Aluminium Ltd. at Holyhead, Wales, had a capacity of 100,000 tons per year. No changes were planned.

The serious decline in the European market for rolled products also affected the profitability of the new rolling mill opened in 1978 by the Aluminum Co. of America at Swansea, Wales. The plant was, in addition, bedeviled by operating and technical problems to the extent that an operating loss of about £16 million was suffered in 1980.

Gold.—The Ogofau gold mine, at Pumpsaint, 30 miles north of Swansea, was being investigated by Anglo Dominion Gold Exploration Ltd., under an agreement with the holder of a prospecting license, Anglo Canadian Exploration Ltd. and its parent company, Quebec Sturgeon River Mines Ltd. The mine was worked extensively during Roman times and saw sporadic activity in the last, and earlier in the present, centuries.

Iron Ore.—BSC closed its Beckermet (Florence) Mine near Egremont, Cumbria, when it terminated operations at the Workington plant nearby, which used the ore. A plan was evolved by local interests, including former employees and the landowners, to reactivate the mine on a smaller scale because its high-grade ore would have value in special foundry uses, and even as specimens. The mine is reportedly the only working hematite mine in Western Europe.

Iron and Steel.—BSC recorded the highest loss ever by a British company when its results for the year ending in March 1980 were put at £545 million, compared with a loss of £309 million for the previous year. Over £200 million of the loss was attributed to a 13-week strike early in 1980. The new American chairman of BSC, Ian McGregor, warned in presenting the report that the outlook for steel was bleak and that further cuts in BSC operating costs would have to be made. In the year ending in March 1981, the loss was even larger, amounting to £668 million.

In September, the British Government announced that it had increased BSC's external financing limit for 1980 from the initial £450 million to £971 million. This amount, equivalent to the Treasury subsidy, was expected to exceed possibly £1,000 million by yearend, because BSC's losses continued at a rate of £15 million per week and orders for crude steel declined to 150,000 tons per week.

At yearend, the company unveiled a package of cutbacks and reductions in force to enable it to survive. A cut of 20,000 in the labor force was accompanied by a reduction in capacity from 15 million to 14.4 million tons per year. There were no plans to close a major integrated plant, but some half dozen large units, including rodmills, foundries, tin-plating works, and coke ovens, would be closed at plants in the Midlands and Wales. It was hoped thereby to increase steelmaking capacity utilization from 64% in October to 90% by the end of the financial year. Early in 1981, the Government sought legislative authority to wind up affairs of the company if the survival plan did not succeed.

Lead.—New and more stringent regulations governing exposure to lead at the working place were presented for Parliamentary approval in September. The new rules, which replace legislation largely dating back to before 1927, were to come into force on August 18, 1981. They cut the permissible lead content of the blood of exposed workers from 100 micrograms to 80 micrograms per 100 milliliters of blood.

Britannia Lead Co. Ltd., at Northfleet, Kent, on the Thames Estuary, suffered a 7-week strike in February and March, causing a loss of an estimated 20,000 tons of refined lead production. After 50 years of operation, the company was having trouble meeting the pressure to reduce emissions and was considering either modernization or replacement. No decision was reached on possible expansion of the 150,000-ton capacity, or relocation if a new plant is built. Britannia is a subsidiary of M.I.M. Holdings Ltd. and refines the output of the Mount Isa Mine in Australia; there is also a modern secondary lead refinery rated at 30,000 tons per year.

Nickel.—In June, Inco Europe Ltd. inaugurated a new roaster and sulfuric acid plant at its Clydach, Wales, refinery, built at a cost of over £10 million, enabling sulfide matte from Inco's new mines in Guatemala and Indonesia to be treated and raising Clydach's capacity from 100 million to 120 million pounds per year of nickel products. The nickel carbonyl plant, which began operation in 1902, had hitherto treated only roasted nickel concentrates from Canada; the new sulfide matte was to come from the smelting of the lateritic ores with gypsum at the mines. A 10-week strike of

Inco workers was settled early in 1980, but nevertheless Clydach was forced to cut production in August because of declining nickel sales.

Platinum.—Matthey Rustenburg Refiners Ltd. (MRL), a joint subsidiary of Johnson Matthey Co. Ltd. and Rustenburg Platinum Mines Ltd. of the Republic of South Africa, decided to construct a new £15 million refinery, using solvent extraction techniques, at the site of its existing refinery at Royston, Hertfordshire, north of London. Capacity figures were not released. MRL also operated a complementary refinery at Brimsdown, near Enfield, in north London, where in 1979 a multimillion-pound capital investment program was completed, as well as two refineries in the Republic of South Africa, one at the Rustenburg, Transvaal Mine, and the other at Wadeville, Transvaal.

Tin.—High tin prices early in the year stimulated a great deal of new activity in exploration and reexamination in the tin area of Cornwall. However, the price fell from about £8,000 to about £6,000 per ton from January to December, causing some rethinking. Production during 1980 increased by an estimated 25%, to well over 3,000 tons.

There were three large mining groups active during the year accounting for almost all the production, Carnon, St. Piran, and Geevor, as well as a number of smaller operations, mostly dredging or retreating tailings.

Carnon Consolidated Tin Mines Ltd., owned 95% by Rio Tinto Zinc Corp. (RTZ), brought Wheal Jane back into production in June; holing through to the adjacent Mount Wellington Mine, which RTZ acquired with Wheal Jane in 1979, was accomplished in September but production from Mount Wellington was due only in 1981. Both mines were being refurbished and modernized, as well as the surface plant at Wheal Jane. About 280,000 tons of ore per year, containing 0.84% tin, will be produced, resulting in concentrates containing about 1,500 tons of tin. Recovery of tin in the mill was expected to be about 70%, including 55% in the gravity concentrate and 15% in the flotation concentrate. About 500 tons of copper in concentrates will also be produced.

Geevor Tin Mines Ltd., at Pendeen, commissioned the subincline shaft to connect it with the neighboring Levant Mine, but dewatering of the latter was slow. In order to conserve cash resources, work was also delayed on Allen's shaft at Botallack, which was to be used for examination of the seaward lode extension. The mine pinned its long-term hopes on an eventual increase in the price of tin.

St. Piran, Ltd., which controlled the South Crofty and Wheal Pendarves Mines through subsidiaries, was the object of financial disputes among the stockholders. South Crofty was contemplating expansion of both mining and milling facilities, based on over 2 million tons of reserves, which would provide for at least 10 years of operation if the tin price was favorable. Additional reserves were expected to be encountered after current development is completed in the lowest levels of the mine.

A new company, South West Consolidated Mines Ltd., controlled by Dundonian Ltd., made a stock offering expected to provide £2.75 million to be used in exploration in the southwest. The first work was directed at several tin prospects at Callington and Gunnislake on the Devon-Cornwall border. Several main targets were identified: The old Redmoor Mine, Blogister's Plantation and Haye South, all near Callington, and an old mine working near Gunnislake.

Titanium.—Planning approval was obtained early in the year for construction of a new 5,000-ton-per-year titanium granules plant, to be built on a site at Shotwick, near Shotton, which BSC abandoned when it closed its Shotton plant. Partners in the project were the National Enterprise Board (NEB), Rolls Royce Ltd. and IMI Ltd. NEB and Rolls Royce were interested because of the need of a secure supply of titanium metal for aircraft engines; IMI was the sole U.K. producer at the moment, under contract with ICI Ltd., which was to close its Bains plant on Teesside for economic reasons. The new plant, with a target commissioning date of 1982, was to cost some £25 million and employ about 300 people.

Tungsten.—In June, Amax Exploration of U.K. Inc., with Hemerdon Mining and Smelting Ltd. (U.K.), brought the $2 million pilot plant onstream at the Hemerdon Ball deposit near Plymouth. Early in 1981, Amax completed its study of the commercial feasibility of a mine and mill complex on the site.

The study concluded that about 38 million tons carrying 0.18% tungsten and 0.029% tin were available for open pit mining. The results of the pilot plant testing showed that 64% of the tungsten could

be recovered in a 65% tungsten concentrate and 66% of the tin in a second concentrate containing 25% tin. Planning permission was to be sought from the authorities for a £44 million mine, to produce 6,000 tons of ore per day and employ 300 to 400 people by 1987. The mine should then be able to supply all the United Kingdom's needs for tungsten.

NONMETALS

Barite.—SPO Minerals Ltd., a new company, started construction of a plant at Brassington, in Derbyshire, an area of the South Pennines formerly famous for its lead mining. The company will not mine ore, but will treat 150,000 tons per year of old tailings from a 19-mile radius of the plant. There are estimated to be 0.7 million tons available with an average of 30% barite, 15.5% fluorspar, and 2.4% lead; a further 0.85 million tons was potentially available after exploration. The plant was to produce about 33,600 tons per year of barite for the North Sea drilling market, for which a price increase was expected in 1981. SPO also owned 5% of Carnon, the Cornish tin mine, controlled by RTZ, until selling it to RTZ early in 1981.

Fluorspar.—Swiss Aluminum Mining (U.K.) Ltd. cut back its work force and work time considerably and closed its Redburn Mine, as well as halting development at two other mines, leaving only the Stanhope Burn and Cambokeels Mines in operation, with a run-of-the-mine output of 10,000 or 11,000 tons per week of acid spar ore. Poor domestic demand and the strength of the pound sterling were given as the cause.

Gypsum.—British Gypsum Ltd., the only large producer of gypsum in the United Kingdom, was developing a mine at Barrow-upon-Soar, Leicestershire, for production by 1983. The reserves, about 6 miles south of the company's other mine at East Leake, were put at 30 million tons. Planning permission was received in August for the mine, but not for a gypsum wallboard plant that would have been constructed nearby.

Magnesia.—The bulk of the United Kingdom's industrial requirements was provided by the Hartlepool plant of the Steetley Co. Ltd., which had a capacity of 200,000 tons per year of seawater magnesia, including 25,000 tons of caustic calcined magnesia.

Mica.—The first British mica mine, not a byproduct producer, was organized as a joint venture of Sir Alfred McAlpine and Sons Ltd. and Microfine Minerals & Chemicals Ltd. The venture was to be located in the Pitlochry schist region of north-central Scotland. Mica was to be produced in the 10- to 100-mesh size, with a target of 5,000 tons per year; byproducts would include 2,000 tons per year of silica sand and 1,000 tons per year of almandine garnet.

Potash.—In September, Charter Consolidated Ltd. and the Anglo American Corp. Ltd. decided to cut back the scale of operations at the Boulby Mine, in the North York Moors National Park, near the coast, east of Middlesbrough, to 1.2 million tons of ore per year, equivalent to about 360,000 tons of product, versus an original goal of 1 million tons of product. This will enable employment at the mine to be reduced from 1,500 to 850 and will hopefully bring the mine to profitability, long after startup in 1974. Charter Consolidated, the operator, had felt reasonably optimistic as the year started, but felt later that the only alternative to reducing operations was a shutdown. Problems at the mine included difficult mining conditions, gas, and high insoluble content of the ore.

MINERAL FUELS

Coal.—Preliminary figures showed that coal production, at 130 million tons, increased almost 8 million tons in 1980, with a particularly notable increase in opencast production, to 15.8 million tons.

The public inquiry by the Department of the Industry into the feasibility of mining in the Vale of Belvoir Coalfield focused on the Government's energy plans, and how much coal was needed to supplement the newly announced and ambitious nuclear energy program; much less attention was paid to the environmental aspects of mining, on which the inquiry had previously focused. The Central Electricity Generating Board (CEGB) suggested a possible nuclear capacity of 37 gigawatts by the year 2000, along with the burning of 60 million tons of coal, compared with about 80 million tons at present. Each 2-gigawatt shortfall in nuclear energy would, however, require 5 million tons of coal annually. The CEGB, reacting cautiously, believed there might be very little fall, or none at all, in coal requirements. A growth of 2% to 3% per year was considered more likely, and this steady market, coupled with continued oil price increases, would lead to the cost of coal being only about 59% of that of oil by the year 2000. A substantial investment was also being planned in deepwater import

facilities capable of handling 10 million tons per year, particularly for those grades, like coking coal, that will be needed from abroad.

The largest new coal mine project, Selby in Yorkshire, proceeded on schedule during the year. This £850 million (as of June 1980) project will produce 10 million tons per year by the late 1980's. Six entries were being developed in the coalfield; five are vertical shafts (North Selby, Stillingfleet, Riccall, Whitemoor, and Wistow), which will be used for men and materials. The sixth (Gascoigne Wood) is an incline, where the entire production will be brought out on conveyors. First production, from the Wistow shaft area, will be in late 1982 or early 1983. The program has been kept reasonably well on schedule, although a flood occurred in June in the Wistow area; much of the mine area, south of the city of York, is below sea level at the surface.

The third major new project, in addition to the Vale of Belvoir and Selby, being considered by the National Coal Board, the Government entity that controls all coal mining, was the £200 million Park Mine in Staffordshire, where 100 million tons of coal was estimated to be available for planned extraction at a rate of 2.2 million tons per year. The project was under serious restudy because of the high chlorine content of the coal, which might make it unsuitable for power generation.

Natural Gas.—Gas reserves at the end of 1980 were estimated at 26 trillion (proven) to 76 trillion (probable) cubic feet. Including pipeline shipments from the U.K.-Norwegian Frigg Field, Britain's needs now can be entirely supplied from the North Sea and Morecambe Bay off the west coast. Development of a field in the latter area was planned, as was development of the Rough Gasfield in the southern North Sea Basin. Britain had at yearend a total of eight gasfields in production, in addition to minor production of associated gas from oilfields in the northern North Sea. Associated gas was also being reinjected into several oilfield reservoirs. A seabed gas-gathering pipeline was planned for the purpose of collecting associated gas from northern North Sea oilfields and gas deposits in that area. A 36-inch trunk line, fed by lateral lines, was proposed. No final announcements had yet been made as to ownership, point of landing, or price of the gas collected, but a line several hundred miles long roughly parallel to the Norwegian median line was contemplated. The gas might be landed, speculatively, at St. Fergus, Scotland.

Petroleum.—Britain was almost self-sufficient in petroleum production by the end of 1980, reaching a rate of 1.8 million barrels per day. Shortly after yearend there were 16 producing oilfields in the North Sea and a further 9 fields were being developed. Oil reserves were estimated at 16.3 billion barrels (proven) to 32.6 billion (probable) barrels, and a seventh round of offshore licenses was awarded in December.

Oil production was projected by the Department of Energy at 82 million to 110 million tons (1.7 million to 2.3 million barrels per day) in 1982 and 90 million to 120 million tons (1.8 million to 2.4 million barrels per day) in 1984. In the past such predictions have tended to over estimate future production because of the scale of the technological challenge in producing oil in the storm-prone North Sea from water depths of 300 to 600 feet, 100 miles from land, and because of frequent strikes by diverse groups ashore. Possible limiting factors in the future may be taxation and Government oil depletion policies.

In 1980, one field, Murchison, started production. Shortly after the year ended, the Tartan Field commenced production, and the roster of British oilfields was at that time as follows:

Field	Operator[1]	Approximate production rate (Million barrels per day)
Argyll	Hamilton Bros	20,000
Auk	Shell-ESSO	14,000
Beryl	Mobil	113,000
Brent	Shell-ESSO	201,000
Claymore	Occidental	90,000
South Cormorant.	Shell-ESSO	27,500
Dunlin	____do	103,700
Forties	British Petroleum	502,000
Heather	Unocal	21,000
Montrose	Amoco	35,000
Murchison	Conoco	85,000
Ninian	Chevron	300,500
Piper	Occidental	200,000
Statfjord	Conoco in the United Kingdom, Mobil in Norway.	[2]150,000
Tartan	Texaco	8,500
Thistle	British National Oil Corp.	136,000

[1]Operator only. Operator frequently has minor equity only. For example, Ninian's operator, Chevron, has less than 17% equity, while ICI Petroleum and the British National Oil Corp. each have much larger shares.
[2]15.9% of reserves are in the United Kingdom; the remainder in Norway.

A further eight fields were currently under development, as cited in the following tabulation:

Field	Operator	Estimated production startup
Beatrice	British National Oil Corp.	1981
Beryl B	Mobil	1984
Brae	Marathon	1983
North Cormorant	Shell-ESSO	1982
Fulmar	do	1982
Hutton	Conoco	1984
N. W. Hutton	Amoco	1982
Magnus	British Petroleum	1983
Maureen	Phillips	1983

At midyear, Energy Secretary David Howell said the Government would "take (oilfield development) decisions on a case-by-case basis, but give greater emphasis to the need to limit the sharpness of the peak in production.... In particular, the Government will consider delaying the development of fields discovered after the end of 1975, which are not covered by (previously given) assurances.... The Government will also continue to tighten controls on gas flaring." He also said "there can...be no rigid plan" for oil production controls.

After this announcement, permission for development of at least one field, the Clyde Field of the British National Oil Corp., was postponed. During 1980, a total of three field development permissions were given: Beryl B, Brae, and Hutton. After the end of the year, new Government tax measures were introduced in the form of an increase in the Petroleum Revenue Tax, a reduction in exemptions therefrom, and a new Supplementary Petroleum Duty. Thereafter, two companies announced postponement of development of oilfields, which they said was necessitated by the changes in taxation.

The seventh round of U.K. offshore licenses was announced during the year. For the first time, companies could designate desirable acreage (from an area east of the Shetlands), for which a payment of 5 million pounds sterling would be due upon award of license. By yearend, 42 blocks had been awarded. By early 1981, this number had risen to 79, representing the first modest increase in activity since the fourth round, as shown in the following tabulation:

Round	Year	Total number of blocks awarded
7th	1980-81	79
6th	1978-79	42
5th	1976-77	44
4th	1971-72	282
3d	1970	106
2d	1965	127
1st	1964	348

During 1980, 32 exploration wells were drilled. This was the smallest number since 1971 but was not greatly different from the totals of the previous 2 years. Meanwhile, the total number of exploration, appraisal, and development wells, at 176, stood at its highest total since 1977, as indicated below:

Year	Number of wells			
	Exploration	Appraisal	Development	Total
1980	32	22	122	176
1979	33	15	102	150
1978	37	25	96	158
1977	67	38	96	201
1976	58	28	54	140
1975	79	37	21	137
1974	67	33	20	120
1973	42	19	21	82
1972	33	8	36	77
1971	24	4	34	62

The oil-landing pipeline terminal at Sullom Voe in the Shetlands became operational during the year and had the capacity to accept some "live" crude as well as crude oil from which the gas has already been separated. The Brent and Ninian pipeline systems, from northern North Sea oilfields, both terminate at Sullom Voe and had a combined capacity of over 1 million barrels per day. Final completion of gas-processing facilities was estimated still to be more than a year away.

Total oil refining capacity in Great Britain stood at 2,630,000 barrels of crude per day during 1980, and no major expansions of basic capacity were underway. There are 19 refineries with basic crude capacities ranging from 5,500 to 355,000 barrels per day. Although various work on upgrading of refinery capability continued, particularly with respect to light ends, no new refineries were announced. No such announcement was anticipated in the near future, as refining activity continued to decline. By yearend, only 60% of basic capacity was being used.

[2]Exchange rate against the dollar was 0.450 in January and 0.419 in December.

The Mineral Industry of Venezuela

By Doris M. Hyde[1]

In real terms, the gross domestic product (GDP) grew by an officially estimated 1.6% in 1980 and amounted to $18.4 billion.[2] The deliberately low economic growth programmed by the Government for 1979 and 1980 was expected to rise to as much as 4.5% in real terms for 1981. The Sixth National Development Plan (1981-85) has projected an estimated average growth rate of 6.5% for the period. As shown below, revisions in the GDP for previous years indicate mostly lower percent growth rate figures since 1975 than were previously cited.

	1975	1976	1977	1978	1979
Current	5.9	8.3	7.0	3.3	0.8
Previous	5.7	7.9	7.7	4.9	4.1

In 1980, the mineral export sector, primarily the petroleum industry, accounted for 9.4% of the GDP. External sales of petroleum also contributed an estimated 72% of total Government income earnings compared with 67% in 1979.

The percentage contribution to the GDP made by the petroleum and mineral sectors are shown below:

	Contribution to GDP		Change from previous year	
	1979	1980	1979	1980
Petroleum	9.3	8.5	+6.1	-7.0
Mineral	.8	.9	+7.9	+6.9

The revised balance of trade surplus for 1979 was almost $3.4 billion instead of the $3.9 billion estimated earlier. For 1980, again primarily owing to gains in the petroleum market, the balance of trade surplus increased and was estimated at about $6.5 billion. In 1980, after 3 deficit years, a surplus of $2.6 billion was estimated on the current account of the balance of payments. Inflation grew to an unprecedented 23.1%, but leveled off to average an estimated 18% for the year.

Crude oil production generally declined in 1980 owing to well maintenance shutdowns and refinery modification projects, resulting in an output 3% less than targeted and almost 9% less than output produced in 1979. Internal demand for refined products continued to grow and increased by 9.4%. If domestic demand continues to rise at recent levels, internal consumption of crude oil by the end of this century could surpass 1.6 million barrels per day, up 360% over the 362,000 barrels per day consumed in 1980. There appeared to be a growing consensus within Government circles that domestic product prices, which now average about $8.00 per barrel of crude oil, must be increased to induce public conservation practices.

In 1980, iron ore production increased substantially, and internal sales accounted for 18% of total production. This represented a 314% gain over production sold domestically in 1979. Iron ore sales represented 82% of the estimated $259 million value of 1980 nonpetroleum mineral production. Coal continued a downward production trend and was almost 21% under production of 1979.

The taxable value of mined coal represented 0.3% of the total value of mineral production. Although production is projected to increase to 78,000 tons in 1981, until the coal deposits of Zulia State are developed, the near-future prospect for coal

is to remain of minor importance.

Gold, which in 1980 represented about 4% of total mineral production value, is expected to show a substantial production increase in 1981. The Minerven project, which initiated production in 1980, represents the major factor for projected production increases.

Diamond production has been subject to variations in grade and volume owing to the nature of occurrences. In 1980, diamonds represented about 14% of the value of total mineral production, down from 19% in 1979.

The prospect of bauxite mining by 1983 dimmed as the Fondo de Inversiones (FIV) continued to deliberate on various aspects of the final Los Pijiguaos feasibility study.

Government Policies and Programs.—The Sixth National Development Plan was designed to produce a balanced growth in all sectors, and it envisioned a larger role for the private sector. Petroleum, petrochemicals, steel, aluminum, and other areas in the metallurgical sector were given priority status. Stimulation is to be given to the private sector by reducing Governmental intervention and by opening the door to a freer play of market forces, both domestic and international.

In October 1980, the Government announced that about 60 State-owned companies (mostly in the metal, mechanical, tourism, and agroindustrial sectors) would be sold to private investors. All these companies are administered by the Corporación Venezolana de Fomento (CVF), which may retain a minority interest in some of them. It was reported that the private sector was considering the Government offerings with mixed enthusiasm.

Authorizations granted for new foreign investment practically doubled in 1980 and amounted to about $416 million, of which 80% was in the manufacturing sector and about 10% was in the construction sector. Actual foreign investment, however, increased by $104 million during 1980, a 5.2% growth, almost the lowest in 5 years. The Superintendencia de Inversiones Extranjeras (SIEX) has become more responsive to requests for authorizing foreign investment and somewhat more liberal in the interpretation of Andean Pact Decision 24. Increased foreign investment and SIEX's recent positive attitude toward it has not met with total approval from all political and Government sectors, and this reaction could impede foreign investment as investors weigh the consequences of possible future policy reversals.

The legal battle between the Government and the foreign oil company ex-concessionaires over back taxes and royalty payments continued. The Government has indicated that it will not negotiate, and the companies reportedly have indicated they will not acquiesce. To date, court decisions have been going against the companies, but appeal procedures have been initiated.

The unresolved question of the exact location of maritime boundaries between Venezuela and Colombia has been under negotiation for about 12 years. In October 1980, a draft agreement was published by the two countries, but internal opposition on both sides delayed formal signing. The main issues have been Venezuela's insistence that the Gulf of Venezuela is an "internal sea," over which it should have absolute sovereignty, and Colombia's insistence that the Los Monjes Islands are the territory of Colombia. In the proposed agreement, Colombia cedes its claim to Los Monjes and Venezuela recognizes limited Colombian rights in the Gulf. The draft covers, among other issues, the sharing and/or ownership of hydrocarbons. Although there has been no drilling in the gulf, Venezuela believes there may be about 10 billion barrels of oil in the area.

Venezuela's large territorial claim against Guyana was placed in a standby status in 1970 by the Port of Spain Protocol. This agreement expires at the end of 1981, and some discussions will probably ensue during 1981 on this matter.

On December 31, 1979, the Government published Decree 476, which consisted of new regulations pertaining to the treatment of technology contracts, including those for the provision of technical services, technical assistance, engineering and consulting services, and research and development. The regulations represent the determination of how (as provided in the Venezuelan income tax law) payments for technical assistance and services rendered abroad, but used to produce income in Venezuela, will be taxed. The decree marks the beginning of taxation on certain kinds of income received for work done in foreign countries. This could present double taxation problems to some U.S. companies and place them at a disadvantage when bidding against European and other competitors for technology contracts.

On August 3, 1980, Venezuela and Mexico

signed a joint agreement to guarantee a supply of 160,000 barrels of crude oil per day to Central American and Caribbean countries under special financing arrangements. Owing to a delay in signing all of the bilateral agreements with each recipient, only $49 million of the theoretical $306 million that Venezuela committed for the first year was actually dispersed during 1980. Jamaica and the Dominican Republic were the 1980 beneficiaries.

The basic principle of the financing facility (administered in Venezuela by the FIV) is to provide financing for 30% of the value of each participant's domestic consumption of crude oil. Venezuela's contribution should be one-half of the participant's total domestic consumption, the remainder coming from Mexico. The maximum amount of imported crude oil covered is stipulated in each separate agreement. Deposits are made by Venezuela quarterly (for its share of the total) in the recipient's central bank; terms are 4% interest, with repayment due after 5 years. The recipient's central bank issues a certificate of deposit with these terms to the FIV. The loans may be converted to a 20-year repayment schedule at 2% interest if the money is applied to energy or other development projects approved by the FIV.

Participants actually pay full price for the oil to Petróleos de Venezuela, S.A. (PDVSA). The loan funds come through FIV from its budget allocations received from the central Government, the source of which comes from petroleum revenues.

The Venezuela-Mexico financing accord was not Venezuela's first such arrangement. The first facility was uniquely Venezuela's and applied to the years 1975-80. It differed from the new facility in the criteria for determining how much financing should be made available and the terms of financing.

PRODUCTION

Petroleum continued to be the mainstay of Venezuela's mineral production. Output fell to 2.174 million barrels per day, somewhat below the targeted level of 2.22 million barrels per day, because of major maintenance projects on some of the wells in the Lake Maracaibo region and to work being undertaken at two refineries which necessitated production cutbacks. The 1981 production target was set at 2.158 million barrels per day.

For the second year, aluminum continued to be the second most valuable mineral industry, with output increasing substantially from both producers. The value of 1980 production was estimated at over $554 million. Production for 1981 was projected to approach maximum utilization of plant capacities.

The significant increase in steel production by C.V.G. Siderúrgica del Orinoco C.A. (SIDOR) did not alleviate the financial problems which have plagued the company.

Increased production and higher prices provided a boost to the iron ore industry as the value of production rose to $213 million, a 19% increase over that of 1979. Net profit to C.V.G. Ferrominera Orinoco C.A., however, dropped to insignificance as the company absorbed high production costs and its share of losses incurred by Compañía de Minerales Ordaz, C.A., the high-iron briquette plant jointly owned with United States Steel Corp. and Corporación Venezolana de Guyana (C.V.G.). For 1981, production has been targeted at about 19 million tons.

Coal production continued to decline, and the rehabilitation of the Naricual Mines was abandoned. Coal production will probably continue to be of minor importance until the Carbones del Zulia C.A. (Carbozulia) Mines are brought into production. Laboratory testing and engineering studies were under way on the Zulia coal. For 1981, national coal production has been targeted at 78,000 tons.

Other mineral production indicated a mixed performance during 1980. Gold showed almost a 100% increase in value for a 10% production increase over that of 1979. A 10% decrease in the output of industrial and bort diamonds and lower prices were responsible for the 21% decline in the total value of diamonds produced during 1980.

Table 1.—Venezuela: Production of mineral commodities[1]

(Metric tons unless otherwise specified)

Commodity[2]	1976	1977	1978	1979	1980[p]

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.

[1]Table includes data available through July 14, 1981.

[2]In addition to the commodities listed, lime is produced, but available information is inadequate to make reliable estimates of output levels.

[3]Officially reported figure, but may be incomplete.

[4]From nonassociated natural gas only.

[5]Includes associated natural gas lease condensate and natural gasoline. Lease condensate is included as follows, in thousand 42-gallon barrels: 1976—1,088; 1977—1,174; 1978—1,048; 1979—1,803; and 1980—1,900. Natural gasoline is included as follows, in thousand 42-gallon barrels: 1976—283; 1977—none reported; 1978—329; 1979—255; and 1980—250.

[6]Liquid equivalent.

TRADE

In 1980, crude oil and refined products valued at an estimated $17 billion accounted for about 94% of the total value of exports in contrast to the almost 96% share of value registered in 1979. Exports from the petroleum sector decreased from about 2.12 million barrels per day in 1979 to 1.81 million barrels per day in 1980. Total crude oil exports in 1980 amounted to 458.5 million barrels, and refined products amounted to 201.9 million barrels, an 11% and 22% decrease from that of 1979, respectively. This decline was attributed to a decreased world demand owing to generally depressed economies in the industrialized countries and to the energy policies of these countries which have intensified conservation. The average $17.36 per barrel value for 1979 petroleum exports increased substantially to $30.86 for 1980.

Lagoven, S.A., contributed about 45% of the total petroleum exports; Maraven, S.A., 35%; Corpoven, S.A., 16%; and Meneven, S.A., 4%.

In 1980, Venezuela provided directly about 3% of the total U.S. imports of crude oil and 6.5% of the combined direct imports of crude oil and refined products. The volume of crude oil and petroleum products exported to the United States decreased almost 40%, from 260.5 million barrels in 1979 to 156.6 million barrels in 1980. In 1981, Venezuela expects to export a total of 1.89 million barrels per day of crude oil, with about one-half directly and indirectly going to the United States.

Oil export policy changes in 1980 included limiting export contracts to 1 or 2 years, with provisions for price adjustments. Certificates of destination will be required to prevent Venezuelan oil from being manipulated or used in the spot market. Heavy crude oil will become the major export, while lighter grades will be used for negotiating purposes.

In 1980, iron ore exports decreased 9% from that of 1979. Of the 11.8 million tons exported, the United States received 31%, the Federal Republic of Germany 15%, Belgium 9%, Spain 8%, and lesser amounts to England, France, Holland, and other countries. The value of iron ore exports increased slightly to $142 million, or about 3% over the 1979 value, as the per ton value rose almost 6%, to $13.08. The value of internal sales leaped 371% over that of 1979 and amounted to $37.5 million in 1980. SIDOR accounted for 88% of domestic sales.

Total steel and sponge iron exports for 1979 were valued at $51 million, but in 1980 increased 46% to $72 million. Aluminum exports, which in 1979 reached $144 million and surpassed iron ore in value, by August 1980 were valued at almost $212 million and firmly established this product's second-place position among mineral and mineral-related exports for the foreseeable future.

Mineral imports in 1979 were valued at $269 million and accounted for about 2% of total imports.

COMMODITY REVIEW

METALS

Aluminum.—The 1-million-ton-per-year alumina plant under construction by Interamericana de Alumina, C.A. (Interalumina), was about one-quarter complete at the end of 1980. The plant, now estimated to cost over $1.1 billion due to cost overruns, is scheduled for completion in November 1982. This plant is expected to employ about 1,200 workers. It was reported that 45 to 60 Venezuelan engineers will be trained at a similar facility in Gove, Australia.

Venezuela has remained enthusiastic about the future of its aluminum industry in spite of some past financial disappointments. A draft of the new national plan for 1981-85 projected that by 1985 aluminum production would be 610,000 tons per year and that by 1990 it should reach 1 million tons per year. Current total capacity is 400,000 tons per year—120,000 tons from Aluminio del Caroni, S.A. (Alcasa), and 280,000 tons from Industria Venezolana de Aluminio (Venalum). There were reports that a merger between the two companies may be under consideration.

After 2 successive years of net losses, Alcasa ended its 1980 fiscal year registering almost a $2.5 million profit, as opposed to losses of $7.9 million in 1978 and $16.5 million in 1979. This has been described as a deceptive profit because Alcasa also received a Government export subsidy which amounted to $22 million for 1980. Alcasa's production and sales were both up in 1980, but the company maintained a high debt and/or equity ratio. At the end of 1980, Alcasa received a $58 million capital investment contribution from the FIV, which increased its interest in the company to 57.5% and reduced the Reynolds International, Inc., holding from 50% to 27.9%. Corp. Venezolana de Guayana has a 14.6% interest in Alcasa.

In August 1980, Alcasa completed its Phase IV plant expansion to 120,000 tons per year. Capacity to produce rolled aluminum also increased from 13,000 tons to 30,000 tons per year in 1980. Expansion to 320,000 tons of aluminum per year at Alcasa is expected to provide most of the projected 1985 increased national aluminum capacity. Financing for the estimated $300 million cost of this expansion has not been obtained.

The Venalum aluminum smelter operated at about 79% of its 280,000-ton-per-year capacity in 1980, producing 222,068 tons of aluminum. Expansion plans called for a fifth 70,000-ton-per-year potline to be installed by 1983 at a projected cost of $150 million. Venalum's startup losses, which amounted to about $22 million for 1979, were reversed in 1980, and the company showed a profit of about $50 million (including the Government export incentive subsidy of $23 million). Venalum was the second leading earner of foreign exchange after PDVSA, with 1980 export volumes amounting to 151,200 tons, valued at almost $248 million. Internal sales amounted to 55,200 tons, valued at $87 million. Japan received 130,600 tons, the major portion of Venalum's exports.

Venalum has encountered production problems owing to Venezuela's electricity shortage caused by delays in completing the Guri hydroelectric scheme. This shortage may cause Venalum to miss its targeted 1981 production figure of 268,000 tons. There is also the prospect of an increased power rate from the 2.56 cents per kilowatt-hour paid in 1980.

Another highly publicized Venalum problem has stemmed from efforts to renegotiate contracts with two of its alumina suppliers, Philipp Bros. and Metallgesellschaft AG. Venalum wanted to reduce the contract alumina price to 13% of Aluminum Co. of Canada Ltd.'s international reference price for aluminum ingot. This would represent a 2% reduction in the contract price during 1980, 2.5% in 1981, and 3% in 1982. Alumina shipments to Venalum were halted during the negotiations. Before the end of 1980, Venalum had successfully negotiated with Philipp Bros. and alumina shipments were resumed. The dispute with Metallgesellschaft may be taken to international arbitration.

Venalum management reportedly would also like to make some changes in its export contract with its Japanese consortium shareholder. The present 10-year contract provides for the delivery of 160,000 tons of aluminum per year at the Alcan international reference price minus a discount of 6%.

Bauxite.—The proposal to develop the Los Pijiguaos bauxite deposits has fallen about 1 year behind schedule owing to

funding delays and efforts to further maximize the efficiency of the operation. The FIV holds a 50% interest in the operating company, C.V.G. Bauxita Venezolana C.A. (Bauxiven), and Corp. Venezolana de Guayana (CVG) is the other partner in the joint venture. Final FIV approval and financing for the estimated $620 million project remained pending as alternative transportation and infrastructural plans were studied. The feasibility study by Aluminio Suizo, S.A. (Alusuisse), has also been closely scrutinized. If FIV gives final approval by mid-1981, the first ore shipment could take place in 1984.

It was reported that exploration surveys have indicated the presence of as much as 3 billion tons of bauxite reserves in eastern Venezuela, particularly in the Amazonas Territory.

Ferroalloys.—Fesilven (formerly Venbozel) mines a large silica-rich Cretaceous quartzite in eastern Venezuela. Ore is trucked to Puerto Ordaz where the 60,000-ton-per-year plant produces silicon metal and ferrosilicon. Venbozel was jointly owned by FIV (50%), CVG (25%), and the French company, Nobel Bozel (25%), until differences in 1980 caused Bozel to withdraw. The company, renamed Fesilven, was reorganized, received additional subscribed capital, and ownership was then distributed among FIV, CVG, SIDOR, and Credit Lyonnaise through the conversion of Venbozel's debt into preferred shares. In 1980, FIV increased its interest to 34.6% by subscribing additional capital.

Production was expected to reach capacity in 1981, and after some plant modifications, 1982 production is expected to reach 64,000 tons. About 90% of production has usually been exported, Japan being the prime receiver followed by the United States. The remaining production is consumed by SIDOR in steel deoxydizing and in silicon steel production.

Ferromanganese is produced by Hornos Electricos de Venezuela, S.A. (Hevensa), a mixed company composed of 50% Mexican, 25% Venezuelan, and 25% Japanese capital. Originally established as a ferrosilicon producer, operations changed to ferromanganese production using imported raw material. Production capacity was reported to be about 18,000 tons per year, with reports of actual production varying between 6,000 and 12,000 tons per year.

Venezuela has been reported as having about 2 million tons of ore reserves grading 20% to 40% manganese located in the Upata region of northern Bolívar State. Other deposits of manganese have been reported as associated with the metamorphic iron belt also in northern Bolívar State.

Gold.—The increased price of gold during 1979 and 1980 has stimulated some additional production. While 1980 production increased about 10% over that of 1979, the value increased by almost 100% to $9.56 million in 1980. The Government expects a sharp increase in 1981 gold production of almost 80,000 ounces.

In 1980, State-owned Cía. Minera de Venezuela (Minerven) accounted for 26% of total gold production. The Sindicato de Patrones Mineros contributed 50% of production, independent miners 18%, and other concessionaires 6%. Minerven completed mining preparations in the El Callao region of Bolívar State. Proven reserves were established at 250,000 tons grading almost 0.39 ounce gold per ton. The processing plant began operations at a capacity of 240 tons per day.

Iron Ore.—About 45% of iron ore production came from the Cerro Bolívar Mines, 29% from Cerro El Pao, and 25% from Cerro Altamira. Production at Cerro San Isidro dropped to about 105,300 tons, and no production was reported after March 1980. Net profit to CVG Ferrominera del Orinoco, C.A., was about $40,000, drastically lower than last year's revised profit of $6.8 million. The low profit was attributed to losses incurred at the Cía. Minerales Ordaz briquette plant. Ore production for 1981 was expected to reach 18.8 million tons as a result of an investment of $7 million to expand and improve the mining installations and over $10 million for equipment maintenance and to upgrade facilities. The 20-kilometer railroad linking SIDOR's pelletizing plant and Ferrominera was opened during the first half of 1980.

In 1980, internal sales of iron ore amounted to 2.9 million tons, an increase of 314% over that of 1979. SIDOR accounted for 88%, and Fior de Venezuela accounted for 12% of internal sales.

At the end of 1980, proven high-iron content ore reserves were estimated at 1.73 billion tons, about 10% less than at the beginning of the year. The distribution of reserves is as follows in million tons: San Isidro 390, María Luisa 258, Los Barrancos 232, Cerro Bolívar 218, La Estrella y Redondo 165, Arimagua 136, Altamira 128, Las

Pailas 80, San Joaquin 65, El Pao 44, and Toribio 18. In addition, ferruginous quartzite reserves (29% to 50% Fe) in the Cinturón Ferrifero de Imataca are estimated at 10 billion tons.

Iron and Steel.—After pilot testing in 1979 and early 1980, the high-iron briquette direct-reduction plant of Cia. de Minerals Ordaz, C.A. (Minorca) resumed operations in mid-1980 and was expected to produce 400,000 tons that year and 600,000 tons in 1981. Minorca is 51% owned by Ferrominera, with United States Steel Corp. holding the minority interest. Actual production at Minorca was 226,000 tons, of which about 29% was exported, and the rest sold locally.

SIDOR increased steel production to 1.78 million tons in 1980, an increase of 39% over that of 1979. Interior sales were estimated at 1.64 million tons, valued at $762 million. Export sales were estimated at about 300,000 tons, valued at $72 million. These figures represent increases over that of 1979 of 43% and 46%, respectively. Export sales of semimanufactured steel totaled over 245,000 tons, while sponge iron exports were about 53,500 tons.

NONMETALS

In 1980, it was reported that more than $2 billion has been planned for investment in various industrial mineral projects. The private cement, ceramic, glass, refractory, and paint industries are actively developing new mines to produce raw materials for their plants. Many of these industrial minerals do not require special mining permits, mineral ownership being vested in the landowner.

Nonmetallic minerals occurring in Venezuela include: Asbestos, barite, bentonite, chalk, diamonds, diatomite, dolomite, feldspar, gneiss and granite, gypsum, ilmenite, kaolin, kyanite, limestone, magnesium, marble, mica, natural asphalt, ocher, peat, phosphate, quartz and quartzite, rare earth, salt, sand, silica, sulfur, talc, and white clays. Of these known mineral occurrences, 17 are reported as presently mined, 4 are scheduled for mining in the near future, and 8 are under exploration and evaluation studies.

The Government does not report the value of industrial mineral production, and their worth is not taken into account when estimating the mineral sector's contribution to the economy. The reporting of production and classification of material is not always consistent and may not be inclusive.

Cement.—Producers were unable to provide for domestic demand and as import contracts expired, renewal was hampered because the price of Venezuelan cement is fixed at an amount considerably lower than the world market price. This situation could result in a cement shortage during 1981 of up to 18 million bags.

The new computerized cement plant of Cementos Caribe S.A. came onstream in Falcón State in late 1979 at a rating of 3,000 tons per day of finished cement. Consolidada de Cementos C.A. initiated construction of a 2,400-ton-per-day dry-process cement plant in San Sebastian. The $46 million plant is expected to become operatonal at the end of 1982.

Diamonds.—The controlled production of diamonds declined over 10% in 1980, because of lower production of bort-grade diamonds. Concessionaires were reported as producing less than 1% of the total national production; independent miners provided the remainder. Production in 1980 was valued for tax purposes at $35.2 million, a decrease of almost 21% from the 1979 value of $44.3 million.

Magnesite.—The mining law presently classifies magnesite as a common mineral not subject to special regulation. Certain legal and ownership problems have effectively blocked mining, and there has been no production. Reserves on Margarita Island are estimated at 14 million tons.

MINERAL FUELS

Coal.—The C. A. Minas de Carbón de Lobatera Mines in Tachira State supplied 94% of total 1980 coal production. C. A. Minas de Carbón de Naricual produced 5% of total production. The Consejo Nacional de la Industria del Carbón, in consensus with the Ministry of Energy and Mines and the Oficina Central de Coordinación y Planificación (CORDIPLAN) concluded that the rehabilitation of the Naricual Mines was not progressing satisfactorily, and the company was liquidated with the coal deposits passing to Corp. de Desarrollo de la Region Nor-Oriental (CORPORIENTE) ownership.

Carbones del Zulia, C.A. (CARBOZULIA), the State company established to exploit the Guasare coal deposits in the State of Zulia, continued its mine drilling program. Coal exploration activities were under way in the carboniferous zone of Tachira State. Topographic mapping was concluded in the area, and drilling was expected to begin in

early 1981.

Petroleum and Natural Gas.—In 1980, PDVSA was the largest Third World firm and ranked in 15th place among the 100 largest companies outside the United States. In 1980, PDVSA invested almost $2 billion in exploration, production, refining, and complementary operations involved in marketing and administration. This was an amount lower than originally planned, but substantially more than the $1.5 billion spent in 1979. Over 15% of the 1980 investment was allocated to exploration activities, almost 46% to production, and 26% to refining operations. An investment increase to $2.9 billion was planned for the 1981 spending program. About 44% of this amount will be allocated for exploration activities.

The petroleum industry's net earnings in 1980 increased to $3.3 billion, a 13% increase over 1979 net earnings. The profit gain reflected increases in prices. During 1980, the average realized per barrel price of exported crude oil rose from $17.47 to $25.85, while the average price for refined products increased from $19.50 to $27.30 per barrel.

The 1980 yearend estimate of crude oil reserves increased to 19.6 billion barrels, a gain of 6% over that of 1979. Natural gas reserves at the end of 1980 increased slightly to an estimated 45.5 trillion cubic feet. Almost 95% of the reserves are classified as associated gas.

More natural gas was utilized during 1980 despite a production decrease from that of 1979. Of total production, 47% was injected into formations, 16% was used by the petroleum industry, 26% was marketed, 5% was transformed into products, and 6% was flared.

Light-gravity crude oil—more than 22.9° A.P.I.—production decreased 12% from production of 1979, and in 1980 accounted for over 54% of total production. Medium-gravity oil—from 22.9° A.P.I. to 14° A.P.I.—constituted 26% of production, and heavy oil—less than 14° A.P.I.—contributed almost 20% to total production. Medium and heavy oil production decreased 3% and 0.7%, respectively, from that of 1979. Lagoven, S.A., was the largest crude oil producer (41%), followed by Maraven, S.A. (28%), Corpoven, S.A. (15%), and S.A. Meneven (16%).

All four of these PDVSA subsidiary companies produced petroleum from the Maracaibo region, which accounted for 78% of total national production. Corpoven, Lagoven, and Meneven together produced 8% of total national production from the Maturin region; Corpoven and Meneven produced 12% from the Barcelona region; and Corpoven alone accounted for the 2% contribution to total national production from the Barinas region.

In 1980, there were 43 producing fields in the Maracaibo Basin, and they contributed 78% to total national production. The Eastern (Oriental) Basin, with 116 producing fields, accounted for 20% of production; the Apure Basin, with 8 fields, accounted for almost 2%; and the 3 active fields in the Falcón Basin contributed considerably less than 1%. At the end of 1980, there were 13,491 active wells, of which 13,453 produced crude oil and 38 produced natural gas. There were also 843 injection wells.

The operating companies continued exploration work, searching primarily for light- and medium-grade crude oil through extensions of exiting fields and in new areas where geophysical testing was favorable. Successful offshore drilling continued in the same general areas which showed promise in the 1979 drilling programs. A gas exploration program was begun in north-central Venezuela in the States of Guárico and Monagas.

Exploration also continued in the Orinoco heavy oil belt to better determine the extent and potential reserves of this 19,000-square-mile area along the northern side of the Orinoco River. Development of the "Faja," as this region is commonly called, has been divided among the four operating companies. Lagoven has outlined an ambitious drilling and recovery program projected to cost $8 billion for its Cerro Negro project, or Desarrollo del Sur de Mongas y Anzoátegui (DSMA). At Cerro Negro, Lagoven is experimenting with different methods of steam injection. Lagoven's plans include drilling 1,000 wells, constructing 15 flow stations, 60 steam boilers, and a plant to remove heavy carbons from the crude oil. A $3 billion infrastructure development includes a town and 1,000 kilometers of water and oil pipelines. Lagoven plans to include as many local companies as possible in the project, but its scope necessarily requires some foreign consultants. Bids for a general executive coordinator have been received, and a selection is expected early in 1981.

The use of foreign contractors and the push to develop the Orinoco reserves at this

time has not received unanimous private and public approval. Pro-developmentalists deny the presence of foreign influence in Venezuelan petroleum affairs and emphasize the necessity for preparing now for projected national energy demands in the next century and for continued production for the export market.

Meneven's development of the Faja crude oil reserves is expected to be assisted by the company's existing production facilities nearby in Anzoátegui State. Maraven is exploring and evaluating the "Zuata" L area in the States of Guarico and Anzoátegui. The company planned to have 73 wells completed by the end of 1981. Corpoven has been exploring the Machete area in Guarico State and planned to complete 123 wells by the end of 1981.

Venezuela is proceeding with its $2 billion refinery upgrading projects designed to produce more gasoline to meet a growing internal demand and to accommodate a greater percentage of heavy crude oil in the refinery input. In 1980, refinery capacity did not change from the 1979 total of 1,445,000 barrels per calendar day.

Projected costs have increased on Lagoven's Amuay refinery modification, now estimated at $770 million. Construction is on schedule for the mid-1982 startup which will add 50,000 barrels per day to Amuay's gasoline production capacity, 22,000 barrels per day to distillate output, and will lower high-sulfur fuel oil production by 77,000 barrels per day. The refinery is expected to be able to handle a throughput of 44% extra-heavy crude oil.

Corpoven's $360 million El Palito refinery upgrading project fell behind schedule, but was expected to be completed in September 1981. Gasoline production capacity at El Palito should reach 77,000 barrels per day, and residual output will drop to 29,000 barrels per day with a viscosity over seven times higher than that now produced. The residual will be piped to a nearby electrical generating plant.

By 1985, Meneven's Puerto La Cruz refinery is scheduled to replace its catalytic cracker with a 52,500-barrel-per-day Pullman Kellogg fluid unit and two new vacuum units. Heavy oil refining capacity will be increased by 25,000 barrels per day. The investment cost was estimated at $730 million.

Maraven's Cardón refinery at Punto Fijo on the Paraguaná Peninsula, 16 miles south of the Amuay refinery, has also been slated for modification. The heavy crude input, now about 30,000 barrels per day, is to be converted into diesel and other products rather than the present production of reconstituted crude oil.

By 1984, Venezuela's refineries should have decreased the input of light- and medium-gravity crude oil while increasing heavy and extra-heavy grades. Output of gasoline, No. 2 fuel oil, and low-sulfur fuel oil should increase, while that of kerosine, jet fuel, and high-sulfur fuel oil are expected to decrease. Projections of increased internal demand for gasoline are expected to require additional refinery modifications every 2 to 3 years after 1986.

The Mineral Industry of Yugoslavia

By Roman V. Sondermayer[1]

Although Yugoslavia continued to be one of the prominent producers of nonferrous metals in Europe during 1980, lead and zinc output was not adequate to supply all domestic needs. It is uncertain whether significant imports of lead and zinc concentrates, which started in 1970-75, will become permanent, or whether they were a temporary measure. Efforts to increase mine output of ores during 1980 were not satisfactory.

By world standards, the mineral industry of Yugoslavia was modest. The more prominent minerals with production in 1980 expressed as percentage of world output were as follows: Antimony 2.3%, bauxite 3.5%, lead mine 3.4%, alumina 2.6%, lead smelter 2.6%, magnesite 2.4%, bismuth 2.2%, zinc mine 1.7%, zinc smelter 1.4%, copper smelter 2.3%, copper refined 1.5%, copper mine 1.8%, and aluminum 1.2%. Production of other minerals was of domestic significance only.

The mineral industry contributed 7.1% of the gross social product (GSP) and 6.1% of the total employment. The share of the mineral industry including processing in the GSP (tantamount to the Western equivalent of gross national product) for 1979 (latest year available) and employment is shown in the following tabulation:[2]

Branch	Million dinars	Employment, thousand persons
Coal:		
Production	11,025	53.8
Processing	1,021	3.2
Crude oil:		
Production	3,896	4.4
Processing	8,434	9.8
Iron and steel:		
Iron ore, production	990	5.1
Steel, production	13,774	52.7
Nonferrous metals:		
Production of ores	5,595	26.8
Metal, production	3,688	15.2
Metal, processing	4,096	14.1
Nonmetallics:		
Production	2,167	12.4
Processing	8,004	46.9
Sand and gravel	4,635	22.9
Construction material	14,935	71.3
Total	82,260	338.6

Principal events related to the mineral industry during 1980 were as follows: Development of the copper mine at Veliki Krivelj in Srbija (Serbia); construction of an aluminum plant at Bacevici, Bosna i Hercegovina (BiH); startup of a new furnace for production of silicon at Ruse, Slovenija (Slovenia); start of production from first magnesium metal-producing plant in Yugoslavia, located in Serbia; continuing development of a nickel mine and plant in Rzanovo, Makedonija (Macedonia); construction of ammo-

nia plants in Pancevo, Serbia, and Kutina, Hrvatska (Croatia); and startup of a gasfield at Molve in Croatia.

PRODUCTION

The mineral industry was State-owned; however, investment of foreign capital in Yugoslavia's mineral industry was allowed. The size of enterprises ranges from large, integrated operations, mostly in production of metals, to small mines, mostly in production of nonmetals. Table 1 shows latest trends in the mineral production of Yugoslavia.

Table 1.—Yugoslavia: Production of mineral commodities[1]

(Metric tons unless otherwise specified)

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.

[1]Table includes data available through June 16, 1981.

[2]In addition to the commodities listed, germanium, bentonite, common clay, and diatomite are also produced, and tellurium may be recovered as a copper refinery byproduct, but available information is inadequate to make reliable estimates of output levels.

[3]Reported figure.

[4]Apparently included with ferrosilicon.

[5]Calculated as the difference between reported total and reported primary figure.

[6]Calculated as the difference between reported total and reported secondary figure.

[7]For ore production, see under "Lead."

[8]Excludes refinery gas, which was as follows, in million cubic feet: 1976—12,639; 1977—15,351; 1978—14,086; 1979—15,050; and 1980—NA; also excludes other materials produced by and used in the refineries as fuel.

TRADE

During 1980, Yugoslavia remained a net importer of minerals. Tables 2 and 3 show details of mineral trade of Yugoslavia.

Table 2.—Yugoslavia: Exports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1978	1979	Destinations, 1979	
			United States	Other (principal)
METALS				
Aluminum:				
Bauxite and concentrate	676,163	524,928	--	U.S.S.R. 248,722; Czechoslovakia 142,189; Romania 92,260.
Alumina	79,028	395,378	--	U.S.S.R. 289,256; Poland 84,577; Czechoslovakia 19,707.
Oxide and hydroxide	23,090	68,374	--	West Germany 35,831; Poland 32,420.
Metal including alloys:				
Scrap	3,127	352	--	Italy 301; West Germany 46; Austria 5.
Unwrought	58,730	46,180	--	East Germany 27,620; Czechoslovakia 5,101.
Semimanufactures	55,055	50,302	9,125	Czechoslovakia 16,032; East Germany 5,655.
Antimony, regulus	1,485	975	45	U.S.S.R. 730; Bulgaria 200.
Cadmium metal including alloys, all forms	176	133	71	West Germany 38; United Kingdom 10.
Chromium:				
Chromite	5,854	10,475	--	All to Czechoslovakia.
Oxide and hydroxide	10	125	--	All to Italy.
Copper:				
Copper sulfate	11,699	21,843	--	Turkey 15,384; Greece 3,572; China, mainland 2,205.
Metal including alloys:				
Scrap	3,682	7,948	--	West Germany 3,013; Switzerland 2,464; Italy 2,159.
Unwrought	16,070	8,356	3,563	East Germany 1,431; Italy 1,308.
Semimanufactures	26,711	29,814	2,495	U.S.S.R. 8,298; Czechoslovakia 4,277; West Germany 3,751.
Iron and steel:				
Ore and concentrate	16,290	2	--	Mainly to Sweden.
Roasted pyrite	33,833	48,302	--	Hungary 43,107; Austria 5,195.

See footnotes at end of table.

Potassic kilograms	--	885	--	All to U.S.S.R.
Other including mixed	184,090	319,243	--	Hungary 104,708; Turkey 97,312; Nigeria 36,000.
Gypsum and plasters	288	357	--	Hungary 308; Poland 22; Kuwait 10.
Lime	27,534	59,319	--	Hungary 33,371; Kuwait 25,775.
Magnesite	31,348	28,325	--	Poland 17,089; Italy 3,783; West Germany 3,589.
Pyrite (gross weight)	93,421	75,828	--	Romania 75,825.
Salt and brine	54	3,078	(1)	Hungary 3,073.
Sodium and potassium compounds, n.e.s	1,274	4,451	--	Turkey 1,000; France 746; India 600; Syria 500.
Stone, sand and gravel:				
Dimension stone:				
Crude and partly worked	49,745	50,151	--	Italy 26,206; Czechoslovakia 15,120.
Worked	6,252	4,254	--	West Germany 1,669; Austria 1,653.
Dolomite, chiefly refractory grade	1	--		
Gravel and crushed rock	57,238	5,195	--	Hungary 3,059; United Kingdom 545; Italy 423.
Limestone (except dimension)	10	3	--	All to West Germany.
Quartz and quartzite	9,767	13,056	--	Do.
Sand excluding metal-bearing	2,376	3,294	--	Greece 1,984; Albania 957; Libya 205.
Sulfur:				
Elemental, all forms	r3,826	6,543	--	Bulgaria 3,492; Turkey 1,768; Romania 1,130.
Sulfuric acid	1,192	162	--	Czechoslovakia 159.
Talc, steatite, soapstone, pyrophyllite	NA	590	--	All to Albania.
Other:				
Crude:				
Calcite	2,149	194	--	Pakistan 150; West Germany 44.
Unspecified	257	1,126	--	Greece 1,015; Austria 93.
Slag, dross, and similar waste, not metal-bearing	1,615	1,506	--	Austria 1,448; Italy 30; Lebanon 23.
MINERAL FUELS AND RELATED MATERIALS				
Carbon black	55	87	--	West Germany 86; Poland 1.
Coal and briquets:				
Anthracite and bituminous coal	940	--		
Lignite and lignite briquets	434,929	375,118	--	Austria 212,113; Czechoslovakia 102,139; Italy 39,714.
Coke and semicoke	148,596	307,538	--	Hungary 169,391; Romania 71,742; Austria 34,114.
Hydrogen, helium, rare gases	633	459	--	Austria 428; Egypt 12; Czechoslovakia 9.
Peat including peat briquets and litter	25	1,820	--	Italy 1,692; France 127.
Petroleum:				
Crude thousand 42-gallon barrels	(1)	--		
Refinery products:				
Gasoline do	r3,539	4,337	(1)	Switzerland 2,493; Netherlands 1,404.
Kerosine and jet fuel do	r405	448	8	Italy 158; United Kingdom 112; France 34.
Distillate fuel oil do	r2,383	584	1	Italy 281; Switzerland 141.
Residual fuel oil do	r309	269	(1)	Liberia 102; Greece 30.
Lubricants do	r340	349	--	Austria 278; Czechoslovakia 48.
Other:				
Liquefied petroleum gas do	r175	--		
White spirit do	33	6	--	All to Austria.
Mineral jelly and wax do	r44	46	3	West Germany 18; Italy 18.
Petroleum coke, pitch coke, bituminous mixtures do	40	43	--	West Germany 27; Poland 8; Italy 6.
Total do	7,268	6,082		
Mineral tar and other coal-, petroleum-, or gas-derived crude chemicals	20,293	36,727	2,304	Italy 29,404; Austria 3,580; West Germany 654.

Table 3.—Yugoslavia: Imports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1978	1979	Sources, 1979	
			United States	Other (principal)
METALS				
Aluminum:				
Bauxite and concentrate	43,643	63,883	--	Guinea 27,563; Greece 22,719; Australia 9,226.
Oxide and hydroxide	30,162	1,367	9	West Germany 1,274.
Metal including alloys:				
Unwrought	41,590	41,219	7	U.S.S.R. 30,996; West Germany 2,039.
Semimanufactures	9,538	8,510	26	West Germany 2,012; U.S.S.R. 1,652; France 1,589.
Antimony:				
Ore and concentrate	2,789	3,261	--	China, mainland 2,015; Turkey 850; Morocco 396.
Metal including alloys, all forms	145	--		--
Arsenic:				
Trioxide, pentoxide, acids	NA	66	--	West Germany 24; Belgium-Luxembourg 20; Netherlands 18.
Metal including alloys, all forms	36	138	(1)	U.S.S.R. 75; Austria 27; West Germany 26.
Beryllium metal including alloys, all forms kilograms	167	635	3	Denmark 500; West Germany 132.
Bismuth metal including alloys, all forms	18	5	--	Mainly from West Germany.
Chromium:				
Chromite	219,069	297,919	--	Albania 200,010; U.S.S.R. 84,072; Turkey 5,000.
Oxide and hydroxide	619	378	--	U.S.S.R. 300; West Germany 49.
Cobalt oxide and hydroxide	32	22	6	Belgium-Luxembourg 7; West Germany 5; Netherlands 2.
Columbium and tantalum including alloys, all forms kilograms	859	1,456	100	West Germany 1,219; Austria 68; Hungary 65.
Copper:				
Ore and concentrate	23,994	7,739	--	Mexico 7,352; Peru 387.
Copper sulfate	1,553	1,304	--	U.S.S.R. 1,298; Switzerland 3; West Germany 3.
Metal including alloys:				
Scrap kilograms	50	50	--	All from West Germany.
Unwrought	r40,061	36,095	2	Zambia 18,596; Peru 16,701.
Semimanufactures	8,469	5,414	7	West Germany 1,588; Poland 1,262; U.S.S.R. 1,193.
Iron and steel:				
Ore and concentrate thousand tons	547	1,060	--	India 365; Peru 355; U.S.S.R. 305.
Metal:				
Scrap	402,594	264,800	--	U.S.S.R. 238,257; Bulgaria 21,878; Poland 2,261.
Ingots	26,408	86,879	(1)	Poland 78,740; Romania 8,096.
Pig iron including cast iron	71,612	99,494	--	Spain 30,056; U.S.S.R. 27,647; East Germany 16,783.
Sponge iron, powder, shot	2,626	1,689	(1)	Sweden 1,502; France 77; West Germany 51.
Ferroalloys:				
Manganese	815	902	--	West Germany 623; France 279.
Other	6,584	7,083	79	West Germany 3,428; France 2,045.
Steel, primary forms:				
Blooms, billets, slabs, sheets, bars	581,773	464,937	--	Romania 167,692; Poland 97,579; Czechoslovakia 96,730.
Coils for recoiling	435,191	493,838	--	Czechoslovakia 134,601; U.S.S.R. 87,130; Bulgaria 60,016.
Semimanufactures:				
Bars, rods, angles, shapes, sections	278,601	204,194	10	Czechoslovakia 30,380; West Germany 28,089; Hungary 24,932.
Universals, plates, sheets	441,289	466,031	3	Czechoslovakia 90,360; West Germany 70,398; Austria 62,090.
Hoop and strip	90,270	104,811	70	West Germany 39,809; Poland 27,226.
Rails and accessories	7,482	59,123	136	West Germany 31,180; Austria 26,238.
Wire	30,145	36,288	5	West Germany 8,901; Austria 5,364.
Tubes, pipes, fittings	88,054	113,532	956	West Germany 19,626; France 18,813.
Castings and forgings, rough	2,198	3,438	1	Czechoslovakia 1,390; West Germany 874; France 480.
Lead:				
Ore and concentrate	5,623	1,978	--	All from Greece.
Oxide	3,084	3,365	5	Bulgaria 1,397; Austria 1,054; West Germany 401.
Metal including alloys:				
Scrap	NA	1,124	1,124	
Unwrought	8,192	9,539	--	Bulgaria 6,779; West Germany 1,364.
Semimanufactures	r110	97	(1)	Mainly to West Germany.
Magnesium metal including alloys, all forms	976	1,087	117	Norway 484; U.S.S.R. 433.

See footnotes at end of table.

Table 3.—Yugoslavia: Imports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1978	1979	Sources, 1979	
			United States	Other (principal)
METALS —Continued				
Manganese:				
Ore and concentrate	96,346	115,041	--	Gabon 46,275; Botswana 40,864; U.S.S.R. 26,998.
Oxide	794	909	--	France 471; Belgium-Luxembourg 156; Ireland 130.
Mercury 76-pound flasks	230	301	--	China, mainland 300.
Molybdenum metal including alloys, all forms	18	16	--	Austria 12; United Kingdom 3.
Nickel metal including alloys:				
Scrap	10	2	--	Mainly from Austria.
Matte, speiss, similar materials	108	241	--	Mainly from Netherlands.
Unwrought	r1,486	1,507	--	U.S.S.R. 1,422; Italy 33; Canada 20.
Semimanufactures	r1,006	657	4	West Germany 266; U.S.S.R. 111.
Platinum-group metals including alloys, all forms:				
Platinum troy ounces	71,375	92,080	NA	U.S.S.R. 63,530; West Germany 13,825.
Other do	9,484	1,447	--	West Germany 1,029; France 257; United Kingdom 161.
Silicon, elemental kilograms	1,766	2,464	118	Italy 1,350; West Germany 804; United Kingdom 100.
Silver metal including alloys, all forms thousand troy ounces	1,475	869	(1)	Austria 292; West Germany 257; Italy 118.
Tin:				
Oxide	13	8	--	All from West Germany.
Metal including alloys:				
Unwrought	1,833	1,304	--	China, mainland 1,156; Malaysia 110.
Semimanufactures	36	53	(1)	West Germany 47; United Kingdom 3.
Titanium:				
Ore and concentrate	45,980	23,742	--	Australia 23,727; West Germany 15.
Oxide	2,578	1,420	--	West Germany 1,019; France 247; Belgium-Luxembourg 111.
Tungsten metal including alloys, all forms	23	25	(1)	China, mainland 8; Austria 5; Netherlands 3.
Zinc:				
Ore and concentrate	33,465	55,760	--	Peru 26,057; North Korea 17,956; Mexico 4,966.
Oxide	227	269	--	West Germany 268.
Metal including alloys:				
Unwrought	4,794	4,779	(1)	Zambia 4,749.
Semimanufactures	74	162	--	Italy 109; Netherlands 25; France 16.
Other:				
Ores and concentrates of vanadium, tantalum, zirconium	2,117	1,596	--	West Germany 763; Australia 760.
Ash and residue containing nonferrous metals	1,614	1,071	--	Switzerland 941; Italy 51; France 48.
Oxides, hydroxides, peroxides of metals, n.e.s	1,222	1,135	4	West Germany 699; Austria 130; U.S.S.R. 88.
Metals including alloys, all forms:				
Alkali, alkaline-earth, rare-earth metals	230	202	3	France 119; Italy 30; Austria 25.
Pyrophoric alloys	33	4	--	China, mainland 2; West Germany 1.
Base metals including alloys, all forms, n.e.s	615	744	142	Japan 155; West Germany 143; United Kingdom 112.
NONMETALS				
Abrasives, natural, n.e.s.:				
Pumice, emery, natural corundum, etc	505	191	(1)	Denmark 92; Italy 58; West Germany 22.
Grinding and polishing wheels and stones	793	706	17	Austria 305; Italy 108; West Germany 83.
Asbestos	47,797	47,475	(1)	U.S.S.R. 25,599; Canada 10,504; Botswana 9,418.
Barite and witherite	1,206	1,204	--	West Germany 914; Czechoslovakia 240.
Boron materials:				
Crude natural borates	28,736	28,289	20,629	Turkey 7,350; Italy 250; Netherlands 60.
Oxides and acids	r373	723	--	U.S.S.R. 619; France 44; Austria 28.
Bromine	12	10	--	Israel 3; Japan 3; Netherlands 3.
Cement:				
Portland thousand tons	552	1,040	--	U.S.S.R. 370; Hungary 266; Romania 166.
Other	89,400	67,560	--	Bulgaria 63,288; West Germany 3,568.
Chalk	2,383	2,890	--	France 2,268; Austria 413; Switzerland 97.

See footnotes at end of table.

NONMETALS —Continued				
Clays and clay products including all refractory brick:				
Crude:				
Bentonite	16	19	--	Austria 17; United Kingdom 1.
Fire clay	35,610	38,771	827	Czechoslovakia 35,949; Austria 670; United Kingdom 641.
Fuller's earth, dinas, chamotte	5,442	2,294	56	Czechoslovakia 1,610; Poland 410; France 143.
Kaolin	73,464	75,804	2,896	Czechoslovakia 29,237; West Germany 12,685; U.S.S.R. 10,742.
Other	r8,661	16,946	21	Czechoslovakia 11,076; Poland 5,308.
Products:				
Refractory (including nonclay bricks)	40,928	37,119	8,346	West Germany 11,493; France 4,717.
Nonrefractory	27,487	23,233	(1)	Czechoslovakia 11,057; Italy 5,755.
Cryolite and chiolite	120	913	--	Denmark 890; Sweden 22.
Diamond:				
Gem, not set or strung carats	100,000	120,000	--	Bulgaria 50,000; Belgium-Luxembourg 40,000.
Industrial do	35,000	105,000	95,000	United Kingdom 10,000.
Powder kilograms	26	21	4	U.S.S.R. 9; Belgium-Luxembourg 6; United Kingdom 2.
Diatomite and other infusorial earth	152	285	48	U.S.S.R. 114; Austria 69; West Germany 32.
Feldspar	1,001	1,150	--	All from France.
Fertilizer materials:				
Crude:				
Nitrogenous	109	2	--	Do.
Phosphatic	902,610	896,443	--	Togo 440,198; Morocco 225,396; Jordan 85,622.
Other including mixed	--	23	--	All from Netherlands.
Manufactured:				
Nitrogenous	210,581	208,242	--	Hungary 66,465; U.S.S.R. 52,461; Czechoslovakia 38,101.
Phosphatic	47,089	48,804	--	Tunisia 35,738; Mexico 12,500.
Potassic	443,173	394,996	--	East Germany 239,419; U.S.S.R. 148,649.
Other including mixed	97,361	65,163	19,983	Romania 43,686; Poland 739.
Ammonia	65,908	95,946	1	Hungary 61,147; Romania 29,455; U.S.S.R. 4,654.
Fluorspar	r6,552	5,121	--	China, mainland 2,438; France 998; East Germany 900.
Graphite, natural	1,812	1,824	40	Czechoslovakia 678; Austria 526; East Germany 200.
Gypsum and plaster	9	8	--	West Germany 5; Italy 3.
Iodine	28	71	--	Japan 49; France 17.
Magnesite	r27,670	43,882	--	Greece 32,438; Turkey 6,000; Norway 3,460.
Mica:				
Crude including splittings and waste	716	1,177	(1)	India 733; Norway 241; West Germany 135.
Worked including agglomerated splittings	144	129	(1)	Czechoslovakia 45; Austria 34; Belgium-Luxembourg 25.
Pigments, mineral, iron oxides, processed	4,506	2,880	17	Hungary 909; West Germany 722; Spain 534.
Precious and semiprecious stones, except diamond:				
Natural kilograms	61	128	--	West Germany 83; China, mainland 38.
Manufactured do	483	701	--	Austria 302; Switzerland 234; France 124.
Pyrite, gross weight	19,126	124,227	--	U.S.S.R. 72,516; Cyprus 51,711.
Salt and brine	149,216	194,103	--	Romania 131,116; Tunisia 26,654; Spain 13,663.
Sodium and potassium compounds, n.e.s.:				
Caustic soda	206,639	264,904	--	France 77,450; Italy 60,362; West Germany 30,330.
Caustic potash and sodic and potassic peroxides	120	203	(1)	Czechoslovakia 191; West Germany 6; Italy 6.
Stone, sand and gravel:				
Dimension stone:				
Crude and partly worked:				
Calcareous	r325	2,871	--	Greece 2,820; Italy 51.
Slate	374	463	--	France 400; Austria 43; West Germany 20.
Other	r1,371	1,123	--	Italy 1,070; Sweden 46; West Germany 7.
Worked, not specified	197	327	--	Italy 322.

See footnotes at end of table.

COMMODITY REVIEW

METALS

Aluminum.—Expansion of the Titograd Aluminum Plant in Titograd, Montenegro, continued during 1980, and completion was foreseen in the first quarter of 1981. When completed, the plant should have an annual capacity of 100,000 tons of aluminum and 280,000 tons of alumina, approximately double its present capacity. Construction continued of the 92,000-ton-per-year aluminum plant at Bacevici near Mostar, BiH. Plans call for completion in early 1981.

Copper.—Development of the Veliki Krivelj copper deposit continued during the year. A recently published report indicated reserves at Veliki Krivelj to be about 702 million tons of ore, with an average copper content of 0.41%. The category of the reserves was not indicated. During 1980, most of the initial overburden was removed, and zones of mineralization were uncovered for a future planned production of 8 million tons of ore per year. Construction also started on a crushing and flotation plant to produce annually about 110,000 tons of copper concentrates, containing 25,000 tons of recoverable copper, which will be smelted at Bor, Serbia. Recovery of 60,000 tons of magnetite, with an average content of 62% iron; 250,000 tons of pyrite; and 200 tons of molybdenum was also planned, in addition to unspecified quantities of gold, silver, platinum, palladium, selenium, and rhenium. Regular ore production at Krivelj was scheduled for the latter part of 1981.

At Bor, a new shaft, 540 meters deep, was completed. The new haulage system at Bor was designed to move 4.5 million tons of materials per year.

At Bucim in Macedonia, the first year of regular production of copper ore and concentrates was below expectation because the grade of ore was far lower than expected. A decision was thus made to switch production to a new and richer ore body.

Chromite.—Hopes were expressed that reserves of chromite at Vitina Padina on Sara Mountain in Macedonia, reported at 3 million tons, would ultimately make unnecessary continued imports for the Jegunovci ferroalloy plant. However, no further details as to grade of ore or prospective startup date for mining were available.

Iron and Steel.—The iron and steel industry had an uneventful year. Development of a 2-million-ton-per-year iron ore mine at Omarska, BiH, continued. The mines at Vares and Ljubija operated by Rudarsko Metalurski-Kombinat-Zenica (RMK-Zenica) remained the largest producing iron ore mines in the country. Recovery of magnetite at the Majdanpek copper flotation plant was small, but new facilities for recovery of magnetite at the new copper flotation plant at Krivelj, when completed, should add another 60,000 tons per year of high-grade 62% iron magnetite concentrates and make byproduct magnetite a better domestic source of iron. Some of the domestic iron ores produced in Yugoslavia run as low as 27% iron.

Yugoslavia remained a net importer of iron ore in 1979, the latest year for which complete trade data were available, but the domestic production supplied almost 81% of the country's demand.

Ferroalloys.—The ferroalloy industry of Yugoslavia exported about two-thirds of its output during 1980. The following producers were in operation at the beginning of 1980: Elektrobosna at Jajce, BiH; Tvornica Elektroda i Ferolegura, Sibenik, Croatia; Tvornica Dalmacija, Dugi Rat, near Split, Croatia; Tovarna Dusika Ruse, near Maribor, Slovenia; and Kombinat Jegunovci.

At Tovarna Dusika Ruse, a new 20-megawatt ferrosilicon furnace started production in the fall, making a total of six furnaces in operation at Tovarna Dusika Ruse.

At Kosovska Kamenica, Kosovo, Serbia, a decision was made to build a plant for a yearly production of 33,000 tons of ferrosilicon and 25,000 tons of silicon metal. The new plant will be supplied with high-grade quartzite from a new mine located in the vicinity of Kosovska Kamenica.

Steel.—Modernization of the steel plant, Zeljezara Boris Kidric in Niksic, Montenegro, continued. It is the fifth year since the beginning of reconstruction. When completed, the plant should have a capacity of 315,000 tons of steel per year.

Two of the four blast furnaces in RMK-Zenica were shut down for repairs during 1980. One blast furnace came back on-stream at yearend.

The management of the steel plant at Sisak, Croatia, the largest producer of seamless pipes in the country, was planning to build new facilities to produce 200,000 tons of seamless pipes.

At the country's largest producer of welded pipes,II Oktomvri in Kumanovo, a plant was under construction for annual production of 170,000 tons of pipes, profiles, and shapes. When expansion is completed, total capacity of II Oktomvri should be 300,000 tons of fabricated steel products.

Plans were announced for expansion of the capacity of the steel plant at Skopje, Macedonia, to 950,000 tons of steel, up from the present 500,000-ton level.

Lead and Zinc.—During 1980, the lead and zinc sector of the minerals industry faced problems of lagging mine output resulting from mining low-grade ores, with low recovery of metals. Yugoslavia imported about 50,000 tons of zinc concentrates and smaller quantities of lead concentrates

during 1979, the latest year for which trade figures were available, indicating that the country may be becoming less than self-sufficient. During 1980, however, efforts were made to increase domestic mine production. The Trepca Mine in Kosovo, Serbia, and the mines in Blagodat, Kisnica, and Novo Brdo, Rudnik, Srebrenica, were also planning higher output, but faced difficulties in securing adequate financing. Development of the recently discovered Veovaca Mine near Vares in BiH continued. Tailings of some mines were also assayed, and their metal content indicated some possibility of economic recovery of lead and zinc. In the past, significant quantities of metals were lost because of low recovery during beneficiation.

The Belgian company, Mechim, and RMHK Trepca signed a contract for modernization and expansion of Trepca's electrolytic zinc plant at Kosovska Mitrovica, Kosovo, Serbia. The contract, worth more than 1.5 billion Belgian francs (about US$500 million), provides for use of "Super Jumbo" electrolysis bays developed by Vieille-Montagne. Mechim was to provide design of the process and supply of equipment, as well as technical assistance. Norzinc, a Norwegian company, was to provide technology for the processing of residues. The Société Générale de Banque provided financing. The so-called Super Jumbo technology uses cathodes of 2.6-square meters immersed surface area, with a high-power density, thus saving about 55% of the area used, and reducing the weight of cathodes by 8%.

Magnesium.—Production began at the first Yugoslavian magnesium plant, Bela Stena, near Baljevac na Ibru, Serbia. Annual capacity was reported at 5,000 tons of 99.8% magnesium.

The plant uses the Magnetherm process of the Société Francaise d' Electrometallurgie, which also gave technical assistance in bringing the plant into production.

Nickel.—Construction of Feni's nickel mine and a 16,000-ton-per-year contained nickel ferronickel plant at Rzanovo near Kavadarci, Macedonia, continued. At Glogovac in Kosovo and Methohija, Serbia, respectively, another nickel mine and a 12,000-ton-per-year contained nickel plant were under construction. The Rzanovo facility was slated for production in 1980, but financial problems caused a delay until 1981. The Glogovac facility was planned to come onstream in 1983 or 1984.

Other Metals.—As shown in table 1, Yugoslavia produced a number of byproducts of copper and lead-zinc production. Bismuth was a byproduct of lead and zinc output at Trepca, Serbia, and at Titov Veles, Macedonia; cadmium was produced at Trepca's plant at Kosovska Mitrovica and at Zorka's plant at Sabac. The Bor complex recovered gold, germanium, platinum, palladium, selenium, and silver as byproducts of its copper production. Trepca's smelter at Zvecan was the main source of silver, a byproduct of lead processing.

NONMETALS

Ammonia.—Two new ammonia plants were under construction in Yugoslavia during 1980. One plant at Pancevo was planned for an annual output of 280,000 tons by 1982. A 369,000-ton-per-year plant, to be completed by 1981, was also under construction at Kutina, Croatia, as part of the Industrija Nafte's (INA) petrochemical project. Both plants will use natural gas feedstock.

Asbestos.—Humboldt Wedag AG of the Federal Republic of Germany was awarded a contract for supplying equipment for an asbestos ore preparation plant at Stragari, Serbia. No further details were made public. A mine owned by Bosna Asbest, located near Bosanski Petrovac in BiH, was the largest producer of asbestos in the country. Yugoslavia remained a net importer of asbestos, and more than four-fifths of its demand was met through imports.

Barite.—On Bobija Mountain, near the town of Ljubovija in Serbia, several years of exploration confirmed existence of important deposits of barite. If investment capital can be found, a 150,000-ton-per-year mine was planned. Completion of the mine and plant would require 3 years from the date of the beginning of construction.

Cement.—At the cement plant located in Kosjeric, Serbia, experiments were conducted to use fly ash from the Kolubara powerplants in the production of cement. About 100 tons of cement was produced during 1980, and regular production was planned for the spring of 1981.

At Bela Palanka, Serbia, an 800,000-ton-per-year cement plant, to be in operation by 1983, was planned. At yearend, about 75% of the capital for construction was assured. In Podrutama, near Zagreb, Croatia, a 2-million-ton-per-year cement plant was planned in two stages of construction, each with 1 million tons of capacity. Startup was also scheduled for 1983.

Quartz.—The Opalit enterprise started

development of a quartz mine and beneficiation plant at Lokavica, near Casinovo in the general area of Stip, Macedonia, to be completed in 1981. Mine production was planned at 250,000 tons per year of quartz sand, which would yield about 45,000 tons of high-quality beneficated quartz.

Salt.—At Majevica Mountain, in BiH, a new salt deposit was discovered at a depth of around 800 meters; thickness varies from 22 to 190 meters. Four drill holes, all positive, were located near the village Teti on the southern slopes of Majevica Mountain. If additional drilling indicates a mineable deposit, development may start in 1985.

MINERALS FUELS

High prices for imported crude oil and natural gas continued to heavily tax Yugoslavia's balance of payments during 1980. Exploration was thus intensified for domestic coal, petroleum, natural gas, and uranium; plans were prepared to build new hydropower installations; and as many as 16 thermoelectric facilities were considered for completion by 1985. Development of oil shale deposits and expanded lignite beneficiation facilities were studied. Yugoslavia, meanwhile, remained dependent on imported high-rank coals, crude oil, and natural gas to meet its energy demand. Low-rank coals, mostly lignites, were the principal energy source produced in the country during 1980.

Coal.—It was planned to increase coal production to 82 million tons in 1985, about 37 million tons more than in 1980. Exploration and investment were stepped up, but labor shortages and financing difficulties prevented reaching planned objectives.

In Slovenia, the most productive mine in the Zasava Coal Basin (Zasavski Revir), near Hrastnik, Ojstre, was out of production for 3 months because of a cave-in and flooding. The mine was expected to reach its preflood production of 900 tons of coal per day some time in 1981 when new mining equipment purchased in France would be operational. In BiH, the State with the largest production of brown coal in Yugoslavia, new brown coal reserves were discovered at Moscanica, near Zenica. Apparently, the new coal deposit is an extension of the nearby Kakanj Coal Basin. Proven coal reserves in the new field amounted to 60 million tons, with a calorific value of 6,000 kilocalories per kilogram. In 1984, preparation for starting up a 500,000-ton-per-year mine at Moscanica will begin, if capital is available. In the Mostar Coal Basin, BiH, near Mostar, Lisana-Bijelo Polje, a 120-million-ton brown coal deposit was delineated, and work started on opening of a new mine, which will appreciably extend the life of the Mostar Mine.

About 70 million tons of brown coal are found in the area between the localities of Maglaj and Zepce in BiH. A mine was to be established there, to supply the Natronka paper bag factory at Maglaj now using residual oil. Work continued on exploration and preparation for production at the Juzna Sinklinala deposit, located near Tuzla, BiH. The new 3-million-ton-per-year opencast mine was planned to start production in 1986.

In Serbia, the largest coal producing State in Yugoslavia, the most important development was the confirmation of reserves of about 90 million tons of lignite near Kovin, in Banat, Serbia. Reports also indicated possible reserves in the region of up to 200 million tons of lignite. Important deposits of solid fuels had not been known in Banat, but a mine and thermal powerplant near Kovin were being considered. In addition, a lignite deposit was discovered on Fruska Gora Mountain, between Beocin and Suseka near Novi Sad, Serbia. Proven reserves were reported at 100 million tons of lignite, with calorific values between 1,600 and 2,000 kilocalories per kilogram.

In the Kolubara Basin, after earlier start-up of the mines at Tamnava, a new opencast mine, Tamnava West, went onstream in August 1980. Plans called for an output of 18 to 20 million tons of lignite from the two Tamnava mines by 1985. Most of the production was to be used by powerplants situated, or to be built, near Obrenovac, Serbia.

At the Kostolac lignite basin, near Kostolac in Serbia, the 2.5-million-ton-per-year Cirkovac opencast mine started trial production at yearend. During the year, work on the Drmno coal deposit nearby continued, and a new opencast mine with an annual capacity of 6 million tons should be in production there by 1986, with an additional 3 million tons planned for 1990. Plans also called for the opening of a new mine at Poljani near Pozarevac and the reopening of an old mine at Melnica near Petrovac.

In Macedonia, which recently became a coal producer, exploration in the Pelagonian coal basin lead to the discovery of three lignite deposits. The largest, with proven reserves of 200 million tons, is near Suvodol,

about 20 kilometers northeast of Bitola. A mine at Suvodol and two thermal powerplants nearby were under construction in 1980.

Natural Gas and Petroleum.—In 1980, imports equal to about 70% of crude oil demand and to about 20% of natural gas demand were necessary. In an effort to assure a supply of crude oil from abroad, Yugoslavia's petroleum-producing enterprises explored for oil in Africa, Italy, and Bangladesh, and a contract for exploration in Indonesia was concluded during 1980.

The Pannonian Basin, located in the northern part of the country, remained the principal area of activity in exploration and production of liquid and gaseous hydrocarbons. In Croatia, new discoveries of gas were announced at Stari Gradec, near Pitomaca. In addition, the oilfield at Stekovica, Croatia, was expanded. The large gasfield at Molve near Durdevac, Croatia, started production officially at yearend. Initial production was planned to reach 300,000 million cubic meters of natural gas per year. It took Naftaplin-INA, the operating company, 7 years and 2.3 billion dinars to develop and equip this field. A smaller gasfield also went onstream at Obradovci, Croatia, with a possible output of about 9 million cubic meters of natural gas per year.

Exploration offshore in the Adriatic Sea continued. Reports indicated an offshore gas discovery in a well in the northern Adriatic, in the general area of Pula, Croatia, drilled by Naftaplin's offshore rig Panon. No other details were made public. In the southern Adriatic between Boka Kotorska and Ulcinj, Montenegro, seismic work was in progress all summer. Although two offshore wells were dry, the partners of the venture, Butes Gas, Chevron, and Yugopetrol, hoped that results of seismics would justify drilling a third well in the southern Adriatic. According to unconfirmed reports, Naftaplin will request bids for joint ventures with foreign oil companies in offshore Adriatic waters sometime early in 1981.

In Serbia, a new oilfield near Banatsko Karadjordjevo started production during the summer; production plans called for a yearly output of 60,000 tons of crude oil.

Construction continued on a 2.5-million-ton-per-year petroleum refinery near Skopje in Macedonia. Reportedly, first production was to start in 1981. In Modric, a new refinery for production of 60,000 tons per year of lubricating oil, and 20,000 tons of paraffin was brought onstream during the summer by Energoinvest of Sarajevo.

The pipeline in eastern Yugoslavia, connecting Horgos at the Hungarian border with Novi Sad, Beocin, Pancevo, and Zvornik, went onstream during the year, supplying domestic and Hungarian natural gas.

The pipeline connecting the oil terminal at Omisalj on the Adriatic Sea with domestic inland refineries and with Hungary was filled with crude oil, and the oil reached the more distant refineries in Lendava and Pancevo during 1980. About 300,000 tons of the crude oil were pumped to Hungary.

Uranium.—Construction of the first Yugoslav nuclear powerplant at Krsko Slovenia (615 megawatts electrical) continued during 1980. In the fall, the Krsko plant passed successfully a "hot functional test." Plans called for core loading in March 1981 and 100% power to be reached in September 1981.

The development of a uranium mine and construction of a yellow cake plant continued at Zirovski Vrh, Slovenia. Production should start in 1981. Development of the mine commenced in the early 1960's, but was hampered by environmental concerns. Flour Mining and Metal Inc. (Flour) performed the technical design of the project. During the latter part of 1980, Flour was purchasing process and instrumentation equipment. When completed by early 1981, the mill will process 210,000 tons of uranium ore and produce 600,000 pounds (272 tons) of uranium oxide per year. The plant was located in an area with a high population density, with permeable geology and heavy rain and snowfall. Reportedly, water runoff and subterranean water from the plant and tailings could contaminate the water supply for the surrounding area and for the nearby large city of Ljubljana. The treatment plant is designed to contain all liquors within the facility, hoping to eliminate liquid effluent which could contaminate the environment. The Jozef Stefan Institute (IJS) of Ljubljana developed the completely closed-circuit operation.

The basic process used in the mill at Zirovski Vrh is leaching with sulfuric acid. A novelty included is a patented process developed by the IJS ensuring almost total elimination of magnesium without use of the expensive high alkalinities normally used for cation removal.[3]

In Serbia, near Kalna, indications of new uranium mineralization were discovered near localities at Radicevac, Papratni,

and near Adinska Reka in eastern Serbia. A uranium mine and plant were formerly operated at Kalna by political prisoners, but both are now closed.

The Mineral Industry of Zaire

By Miller W. Ellis[1]

In 1980, Zaire's mineral industry provided 85% of the country's foreign exchange and maintained its position as the world's leading producer of industrial diamonds and cobalt, and the world's sixth largest producer of copper. Despite high transport costs, shortages of skilled labor and fuel, and a diminishing price for copper, production of most of Zaire's mineral commodities increased as the industry resumed normal operations after the armed invasion of the Shaba Region in 1978, and after the higher metal prices of 1979.

The Government of Zaire (GOZ) declared a 30% devaluation of the national currency, the Zaire (Z), on February 22, 1980, following the 25% devaluation of August 1979. The measure was designed to comply with conditions set down by the International Monetary Fund (IMF) to which the central government had appealed for economic assistance. The result was a reduction of the worth of the Z to about 34 cents, U.S. currency, or Z2.94=US$1.00, by yearend. A rescheduling agreement with Zaire's international bank creditors was signed in April 1980, and the International Bank for Research and Development (IBRD) consultative group met in late May. Zaire's debt-servicing payments for 1980 were estimated at $470 million, compared with only $120 million in 1979. By the end of September, the GOZ had met the IMF standby conditions and had maintained the rigorous budget deficit and credit ceilings as agreed. It had also adhered to the 1980 repayment terms and the rescheduled public and private debt reimbursement of $300 million (three times the total of debt repayment for 1979). There was also a signal improvement in the GOZ attitude towards general development programs, particularly those with respect to health and agriculture.

In mid-January 1980, President Mobutu Sese Seko requested resignations from 13 of his 22 cabinet ministers and reassigned some of the others. Prime Minister Nguza Karl-I-Bond retained his post, but a former opposition leader, Kamitatu Massambwa, became Minister of Environment and Tourism. General Babia Nzongbi Malobia, formerly chief of the armed forces, became Minister of Social Affairs. Magazba Mbuka was appointed Commissioner for Mines, but was replaced by Lwamba Katansi on August 27, 1980.

More than one-half (53%) of the 1979 export traffic was carried on the river barge and rail Voie National and shipped from Matadi. Of the 39% of traffic shipped through South African ports, 8% took the barge route across Lake Tanganyika, and the Tanzanian railway to Dar es Salaam. During early 1980, virtually all cobalt was shipped by air, 51% of the copper was railed to South African ports, 46% was shipped to Matadi by the Voie National, and 3% was shipped through Tanzania to Dar es Salaam. Less than 10% of the tin shipments also went through Tanzania to Dar es Salaam, and more than 90% went by the Voie National to Matadi.

Studies of the Banana-Boma-Matadi section of the Zaire River Bay continued as did examination of proposals for improvement of river barge and rail transport within the country. Electrification of the Matadi-Kinshasa railroad was scheduled for 1981. Operation of the 615-millimeter-gauge Mayumbe railroad from Boma, 140 kilometers north to Tshela near the bauxite deposits, was halted. Alternative routes for a rail link between Matadi or Kinshasa and the copperbelt terminal at Ilebo were restudied, and a schedule for the repair of internal road transport routes was initiated.

The target date for completion of the Inga-Shaba DC power transmission lines and the two massive inverter stations was reestimated as mid-1982 by the U.S. Constructeurs Inga Shaba (CIS) officials at their Kolwezi terminal base. Potential demand was lower than had been anticipated in 1976, mostly because of uncertainty over reduced requirements from the installed 560-megawatt capacity.

PRODUCTION AND TRADE

All of Zaire's cadmium, cobalt, zinc, most of its copper, and a substantial share of its gold and silver were produced by the giant Government-owned firm La Générale des Carrieres et des Mines du Zaire (Gécamines) from their three operating centers at Kolwezi, Likasi, and Lubumbashi in the Shaba Region of southeastern Zaire. The remainder of Zaire's copper was produced by the Société de Développement Industriel et Minière du Zaire (Sodimiza), owned 80% by a Japanese consortium and 20% by the GOZ. Sodimiza operated two mines and the Musoshi concentrator near the Zambian border southeast of Lubumbashi. Its copper concentrates were railed to a South African port for shipment to Japan for smelting.

A preliminary estimate of Zaire's balance-of-payment status for 1980 indicated that the dollar value of imports had increased to $2,509.5 million, and exports totaled $2,209.5 million. The principal exports were copper at $898.1 million, cobalt at $529.0 million, diamonds at $256.3 million, petroleum at $60 million, silver at $55.5 million, tin at $42.8 million, gold at $32.6 million, and zinc at $13.0 million, with mineral exports totaling $1,897.3 million. The principal agricultural export was coffee valued at $208.8 million.

The Sino-Zairian cooperation agreement was reaffirmed in February when the Zairian marketing agency, Société Zaircise de Commercialisation des Minerais (Sozacom), arranged for a delegation from the China National Metals & Minerals Import & Export Corp. to purchase 20,000 tons of copper and 250 tons of cobalt from Gécamines in 1980. A joint statement by the Zairian and Zambian authorities in February 1980 assured their customers of a regular and stable supply of cobalt for the remainder of the year at a price of $25 per pound. On July 7, 1980, Sozacom announced the abandonment of the 70% sales allocation of cobalt in force since May 1, 1978.

In mid-September, Sozacom's director led a delegation to the United States to discuss arrangements for long-term direct sales of cobalt with end users, and bulk sales with the General Services Administration cobalt stockpile authorities. There was little demand for cobalt at the producer price of $25 per pound, and the spot price for cobalt subsequently dropped to $23 and finally to $18 per pound. The U.S. Department of Commerce arranged for a mining trade mission which visited Lubumbashi in the latter part of October 1980.

The 1979 surge in cobalt and copper prices raised Gécamines' revenues to $1.5 billion for the year, of which 45%, or $677 million, would have been available to Gécamines as foreign exchange. Actually, about $135 million reportedly remained in the hands of Kinshasa officials, and $542 million was available to Gécamines. In March 1980, the GOZ announced that it would retain Gécamines' foreign funds and disburse specific amounts to meet specific needs when requested.

Details of Zaire's mineral products are shown in table 1. Apparent exports and apparent imports of mineral commodities are listed in table 2 and table 3, respectively.

(Metric tons unless otherwise specified)

Commodity	1978	1979	Principal destinations, 1979
METALS			
Aluminum metal including alloys, scrap	--	35	Belgium-Luxembourg 34.
Cadmium metal including alloys, all forms	185	101	Belgium-Luxembourg 76; United States 25.
Cobalt:			
Oxide and hydroxide	--	10	All to United States.
Metal including alloys, all forms	4,407	4,771	United States 3,984; West Germany 464; Sweden 194.
Copper:			
Ore and concentrate	102,144	94,864	Japan 94,863.
Metal including alloys:			
Unwrought:[3]			
Blister	301,290	266,164	Belgium-Luxembourg 249,733; France 16,431.
Refined	103,645	70,041	Brazil 17,465; Italy 12,600; Japan 12,471; France 8,451.
Semimanufactures	16	2,471	All to United States.
Iron ore and concentrate	--	1,114	All to Belgium-Luxembourg.
Lead metal including alloys:			
Scrap	--	45	All to Italy.
Unwrought	NA	27	All to Nigeria.
Manganese ore and concentrate	59,614	39,107	Belgium-Luxembourg 36,714; United Kingdom 2,177.
Silver metal including alloys, unwrought or wrought, value, thousands	$37	$54	All to Belgium-Luxembourg.
Tin:			
Ore and concentrate	3,477	1,923	Do.
Metal including alloys, unwrought	1,139	544	Belgium-Luxembourg 379; France 165.
Tungsten ore and concentrate	249	161	United States 72; France 37; West Germany 21; Japan 20.
Zinc metal including alloys, unwrought	[3]40,900	[3]30,800	United States 14,880; Brazil 3,727; Greece 2,615.
Other:			
Ore and concentrate	134	39	Japan 30; United States 6.
Ash and residues, nonferrous	225	467	West Germany 308; Belgium-Luxembourg 159.
Base metals including alloys, all forms, n.e.s	2,053	51	Switzerland 28; Yugoslavia 15.
NONMETALS			
Abrasives: Dust and powder of natural and synthetic precious and semiprecious stones, value, thousands	$2,346	$1,820	Japan $1,151; United States $595.
Cement	9,916	8,172	All to Central Africa.
Diamond:			
Gem, not set or strung, value, thousands	$2,226	$3,109	Belgium-Luxembourg $2,083; Australia $1,011.
Industrial, do	$8,230	$12,729	United States $7,547; West Germany $2,971.
Precious and semiprecious stones except diamond:			
Natural, do	$3,195	$845	Switzerland $288; United States $130; Thailand $82; United Kingdom $79; Hong Kong $75.
Synthetic, do	$2	$5	Thailand $4.
MINERAL FUELS AND RELATED MATERIALS			
Coal, anthracite and bituminous	--	18,287	All to Belgium-Luxembourg.
Petroleum:			
Crude or partly refined, thousand 42-gallon barrels	248	1,514	All to United States.
Refinery products:			
Residual fuel oil, do	--	431	Sweden 292; France 139.
Other: Liquified petroleum gas, 42-gallon barrels	NA	23	All to Central Africa.

NA Not available.

[1]Owing to the lack of available official trade data published by Zaire, this table should not be taken as a complete presentation of Zaire's mineral exports. These data have been compiled from various sources which include United Nations information and data published by the trading partners.

[2]Unless otherwise specified, data are compiled from trade statistics of individual trading partners.

[2] These data are compiled from trade statistics of individual trading partners.

[3] Less than 1/2 unit.

[4] Value only reported at $23,549,000; the 1978 quantity was valued at $21,830,449.

COMMODITY REVIEW

METALS

Copper, Cobalt, Zinc, and Associated Metals (Shaba Region).— Gécamines increased its production of cobalt, copper, zinc, and byproduct silver during 1980, and reported a generally good year, although metal prices declined on the international market, diminishing Gécamines' and Zaire's foreign exchange earnings. Commissioning of the Dikuluwe and Mashamba open pits was completed, including the installation of primary crushers at both pits and conveyors to the new Dima concentrator at Kamoto. The Dima oxide mill was started up on March 1, 1980, at 50% capacity and was later completed to full capacity, as was the Dima sulfide mill. The flash-smelter, and other units of the Luilu refinery, near Kolwezi, were still incomplete, but were scheduled to be onstream by mid-1982 when the Inga-Shaba powerline was due to

be energized. During the first 9 months after the May 1978 invasion of Kolwezi, Gécamines was able to recruit only 100 expatriate employees, most of them unwilling to bring their families to Zaire. Since then, another 100 recruits have arrived, some accompanied by wives and children. By the end of 1980, at least 200 posts remained unfilled, and supervision of on-the-job training of Zairian staff was far behind schedule.

Sodimiza improved its mine and mill production by approximately 14% over the 1979 throughput, and improved its recovery of copper slightly. Its staff was reduced from 3,071 to 3,019 African and from 94 to 86 Japanese employees during 1980, but was increased by yearend because of expansion of the Kinsenda Mine. Increased production of the higher-grade Kinsenda ore was expected to improve the copper content of Sodimiza's concentrate. During 1980, the Kinsenda and Musoshi Mines produced a total of 1,305,256 tons of ore from which the Musoshi mill produced 93,286 tons of concentrate, with an average copper content of 36.78%. The concentrate was railed through Zambia, Zimbabwe (formerly Rhodesia), Botswana, and the Republic of South Africa to the port of East London for shipment to Japan.

Following reorganization of the Société Minière de Tenke-Fungurume (SMTF) in mid-1979, the new French managers, Bureau de Recherches Géologiques et Minières (BRGM), conducted viability-feasibility studies to determine if the company might recoup part of its investment by mining some of the more accessible ore, and upgrading it to a marketable product through Gécamines' facilities. BRGM was also planning to exploit high-grade copper mineralization at Dikulushi near Kapulo, northeast of Lake Mweru.

Gold.—The State agency, Office des Mines d'Or de Kilo-Moto, continued as Zaire's chief producer of gold. Other producers included Société Minière et Industrielle de Kivu (SOMINKI) and Gécamines. Kilo-Moto operated a number of mines near the Ugandan and Sudanese borders in the Haute-Zaire Region of northeastern Zaire. Reserves were approximately 90 metric tons, or 2.9 million troy ounces of gold. Kilo-Moto planned to increase its output from about 50,000 to 160,000 troy ounces per year by 1985. A new processing facility was planned to replace the decrepit Kanga plant, and a new deposit with reserves of 1.3 million troy ounces was to be developed for the Kilo Division. For the Moto Division, laboratory staff were testing ores from a new sulfide ore body. Kilo-Moto was seeking help from the Homestake Mining Co. in adapting the Durba facility for Homestake's activated carbon technology. The Zairian Ministry of Mines was also seeking outside investors to rejuvenate Kilo-Moto.

Manganese.—The Zairian-owned company, Société Minière de Kisenge (SMK), has successfully shipped 11,000 tons of manganese ore on the Benguela Railroad to Lobito Bay since April 1979. It has also managed to achieve a stockpile of 500,000 tons of crushed carbonate ore, and 700,000 tons of uncrushed ore at Kisenge. Reportedly, South African Manganese Amcor Ltd. has indicated an interest in buying 100,000 tons of ore per year, and in mid-1980 was shipped 246 tons of ore for analysis and bulk testing. SMK also planned a dry cell battery factory, including a refinery to convert the mangnese carbonate into electrolyte manganese oxide for battery manufacture.

Tin, Tungsten, and Columbium-Tantalum.—The Société Zairetain continued its tin-tantalum operations at Manono in northeastern Shaba Region, 400 kilometers north of Lubumbashi. The 50% State-owned company, managed and 50% owned by the private Belgian company, Geomines Cie., washed tin oxide (cassiterite) ore from five open pit mines through its concentrator and separated out byproduct columbite-tantalite. The cassiterite concentrate was smelted in Zaire's only tin foundry to produce refined tin metal and a marketable tantaliferous slag or scoria. Most of the near-surface weathered ores have been exhausted, and the remaining unweathered rock was too hard for efficient handling by Zairetain's old earthmoving equipment. The company was seeking additional capital for equipment more suited to the harder ore, and capable of extracting the lithium mineral, spodumene, as well as cassiterite. A 5,000-ton-per-year lithium carbonate plant was proposed.

The BRGM subsidiary, Compagnie Française de Mines, was studying the feasibility of extracting about 500 tons per year of cassiterite from the Kania and Kabondo prospects in the northern Shaba Region. Another subsidiary, Société Minière de Goma, anticipated producing 100 tons of cassiterite per year from the Kalimbi eluvial deposit in the Kivu Region.

Tin ore (cassiterite) was also mined by SOMINKI; other products included tungsten, columbium-tantalum, gold, and monazite. Owned 28% by the GOZ and 72% by Cogemin of the Belgo-French Empain Group, the company was an amalgamation of the many smaller operations in the Kivu Region, with the largest mine and headquarters at Kalima. Other mines were clustered nearby, and still others were grouped near Buni in the north and Kamituga to the east. Transport difficulties aggravated by shortages of diesel fuel and spare parts caused a gradual decline in production.

An affiliated company, SOMIKUBI, was 90% owned by the New York-based Metallurgy Mining Group and 10% by the Group Empain. On their behalf, SOMINKI was investigating the Lueshe carbonatite and its potential as a source of the columbium mineral, pyrochlore. They have completed 3,000 meters of underground development workings in the deposit and have planned construction of a 1.5- to 2-ton-per-hour pilot mill at a cost of $2 million for metallurgical testing as part of a feasibility study. If the results are favorable, full-scale production might start in 1984.

NONMETALS

Cement.— Cimenteries du Shaba was 40% owned by Gécamines and 60% by the Belgian firm, Société d'Etudes et de Gestion de Cimenteries (EGECIM). Renovation by the Belgo-German firm, Ateliers Louis Carton Tournai, was expected to increase production capacity by 40% by the end of 1980 at its Lubumbashi plant. Gécamines' other subsidiary, Calcaire, Chaux, Ciments of Kakontwe, northwest of Lubumbashi, recovered from the effects of breakdowns in 1979 and, with a third rotary oven commencing in January 1980, supplied all the lime required by Gécamines' copper and cobalt refining plants, plus a surplus which was sold on the open market.

Zaire's largest cement plant, owned 51% by EGECIM, and 15% by the GOZ, was the Société des Ciments du Zaire plant at Lukala, near Kinshasa. Shortages of fuel oil and of paper sacks caused declining production in 1980. The second largest manufacturer was the Cimenterie Nationale (CINAT) of Kimpese, also near Kinshasa. The GOZ owned 25% of CINAT, and the 75% equity was owned by West German (Klockner), Belgian, and French interests.

Diamond.—Société Minière de Bakwanga (MIBA), under the management and 20% ownership of the Société Géneral de Belgique and the Oppenheimer group, was still searching for new alluvial deposits of diamonds, but gradually shifting to processing kimberlite ores, of which they have substantial reserves. The company planned to modify and expand its concentrator to handle the harder material and was negotiating with IBRD to finance the renovation which was to be completed by 1983 or 1984. MIBA officials again calculated that about 5 million carats of industrial diamonds were smuggled out of its concession area in 1980, and most were marketed at Bujumbura in Burundi, and at Brazzaville in the Republic of the Congo. Alluvial diggings near Tshikapa and towards the Angolan border continued to be the source for additional diamonds sold by small "diggers" to buying offices maintained by BRITMOND and MELTAX in Tshikapa, Ilebo, and elsewhere in the area. Until early in 1980, the GOZ allowed the diamonds to be bought at a special exchange rate that removed the incentives for smuggling, but this was phased out and the buyers now have to pay for the diamonds in hard currency (dollars). Production from the Bakwenga deposits consists of 70% ordinary industrial stones, 27% high-grade industrial stones, and 3% gems. The Tshikapa deposits include as much as 50% gem-quality stones.

MINERAL FUELS

Petroleum.—Production from Gulf Oil's offshore wells during the early part of 1980 was slightly above 19,000 barrels per day, but on May 27, the Cometra Oil Company's two wells at Mibale-Est and Kinkasi commenced production and were expected to contribute at least 2,000 barrels per day during the latter part of the year.

On June 1, 1980, the Zairian papers reported that Esso-Zaire, an affiliate of American Exxon Oil Co., had signed an agreement with the Executive Council for oil exploration and drilling in Zaire's Central Basin. The joint undertaking with Texaco will include construction of roads and an airstrip in the equatorial jungle and approximately 18 months of preliminary drilling.

The Mineral Industry of Zambia

By Miller W. Ellis[1]

The mineral industry of the Republic of Zambia provided more than 90% of the country's foreign exchange credit and supported its position as the world's fifth largest producer of copper and the second largest in mine output of cobalt during 1980. Despite the reopening of the southern railroad routes following the elections in newly independent Zimbabwe in February-March 1980, transport charges continued to be an expensive part of the cost of delivering copper and cobalt metal to the world markets. After being closed for nearly 7 years, the Victoria Falls rail and road bridge over the Zambezi River was reopened to all traffic on February 2, 1980, and the road bridge at Chirundu, downstream from Kariba, was opened for maize-hauling trucks and road traffic on February 11. Road traffic to Botswana was also resumed early in February when the pontoon ferry at Kazungula was repaired and restored to service.

The railroad bridge over the Chambeshi River in northeastern Zambia—destroyed by a military raid in late 1979—was repaired at an estimated cost of $6.5 million by Chinese engineers and hundreds of Tanzania-Zambia Railway (Tazara) workers between August 1980 and the rainy season flooding at yearend. Tazara engineers, who had initially deviated the railway line to cross the nearby road bridge, restored a large measure of rail traffic to the Tanzanian port of Dar es Salaam before the end of February 1980.

The 16th session of the conference of Ministers of Conseil Intergouvernemental des Pays Exportateurs de Cuivre (CIPEC) was held in Lusaka, Zambia, on July 21 to 23, 1980. Full member countries were Chile, Indonesia, Peru, Zaire, and Zambia, but the associate member countries of Australia, Papua New Guinea, and Yugoslavia were also represented. Delegates-observers from Canada, China, Finland, Japan, Mexico, Romania, Sweden, Uganda, the United Kingdom, the United States, and Zimbabwe also attended. The conference noted that marketing of cathode copper was replacing the wirebar demand and that payment of premiums for higher quality products was now a feature of the world market. It passed various resolutions in favor of the marketing and price stabilization policies of the organization, and others for improving technological training at all levels of the industry. It expressed disapproval of the new U.S. law authorizing exploration of seabed minerals beyond the limits of national jurisdiction and agreed to present declarations of its stand on this subject to the Secretary General of the United Nations and to the Chairman of the Third United Nations Conference on the Law of the Sea.

Also in July, the Government of the Republic of Zambia agreed to contract for the sale of copper metal to the German Democratic Republic against the utilization of a commercial credit of about $51 million signed last year between the two countries for rural development and agricultural production. On August 23, 1980, officials from Romania and Zambia signed a joint investment agreement to reopen the Mokambo copper mine, closed by flooding in 1976. Zambia was to supply $2.4 million of the $3.8 million required to capitalize the project, and Romania agreed to provide the remaining $1.4 million and supply technical staff to reopen and operate the mine. A final agreement, signed on November 11, 1980, included a pact for the exploration and exploitation of coal, nickel, phos-

phate, and uranium deposits in Zambia and provided for agricultural assistance. Romanian experts were to expedite the raising of cotton, maize, and sunflower oilseed on 20,000 hectares of land and would barter tractors, fertilizers, and other commodities, thus widening the scope of technical cooperation in trade and economy between the two countries. No mining operations had been started at Mokambo by yearend 1980 because of the uncertain availability of finances.

In May 1980, Zambia drew its final allotment from the $400 million International Monetary Fund (IMF) loan negotiated in 1978. This resulted in a shortening of the country's pipeline of payments arrears to about 13 months. Total arrears were reduced to $355 million by mid-May, at least $86 million below the level for yearend 1979. In December 1980, the World Bank approved a loan of $15 million to the Development Bank of Zambia that was scheduled to result in the creation of some 1,800 new jobs and total investments of more than $48 million. The loan was for 20 years including a grace period of 5 years, with interest at 9.25% per year. The last World Bank loan to this institution was for $15 million in 1976. Officials of the IMF continued to study Zambia's complex financial situation and restricted the issue of letters of credit during the latter months of the year. They were expected to provide the country with a large credit facility and an arrangement for debt servicing early in 1981.

PRODUCTION AND TRADE

Zambia's production of copper increased by about 5% during 1980 and cobalt production rose by nearly as much. An increase of 8% in refined copper output reflected greater use of excess Roan Consolidated Mines Ltd. (RCM) refining capacity by Nchanga Consolidated Copper Mines Ltd. (NCCM). RCM's Ndola plant for treatment of tankhouse slimes was largely responsible for the increase of 30% in gold and 14% in selenium byproduct recovery. The 16% drop in silver output was due in part to diminished production from NCCM's Broken Hill Mine at Kabwe, to the exhaustion of high-grade sulfide ore at RCM's Kalengwa Mine, and to the shutdown of the Kalengwa open pit. Table 1 shows details of Zambia's mineral production.

One of the factors maintaining the price of copper was the U.S. strike of copper-producing workers on July 1, 1980. Settlement of the strike started with Kennecott Copper Corp. on September 9 and continued until The Anaconda Company and ASARCO Incorporated settlements on November 12, 1980. Despite the fact that the strike cost U.S. producers an estimated 400,000 short tons of copper, its effect on copper price was not sufficient to lift copper from the 90-cent-per-pound price on the U.S. market.

The dollar values of Zambia's 1976-79 trade and currency are shown in the following tabulation:

	1976	1977	1978	1979
Total exports (A)	$1050.3	$893.8	$818.4	$1412.0
Copper exports (B)	965.3	818.7	760.3	1167.8
Total imports (C)	791.9	797.9	718.8	904.3
A-C balance	+258.4	+95.9	+99.6	+507.7
Value of 1 kwacha	1.4019	1.2675	1.2307	1.2621

Source: International Financial Statistics. V. 34, No. 6, June 1981, p. 430.

The balances do not indicate an accumulation of foreign exchange because of repayments, servicing of loans, and other disbursements.

On July 26, 1980, the Zambian President announced the banning of essential imports from Europe and the United States in favor of those from apparently cheaper sources in Zimbabwe and South Africa. Some effects of this order on trade routes, as well as railway availability, are shown in table 2. Table 3 shows exports of copper by type and destination. The latest available data about Zambia's exports and imports were tabulated in the chapter for 1978-79.

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.

[1]Table includes data available through Aug. 3, 1981.

[2]Includes leach cathodes.

[3]Primarily contained in blister copper and refinery muds.

[4]For all practical purposes, Zambian output of crude lead and refined lead are regarded as equal; the latter is reported, and inasmuch as no impure lead is marketable, no attempt had been made to estimate the trivial difference between the two stages of processing.

[5]Refined silver and silver contained in blister copper and refinery muds.

[6]Less than 1/2 unit.

[7]Converted from figure reported in cubic meters; believed to represent only a small part of total output.

[8]Figure for 1979 reported as cubic meters, while that for 1980 reported as metric tons; it is believed that both figures actually represent metric tons.

In March 1980, it was widely reported that Zambia had negotiated a trade of cobalt to the U.S.S.R. for about $85 million worth of military aircraft (MiG-21) and other weaponry. This represented less than 1,542 tons of cobalt, or about half the country's annual production of that metal, and could have been transported readily as cargo on the scheduled Lusaka-Moscow airline flights during the remainder of the year.

COMMODITY REVIEW

METALS

Copper, Cobalt, Byproduct Gold, Selenium, and Silver.— Zambia's two major mining companies treated about 32 million tons of ore containing more than 750,000 tons of copper. Estimates of ore milled by RCM during 1980 and the RCM ore reserve figures as published in the RCM annual report for the yearend March 31, 1980, are shown in table 4. RCM noted that 1980 was the 10th anniversary of its existence following the acquisition by Zambia of a 51% interest in the operating subsidiaries of Roan Selection Trust Ltd. on January 1, 1970. During the decade, expansion of production was achieved by the acquisition and development of the Baluba Mine and the expansion of Chambishi. Minor expansion programs included deepening and equipping the service shaft at Mufulira to allow stoping below the existing facilities by 1986.

Table 4.—Zambia: RCM copper production and ore reserves

Mine	Ore mined and treated			Ore reserves		
	Gross weight (thousand metric tons)	Copper (percent)	Copper content (metric tons)	Gross weight (thousand metric tons)	Copper (percent)	Cobalt (percent)

OP Open pit. UG Underground.

[1]Stockpiled ore was used for Kalengwa mill feed.

The Chibuluma West main hoisting shaft was completed early in 1980 and new ore and waste rock passes were raise-bored to a 1.8-meter diameter for a distance of 365 meters. A connection between the new shaft and the 385-meter level of the 5A subinclined shaft was to be the main extraction level for Chibuluma West ore. The Chambishi shaft and underground workings were completely readied for maximum ore extraction down to the 500-meter level, and planning and feasibility studies for extracting the ore below the 500-meter level were started. Construction of additional copper tankhouse and cobalt refining facilities at Chambishi was started in the latter half of 1980. At Baluba, deepening of the rock hoisting shaft was completed, and lateral development was proceeding from some of the completed station installations while other stations were being installed. Extensions to the concentrator and expansion of the engineering services continued, and housing and transportation were provided for the additional labor needed to maximize output. The recovery of gold and selenium at RCM's Ndola refinery set records for this recently constructed plant.

NCCM's estimated ore production of 17.1 million tons included some 5 million tons of Rokana ore containing 87,000 tons of copper and 5,490 tons of cobalt. Table 5 lists the estimated tonnage of ore treated and held in ore reserves at NCCM's mines for 1980. Delays in the delivery of spares and lack of skilled and experienced maintenance staff have caused a general and gradual deterioration of plant and equipment throughout Zambia's Copperbelt. Reduced production rates were also the result of reduced expenditure because of lowering copper prices in the latter part of the year. Cobalt prices remained unchanged at $25 per pound.

Table 5.—Zambia: NCCM copper production and ore reserves

Mine	Ore mined and treated			Ore reserves		
	Gross weight (thousand metric tons)	Copper (percent)	Copper content (metric tons)	Gross weight (thousand metric tons)	Copper (percent)	Cobalt (percent)

OP Open pit. UG Underground.

At the Chingola Division, the shortage of spares for open pit vehicles caused a continuing shortfall of overburden stripping at the Nchanga open pit. The rehabilitation of the Chingola West Mill was completed and resulted in improved performance. Production from the tailings leach plant remained high despite the constraints caused by intermittant shortages of acid. Drilling indicated that cobaltiferous ore in the lower orebody of the Nchanga underground mine was richer in both copper and cobalt than previously estimated.

At the Rokana Division, good ore grades continued from both South Orebody and Central Shaft production. Big hole blasting techniques were extended in the Mindola section stopes and the technique was introduced in suitable areas at the South Orebody. At the concentrator, the first bank of 12 new 300-cubic-foot flotation cells was completed. Rehabilitation and enlargement of the cobalt plant and the copper tankhouse were started, as was construction of the new roast-leach-electrowin cobalt plant. Water extraction at the Konkola Division continued at an average rate of 399,478 cubic meters per day or 79 tons of water per ton of ore. NCCM's Bwana Mkubwa Mine near Ndola was declared likely to close by 1982 although a small production was scheduled if a feasible process was found for treating tailings and old dumps. Bwana Mkubwa was one of Zambia's scenes of prehistoric copper mining when it was discovered in 1902. Its high-grade malachite ores were found the following year, but commercial exploitation awaited the arrival of the railway extension north from Broken Hill, and production was started in 1913. Production was halted several times before an open pit operation commenced in 1926.

The mine was soon closed because of unprofitability and sold to Rhokana Corp. Ltd. in 1931. The Rokana Division of NCCM operated the mine in the 1970's.

The NCCM plan for increased cobalt production was reportedly designed to triple Zambia's output of that metal to 10,000 tons per year by a two-stage development program. A new cobalt refinery was to be established at Kitwe to produce 5,700 tons of cobalt metal per year on completion of the second phase of the project in 1985. The first stage was due to come onstream in 1982 with 2,600 tons per year capacity. A small-scale project to recover 700 tons per year initially from Rokana copper smelter slag was designed and would presumably be enlarged for the additional 2,400 tons capacity envisaged for stage 2. Production at NCCM's Nampundwe pyrite mine west of Lusaka was curtailed by the deepening of No. 1 shaft to ensure future ore production at the rate of more than 1,000 tons of ore per day to provide concentrates for the planned new acid plants.

Lead, Zinc, and Byproduct Cadmium.—Ore and concentrate production dropped during the year, finished lead metal declined 21%, and finished zinc metal was 14% lower than in 1979. Excessive plant downtime for repairs and the exhaustion of coke stocks were major reasons for reduced output. Byproduct cadmium output totaled 1.385 tons. Exploration by diamond drilling at NCCM's Broken Hill Mine revealed an additional 300,000 tons of lead and zinc ore that was to be reached by sinking the present subvertical shaft to a depth of 1,650 feet at a cost of $4 million. These reserves were estimated to extend the life of the mine by about 5 years. The managing director of the Metal Marketing Corp. of Zambia, Ltd. (MEMACO), reported that exports of lead and zinc to Zimbabwe customers were resumed after April 1980 and were expected to reach a rate of about 2,000 tons of each metal per year by the end of the year.

NONMETALS

Cement.—Cement Ltd. of Dublin, Ireland, has agreed to provide management and training of technical skills for local personnel both in Zambia and in Ireland. Chilanga Cement Ltd., south of Lusaka, continued to operate its coal-fired plant.

Fertilizer Materials.—In mid-1980, it was announced that Mitsubishi of Japan had won a contract and was to build a 100,000-ton-per-year sulfuric acid plant at the Kafue fertilizer factory. The plant was scheduled to have a turnkey cost of $40 million and to be onstream by 1983. This was an addition to the $400 million plus fertilizer complex of Nitrogen Chemicals of Zambia (NCZ), the commissioning of which was started by Klockner-Werke AG in November 1980. The complex included a 60,000-ton-per-year ammonia plant and facilities to upgrade Zambia's fertilizer capacity from 50,000 to 200,000 tons per year. Klockner agreed to back up NCZ's technical staff during commissioning and a trial run, which was expected to take from 8 to 10 months.

Gem Stones (Amethyst and Emerald).—Production of amethyst declined 31% in 1980, but preparation of rough amethyst cutting material for export continued as did fabrication into cut and polished stones and jewelry. A new company, Gem Industries Ltd., reportedly was successfully marketing Zambian gems at shops in Ndola and at the duty-free Lusaka International Airport, as well as on Zambia Airways international flights since August 1980. Production of Zambian emeralds was not specifically reported in 1980.

MINERAL FUELS

Production of bituminous coal from Maamba colliery declined to 569,000 tons of washed material. The Government of Austria agreed to grant Zambia $1.3 million to construct a coal reclamation plant and storage facilities at Maamba and also arranged to convert an earlier loan of the same amount to a grant.

A new company, Lublend, composed of Mobile Petroleum Co. Inc. (40%), the Zambia Industrial and Mining Corp. (ZIMCO) (35%), and Zambian National Energy Ltd. (ZNEL) (25%) was to construct a new $7.6 million plant at Bwana Mkubwa, south of Ndola. The plant was to produce some 100,000 barrels of lubricating oils and greases per year, and construction was to be completed about June of 1982.

The Mineral Industry of Zimbabwe

By George A. Morgan[1]

In March 1980, national elections were held and a new Government came into power, achieving internationally recognized independent nation status with the name Zimbabwe (formerly Southern Rhodesia). A prior cease-fire among hostile factions in a 7-year war led to the termination of trade sanctions. Trade sanctions had been imposed against the country by the United Kingdom, the United States, and other countries following the Unilateral Declaration of Independence (UDI) in November 1965. In April 1980 the U.S. Liaison Office in Salisbury was elevated to Embassy status and the country became the beneficiary of the U.S. General System of Preferences (GSP) trade benefits. Provisions of the GSP allowed for duty-free status for a number of mineral commodities. The Government has indicated that foreign investment in new plants and mining ventures can be repatriated after 2 years, and 50% of aftertax profit can be sent abroad. It had also encouraged joint ventures and has reserved the option to participate in major investment projects. A 10% surcharge on income tax was instituted in early 1980 to help balance the budget, and all foreign exchange transactions had to be approved by the Reserve Bank of Zimbabwe.

The mining industry prospered substantially during the past 15 years, with fundraising for capital investment and the maintenance of equipment carried on internally. Only in the field of exploration was there significant reduction of activity because of the withdrawal of survey teams from insecure areas. The Mines and Minerals Act of 1961 continued to be the legitimate mining law in Zimbabwe, and it was administered through the Ministry of Mines and Energy Resources. The country was divided into four mining districts, each governed by a district mining commissioner who reported directly to the Minister of Mines. The management and safety of all operating or abandoned mines in Zimbabwe was governed by the Mining (Management and Safety) Regulation of 1974. A depletion allowance of 5% was allowed on all minerals. About 61,000 people, or 6% of all wage earners in Zimbabwe, excluding peasant agriculture, were employed in the mining and quarrying industry.

PRODUCTION AND TRADE

Mineral production was valued at $614 million[2] in 1980 compared with $466 million in 1979. However, the index of volume of crude mineral output declined for the fourth consecutive year from a high of 206 (1964=100) in 1976 to 182 in 1980. The mining and quarrying sector of the economy accounted for about 7% of the gross domestic product (GDP), which was estimated at $2,750 million in 1980, up 12% from the previous year. The index of volume of production for manufactured nonmetallic mineral products increased 16.6%, and the index for metals and metal products increased 11%. The manufacturing sector, which included production of metal and nonmetal products, made up about 25% of the GDP.[3]

Zimbabwe's input to the Central African Power Corp. (CAPC), which was the source for the major portion of electric power

[2]In addition to the commodities listed, a few others were occasionally reported. These, with quantities in metric tons, 1979—1,632.

[3]Smelter copper includes impure cathodes produced by electrowinning in nickel processing. Output of fire-refined date include only electrolytic copper output by Corsyn Consolidated Mines at the Inyati Mine.

[4]Includes Ni content of nickel oxide and nickel fonte.

[5]Other gem stones were sporadically produced, as follows, in kilograms: Amazonite: 1965—2,532, 1966—2,259, 1967—

[6]Includes rough and ground quartz as well as silica sand. Quartz crystal was also produced in the amount of 3 metric

[7]Data represent output by the Wankie Colliery for years ending Aug. 31 of that stated; additional output by the Radcliff

generation for Zambia and Zimbabwe, increased 7.8%. Total electricity usage by Zimbabwe was up 8.5% to 7.3 billion kilowatt-hours. In addition to coal and hydroelectric power, the first ethanol plant was commissioned in April to supplant imports of gasoline and diesel fuel.

The new Government expressed commitment to the needs of the mining industry, with the Ministry of Mines and Energy Resources responsible for supplying advice and financial assistance. The Gold Mining Act was repassed in September to provide financial assistance to miners in case of declining prices. The Government also indicated interest in furthering its control of the mining industry by supporting a 35%-equity participation in current operations and a 50%-equity participation in new mines. At yearend, the Government proposed the creation of a central marketing agency for all mineral industry products.

Overall costs increased substantially for the mining sector. Mines also suffered from a severe shortage of skilled workers either because of prior military callups or emigration. A minimum wage, passed in late 1980, mandated statuatory wage increases. One company reported that salaries and wages accounted for 55% of total costs, while

tons in 1979.
plant of Risco Ltd. may total 250,000 metric tons per year of metallurgical coke and coke breeze.

working costs increased 38% mainly because of adjustments in salaries and wage scales. Taxes increased on gold produced because of a reduction in the depletion allowance to 5% from 15%.[4]

Trade data relating to individual mineral commodities by recipient or source country continued to be unavailable. However, 11 months of data for 1980 indicated that mineral-related products accounted for 56% of the total value of all commodities exported. Among individual mineral commodities, gold made up 71% of the total value of mineral products exported and thus was the principal foreign exchange earner. Exports of iron and steel ingots, rods, and sections amounted to nearly 500,000 tons for the period, while over 245,000 tons of ferroalloys were exported. The major import items by value were energy related, with refined petroleum products accounting for the largest portion.

Prior to closure of rail routes through Mozambique, about two-thirds of Zimbabwe's rail traffic was to the ports of Beira and Maputo. By 1980, nearly 90% of all Zimbabwe's export and import traffic used the Republic of South Africa rail system, with limited use of Mozambique ports.

COMMODITY REVIEW

METALS

Chromite.—Production of chromite in Zimbabwe was from both podiform and stratiform deposits. Production from an eluvial chromite deposit ceased in 1956 with the closure of the Feoch Mine, west of Motorshanga Pass. Union Carbide Corp. operated the Selukwe Peak and Railway Block Mines in podiform deposits through Zimbabwe Mining and Smelting Co. Ltd., formerly Rhodesia Chrome Mines Ltd. Output from the two mines accounted for about 70% of the country's total production. Rhodall Ltd., formerly Rhodesia Alloys Ltd., a subsidiary of Anglo-American Corp., operated a number of mines in the Salisbury district. About 30 mines were estimated to be producing chromite in the stratiform deposits of the Great Dyke, with output from mining operations on the Great Dyke accounting for about 25% of the total production. Chromite seams ranged in thickness from several centimeters to 40 centimeters. Mining of productive seams was by resue stoping, with waste rock removed prior to handpicking of ore. Total mine capacity for production of chromite in Zimbabwe was about 1 million tons per year.

Rhodall Ltd. had five ferrochromium furnaces operating at Gwelo, with a total capacity of 70 megawatts or about 113,000 tons per year of high-carbon ferrochromium, low-carbon ferrochromium and ferrosilicon chromium. A new 30-megawatt

furnace, scheduled for completion in 1982, was expected to increase production capacity of high-carbon ferrochromium by 50,000 tons per year. The Zimbabwe Mining and Smelting Co., Ltd., had four furnaces in operation at Que Que, with a total capacity of 50 megawatts or about 90,000 tons per year of ferrochrome. Two new furnaces of 24-megawatt capacity each were under construction and scheduled for completion in 1981 and 1982. They would each add about 45,000 tons per year of ferrochromium capacity to the plant at Que Que.

Cobalt.—Byproduct production of cobalt from nickel was initially solely from the Bindura smelting plant of Bindura Nickel Corp. (BNC), formerly Rhodesian Nickel Corp. (Rhonick). A cobalt recovery plant was added to the nickel smelter at Eiffel Flats in 1979 to process residue from the Empress Mine. About 50 tons of cobalt sludge was produced by BNC from Trojan, Madziwa, and Epoch nickel mine concentrates, and 31 tons of cobalt in sludge was produced from Shangani nickel concentrates in 1979. The remainder was from Rio Tinto (Zimbabwe) Ltd.'s (formerly Rio Tinto Rhodesia Ltd.) Empress Mine. Future output was expected to stabilize below 200 tons per year due to the exhaustion of stockpiled material.

Copper.—Production of copper continued to decline despite a mild recovery in price in early 1980. Approximately 30 mines produced copper either as a primary metal or as a byproduct or coproduct of other metal output. About 3,000 tons of copper was produced as a byproduct of nickel mining, mainly from the Empress and Madziwa Mines. Impure copper cathodes from nickel electrowinning plants were refined outside the country.[5] M.T.D. (Mangula) Ltd. was the leading producer, with output of 14,500 tons in 1980 compared with 16,600 tons in 1979. The principal copper deposits in Zimbabwe, along with reserves and grade, are listed in the following tabulation:

Deposit	Reserves (thousand tons)	Grade (percent copper)
Alaska	579	1.11
Avondale	320	1.14
Copper Queen	15,000	1.40
Inyati	870	1.54
Miriam	14,000	1.27
Norah	3,000	1.35
Shackleton	837	1.26

A number of mines were on a care and maintenance basis, such as the Shamrocke, Alaska, and Gwai River Mines. The Mangula operation, which includes the Miriam and Norah Mines, was the leading copper producer. In the year ending September 30, 1980, ore production was 1.2 million tons grading 0.86% copper at the Miriam Mine and 509,000 tons grading 1.08% at the Norah Mine. Data available on copper milling operations in 1980 are listed in the following tabulation:

Mill	Throughput (thousand tons)	Grade (percent copper)	Copper in concentrates (tons)
Inyati	193	1.54	2,964
Miriam	1,203	.86	9,641
Muriel	63	NA	348
Norah	534	1.07	5,332
Shackleton	466	1.05	e4,800

eEstimated. NA Not available.

Mangula began commissioning its 20,000-ton-per-year refinery in November. Full capacity was expected to be online in April 1981. Financing for the project was from local borrowing, with Zimbabwean labor and materials used for most of the construction. The Lonrho Investments Group's subsidiary, Coronation Syndicate, operated the Inyati and Muriel Mines through Corsyn Consolidated Mines. A smelter and refinery existed at the Inyati Mine for treating a portion of the mines' output for production of 3,100 tons per year of refined copper. Refined copper produced at Inyati was used locally for the manufacture of copper cable, most of which was exported. Lonrho gained full ownership of Nyaschere Copper (Pvt.), in which it already controlled 50%. The company was the operator for the Nyaschere and Shamrocke Mines.

Gold.—About 260 gold mines were operational in 1980, with 22 mines accounting for nearly 78% of the total output.[6] The principal mining concerns were Lonrho, Falcon Mines Ltd., Falconbridge Nickel Corp., Homestake Mines (Pvt.) Ltd., and Rio Tinto Zimbabwe Ltd. Lonrho was the largest gold producer with eight mines, five of which were opened since UDI. Lonrho's subsidiary, Coronation Syndicate, owned Corsyn Consolidated Mines, which operated the Arcturus, Mazoe, Muriel, and Inyati Mines. Another subsidiary, Attica Mines (Pvt.) Ltd., operated the Shamva and How Mines. Independence Mining (Pvt.) Ltd. also a Lonrho affiliate, operated the Old West and Redwing Mines near Umtali. The group's Mashona Kop Mine near Salisbury ceased operation in early 1980 due to depletion of ore reserves.[7] Assets remaining from the operation were transferred to the Arcturus

Mine, which was one of the leading gold producers in Zimbabwe, employing 730 personnel. Production in the year ending September 30, 1980, was 19,000 troy ounces. Crosscut extensions made on number 10 level during what was expected to be the last month of mine life intersected new ore. As of June 30, 1980, proved reserves were 501,000 tons grading 0.28 troy ounce of gold per ton. Modifications of the mill were also under way to allow processing of weathered ore by 1981. In the year ending September 30, 1980, Corsyn Consolidated Mines had a total mill throughput of 462,000 tons, with a production of 56,600 troy ounces of gold, 68,700 troy ounces of silver, and 3,300 tons of copper. The company expected to improve recovery of gold, silver, and copper, with a slight increase in mill throughput. In addition, 14,700 meters of primary development and 700 meters of shaft sinking were planned in the new year.[8]

Falcon Mines Ltd. was the second largest producer of gold in Zimbabwe after Lonrho. The company operated the Arlandzer, Dalny, Mascot, Turkois, and Venice Mines. The company also had a 40% share in Olympus Consolidated Mines Ltd., which operated the Commoner Mine in Gatooma and the Old Nic and Dawn Mines near Bulawayo. Falcon Mines Ltd. placed its recently acquired Golden Oriole Mine into production in May 1980. However, results were below those expected because of metallurgical problems. A new concentrator was being built at the Venice Mine, along with a new shaft to supply the 6,000-ton-per-month capacity of the plant. This production will be in addition to the 5,000 tons per month supplied to the Dalny plant, which also was to be expanded to 7,000 tons per month. The Dalny Mine was the largest gold producer in Zimbabwe, employing over 1,500 personnel. The company reported a total mill throughput of 241,550 tons in 1980, yielding 47,900 troy ounces of gold. Reserves were reported at 2 million tons, averaging 0.29 troy ounce per ton. Working costs increased 38% in 1980, mainly due to salary and wage scale adjustments. Additionally, the taxation charge increased due to reduction of the depletion allowance from 15% to 5%. Capital expenditures of $6.7 million were planned for the new year, mainly for the Venice and Dalny Mines.

Iron and Steel.—Rhodesian Iron and Steel Co. Ltd. (RISCO), the country's sole iron and steel producer, expanded its export markets with increased sales of billets to other African nations having rerolling facilities. With only about 25% of production used locally, RISCO was capable of supplying 100,000 tons per year of billets for export. A $148 million expansion plan was under way to double this capacity. In addition to Kenya, overseas markets included Bangladesh, the Republic of Korea, Saudi Arabia, and several members of the European Communities.[9]

Iron ore feed to the four blast furnaces at the steel plant was from the Ripple Creek Mine at Redcliff and the Buchwa Mine, about 200 kilometers southeast of Redcliff near Shabani. Buchwa was the principal source and supplied about 1 million tons of hematite ore grading 43% iron. Reserves were 20 million tons. Production at Ripple Creek was 300,000 tons per year of manganiferous iron ore grading 51.4% iron and 2.1% manganese. Proved reserves at Ripple Creek were 44 million tons, with an additional 100 million tons indicated. A study was under way to determine the feasibility of building a sintering plant at Redcliff to treat Ripple Creek ore. If successful, blast furnace feed would be 80% sinter in the ratio of 4 tons of Ripple Creek ore to 1 ton of Buchwa ore and 20% of lump ore.[10]

Nickel.—Nickel has been found in Zimbabwe in five different geologic environments: Hydrothermal shear-zone deposits, lateritic ore deposits, ultrabasic lava deposits, unlayered mafic intrusions, and layered mafic intrusions.[11] Output from hydrothermal shear-zone deposits terminated in 1957 with closure of the Noel Mine southeast of Bulawayo. Lateritic deposits, such as the Musengezi complex in the northern part of the Great Dyke, and layered mafic intrusions in the Great Dyke itself were under investigation for development. Nickel in ultrabasic lava flows at the Trojan Mine was in talc and serpentinite host rock, which was easy to mine, but costly to beneficiate. Nickel in unlayered mafic intrusions at the Madziwa Mine was in gabbroic or dioritic rock, which was difficult to drill and had erratic mineral distribution. Ore reserves in Zimbabwe were 60 million tons grading 0.6% to 1.2% nickel. Possible reserves of 2,000 million tons grading 0.25% nickel, 0.25% copper and 3 to 5 grams of combined platinum and palladium per ton of ore existed at the Hartley and Wedza complexes of the Great Dyke. In addition, nickel mineralization at Hunters Road near Que Que has been put at 15 to 20 million tons grading 0.75% nickel.

Primary nickel production was from six mines by three companies. BNC owned three mines, as well as the smelter at Bin-

dura operated by Bindura Smelting and Refinery Co. BNC was partly controlled by Anglo-American Corp. Rio Tinto (Zimbabwe) Ltd. owned two mines and a refinery at Eiffel Flats, Gatooma. The following tabulation gives primary nickel mines by year of development, as well as owners and operators.

Mine	Startup	Owner	Operator
Trojan	1964	Bindura Nickel Corp	Trojan Nickel Ltd.
Madziwa	1969	do	Madziwa Mines Ltd.
Empress	1971	Rio Tinto Zimbabwe Ltd	Empress Nickel Mining Co.
Perserverance	1972	do	Do.
Shangani	1975	Johannesburg Consolidated Investment Co. Ltd. (49%); Bindura Nickel Corp. (37%).	Shangani Mining Corp. Ltd.
Epoch	1976	Bindura Nickel Corp	Trojan Nickel Ltd.

Delays in development work at the Empress Mine because of poor ground stability as well as dilution and support problems encountered in early pillar removal resulted in a decline in tonnage and grade of ore produced. Production was also affected by a strike of 1,350 laborers in May. Mill throughput of 840,000 tons was planned for 1981 compared with 880,000 tons in 1980 and 934,000 tons in 1979. Rio Tinto (Zimbabwe) Ltd. acquired the remaining shares of Empress Nickel Mining Co. in what was essentially a rationalization of its interest in Zimbabwe.

Mining operations at the Shangani Mine have been highly sensitive to metal prices over the period of operations since 1976, and financial losses have been significant. The fiscal year ending June 30, 1980, was its first profitable year. Mill throughput was at the rate of 5 tons of open pit ore to 1 ton of underground ore following an underground development program. Production at both the Shangani Mine and the Trojan Mine was halted in November because of strikes.

Tin.—The Kamativi Mine east of Wankie continued to account for nearly all the tin output of Zimbabwe in 1980. The Industrial Development Corp. of Zimbabwe had a 91% controlling interest in Kamativi Tin Mines Ltd., which owned and operated the mine. Mill throughput was 60,000 tons per month of underground ore averaging 0.18% tin. New analytical equipment was being installed to enhance identification of tantalite bearing tin ore for exploitation. An exploration program aimed at documenting higher grade ore was under way. Development work was also being carried out for an opencast mine, which was to be brought into operation to reduce demands made on the underground workings.[12]

NONMETALS

Asbestos.—Shabani and Mashaba (Pvt.) Ltd., a subsidiary of Turner and Newall, operated the largest asbestos mining operation in Africa at Shabani, employing 4,300 people.[13] It also operated the Gaths, King, and Temeraire Mines east of Fort Victoria, which together with the Shabani Mine accounted for 90% of the country's total output of 260,000 tons in 1979. Chrysotile deposits at Shabani were located at the center of a 15-kilometer-long ultramafic sill, forming over 30 irregular shaped podlike ore bodies. Numerous minor faults and rock fractures cut the ore bodies and surrounding rock with considerable effect on rock competency. Both block caving and sublevel caving were the preferred mining methods, while the vertical crater retreat system of mining was being evaluated. Ore was accessed by two main shafts with a multi-level hoisting system employed to avoid gravity loading of asbestos ore through long ore passes. Initial rock assessment tests were initiated 11 years prior to main access development of a given ore block, with actual development of the block based on data from previously monitored blocks, rather than mathematical models. A new mill was activated at Shabani in September, built almost entirely by indigenous companies using locally supplied materials. Total mill throughput at Shabani was 2.4 million tons per year of new ore and 720,000 tons per year of reclaimed ore. Sizing and cleaning stages of asbestos fiber processing, followed by fluffing and blending, yielded a low-iron product for volume reduction and bagging. The Gaths and King mills had a combined throughput of 2.16 million tons per year, and the Temeraire mill had a

throughput of 480,000 tons per year of reclaimed material.

The Boss, Rex, Pangani and Vanguard Mines were operated by Pangani Asbestos Mines (Pvt.) Ltd., a subsidiary of Asbestos Investments Pty., Ltd. The Kudu Mine, an opencast mining operation, had a mill throughput of 360,000 tons per year. It was operated by Kudu Mines (Pvt.) Ltd., a subsidiary of Essexvale Asbestos (Pvt.) Ltd. The Thornwood Mine was owned and operated by A.D. Theron and Sons (Pvt.) Ltd., and the D.S.O. Mine was owned and operated by D.S.O. Asbestos (Pvt.) Ltd. The Ethel Mine, originally owned by Swedish interests, ceased operation in 1966 when markets for the mines' output were terminated. At the time of termination, the operating company had 11 production levels laid out, with each level having 4 years of ore supply.

Corundum.—Zimbabwe was the leading world producer of natural corundum, with output from only two mines. The major portion of output was in the form of boulder corundum produced at the O'Brien Mine near Concession. Reserves at the O'Brien Mine were reported at 60,000 tons, including both quarry and alluvial corundum. The alluvial deposit, with generally higher grade corundum, covered 72 acres and was mined by hand. Crystal corundum was produced at the Andrew alluvial claim, east of Chiredzi. Other deposits of corundum were located in the areas of Fungwi, Wedza, Mrewa, Beit Bridge, and Belingwe.

Graphite.—The Lynx Mine northwest of Karoi was the sole graphite producer, with an output of 5,760 tons in 1979. Operated by Rho German Graphite (Pvt.) Ltd., production had begun in 1966 at the rate of 4,800 tons per year. A new plant was under construction to increase output to 1,000 tons per month. The deposit was reported to contain high-grade flake graphite, with 26% to 28% carbon in ore. The final product after flotation was 90% to 92% carbon. Reserves were equivalent to 50 years at current levels of output, with 98% of production exported, mainly for use in foundry facings.[14] Other deposits have been found, as in the Dett area near Wankie, but have not been mined because of marketing problems.

Limestone.—Production of limestone, including dolomite and calcite, exceeded 1 million tons and was valued at nearly $4 million. Deposits were widely distributed throughout the country and were found mainly as lenticular masses in close conformity with banded ironstones of the Bulawayan Group. The most important source was the Early Worm Mine at Concession with vast reserves and high grade. A substantial portion of high-grade metallurgical limestone was consumed by the ferrochrome industry. Numerous other deposits were mined for local consumption. The Rushinga dolomite near Mount Darwin was reported as high grade, with reserves exceeding 100 million tons. The Sternblick deposit near Salisbury and the Colleen Bawn deposit near Gwanda were both used exclusively for cement manufacture. In the Mazoe Valley, the Pioneer lime works produced high-grade agricultural lime, and the Risco limestone was mined to supply the country's sole steel plant at Redcliff. The generally high iron content of domestic supplies required the importation of about $740,000 worth of burnt limestone. Expansion of the agricultural sector was expected to require about 500,000 tons of limestone annually.

Lithium.—Bikita Minerals (Pvt.) Ltd., a subsidiary of Selection Trust, operated the principal lithium deposit in Zimbabwe at Bikita, 67 kilometers east of Fort Victoria. Reserves at the deposit were reported at 8.1 million tons grading 1.4% lithium. About 230 people were employed at the site which produced petalite, spodumene, lepidolite, eucryptite, bikitaite, and amblygonite. Mining was concentrated in the Al Hayat quarry where the predominant mineral mined was petalite. Production was about 10,000 tons per month, with about 4,500 tons per month of salable product hand-sorted and stockpiled at the sorting plant. The remaining quantity was classed mainly as petalite rejects of low concentration and was stockpiled for possible future use as a chemical feed. A dry grinding plant employing a semiautogenous process was installed in 1978 to meet individual customer size specifications for marketable products.[15]

Magnesite.—Zimbabwe produced over 84,000 tons of magnesite in 1979, most of which was exported for production of refractory brick for use in the steel and copper industries. A small portion was calcined and ground for local use by Sable Chemical Industries Ltd. to produce fertilizer. All output was mined underground from a sedimentary deposit at Barton farm, southeast of Gatooma. Other occurrences included the Mat Mine, near Beit Bridge and the Calac deposit in the Nuanetsi area.

MINERAL FUELS

Coal.—The International Finance Corp. was assessing a loan requirement of $148 million to expand coal production at Wankie, the country's sole coal producer. Output was to be increased from the current level of about 3 million tons per year by the opening of a new mine producing high-ash coal. The major portion of the additional output, which was to commence in 1982, was planned to supply the first stage of a new coal-fired powerplant at Wankie, with an initial capacity of 480 megawatts. New coal production amounting to 4.5 million tons may be required from Wankie upon full completion of the powerplant with a capacity of 1,280 megawatts.

Strikes affected coal production in May and November, with as many as 4,000 of the 5,735 people employed at the site refusing to work. Limited quantities of coal were imported from the Republic of South Africa in May to make up the loss of coal supplied to steam engines caused by the strike.[16] Production from individual mines and sales in tons is listed in the following tabulation for years ending August 31 of the year stated:

	1979	1980
Underground mines: No. 3	1,126,430	1,122,248
Opencast mines:		
No. 1	164,668	99,309
No. 2	259,656	524,926
No. 2A	384,689	
No. 4	1,324,194	1,423,246
Total	3,259,637	3,169,729
Discards	491,655	617,393
Salable products	2,767,982	2,552,336
Used internally	385,783	331,032
Total coal sales	2,382,199	2,221,304

The No. 4 underground mine was to be opened in anticipation of depletion of No. 3 underground mine reserves. The No. 2 opencast mine reached the limit of overburden removal and was being replaced by No. 2A. Output from No. 1 opencast mine was used solely to supply customers with low phosphorus coal requirements. Total sales of coke were 235,168 tons compared with 201,471 tons in 1979.[17]

Petroleum.—The country's sole petroleum refinery at Umtali was evaluated for refurbishing and recommissioning, perhaps by 1982. The refinery remained inactive since the closure of its supply line, the Beira pipeline, in 1967. It originally processed light Iranian crude oil, with a capacity of 900,000 tons per year. Changes in feed material as well as product yield were anticipated as new fuel requirements were to be met. Output of regular gasoline from the Feruka refinery was expected to be blended with ethanol produced from sugarcane at Triangle. Zimbabwe, Mozambique, and seven oil companies were shareholders in the Feruka refinery.

The first ethanol plant in Zimbabwe went into production at Triangle in April 1980, using sugar as a feedstock. Fuel from the plant was blended with gasoline to produce a 15% ethanol-85% gasoline mixture.

CAMEROON

The successful expansion of crude oil production begun in late 1977, led to promising development of the nonfuel minerals sector. Although actual production of nonfuel minerals was limited both in variety and in percentage of output on a world scale, the potential for expansion with a rapidly developing infrastructure was significant. The energy base was expanding with construction of two new hydroelectric powerplants in addition to the existing plant near Edea. The Song Loulou plant will have a 240-megawatt capacity, and a hydroelectric plant under construction in the northern part of the country by mainland China will have 72 megawatts of installed capacity.

Inflation of between 15% and 20% resulted in a real gross domestic product (GDP) of $2.8 billion[2] in fiscal year 1980 (July 31 to June 1), up 6% from that of the previous fiscal year. Petroleum became the leading export item in terms of value, surpassing coffee and cocoa exports. Mineral exports as a whole increased eightfold in value, mainly because of oil sales. Oil exports also caused a reduction in the trade deficit by nearly one-third, and the Government expected its 1980-81 budget to be balanced at $1.17 billion. The Port of Douala accounted for about 3 million tons of cargo, or 93% of total maritime traffic for Cameroon. Expansion plans for the port call for an initial increase to 5 million tons, and a cargo handling capacity of 7.5 million tons in 1985 and 10 million tons by 1990. The Port of Victoria will gain importance with the startup of an oil refinery. The country's third seaport at Kribi was used solely for timber shipments, and capacity at the Port was to triple by 1981. The Government operated its own shipping line with six oceangoing freighters. France was the dominant trading partner, accounting for 25%

and 45% of the value of Cameroon's exports and imports, respectively. The United States imported $186 million worth of crude oil from Cameroon in fiscal year 1980.

The aluminum smelter at Edea, operated by Campagnie Camerounaise de l' Aluminium Pechiney-Ugine, had a capacity of 62,000 tons per year. Alumina for the smelter was imported from Fria, Guinea. The facility utilized about 65% of the hydroelectric power generated, mainly from the powerplant at Edea. Proposals have been made to expand capacity to 80,000 tons per year at a cost of $120 million. The International Finance Corp. of the World Bank was to provide $100 million for the project. Power requirements for the expansion would be provided by a new hydroelectric plant nearing completion at Song Loulou with a capacity of 240 megawatts. Development of an estimated 1 billion tons of indigenous bauxite resources near Minim-Martap, about 100 kilometers south of Ngoundéré, was hampered by the continued lack of adequate transport capacity. Several international concerns have been interested in the deposits. A recently completed study indicated a cost of $300 million for upgrading the railroad and port system. The potential construction of an alumina plant at Kribi has also been considered in conjunction with exploitation of the deposits.

Small-scale tin production from alluvial deposits continued at Mayo Darlé in northwest Cameroon. Output has declined to less than 10 tons of tin in concentrate for export from the early 1940's when several hundred tons of tin in concentrate were produced. A feasibility study began on tin mining and the exploitation of other nonferrous metals in southwest Cameroon by the Bureau de Recherches Géologiques et Miniéres (BRGM) of France. The French Government and the European Development Fund were financing the project.

The fertilizer plant at Bonaberi, operated by Société Camerounaise des Engraise, resumed operations following several years of inoperation. Full production capacity was 90,000 tons per year of various fertilizer products, using imported raw material. About 200 people were employed at the plant.

Natural gas resources underwent appraisal for utilization in a liquefied natural gas (LNG) plant. Kribi has been proposed as the site of the project, as well as for a LNG shipping terminal. Sea floor studies were underway to determine the most favorable coastal channel for LNG tankers. Five offshore gas areas were converted from exploration permits to production concessions based on their commerical viability: Sandy-gaz, Kita-gaz, Kolé-gaz, Ekundu-gaz, and Bravo-gaz. Gulf Oil Co. announced the discovery of a large natural gas deposit near Douala. Additional drilling continued in the area to determine the deposit's commercial viability.

The Government established the state-owned Ste. Nationale de Hydrocarbures (SNH). SNH had a 60% share in offshore operations and 50% interest in all exploration permits. All production was by Société Nationale Elf Aquitaine, which completed development of two offshore fields. Output averaged 56,767 barrels per day in 1980, compared with an average of 34,466 barrels per day in 1979. Average daily production in 1981 was projected to be about 81,000 barrels. All crude oil output has been exported. An oil refinery, under construction since October 1978 near Victoria, will have an initial capacity of about 30,000 barrels of throughput per day. SNH will be the sole supplier of the refinery's feedstock, which will be about one-half of the company's share of total production. The remaining portion of the Government's allotment of crude oil will be available for export. SNH has 66% equity in the refinery and France has 10%; the remainder was divided evenly among four separate companies. Commissioning of the refinery, planned for 1981, will make Cameroon self-sufficient in refined products. Sales of refined products to the Central African Republic and Chad were also planned.

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.

[1]Includes data available through Oct. 12, 1981.

[2]In addition to the countries listed, Equatorial Guinea and São Tomé e Principe, covered textually in this chapter, presumably produce modest quantities of a variety of crude construction materials (clays, stone, and sand and gravel), and may produce minor amounts of other mineral commodities (most notably gypsum, lime, and salt), but output is not reported quantitatively and available information is inadequate to make reliable estimates of output levels.

[3]In addition to the commodities listed, modest quantities of unlisted varieties of crude construction materials (clays, stone, and sand and gravel) presumably are produced, but output is not reported quantitatively and available information is inadequate to make reliable estimates of output levels.

[4]Revised to none.

CENTRAL AFRICAN REPUBLIC

Mineral production in 1980 was limited to diamonds and a small output of gold and mainly test shipments of uranium ore. Diamonds replaced coffee as the country's principal export commodity in 1978 and continued to dominate the overall economy in 1980. In 1979, nearly 41% of the value of exports, or $43 million,[3] was provided by diamonds. The high ratio of gem to industrial diamonds significantly affected the value.

The national debt increased to $287.8 million, and the Government was heavily dependent upon foreign loans and grants. The 1980-81 recovery plan was comprised of investments totaling $200 million, of which the mining sector was allocated $5.4 million. Of this amount, $4.8 million was to cover the cost of a pilot plant in France for the treatment of uranium ore mined from the Bakouma deposit.[4] The Société de l'Uranium Centrafricain, formed in 1975, had exclusive uranium mining rights in the Central African Republic.

Diamond production increased by 11% in 1980. Diamond Distributors International of the United States operated the domestic diamond cutting industry in conjunction with the Government of the Central African Republic through Comptoir National du Diamant. The Central African Mining Exploitation Co. was granted exploration and exploitation permits for gold and diamonds in several regions, including the western diamond-bearing region. Prospecting permits were valid for 5 years; exploitation permits were issued for 4 years.

Financing was being sought for development of the Fatima-Bobosa limestone deposit. Limestone from the deposit would be used to supply the country's first cement plant. Proposed development of an iron ore deposit in Bogoin was postponed in view of the current state of disarray of the economy and was expected to be reexamined in the 5-year plan for 1982-86.

Continental Oil Co., which had oil discoveries in Chad, continued exploration in the northern region close to the Chadian border.

CHAD

The only mineral production of significance in 1980 was natron, a hydrous sodium carbonate derived from brines and evaporite deposits at Lake Chad. Output of salt, clays, and building materials occurred in limited quantities for local consumption. Open civil war between several factions disrupted the major portion of the country, and heavy fighting in the capital led to evacuation by large numbers of Chadian citizens and most foreign personnel. The war continued to forestall development of the country's fledgling petroleum industry, which was expected to be capable of supplying local demand through the construction of a small refinery. Oil has been discovered at Kanem, north of Lake Chad, and near Moundou in southwestern Chad. The area south of the Chari River continued to be an oil exploration target. Consumption was about 1,100 barrels per day of refined oil products. Diesel fuel was the main fuel import item to power generators located in Ndjamena, Sarh, Moundou, and Abeche. The fuel supply to Chad was mainly from Nigeria, passing overland through northern Cameroon. Because there was no refinery, pipeline terminal, or national stocks, supplies of fuel oil amounted to only about 2 months' stocks located at power generator sites. Fuel transport was generally nonexistent during the rainy season.

CONGO (PEOPLE'S REPUBLIC OF THE)

In 1980, output of crude oil again increased and was the country's principal export item. The GDP was estimated at $1.3 billion.[5] Government revenue amounted to $567 million, of which petroleum accounted for 60%. The economy in general was in poor financial condition. Production and distribution of products, which were the responsibility of state organizations with import monopolies, were erratic. Marketing of cement was paralyzed at times. Production of nonfuel mineral commodities was relatively insignificant, but several mining projects were slated for rehabilitation.

The ABF Mining Co. of the United States negotiated with the State Mining Corp. for reopening the Holle potash mine. Potash production would be exported to the United States. The mine was closed in June 1977 following flooding because of a rupture of the overlying dolomite aquifer. Output from the mine has been as high as 240,000 tons of crude potash, K_2O equivalent, per year. The lead and zinc mining sector was to receive assistance from the U.S.S.R. A new lead-zinc find was reported near Mfouati, which was the location for existing production. The concentrator at Mfouati was only operating at 25% of its 30,000-ton-per-year rated capacity. Soviet assistance was also expected for development of an iron deposit at Zanago, which contained 1 billion tons of ore grading 50% iron.

A strike by workers of the manganese mine at Mbinda in Gabon in February led to a decline in transport earnings by Chemin de Fer Congo in 1980.[6] Shipment of other mineral-related commodities included 44,000 tons of cement and 178,000 tons of mixed fuels. The European Economic Community granted a loan of $8.9 million for completion of modernization and realinement of the railroad.

Crude oil was produced from four areas in 1980. Production from Pointe-Indienne, the only onshore deposit, was small, and the deposit was nearly exhausted. Main production was from Emerande, where 1.4 million tons was recovered. Of a total recoverable amount of 17 million tons at Emerande, 13 million tons had been produced by yearend 1979. Output at Loango was 1.3 million tons, and production from Lekouala Marine, which commenced output in April, was estimated to be 500,000 tons in 1980. Two companies produced oil in the Congo, Elf Congo and Azienda Generale Italiani Petroli S.p.A. The state-controlled Hydro-Congo held 20% of the capital of both companies. Government participation was to increase with higher production levels. A grant of $5 million was received from the International Development Association for the services of petroleum specialists as well as a training program and survey.

EQUATORIAL GUINEA

The economy, in a state of collapse in 1979, stagnated in 1980 while a new Government attempted to bring stability to the country. Substantial foreign assistance was required for rehabilitation of the transportation, farming, and electric power sectors. Although no mineral production was officially recorded for Equatorial Guinea, output of small quantities of materials such as clays, sand, and possibly salt presumably occurred. The prospects for future mineral industry development were under evaluation through the efforts of several foreign entities. BRGM conducted exploration studies in Rio Muni, particularly for uranium. France was also financing a hydroelectric powerplant for the country and had provided $2.4 million by late 1979 to promote development of fishing, mineral prospecting, and repair of the port facilities at Molabo. Mineral-related activities included the training of local personnel and providing technical mineral prospecting expertise.

The U.S.S.R. supplied oil to Equatorial

Guinea at below world prices. Empresa Guineo Española de Petróleos (GERSA), controlled equally by Hispanoil of Spain and the Government of Equatorial Guinea, was granted four sectors on the Continental Shelf northeast of Bioko Island for oil exploration. GERSA was to invest $24.25 million over the next 3 years for oil exploration. New petroleum and mining laws were being formulated. All mineral deposits, including petroleum, were expected to be the property of the state.

SAO TOME E PRINCIPE

In 1980, both foreign aid and domestic economic policy were directed at the agricultural sector, primarily for the purpose of reducing expensive food imports. French, Portuguese, and Chinese aid has been mainly in the areas of agriculture and medicine. The U.S.S.R., Cuba, and the German Democratic Republic have provided political and military assistance to the country's single political party. The German Democratic Republic was also constructing a ceramic factory. No new developments occurred in the oil and gas exploration sector, where there was only one permit holder.

In July 1980, Decree Law No. 30-80, relating to foreign investment in São Tomé e Principe, went into effect.[7] Many sectors were excluded from foreign ownership or participation, such as foreign trade, telecommunications, insurance, and news media. Private enterprises, mixed companies, and partnership associations were allowed to form. Mixed enterprises, with few exceptions, had to be 51% owned by São Tomean principals. Associations could be formed for the purpose of importing capital, equipment, or technology, but they would not have the status of a corporation. The transfer abroad of annual profits was allowed. The decree law did not rule out nationalization of an enterprise. However, indemnification of the enterprise was guaranteed and could not be less than the value invested less the portion of the value already reimbursed. Exemption from taxes on earnings during the first few years of activity and reduction in or exemption from customs duties was possible. Both the exportation and importation of products and equipment were to be conducted in close association with the State Foreign Trade Enterprise.

BURUNDI

The mineral industry in Burundi continued to be a minor contributor to the 1980 gross domestic product (GDP) estimated at $293 million in constant 1970 prices.[2] Mineral export revenues, primarily from cassiterite, increased by a factor of 15 between 1979-80, reaching approximately $430,000 by yearend 1980. Gold, bastnäsite, colombite-tantalite, and wolframite continued to be exploited on a small scale, using manual and semimechanical methods. Despite a sharp decline in mining activities during 1979, attributed to a lack of profitability and shortage of construction materials, the mining sector exhibited signs of recovery during 1980.

The mineral exploration budget grew 32% over 1979 levels and was equivalent to approximately $42,000 in 1980. In addition, the Burundi Geographical Institute (IGEBU) was created in September 1980 and given responsibilities to collect cartographic, topographic, hydrogeologic, and other geomorphological data.[3] SONIBUROM, the Burundian and Romanian Government joint mineral corporation, conducted mineral deposit inventories during 1979-80 and has been charged with exploiting some of these as yet unspecified resource areas. Another Burundian-Romanian effort, called Mabaya-Butahana, was initiated to search for gold deposits. Meanwhile on the Ruzizi plain, alluvial gold prospecting, with an estimated grade between 0.2 to 1.0 gram per ton, was carried out on a small scale.

Remote sensing surveys have identified possible iron, titanium, and vanadium deposits near Kinganda, in the Buhoro region. In the Butara-Bubanza-Masango area, potential uranium mineralization was investigated and drilling programs were planned. Drilling was initiated in the Matongo-Bandaga area in the Ngozi Province to evaluate limestone and phosphate deposits. Plans were made by the Burundi National Lime and Cement Making Co. to expand production capacity through the installation of a 50-ton-per-day lime kiln.

Progress was made on the nickel laterite project, and prefeasibility studies were prepared. The deposit with the greatest exploitation potential was located in the Buhinda

sector at Musongati. The nickel ore reserves were estimated to contain 73 million tons with an average grade of 1.6% nickel, 0.1% cobalt, and 0.3% copper. Approximately 30 million tons were thought to be higher grade ores, averaging 2% nickel. Development of a 2-million-ton-per-year open pit mining operation was under consideration, and metallurgical processing alternatives were investigated.

Large infrastructure costs were projected for the nickel project, and the construction of new transportation and port facilities required the cooperation of at least one neighboring country. Potential energy from hydroelectric or peat resources was considered available in the Musongati area. Development of a 500-million-ton peat deposit in the Akanyaru region, 110 kilometers away, was being considered. The nickel project was expected to enter the detailed feasibility phase during 1981.

Several multilateral and unilateral aid programs have helped to finance Burundi development projects. The average external aid granted over the period 1977-81 was estimated at $57 million. The United Nations and World Bank programs were estimated to provide nearly 30% of the total. A slight decrease in aid was projected for 1980, and by yearend, both the Government deficit and balance-of-trade deficit increased to approximately $18 million and $92 million, respectively. This was largely attributed to bottlenecks caused by crane difficulties at the Port of Bujumbura, a concurrent decline in coffee and cotton export revenues, and the near doubling of the petroleum import bill to $25 million by yearend 1980.

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.

[1]Table includes data available through Oct. 12, 1981.

[2]In addition to the commodities listed, modest quantities of unlisted varieties of crude construction materials (clays, stone, and sand and gravel) presumably are produced, but output is not reported quantitatively and available information is inadequate to make reliable estimates of output levels.

[3]Limited quantities of other pegmatite minerals may also be produced, but output is not reported.

[4]Reported figure.

[5]Data represent sales; actual production is not reported.

DJIBOUTI

Stategically located between Somalia and Ethiopia, Djibouti controlled the coastal access to the Bab el Mandeb Strait, which connects the Red Sea with the Indian Ocean (Gulf of Aden). Djibouti was not endowed with natural resources, and only small amounts of construction materials were exploited. During 1980, Iraq granted Djibouti a loan worth $25 million to establish a cement facility. France was installing a solar pump for irrigation purposes at yearend 1980. Future solar energy and possible hydroelectric applications were being considered for Assual Lake and Goubed Bay. Additional expenditures were expected to improve and modernize the Port of Djibouti and increase water, health, and education services.

Djibouti depends on foreign economic and technical assistance, and roughly $120 million was committed during 1979-81. France, Saudi Arabia, Iraq, and Kuwait were the major unilateral aid donors. The European Development Fund has consistently provided the largest share of financial and technical assistance since the country's independence in 1977. Increased aid has allowed for the near 25% expansion of the 1981 proposed budget. Additional revenues were projected to be furnished through direct taxes (25%) and indirect taxes (75%). The public debt was estimated to comprise only 2% of the Government expenditures in 1980. The current and proposed budgets emphasized infrastructure development.

ETHIOPIA

Ethiopia's mineral industry contributed a modest 1% to the gross national product (GNP), estimated at $4 billion during 1980.[4] Salt, cement, and gold continued to be the most valuable commodities, accounting for approximately 90% or $40 million of the total value of minerals produced in 1980. Cement production accounted for nearly one-half of the mineral industry revenues realized by fiscal yearend 1980.[5] The value of other mineral products grew by approximately 35% over that of the previous fiscal year, owing primarily to increased salt and gold production and high world market prices for precious metals.

A cement plant contract was concluded in September 1980 for the construction of a 1,000-ton-per-day facility at Mugher, in the Menagesha Province. The Ethiopian Building Materials Corp. was constructing the plant and projected a startup date of 1984. The cost of the project was estimated at $96 million with joint financing by Ethiopia (60%) and the German Democratic Republic (40%). Plans were made to minimize cement imports (approximately 1 million tons in 1979) by expanding cement production capacity to 300,000 tons per year. Long-range plans included the construction of a fifth cement plant near Dire Dawa, during which time the three existing, 30-year-old plants would be updated or phased out.

There was a 50% increase in gold production between 1979 and 1980, owing primarily from the increased workings of the Adola alluvial deposits. During the same period, the gold washing pilot plant located at Nejo in western Ethiopia and under the supervision of a United Nations consultant, increased the number of sluiceways from four to nine. The annual output from the pilot plant was approaching 2 kilograms of placer gold by yearend 1980.

Mineral prospecting was conducted for gold, copper, nickel, potash, raw materials for construction and glass industries, petroleum, and other energy resources. Potash prospecting in the Dalol area of Tigre was carried out by the Ralph M. Parsons Co. An attempt was made to construct a deep mine, utilizing the room-and-pillar method. A 92-meter shaft was sunk and drives were made totaling 805 meters. The ore body was described as a mixed potash-salt evaporite with reserves of about 80 million tons. The deposit site had good transportation potential since it was 70 kilometers from the Red Sea port of Mersa Fatima.

Copper prospecting was conducted in the Nejo area of Welega during 1980 and over the past decade in the Debarwa area. The main copper minerals found included bornite and covellite, with minor amounts of chalcopyrite. One of the 1981 proposed projects of the Eastern and Southern African Mineral Resource Development Center (ESAMRDC) included increasing copper exploration and updating a 1974 copper feasibility study. ESAMRDC was also expected to carry out a feasibility study and recom-

mend a method for the exploitation of diatomite resources in the Ethiopian Rift Valley.

Geothermal exploration and deep drilling preparations were made, with financial assistance expected from the European Economic Community and the United Nations. Exploration work was also targeted for the Alufu Volcanic Center in the Rift Valley Lakes area and in the Dallol-Danekil Depression.

Intensive petroleum exploration was conducted in the Ogaden area, southeast Ethiopia, and along the Red Sea coast. A total of 14 deep holes were drilled in the Ogaden and 16 in the Red Sea, with approximately one-half of the total drillings showing oil and/or gas. A most promising hole was drilled at Calub in the Ogaden. The penetrated gas reservoir was estimated to extend 19 kilometers long, 8 kilometers across, and contain 45 billion cubic meters of gas, 75% of which was thought to be recoverable.

Large crude oil imports of approximately 3,310,000 barrels in 1980 consumed roughly one-half of the Nation's export revenues. Coffee and, to a lesser extent, other agricultural products were the principal foreign exchange earners. Ethiopia's overall 1980 trade deficit was approaching $200 million, and the Government budget deficit was projected to exceed $450 million. The budget was expected to be financed 49% by internal borrowing and 51% by external loans and grants.

During 1980, Ethiopia received approximately $3 billion in mostly military aid from the Soviet Union and approximately $220 million from the Western industrialized nations for infrastucture development. The mining sector of the economy continued to be underexploited and hampered by the country's poor political, economic, and investment climate.

LESOTHO

The Kingdom of Lesotho, one of the world's least developed countries, continued to be heavily dependent on the remittances of Lesotho workers in South African gold and coal mines. Earnings from abroad comprised 41%, and foreign assistance constituted approximately 30% of the 1980 GNP. The value of mineral production, primarily from diamonds, was approximately 6% of the GNP, estimated at $544 million during 1980.[6] Stone, sand and gravel, and bricks continued to be produced on a small scale.

De Beers Consolidated Mines Ltd. (South Africa) produced approximately 51% of Lesotho's diamonds at the Letseng-la-terai Mine. The number of carats recovered by the De Beers operation increased by 15%, and the volume of rock undergoing treatment increased 12% between 1979 and 1980. The grade fell from 3.09 to 2.82 carats per ton, but there was an increase in the average diamond size. The plant throughput was near capacity at 150,000 tons per month, and roughly 13% of the production was hand sorted. The ore reserves were estimated at 9 million tons between the main and satellite pipes, and the mine life was projected to be about 8 years.

The Government was considering the establishment of another diamond pipe mine at Kao, just west of the Letseng-la-terai Mine. The Kao pipe was being worked by Lesotho smallworkers. (Smallworker is a term used to describe a limited number of independent miners, working individually and/or in small groups. This number differs in various countries.) The Lesotho Government received a 10% diamond export levy (equivalent to approximately $2.5 million) and owned 25% of the equity in the De Beers mining operation during 1980.

A United Nations team searched Lesotho's Maluti Mountains for uranium. Traces of uranium were found and samples were sent to the capital, Maseru, for laboratory analyses. The final report on the uranium finds and confirmed deposits were being withheld.

Lesotho's large and growing trade deficit, primarily with the Republic of South Africa, was approaching $350 million by year-end 1980. External aid was projected to total $140 million for fiscal year 1981-82. The bulk of Lesotho's new 5-year plan (1980-85) was expected to be financed by the following major aid donors: The United Kingdom, the Republic of South Africa, the United Nations, the Commonwealth Development Bank, and the African Development Bank. The 1981-82 budget emphasized infrastructure development. The Federal Republic of Germany and the Abu Dhabi Fund for Arab Economic Development were expected to help finance the construction of a new airport project.

MALAWI

Malawi's mineral industry continued to be confined to cement and industrial minerals production. Large-scale exploitation of limestone resources; small-scale mining of clays, stone, sand and gravel; and smallworker lime and gold prospecting were the major activities in 1980. Exploration and initial analyses were conducted for known uranium, coal, phosphate, strontianite-monazite, vermiculite, and glass sand deposits. The Malawi Geological Survey conducted explorations for coal and industrial minerals. Private sector exploration for uranium was halted temporarily during the year, pending the enactment of more favorable mining legislation early in 1981.

Portland Cement Co. (Malawi) Ltd. reported a 31% decline in 1980 cement production from that of the previous year, owing primarily to mill breakdowns. A new mill was installed late in 1980 and production was expected to resume to normal levels early in 1981. A feasibility study for a second cement plant near Kasungu was undertaken by Cementia Engineering Consulting Ltd. (Switzerland). Press Holdings Ltd. was awarded the contract for implementing the cement project.

The agricultural sector comprised approximately 40% of the GDP estimated at $700 million in constant 1973 prices, 90% of the export earnings, and 50% of the total employment in 1980. The growth rate of the economy decreased 0.6% in terms of real GDP between 1979 and 1980. This was attributed to the declining growth in agricultural production and depressed international prices for tobacco and tea, the country's leading exports.

The 1980 balance-of-payments deficit

represented by net reserve figures worsened in 1980 to approximately $55 million. The increased budget deficit, increased oil import bills, and the necessary expansion of debt servicing were all contributing factors. The large 1980-81 development budget, financed primarily with foreign loans, targeted approximately 50% of the expenditures for transportation, agriculture, and education. Malawi's trade deficit, primarily with the United Kingdom, the Republic of South Africa, and other Western Nations was estimated to exceed $80 million by yearend 1979. International assistance agreements concluded in 1980 included the International Monetary Fund (IMF) 2-year, $65 million balance of payments assistance; World Bank 1-year, $30 million structural readjustment loan; and European Economic Community 5-year, $120 million loan.

MAURITIUS

Mauritius, an island of volcanic origin located approximately 800 kilometers east of Madagascar in the Indian Ocean, was severely affected by four cyclones in early 1980. The country was the world's 10th largest sugar producer, and sugar contributed approximately 35% of the GDP, 75% of exports, and 30% of employment by yearend 1979. Adverse weather conditions resulted in flooding and a 35% decline in 1980 sugar production. Floods were also responsible for inhibiting the small-scale mineral production and transportation of the island's mineral resources—stone (basalt), salt, and lime.

The most significant development in the Mauritian economy was the October 1979 23% devaluation of the rupee against the IMF Special Drawing Rights. The net effect of the devaluation and other restrictive monetary and fiscal policies imposed by the IMF was to raise domestic inflation to approximately 40% at yearend 1979 and make Mauritian exports more competitive in international markets. The IMF loan of $980,000 and $1.8 million worth of aid from the Republic of South Africa were expected to help the growing balance-of-payments deficit, estimated at $126 million by yearend 1980.

REPUBLIC OF COMOROS

The Comoros island archipelago was classified as a low-income developing country with an estimated GDP of $50 million. There were no known exploitable mineral deposits in 1980, and only small amounts of sand and gravel were mined for local consumption.

The Republic of Comoros became a member of the ESAMRDC in 1977. The first ESAMRDC work program was outlined in 1980 and included among its proposed projects the evaluation of geothermal energy resources in the Comoros. The United Nations Development Program (UNDP) recently completed a geothermal project, but no information was available by yearend 1980.

The growing balance-of-trade and budget deficits were supported primarily through unilateral aid programs (France, Kuwait, and Madagascar). Most of the assistance proposed for 1980-81 focused on improving transportation infrastructure. Numerous Arab Regional Banks and Development Funds have indicated an interest in offering financial assistance.

REUNION

The Department of Reunion is a French island located approximately 640 kilometers east of Madagascar in the Indian Ocean. Reunion's predominantly agricultural economy experienced a slowdown in 1979-80 owing primarily to a decline in sugar production. Construction and public works also experienced difficulties, which resulted in the closing of a number of important companies. Unemployment was estimated at 31.5%, and approximately 50% of the population was under 25 years of age. The mineral industry continued to be confined to the 200,000-ton-per-year clinker cement grinding plant at Saint Denis. Production and consumption data were unavailable for cement and other domestically consumed construction materials.

Reunion's trade deficit, represented by the value of imports divided by the value of exports, was projected to reach 20% by yearend 1980. Reunion imports 80% of what the island consumes; however, unlike most nonoil-producing developing countries, the share of fuel imports have been minimized. The island's hydroelectric power potential was nearly 500 million kilowatt-hours by yearend 1980. The Rivière de l'Est powerplant, located at Saint Rose, was completed and commissioned during the year. The first stage with 44,000 kilowatts of installed power was expected to yield an average annual production of 380 million kilowatt-hours, slightly exceeding 1980 energy consumption requirements.

RWANDA

Rwanda's mineral industry continued to be a small yet significant contributor to the GDP, estimated at $1.1 billion in current 1980 prices.[7] During 1980, the value of mineral production was second only to coffee in terms of GDP. Mineral exports provided approximately 25% of the 1980 foreign exchange earnings and when combined with coffee, they comprised roughly two-thirds of the Nation's total exports. Rwanda produced approximately 1.1% of the world's output of tin concentrates and also produced cassiterite, beryllium, columbium-tantalum, wolframite, and alluvial gold. The mineral industry started showing signs of recovery in 1980, after the industry's downturn and stagnation during the late 1970's. Cassiterite and tungsten production were reported to have moderately increased, beryl and columbite-tantalite production increased by over 25%, and the output of gold increased a hundredfold between 1979 and 1980.

Société Minière du Rwanda (Somirwa) continued to operate the major mines, employing between 8,000 and 9,000 workers and accounting for approximately 70% of total mineral production. The remainder of the output was mined by the tens of thousands of tributors. These individuals, and/or small cooperatives, exploited the small valuable mineral pockets scattered throughout the country (mostly gold and cassiterite). Somirwa had a 5-year development budget of $11.8 million, which was depleted by only slightly over 10% by yearend 1980. Strong financial support by the Government and foreign investment incentives, including tax holidays and duty-free import privileges for new industrial operations (5-year maximum), have facilitated the growth of the mineral sector of the economy.

Detailed followup studies of UNDP's geophysical and geochemical surveys were underway. The French Bureau des Recherches Géologiques et Minières, partly funded through UNDP, was concentrating investigations on 2,100 square kilometers in the central northern part of the country. Evaluations of the Mushunga limestone deposits were completed in 1980. Discussions for the construction of a 50,000- to 100,000-ton-per-year cement facility adjacent to the deposits in Cyangunzu were initiated. Construction of a 12-megawatt power station near Lake Luhonde commenced after the Geological Survey completed the evaluation of the country's extensive peat deposits.

The growing trade deficit of approximately $57.4 million in 1980 was a product of supply shortages, declining exports, and increasing oil import bills. The balance-of-payments surplus reported in 1979 was attributed to international financial assistance primarily through the 5th European Development Fund (Lome II) and aid programs with the Federal Republic of Germany, France, Japan, and several Arab Nations.

SEYCHELLES

The only mineral commodity produced and exported in Seychelles during 1980 continued to be guano. The mineral industry contributed less than 1% to the 1980 GDP estimated at less than $100 million.[8] The value and production of guano declined by 27% and 35%, respectively, between 1979 and 1980. Discussions were underway between the Seychelles Government and an Italian firm to exploit the islands' valuable 600-million-year-old granite resources.

The Assab refinery significantly contributed to the availability of domestic oil products and exported nearly 75% (1.4 million barrels) of the black naphtha produced in 1980. Oil explorations by AMOCO Seychelles Petroleum Co. continued throughout 1979-80. By yearend 1979, AMOCO in participation with other foreign oil companies possessed the rights for 24 offshore blocks. The partners withdrew and AMOCO expanded their exploration area to 26 blocks. The first test well drilled in 1980, was Owen Bank No. 1, located offshore Mahe, Seychelles' largest island. The cost was estimated to exceed $14 million. Plans were made to conduct future drillings on the Reith Bank, closer to the Mahe island.

Seychelles is strategically located off East Africa in the middle of the Indian Ocean, and the islands have excellent harbor facilities. Tourism and international assistance have largely contributed to the record balance-of-payments surplus of approximately $7.3 million by yearend 1980. Discussions were underway with the World Bank to lend financial assistance to the Seychelles East Coast Reclamation Project. Nearly 21% of the country's 1980-84 development budget was allocated for this comprehensive road, harbor, and port facility improvement plan. A contract was signed in 1980 with Zanen Verstoep Co. (Netherlands) to dredge and initiate reclamation work at Port Victoria and Mahe Quay.

SOMALIA

Mineral production in the Somali Democratic Republic was confined to small-scale mining of tin (cassiterite ore), sea salt, stone, limestone, and meerschaum (sepiolite). The mineral industry continued to be a very small contributor to the Nation's economy. The construction of a 200,000-ton-per-day cement facility in Berbera was near completion, and discussions were underway to construct a fertilizer plant by yearend 1980. Exploration continued on the prospective uranium, coal, and lead deposits in the northern part of the country.

The Somali Arab Mining Co. (a joint venture with the Pan-Arab Mining Co.) was investigating the economic feasibility of uranium mining at Galgudad. Other uranium prospecting continued, including a radiometric survey of the Nagal area. In addition, an 85,000-square-kilometer area located between Kolkodo and Modok was reported to contain commercial uranium deposits. Pilot-scale tests were being planned for several sites, and the Arab Community Fund was expected to finance a uranium processing plant. Somalia's Geological Survey continued the search for coal in 1980.

Oil explorations were intensified, since petroleum imports accounted for $43 million in 1980. During June 1980, the International Development Administration (IDA) granted $6 million in credit for a Petroleum Exploration Promotion Project. Agreements were negotiated between Somalia and Cities Service Co. (United States), Texaco Oil Co. (United States and Federal Republic of Germany subsidiaries), and Atlantic Richfield Oil Co. (United States) to explore nearly 750,000 square kilometers throughout Somalia.

Somalia's overall energy future looked promising in 1980, despite the dependence on Iraqi crude oil imports. Production at the recently completed Magadiscio oil refinery was brought close to capacity of 10,000 barrels per day. Approximately 1.8 million barrels of crude oil and oil products were imported primarily from Iraq and later in the year from the People's Democratic Republic of Yemen. The completion of the Gezia power station increased Somalia's electric power generating capacity by nearly 92% early in 1980.

Somalia's balance-of-payments deficit continued to worsen in 1980 owing primarily to the influx of refugees and the extended drought. Approximately 30% of the GNP, estimated at $407 million in 1980, was comprised of livestock and agricultural

products. International and bilateral assistance continued to keep the country afloat in 1980, despite the acute lack of foreign exchange, near fuel crisis and exorbitant rates of domestic inflation. In August 1980, the United States agreed to give $40 million in military aid and $5 million in economic assistance to Somalia over a 2-year period in return for access to the port and airbase facilities at Berbera. Approximately $132 million was provided for refugee and related development assistance in 1980, primarily through the United Nations and other Western and Arab countries' bilateral assistance programs.[9]

SWAZILAND

The value of Swaziland's mineral industry continued to decline, contributing less than 15% to the 1980 GDP, estimated at $385 million.[10] The percent change in mineral revenues between (1979-1980) was negative for nearly all mineral commodities including iron ore, asbestos, and quarried stone except for anthracite coal. The decline in revenues was attributed primarily to the cessation of the Ngwenya iron ore exports in August 1980, diminished production and sales from the Havelock asbestos mine, and decreased demand for quarry stone. The chrysolite asbestos mine at Bulembu, northwest Swaziland, became the Nation's leading mineral export in 1980, despite the mining of lower grades (larger proportion of short asbestos fibers over higher priced long fibers) encountered at increasing depths.

By yearend 1980, coal appeared to be the mineral commodity with the most promising future. The majority of the identified reserves of approximately 200 million tons were considered to be chiefly of the type with low sulfur and high energy content. Swaziland Coal Corp.'s only existing mine, Mpaka Mine, exported roughly two-thirds of its production and expansion plans were being considered. In addition, two new coal mines in eastern Swaziland were proposed. Several foreign firms indicated an interest in prospecting for tin, gold, diamond, and kaolin as well as coal. The regional geochemical sampling program was completed, and a report was published indicating potential mineral occurrences of copper, lead, zinc, manganese, cobalt, nickel, molybdenum, and tin.

The Swaziland Geological Survey and Mines Department continued to investigate coal deposits in the Lowveld and encouraged joint venture participation with foreign firms. The Japanese and Swaziland Governments were negotiating respective financial and supervisory roles for the deep coal exploration and drilling project at Libhuku, within the Lowveld. Shell Coal Swaziland (Pty.) Ltd. submitted a mining rights application, after completing the shaft and underground mine development work at Mhlume. Mining rights were granted to Swaziland Coal Corp. for a promising 760 hectares in the Lowveld. A new Special Exclusive Prospecting License for a 115,000-hectare area in the southern portion of the Lowveld was transferred from Inter-Coal Trading A.G. Ltd. to Inter-Coal Mining and Trading Ltd. (Switzerland).

Evaluation of residual tin deposits with assistance from the Federal Republic of Germany continued in the Makwanekop-Motshane and Sinceni areas. A small-scale pilot treatment plant was constructed and operated at Sinceni during 1980.

Swaziland's balance-of-payments continued to worsen in 1980 owing primarily to slow growth in export volume, rapid rise in import expenditures, an increasing Government budget deficit (covered by foreign financing), and a gradual decline in worker remittances from South African mines. The economy was expected to be stimulated in part by increased capital spending in the public sector, expansion of the country's hydroelectric power systems, and completion of the North-South rail line. A 20-megawatt hydroelectric power station with a 90-million-kilowatt-hour annual capacity was proposed in the Sipocosini area. The Swaziland Railroad Co. was awaiting Government approval for the construction of the northern railroad link to Komatipoort. The railroad was operating at a loss because of the decline in iron ore shipments, but the completed rail system was expected to recover from mineral and agricultural product traffic from the South African Transvaal and from anticipated Swaziland coal shipments from the Tshaneni area.

UGANDA

Uganda's mineral industry and overall economy stagnated during 1979-1980. Despite promises made by the transition and new Government to rehabilitate the mining sector, tungsten, cassiterite, columbite-tantalite, phosphate, gold, cement, and asbestos production virtually ceased. The three previously operating tungsten mines at Bjorda, Luhizha, and Buyaga; the Buhanga tin mine; gold mining in the Mushanga, Busia, and Kigezi areas; the Toros cement plant; and the Universal Asbestos and Plastics Co. manufacturing plant all suffered from severe shortages of machinery, equipment, and replacement parts. These factors, combined with transportation difficulties through Kenya's Port of Mombasa and a lack of vehicles and/or foreign exchange for private road haulage, contributed to the sharp decline in mineral production and trade during the year. In December 1980, the new Government granted full tax holidays for industrial enterprises (over defined periods of time) to induce investment in mineral and other industrial activities.

Investigations to rehabilitate the Kilembe copper-cobalt mine continued throughout the year. The mine's cobaltiferous tailings that have accumulated during the mine life (1956-77) were estimated to contain between 1.41% and 1.44% cobalt, 38% iron, and minor amounts of gold and silver.[11] The Ugandan Government, which owns 100% of the Kilembe Mine, invited tenders to contract for both the rehabilitation of the mine, concentrator, and smelter facilities and the establishment of a cobalt project, including downstream recovery of sulfuric acid.

In December 1980, a memorandum of agreement was signed with Falconbridge Nickel Mines Ltd. (Canada) to undertake two feasiblity studies addressing the mine reopening and cobalt concentrate processing and marketing. The contract specified that mineral production would belong to the Ugandan Government and Falconbridge Nickel Ltd. would receive the exploitation rights only. No other details were disclosed by yearend 1980.

The Lake Katwe Salt Co. opened a 150-ton-per-day salt manufacturing plant in June 1980. The main contractor for the facility was a West German firm, and financing was provided by the Federal Republic of Germany, the East African Development Bank, the African Development Bank, and the Ugandan Development Corp. Anticipated annual production included 45,000 tons of common salt, 15,000 tons of potassium chloride, 500 tons of elemental sulfur, and other chemicals. The economic viability of the salt pan was estimated at 20 years.

Uganda's balance-of-payments deficit was estimated at $200 million by yearend 1980.[12] IDA financed $8 million worth of technical assistance for the Ugandan Government to prepare rehabilitation and development projects. The African Development Bank and Iraq granted approximately $18 million primarily for ranch restorations and other development projects. Discussions were underway with the various United Nations organizations and the European Common Market for additional assistance.

BENIN

Said to be one of the world's most underdeveloped countries, Benin had a gross national product (GNP) estimated at $1 billion in 1980.[2] Contribution of the mineral industry such as cement and limestone to the GNP was negligible, but exploration of mineral potential continued.

Minerals.—The United Nations Development Program (UNDP) conducted an investigation of three deposits from 1977 to 1980: Phosphates (Mekrou), gold (Perma), and chromite (Buem). A phosphate rock deposit containing about 4.5 million tons recoverable by opencast techniques was discovered. It was not known if the gold and chromite deposits were recoverable economically. Iron ore deposits of some 230 million tons near Loumbo-Loumbo are at present not exploitable because of lack of infrastructure in the northern part of the country. Geologic mapping with British and French assistance was also pursued in 1980.

Electric Power.—Power was mostly imported from Togo and Ghana. However, it was decided to expand the capacity of the Cotonou thermal powerplant by 15 megawatts. The Government also decided to call for bids for a dam project with a hydroelectric powerplant of 60 megawatts on the Mono River near Nangbetou.

Kaolin.—The Ceramic Experience, of Chester, W. Va. (United States), sponsored by the United Nations Revolving Fund, made a series of testpits at an unspecified location, indicating about 50,000 tons of kaolin in an area of 10 acres, with further indications over another 60 acres.

Petroleum.—The Norwegian Government approved a $104 million loan to finance development of the small offshore Seme Oilfield. The field is being developed by Saga Petroleum AS of Norway; Kvaerner Engineering, also from Norway, manages the project. Reserves were only 3 million tons, and production was to start in 1982 at the rate of 250,000 tons per year. In the meantime, Mechanical and Industrial Technicians (United States) signed a letter of intent to build a reported $900 million oil refinery with a capacity of 8 million tons per year in partnership with the Government.

eEstimated. pPreliminary. rRevised. NA Not available.

[1]Includes data available through Oct. 12, 1981.

[2]In addition to the countries listed, The Gambia, Guinea-Bissau, and Upper Volta, which are covered in the text of this chapter, presumably produce modest quantities of a variety of crude construction materials (clays, stone, and sand and gravel) and may produce minor amounts of other mineral commodities (most notably gypsum, lime, and salt), but output is not reported quantitatively and available information is inadequate to make reliable estimates of output levels.

[3]In addition to the commodities listed, modest quantities of unlisted varieties of crude construction materials (clays, stone, and sand and gravel) presumably are produced, but output is not reported quantitatively and available information is inadequate to make reliable estimates of output levels.

[4]Output apparently based entirely on imported clinker.

[5]Products marketed under the trade names "Balifos," "Phospal," and (in 1980 only) "P 125" (the latter described as crushed aluminum phosphate).

CAPE VERDE ISLANDS

Mineral production on the Cape Verde Islands was limited to modest quantities of crude construction materials, such as clays, stone, sand and gravel, and some solar evaporated salt. GNP in 1980 was an estimated $135 million,[3] with minerals contributing negligible amounts.

In 1980 Cape Verde awarded a $118,000 contract to a South African company to build a seawater desalinization plant.

THE GAMBIA

The Gambia consists of the shores of The Gambia River and is surrounded on land by Senegal. In 1980, The Gambia had no mineral production besides unreported quantities of crude building materials. However, there were several tentative mineral projects, as mentioned hereinafter. In 1980, estimated GNP was $200 million.[4] Contribution of minerals to the GNP was negligible.

Energy.—The hydroelectric project on The Gambia River, supported by the African Development Bank, continued and was to be commissioned in 1981. One of the dams is located at Mansa Konko.

Petroleum.—Chevron Overseas Petroleum Company (United States) and Compagnie Française des Pétroles S.A. (Total) completed a 2-month offshore drilling program, but results were not made known. Chevron reportedly intended to retain its exploration and prospecting license in The Gambia.

Titanium.—Recently explored deposits of heavy beach sands south of The Gambia River contain about 5 million tons of zircon, rutile, and ilmenite, and further upstream kaolin has been known, but no plans for industrial exploitation have been published.

GUINEA

In 1980, Guinea's centrally controlled economy, dominated by the mineral sector, leveled off. The GNP was $1.5 billion.[5] The mineral sector accounted for 23% of the GNP and 95% of export earnings, with bauxite remaining the most important mineral. Liberalization of the Guinean economy continued with the publication of a new investment code and the country's fourth development plan (1981-85). In the mineral sector, foreign investors were encouraged by the Government of Guinea in the hope that they would contribute to the development of iron ore, uranium, and gold in the near future, and of petroleum, copper, manganese, and other minerals at a later date.

Bauxite and Alumina.—In 1980, Guinea was the world's second largest producer of bauxite, and its reserves of 6.5 billion tons were the largest in the world.

The country's largest bauxite producer was the Compagnie des Bauxites de Guinée, owned by the Government (49%) in partnership with a consortium composed of the Aluminum Co. of America, the Aluminum Co. of Canada, Martin Marietta, Péchiney, Vereinigte Aluminiumwerke AG, and Montedison. In 1980, the company produced 9 million tons of bauxite for export at the Boké-Sangaredi mining complex located in the northwest, at the terminal of the Kamsar-Sangaredi Railroad line.

The second largest producer was the Office des Bauxites de Kindia, a Government-owned, Soviet built and managed project. In 1980 production was 2.5 million tons. Ninety percent of production was contracted to the Soviet Union and the rest to Eastern Europe. The mine is located at Kindia, on the Conakry-Kankan Railroad line.

The third largest producer of bauxite was the Société d' Économie Mixte Friguia owned by the Government (49%) and Frialco Co. (51%), the latter consisting of Noranda Mines Ltd. (38.5%), Pechiney-Ugine-Kuhlmann (36.5%), British Aluminum Ltd. (10%), and Vereinigte Aluminium Werke AG (5%). Over 2 million tons of bauxite were mined at Fria, at the terminal of the Conakry-Fria Railroad line, and converted at the same location into 660,000 tons of alumina. The alumina plant was being expanded to 700,000 tons of alumina per year at a cost of $33 million.

Besides these existing operations, others were in various stages of planning, involving deposits at Ayékoyé near Boké (northwest) and at Tougoué and nearby Dabola, in central Guinea.

Cement.—A $12 million grinding plant to produce bagged cement from imported clinker was completed but lay idle because of a power shortage.

Diamond.—In 1980, the Bourse Nationale des Diamants, in the name of the Government's Central Bank, held its first auction since the early 1970's, selling 6,000 carats valued at $1 million. This production came from private Guinean operators who were given permits to operate near the rich diamond concession of Beyla in the southeast.

Among a number of diamond mining concessions awarded in recent years were those of Industrial Diamond Co. of the United Kingdom, with an area covering 30,000 square kilometers, and Charles Anthony of the United States, covering 20,000 square kilometers.

Reportedly, diamond reserves in 1980 were estimated at 300 million carats worth $40 to $60 billion.

Gold.—The Société Minière Internationale du Quebec (Somiq) announced plans to develop a gold deposit in Guinea. An exploration program was conducted under lease rights covering a 39,000-square-kilometer area in the northeast of the country. Somiq plans to develop shallow alluvial deposits in the area.

Hydroelectric Power.—The Government, the World Bank, Arab funds, and a number of aluminum companies, including Alusuisse, Péchiney, and Vereinigte Aluminiumwerke AG, met in 1980 to discuss ordering feasibility studies for a 750-megawatt hydroelectric project and a 155,000-ton aluminum smelter worth $2.5 billion, both at Konkouré. It was decided that further studies were necessary to evaluate the effect of the project on the Guinean economy.

Iron Ore.—The Mifergui-Nimba iron ore project in southern Guinea moved closer to realization as its prospective partners, the Government (50%) and unnamed foreign interests (50%), reached an agreement with Liberia on transport charges for the movement of iron ore across Liberia on the existing Liberian-American-Swedish Minerals Co. railway to the Port of Buchanan.

Petroleum.—Société Guinéenne des Hydrocarbures, a joint venture between the Government of Guinea and Union Texas Petroleum (United States), conducted a seismic survey in the northern third of Guinea's territorial waters in the fall of 1980. It was expected that decisions on drilling will

be made on the basis of the surveys when results are available. Negotiations for other offshore concessions were underway. At present, Guinea has no petroleum production.

Uranium.—The Compagnie Générale des Matières Nucléaires (Cogema), a French, Italian, and Japanese joint venture, continued to explore for uranium in the north (above 110° N latitude). Traces of uranium were found there, but it was not yet known if any deposits are of commercial value.

Geosurvey, a geological research company, conducted aerial surveys in the southern part of the country, with results not known. Besides these, the Government asked Romania, the Federal Republic of Germany, Switzerland, and Yugoslavia for technical assistance to conduct ground surveys for radioactive minerals.

GUINEA-BISSAU

In 1980, Guinea-Bissau continued to have major economic problems but was completing an ambitious development plan. GNP was $174 million.[6] There was no mineral industry production, but several mineral projects were in various stages of development.

Aluminum.—The Government was considering a modern aluminum industry using its bauxite resources in the Boe region. This project is in the distant future and depends upon the feasibility of the proposed Corrubal River Dam as an energy source. The UNDP was conducting feasibility studies.

Petroleum.—A potential of 7 to 8 million tons per year has been estimated for the offshore Boe region. However, sensitive territorial water disputes with both of Guinea-Bissau's neighbors, Guinea and Senegal, must be solved before exploitation can begin. The World Bank has offered help in financing exploration on the Continental Shelf.

Phosphate.—The Government, in conjunction with the French Bureau de Récherches Géologiques et Minières (BRGM), was studying phosphate deposits in Cacheu and Oio.

IVORY COAST[7]

The Ivory Coast witnessed its economic growth stagnate at about 1.5% annually—down from more than 9% during the years of the robust coffee and cocoa markets of the mid-1970's. The nation's oil bill climbed to about $450 million in 1980 from $200 million 2 years earlier, and debt services stood at 30% of its entire export earnings.

Mineral exploration efforts of the Ivory Coast state oil company Société Nationale d'Operation Pétrolière de la Côte d'Ivoire (Petroci), Société pour le Développement Minière de la Côte d'Ivoire, and the BRGM of France continued during 1980. These activities included aerial geophysical exploration and work on selected anomalies, which had been identified by these groups in the past several years. Their targets were mostly uranium, copper, lead, zinc, and silver. By the end of 1980 no further details of exploration results had been announced.

Diamond.—The Société Franco-Ivoirienne Tortiya, which operated diamond mines in the Ivory Coast, ceased mining in 1980 because of ore exhaustion. Thus, the only mine operation of any kind in the country came to an end.

Petroleum.—The Ivory Coast became the newest oil-producing nation in West Africa in 1980. During the year, production from the offshore Bélier Field became a reality, while appraising of the Espoir Field, one of the largest offshore fields found in West Africa, continued.

The Bélier Field, owned by Exxon subsidiaries (63.75%), Shell Côte d'Ivoire (21.25%), and Petroci (15%), is located about 20 kilometers southeast of Abidjan. It was put into production in mid-1980; crude oil was moved through a 10-inch pipeline to shore, where, by virtue of another 7-kilometer, 10-inch pipeline, it was delivered to Ste. Ivoirienne de Raffinage, the state-owned refinery. This field produced an average of 10,000 barrels per day late in 1980, but output was expected to rise to 30,000 barrels per day by the mid-1980's.

The Espoir Field, owned by Phillips Petroleum (57.5%), Italian Petroleum Enterprise-National Hydrocarbon Agency (22.5%), Sedco of the Ivory Coast (10%), and Petroci (10%), is located in the Gulf of Guinea 40 kilometers to the southwest of Abidjan, in water depths between 300 and 2,400 feet. During the year, Phillips, as operator, drilled six wells, in which the flow rate averaged 4,000 barrels per day. The find was certain to spur exploration

in deeper waters all along the West African oil province. Oil production from Espoir, expected by the mid-1980's, would enable the country to become not only self-sufficient in oil, but also an exporter by the late 1980's.

MALI

In 1980, Mali's mineral industry contributed only a small portion of the GNP of about $1 billion,[8] although there was a small increase in 1980. The industry consisted of a small gold mine operation, modest phosphate and salt mines, the quarrying of building materials, and grinding of imported clinker.

The Sindicat Franco-Malien de Récherches Minières, formed by Société Nationale de Récherches Minières (Sonarem) with the BRGM for geological exploration, was exploring for copper, gold, tin, and diamonds in various areas of the country.

Bauxite.—Péchiney made feasibility studies for mining bauxite in three areas between Kenieba and Bamako, believed to contain deposits of more than 1 billion tons. The Manantali River Dam project would provide the necessary electric power, if completed.

Gold.—Production started at the reactivated Kalana Mine at the rate of 400 kilograms per year, due to rise to about 1,800 kilograms per year. Reserves were estimated at 24 tons of gold. Mining was by the Government-owned Sonarem, with technical assistance from the Soviet Union.

Hydroelectric Power.—The Selinque Dam was partly operational in 1980, providing 9 megawatts in addition to 36 megawatts available previously. By 1982, capacity of the dam was to be 60 megawatts.

Iron Ore.—There were plans to develop two iron ore deposits in the southwest of the country, near the Senegal border. The Bafing-Makana deposit was estimated by Soviet geologists to contain 150 million tons of ore with 36% to 67% iron content. The Soviet group worked on feasibility studies for the deposit. The other deposit, located on the right bank of the Falème River an extension of the Senegalese Falème deposit, was investigated by the French BRGM, which estimated reserves of 8 million tons. Both deposits need improvements of regional infrastructure, such as the Manantali River power project, roads, and railroads, for exploitation to be economic.

Petroleum.—Esso Oil Co., Elf-Aquitaine, and Murphy Oil were all prospecting in various areas of the country in strata similar to the oil-bearing zones in neighboring Algeria. The Government was also preparing a geological map of the country with foreign assistance.

Phosphate Rock.—Sonarem, after having mined 2,000 tons per year of phosphate rock in the Tilemsi Valley, 150 kilometers north of Gao, was raising production to 10,000 tons per year; feasibility studies were continued on raising production to 240,000 tons per year. Reserves were estimated at 25 million tons with 27% P_2O_5. The French Fonds d'Aide de Coopération was also financing a project to extract 20,000 tons per year from the Tamaguillet deposit.

Uranium.—Japan's Power Reactor and Nuclear Fuel Development Corp. and Cogema, a subsidiary of France's Commisariat á l'Énergie Atomique (CEA), have both had exploration rights in various parts of the country and after several indications of the presence of uranium, continued their exploration activities.

NIGER

In 1980, Niger's economy, with an estimated GNP of over $2.5 billion,[9] continued its rapid growth, propelled, among other things, by the doubling of uranium production (1979 to 1980) and increases in the related transportation and service sectors.

The 650-kilometer-long "Uranium Road," to link the mines in the north of the country to existing road networks, was recently completed at a cost of $190 million. Foreign donors were financing the ongoing hard-surfacing of one section of the east-west axis that remained unpaved.

In 1980, the Government published its first 5-year plan, covering 1979 to 1983. For the mineral industry, the plan targeted large investments, while recognizing the important role of private enterprise and foreign investors in reaching its goals.

Coal.—The Société Nigérienne du Charbon was completing a $125 million coal mine and powerplant project at the Anou Araren deposit near the city of Agadés, estimated to contain 6 million tons of coal. Coal was already being mined and stockpiled in anticipation of startup in 1981 of a plant with a capacity of 16 megawatts, to double in the near future; coal output is to reach 200,000 tons per year. In its second stage, the electric powerplant will save one-half of the country's oil imports and supply the mining region plus the City of Agadés with power.

Petroleum.—Esso and Texaco Oil Co. negotiated with Elf-Aquitaine for performing additional exploration in the eastern Lake Chad and northern Djado regions. Recent exploration has been fruitless.

Tin.—The Société Minière du Niger produced about 80 tons of tin in cassiterite concentrates at two locations, Tarrouadji and Elmeki, in the Aïr Mountains. There were plans to expand operations.

Uranium.—In 1980, Niger was one of the world's largest producers and exporters of uranium, with Government earnings reaching $122 million, but this was expected to fall in 1981 as Niger's sales price drops closer to depressed world market levels. It was expected that uranium exports would continue to provide at least 75% of the country's foreign trade receipts in the near future. The Niger Government holds equity participation in all present uranium mining concessions through its National Minerals Office (Onarem), although this is not required by law and is apparently negotiable. Niger's estimated uranium reserves exceeded 160,000 tons and have attracted, to date, exploration efforts by 16 foreign companies from 9 different countries. Even as recently as mid-1979, there were three different groups planning to begin new mine construction. Included among these were the SMTT group, with operating permits and financing settled, the CEA group with plans for the Ajlit area, and a Nigerian-French-American (Conoco) consortium which planned to exploit the Imouraren deposit. However, as a result of the recent severe decline in world uranium prices, all three of these projects were postponed.

There were two operating mines in Niger in 1980. The first mine, Arlit, was located in the Aïr region in the northwest, and was operated by the Société des Mines de l'Aïr, a consortium that included the Government's Onarem (33%), CEA's subsidiary Cogema (27%), the Compagnie Française des Minerais de l' Uranium (11.8%), Mokta (7.6%), Minatome (7.6%), Urangesellschaft (6.5%), and Agip Nucléaire (6.5%). The Arlit deposit consists of a 20- to 25-meter-thick stratum of clay and sandstone with 0.25% U_3O_8 under a 40- to 50-meter overburden. It contains some coffinite with pitchblende. Capacity of the Arlit Mine was 1,800 tons of uranium in 1980 and is to increase to 2,300 tons in 1982.

The second uranium mine was the Akouta Mine, located 20 kilometers from the Arlit Mine. It is owned by the Compagnie Minière d' Akouta, a consortium composed of Cogema (34%), Onarem (31%), the Overseas Uranium Resources Development Co. of Japan (25%), and the Empresa Nacional del Uranio of Spain (10%). The underground mine exploits deposits at a 250-meter depth with 0.4% U_3O_8, but similar otherwise to those at Arlit. Capacity was 2,200 tons of U_3O_8 in 1980. The mine also produces 450 tons per year of molybdenum as a byproduct.

SENEGAL

In 1980, the Government launched a 5-year recovery program that it hopes will reverse Senegal's declining economic performance by financial constraint and a tight monetary policy. The plan was a condition for a $270 million, 3-year financing facility

from the International Monetary Fund, which dominated Senegal's economy. In 1980 the GNP decreased to $2.1 billion.[10] The mineral industry's contribution to this total was about 14%, consisting mainly of phosphates.

Iron Ore.—There were plans to develop an iron ore mine by 1987 at the Falème iron ore deposit, on the country's southeastern border, which was estimated to contain about 400 million tons of magnetite with 48% Fe, and 100 million tons of hematite with over 63% Fe. Feasibility studies indicate a production of 10 million tons of iron ore per year for 20 years. The project was undertaken by the Mines de Fer du Sénégal Oriental composed of the Government (28.5%), the BRGM (23.8%), Kanematsu Gosho (23.8%), and Krupp (23.8%). The BRGM is the project's operator.

Marble.—In 1980, the Société d'Exploitation des Marbres du Sénégal was formed to produce marble in eastern Senegal from reserves of 350,000 tons, which may ultimately be expanded to 1 million tons. The present small production is to be expanded to 30,000 tons of marble per year.

Petroleum.—The Government has not given up hope of finding oil in the country and was assisted in this effort by Chevron, Shell, and Elf-Aquitaine. In the meantime, a feasibility study was prepared for exploiting the heavy oil deposit in the coastal waters off Casamance, estimated to contain 100 million tons.

Phosphate Rock.—While phosphate production dropped 15% in 1980, because of slack demand, rising world prices pulled export earnings up 16%. To obtain added value from its phosphate resources, Senegal began construction in April of a phosphatic fertilizer complex, consisting of plants for the production of 560,000 tons of sulfuric acid, 220,000 tons of phosphoric acid, 45,000 tons of superphosphate, and 300,000 tons of ammonium phosphate; it will process 650,000 tons of phosphate rock per year. The project, termed Industries Chimiques du Sénégal, was slated for completion in 1984 and was expected to earn $110 million each year.

The largest of Senegal's two phosphate rock producers was the Compagnie Sénégalaise des Phosphates de Taïba, 50% Government-owned; the other owners were Coframines (BRGM) (15.6%), IMC (11.1%), Cofimer (7.8%), Omnium de Produits Chimiques pour l'Industrie et Agriculture (4.7%), the Caisse des Depôts et Consignations (4.5%), and Rhône Poulenc's subsidiary, the Compagnie Industrielle et Minière (2.9%). The mine is located at the Ndomour Diop deposit in the Tivouane area. Capacity is to increase from 1,650,000 tons of phosphate rock per year to 2,100,000 tons per year in 1982. Production was shifted in 1980 to the Keur Mor Fall pit, an extension of the Taiba deposit, involving a temporary drop in production to 1.3 million tons per year. Shareholders and France's CCCE financed the changeover. The second of two phosphate operations was that of the Société Sénégalaise des Phosphates de Thiés, also 50% Government-owned, with Péchiney as equal partner. The Pallo deposit near Thiés was the source of the production of about 120,000 tons of calcium phosphate and about 225,000 tons of aluminum phosphate in 1980, the latter being the only known such production in the world.

TOGO

In 1980 Togo's economy grew an estimated 8%, and the GNP was an estimated $850 million.[11] The mineral industry, producing mainly phosphate rock, contributed about 40% of the country's export earnings. In 1980, Togo's modern port at Lomé handled 1 million tons of cargo. A $40 million expansion of the port was underway and was scheduled for completion in 1981.

Cement.—In 1980, the Cimao cement clinker plant, located 80 kilometers north of Lomé, started operation. The 1.2-million-ton-per-year plant, jointly owned by the Governments of Togo, Ghana, and the Ivory Coast, used limestone from the 155-million-ton deposit at Tabligbo. An 80-kilometer rail line linked it to the Port of Lomé. Financing of the project was by the World Bank; it was hoped to double the plant's capacity in the 1980's.

Petroleum.—The Togolese Government continued to encourage oil exploration by interested companies, but no oil had been found by yearend. In the meantime, the country's 1-million-ton-per-year oil refinery, managed by the Government's Société Togolaise des Hydrocarbures, continued to operate on Nigerian crude and operated near capacity in 1980.

Phosphate Rock.—In 1980, in a major

reorganization of the Government-owned phosphate industry, the Government's phosphate mining company Compagnie Togolaise des Mines du Bénin, was joined with its phosphate-marketing unit, the Office Togolais des Phosphates, under the latter's name. In 1980, the industry shipped over 3.3. million tons of phosphate rock from deposits located near the coast in the Kahotoe and Kpogame areas where phosphate rock reserves were estimated to exceed 100 million tons. The crude rock was processed nearby at the Kpome processing plant, which was expanded in 1980 by a fifth processing line. In 1980, production is expected to reach 3.6 million tons.

UPPER VOLTA

In 1980, Upper Volta continued to be one of Africa's poorest nations, with no significant mining activity. The GNP was estimated at $1.1 billion[12] corresponding to a growth of 2.5% in real terms. Although the mineral sector contributed virtually nothing to the GNP, several mineral deposits were known or were being explored. Copper, molybdenum, lead, and zinc were known in the Boromo and Hunde regions, 200 kilometers southwest of the capital, where the UNDP was involved. Near the eastern frontier at Abobo-Djouna and Kodjari a potential for a phosphate deposit with possible reserves of 200 million tons was found.

Gold.—At the beginning of 1981, work started to reopen the Poura gold mine located 180 kilometers southwest of Ougadougou. According to feasibility studies reserves at the mine were estimated to contain 25 tons of gold. About 4 years of site preparations were necessary before mining can recommence. Two other gold deposits have been found in the country recently, one located at Kwademen in the south, and the other in the northeast. The UNDP assisted in the exploration.

Manganese Ore.—The Tambao manganese ore deposit, located in the northeast, was estimated to contain more than 13 million tons of high-grade manganese ore with 50% to 55% Mn, and a further 13 million tons of carbonate ore with 48% Mn. The property was leased to the Société Minière de Tambao by the Government, which owns 51% of the equity; the balance was owned by Thyssen AG (West Germany) and Tamco (Japan). Investment plans were postponed indefinitely because of high infrastructure costs (railroad, etc.) and uncertain world market conditions.

The Mineral Industry of the Islands of the Caribbean

By Doris M. Hyde[1]

CONTENTS

	Page		Page

Barbados	1201	Jamaica	1218
Bermuda	1206	Martinique and Guadeloupe	1224
Cuba	1207	Netherlands Antilles	1224
Dominican Republic	1212	Trinidad and Tobago	1225

There were no significant changes in the mineral industries of the smaller Caribbean Islands during 1980. Imported petroleum requirements continued to erode economic gains that may have occurred in other sectors. Some relief may be forthcoming as more qualified Caribbean countries take advantage of Trinidad and Tobago's petroleum product financing program (see Trinidad and Tobago). There were no crude oil discoveries in these areas during 1980, although some geophysical testing around the British Virgin Islands and Antigua was underway.

In March 1980, the Government of Antigua sold a 75% interest in the 16,000-barrel-per-day West Indies Oil Co. refinery to the Swiss Intermaritime Bank and Intermaritime Management Services for $6 million. The new refinery company is called the National Petroleum Co. Shutdown since 1976, it was originally planned for the refinery to reopen in 1980, but refurbishing has proved to be more extensive than anticipated. The reopening is now expected in 1981.

The Amerada Hess crude oil transshipment terminal on St. Lucia was not completed during 1980, but it was expected to become operational in 1981. Construction has not yet begun on the Hess refinery which would complete the planned petroleum complex on the island.

BAHAMAS

In 1980, the mineral industries continued to have little effect on the Bahamian economy which remains strongly influenced by the tourist and banking sectors. The real gross national product (GNP) was estimated at almost $1.1 billion in 1979, showing a real growth rate of about 8%, down from the 11% growth registered in 1978.

The Diamond Crystal Salt Co. reported that they will close down the salt facility on Long Island at the end of their fiscal year in September 1981. Both Diamond Salt Co. and Morton Salt Co., located on Great Inagua Island, suffered production setbacks because of a large tropical storm in 1979.

In 1980, it was reported that Lone Star

Industries, Inc., had agreed in principle to acquire for $11 million, a 50% interest in the 800,000-ton-per-year Bahamas Cement Co. The cement company was sold in 1978 to International Development Corp., S.A., by United States Steel Corp. which had closed the plant in 1977.

In December 1980, Geophysical Service Inc. (GSI), a subsidiary of Texas Instruments, Inc., received a contract for a nonexclusive seismic survey of areas between the Bahamas and Florida. The survey will involve about 2,500 line miles and include areas near Bimini, Cay Sal, and north of Grand Bahama Island. The information will be used by the Government to prepare for an offshore lease sale expected to be held about midyear 1981. Some petroleum experts believe there is a deep basin below the Bahamas that could offer a high oil potential. The permit issued to GSI is the first under the new petroleum regulations enacted in 1978.

The Charter Co. has apparently been successful in moving the Bahamas Oil Refining Co. to a more profitable position and has reportedly secured additional crude oil supplies from Alaskan sources.

eEstimated. pPreliminary. rRevised. NA Not available.

[1]Table includes data available through June 23, 1981.

[2]In addition to the countries listed, Antigua, Bermuda, Grenada, and St. Lucia presumably produced crude construction materials (clays, sand and gravel, and stone), but output is not reported and available information is inadequate to make reliable estimates of output levels. Antigua also has a petroleum refinery that was closed in 1976 but may be operational again in 1981.

[3]In addition to the commodities listed, other crude construction materials (lime, salt, and sand and gravel) may also be produced, but data on such production are not collected and available information is inadequate to make reliable estimates of output levels.

[4]Reported figure.

[5]In addition to the commodities listed, iron ore and manganese ore, both produced in significant quantities prior to the termination of publication of official statistics, presumably were produced during the period covered by this table, but available information is inadequate to make reliable estimates of output levels.

[6]Revised to none.

[7]Includes crushed volcanic rock, limestone, diorite, and quartzite used for building stone, aggregate, road construction, etc.

[8]Trinidad and Tobago initiated production of pig iron and sponge iron near yearend 1980 and may also have produced a small quantity of steel, but output is not reported and available information is inadequate to make reliable estimates of output levels.

[9]Less than 1/2 unit.

[10]Limited quantities of sulfur as a byproduct of natural gas may also be produced.

BARBADOS

Preliminary information indicates that in 1980 growth in the gross domestic product (GDP) was about 4% or 5%, in real terms, down from the 7.3% growth experienced in 1979 when the GDP reached $574 million. Nonfuel industrial mineral production has not expanded significantly and the sector exerts only a small influence on the economy which is dominated by tourism and agriculture. A heavy dependence on imports has also made Barbados susceptible to external economic changes and has complicated Government efforts to control factors affecting the domestic economy.

Crude oil production was valued at slightly over $3 million in 1979, but the 1980 value, estimated at $5.9 million, was substantially higher in view of significant price adjustments. First quarter figures for 1980 imported crude oil and partly refined oil

indicated a trebling of cost over the same period in 1979, mainly as a result of successive price increases during the intervening time. The Government continued to encourage an increased use of domestic natural gas resources. Only 48% of natural gas production was marketed or otherwise used in 1979, but in 1980 the Government began integrating natural gas into the power system of the Barbados Light and Power Co. to provide additional energy for home use and 53% of total production was consumed.

The 250,000-ton-per-year cement clinker grinding project to be jointly owned by the Governments of Barbados and Guyana has been cancelled. However, Barbados did join in a venture with the Government of Trinidad and Tobago to construct a similar facility. Construction was scheduled to begin in 1981 and be completed in 1983.

Interpretations of an offshore seismic survey begun in December 1979 indicated possible oil deposits. The potential reservoirs reportedly lie in areas where the water depth reaches 2,000 feet, a condition which would complicate drilling and recovery.

[4]Excludes quantities of glazed and unglazed ceramic tiles valued at $1,081,491 in 1977 and $350,221 in 1978.
[5]Excludes quantity valued at $1,760.

BERMUDA

The mineral industry on this tight cluster of small islands collectively known as Bermuda is practically nonexistent. It consists of minor quantities of sand and limestone used for local construction purposes. There have been no reports of companies interested in petroleum exploration in this area.

CUBA

Cuba ended its first 5-year plan (1976-80) with an overall economic growth rate estimated at 4%, lower than the 6% envisaged when the plan was formulated. Several unforseen factors combined to slow economic growth. They include: agricultural and animal diseases; increased energy costs; structural deficiencies in the administration of the various sectors of the economy, which resulted in inefficient management and low productivity; and a deterioration of terms of trade with countries not members of the Council for Mutual Economic Assistance (CEMA).

In regards to the latter, it has been estimated that non-CEMA trade terms, while for the most part sustaining volumes, have deteriorated by 53% during the last 5 years and resulted in less foreign exchange being earned than during the previous 5-year period. Cuba's balance of trade with non-CEMA countries indicates a trend toward more balanced exchanges, although still on the deficit side. Export trade with CEMA member countries has increased from 68% in 1975 to over 80% in 1979. The U.S.S.R.'s share of trade rose from 48% to about 67% during this period. Trade dependence with CEMA countries continues to grow, but Cuba's new economic plans include future projects designed to diversify and increase its trading opportunities with non-CEMA countries.

The rising cost of oil imports was one of the causes for Cuba's economic difficulties. In 1979, Cuba imported about 46.4 million barrels of crude oil, slightly less than in 1978. Early in 1980, Cuba reported that the cost of petroleum imports in 1980 was expected to be between $2.5 billion and $3 billion at current market prices. Since Cuba purchases petroleum through the U.S.S.R. at a discount, it is assumed that the actual cost to Cuba would be less than the above figure.

In early 1980, after strong self-criticism regarding administrative and economic deficiencies, Cuba began reforming its administrative structure. The reorganization emphasis was on establishing a clear centralization of command with the 13 members of the executive committee of the Council of Ministers dividing responsibility for the supervision, control, and coordination of all the ministries and State agencies.

In the latter part of 1980, laws were passed that affected industrial relations. Enterprises were given more control over the hiring of workers, a process which had been subject to various regulations obstructing timely, cost-efficient operations. Also, employees are now required to sign individual contracts defining their responsibilities. Piecework payment methods and bonuses have also been introduced in some instances, and this incentive measure may

be expanded if studies reveal favorable results.

In mid-1980, Cuba unveiled the new 1981-85 5-year plan that included references to the work and pay incentive measures later enacted and discussed above. The new plan also placed considerable emphasis on industrialization, including the development of mineral resources as raw material for future processing and end-use industries. Increased nickel and cobalt production were considered to be of strategic importance. The iron ore resulting from nickel extraction will eventually be utilized as the basis for a steel industry. Copper, along with the other metal production, will be used as material for establishing domestic machinery and equipment manufacture and decreasing or eliminating import needs. All of the industrialization set forth in the plan was not projected to occur during the 1981-85 period, but represents the first steps toward future planning.

Electrical power requirements were recognized in the plan and the construction of nuclear plants was advanced as the probable means to satisfy much of the future demand.

COMMODITY REVIEW

In 1980, Cuba continued to enter into cooperative projects with non-CEMA countries. It was reported that French companies have obtained the right to prospect for gold, lead, zinc, and other metals. Other French cooperative projects that may materialize include a fertilizer plant at Cienfuegos; a $500 million, 60,000-ton-capacity, stainless steel project in Oriente Province; and a thermoelectric plant at Santa Cruz del Norte. Financing arrangements and other specifics of any final decision to proceed with these projects have not yet been revealed. Bulgaria was reported to be increasing their assistance towards nonferrous metals prospecting in the Santa Clara region.

Metals.—*Iron and Steel.*—The second-stage expansion of the José Marti steel complex at El Cotorro was scheduled for completion in July 1981. This expansion will increase raw steel capacity to 350,000 tons per year and finished steel capacity to about 300,000 tons per year. A third expansion stage has been proposed that would bring raw steel capacity to 675,000 tons per year.

The first gray iron and malleable cast iron foundry in Cuba is under construction at the City of Guantánamo. Using Polish technology, this plant is projected to cost about $16 million. Output of machined elements, connectors for aqueducts, grating, and other items are expected to reduce demands for foreign exchange and eliminate delivery delays.

Nickel.—Cuba announced that construction at the new Punta Gorda nickel refinery has fallen behind schedule. Delays were attributed to labor problems, infrastructural deficiencies, and the management of the project. This plant, which is projected to have a 30,000-ton-per-year capacity of nickel oxides, was scheduled to come onstream in 1981, followed shortly thereafter by a second nickel oxide plant at Las Camariocas. Revised scheduling places the Punta Gorda plant onstream by late 1983, with full production of 30,000 tons per day by 1985. Then, if the planned expansions at the Nicaro (to 22,500 tons per year of nickel-cobalt oxides) and Moa (to 24,000 tons per year of nickel-cobalt sulfide) plants are completed, 1985 capacity from the three plants is expected to be 76,500 tons per year.

The Las Camariocas plant has also fallen behind schedule and may not be completed until 1990, at which time total capacity from the four plants would be 106,500 tons per year.

Nonmetals.—*Cement.*—In May 1980, the first production line of the new Karl Marx Cement Plant, in the Guabairo zone of the Cienfuegos Province, went onstream. The second and third production lines were to begin testing before the end of the year. This plant, with a projected cost of more than $205 million, has a capacity of 1.65 million tons per year.

A new cement plant was under construction adjacent to the 350,000-ton-per-year Rene Arcay Cement Plant. The new plant, basically an expansion of the Rene Arcay plant, was scheduled for completion in 1980 with an annual capacity of 1.4 million tons per year. Completion of this plant and the Cienfuegos plant will raise Cuba's total cement capacity to about 5.6 million tons per year.

Stone.—The new El Cacao Rock Crushing Plant, located near Santa Rita in Granma Province, and the Alacranes plant expansion in Matanzas Province, were scheduled for completion in 1980. The combined total capacity of these plants will be about 1.2 million cubic meters per year of crushed rock, processed sand, granite, and aggregate.

The sodium feldspar plant at Holguín was to go into operation in September 1980, after 4 years of construction activity and an estimated cost of $3.5 million. The plant will employ 58 workers to produce 18,000 tons of sodium feldspar per year. Output will be used as raw material for a glass packaging plant in Las Tunas and a sanitary fixtures factory in Holguín.

Mineral Fuels.—*Petroleum.*—Based on officially released Cuban statistics, revisions have been made regarding the production of crude oil and are reflected in table 1. Published information in trade journals continued to show considerable variance.

One of the important fuel-related activities in Cuba was the December 1980 agreement with Mexico for cooperation in petroleum affairs. The agreement provides for an exchange of petroleum products and derivatives, Mexican technical assistance in expanding the catalytic cracking section of Havana's Nico Lopez refinery to increase production of liquid gas, and a joint offshore exploration program of the continental shelf areas of the Yucatán Peninsula, Caribbean Sea, and an area north of Cuba. Exploration work was expected to begin immediately and include seismic surveys and drilling. This agreement marks Mexico's first foreign exploratory program.

As part of the French cooperative agreement mentioned earlier, Société Nationale Elf Aquitaine was awarded rights to explore for and produce petroleum. The Finnish State-owned oil company Neste Oy, was also reported to have been invited to negotiate for offshore exploration rights.

DOMINICAN REPUBLIC

Revised data indicate that the rate of growth in the GDP of the Dominican Republic in 1979 was 3.7%, in real terms, instead of the 5.3% estimated earlier. However, preliminary reports show the 1980 GDP at almost $2.9 billion, indicating a real growth rate of 5.6% for that year. The Dominican economy is subject to external economic influences, particularly world inflation and rising petroleum prices.

In 1979, the three major mineral commodities, bauxite, ferronickel, and doré bullion, accounted for about 31% of the total export earnings. In 1980, these three products accounted for an estimated 40% of total exports. This increase in mineral export value was due entirely to strong gains in the world market price of gold and silver. Despite a lengthy plant shutdown, ferronickel exports were off 18% in value owing to stock selloff and marginally increased prices. Export volumes of all three commodities declined in 1980.

Value of mineral exports (in millions of U.S. dollars)

Commodity	1977	1978	1979	1980[e]
Bauxite	22.0	23.4	20.9	19.8
Doré	59.6	76.9	127.8	259.5
Ferronickel	93.0	75.2	123.4	101.3
Total	174.6	175.5	272.1	380.6
Percent of total exports	22.4	26.0	31.3	39.5

[e]Estimated.

Petroleum import costs were less than anticipated early in 1980, but even so, increased from $315 million in 1979 to almost $449 million in 1980, accounting for about 31% of the estimated cost of all imports. Petroleum costs were largely responsible for the doubling of the trade balance deficit in 1980. A shutdown of the ferronickel plant for 5 months during 1980 and slightly reduced domestic gasoline consumption were the reasons for this lower-than-anticipated oil import bill. The recent Venezuela-Mexico agreement to provide concessional financing for 30% of the cost of crude petroleum that they sell to Caribbean and Central American countries should diminish the impact of future price increases on the balance-of-payments.

Aluminum Co. of America (Alcoa) and the Government concluded their long-delayed renegotiation on bauxite production taxes and royalty payments. The new contract will remain in force through 1982 and provided that Alcoa pay the Government $17 per ton of bauxite produced plus a royalty payment of $0.60 on each ton exported. Although there was an isolated report that the Cabo Rojo operation might be closed down, Alcoa denied the allegation.

After completing a feasibility study in 1980, the Government announced it would proceed with the construction of a gold and silver refinery. It was maintained that domestic refining would promote new end-use industries and encourage the exploitation of

virtually untouched alluvial gold deposits. It was estimated that a refinery capable of processing current Dominican gold production would cost about $3 million. Construction was scheduled to start before 1981 but the plant site was not announced.

Responding to a depressed world market for ferronickel, Falconbridge Dominicana C. por A. (Falcondo) shutdown their Bonao Mine and plant at the end of July 1980. Originally announced as a 3-month closure, the plant was idle throughout the remainder of the year. Increasing petroleum prices were cited as the major reason that direct production costs have risen to about $3 per pound of nickel, and continued operation would have resulted in unacceptable net losses to the company. Falcondo continued workers salaries and assigned them to maintenance and other duties.

Coal has become more frequently mentioned as an acceptable alternative energy source to petroleum. Late in 1980 it was announced that major "coal" deposits had been identified at Sanchez, near the head of Sabana Bay in the northeast. Information on the quality and quantity was not made available. It is well-known that there are deposits of lignite in this area, but it is not thought that these are the deposits referred to as "coal." It was also announced that in the future only coal-fired thermal electric generating plants would be constructed; whether the newly discovered domestic "coal" or solely imported coal would be used for fuel is not yet clear.

Canadian Superior, Ltd., completed their studies in the Barahona Basin area, about 100 miles west of Santo Domingo, and expected to spend $7 million to drill a 15,000-foot wildcat early in 1981. Anschutz Corp. replaced Weeks Petroleum Co. as the fourth partner in the Carboil Corp. consortium and its interest in the San Juan Basin, located to the north of the Barahona Basin. A test well has been planned for the San Juan area after the Superior test has been drilled. A seismic survey of the area was contracted to Western Geophysical Co. The San Juan Basin extends into Haiti where Anschutz also holds an exploration concession. Western Geophysical has expressed its own interest in conducting offshore surveys which would become Government property with Western to receive compensation should any company use the data. Other companies, including Gulf Oil Co., Mobil Oil Co., Marathon Oil Co., and Société Nationale Elf Aquitaine, have indicated an interest in the onshore and offshore areas of Quisqueya State.

The Government was reported to be studying the advisability of purchasing the 50% interest held by Shell Oil Co. in the Nagua oil refinery.

HAITI

A 2.8% real growth in the GNP has been estimated for 1980. The balance of trade deficit was expected to decrease due to a substantial increase in coffee exports, the primary source of foreign exchange. Bauxite remained the only significant mineral export with volumes holding fairly steady during recent years, although production is expected to decline by about 37% in 1981.

In May 1980, Haiti received a blow to its future economic planning when Reynolds Metals, Inc., announced it would cease bauxite mining at Miragoâne. Reynolds cited large stockpiles in the United States and declining profitability of the Haitian mines as reasons for terminating their operation. After discussions were held with the Government, Reynolds agreed to continue mining as long as it was economically feasible, but with a possibility of closing in 1982. This would forestall the effects of an immediate loss of foreign exchange earnings and Government revenue. Bauxite exports were valued at almost $18 million in 1980 and accounted for 8.7% of total exports. A press release revealed that Reynolds' "obliga-

tions" had decreased owing to the low quality of extracted bauxite. This statement implies that Reynolds negotiated an agreement that would result in lower revenues for Haiti, but even so, it should certainly be more satisfactory than the sudden cessation of this small but important budgetary contribution. Reynolds has been criticized in the press for its failure to provide an adequate soil rehabilitation and reforestation program.

Anschutz began seismic surveys on its offshore and onshore concessions and planned to drill a wildcat well on the Plateau Centrale concession during 1981. This Anschutz concession is across the border from the Canadian Superior concession in the Dominican Republic where a well is also scheduled to be drilled in 1981.

Late in 1980, it was reported that Haiti will participate in the Mexico-Venezuela crude oil financing facility that these two countries have jointly made available to Caribbean and Central American Governments. A complicating factor is that Haiti does not have a petroleum refinery. Since this financing arrangement involves only crude oil, not petroleum products, Haiti must make arrangements for refining and transportation. Haiti has traditionally obtained its petroleum product needs from the Shell Oil Co. refinery on Curaçao. In 1980, Haiti's petroleum import bill was $51 million and represented 16% of total import costs.

JAMAICA

In 1980, GDP declined 3.5%, representing the sixth consecutive year that Jamaica has failed to register any overall economic growth. Severe foreign exchange shortages persisted throughout the year, although import levels were reduced to bare necessities. These import restrictions resulted in widespread plant closings due to a lack of raw materials and spare parts. This increased unemployment to almost 31% during 1980. The rate of inflation was expected to average 28% for the year.

The rising cost of petroleum imports has certainly played a major part in Jamaica's

financial difficulties. The Government initiated mandatory energy conservation measures and indicated it would seek agreements to participate in the Mexico-Venezuela crude oil financing facility as well as the petroleum products financing mechanism sponsored by Trinidad and Tobago.

In the last quarter of 1980, a change in Government leadership also brought a shift in Government policy. This, in turn, created a receptive attitude on the part of international lenders who became more amenable to granting loans and reopening lines of credit.

One of Jamaica's problems has been that although the Government maintained that it welcomed foreign investors and continued to negotiate for projects involving foreign companies, there remained a certain skepticism on the part of investors as to their ultimate intentions. Government-initiated statements on socialistic commitments and economic independence combined with rhetoric against capitalism and international imperialism resulted in a flight of local capital and caused potential foreign investors to seek a friendlier atmosphere elsewhere. The Government has now begun an intense program of reestablishing investor confidence in Jamaica's stability and receptiveness to foreign involvement in its development projects.

The bauxite industry appeared to have responded positively to the bauxite levy decrease and production incentives established in 1979. Bauxite and alumina production increased Jamaica's share of earnings to $209 million in 1980. Bauxite production increased to the highest level since 1974 and alumina production also increased substantially. A slightly lower quantity of bauxite, almost 6.2 million tons, was available for export to the United States in 1980 due to increased domestic alumina production. Lower exports also reflected reduced requirements for Jamaican bauxite on the part of the U.S. consumers.

The increased production, which evidently stemmed from the 1979 reduced bauxite levy, led to speculation that the Government might be persuaded to make further adjustments as an inducement for increasing utilization of, or expanding, current alumina capacity. The Government has not yet indicated what action, if any, it will take on this sensitive issue.

The Alumina Partners of Jamaica (Alpart) announced a development program designed to increase efficiency and competitiveness and expand capacity to 1.3 million tons by 1983. In 1980, Alpart's alumina output increased 23% over that of 1979, nearing the present 1.2-million-ton production capacity.

At Jalmacan, 93% owned by Alcan Jamaica, Ltd., 1980 alumina output increased 9% above that of 1979 and production approached the 1.1 million-ton plant capacity. At Alcoa Minerals of Jamaica, where alumina capacity at 550,000 tons is the lowest of the three producers, production dropped slightly in 1980. With strong Government approval and participation, negotiations were underway to expand alumina production capacity to 1.1 million tons per year. The feasibility studies for this $360 million expansion are expected to be completed by late 1981. Interest in the expansion may be divided between Alcoa, the Jamaican Government, and three Norweigian firms, Elkem, Norsk Hydro, and Ardal og Sunndal Verk. Negotiations involve project costs, financing, and the production levy.

The ultimate decision for the Government's planned $600 million South Manchester alumina refinery remained uncertain at the end of 1980. Questions arose as to whether increased capacity at existing facilities would be a more practical solution towards expanding alumina exports.

In 1980, Revere Copper and Brass Inc. lost its last bid to vacate part of the arbitration panel's award in its claim against the Overseas Private Investment Corp. (OPIC). In June 1980, Revere accepted the $1.18 million from OPIC for the award and related expenses.

Fuel conservation, development of alternative energy sources, and exploration for domestic petroleum reserves form the bulwark of Jamaica's struggle to escape the devastating impact of soaring energy costs. About 48% of total oil imports are purchased, paid for, and consumed by the energy-intensive bauxite-alumina industry, but the remaining costs must be met by Jamaica's hard-pressed economy. The Jamaica Public Service Co. and the cement plant, both State-owned, consume an estimated 40% of Jamaica's nonbauxite oriented oil imports. The Government was studying the substitution of imported coal as an alternative and possibly cheaper fuel for electricity and cement production. The cost of converting the Nation's electrical plants may be a deterring factor until

Jamaica's economic revival.

The State-owned Petroleum Corp. of Jamaica (PCJ) has negotiated offshore petroleum exploration agreements with foreign companies. A consortium composed of Union Texas Petroleum Corp. and Azienda General Italiani Petroli S.p.A. (AGIP), a subsidiary of Ente Nazionale Idrocarburi (ENI), the Italian State oil company, planned to drill offshore in the Pedro Banks area in 1981. PCJ continued shallow testing onshore areas during 1980 and received a $23.5 million Inter-American Development Bank (IDB) loan to begin drilling in 1981. This loan marks the first time the IDB has extended a loan for petroleum exploration.

[3]Excludes quantity valued at $468.
[4]Value only reported at $454.

MARTINIQUE AND GUADELOUPE

The two cement plants, one operating on Martinique and the other on Guadeloupe, were each reported as having a 1979-80 annual capacity of 250,000 tons. It was unclear as to whether this increase in capacity from 180,000 tons was due to expansions of existing facilities or new construction. Otherwise, there has been no known changes in the status of the small rock-quarrying industries located on the two islands.

NETHERLANDS ANTILLES

The two island groups known collectively as the Netherlands Antilles are an autonomous part of the Kingdom of the Netherlands. The largest islands are in the Aruba, Bonaire, and Curaçao group where 92% of the Federation's population reside. The smaller islands, St. Eustatius, Saba, and St. Maarten, are located toward the northern end of the Lesser Antilles chain. Independence is not anticipated until 1990, after problems relating to the exact form of the future Government have been discussed and resolved.

Major foundations of the Netherlands Antilles economy are the refining of imported oil and petrochemicals. These industries represent the majority of foreign investment and account for over 85% of export earnings. The growing use of established free trade zones as a base of operation for foreign companies may help offset losses to the economy from reduced refinery production.

The two large refineries located on Aruba and Curaçao have not fared well the last few years, suffering from a loss of markets and comparatively older and less efficient plants. Capacity utilization has fallen to about 60%. The decreased performance of the refineries has been reflected in a growing unemployment rate that appears to be greater on Curaçao. As a whole, unemploy-

ment averaged about 22% of the labor force, attributed to a rising population and the gradual drop in refinery employment over the years from 20,000 to about 4,000. Other employment opportunities have not been available to absorb this excess labor.

The proposed legislation to regulate petroleum exploration in Aruba, Bonaire, and Curaçao was closer to resolution in 1980. Dissention came from Aruba which objected to any division of proceeds with the other islands through the Central Government. The proposed regulations called for a 75:25 split with the other islands. There already exists a Saba Bank Act which covers that area and under which exploration concessions have been granted.

Successful drilling offshore Venezuela has spurred exploration interest in the Netherlands Antilles, especially Aruba. The delay in passing the necessary legislation has deferred the awarding of concessions on Aruba. It was reported that unless a resolution can be found, legislation may be passed excluding Aruba. British Petroleum Corp. has obtained exploration rights for an area southeast of Curaçao.

TRINIDAD AND TOBAGO

Trinidad and Tobago has continued to maintain substantial economic growth, although the real growth rate has shown a steady decline from the over 11% registered in 1976. In 1980, the GDP grew in real terms by 5%. At current prices the GDP was estimated at substantially over $4 billion in 1980. Economic growth has been slackening owing to an overall decline in petroleum-related activities, to which in 1980 was added a poor performance in the agricultural sector and some stagnation in manufacturing. Current revenues from taxes on the petroleum sector increased to over $1 billion in 1979, equalling over 60% of total Government revenues. This sector also accounted for one-half of the GDP and about 90% of total export earnings. A strong balance-of-payments surplus has been maintained and foreign exchange reserves are high owing to the rise in international oil prices.

A heavy dependence on imported goods combined with wages increasing faster than productivity has increased the rate of inflation. The inflation rate was over 10% in 1978, reached almost 15% in 1979, and by mid-1980 averaged about 18%.

In July 1980, in recognition of the serious financial difficulties confronting oil-importing countries, in general, and the member states of the Caribbean Community (CARICOM), in particular, the Government of Trinidad and Tobago announced its intention to establish an aid mechanism for the benefit of eligible member countries of CARICOM to provide against the price increases of petroleum products, fertilizers, and asphalt.

To be eligible, participants must qualify for financial assistance from Trinidad and Tobago under the general guidelines by which the Caribbean Aid Council operates. The facility limits financing for incremental costs relative only to price changes of petroleum products, fertilizers, and asphalts since January 1, 1979. The effective date of the facility was established January 1, 1980, with an initial life span of 3 years. Continuation of the facility and further commitments would depend on a reexamination of the events in the international market, experiences with the present facility, and the economic strength of Trinidad and Tobago.

The present facility is not to exceed a total of $209 million over the 3-year period. There are two formats to cover the loans and the one applied is dependent on the economic development of the receiver country. Both loan schedules have a 15-year maturity and a 3-year grace period. The rate of interest for the more developed countries (such as Barbados, Guyana, and Jamaica) would be 3% with interest capitalized during the grace period. Those classified as less developed countries would pay 2%, with interest capitalized during the grace period. Borrowers will be permitted to service their debt by the supply of commodities to Trinidad and Tobago with the value of such shipments to be estimated at prevailing market prices.

By October, the complicated procedural arrangements had been approved. Trinidad and Tobago expected the facility would require an allocation of about 25,000 barrels of oil per day, amounting to about 12% of its

crude oil production.

The year ended without passage of the petroleum tax legislation that had been proposed at the end of 1979. However, it was announced that new legislation was being drafted that would probably be retroactive to January 1, 1980. According to the Government announcement, the new tax legislation would concern all companies active in Trinidad and Tobago and affect production taxation, accelerated depreciation eligibility, capital expenditure deductions, exploration deductions, and refining operations.

COMMODITY REVIEW

Metals.—*Aluminum.*—During 1980, Trinidad and Tobago resumed negotiations with Jamaica for the supply of 150,000 to 200,000 tons per year of alumina for the gas-fueled aluminum plant proposed for construction at Port Lisas. The alumina was to come from the proposed Jamaican South Manchester alumina project, which still remained in an uncertain status at yearend.

Iron and Steel.—The Iron and Steel Co. of Trinidad and Tobago (Iscott) brought its first Midrex direct-reduction, 400,000-ton-per-year-capacity plant into commercial production in September 1980. This capacity will be doubled in 1982 when the second plant, now under construction, comes onstream. Feasibility studies for greater sponge iron capacity have been taken under consideration by Trinidad and Tobago and could involve AMAX Corp. as a partner.

The steel-making furnaces were reported as starting up in December 1980, although this may be a premature report. The melt-cast shop consists of two electric arc furnaces and two continuous-casters with an eventual annual capacity of 600,000 tons of steel billets. The wire rod mill, with an annual capacity of 465,000 tons, fell behind the construction schedule and was expected to come onstream early in 1981.

In late 1980, it was reported that Dansteel, a Trinidadian producer of wire products, was considering the construction of a rerolling plant for completion around the middle of 1982. The projected plant would be a 9-strand, continuous-merchant bar mill. Steel billets would be supplied by Iscott. Initial capacity was expected to be 90,000 tons per year with an eventual capacity of 240,000 tons per year, depending on market conditions. The rerolling plant would be operated by an Italian firm identified as Danieli, under a 2-year contract. Dansteel also revealed that they plan to install a 25,000-ton-per-year wire drawing and galvanizing plant that would come onstream in mid-1981. This plant would use wire rod from the mill that Iscott has under construction.

Nonmetals.—*Fertilizer Materials.*— Trinidad and Tobago's capacity for upgrading ammonia consists of a synthetic ammonium sulfate plant and a urea unit owned by W. R. Grace & Co. through its subsidiary Federation Chemicals. In 1977, the Trinidad and Tobago Nitrogen Co. Ltd. anhydrous ammonia plant came onstream with a capacity of 400,000 tons per year (296,000 tons per year nitrogen), and ammonia exports more than doubled in 1978. Fertilizers of Trinidad and Tobago, Ltd. (Fertrin), will bring its two new plants onstream during the first half of 1981, bringing ammonia production capacity at Point Lisas to over 1 million tons per year of nitrogen, mostly destined for export due to Trinidad and Tobago's limited domestic markets.

In 1980, approval was expected for the construction of a $155 million granular urea plant at Point Lisas. Planned capacity was 1,620 tons per day. It was reported that Agrico Chemical Co. of the United States will hold a 49% interest and the Government will have the majority interest. When operating at full capacity, perhaps by 1984, the urea plant will absorb the entire output from one of Fertrin's two ammonia plants, reducing ammonia export potential to about 700,000 tons per year. Urea production from the new plant, less domestic requirements, will mostly be exported to the United States and smaller amounts may be sold in Latin America.

Mineral Fuels.—*Natural Gas and Petroleum.*—A decision whether to proceed with a liquefied natural gas (LNG) plant will probably be made in 1981. If approved, the projected completion date would be in 1985. Recent increases in the international gas prices have made the project more feasible.

Wasteful flaring of natural gas remains of utmost concern to the Government. The iron and steel plant that began production in late 1980 and the fertilizer plants projected to come onstream in 1981 will consume some gas production. The delay in approval for the construction of the proposed LNG facility will prevent full gas utilization in the near future.

Based on the first 6 months of 1980, crude oil production at about 213,900 barrels per

day fell below the comparative period in 1979. Natural gas production increased from 465 million cubic feet per day in 1979 to over 500 million cubic feet per day in 1980. The average daily crude oil production by company is shown in the following table and is based on production during the first half of the year.

Company	1979	Percent of production	1980	Percent of production
Amoco Trinidad Oil Co. Ltd	120,000	56	121,100	56
Trinidad Northern Areas, Ltd	43,800	20	40,400	19
Trinidad and Tobago Oil Co., Ltd	9,400	4	18,900	9
Texaco-Trinidad, Inc	26,300	13	16,800	8
Trinidad Tesoro Petroleum Corp	15,700	7	16,700	8
Total	215,200	100	213,900	100

There was some successful drilling in offshore areas east of Galeota Point during 1980. Texaco-Trinidad, Inc., Mobil Oil Co., and Trinidad and Tobago Oil Co., Ltd. have planned exploratory drilling in the Gulf of Paria. It was announced that a new state oil company would be formed for the purpose of initiating deep-water exploration. Lacking expertise for this type of drilling, the company at first will take a minority interest in ventures with more experienced foreign companies.

BELIZE

The Belize economy recorded modest growth during 1980; the growth of the gross domestic product (GDP) in real terms was between 1% and 2%. At current prices, the 1980 GDP reached $108 million[2]. This output was largely attributed to the performance of a few industries, mostly nonminerals. Such performance improved significantly the balance of payments situation by reducing the deficit from $19 million in 1979 to $4 million in 1980. The rate of inflation was an estimated 18% in 1980 and would have been greater if not for a conservative monetary policy and price control on a number of essential items. Export earnings increased $43 million, or 50%, from the 1979 level. After increasing more than 25% in 1979, imports increased only 6% in 1980 to a level of $141 million owing to the decline in investment and stabilization of petroleum prices. The balance of trade deficit was $9.8 million in 1980, a marked improvement from the 1979 level of $45.1 million.

The mineral output for Belize accounted for only a fraction of 1% of the GDP. Such activity was limited to the production of limestone, marl, and sand and gravel, all of which were primarily used in construction of the Northern Highway between Orangewalk and Belize City. Mineral resources are deficient or nonexistent in Belize for the majority of metals and nonmetals, although the Government and others continue to believe that petroleum must exist in Belize. The proximity to Mexican oilfields and the growing finds in the Petén area of Guatemala support this expectation. The Government continues encouraging exploration onshore and offshore and offers terms that

are generally similar to worldwide agreements. Major oil companies left the country in the past after frustrating efforts to find oil. The record of dry holes drilled in Belize since the 1950's has been discouraging.

In December 1980, the Organization of American States meeting in Washington backed the United Nations request to Britain to grant Belize independence in 1981. Britain was planning to call a constitutional conference early in 1981 to arrange a timetable for Belizean independence, which was expected to take place in the autumn of 1981.

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.

[1]Table includes data available through Oct. 5, 1981.

[2]Reported figure.

[3]Ni content of sinter.

[4]Exports.

[5]In addition to the commodities listed, Nicaragua produces a small but undetermined quantity of cadmium contained in zinc concentrates for export.

[6]Excludes approximately 8,000 cubic meters per year, apparently dimension stone.

[7]Refinery fuel is apparently included as a part of the products listed above; subtraction of the reported detail from the reported total gives a result of -7, indicating a net gain as a result of refining operations, but this cannot allow for refinery fuel.

[8]Detail adds to 7 more than this reported total; see footnote 7.

COSTA RICA

The rate of economic growth in 1980 was the lowest for the Costa Rican economy in more than a decade and continued a steady downward growth trend since 1977. The GDP grew in real terms by about 1.6% to an estimated $4.85 billion[3] at current prices. Disequilibrium in the economy was reflected in the balance of payments, which registered a deficit in the current account of $653 million during 1980. The rate of infla-

tion increased to 23%.

Costa Rica's trade balance continued to deteriorate; coffee prices during 1980 decreased as oil prices increased. Exports were $1.0 billion or about 8% higher than in 1979, while imports continued at a high level, reaching $1.5 billion by yearend, an increase of 9% over that of 1979. About 15% of Costa Rica's import bill was accounted for by petroleum imports.

On October 8, 1980, the Costa Rican financial authorities decided to allow the colón to float. Previously the exchange rate had stood at 8.57 colónes to the U.S. dollar, but following the decision to float, the colón rose to 13.25 to the dollar.

Costa Rica's new mineral code approved by the Economic Affairs Committee was reportedly not passed by the legislature. As a result, exploration for copper in the Talamanca district by Aluminios Suizos y Minería de Costa Rica (Samcosa), a subsidiary of Alusuisse Charter Consolidated, and Mitsubishi was apparently delayed.

Costarricense de Desarrollo (Codesa), the Costa Rican development agency, signed an agreement with Romania at the end of 1980 to develop the bauxite deposits in the south of the country. The low-grade bauxite, located at San Isidro on the river El General, was previously of interest to Aluminum Co. of America (Alcoa) in 1976 and Reynolds Aluminum Co. in 1979. The Romanians may also supply a plant for the production of aluminum. This would depend upon the supply of 600 megawatts of electricity from the 760-megawatt Boruca hydroelectric power project in Puntarenas Province.

The Canadian Barranca Corp. Ltd. confirmed that production at the Santa Clara open pit gold mine in Costa Rica, of which the company owns 40%, has begun at the rate of 1,500 tons of ore per day. The company's partner, United Hearne Resources Ltd., expects an increase to 3,000 tons per day within approximately 6 weeks. The current ore reserve is 4,100,000 tons with an average grade of 1.6 grams of gold per ton in the Mondongo zone alone. A further large potential exists to the north and west. After completing about 75% of the drilling program on its Río Tigre gold prospect on the Osa Península, Barranca Corp. reported disappointing results. No further drilling is planned at present.

Allis-Chalmers had the major contract from Codesa to build a new 1,300-metric-ton-per-day dry process cement plant in Guanacaste Province, 75 miles west of San José. Financing is by the External Bank of Spain and several others. Part of the production is destined for markets in Costa Rica and Nicaragua.

The energy sector has been given priority investment status. Exploration efforts have increased, and oil deposits with a possible yield of 60,000 barrels of oil per day, have been discovered in a 36-square-kilometer zone known as Watsi-Cocoles. Both the Caribbean and Pacific continental platforms have been of interest to various oil companies. Mexico's PEMEX, the state oil agency, started oil exploration work in Costa Rica's Baja Talamaca as part of Mexico's technical cooperation offered by the Mexican Government in August 1980.

Mexico and Venezuela agreed to help Costa Rica—as well as nine other Central American and Caribbean countries—by lending it back 30% of the $250 million worth of crude oil that Costa Rica will buy from them in 1981. These funds will be used to help finance energy generation and distribution projects under loans of up to 20 years repayment at 2% per year interest.

In September 1980, the Government stated to the legislative assembly that oil exploration and production is to be nationalized and that the energy aid program undertaken by Mexico and Venezuela would enable the country to suspend foreign participation in oil exploration. PEMEX continued its technical assistance to the Government in oil exploration. Seismic work was being carried out in Baja Talamaca and on the Atlantic coast near Cahuita. The negotiations with Mexico and Venezuela had allowed the Puerto Limón refinery, which was acquired from the Allied Chemical Corp. by the Government under the name of Refinadora Costarricense de Petróleo (RECOPE), to expand from 10,000 barrels per day capacity to 17,000 barrels per day.

The Government was giving high priority to the development of its hydroelectric resources to reduce its dependence on imported petroleum to generate electricity. Installed hydroelectric capacity rose to 668 megawatts in 1979, when the Arenal hydroelectric project went onstream compared with the 37 megawatts of 1950. Hydropower now represents 69% of the total electrical output of the country. Providing additional cooperation for this effort, the Interamerican Development Bank (IDB) in 1980 ap-

proved a loan of $82.5 million to the Institute Costarricense de Electridad (ICE), Costa Rica's power agency, to construct the 90-megawatt Ventanas-Garita hydroelectric powerplant near San Miguel de Turrúcares in Alajuela Province, using the waters from the Virilla and Ciruelas Rivers. In 1977, IDB approved a loan of $4.1 million to enable Costa Rica to drill test holes in geothermal fields located in the slopes of the Miravalles volcano in the Province of Guanacaste to determine the feasibility of using geothermal power to generate electricity. Based on results obtained, IDB in 1980 approved a loan of $8.8 million to ICE to drill four deep holes to assure an adequate flow of steam for the country's first 55-megawatt generator using geothermal power. The plant was expected to come onstream in 1981.

By 1985, the electrical generating capacity of Costa Rica is projected at 621 megawatts hydropower, 205 megawatts thermal power, and 55 megawatts geothermal, for a total of 881 megawatts. Costa Rica may become an exporter of electricity to neighboring Panamá and Nicaragua after the inauguration of the 760-megawatt Boruca hydroelectric project on the Rio Grande de Térraba in the south of the country.

EL SALVADOR

El Salvador's real growth in its GDP averaged 5.1% between 1975 and 1977, was 4% in 1978, but fell by 1.5% in 1979 and by 6% in 1980, reflecting in particular a sharp fall in private investment associated with loss in business confidence. In current prices, the 1980 GDP reached an estimated $3.8 billion.[4] The inflation rate averaged 30% during 1980.

Civil strife was severely damaging El

Salvador's economy. The balance of payments deficit of $94 million was increasing and capital flight estimated by the Government at $1.5 billion over the past 2 years continued. In addition, inflation was accelerating and the level of unemployment remained high.

The economy of El Salvador is still primarily agricultural, with coffee representing more than 50% of total exports. The socioeconomic reforms announced by the Government in 1980 are expected to have a positive long-term impact. The land reform announced in March 1980 is being implemented in three stages. The Government has also initiated banking reforms by which it assumed 51% of the ownership of all local banks and savings institutions.

El Salvador's new petroleum law was expected to go into effect in early 1981. According to the new statute, all exploration costs will be borne by private petroleum companies in return for relatively generous exploitation terms if petroleum is discovered. Individual contracts will establish exploration periods of up to 5 years with possible renewals up to 20 years. During the agreed exploitation periods, the private producer will receive a percentage of petroleum output. Taxes will be based on production levels. CEL, the Government energy utility agency, reserves the right to purchase this petroleum, if necessary, to supply the domestic market at international prices. The proposed new law stipulates a similar procedure for natural gas producers.

The mining industry of El Salvador contributed about 0.1% of the country's GDP in 1980. The mineral resources of the country include gold, silver, copper, iron ore, sulfur, mercury, lead, zinc, salt, and lime, but the reserves are small and not all are exploited. The most important mining operation in El Salvador concerns the gold mines of San Cristobal S.A., a wholly owned subsidiary of Canadian Javelin Ltd.—namely El Divisadero and Los Encuentros Mines. Javelin still retains an option on the Monte Mayor silver-gold mine, including the Banadero and Tempisque veins where exploration has yielded some promising results.

El Dorado gold-silver mine, in the Cabañas Department, continued to be active in 1980, although the Bruneau Mining Corp. will not make further investments until the end of the current political unrest. The 1.12-square-kilometer mining concession has reserves estimated at 200,000 tons of ore, grading 6.2 grams per ton of gold and 23.7 grams per ton of silver. It is surrounded by an additional 37-square-kilometer exploratory concession where 3,000 meters of exploratory drilling is scheduled in the near future to determine more accurate reserves figures. The reactivation of a 300-ton-per-day processing plant was postponed until at least 1984.

El Salvador's production of gold and silver in 1980 declined 8% and 3.5%, respectively, compared with 1979 production.

Reports from Alcoa and from Siderúrgica Salvadorena S.A. and Acero S.A., indicate that the production of aluminum metal semimanufactures and steel semimanufactures declined also in 1980, 31% and 12%, respectively, compared with 1979 output.

Considerable progress was achieved during the first half of 1980 toward revitalizing the local fertilizer industry. Seres S.A. was in the process of establishing a joint venture operation based on the old Fertica ammonium sulfate and NPK facilities at Acajutla with Pullman Kellogg for the supply of technical and economic assistance. The project, known as Fertisal, involves the revamping of the Acajutla plant for the production of complex fertilizers based on phosphoric acid, as well as ammonium sulfate. Seres intends to maintain the capacity of 240,000 tons per year to cover domestic demand but will eventually increase production for export to other Central American markets. Fertisal is to be organized as a cooperative enterprise, with equity shares to be offered to workers within the company as well as merchants, farmers, and other private investors.

Allis-Chalmers was granted the contract by Cemento de El Salvador S.A. for expanding the production capacity of the El Ronco plant located near Metapán from 900 tons per day to 1,000 tons per day. Allis-Chalmers assisted Cemento de El Salvador in arranging financing for the expansion from the Export-Import Bank of the United States, Private Export Funding Corp. (PEFCO), and three major U.S. commercial banks.

El Salvador still relies entirely on imported oil, the cost of which increased to 19% of export earnings in 1979, compared with the 16% share in 1978. The Comisión Nacional de Energía (CNE) reported that 14,000 barrels per day of oil are currently being consumed and that petroleum represents

29% of El Salvador's energy consumption. Under the San José agreement signed between Mexico and Venezuela, El Salvador will receive half its oil supply from each country, up to a maximum of 16,000 barrels per day.

A bilateral agreement signed on January 15, 1980, with Venezuela provides for 30% of the oil bill to be paid in local currency (colónes) under a general development loan at 4% interest for 5 years. If the Government of El Salvador invests these funds in energy development, the loan will automatically receive better terms: 20 years at 2% interest. The final agreement on the terms of a concessionary loan from Mexico was not reached but was expected to be similar to the Venezuelan terms.

Based on results from 110,000 barrels already processed at Refinería Petrolera Acajutla S.A. (RASA), Government officials believe that major technical modifications will not be necessary to process Mexican crude oil. RASA, the only refinery in the country, is owned jointly by Exxon and Shell with a minority share in the hands of local stockholders. CNE is formulating two plans: The first covers how to use petroleum more efficiently in the coming years, and the second concerns alternate energy sources to be developed over the next 20 years. Currently, geothermal power provides for 15% of total demand, and hydroelectric power accounts for 45%. Government officials estimate that about 19% of hydroelectric potential is now being exploited and that with the completion of the San Lorenzo Dam in 1984, 35% of the potential will be initiated. Collaboration with Honduras would enable the country to tap the potential of the Río Lempa located along their common border. The possibility of constructing small, independent hydroelectric plants on minor rivers was being considered.

Preliminary studies undertaken by the United Nations indicate possible offshore oil deposits, the exploration of which is to be encouraged by the Government. Alternate sources of energy were being studied involving the sun, windmills, alcohol, and vegetation converted into butane gas.

GUATEMALA

Guatemala's economic growth rates have run above the Latin American average of 5% to an average of 7% per year during the recent past.

In 1980, the rate of growth of the GDP continued its downward trend to 3.5% compared with 8.3% in 1977, when coffee prices reached an alltime high. At current prices, 1980 GDP reached $7.8 billion.[5] The slowdown in growth is attributed to several factors. The continuation of the Central Bank's low interest rate policy induced a substantial outflow of capital in search of higher returns abroad. Another factor was the drop in construction as well as a lack of bank financing and business uncertainty because of unsettled conditions in neighboring countries and local political problems. A third factor was the disruption of trade in the Central American Common Market (CACM), where much of Guatemala's manufactured products have been exported in recent years.

The rate of inflation increased from 13% in 1979 to 15% in 1980, owing to petroleum price increases and the higher costs of imports in general. The petroleum import cost in 1980 rose 29% to $343 million, compared with $242 million in 1979, increasing the total imports 3% to $1.54 billion.

Total Guatemalan exports rose by 22% in 1980 to $1.51 billion. Guatemala expects to receive $43 million from petroleum exports in 1980, which will partially offset the overall balance of payments impact.

Perhaps the most significant medium-term economic development in recent years has been the discovery of oil in Guatemala. There is currently one company with a petroleum concession and three consortia with "risk" contracts to explore and exploit petroleum. These consortia are working under two different petroleum laws. The 1955 oil code establishes that once production begins, the oil companies are obligated to pay the Government a 12.5% royalty; in 1975, another law was passed increasing the Government's share to 51%. The 1978 law increases the Government's share to no less

than 55% of the sale price. The disparity has stimulated the effort by political forces to bring oil companies under one central code. The company in the center of this dispute is Petromaya S.A., a joint venture formed by Basic Resources International S.A. (BRISA), Shenandoah Guatemala, Saga Petroleum A/S, and recently, Ashland Oil Co., which has been exploring for petroleum for 10 years. The joint venture is currently producing crude oil from its fields in Rubelsanto (3,500 barrels per day) and Chinaja (1,600 barrels per day.). These levels of production are Government-imposed and have also been a point of dispute between the Government and Petromaya.

Oil production from the Rubelsanto Field in Alta Verapaz has reached about 12,000 barrels per day—thus supplying a substantial proportion of domestic consumption, estimated to be less than 25,000 barrels per day. BRISA was given permission to start using the recently completed $65 million pipeline from Rubelsanto to the Caribbean terminal at Puerto Barrios.

Guatemala's first petroleum exports departed for the United States in April 1980. The 120,000 barrels destined for refining in the United States were sold at $29.40 per barrel.

The mineral industry of Guatemala is still in an incipient stage of development. Currently, Guatemala is a modest producer of nickel, copper, antimony, zinc, and tungsten, and nonmetals such as calcium carbonate, cement, feldspar, gypsum, limestone, marble, silica sand, sand and gravel, and barite. Among hydrocarbons, crude oil and petroleum products are produced. Oil is produced in the northern part of the country and is becoming an increasingly valuable export commodity.

Guatemala is the third most important producer of nickel in Latin America, mainly from the El Estor Mine. In September 1980, the mine and the nickel processing plant at El Estor at the western end of Lake Izabal operated by Exploraciones y Explotaciones Mineras Izabal (Exmibal), 80% held by Inco Ltd. and 20% by Hanna Mining Co., has been closed and will remain shut for the whole of 1981 owing to high energy costs. The estimated operating loss for 1980 is $13 million. The cost of fuel oil for the mine has risen since the mine started production in 1978 from $11 to over $40 per barrel. At the same time, weak world demand has forced Inco's nickel prices down by 6%. In 1979, the mine produced 6,199 tons of nickel, and up to September 1980, output was 6,744 tons (57% of capacity) valued at about $65 million. The mine will be maintained on a standby basis, enabling a restart at the end of 1981 if that is economically warranted. It is estimated that to maintain the Exmibal operation on a standby basis, it will cost about $14 million in 1981. Closure, however, would result in cash savings of some $40 million.

Copper continued to be produced by Transmetales Limitada, a wholly owned subsidiary of Basic Resources International S.A. (BRISA) of Luxembourg. Production of copper declined 52% in 1980 compared with 1979 output.

Minas de Oriente S.A. (Minorsa), as owner with 40% equity in a joint venture with Asamera Inc. of Calgary, Canada, (with 60% equity) was planning to develop a base metal (copper, lead, zinc, and silver) property at Chiquimula in the southeastern part of Guatemala, where reserves were estimated at 1.8 million tons.

Baritas de Guatemala S.A. was seeking an investment of $1 million to proceed with the development of its barite mine, located at Cabulco municipality, Baja Verapaz Province. The reserves have been estimated at 1 million tons of barite. The company planned to mine at a rate of 200 tons per day in 1981. Production of barite in 1980 increased 20% to 4,610 tons compared with 3,680 tons in 1979. Greater production was stimulated by the increase in oil exploration in the country.

Minas de Guatemala S.A. has been mining antimony in small quantities for the past 10 years at the Anabella and Los Lirios Mines in the locality of Ixtahuacan, in Huehuetenango Province, at the rate of about 200 metric tons of ore per day. Reserves are still unknown, and no exploration is taking place at the present time.

Texaco Oil Co. was searching for oil in the northwest corner of Guatemala, only 60 kilometers from the rich oilfields of the Mexican State of Tabasco. Texaco's belief that oil can be found in Block D is based on the region's geology. According to the terms of the lease Texaco obtained from the Government, Texaco is committed to drill two 4,000-meter-deep wells by the end of Nov-

ember 1981. The company must also build a road from El Naranjo town to the drilling site within the interior of the block. Finally, Texaco must turn over all information it develops on Block D to the Minister of Mines. Texaco may extend the life of its lease for an additional year by drilling an additional 4,000-meter-deep well.

Production of cement declined in 1980 by less than 1% compared with 1979 output. F. L. Smith received in 1979 the latest expansion contract of the oldest cement producing firm in Latin America (since 1897). Cementos Novella S.A. was adding 1,600 metric tons per day to its San Miguel plant; 40% of the clinker will be sent to its older La Pedrera plant in Guatemala City. The new production line was scheduled to go onstream in early 1980.

Basic Resources International S.A. (BRISA) has committed itself to an exploratory drilling program covering blocks 87, 88, 90, 91, and 92 in Guatemala. Under a 40-year production contract, the company is to drill on each block within 6 months. BRISA officials indicated that extensive geological and seismic work done during the past 2 years has uncovered the presence of more than 20 major structures.

Ashland Oil Co. became the newest member of the joint venture led by BRISA. Ashland, expected to invest $50 million, is contracted to drill six exploratory wells with BRISA holding 50% of the interest in any commercial oil found in the structure of Ashland.

A consortium led by Getty Oil Co. (50%), and consisting of Monsanto (25%) and Texas Eastern (25%), was exploring in area B:B in northern Alta Verapaz and the southern Petén. The first well drilled by Getty Oil Co. reached a depth of 11,500 feet with only a minor show. Getty Oil Co. is contracted to drill five wells to a minimum depth of 9,000 feet and was expected to invest $19 million by the time the contract expires in June 1981.

Hispanoil was contracted to drill three wells to a minimum depth of 9,000 feet. The expected productive zone of the first well being drilled is between 3,000 and 12,000 feet. Hispanoil's contract expires in June 1981. Hispanoil was expected to invest over $12 million.

The Texaco-Amoco partnership continued its drilling operations under a contract signed in 1978, which requires two wells to be drilled to a minimum depth of 12,000 feet.

BRISA announced in July that the French state oil company, ELF-AQUITAINE, bought a 10% share in BRISA for about $34 million subject to approval of BRISA stockholders. ELF-AQUITAINE will assume technical direction of exploration operations as well as exploitation of existing wells. In September 1980, an exploration well was spudded on a new structure, La Felicidad, located 10 kilometers southwest of the Rubelsanto structure, which is already producing oil. The new exploration well is targeted for a depth of 14,000 feet at an estimated cost of $8 million.

In December 1980, the Secretary of Mining and Hydrocarbons announced that the Government of Guatemala had awarded a contract to a consortium of companies consisting of Hispanoil, ELF-AQUITAINE, and BRASPETRO for oil exploration and exploitation in Block E, which is in the northwest portion of the Petén. Seismic exploration was scheduled to begin in early 1981.

Two refineries were in operation in Guatemala. The first was operated by Texaco on the southern coast of Guatemala, south of Escuintla. This refinery has a capacity of 17,000 barrels per day. The second, located in Puerto Barrios along the Atlantic coast, was operated by Shell-Chevron refinery and has a refining capacity of 10,000 barrels per day.

A third of Guatemala's 4-year development plan has been allotted mainly to hydroelectric development. The Aguacapa plant, initiated in 1977, was practically completed, and the Chixoy plant was scheduled to come onstream by 1982. The $580 million Chulac hydroelectric project was being delayed because of lack of adequate financial arrangements. The agreement to interconnect the Guatemalan and Salvadoran energy grids, expected to become operational in 1981, is seen by officials as a major medium-term solution to the country's energy needs.

HONDURAS

In 1980, Honduras experienced a sharp downturn in economic growth. A severe shortage of credit, disappointing export performance, soaring petroleum import costs, and most of all lack of investor confidence were the main factors behind the decline. In real terms the GDP grew 2.5% to an estimated $2.6 billion,[6] compared with the 7.8% growth in 1979. Inflation continued its upward trend, which according to the consumer price index on December 31, 1980, was 10% higher than in 1979. Imports grew 23% to $1.3 billion in 1980, of which petroleum imports registered another increase from $113 million in 1979 to $171 million in 1980.

In recent years, the mining industry has contributed about 3% of the country's GDP. The underground El Mochito precious and base metal mine is by far the most important mining operation in Honduras, accounting for about 90% of the total precious metal and 100% of the lead-zinc production. Rosario Resources Corp., acquired by AMAX Inc., on April 10, 1980, operated the mine, which produced silver, gold, lead, zinc, and cadmium. In 1980, the El Mochito produced 1.7 million troy ounces of silver, 1,465 troy ounces of gold, 14,677 tons of lead, and 17,666 tons of zinc.

The production of cadmium had not been released but is estimated at about 300 tons. El Mochito is being expanded from a current level of approximately 1,100 tons of ore processed per day to 2,500 tons per day scheduled for 1983. Most current production is from the main ore body, which at depth is declining in tonnage and grade.

During 1980, production began from the nearby San Juan ore body, a large lower grade deposit that must be mined at significantly larger tonnages with more mechanization for a lower unit cost. Overall reserves at El Mochito at yearend 1980 were approximately 8 million tons, grading per ton 4.0 ounces of silver, 0.002 ounce of gold, 4.2% lead, 8.0% zinc, and 0.5% copper. A previous year's statement included 0.47% cadmium per ton.

Other metal mines include the Tatumbla Mine, a gold-silver property operated by Alianza Industrial S.A. Honduras also produced other metallic products, including antimony and cadmium, which since 1973 have been at a rate of production of 100 tons and 200 to 300 tons of contained metal per year, respectively.

As part of the mining of a large iron ore deposit in the Agalteca region, a metallurgical project is being planned as a joint Honduran-Mexican venture. The plant is scheduled to be constructed over 3 years at an estimated cost of $95 million. Out of a proposed annual production of 100,000 tons of steel, 50% is intended for domestic consumption, and the other 50%, for export.

Kawasaki Heavy Industries Ltd. was awarded a $60 million contract from Industria Cementera Hondureña S.A. to build a new 1,800-ton-per-day plant at Piedras Azules, 120 kilometers from Tegucigalpa, the capital. The plant is to go onstream by mid-1981, with its pozzolan cement to supply the Cajón area where construction of a dam is to begin. Output is to be 1,200 tons per day of clinker mixed with 600 tons of pozzolan.

Cementos de Honduras, S.A., a privately-owned company, will expand its Rio Bijao plant near the town of San Pedro Sula to a 2,000-ton-per-day production capacity. The expansion project has been awarded to F. L. Smith & Co., A/S, of Copenhagen, Denmark.

In March, the World Bank approved a $125 million lending operation to assist in the financing of the El Cajón hydroelectric power project estimated to cost $583 million. The lending operation will include a $105 million World Bank Loan to Empresa Nacional de Energía Electrica (ENEE) and a $20 million International Development Association (IDA) credit to the Republic of Honduras.

The 292-megawatt El Cajón hydroelectric plant is to be located approximately 80 kilometers southeast of Honduras' major industrial center, San Pedro Sula.

In June 1980, the World Bank approved a $3 million loan to help finance a petroleum exploration promotion project in Honduras, which represents a first step in bank assistance to the development of the country's petroleum sector. The first wildcat of Texaco-Amerada Hess in the Caribbean Sea off Honduras was dry. The Zepher I semisubmersible drilling rig and platform is slated to drill a second wildcat in the area.

No gas or oil has been discovered to date. However, a larger deposit of coal lignite has recently been located in the western part of the country.

NICARAGUA

Following the civil war, the country continued to suffer the effects of war damage and reduced economic output. Capital flight was estimated at $1.8 billion[7] or more than the 1978 GDP. The GDP dropped in 1979 by 26%, and recovery is likely to be slow, considering the damage and disruption to industry, agriculture, trade, and infrastructure. The inflation rate is running at about 40%.

The "reactivation" plan published at the beginning of 1980 provides for a growth of 22.5% in GDP, unemployment of 19%, and lowered inflation to about 15%. An added boost to the economy will come from participation in the concessionary oil sales arrangement provided by Mexico and Venezuela. Venezuela has agreed to allow Nicaragua to purchase 27,000 barrels of oil per day at a 10% discount on world prices if such portion is invested in local energy development projects. Venezuela's cooperation plan reported in January also included technical assistance.

In April, as part of a cooperation agreement reached during the visit to Managua by officials of the Mexican Government, Mexico will supply 7,500 barrels of oil per day, together with technical assistance from PEMEX to the Corporacion Nicaraguense de Minas e Hidrocarburos CONDEMINAH on training in petroleum exploration and production.

In the mineral sector, the most significant development was the nationalization, in November 1979, of the entire domestic mining industry. The Government created CONDEMINAH, which will manage all mining activities in Nicaragua and will also be responsible for petroleum policy. CONDEMINAH will be advised and coordinated by IRENA (Institute of National Resources and Environment).

In August, CONDEMINAH reported that work on a new petroleum policy was proceeding satisfactorily and would be ready for approval by the Council of State. CONDEMINAH also reported that the necessary audits for the compensation of the expropriated gold mines were moving slowly owing to the great task of evaluating the complex and diversified inventory. Nevertheless, CONDEMINAH believed that the Government would soon be ready to begin negotiations with the expropriated companies. On June 28, the U.S. Senate approved the appropriation of the 1980 $75 million aid package to Nicaragua. The aid includes $5 million in grants and $70 million in loans for purchase of U.S. goods. In August, the Government was to take control of imports and the distribution of fuel, according to news agency reports. Crude oil imports are to be handled by Petronic, the state company.

Since the nationalization of the Nicaraguan mining industry, little information on developments within this sector has been made available to the public. The limited mineral output has been dominated by the production of the precious metals gold and silver, largely in Zelaya Province, from mines operated by Rosario Mining of Nicaragua Inc., before nationalization. CONDEMINAH is reported to be interested in expanding gold production in the country, the value of which rose from $7.9 million in 1979 to 23.4 million in 1980. Nicaragua currently is producing about 5,000 troy ounces of gold per month. Silver output declined 58% in 1980 compared with that in 1979. Production of hydraulic cement increased 44% in 1980 compared with 1979 output.

Oil exploration in Nicaragua's offshore concession areas has been at a standstill because of the political unrest in the country. However, renewed activity is expected in the near future once companies such as Union Oil of California, Oceanic Exploration of Denver, and others renegotiate their exploration leases.

Because of oil price increases and the lack of success in discovering oil and natural gas, the Government was emphasizing the development of alternative domestic sources of energy. Some of the projects under consideration included the $36 million Austrias hydroelectric project, the construction of which was expected to be bid in September 1980, and a $18 million geothermal field feasibility study that was also expected to be bid in September. These projects were being financed by the IDB, which may also be requested to finance the $47 million Larreynaga hydroelectric project (complementary to Austrias) and the more ambitious $483 million Copalar hydroelectric project, scheduled for a later period.

Progress continued on the second stage of the Momotombo geothermal project at Lake Managua being undertaken by Empresa Nacional de Luz y Fuerza (Enaluf). The 35-megawatt geothermal plant was expected to become operational in 1982, but startup was likely to be delayed because of the political situation.

PANAMA

The Panamanian GDP grew by 7% in real terms in 1979 and is estimated to have grown by almost 5% in 1980. The improvement in economic performance was derived from increased investment and continued strong growth in the construction industry. Manufacturing and electric power output were also growing rapidly. The GDP at current prices reached an estimated $3.4 billion[8] in 1980. Inflation was 14% to 15% in 1980. Unemployment continued at a high level and was expected to remain a serious problem.

The trade deficit was estimated at $870 million in 1980, a 13% increase over that of 1979. Petroleum products exported increased 37% by value and 4% by volume. Petroleum imports were expected to decrease in the future when most of Panama's electric power generation would be by hydroelectric resources now being developed.

The mineral industry of Panamá was of minor significance to the country's economy. The main activity in this sector besides the refining of petroleum was concentrated in mining small quantities of gold, manganese, salt, limestone, sand and gravel, cement, and clay.

Large inflows of foreign capital were expected as a result of the large development projects now underway or planned, including hydroelectric projects, the transisthmus oil pipeline, and the Cerro Colorado copper project.

Two projects of great economic and commercial significance, the transisthmus oil pipeline and the Cerro Colorado copper project, are likely to be initiated in 1981-82. The implementation of the $250 million pipeline project awaited final approval by Panama's legislative body. The 78-mile-long, 36-inch-diameter crude oil pipeline is to move as much as 700,000 barrels per day of crude from the Pacific to the Atlantic. The pipeline will originate at Puerto Armuelles on the Pacific side and extend north and east to the Atlantic side at Chiriqui Grande. A contract for the design and construction of the pipeline was expected to be awarded in early 1981 by

Petroterminal Panama, S.A., a joint venture of the Government of Panamá working through Corporación Finaciera Nacional (COFINA), its national finance corporation; Northville Industries Corp. of Melville, N.Y.; and CBI Industries of Oak Brook, Ill. The pipeline would substantially cut transportation costs for crude moving from Alaska to the gulf coast and east coast refineries. Five hundred thousand barrels per day of Alaskan crude is moving through the Panamá Canal via tankers. Northville Industries Corp., which operates the transfer terminal for crude transiting the canal, reported that a consortium of banks will finance the venture for themselves and CBI Industries Inc. Final contracts were being negotiated. The three oil companies that move the bulk of crude oil through the canal, Exxon Co., Atlantic Richfield Co., and Sohio Petroleum Co., have agreed in principle to use the pipeline but have not yet signed contracts.

Contracts will also be made to construct 2.5 million barrels of oil storage and two offshore tanker loading structures on the Atlantic. Two pump stations will be built. The pipeline will require 16 months to build and should be operational in late 1982. A road to be built adjacent to the pipeline will open up a new area of Panamá to vehicular traffic, and hence to economic development. Income taxes, royalties, and interest income accruing to the country because of the project was estimated at $74 million per year.

When the proposed Cerro Colorado copper project becomes a reality in the future, it is expected to transform the mineral industry of Panamá. Cerro Colorado copper deposit is one of the world's five largest with 1.4 billion metric tons of ore reserves that contains 0.78% copper, 0.01% molybdenum, 5.1 grams of silver, and 0.08 gram of gold per ton. A joint venture by the state-owned Corporación de Desarrollo Minero Cerro Colorado (CODEMIN) and Texasgulf Inc. to develop the deposits in Chiriqui Province, was severely affected by world inflation, and in early 1980, Texasgulf sold its 20% interest in the project to the Río Tinto-Zinc Corp. Ltd. (RTZ) of England for $5.5 million. This sum represented Texasgulf's expenditure on the project. In June 1980, RTZ signed a contract with Empresa de Cobre Cerro Colorado S.A. stipulating a 49% participation, the remainder to be held by CODEMIN.

RTZ is to carry out a work program early in 1981 to review the feasibility of the project, the cost of which is estimated at $2.0 billion. A final decision on whether to proceed with the development of the project was set for July 1981. Texasgulf, which retained an option enabling it to acquire from RTZ an interest of about 15% in the project, estimated that a price of between $1.50 and $2.00 per pound of copper would be necessary to yield an adequate return on the large investment.

Other smaller mineral-related projects involve an increase in the production capacity of Cemento Panamá and a $12 million investment of Panalac S.A., the country's only steelmaker, which was in the process of establishing a 70,000-ton-per-year ministeelworks at Panamá City, scheduled for startup in April 1981.

Petroleum and natural gas exploration continued in 1980, mostly in the Gulf of Panamá, an area largely unexplored. Results obtained in the gulf concession areas were unfavorable to date, although the United States-Panamanian Sossa Petróleo announced, in 1980, the discovery of an oil deposit in the Darien Strait. Plans to start commercial production were underway. An oil strike was also reported off the San Blas Island along the Caribbean coast, east of Panamá.

The World Bank announced on March 19, 1981, the approval of a $6.5 million loan to assist the Government in accelerating petroleum exploration, improving energy planning, and investigating the potential for development of energy alternatives. Panamá has currently no petroleum production, although the existence of tar pits and gas encountered in water holes has long suggested the possibility of petroleum resources. The project also includes investigation of the coal potential in the Boca del Ratón region and geothermal studies of the Cerro del Pando site.

Mexico and Venezuela are to supply Panamá with 12,000 barrels per day of oil under their special agreement for assisting countries of Central America and the Caribbean. This will enable Panamá to retain 30% of the purchase price of $300 million per year for application to projects in the energy sector.

The Government was following a two-part strategy for satisfying Panamá's increasing demand for electricity. The first part in-

volves the development of hydroelectric facilities to replace imported oil. The 264-megawatt Changuinola I hydroelectric project in western Panamá has been identified as the next facility to be developed. This $700 million project has recently been incorporated into the Cerro Colorado copper project. A Canadian firm, Acrees International Ltd., was also studying the feasibility of a 120-megawatt hydroelectric plant on the Río Tabasara, which will be developed to take the place of the Changuinola I project in the natural grid if the Cerro Colorado project proceeds. The second part of the Government strategy involves the extension of electricity to new users, particularly in the rural areas of the country.

BANGLADESH[1]

Mineral production was of minor importance to the country's economy, and Bangladesh was not a ranking world producer of any mineral commodity in 1980. Natural gas was the most important mineral exploited, and reserves were sufficient to allow a significant increase in its use. A greater proportion of the domestic heat and electrical energy needs could be filled by increased production and distribution of natural gas. Also, the export of natural gas was feasible either by pipeline to India or in the form of liquefied natural gas (LNG). Some nonmetallic minerals could be developed, as well as coal and peat, given sufficient capital investment.

Bangladesh's strongly agricultural economy made fair progress in 1979-80.[2] The major harvest of November-December 1979 turned out to be better than had been anticipated after an early drought left poor planting conditions. Secondary crops (harvested in February-March 1980 and June-July 1980) were excellent. There were prospects for a record harvest in fiscal year 1980-81.

Gross domestic product (GDP) at current prices rose to an estimated $9.9 billion[3] in fiscal year 1979-80 from a total of $9.3 billion in fiscal year 1978-79.[4] The population continued to increase at 2.8% per year, a rate nearly equal to the real growth in GDP, resulting in a very slow growth in per capita income, which was one of the lowest in the world for a large country.

Small sectors of the overall economy have done relatively well, such as construction, power and gas, and industry. Currently important and larger sectors—agriculture and housing—have done relatively poorly in recent years, not keeping pace with the overall average growth rate.

Bangladesh entered the decade of the 1980's at about the same per capita income level as at the beginning of the 1970's, despite $5.3 billion foreign aid receipts be-

tween December 1971 and June 1979. The main reasons for the lack of economic progress included rapid population growth, constant food deficits of 1.5 to 2.0 million tons per year, limited infrastructure, low productivity, lack of raw materials, large trade deficits, and low rates of domestic saving and investment.

The high annual population increase was recognized by the Government as the basic cause underlying many of the economic problems in the already grossly crowded country. Average population density has now passed 600 persons per square kilometer, one of the highest rural densities in the world.

While nonagricultural industry contributed only 12% of the value added to GDP and employed only 11% of the labor force, its development was essential to reduce the balance of payments and unemployment. Because of noted inefficiencies of publicly owned enterprises, the need for Government funding in other sectors, and the Government's more positive attitude toward private enterprise, both domestic and foreign components of the private sector were expected to have an increasingly important role in industrial development. Discouraged after massive nationalizations between 1971 and 1974, domestic investors have been slow to accept the new Government's attitude. There were recent indications of more willingness to accept investment risk. In 1975, there were few new private investments sanctioned; in fiscal year 1976-77, there were 548 business units at $54 million investment value; in fiscal year 1978-79, 749 at $145 million; and in 1979-80, 895 at $290 million.

To encourage private investment, the Government has adopted incentives, including tax holidays, liberal depreciation, industrial parks, and reductions or exemptions in duties and tariffs. The Government particularly encouraged foreign investment in industries that were (1) export oriented, (2) based on local raw materials, and/or (3) involved high technology or capital input. In addition, incentives for foreign investment included tax exemptions on foreign loans and salaries of foreign technicians, special loan rates, special foreign exchange facilities based on exports, and a new Investment Guarantee Act of 1980. This act protects repatriation of profits, capital, royalties, and many usual fees. The act states that private industries should not be nationalized, but if nationalization becomes necessary, there was a guarantee of prompt and fair payment.

In 1980, there was little left in the public sector except utilities and the jute and textile mills. Although the Government retained the jute and textile plants, it did open to private investment some specialized jute and textile operations. The Government particularly desired private investment in major sectors such as iron and steel, natural gas-based petrochemicals, cement, heavy engineering, and heavy electrical equipment. Deterrents to investments were very poor infrastructure support (electric power, transportation, communications, etc.), an unskilled labor force, an often lethargic bureaucracy, and limited domestic demand.

Electric power was the major constraint to most development in Bangladesh because of insufficient generating capacity, aging generators and equipment, and an inadequate power distribution system. There has traditionally been an excess of low-cost hydropower and natural gas-fueled generation in the east, and insufficient, expensive petroleum-fueled generation in the west.

The power shortage continued to increase during 1980. The official installed capacity was 752 megawatts in 1978 and declined to 718 megawatts in 1979.[5] The system was poorly maintained and inefficient. Transmission loss reportedly was over 27% for the system in 1980.

The Government's second 5-year plan (1980-85) called for a substantial increase in generating capacity, to a total of around 1,300 megawatts. Key powerplants were to be overhauled and the power distribution system greatly expanded.

Government measures restricted the increase in the general cost of living index to 12.4% in fiscal year 1979-80, which compared favorably with other developing countries without domestic crude oil production. During 1980, there were four devaluations of the taka totaling 12%.

Exports rose from $602 million in fiscal year 1978-79 to $719 million in fiscal year 1979-80. Minerals played virtually no part in export revenue. Jute, jute products, and tea accounted for nearly all of the value. During the last half of fiscal year 1979-80, the market for jute products dropped, causing a considerable loss of revenue. Low prices continued into the first part of fiscal year 1980-81. Fiscal year 1980-81 exports were projected at $740 million.

Imports climbed even faster than exports, from $1.27 billion in fiscal year 1977-78, to an estimated $1.60 billion in fiscal year 1978-79, and to around $2.35 billion in fiscal year 1979-80. The fiscal year 1979-80 imports included large foodgrain purchases before the Government became aware of the

good secondary harvest. The value of petroleum imports increased by 190% over that of the previous year and was 17% of total imports. In fiscal year 1980-81, food imports were expected to be much lower. The value of petroleum imports was expected to continue to increase, despite the Government's attempts to control the use of petroleum. Imports were projected at $2.7 billion for fiscal year 1980-81. The $1.6 billion trade deficit was the largest since the country was formed. As in the past, most of the deficit was to be met by foreign aid. The Government budgeted foreign aid at $1.5 billion for fiscal year 1980-81, a 15% increase over the $1.3 billion in 1979-80. The International Bank for Reconstruction and Development, Asian Development Bank, United Nations Development Program, and a number of donor nations extended financial assistance to Bangladesh.

COMMODITY REVIEW

Natural gas was by far the most valuable mineral resource being exploited in Bangladesh. During the past 69 years, a total of only 48 wells have been drilled onshore in the entire country, resulting in 8 commercial gasfields. The potential for additional development was considerable but dependent on further exploration both at known gasfields and in other favorable geologic structures that have not been drilled. Data on gas reserves have varied widely in recent years, partly because some of the gasfields have not been drilled sufficiently to make an accurate assessment of the recoverable reserve. However, over 250 billion cubic meters of recoverable gas was probably available. The country's reserves were expected to rise considerably as developmental and exploratory drilling continued.

During 1980, final arrangements were made for the start of the $164 million Bakhrabad gas development project. Initially, the Bakhrabad Gasfield was to be developed and a pipeline built for transmitting gas for distribution in Chittagong, the country's second largest city and major port.

Four new wells were to be drilled and the initial discovery well completed for production. Reserves at Bakhrabad have been set at 81 billion cubic meters by the State Minister for Petroleum. A Japanese loan will help finance this part of the project as well as the gas gathering and processing equipment. The Japan Petroleum Exploration Co. was bidding for the drilling contract. In addition to the Japanese loan, the World Bank, Kuwait, and the Organization of Petroleum Exporting Countries (OPEC) are financially involved in the project.

The main Chittagong pipeline will be 60 centimeters in diameter and approximately 200 kilometers long. The distribution system in the Chittagong area will total another 80 kilometers of 51-centimeter, 41-centimeter, and 25-centimeter distribution lines. The main consumers of the gas will be the Chittagong steel mill, a thermal powerplant, a paper mill, the Masirabad and Kalughat industrial estates, and domestic customers in the urban area. The proposed Chittagong urea fertilizer plant would also be a major consumer.

Bangladesh and Indian officials began discussing, in July 1980, the possibility of exporting natural gas by pipeline to the Calcutta area. There is a pressing need for a reliable energy source in the heavily industrialized, power short, eastern region of India. Bangladesh would supply 100 million cubic feet per day for 20 years through a 280-kilometer-long pipeline. In spite of immediate political opposition, President Zia-ur-Rahman remained in favor of the proposal. This plan would be the quickest and least expensive way of gaining substantial foreign exchange to reduce the country's chronic trade deficit.

An alternate and much more expensive plan was the construction of a natural gas liquefaction plant to export LNG. Cost of the project would be borne by the receiving country, which would then be repaid by the value of the LNG exported. Objections to this alternative included the huge capital outlay. Another was a lack of sufficient data on proved reserves at some of the potential gasfields, inasmuch as specific and detailed gasfield geology was critical to the design and economic viability of a $1 billion plus LNG complex. However, there was disagreement whether gas should be exported or used domestically to develop a wider industrial base and higher value products such as petrochemicals, steel, cement, and fertilizer.

During 1980, 2 gas deposits were added to the 10 known fields. The first discovery was in Bianibazar in Sylhet District; the Federal Republic of Germany was providing financial assistance and a U.S. firm supplied technical expertise. Gas was struck at about 3,660 meters and drilling was continuing. Drilling began in July at Dhalia near Feni in Noakhali District; gas was struck in December 1980. Preliminary estimates for

the combined gas reserves at these discoveries totaled 28 to 42 billion cubic meters (1.0 to 1.5 trillion cubic feet).

Exploration for crude petroleum continued in 1980 with a detailed aeromagnetic survey being performed over most of the country with British technical assistance. The survey attempted to identify specific areas most suitable for further exploration and drilling. The President also ordered a step-up in the rate of exploratory drilling and asked that more drilling equipment be obtained.

Bangladesh produced no crude oil during 1980 but was scheduled to begin using a small amount of light-end condensate from the Titas Gasfield during the year.

During 1980, the National Economic Council approved the construction of the country's second oil refinery. The 2-million-ton-per-year plant will cost approximately $330 million. Twenty international firms reportedly submitted tenders for the project.

The Government was planning the establishment of a direct-reduction iron plant based on imported iron ore pellets and domestic natural gas as fuel and reductant. The plant would be located in Chittagong and have an output between 500,000 and 800,000 tons per year. Chittagong Steel Mills Ltd. would also be expanded from 160,000 to 250,000 tons per year. India was expected to be the pellet supplier and was expected to buy back any direct-reduced iron that Bangladesh did not consume. At yearend, discussions were under way with Austria for the preparation of a feasibility report and financing of the $160 million project.[6]

The Government showed continuing interest in the heavy mineral beach sands off the Chittagong coast, but no development was undertaken during the year. The deposit contains ilmenite, zircon, rutile, and monazite. There were conflicting statements published during 1980 as to the quantity of the reserves and their potential value. It was stated, however, that the deposits were comparable in quality with similar occurrences in Sri Lanka, India, and Australia.

A news report from Dacca stated that the country's first nuclear power station would be built at Roopur, near Ishwardi in Pabna District. First-stage capacity would be 125 megawatts. Financing had not been arranged at yearend. This project could be several years in the discussion and planning stage before construction actually begins.

Planning for the expansion of the cement industry continued during 1980. The Geologic Survey of Bangladesh has completed a survey of the limestone deposit near Jaipurhat in Bogra District where extensive drilling has revealed an estimated 270 million tons of cement-grade limestone in a 6.5-square-kilometer area. The deposit averages 50+% CaO and 2.4% to 7.9% SiO_2. The sinking of the 550-meter shaft was to begin as soon as a contractor was chosen. The mining part of the project has escalated in cost to approximately $160 million.

A cement plant was to be built in three stages at Jaipurhat with an ultimate capacity of 3,000 tons per day clinker. The plant's first-phase construction would furnish 1,000 tons per day of clinker to the existing Chittagong grinding plant, which currently uses imported clinker. The second-phase construction would supply a planned grinding plant at Khulna. The final stage of the $120 million project would be a grinding mill at the Jaipurhat plant. The timetable for the construction of the cement plant was unclear as of yearend 1980. Bangladesh imported cement valued at approximately $21 million in 1979, but planned to be self-sufficient in cement when the project was completed.

Bangladesh had three chemical fertilizer plants operating during 1980, and one under construction and scheduled for start-up in early 1981. The Ghorasal and Fenchuganj plants produced ammonia, and urea or ammonium sulfate. The Chittagong plant produces triple superphosphate from imported raw materials.

All of these plants are one to two decades old and have been operating at 54% of combined capacity during the last decade. The Government began an overhaul program to increase the production level of the Ghorasal and Chittagong plants and also to begin a diligent preventive maintenance program at the Fenchuganj plant.

The Ashuganj plant will produce ammonia and urea from natural gas. Capacity has been cited as 528,000 tons per year of urea. Startup date was to be yearend 1980, but construction problems have delayed completion of the plant.

Two additional ammonia-urea plants were planned, one at Chittagong with the World Bank assisting in the funding and a second plant at Ghorasal to be built with Chinese aid. Both of these plants will use natural gas as fuel and raw material.

By Government design, Bangladesh was to be self-sufficient in nitrogenous fertilizer production. Phosphate and potassium raw materials were not mined locally, and no deposits suitable for mining have been identified.

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.

[1]Table includes data available through Aug. 18, 1981.

[2]In addition to the commodities listed, other crude construction materials such as sand and gravel and other varieties of stone presumably are produced, but available general information is inadequate to make reliable estimates of output levels.

[3]Data are for years ending June 30 of that stated.

[4]Reported figure.

[5]May include other clays.

[6]Gross production is not reported; the quantity vented, flared, or reinjected is believed to be negligible.

[7]Revised to zero.

[8]In addition to the commodities listed in the body and footnote 2, molybdenum production was initiated in October 1978, but output is not reported and no basis is available for reliable estimates of output levels.

[9]As reported by Statistical Office of the United Nations in 1979 Yearbook of World Energy Statistics, p. 557.

[10]Data are for the Nepalese fiscal year ending mid-July of that stated.

[11]Figure includes both gem- and industrial-grade garnet; 4,295 kilograms gem quality and 37,000 kilograms industrial quality.

[12]In addition to the commodities listed, iron ore was mined in the past and pig iron was produced at industrial facilities, but the status of these industries under prevailing conditions is not sufficiently clear to allow formulation of reliable estimates of output levels. Similarly, data on output of crude construction materials are not available and no basis is available to make reliable estimates of output levels.

BRUNEI[7]

Oil and natural gas production accounted for 88% of the gross national product (GNP) for Brunei during 1980 and approximately 98.4% of total export earnings.

This tiny (5,765 square kilometers) sultanate situated on the northwest coast of Kalimantan Island (formerly Borneo) and inhabited by only about 215,000 people, was a major South Asian producer of both oil and natural gas. As a result of this production, the people of Brunei enjoy the highest per capita income in Asia and one of the highest in the world.

1980 was the first year in a new 5-year development plan for Brunei. The main objectives of the new plan include improvements in the economic, social, and cultural life of the people. They aim toward a high level of employment, diversification through the development of natural resources such as agriculture, forestry, and fisheries, and the achievement of a minimum annual growth rate of 6%.[8]

Although a British protectorate since

1888, in 1978 agreement was reached with Britain that Brunei would assume full international responsibility for defense and foreign affairs as an independent nation at the end of 1983. After independence is complete, Brunei will have the choice of joining the British Commonwealth or accepting the expected invitation to become the sixth member of the Association of Southeast Asian Nations (ASEAN).

Brunei is now run almost entirely by Chinese businessmen, accountants and shopkeepers who maintain everyday services. Apart from a small minority, the 54,000 Chinese have British-protected passports. After the British leave, the Chinese could become stateless—a consideration that worried both the Chinese and British officials who have been helping the Brunei Government get ready for a smooth transition. One of Britain's conditions for independence was proper treatment for the Chinese.

Rather than wait until 1983 to find out what would happen, many Chinese, including important contractors in the offshore oilfields, have made plans to move their money out of Brunei—in most cases to Singapore—and were getting ready to move themselves and their families. The Chinese would take with them much of Brunei's business infrastructure, leaving doubts about how the relatively unskilled Brunei native population would cope.[9]

COMMODITY REVIEW

Brunei's crude oil production during the first half of 1980 was reported by Brunei Shell Petroleum Co. (BSP) to be in the neighborhood of 240,000 barrels per day, slightly lower than the 1979 level of 268,000 barrels per day. This reduction apparently reflected a deliberate effort to maximize ultimate hydrocarbon recovery from the estimated reserves of 1.8 billion barrels of crude oil and 7.7 trillion cubic feet of gas in BSP fields.

There were more than 550 wells in the BSP system of 5 major fields including Southwest Ampa, Seria, Fairley, Fairly-Baram, and Champion.

Champion, the newest of the fields, was being expanded during 1980 from three offshore platforms to a total of nine, to be functional by the end of 1981. A new gas compression station was being added as a part of the project and was expected to provide an additional 150-million-cubic-foot-per-day lifting capacity when completed.

In mid-1980, BSP ordered additional offshore production platforms from Hyundai Shipbuilding of the Republic of Korea, to be delivered at yearend 1981. The purchase of up to 80 such structures over the next 15 years was reportedly planned.

BSP's decades-old oil marketing monopoly was interrupted by the appearance of Saberu Co., owned by high Government officials. The company made a profitable 50,000-barrel-per-day sale during the year to a Japanese trading company in an apparent attempt to loosen Shell's hold over the marketing of Brunei's major natural resource.[10]

Natural gas production was estimated by BSP at 1,060 million cubic feet per day during most of 1980. Two 71-centimeter (28-inch) pipelines carry gas from the Southwest Ampa Field to the Brunei LNG facility at Lumut. The reported production appeared beyond the market capacity of the LNG plant, which utilizes five production trains at 150 million cubic feet per day each. The loading facilities and tanker transport fleet are balanced to operate most efficiently at the design rate. It was possible that the reported excess gas production was reinjected into the oilfields to maintain field pressure.

Only one of the 1979 exploratory finds, Rasau-6x, was still being considered by BSP for development. During 1980, one exploratory well, Parak-ISTR, was sunk off the shore of Brunei. It reportedly flowed at 12,900 barrels per day.[11]

CHRISTMAS ISLAND[12]

Phosphate rock and dust remained the only commercially produced mineral commodity on Christmas Island during 1980. The island, located in the Indian Ocean 2,600 kilometers northwest of Perth, Australia, was made up of volcanic bedrock covered by coral limestone that forms an irregular pattern of pinnacles. The coral limestone was covered by phosphate rock in beds averaging 6 meters in depth. There were three basic grades of phosphate, ranging from 25% to 36.5% P_2O_5. The main export grades averaged 35.24% P_2O_5 for the top quality and 33.0% P_2O_5 for the second

grade. A small amount of 30.0% P_2O_5 average grade material was also exported. The total value of phosphate exports for 1980 was $67 million.[13]

Production took a significant jump in 1980. The island's aggregate production was nearly 30 million tons of ore in 81 years of mining.

The major importers using the Christmas Island product were Australia and New Zealand. Malaysia increased its purchase of high iron and aluminum material suitable for direct application to particular crops.

Table 2.—Christmas Island: Exports of phosphate rock, by destination

(Thousand metric tons)

Destination	1977	1978	1979
Australia	541	610	632
Indonesia	13	15	--
Malaysia	--	135	111
New Zealand	575	624	612
Singapore	133	4	5
Total	1,262	1,388	1,360

HONG KONG[14]

Mineral production in 1980 in Hong Kong was limited to quartzite and small amounts of feldspar and kaolin. All mining was by opencast methods. Most of the feldspar was exported to Taiwan, while the quartz and kaolin were consumed by local industries. Total production of both fine and coarse quartzite aggregates was close to 13.5 million tons. During the year, there were two Government-operated quarries, eight contract quarries, and one rock-crushing facility in operation. One of the contract quarries, established in 1978, completed the installation of its main crushing plant in early 1980. During the year, a little over 1 million cubic meters of fine marine dredge sand was imported for use by the building industry, and a smaller quantity of river sand was also imported from China.[15]

Hong Kong's production capacity for cement was around 1.5 million tons per year at the end of 1980 compared with an annual demand of 2.4 million tons. Current production is from imported clinker. In January 1980, the Government approved the construction of a 1.4-million-ton-per-year cement plant at Sui Lang Shui, near Tuen Mun. The $265 million plant, to be opened in 1982, will be owned by the China Cement Co. Kaiser Cement Corp. of California holds 40% equity in China Cement, and the remainder is held by Cheung Kong Holdings, which also has a 30% share holding in Green Island Cement of Hong Kong.[16]

With the development of China's international trade, Hong Kong continued to reap the benefits of a long established entrepot-entity, most importantly in the role of an Asian financial center and gateway to China.[17] Hong Kong's total trade in 1980 was valued at $42.8 billion. Domestic exports totaled $13.9 billion; reexports, $6.1 billion; and imports, $22.8 billion. The major sources for Hong Kong's imports in 1980 were Japan, $5.2 billion; China, $4.5 billion; and the United States, $2.7 billion. The major export destinations during the year were the United States, $4.6 billion; the Federal Republic of Germany, $1.5 billion; and the United Kingdom, $1.4 billion. Major destinations for reexports were China, $1.7 billion; Japan, $1.2 billion; the United States, $0.6 billion; and Taiwan, $0.4 billion. In 1980, imports of raw materials and semimanufactures alone totaled $9.5 billion (imports of fuels was $1.5 billion). The principal commodities exported included apparel and clothing accessories; watches and clocks; toys and dolls; textile fabrics; radios; metal manufactures (mostly cutlery and household utensils); travel goods, handbags, and similar items; and electronic components.[18]

Table 3.—Hong Kong: Exports and reexports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1978	1979	Destinations, 1979	
			United States	Other (principal)
METALS				
Aluminum:				
Bauxite and concentrate	4,500	8,760	--	Taiwan 6,500; Japan 2,000.
Oxide and hydroxide	3,620	1,396	--	Mainly to Indonesia.
Metal including alloys, all forms	r20,551	23,929	2,043	Japan 8,195; Taiwan 2,805; North Korea 2,338; Singapore 1,161.
Arsenic trioxide, pentoxide, acids	8	7	--	Thailand 5; Indonesia 2.
Beryllium metal including alloys, unwrought	3	--	--	
Chromium oxide and hydroxide	63	61	--	Indonesia 46; Singapore 7; Taiwan 5.
Cobalt oxide and hydroxide	21	7	--	Singapore 3; Taiwan 3.
Copper:				
Sulfate	24	32	--	Indonesia 29; Singapore 2; Taiwan 1.
Oxide and hydroxide	3	3	--	All to Malaysia.
Metal including alloys, all forms	r12,694	15,447	480	Japan 11,636; India 1,393.
Gold metal including alloys, unworked or partly worked, troy ounces	83,946	299,612	3,151	Taiwan 223,833; Japan 66,809.
Iron and steel metal:				
Scrap, thousand tons	286	374	(1)	Taiwan 236; Thailand 64; Japan 37.
Pig iron, steel ingot, similar material	100	1,418	--	China, mainland 1,134; Republic of Korea 38.
Steel, primary forms	6,352	9,692	--	Singapore 6,541; Philippines 2,781.
Semimanufactures	50,614	91,965	113	Indonesia 20,968; China, mainland 15,043; Macau 14,078.
Lead:				
Oxide	23	33	--	Indonesia 30; Singapore 3.
Metal including alloys, all forms	1,445	1,838	3	Taiwan 1,034; China, mainland 72; Republic of Korea 43.
Magnesium metal including alloys, all forms	28	140	--	North Korea 117; Japan 14.
Manganese oxide	60	74	--	Indonesia 50; China, mainland 18.
Nickel:				
Oxide and hydroxide	37	38	--	Taiwan 24; Belgium 13.
Metal including alloys, all forms	1,292	1,830	--	North Korea 508; Japan 425; Republic of Korea 371.
Platinum-group metals:				
Waste and sweepings, value	$55,270	$584,663	--	United Kingdom $427,352; Japan $97,219; Switzerland $60,092.
Metal including alloys, unworked or partly worked, troy ounces	22,152	19,483	--	Taiwan 15,754; Japan 2,090; Australia 1,254.
Silver:				
Waste and sweepings, value, thousands	--	$13,210	$32	Switzerland $8,471; West Germany $3,308; United Kingdom $1,304.
Metal including alloys, unworked and partly worked, thousand troy ounces	429	1,455	7	United Kingdom 915; Switzerland 448.
Tin metal including alloys, all forms	1,013	1,818	--	Taiwan 434; China, mainland 362; North Korea 295.
Titanium oxide	3,036	1,878	--	Indonesia 1,413; Taiwan 183; Malaysia 61.
Tungsten metal including alloys, all forms	3	3	--	Mainly to United Kingdom.
Zinc:				
Oxide	41	89	--	Singapore 40; Nigeria 23; China, mainland 10.
Metal including alloys, all forms	3,963	2,979	--	Philippines 1,532; Japan 759; Thailand 226; Malaysia 215.
Other metals, n.e.s.:				
Oxides, hydroxides, peroxides of metals	24	239	--	All to Republic of Korea.
Metals:				
Metalloids	7	16	11	Netherlands 3.
Base metals including alloys	446	909	66	Japan 345; Belgium 165; North Korea 110; Philippines 94.
Ash and residue containing nonferrous metals	346	540	(1)	Taiwan 540.
NONMETALS				
Abrasives, natural, n.e.s.:				
Grinding and polishing wheels and stones	471	620	5	Indonesia 315; Nigeria 103; Pakistan 57.
Dust and powder of precious and semiprecious stones, value	$850	$4,099	--	Thailand $2,293; China, mainland $1,268; Vietnam $538.
Unspecified	102	95	--	Japan 72; Indonesia 11; Taiwan 7.
Asbestos	225	1,844	--	Indonesia 1,330; Venezuela 504.
Barite and witherite	72	98	--	Indonesia 91; Malaysia 6.

Gypsum and plasters	528	31,433	--	Indonesia 31,342.
Lime	128	47	--	Macau 35; Indonesia 12.
Magnesite	1,213	1,320	--	Taiwan 900; Nigeria 300; Philippines 100.
Mica:				
Unworked	33	104	51	Taiwan 47.
Worked including agglomerated splittings	21	27	4	France 7; Sweden 7; Italy 4.
Pigments, mineral, including processed iron oxide	1,015	956	--	Indonesia 890; Singapore 37.
Precious and semiprecious stones, natural and synthetic, other than diamond value, thousands	$137,322	$174,416	$23,751	Japan $73,689; Singapore $25,289.
Salt and brine	35	52	--	Papua New Guinea 50.
Sodium and potassium compounds, n.e.s.:				
Caustic soda	10,194	750	--	Philippines 342; Thailand 115; China, mainland 114.
Caustic potash	83	5	--	Mainly to Indonesia.
Soda ash	358	74	--	Macau 36; Malaysia 20; China, mainland 5; India 5.
Stone, sand and gravel:				
Dimension stone	4,350	3,043	13	Taiwan 1,716; Indonesia 895; Philippines 208.
Gravel and crushed rock	116	110	--	Indonesia 88; Cameroon 17.
Quartz and quartzite	544	668	--	Thailand 291; Indonesia 150; Singapore 30; Sudan 30.
Sand excluding metal-bearing	2	16	--	Thailand 7; Republic of Korea 5.
Sulfur:				
Elemental, all forms	54	--		
Sulfuric acid	50	21	--	Macau 10; Indonesia 4; Thailand 3.
Talc, steatite, soapstone, pyrophyllite	5,729	8,908	--	Indonesia 7,433; Taiwan 1,012.
Other nonmetals, n.e.s.:				
Crude	102	603	--	All to Taiwan.
Building materials of asphalt, asbestos and fiber cements, and unfired nonmetals	352	653	--	Macau 406; China, mainland 107; Indonesia 107.
Oxides and hydroxides of strontium, magnesium, barium	(1)	10	--	Mainly to Indonesia.
MINERAL FUELS AND RELATED MATERIALS				
Asphalt and bitumen, natural	73	373	--	Macau 319; Republic of Korea 54.
Carbon black and gas carbon	830	298	--	China, mainland 274; Indonesia 20.
Coal and coke including briquets	39	3	--	All to Macau.
Petroleum refinery products:				
Gasoline thousand 42-gallon barrels	r63	70	--	Do.
Kerosine and jet fuel do	65	151	--	Singapore 49; Indonesia 45; Philippines 37.
Distillate fuel oil do	1,051	430	--	Macau 207; Philippines 199.
Residual fuel oil do	218	431	--	All to Macau.
Lubricants do	223	265	(1)	Tawian 84; Indonesia 82; Saudi Arabia 36.
Mineral jelly and wax do	12	23	--	Singapore 15; Indonesia 3.
Liquefied petroleum gas do	28	33	--	All to Macau.
Other do	r19	12	--	Macau 5; Philippines 2.
Mineral tar and other coal-, petroleum-, or gas-derived crude chemicals	5	6	--	Taiwan 3; Malaysia 1; Philippines 1.

rRevised.
1Less than 1/2 unit.
2Excludes unreported quantity exported in 1978 valued at $1,772.

[1] Includes ores of vanadium, niobium, etc.

[2] Excludes unreported quantities imported in 1978 valued at $29,983 and in 1979 valued at $311,850.

[3] Less than 1/2 unit.

KAMPUCHEA[19]

The overall output value of the mineral sector has never been significant in Kampuchea (formerly Cambodia) and this condition continued throughout 1980. The country was not an important world producer of any mineral commodity, and given the present state of the economy, this will not change in the near future. The only minerals that have been produced on a locally significant level were phosphate rock, gem minerals, salt, and nonmetallic construction materials for cement, brick, and tile manufacture.

A variety of minerals might be developed given ideal conditions and an intensive exploration effort using modern equipment and techniques.

The armed conflict continued throughout 1980 in Kampuchea but at a reduced level compared with that of 1979. It was reported that approximately 200,000 Vietnamese military personnel remained in the country at yearend 1980. Remnants of Pol Pot's troops continued hit-and-run raids over much of the rural countryside.

As a result of the continued unstable political and military situation, the economy of the country remained in a state of upheaval and no meaningful statistics were available for the year.

In October 1979, the Government authorized the reissuing of money. In March 1980, new banknotes in amounts from 50 riel down to 0.10 riel were issued and a single coin of 0.05 riel value was also issued. During the previous months, transactions had been by barter, with a measure of rice being the usual scale by which value was determined.

Except for donations of food and medical supplies from various international aid groups and foreign countries, virtually no trade was carried on during 1979. It was not until September 1980 that the private Japan-Kampuchea Trade Association announced that it had agreed with Kampuchea's Heng Samrin Government to reopen bilateral trade. The first transaction was to be the export of $200,000 worth of kapok.

COMMODITY REVIEW

A small deposit of phosphate rock has been worked at Tuk Meas in Kampot Province since 1919. Production was not believed to have exceeded 12,000 tons in any one year. Remaining reserves were estimated at 320,000 tons. The Monkol Borei phosphate fertilizer plant in Battambang Province opened in 1977. Reserves near the plant were estimated at between 360,000 and 400,000 tons of 20% P_2O_5 ore. The ore was ground to under 0.1 millimeter grain size and applied directly to the cropland with no chemical processing or blending attempted. Current production level at these plants was not known but every effort was made to keep them operating because of their importance to the agricultural sector.

Kampuchea produced salt for domestic use from at least two areas, mostly by evaporation of seawater. The salt pans in Kampot Province covered 4,000 hectares and employed 400 workers. Production was believed to have more than doubled in 1979 and probably increased a small amount in 1980.

A small glassware factory was operating at Boeng Cheung Ek, using local sand and other raw materials.

Small, batch-fired, charcoal-fueled foundries operated at several locations. The furnaces were charged with steel scrap and locally mined iron ore. Output from the foundries was used to make agricultural tools, kitchen utensils, metal fasteners, and replacement parts for a variety of equipment.

The largest known iron ore deposit in Kampuchea was at Phnom Deck (13°14'N, 105°03'E) in Preah Vihear Province, where small amounts of magnetite and hematite have been mined since ancient times. French and Japanese firms explored the deposits before 1945, but large-scale exploitation was not feasible because the 6-million-ton reserve was insufficient to justify the expense of building infrastructure into this remote area.

Both primary and placer gold deposits are known. The Bo Sup Trup deposit in the northwestern Province of Otdar Meanchey has been exploited since 1877. The gold-bearing quartz veins also contain trace amounts of pyrite, sphalerite, galena, chalcopyrite, malachite, and silver. The reserve was estimated at 440,000 tons of 15-gram-per-ton gold ore. Current production level, if any, was not known.

Bricks and roofing tile were made from local deposits of clay in several areas. Kilns were reported in Phnom Penh, Phum Prek

Rieng, and in Tram Kak, Angkor Chey, and Chamkar Lev Districts. The production status of these plants was not known in 1980. Presumably, at least some of them were operating to furnish needed building materials for reconstruction.

Tin occurs near Knangay as fine-grained primary mineralization in aplite. The cassiterite grains were smaller than 0.12 millimeters and made extraction difficult. The nearby eluvial and alluvial deposits were not large enough for profitable mining. Tin is mined commercially across the border in Thailand and further exploration could reveal more exploitable occurrences.

Sulfide mineralization containing lead, zinc, and iron has been reported at Samrong (11°50'N, 103°55'E); lead, zinc, and copper at Banchai in the Seasan Valley; and copper and lead at Rorieng (Phnamker). The Samrong deposits were exploited by Chinese miners in the 1850's but were subsequently abandoned. In 1961, the Samrong area was recommended for a modern geochemical soil survey by a French exploration team. However, political conditions have prevented any further work in the area.

The mineral fuel situation in Kampuchea was not encouraging. No oil or natural gas was produced, and there was no known exploration conducted either onshore or offshore during 1980. Some coal occurrences were reported in Kracheh, Battambang, and Kampong Thum Provinces, but none were of a grade or thickness that would warrant exploitation.

The small French-built petroleum refinery at Kampong Som, damaged 8 years ago in a military conflict, was not repaired in 1980. The country's very small petroleum needs were satisfied by imports of petroleum products.

LAOS[20]

During 1980, the Lao People's Democratic Republic completed a 3-year interim plan for economic recovery with limited success. These years were traumatic and frustrating for both the Laotian people and the new Government as they sought to transform the country along Socialist lines. The result has been a steady exodus of refugees, continuing economic problems, and sporadic armed resistance in the southern provinces. Some advances have been made in reconstruction, increasing agricultural output, transportation improvements, and other public services and social conditions.[21]

In November 1980, the Laos Council of Ministers outlined the aims of the first 5-year plan (1981-85). Some of the minimum goals included increasing gross social product by 65%, gross national income by 38%, agricultural production by 23%, transport capability by 80%, and gross industrial production by 200%. As part of the industrial goal, the Ministry of Industry and Trade was instructed to "...use more effectively all available...natural resources so as to create primary factors for transforming the country into an industrialized state." No specific goals were mentioned in the mineral sector.

Official data on the economy of the country as a whole were not available, and little was known of the present status of the mineral sector.

Laos was one of the poorest countries in the world with a GNP probably less than $325 million and a per capita income on the order of $95 per year. Inflation was reportedly under control at the end of 1979 and for the first 3 months of 1980, but climbed sharply in the later months of 1980. One of the reasons for the inflation was a 2-month closing of the Thailand border after an armed clash on the Mekong River in June. Only one border crossing point reopened, causing continuing problems to border trading activities. This constriction of trade, especially in basic consumer goods, has contributed to continuing price increases.

In order to moderate the effects of the border bottlenecks, the Government was putting a priority on rebuilding Route 13 between Vientiane and Savannakhet, and Route 9 between Savannakhet and the Vietnamese border crossing, where it connects with a road network leading to the port of Da Nang. Sweden, the Soviet Union, and at least one other East European country have agreed to help in the work. Currently, the route is a limited fair-weather road of very low capacity. Trade through Vietnam will bypass the politically sensitive Thai-Laos border areas.

One major hindrance to revitalizing the economy and trade was the critical lack of skilled personnel. It was estimated that up to 300,000 people, or 10% of the population, have left the country since 1975. In many cases the refugees were the commercial and educated elite of Laos, causing a severe shortage of trained personnel most needed to help in the rebuilding process. Attempts

at forcibly preventing people from leaving had been counterproductive, and the Government now uses political education and persuasion to restrict the exodus. The official policy regarding those who do leave, however, is that they are welcome to return at any time.[22]

Some progress was being made toward delineating the mineral resources of the country. Exploration agreements have been signed with Vietnam and Czechoslovakia. Vietnam was to help in preparing geological maps of the Xieng Kmoung and Samneua regions, survey the iron deposits in Ieng Khouang, and explore for construction material resources in Kieng Khouang, Khammoune, and Savannakhet Provinces. In July 1980, Czechoslovak and Laotian officials signed a "mine exploration cooperation agreement."[23] The terms of the agreement were not available.

Laos has potentially rich occurrences of a number of valuable minerals. There are known deposits of coal, gypsum, iron ore, potash, salt, and tin. However, Laos' mineral resources continued to be virtually unused during 1980. As in past years, except for tin, Laos produced no minerals of significance to the world market. The overall mineral output was too small to be an important factor in this highly agricultural country. The French-owned Phontiou tin mine used to produce several hundred tons of concentrate annually before it was nationalized in 1977. Production declined for the next 2 years but was believed to have recovered during 1980. Tin was probably the only mineral currently minable for the export market without the necessity of an unmanageably large capital outlay.

The Nam Ngum hydroelectric power project continued to be one of the two largest foreign exchange earners for Laos. Over 80% of the total power generated from the 110,000-kilowatt plant was sold across the border to the northeast section of Thailand. Despite the political differences between the countries and the midyear border closing, power was not interrupted during the year.

A fifth generator was reportedly being installed and will bring total capacity to 140,000 kilowatts. The Laos and Japanese Governments signed an agreement in August 1980 for the repair of the two 15,000-kilowatt first-stage generators at the plant. The work was scheduled for completion in 1980.

In a continuing effort to utilize the inexpensive power available from the Nam Ngum plant, the electric power grid in Laos was being extended into some of the more remote communities. The limited availability of power, coupled with poor transportation facilities, has been a hindrance to the development of mineral resources in most provinces.

COMMODITY REVIEW

The export of tin concentrate was the major foreign exchange earner for Laos for a number of years. In 1977, the French-owned tin mine at Phontiou was nationalized without compensation and production stopped for a short period, then resumed at a reduced output. The 5-year plan called for increased production from Phontiou and a smaller mine in Boneng District. Government officials have mentioned that exploration for new tin deposits was continuing and indicated that other small mines may have contributed additional production in 1980. It appeared that the Government intended, with Soviet technical assistance, to surpass the old 500- to 1,000-ton-per-year production level in the next few years.

Salt was produced in at least two provinces during 1980. The main production came from mines or brine wells at Ban Keun, Ban Bo, and Kok Sa-at (Ban Khoksawat) in Thoulakhom District of Vientiane Province. The output easily met the local needs and provided a substantial surplus for distribution to other provinces. A new salt pit was opened in late 1979 at Ban Boten in Laung Namtha Province. Production during 1980 was sufficient to supply the entire demand of the province. Total national salt production was not available but was believed to be sufficient to supply the minimum needs of the country.

A rich deposit on potash minerals straddling the border east of Vientiane was discovered in the 1970's. The main sylvite bed, which continued southward well into Thailand, averages 3.5 meters thick and occurs at depths between 94 and 432 meters. There was no known progress toward developing the deposit during 1980. Development of this much needed fertilizer raw material is dependent on the availability of large amounts of capital. This Lao-Thai deposit is the only known high grade occurrence of potash minerals in Southeast Asia.

Large reserves of iron ore have been reported in the Phu Nhouan Mountain Ridge north of Xiengkhoang. Several hundred million tons of very high-grade magne-

tite has been indentified. Exploitable deposits have also been discovered at Phu San and in the Pha Lek and Sam Neua Districts.[24] Vietnam was helping with exploration of these deposits, none of which were being exploited. Large-scale development of any of these deposits would require a capital outlay beyond the means of the Laotian economy at this time.

There were known occurrences of precious gem stones in Laos. In particular, a sapphire deposit was being mined at Houai Sai in Loung Namtha Province. Czechoslovak technicians were reportedly helping in the mining.

Common mineral construction materials were produced in Laos for domestic consumption. Most quarries or plants were small and produced for canton or district use only. The largest brick plant was located in the outskirts of Vientiane and probably produced about 4,000 tons of finished brick in 1980. Limestone was mined and calcined into agricultural lime in small, single batch kilns. Gypsum was produced in small quantities in several places before 1980. In 1980, a new operation called the Dong Hen Quarry began production in Savannakhet Province. Production was reported to be 13,000 tons in the first part of 1980. Plans were to reach full capacity in 1981. The new quarry probably was the result of a 1978 agreement with Vietnam to cooperate in the development of the Savannakhet gypsum deposit. Vietnam had three large cement plants under construction and will import most of the Dong Hen gypsum. A modern 200,000-ton-per-year cement plant will be built in Vang Viang District (18°56'N, 102°27'E), Vientiane Province, with Soviet technical assistance and financing. Design and construction of the infrastructure for the plant began in 1980.

Laos produced no crude oil or natural gas, and there was no known drilling conducted during 1980 or the previous 2 years. Laos imported small amounts of petroleum products from Thailand and an unknown quantity from Vietnam through a small pipeline.

Coal occurs in Vientiane and Saravane Provinces but is only mined and consumed locally. Production could total a few thousand tons per year.

MONGOLIA[25]

Under an economic and technical cooperation agreement between Mongolia and the U.S.S.R., the Soviet Union was to assist Mongolia in its transition from an agricultural-based economy to an industrial base by the end of 1985. By mid-1979, first-stage construction of the copper-molybdenum mining and concentrating combine at Erdenet was reportedly completed. Commission of the work on the second-stage construction was to be in 1980. When completed, ore output at Erdenet was to increase from 4 million tons per year to 16 million tons per year in 1982. Through joint efforts, expansion of the fluorspar mines at Berhe, Dzun-tsag an Dlle, and Bor-Under could be completed by 1985 as well as the construction of a fluorspar concentrating combine.

Commissioning of the first stage of a coal mine at Baga-Nur was to coincide with the completion of the reconstruction of the coal enterprises at Sharyngol and Adunchulun. The coal-based thermal power station No. 4 in Ulaanbaatar was to be put into operation and the power-generating facilities at Darhan and Choybalsan were to be reequipped.[26]

On August 4, 1980, a contract between the Kompleksimport Association of Mongolia and the All-Union Teknostroyeksport Association of the U.S.S.R. was ratified for the construction of the Hotol cement and lime complex. The project includes a 100,000-ton-per-year limestone quarry, a 65,000-ton-per-year lime plant, and a 500,000-ton-per-year cement plant.[27]

Table 5.— Mongolia: Apparent exports of mineral commodities[1]

(Metric tons unless otherwise specified)

Commmodity	1978	1979	Principal destinations, 1979
METALS			
Aluminum metal including alloys, unwrought	--	81	All to Italy.
Iron and steel metal:			
Scrap	19,110	20,000	All to U.S.S.R.

NEPAL[28]

Nepal is a small landlocked country between the Chinese province of Tibet and the Indian States of Uttar Pradesh and Bihar. It mainly occupies the south slope of the Himalayan Mountains down to the edge of the Indo-Gangetic Plain.

There was no economically significant mineral production in the country during 1980. The rugged upland regions have not been thoroughly explored for mineral occurrences, and the potential for both metallic and nonmetallic mineral production is excellent. High-grade veins of copper were worked by hand in ancient times and some were still being operated at the present. A typical operation would mine and smelt 500 to 1,000 kilograms of copper per year. Nepalese weapons were historically produced from domestic iron ores, which were concentrated by crude magnetic separation.

Currently, the most attractive prospects lie in development of magnesite, limestone, dimension stone, and zinc. Mineral exploration and mining of mineral deposits could provide significant employment opportunities in rural areas. Most of the population was only partly employed because the crowded agricultural situation does not provide full employment.

GDP at current prices was estimated at $2 billion for fiscal year 1979-80.[29] The agricultural sector accounts for about 66% of the GDP and employed over 90% of the work force. Three successive crop failures, caused by poor weather conditions, played havoc with the economy and resulted in an overall drop in real GDP.

The budget for 1980-81 was directed toward improving the economic condition of the rural population, and the success of the program depends heavily on foreign assistance. Spending was expected to total nearly $408 million, of which development expenditure was allotted more than $283 million, an increase of over 45% over that of the previous year. Domestic revenue was estimated at $200 million, and a further 167 million, nearly 60% of development expenditure, was expected from foreign funding including grants and loans from international financial institutions.[30]

During fiscal year 1979-80, regular spending was allotted $100 million, an increase of 14.7%; development spending, $196 million. Serious problems were encountered on the revenue side. Domestic revenues actually declined a small amount. A large part of the income loss resulted from the contraction of volume of imports. Duties on many of Nepal's major imports, petroleum for example, were levied on volume, despite the frequently large increase in value.

Revenue, however, for the first quarter of fiscal year 1980-81 increased by 35% compared with the corresponding period in fiscal year 1979-80. As a result of better crop conditions, the agricultural-based industry and exports of sideline products were expected to show a significant improvement by the end of fiscal year 1980-81.

Nepal's trade situation deteriorated during fiscal year 1979-80 with the trade deficit increasing 43% over that of fiscal year 1978-79. Provisional data indicated total value of exports declined from $108 million in fiscal year 1978-79 to $80 million in fiscal year 1979-80. Imports increased from $240 million to $296 million in the same period.

The main thrust of the Government's economic program was to expand infra-

structure and develop the rural sector. Road construction has been continuing at a steady pace, and many areas are being linked by motorable roads for the first time. The new roads will permit access to areas that contain promising indications of economic mineralization but were formerly inaccessible to modern drilling equipment. Most of the road projects during the last decade have been constructed with the help of foreign technology and financing from India, China, the United Kingdom, the Soviet Union, and the United States. During the sixth plan period, 1,950 kilometers of new roads were to be built; 672 kilometers of blacktop, 775 kilometers of gravel, and 503 kilometers of motorable mud roads.

One of Nepal's greatest natural resources was its many fast-flowing streams. Nepal occupies only 0.09% of the world's total land area but, because of the high rainfall, snowmelt, and geographic relief, it possesses 2.67% of the world's total hydroelectric generating potential. Theoretically, over 80 million kilowatts of power could be developed.

During the past 5 years, peak demand for electric power has increased by 15% per year. Construction of new generating capacity, however, has not kept up with demand. In 1980, growing electrical energy shortages became acute, particularly in metropolitan Kathmandu where very unpopular load shedding was initiated throughout the area.

To relieve the problem, the Government turned to an accelerated construction schedule on the Kulekhani Dam and a 60,000-kilowatt powerplant. The project was about 60% complete in 1980 and was scheduled for startup in November 1981. Construction of the $95 million project, under contract to a South Korean firm, was being financed by the World Bank, the Japanese Government, and the United Nations Development Program.

Designing and survey work for the $72 million Marsyangdi hydroelectric powerplant was underway in fiscal year 1979-80. Construction was scheduled to begin in fiscal year 1980-81, subject to the availability of foreign financial assistance. The project consists of a small dam on the Marsyangdi River that would divert water through a 7-kilometer tunnel into a 50,000-kilowatt powerplant. A 132-kilovolt transmission line will feed the central power grid. Scheduled completion was in 1984.

In addition, a series of small, local hydroelectric generators, from 25 kilowatts to 1,000 kilowatts in size, were being built to supply outlying villages that were not included in present or planned distribution lines. Four were completed in 1980 and 12 more were under construction during the year.

India and Nepal were discussing a regional agreement for construction of a $1.5 billion dam on the Karnali River. The 3,600,000-kilowatt powerplant would be one of the largest in south Asia and require funding by a consortium of world financial organizations. The power would be mostly exported to India and furnish a source of foreign exchange to the Nepal treasury.

A third cement plant was planned as a joint venture. India would hold 49% equity in a 1,500-ton-per-day plant to be constructed at Udaypur in the southeast part of the country. A survey for the rail link from India into Udaypur to service the plant was completed. A detailed project report, completed in early 1980, won wide acceptance by officials of both countries and construction may begin in 1981.

In addition to the limestone quarrying, there was a small marble industry in the Godawari area. The marble was quarried then cut into ashtrays, mortars and pestles, and paperweights. Part of the output was exported to India and Bangladesh. Although the production was of relatively low value and tonnage, the overall operation employed over 500 persons.

Nepal Orind Magnesite Private Ltd. published tender offers for construction of various sections of the 175- to 200-ton-per-day dead-burnt sinter plant during 1980. The company was formed though collaboration between the Nepal Government and Orissa Industries Ltd. of India to exploit the magnesite deposits of Dolakha, east of Kathmandu. Harbison-Walker Refractories Co. of the United States was to supply technical know-how for the $20 million project.

The plant was to be built at Lamusangu, and magnesite was to be supplied by aerial cableway from the mine at Khoridhunga. A 20,000-ton-per-year refractory products plant was also planned and will be located at Birganj. At least 12 million tons of (44.0% to 46.0% MgO) magnesite has been proved and total reserves were estimated at 180 million tons.

COMMODITY REVIEW

The value of cement produced was probably more than the total output value of all minerals or mineral products in Nepal dur-

ing 1980. The demand for cement exceeded production, and prices varied substantially depending on the source. The price of Indian cement was 69 rupees per bag; domestic cement was 76 rupees; Japanese, 86 rupees; and Korean imports, 110 rupees per bag.

Again, problems with raw materials, spare parts, and maintenance contributed to the Himal cement plant not operating at designed capacity during 1980. Actual output has never exceeded 86% of the design capacity of the plant.

The Federal Republic of Germany was to provide grant assistance worth 5 million Deutsche marks to cover part of the cost of increasing the plant's output. It was planned to increase the daily capacity from 160 to 400 tons.

The country's second cement facility was currently under construction. Hetauda Cement Industries Ltd.'s plant has a designed capacity of 750 tons per day. The Asian Development Bank was helping finance the $60 million project. Limestone will be mined nearby at Bhaise and transported to the plant via a 13-kilometer aerial tramway. Construction was behind schedule in 1980 and the planned completion date in early 1981 was not likely to be met.

Nepal Metal Co. Ltd. offered 4.2 million rupees worth of common stock to Nepalese investors in January 1980. The company was set up to exploit the zinc and lead ore around Lari in Rasuwa District. Nepal Metal will be a joint venture of Nepal investors (50%), Hyderabad Asbestos Cement Products Ltd. (India) (25%), and Golder Moffitt and Associates Ltd. (England) (25%).

The company planned to mine zinc-lead ore exposed in the Ganesh Himal region 58 kilometers north-northwest of Kathmandu at an altitude of 4,419 meters (14,500 feet). The ore, which reportedly contains 11.87% zinc and 1.66% lead, will be concentrated at Somdang about 5 kilometers south of the mine and about 1,219 meters (4,000 feet) lower. The estimated 25,000 tons per year of concentrate would be exported. Production was scheduled to begin in 1984. The Government reportedly began construction of a motorable road from Betrabati to Somdang in order to bring in equipment and to ship out metal concentrates. This would be the first modern metal mine in Nepal.

Nepal has no domestic petroleum production and has no refinery capacity. Consumption of petroleum products was increasing rapidly because of increased electrical generation, increased tourism, and the increased use of kerosine instead of firewood in household uses (due to rapid depletion of forest resources).

The petroleum import bill totaled about $60 million in fiscal year 1979-80. Crude oil and products were contracted for delivery to India from Iraq, the U.S.S.R., and China. The crude oil was refined in India for Nepal's use. As prices rose in the world market, the Nepalese Government was forced to increase prices on gasoline (19%), diesel oil (35%), and kerosine (43%) during fiscal year 1979-80.

Nepal's total oil requirement for 1981 was around 300,000 tons. Early in 1980, there were temporary shortages in Nepal because refinery labor problems in India forced closure of the plants that normally supply the Nepalese market. Alternate arrangements were made and the normal supply resumed in April 1980.

To prevent temporary supply problems from causing economic hardship, the Nepal Oil Corp. was to begin a substantial expansion of its petroleum storage capacity. Standby capacity at four major sites would be increased by a total of 10,000 kiloliters. Total storage for the major cities was to be more than doubled.

SINGAPORE[31]

Singapore's economy continued to be service-oriented; services and trade accounted for 71% of the GDP. The share of the manufacturing sector to GDP was 24%. The sectors with the highest growth rates in 1980 were manufacturing, transport and communications, utilities, business services, and construction, in that order. By industrial production, output by the petroleum sector in 1980 was valued at $3.5 billion; electronics, $1.5 billion; transport equipment and oil rigs, $0.7 billion; and food, $0.6 billion. The fastest growing manufacturing subsector was metal engineering, in which output grew by 32%. This manufacturing grouping included machine tools, industrial machinery, tools and dies, and precision metal parts.[32] The value of cement produced in 1980 was $86 million; granite, $11 million; other nonmetallic mineral products, $43 million; iron and steel, $88 million; and nonferrous metals, $26 million.[33]

Singapore has three tin smelters, which rely on foreign concentrates. The oldest smelter, owned by Kin Hok, has a rated metal production capacity of 150 tons per month. The combined tin metal output of Kimetal Pty. Ltd. and Watson Mineral Enterprises was reportedly 750 tons per month. There has been controversy concerning the origin of the tin concentrates and whether the smelters are conduits for smuggled, incoming concentrates.[34]

After Houston and Rotterdam, Singapore is the third leading oil refining center with a 1.1-million-barrel-per-day capacity. Also, it is the second leading offshore rig-building nation in the world with major rig and tanker repair facilities. Singapore is the most important offshore oil exploration base in Asia and manufactures some drilling equipment. Shell Oil Co., Singapore Refining Co., Esso, Mobil Oil Co., and British Petroleum Co. (BP) each have refineries in Singapore. BP, the smallest refinery of the five, was the only company not planning to expand its present facilities. In addition, the Economic Development Board, the Government's investment incentive agency, was discussing the possibility of a sixth refinery.[35]

In 1980, Singapore's total trade was valued at $43.3 billion (imports, $23.9 billion and exports, $19.4 billion). The country's largest trade partners were the United States, Japan, and Malaysia, each accounting for about 13% of Singapore's total trade. Principal commodity imports in 1980 were crude petroleum, $5.7 billion; office machines and other electrical machinery, $1.7 billion; petroleum products, $1.3 billion; and miscellaneous machinery and equipment, $1.0 billion. Singapore's major exports were petroleum products, $5.5 billion; crude rubber, $1.5 billion; office machines and other electrical machinery, $1.5 billion; and telecommunications apparatus, $1.3 billion.

[6]Total excludes bricks of baked clay valued at $505,548 in 1978 and $524,865 in 1979.
[7]Unreported quantity valued at $218 in 1978.

SRI LANKA[36]

The mining industry of Sri Lanka accounted for 3.5% of the GDP and 3.2% of total exports. New economic incentives involving the mining sector as well as other parts of industry and commerce have been a part of the Government's renewed plan for economic recovery.

The major economic problem during 1980 was the drastic rise in the inflation rate—reportedly between 25% and 30% by July, and estimated by a Government official to reach 100% by the end of 1983. A second serious problem was the lack of new sources of financial aid as skyrocketing costs used up previously committed funds before projects were completed.

The three main projects were the massive Mahaweli River diversion project, the Greater Colombo redevelopment project, and the free-trade zone run by the Greater Colombo Economic Commission. Commercial loans were being considered as a source of financial support with the drying up of funds from international aid agencies.

The accelerated development program was begun in 1977 and at first was plagued by problems including inadequacy of equipment and a shortage of skilled personnel and construction materials. In 1980, the Government encountered an inordinate increase in fuel prices, which imposed severe restrictions on financial resources. The cost of imported oil was 3.3 billion rupees (Rs)[37] during the first half of 1980 compared with Rs1.2 billion for the same period in 1979. Efforts to hold down the volume of oil imported met with little or no success as demands of the construction projects and oil-fueled electricity generation forced increased imports.[38]

New incentives for economic recovery were begun in June 1980 and included a 5-year tax holiday for all companies involved in the Mahawela River scheme, and in the industrial sector, the same tax holiday to public companies considered essential to the country's economic progress. Tax concessions were made to the gem and jewelry industry from mines to exporters. These concessions were expected to ensure better prices to gem miners while promoting the export jewelry trade.[39]

In the 1977 economic liberalization, the value of the Sri Lankan rupee was set at Rs16.0=U.S.$1.00. During 1980, the rupee was being slowly depreciated by the Central Bank and by yearend was slightly over Rs17=U.S.$1.00. Although the Government did not admit the pegged devaluation, exporters stopped forward exchange booking, and the exercise seemed to demonstrate a willingness to trim imports by making them more expensive.

In June 1980, the International Development Association (IDA) approved $19 million credit for construction of energy transmission and distribution facilities. The accelerated Mahaweli Ganga Development Program, now constructing hydroelectric stations, will provide the electricity to be distributed throughout the country, enabling all sectors of the economy to benefit.

An increase in production was reported in the agricultural sector in 1980, coming mainly from a record domestic rice crop. Increases in dairy products, livestock production, and improved performances in fisheries also contributed to improvement in the food-producing sector.

Sri Lanka's exports were overwhelmingly agricultural in nature. Tea, rubber, and coconut together generally account for over 60% of total exports. In addition to the gem stone trade, the only other significant mineral-based export was petroleum products. These were surplus refinery end products such as heavy residual fuel oil and international bunkers for ships and aircraft. The petroleum value was substantial, accounting for 12.5% of export value in 1979.

Sri Lanka's imports were dominated by crude oil, but consumer goods and products used in the development projects were also important. The trade balance, which was in surplus 3 years ago, has since turned into deficit. In the first half of 1980, the trade gap reportedly was Rs7.7 billion, compared with a Rs4.2 billion deficit for the same period in 1979.

COMMODITY REVIEW

In mid-1980, the Sri Lankan Government concluded agreements with one native and seven foreign companies to mine gem stones from a total of 33,000 acres in Sabaragamuwa Province. This was the area expected to be submerged in mid-1984 by six reservoirs when the Mahaweli River irrigation and hydroelectric project was due for completion. The agreement provides for the firms to bring in the capital, know-how, technology, and machinery, and carry out the mining under the supervision of the Government-owned State Gem Corp. (SGC). The

royalty payments were individually negotiated and ranged from 5% to 20% of value. In addition, all of the companies agreed to a 50-50 split of all profits earned. The SGC will have first option on the purchase of all finds. Ruby and sapphire were the major stones, but cat's-eye and alexandrite also occur in the mining area.

Until 1980, gem mining in Sri Lanka, while an important money earner for the country, had been a primitive, one-person or family operation, using the traditional wash pans, baskets, and shovels. Bulldozers, trench diggers, sifters, and other large earthmoving equipment will now be used to seek the placer gem stones. The gem stones are found in gravel-sized alluvium either in active streambeds or in former streambed material along the valley floors. The primary source of the gem stones has never been found.

The Government felt the mechanized mining projects would be a quick and practical way of recovering at least some of the gems that will be lost once the Mahaweli valleys are flooded, and also a means of setting up a national gem reserve. Building sizable stocks would enable the SGC to play a regulatory role in international gem markets, as well as boost Sri Lanka's international credit worthiness and provide exhibits for museums to attract tourists.

Gems reportedly worth 660 million rupees were exported in 1980. The target for gem exports in 1981 was 750 million rupees.[40]

A severe shortage of cement developed in 1980 because of the unusual amount of construction underway in the country. The shortage forced the import of substantial amounts of cement in order to keep the construction on schedule. There were three cement facilities in the country in 1980. Plants at Kankesantuarai and Puttalam produce and grind clinker. The plant at Galle only grinds clinker supplied by the other two plants. Total design capacity of the system was just over 700,000 tons per year. A large expansion project was underway during 1980. Scheduled for completion in 1982, the expanded capacity will reportedly produce a surplus of cement for export.[41]

The Sri Lankan Geological Survey Department conducted a yearlong uranium survey during 1980. Along five separate areas in the country, the geologists identified what were described as large deposits of uranium ore. An 8-month detailed survey was to commence in January 1981 to determine quantity, grade of ore, and the economic feasibility of mining the uranium deposits.

Sri Lankan graphite has a purity of 99% carbon when processed and lends itself to being ground down easily to submicrometer sizes, thus being particularly suitable for use in high-quality lubricants. During 1980, Indian collaboration was sought in developing graphite-based industries in Sri Lanka. Under the proposal, India would supply the plants, equipment, and know-how and train the local technicians. Among the products proposed were foundry mold release compounds, carbon brushes and collars for electrical equipment, graphite-based paints, high-quality graphite-based greases and lubricants, dry and chemical cell electrodes, and graphite crucibles.

The value of graphite exported during 1979 totaled $4.8 million, a more than 26% increase over the 1978 value.

Sri Lanka's first ammonia-urea facility was completed during 1980, but by yearend had not yet been brought onstream because of concern over its economic viability. The complex was located at Sapugaskanda, about 11 kilometers from Colombo, and consisted of a 147,000-ton-per-year N naphtha-based ammonia unit and a 143,000-ton-per-year N urea plant. The plant was designed and built by Kellogg Overseas Corp. at a cost exceeding $170 million. Until the expected 10,000-ton-per-month production level is realized, Sri Lanka will continue to import urea as well as ammonium sulfate from Japan.

Apatite was mined manually on a small scale and applied directly to crops without processing. The Government has been considering setting up a phosphate fertilizer plant at the Eppawela deposit but there was little progress toward start of construction during 1980.

Small-scale mining of mica has been underway in Sri Lanka for many years. Local cottage industry type manual mining operations were located in the Rattota District north of Kandy, Madugoda, and the Matale and Andiradhapura Districts. These local mines sell their product to the State Graphite Corp., which handles marketing and sales arrangements. During 1980, the State Graphite Corp. became the State Mining and Mineral Development Corp. and will presumably have an increasing interest in a wider range of Sri Lankan minerals.

At yearend 1980, seismic, magnetic, and

gravity surveys offshore northwestern Sri Lanka were undertaken for three U.S. firms by Prakla Seismos GmbH of the Federal Republic of Germany. The surveys were expected to be completed by early 1981. The efforts were on a production-sharing agreement whereby the concession holders would forego the capital invested in the survey if no petroleum was found. The contract for concession block 11 was held by Citco Sri Lanka Petroleum Corp., blocks 1 and 10 were jointly held by Aracca Petroleum Corp. and Sundance Oil Co., and block 2 was held by Seahawk International Inc. Past surveys carried out by the U.S.S.R. revealed potential reservoirs and cap rock in these areas.

Ceylon Petroleum Corp. (CPC) completed modifications at the country's only petroleum refinery early in 1980. The improvements removed bottlenecks in the Sapugaskanda flowsheet and will permit a 33% increase in refinery throughput. CPC had planned to install a $102 million hydrocracker in order to produce a better mix of middle-distillate products needed in the Sri Lankan economy. The present facility produces a large surplus of heavy residual fuel oils, which have only a small market in the country. Political and economic problems cropped up in late 1979, and construction did not begin on the project as scheduled. The project was under study during 1980 and was interrelated with the problem of startup at the adjacent fertilizer plant, which was designed to use naphtha feedstock at a time when naphtha sold at a much lower price. Events at the fertilizer plant could influence the profile of products desired from the CPC refinery.

Sri Lanka produced no crude oil or natural gas in 1980. It has traditionally relied on the Middle East countries for its crude oil imports. In 1980, however, an agreement was also reached with Indonesia for the purchase of 360,000 tons of crude oil, Sri Lanka's first purchase from outside the Middle East.

VIETNAM[42]

Vietnam was not a major world producer of any mineral commodity during 1980. It did produce economically significant amounts of coal, phosphate rock, tin, chromite, and cement. Clay, used for brick and roofing tiles, was quarried in large quantity from hundreds of small, local, manually exploited clay pits. The brick and tile were fired generally in primitive batch kilns and used locally. A few large modern kilns provided a higher quality product for more important construction projects. Small amounts of antimony, copper, graphite, iron ore, lead, salt, dimension stone, and zinc were also produced. Deposits of bauxite, manganese, silver, and titanium minerals were also known to exist in the country but were probably not exploited to any important extent.

The Vietnamese recognized the need to survey and prospect for mineral resources that could be useful to the economy. Survey work by Government geologists was underway in 1980 with the help of Bulgaria, Czechoslovakia, Hungary, and the Soviet Union. Bauxite deposits were being delineated in the south. Czechoslovak and Bulgarian specialists were to prospect for lead and zinc in central and southern Vietnam. Selected areas in the south were being mapped with a stress on rare metals potential. Czechoslovak scientists were to help train tin and tungsten prospectors. The sixth geological group, with a work force of 1,100, surveyed limestone and coral deposits for the Ha Tien cement plant, evaluated peat occurrences in Minh Hai Province, fertilizer resources in the Central Highlands, and bauxite in Lam Dong, Dac Lac, and Song Be Provinces. During the bauxite exploration, brown coal, kaolin, and bentonite deposits were also discovered.

Late in 1980, the Permanent Geological Committee of the Council for Mutual Economic Assistance signed an agreement with the Vietnam General Department of Geology to provide technical assistance to Vietnam in geological exploration and research techniques in the 1981-90 period.

Specific data on mineral production are seldom released by the Government, particularly if the figures would show unfavorably on that sector's ability to meet or exceed the planned production. When figures are given, however, they are frequently stated in terms of percent increase over an unstated or unknown period. It was estimated that the mineral sector generally accounted for about 5% of the GNP.

The Vietnamese economy in 1980 continued a downward trend started in 1979. Inept management in both the industrial and agricultural sectors, lack of resources, and inadequate food production, in part caused by natural disasters, were the main causes of the decline. Exacerbating the economic problems was the Government's policy of devoting a major portion of the human and material resources to the military sector. The country had more than 1 million men under arms during 1980, and the Government continued to recruit young men into the armed forces throughout the year. Some sources estimated that nearly one-half of the country's budget was devoted to the armed forces.

With Vietnam experiencing declining production in almost every sector and nominal increases in even the best sectors, the Central Committee was compelled to introduce important reforms in its Sixth Resolution (dated August 1979). These reforms were intended to promote productivity by giving greater freedom to private producers in agriculture and industry, as well as offering a wider scope for the free market in general.[43]

In past years the Government had followed a rigid policy of purchasing grain and other surplus domestic products for a very low price. This resulted in a lack of incentive to produce more than the minimum quota. The policy was changed in early 1980 with a fourfold increase in the purchase price for rice. Even that price was subsequently doubled later in the year.

This rise in the Government's purchasing price for agricultural products, however, brought about a sharp rise in free market prices. The already widespread shortage of consumer goods was also aggravated. Then, in an attempt to slow the inflationary effect of the higher prices, the Government adopted a dual pricing policy. Essential goods would be sold at a stable price, lower than the free market price. Nonessential commodities would be sold at prices paralleling the free market price. The new buying policy would be to offer a stable purchasing price, below the free market price, to cooperatives and individuals for a certain quota of their production. A higher price would be

offered for any production above the quota.

In October 1980, the Government stabilized the grain tax for a period of 5 years at an average of 10% of the volume produced. At the same time the obligatory quota to be sold at the fixed price was also set for 5 years. The results of these new policies would not be clear until well into 1981.

Another reform introduced in some sectors during 1980 was to change the manner in which wages were determined. An end product or piecework wage system was introduced to increase individual incentives and productivity. One of the places where the system was tried was the Ha Tu coal mine. Beginning in the third quarter of 1980, wages were paid on the basis of the end product output. The system reportedly worked well and the Ha Tu Mine was one of the few large enterprises to exceed the 1980 production plan.[44]

Details of production and trade were not available for 1980, but some general information was released in the Vietnamese press. Total industrial output value was Dong 9,490 million[45] in 1980 compared with Dong 9,520 million in 1978 (1979 figures were not included). The Statistics General Department reported that the industrial output index (1975=100) was 123.9 in 1977, 130.6 in 1978, and 124.7 in 1979. The 1980 data were not available, but the index will probably fall between the 1978 and 1979 figures. Coal and cement production showed modest gains in 1980 over the 1978 tonnage.

The 1981 production plan called for increasing electric power output by 6%; coal and phosphorous fertilizer, 10%; cement, 67%; and nitrogen fertilizer, 100%. Chromite and tin production was also to be increased.

Merchandise imports were estimated to be $1,200 million in 1979 with food and raw materials accounting for nearly one-half of the total. Merchandise exports were estimated at $630 million in 1979. Vietnam's main mineral exports have been hard coal and phosphate rock. In view of the prevailing economic problems, it was unlikely that these minerals were exported in the usual quantities in 1980.

In June 1980, Czechoslovakia and Vietnam signed a 5-year trade agreement in which the volume of mutual trade was to be doubled over that of the previous 5-year period. Total imports from Czechoslovakia in 1979 were about $46 million, while exports from Vietnam were about $13 million. Vietnam will receive, among other items, power and engineering equipment and machinery and will export rubber, coffee, clothing, and raw materials, including tin.

Aid from Japan, an important source of raw materials and spare parts, was frozen for the second year. The country was thus heavily dependent on imports of raw materials from the Soviet Union. The Vietnamese press, in July 1980, indicated that 50% of Vietnam's exports went to the U.S.S.R., which had supplied the bulk of raw materials, fuel, technical equipment, food, and consumer goods. In 1980, Moscow was believed to have given credit worth $1 billion to Vietnam. One of the major goals of the third 5-year plan (1980-85) was to increase the value of exports, in particular tropical farm products, minerals, and handicrafts, in order to pay for this large inflow of imports.

COMMODITY REVIEW

Metals.—*Tin.*—The Son Duong (possibly 21°40'N, 105°28'E) tin mine was striving to improve production and succeeded in increasing the ore extraction rate by 3% and overfulfilled the 1980 norm by 10 tons. In past years the mine at Cao Bang supplied the majority of the country's tin concentrate to the small smelter at Tinh Tuc. It is not certain if Son Duong represents a new mine or an older operation not previously mentioned in the Vietnamese press. In either case, if Cao Bang is still operational, the tin production could be substantially higher than the reported tonnage.

Nonmetals.—*Brick.*—Two new brick factories began operating during 1980. The Phuc Thinh kiln was inaugurated on December 30, 1979, and began producing at a rate of 25 million bricks per year. The plant was built with Bulgaria's technical and financial assistance and was located in a northern suburb of Hanoi.

The Linh Nam silicate brick factory was dedicated on July 20, 1980, and began operating at a design rate of 30 million bricks per year. The plant was built with technical and financial aid from Poland. The two plants will require a combined total of over 140,000 tons per year of raw materials, clay, silica sand, and limestone.

Cement.—Work on expanding the production capacity of the cement industry continued at a relatively rapid pace. Three major rotary kiln plants were under construction during 1980.

The Bim Son cement mill was nearing completion at yearend 1980 with financial

and technical assistance from the Soviet Union. The plant was located at Bim Son (20°05'N, 105°52'E) in Thanh Hoa Province.[46] Construction progress on the first of two 600,000-ton-per-year kilns was apparently unsatisfactory in 1979 and early 1980. Additional specialized construction groups were brought in and around-the-clock work accelerated progress. The first kiln was then rescheduled for firing by April 20, 1981, and the entire plant was to be completed by the end of 1981. The maximum effort being put into completing the first production line may have disrupted a balanced construction effort on the second production line. As a result, the scheduled yearend completion of the whole plant may be unrealistic.

Construction on the Danish- and Japanese-aided 3,100-ton-per-day Hoang Thach plant was also running behind schedule, and every effort was made to increase the efficiency and speed of construction and to hasten assembly of the imported equipment. The plant was rescheduled for firing by June 1981, and the entire plant was to be completed by yearend 1981.

Equipment for the French-aided Ha Tien cement plant expansion was originally ordered in 1977 but was just being delivered and transported to the construction site during 1980. Site preparation was continuing in late 1980 and installation of equipment was to begin in the first quarter of 1981.

The plant will have a pre-calcining system rated at 3,000 tons per day with a 4.8- by 89.5-meter kiln with planetary coolers, one 4,500-horsepower air-swept raw mill, 5.2 by 11.0 meters, rated for 240 tons per hour, and two 4,200-horsepower cement mills, each 4.2 by 14.0 meters, rated for 90 tons per hour.

Despite the fact that none of the big new rotary kiln plants was completed during 1980, cement production was increased substantially during the year. No mention was made in the press of the Haiphong cement plant successfully overcoming raw material supply problems and fulfilling the 1980 production goal of 500,000 tons. In light of general industry problems in other sectors, extensive press coverage almost certainly would have been made if the plant had met or exceeded its target. The production increase was probably a tangible result of the completion of a number of mini-cement plants during 1979 and 1980. Many of these small vertical shaft kiln plants with capacities between 5,000 and 20,000 tons per year are now operating and supply a satisfactory product for local construction projects. Completion of the big rotary kiln plants will relieve the still persistent shortages of cement and allow more rapid progress on construction projects throughout the country.

Fertilizer.—Lam Thao superphosphate plant, the country's largest, was being expanded during 1980 with Soviet technical assistance and a local labor force of over 750 persons. The expansion was scheduled for completion in the first quarter of 1982.

During 1980, the Lao Cai apatite mining region's administration was occupied with repairing damaged equipment and reorganizing the management of the mines. In particular, the system of paying wages on the basis of the product obtained was instituted here as in other areas of the country. Apparently the system has led to an increase in production but figures suitable for comparison with past production were not available. Although production probably increased over 1979 levels, it was very unlikely that it surpassed the preborder-war output.

At least one 4.6-cubic-meter capacity power shovel, 1 bulldozer, and 20 heavy trucks were returned to service during the first half of 1980.

One event occurred in 1980 that could help remove a transportation bottleneck in fertilizer distribution. Hanoi radio claimed that the Hanoi-Lao Cai Railroad had been completed and a rail line installed on the Duong Bridge. Lao Cai had been believed to be served by an old low-capacity, narrow-gage railroad system. It is possible that the broadcast referred to the completion of a standard gage line to serve the vital apatite mines. Opening a standard gage line would greatly increase the tonnage of raw ore that could be shipped to the numerous phosphate grinding plants around the country.

Graphite.—In early 1980 the Ministry of Engineering and Metals and workers of Hoang Lien Son Province inaugurated the Mau-a (21°53'N, 104°41'E) graphite mine and concentration plant, the first such facility in Vietnam. The local ore contained 18% to 20% carbon and was beneficiated by crushing and flotation to an 80% carbon concentrate. The plant was designed for a capacity of 1,500 tons of concentrate per year. Late in 1980, Hanoi radio claimed that the Provincial authorities had "expanded the graphite mine" and had "since early this year...exploited 3,000 tons of graphite."[47]

Mineral Fuels.—*Coal.*—The coal sector continued to have trouble meeting production goals during 1980. The original 5-year plan target of 10 million tons of washed coal proved to be wildly optimistic and was revised sharply downward. At the beginning of 1980, the year's goal was set at 8.5 million tons and at 10.0 million tons "within the next few years."[48] By May, Hanoi radio was describing the measures to be used to turn out 6.3 million tons in 1980.[49] By yearend 1980, it was apparent that even this goal was not reached.

The Hon Gai-Cam Pha mining area was the major producer of high-quality hard coal. In past years, the area produced enough for all domestic need plus a considerable surplus. The exported surplus provided one of Vietnam's major sources of foreign exchange earnings.

There were a number of articles in the Vietnamese press during the year criticizing progress in the coal sector and trying to determine how to increase production.

One of the biggest problems was all phases of the coal transport network, from the working face to the ultimate consumer. Although an adequate number of trucks were at hand, a high proportion were not operable for lack of proper maintenance and spare parts. Roads were often in such poor shape that trucks were forced to travel at a very low speed. Under these conditions, drive train and tire wear were excessive, further overloading the already inadequate repair facilities. Railroad track was in equally bad condition; rail was badly worn and ties not replaced. A high proportion of coal cars were not operable.

In addition to equipment problems, there were also problems of poor health and nutrition among the miners, particularly those working in the underground mines. The most skilled and experienced workers were the ones leaving, and the new younger workers did not have the technical training or experience to maintain desired production levels or perform required maintenance or repairs on the sophisticated mining equipment.

With the pullout of the experienced Chinese managers and cadre in 1978, much of the job of planning, designing, and development work reverted to Vietnamese cadre. They had the enthusiasm but not the technical or management skills required to keep the complex mining operations running smoothly.

The Government was doing everything in its power to boost production and efficiency in the mines. The incentive pay system, described earlier, was tried in at least some of the pits with apparently good results. In addition, several large new mines were under construction and many operating mines were being expanded or reequipped.

Development of the Cao Son Mine in Quang Ninh Province began in 1977 and has received a good deal of attention in the press. The mine will be a 3-million-ton-per-year operation when fully developed. Built with technical and monetary aid from the Soviets, the mine will be one of the showpieces of the Vietnamese mining industry. Several million cubic meters of overburden had already been removed by the beginning of 1980, and production was to start in May. The pit was to produce a limited tonnage during the startup period then produce about 1 million tons the first full year of operation. Development will continue until the design output of 3 million tons per year is reached.

Another showpiece Soviet-aided project was to be the Mong Duong Mine, reportedly the first vertical shaft coal mine in the country (presumably other underground workings have horizontal or inclined adits). The mine was scheduled for an August 1981 startup at a production of 430,000 tons per year. Development work was to include 17,000 meters of underground crosscuts. By May 1980, 70% of underground work and 80% of aboveground installations had been completed.

Other projects utilizing Soviet aid were the reconstruction of Vang Danh Mine and sorting plant, restoration of Mong Duong sorting plant, design and construction of Ha Tu, Coc Sau, and Deo Nai Mines, and tripling capacity of Uong Bi coal selection plant to 1.8 million tons per year. The Khe Tam Mine with design capacity of 1.8 million tons per year will be built during the third 5-year plan.

An unnamed coal sorting plant built with Polish assistance was inaugurated near Cua Ong Harbor in Quang Ninh Province on July 20, 1980. The plant capacity was designed to reach 3.2 million tons per year.

Petroleum.—The three companies which have been operating offshore, AGIP S.p.A. of Italy, Bow Valley Industries Ltd. of Canada, and Deminex Deutsche Erdoelversorgungsgesellschaft of the Federal Republic of Germany, all met their 1979 and

1980 exploration obligations. The results were a very disappointing succession of 12 dry holes. Bow Valley's contract still called for it to drill two more holes by yearend 1982. There were no U.S.-owned companies operating offshore of Vietnam.

In July 1980, the U.S.S.R. signed an agreement with Vietnam for cooperation in geological prospecting and extraction of oil and gas. The agreement was said to cover the Bach Ho structure where Mobil Oil Corp. (United States) drilled a well that tested 2,400 barrels per day in February 1975.[50]

There was considerable speculation as to the Soviet's technical ability to drill in the open ocean conditions off southern Vietnam. However, they have been operating a Japanese-built jackup rig off Sakhalin Island, which could be brought to Vietnamese waters. Soviet equipment in European waters would take several months to transfer to Vietnam but could be used.

It was confirmed in 1979 by Vietnamese officials that natural gas had been discovered outside of Hanoi. The discovery apparently has not been developed, and it was speculated that the gas was contaminated and would be difficult to handle.

Vietnam produced no oil or natural gas in 1980 and imported petroleum products to fill its needs.

AFGHANISTAN

A year after the Soviet Union invaded Afghanistan and replaced President Amin with their choice, President Karmal, Afghanistan remained in turmoil. In some respects, the political and economic situation in Afghanistan was no better by the end of 1980 than it was preceding the December 1979 invasion. The Government faced widespread and growing alienation and resistance, virulent factionalism within the ruling party, and an acute shortage of material. The mining sector of the country did not fare better either; the only raw material produced in a significant amount was natural gas, which was exported mainly to the Soviet Union. No statistics on production of other minerals and materials were available by yearend.

Most of Afghanistan's gas production was from the Hodja-Gugerdag Field, southeast of Shibarghan. The gas flow from this field had been about 300 million cubic feet per day since 1961. An estimated 230 to 250 million cubic feet per day of Hodja-Gugerdag's production was moved by pipeline across the Amu-Darya River into the Soviet Union. Most of the remainder was transmitted eastward to a 105,000-ton-per-year fertilizer plant and an electric power station built near Mazar-i-Sharif with Soviet assistance. After the Soviet invasion, the second gasfield, Djar-Kuduk, in the Shibarghan area, was brought under production. This field, which will produce about 200 million cubic feet per day, consists of four gas zones in the Jurassic and lower Cretaceous zones between 3,000 and 8,500 feet deep. The gas has a high hydrogen sulfide content, with considerable carbon dioxide. A new treatment plant was built at Djar-Kuduk by Soviet technicians under a turnkey contract at the end of 1980. It is believed that most of the Djar-Kuduk's initial flow will be sent to the Soviet Union.

[e]Estimated. [p]Preliminary. NA Not available.

[1]Table includes data available through Oct. 12, 1981.

[2]In addition to the commodities listed, a variety of other crude construction materials (common clays, stone, and sand and gravel) presumably is produced, but output is not reported quantitatively and available information is inadequate to make reliable estimates of output levels.

[3]Includes gas reinjected into reservoirs, if any.

BAHRAIN

Despite the continuing decline in Bahrain's production of crude oil, revenues from the petroleum sector were at an all-time high in 1980. Bahrain's gross domestic product (GDP) in 1980 was estimated at $2.2 billion[3] in constant 1977 dollars, which represents a real growth rate of 5.4% over the 1979 GDP. Following the Government's successful deflationary policies in 1978-79, planned increases in capital expenditure in the 1980-82 development plan were intended to sustain real growth in the economy at 7% to 8% per year. The rate of inflation was lowered from a high of about 20% in 1977 to 8% in 1980, which gave further stimulus to the Government to increase spending.

Revenues from the petroleum sector amounted to about $3.15 billion, which represents a substantial 33% increase over the 1979 level. Bahrain's only oilfield, the Awali Field located onshore, produced about 47,000 barrels per day. The field has been in operation for nearly 50 years, and requires constant maintenance and the use of highly sophisticated secondary and tertiary recovery techniques to remain productive. These techniques have extended the life of the field for an additional 10 to 12 years, to the late 1990's or possibly beyond the year 2000; original estimates predicted exhaustion of reserves by 1990.

The major source of Bahrain's oil income is the Abu Sa'fah Field, located in the Persian Gulf north of the island. The field is owned and operated by Saudi Arabia, but the revenues from production are split evenly by Saudi Arabia and Bahrain. Abu Sa'fah produced about 150,000 barrels per day in 1980, and consequently over half of Bahrain revenues from crude oil are from this arrangement. Crude oil from the Awali Field, as well as crude oil from Abu Sa'fah, was sold at official Saudi Arabian prices.

Bahrain produced approximately 85 million barrels of refined petroleum products in 1980 from the Sitra oil refinery. Input for the refinery came from Bahrain's own field, with the remainder being imported from Saudi Arabia. Petromin, the Saudi Arabian Petroleum and Minerals Organization, was under contract to supply the refinery with 100,000 barrels per day of crude oil. Another 100,000 barrels per day was supplied by the California Texas Petroleum Co. (Caltex), a joint venture of Chevron U.S.A. Inc. and Texaco Inc. (United States), which operate the refinery. Caltex's input is derived from their crude oil entitlements in Saudi Arabia.

Caltex originally owned the entire oil industry in the country (both the oilfield assets and the Sitra refinery), through its subsidiary company, the Bahrain Petroleum Co. (Bapco). The gradual transfer of ownership of the oilfield assets was completed in 1979. The Bahrain National Oil Co. (Banoco), a Government-owned company, became the new owner. In July 1980, an agreement was signed transferring 60% ownership of the 250,000-barrel-per-day re-

finery to the Government. The remaining 40% share remained in the hands of Caltex. Bapco continued to operate the refinery, receiving crude from both shareholders and processing it on their behalf. Each party had the right to dispose of its share of refinery products, with the normal throughput working out to 150,000 barrels per day for Bahrain and 100,000 barrels per day for Caltex.

To permit the Government to build up its own marketing organization, and to allow Caltex to continue to fulfill its contracts, both sides agreed on a buy-back arrangement, where the Government will sell Caltex a portion of its entitlement over a 3 1/2-year period. The volume started at 135,000 barrels per day in the second half of 1980, and was to be reduced every year to 112,000 barrels per day in 1981, 70,000 barrels per day in 1982, and then phased out entirely by 1983. Banoco was responsible for marketing about 3% of the refinery's output locally within Bahrain.

Banoco also became responsible for directing new exploration efforts for oil and gas. Most exploration was concentrated in the offshore Persian Gulf region. A 12-month, $15 million seismic exploration survey was initiated during the year by Western Geophysical Co. of Houston, Tex. (United States). The survey was funded by the Bahrainian Government along with the Kuwait Oil Co.

Bahrain's reserves of natural gas were becoming increasingly important in light of the decline in oil production. Approximately 140 billion cubic feet of natural gas was produced during the year, most of it was associated gas from crude oil production. An estimated 9 trillion cubic feet of nonassociated gas reserves was located in the Permian Khuff Formation, which underlies the oil-producing Bahrain Formation. The Bahrain National Gas Co. (Banagas) was formed in 1979 to utilize the previously flared natural gas. Banagas was composed of Banoco (75%), Caltex (12.5%), and the Arab Petroleum Investment Corp. (12.5%). Banagas fed most of the associated gas into the domestic distribution system, which became the power source for local industry. Aluminum Bahrain (ALBA) received 85% of its energy requirements from this tailgas. The remainder of the associated gas was fed to the newly completed natural gas liquids (NGL) plant. The plant was built by the Japan Gasoline Co. for $72 million, and the first shipment of liquids was made in March 1980. The plant was designed to utilize 100 million cubic feet per day of associated gas to produce 280,000 tons per year of NGL, 80,000 tons of propane, 79,000 tons of butane, and 125,000 tons of naphtha (natural gasoline). Output of the Banagas facility was sold to Caltex, which was responsible for marketing.

The volume of Khuff gas, or nonassociated gas produced, ranged from 250 million cubic feet to 460 million cubic feet per day, depending on the season. The output is sold to Bapco (88 million cubic feet per day), with the remainder going to the aluminum extrusion plant and local power stations. The use of air-conditioners in the summer explains the increased usage of gas by the power stations.

In other petroleum-related activities, Bahrain, Kuwait, and Saudi Arabia signed a joint venture agreement to establish the Gulf Petrochemicals Industries Co., which was capitalized at $160 million. Initial contracts for the complex were awarded during 1980. The complex was to produce 1,000 tons per day of methanol and 1,000 tons per day of ammonia. Production was scheduled to begin in 1983. Wimpey laboratories (United Kingdom) won a site survey and soil analysis contract for the plant, which was to be located on a 600,000-square-kilometer site to be reclaimed from the sea. King Wilkinson International of Houston, Tex. (United States), was awarded a $9 million contract for initial feasibility studies, and Uhde (Federal Republic of Germany) won a contract for processing technology and technical expertise.

Bahrain's effort to diversify its economy away from the oil sector was centered on several industrial projects, the most established of which was ALBA, which has been operating since 1971. Aluminum production was again slightly above capacity, at 126,000 tons in 1980. Capacity was to be upgraded to 170,000 tons per year in 1981 through the addition of two new potrooms. The Government owned the majority share (57.9%), with Saudi Arabia holding 20% of the equity, and Kaiser Aluminum Bahrain (United States) and Breton Investments (United Kingdom) owning 17% and 5.1%, respectively. The minority shareholders exported their share of production as standard ingots or ran the metal through the aluminum powder plant, Bahrain Atomiser International, in which Breton has an interest through Eckhardtwerke A.G. (Federal Republic of Germany). The Bahrain and Saudi

share of the output was handled by Bahrain Aluminum Co. (Balco), which is the marketing company for ALBA. Revenues from the export of aluminum were down slightly to $96 million, because Balco held back some of its stock awaiting price increases.

Negotiations were underway for Bahrain to host a six- or seven-member partnership in the Gulf Aluminum Rolling Mill Co. The plant was to produce 40,000 to 60,000 tons per year of semifabricated aluminum products. Equity holders were expected to be Bahrain, Kuwait, Saudi Arabia, and Iraq at 20% each, and Oman and Qatar at 10% each. Production was tentatively scheduled to start at the end of 1983. The mill was to be supplied aluminum ingots from ALBA.

The Bahrain Aluminum Extrusion Co. (Balexco), a Government-owned company, was in the process of upgrading capacity by one-third through the installation of additional anodizing facilities. Balexco has maintained its output at about 3,600 tons per year for the last 2 years.

Also in the planning stage was an iron ore pelletizing plant, to be set up in Bahrain by 1985. The Arab Iron and Steel Co. was formed as a joint venture of Kuwait, Bahrain, the United Arab Emirates, private companies, and other gulf lending organizations. The company was capitalized at $150 million. The project was to produce 4 million tons per year of iron pellets, to be exported to neighboring gulf countries. Bahrain hoped to establish a steel industry sometime in the future.

A joint venture to produce cement came onstream during 1980. The Saudi-Bahraini Cement Co. opened its first kiln late in 1980 and began producing about 1,500 tons per day. The plant, which was located in Saudi Arabia, was designed to produce 6,000 tons per day of cement, making it one of the largest plants in the Middle East. Bahrain was to receive one-half of the plant's output.

Bahrain's major infrastructure project, besides the profitable Arab Shipbuilding and Repair Yard and the modernized Port of Mina Sulman, was the Saudi-Bahrain Causeway. A consortium, led by Ballast Nedam (Netherlands) and including Mitsubishi Metal Corp. of Japan and Bandar Trading and Contracting Co. (Saudi Arabia), was selected to build the set of bridges linking Jasra in Bahrain to Khobar in Saudi Arabia. The contract was valued at $564 million. The causeway was expected to have immense implications for the island nation's economy.

JORDAN

The mineral industry in Jordan consisted of the mining of phosphate rock, petroleum refining, the production of cement, and the mining and quarrying of various building materials. The mining industry continued to increase its share of the total GDP from 20% of the $2.3 billion[4] in 1979 to about 22% of the $2.9 billion GDP in 1980, mainly owing to an increase in the production of phosphate rock and an increase in the price of refined petroleum products. The mineral sector was to continue to expand over the next several years, with production commencing from the Dead Sea potash project and the Aqaba phosphate fertilizer complex in 1982.

Jordan's economy continued to prosper in 1980, with an overall growth in the gross national product (GNP) of 23%, from $2.9 billion in 1979 to $3.6 billion in 1980. The overall index of industrial production showed a 23% increase over that of 1979, with phosphate rock production leading the way. Also adding to the economic upswing was a bumper crop in the agricultural sector, where production of wheat and other grains was up an average of 500%. To maintain the combination of high industrial production and agricultural output, the new 1981-85 5-year development plan concentrated on industry and mining (21%), and irrigation, water projects, and agriculture (20%).

Despite the substantial growth in Jordan's GNP over the last several years, the country has experienced chronic and growing trade deficits. The oil import bill alone equaled all export earnings. Although exports increased by 42% and imports increased only 23% from that of 1979, the difference in absolute terms was a $3.2 million increase in the merchandise trade deficit from $1.55 billion in 1979 to $1.86 billion in 1980. As in previous years, the deficit was more than made up for in receipts from tourism, official loans and aid grants, and remittances from Jordanians working abroad. Receipts from these three sources in 1980 were $516 million, $1.3 billion, and $795 million, respectively. With these revenues, the overall balance of payments showed a surplus of $334 million for the year. Jordan's merchandise trade balance was also expected to improve in the coming year. Since 1977, imports of capital goods have exceeded imports of consumer goods. Industrial production was expected to increase significantly when this capital growth becomes productive, probably within the early part of the decade.

The production of phosphate continued to be Jordan's major mineral industry in 1980. Output increased from 2.8 million metric tons in 1979 to over 3.9 million metric tons in 1980. The substantial increase in output was due to production from the newly opened mines at Wadi-El-Abyad. Exports of phosphates amounted to 3.61 million tons in 1980, which brought in revenues of $156 million. Jordan's phosphate production has increased rapidly since 1977. This increase was the result of careful management by the Jordan Phosphate Mines Co. (JPMC) in maintaining production levels at the earliest mining center, Ruseifa, the progressive expansion of the second center, El Hasa, and the development of a new mining and milling operation at Wadi-El-Abyad.

At Ruseifa, 14 kilometers from Amman, phosphate production began in 1937, and output has been maintained at approximately 800,000 tons per year since 1960. The phosphate occurs in beds from 1.5- to 3-meters thick, with an average triphosphate of lime (TPL) content of 62% to 72%.

At El-Hasa, 138 kilometers south of Amman, the JPMC and its contractors were conducting six mining operations on five separate ore bodies. The phosphorite at El Hasa occurs in two horizons, the upper of which is usually 2.5 to 3 meters thick with an average 62% to 75% TPL content. The lower horizon ranges from 2- to 9-meters thick but is not being worked. Proven reserves at El Hasa were 105 million tons. The mining rate of El Hasa has increased from 1.7 million tons in 1979 to over 2.2 million tons in 1980, and was expected to rise to over 6 million or 7 million tons within a 5-year period.

A new mine site came onstream during the year at Wadi-El-Abyad, about 20 kilometers north of El-Hasa. Output from the mine in 1980 was about 900,000 tons, with an average content of 68% TPL. The phosphorite beds at Wadi-El-Abyad were similar in structure to El-Hasa, and proven reserves were put at 72.5 million tons. Only one ore body out of three is currently being worked, but plans were to increase output from the new location to 3 million tons per year by 1985.

Two milling and beneficiation plants were operating in 1980, one at El-Hasa, and a new plant at Wadi-El-Abyad. At El-Hasa, five separate crushers fed phosphate rock into five beneficiation plants, three with a

500,000-ton-per-year capacity and two with an 800,000-ton-per-year capacity. Output from the plant was 72% to 75% TPL, with a moisture content of 18%. The material was loaded onto rail cars at 600 tons per hour, or onto trucks at 1,500 tons per hour. The ore mills at Wadi-El-Abyad consist of three 500,000-ton-per-year process lines with an output of 72% to 73% TPL, or 73% to 75% TPL, which is transported by road to the rail line at El-Hasa.

Jordan's future in the phosphate mining industry was guaranteed by the large but unexploited reserves at Esh-Shidiya, located several kilometers south of Ma'an near Hitiya. Reserves at Esh-Shidiya were estimated at 923 million tons. The JPMC has entered into various negotiations concerning development, but no plans have been made, and exploitation was unlikely before 1990.

Beginning in 1982, the JPMC will begin delivering some product to the Jordan Fertilizer Industry Co.'s (JFI) new fertilizer complex just south of Aqaba. The JFI was formed in 1975 as a joint venture with Agrico (United States) and American Fertilizer Co. The main contractor for the plant was Spie Batignolles (France) using Rhone-Poulenc phosphoric acid process technology. Heurtey Industries (France) was contracted to build the sulfuric acid plant. Agrico pulled out of the project in 1977, and the Jordan Government took up its stake and appointed Mitsui Toatsu (Japan) to supervise the work. Current shareholders in the company were the Jordan Government (26%), JPMC (25%), the Arab Mining Co. (10%), and the International Finance Corp. (5%) along with several other Arab financial institutions and Jordanian private interests.

The plant, being built at an estimated cost of $300 million, is composed of two 650,000-ton-per-year sulfuric plants, a 400,000-ton-per-year phosphoric acid unit, and two granulated diammonium phosphate or nonammonium phosphate plants, each with a 900,000-ton-per-year capacity. All of the units were scheduled for completion at the end of 1981, and commissioning was expected to take 5 months, with commercial production starting in early or middle 1982. The sulfur and ammonia for the plant were to be imported from neighboring Middle Eastern countries. These imports, along with exports of fertilizer and potash, were to be handled by a marine terminal being constructed by the Government adjacent to the JFI complex, near the border of Saudi Arabia. The terminal was to be capable of handling vessels of 30,000 to 50,000 deadweight tons. The fertilizer plant was also to include a $30 million subplant for the production of aluminum fluoride.

Jordan's single largest industrial venture, the Dead Sea potash project, was under construction in 1980. The $425 million operation was scheduled for completion in 1982. The project was initiated by the Arab Potash Co. (APC), a joint venture of the Jordan Government (51%), the Arab Mining Co. (25%), the Islamic Development Bank (7%), and a combination of other Arab Governments and minority shareholders. George Wimpey and Co. (United Kingdom) won a $131 million contract for construction of the solar evaporation ponds and the surrounding dikes. The potash was to be recovered using carnallite harvesting machines, four of which were purchased from R. A. Hanson Co. (United States) at a cost of over $2 million each. Vöest Alpine (Austria) won a $107 million contract to erect a potash-processing refinery to be located about 1 kilometer from the evaporation ponds.

The potash recovery project begins with Dead Sea brines, which are to be pumped from an offshore area about 1 kilometer from the Lisan Peninsula to a canal, which conveys the brine 10 kilometers by gravity to the salt pan, where solar evaporation occurs. This first pan was to precipitate common salt (NaCl). The brine is then pumped to two smaller precarnallite pans, where additional sodium chloride is precipitated. The carnallite saturated brine then flows into three parallel carnallite pans, where carnallite, a potassium chloride, and magnesium chloride double salt ($KCl.MgCl_2.6H_2O$) precipitate along with about 15% common salt. The carnallite is recovered using the laser-controlled harvesting machines, which crawl along, semisubmerged, on wide caterpillar tracks. The carnallite layer is scooped up and pushed into a pipeline, which leads to dewatering cyclones. The final solids produced total 310 tons per hour. In the refinery, MgCl is leached out, creating synthetic sylvanite (potassium and sodium chloride). The KCl is separated using differential solubilities, and then potash is recrystalized, dewatered, dried, and stored. The refinery can produce 1.2 million tons per year of potash.

Potash is to be trucked by road to Aqaba, and exported by ship from there. Potash marketing was contracted to Mitsubishi (Japan) for Asia (600,000 tons per year), Woodward and Dickerson (United States)

for North and South America (275,000 tons per year), Entreprise Minière et Chimique (France) for Western Europe and Africa (250,000 tons per year), IMIC Holdings for Eastern Europe (40,000 tons per year), and the APC for the Middle East (35,000 tons per year). Exports were to begin late in 1982 or 1983.

Jordan's cement production in 1980 averaged about 800,000 tons, which was supplied by the Jordan Cement Co.'s existing facility at Fuheis, 25 kilometers northwest of Amman. An additional production line at the plant came onstream during the year, increasing capacity from 600,000 to 1.2 million tons per year, but still left production short of demand. To satisfy domestic requirements as well as provide some surplus for export, the Jordan Cement Co. planned to double the capacity at Fuheis and build a second plant at Rashidiyah.

A consortium, led by Mitsubishi and including Kobe Steel Ltd. (Japan), was awarded a $120 million contract to expand capacity at the Fuheis cement plant to 2 million tons per year, through the addition of a sixth production line. The new line was to produce nearly 1 million tons annually, or as much as the five existing lines at the plant. The plant was scheduled for completion in November 1982.

Another contract, worth $224 million, was awarded to the same consortium for construction of a 2-million-ton-per-year cement plant at Rashidiyah, 20 kilometers south of Amman. To finance the plant, Mitsubishi extended to Jordan a $116 million loan, at 7.75% interest per year. The loan was to be repaid semiannually over 8 years beginning in 1985. This plant was to be completed in September 1983.

Jordan's petroleum industry consisted of the refining of petroleum at the Jordan Petroleum Refinery Co.'s plant located at Zarqa. The refinery had a total input capacity of 35,000 barrels per day of crude oil and produced over 12 million barrels of refined products in 1980. Crude oil feedstock was supplied by Saudi Arabia through the Trans-Arabian Pipeline (TAPline). Industrialexport of Romania was supervising expansion of the refinery, to handle 90,500 barrels per day, but expansion was delayed several months during the year, and the new completion date was March 1981.

Petroleum exploration in Jordan, although unsuccessful to date, was continuing in 1980. The Jordanian Natural Resources Authority commissioned a $4.2 million, 6-month seismic survey to be conducted by the French prospecting firm Cie, Générale de Gèophysique and Geophysical Services (United States). The areas to be explored were al-Azraq, al-Sorhan, al-Rayshah, al-Jafr, and the Jordan Valley. Potential sites for exploratory wells were to be determined on the basis of the survey. The new 1981-85 5-year plan also called for a nationwide oil search at a cost of about $75 million, to be supervised by the Natural Resources Authority.

Jordan also had large reserves of oil shale, with reserves estimated at about 30 billion tons. Klockner and Lurgi (Federal Republic of Germany) was contracted to do a $630,000, 17-month prefeasibility study for a 50,000-barrel-per-day shale retorting plant at Lajjun, near Karak in central Jordan. Proven reserves at Lajjun were 1.3 billion tons, and in places the shale was in excess of 400-meters thick.

LEBANON

The mineral industry in Lebanon consisted of the refining of imported petroleum, the production of cement, iron and steel products, gypsum, limestone, and salt. Despite the mineral sector's minor contribution to the overall economy, cement and iron and steel semimanufactured items ranked as the country's first and third

largest commodity exports, respectively. Lebanon's major exports and their relative percentage of total exports were cement (29%), lumber (25%), iron and steel (11%), construction materials (9.4%), and limestone and gypsum (3.1%).

Lebanon's economic situation remained relatively stable in 1980, despite continuing disruptions from political violence. The country's economy remained tied to its historical position as a major trading center for the Middle East, as well as a significant supplier of foreign labor. Exports from Lebanese ports in 1980 amounted to approximately $1.2 billion,[5] only 61% of which originated in Lebanon, the remainder being from other Middle Eastern countries. The Lebanese Chamber of Commerce estimated that this export figure represented only 70% of total exports, with the other 30% passing through small ports controlled by local militias, where no duties were collected.

Imports remained about the same as in 1979, about $2.3 billion, which left the country with a sizable merchandise trade deficit. The deficit was more than made up for by remittances from Lebanese workers abroad and loans from other Arab countries. Total Arab aid to Lebanon in 1980 amounted to almost $400 million, mostly from Iraq, the United Arab Emirates, Kuwait, and Saudi Arabia. These two factors left the country with a $700 million surplus in the balance of payments.

Lebanon's two refineries operated slightly below capacity in 1980, owing to disruptions in product distribution and damage to some of the refining units. The Mediterranean Refining Co. (Medreco) refinery in Zahrani in south Lebanon processed 6 million barrels of imported crude oil in 1980, which cost the company $155 million. The Medreco refinery was owned jointly by Caltex (50%) and Mobil Oil Corp. (50%), both U.S. companies. The Tripoli refinery, located in northern Lebanon, processed 11 million barrels of imported crude oil, which is equivalent to about 85% of its total capacity. The import bill for the refinery, which was owned by the Government, amounted to $287 million in 1980. Operations at the Tripoli refinery were shut down for several weeks in April 1980, when the distribution of refined products was halted for security reasons, and the storage tanks could not accommodate any additional production. Technical problems with some of the refining units at the Medreco refinery created a shortage of gasoline, which the Independent Fuel Fund supplemented by importing gasoline at a cost of $120 million. This brought Lebanon's total oil import bill to $562 million in 1980. Because of subsidies on the price of refined products in Lebanon, the Government had to bear an operating loss of $67.5 million for the Tripoli refinery. All of Lebanon's refinery feedstock was supplied by Saudi Arabia through the TAPline.

Cement production in Lebanon continued to exceed domestic demand in 1980, and revenues from cement exports reached $43 million in 1980. There were three cement plants operating in Lebanon in 1980, all located in Chekka. All three plants were owned by private interests within the country. Production capacity at the Société des Ciments Libanais plant was expanded from 1.2 million to 1.8 million tons per year in 1980. Also, production from the Cimenterie Nationale S.A.L. plant increased from 450,000 to 1 million tons per year in 1979. Capacity at the Société Libanais des Ciments Blanc remained the same in 1980, at 160,000 tons per year. Total production during the year was about 2.2 million tons, which was well below capacity, but large enough to provide a surplus for export.

Limestone and gypsum used in Lebanon's cement industry were quarried within the country. Lebanon's mountains provided a nearly inexhaustible source of limestone and large reserves of gypsum. Much of the country's production was used in the domestic cement industry, but a significant quantity, valued at $4 million, was exported.

Iron and steel production remained stable in 1980, at about 220,000 tons. Semimanufactured steel was produced at three plants, all using imported crude steel and scrap. The three plants were Consolidated Steel Lebanon S.A.L., in Bablos-Amchit; the Lebanon Steel Mill Co., in Tripoli; and Société Nationale des Tubes S.A.L., in Dekwaneh. Total capacity of the steel industry in Lebanon was approximately 400,000 tons of reinforcing bars, rounds, and galvanized steel pipes.

OMAN

Oman continued its efforts to develop its nonoil mineral resources in 1980, with emphasis placed on gas, copper, steel, and cement production. The sultanate remained dependent, however, on hydrocarbon resources to fuel this development. Oman's oil industry has turned around since 1978, when oil production was expected to continue its decline. New discoveries and new fields coming onstream have increased the

country's proven reserves, and production was expected to remain near its alltime high through the 1980's.

In terms of world production, Oman was a marginal producer, representing about 0.5% of world production, and it remained the smallest of all the Persian Gulf producers. In terms of the economy, however, oil and gas production was responsible for over 90% of the country's export earnings. Industry and agriculture, on the other hand, accounted for 2% of the GNP and 1% of export earnings, respectively. Government revenues from oil exports in 1980 amounted to $3.3 billion,[6] a 10% increase over the 1979 level despite a decrease in production from 1979. With oil production back on the rise, development spending has increased in 1980. New industries were expected to diversify Oman's economy, while the Government budget was able to maintain a surplus for the second consecutive year.

Oil production in Oman declined for the fourth consecutive year in 1980, with output averaging 287,000 barrels per day. Despite the decline, the industry's performance was considered excellent because production increased significantly in the second half of the year. Output for the first half of 1980 averaged 270,000 barrels per day, while in the second half production increased to over 300,000 barrels per day. The increased production was a result of two new fields coming onstream, both located in southern Oman. The first, the Amal-Marmul Oilfield, came onstream in September. Output from the three closely linked fields of Marmul, Birba, and Qaharir averaged 70,000 barrels per day through the remainder of the year. The producing fields were located in a concession held by Petroleum Development Oman (PDO), the majority state-owned company. PDO was owned 60% by the Government, 34% by Royal Dutch/Shell (Netherlands), 4% by Compagnie Francaise des Petroles (CFP)-Total, and 2% by Participation and Explorations Corp. (Partex) (Portugal).

Until the second half of 1980, PDO was the sultanate's only oil-producing company. In October 1980, however, Essence et Lubricants de France (Elf)-Aquitane (France) brought into production its Sahmah Oilfield, located in the Butabul region, 550 kilometers southwest of Muscat near the Saudi Arabian border. Two wells, Sahmah 1 and Sahmah 3, were discovered in 1979 by a concession operated by a consortium composed of Elf-Aquitane (48%), Sumitomo Metal Mining Co. Ltd. (Sumitomo) (Japan) (32%), and Wintershall A.G. (Federal Republic of Germany) (20%). The wells began producing 12,000 barrels per day in October, and continued at that rate through the end of the year. Sahmah crude oil had an API gravity of 43.5° and a sulfur content of 0.14%.

The southern Dhofar Province fields, which were discovered in the late 1970's, have been linked to the older northern fields and the existing export terminal through construction of a 455-kilometer, 18-inch pipeline, with a 70,000-barrel-per-day capacity. Dodsal Private Ltd. (India) completed the pipeline in December 1980, under the engineering and construction management of Kellogg Continental B.V. The main portion of the line runs from the Marmul Fields, northward to the Qarn Alam Fields and into the existing pipelines, which link up with the main terminal at Mina-a-Fahal near Muscat. The line cost an estimated $73 million. A separate spur line links the Sahmah Field to the Marmul pipeline, with the southern fields linked to the northern fields at Qarn-Alam, Fahud, Lekhwair, Yibal, and Natih, total capacity of Oman's oil industry was approximately 350,000 barrels per day. The country's production for the next 5 years is to average 330,000 barrels per day.

The new pipeline was constructed to bypass new discoveries made during 1980, but not yet in production. The recent discoveries in the southern Dhofar Province spurred exploration in the area, with several oil strikes resulting in 1980. The most important discovery was the Rima Oilfield in PDO's concession, 140 kilometers northeast of Marmul. Four appraisal wells were drilled during the year, which produced 33° API oil from a sandstone reservoir. PDO planned to spend $140 million on development of the field. The pipeline passed over the Rima Field, and gas from the nearby Birba Field was to provide electricity for field development and a pump station at Rima.

Exploration was continuing elsewhere in Oman. Amoco Oman Oil Co., a subsidiary of Standard Oil Co. of Indiana (United States), was awarded a production sharing concession covering 49,000 square kilometers offshore northeast Oman. Amoco was to spend $70 million on exploration over 7 years. Amoco also holds 85.5% of another offshore concession, along with Deutsche Schachtbau (Federal Republic of Germany) and Wintershall A.G. The concession extends from Masirah Island to Sauquirah Bay off the coast of southeast Oman.

Another consortium, including the Japa-

nese Sumitomo Petroleum Development Co. (operator), Elf-Aquitane, International Energy Development Corp. (Netherlands), and the Kuwait Petroleum Corp., was to begin exploring for oil in the eastern part of the country. The group was to spend $130 million on exploration over a 6- or 7-year period.

These new discoveries in Oman have allowed PDO to raise its figures for recoverable oil reserves by 61%, from 1.5 billion to 2.44 billion barrels. With the projected production level for the decade at 330,000 barrels per day, Oman's reserves are expected to last another 25 to 30 years.

The Government was planning to build its first oil refinery at Mina-al-Fahal. Japan's Mitsui Co. won a contract worth $75 million to build the refinery. The plant, with a capacity of 50,000 barrels per day, was to begin production in 1982. Oman previously imported petroleum products from Bahrain and the United Arab Emirates at the rate of 3.5 million barrels per year. The refinery was expected to meet the country's domestic requirements and provide a substantial surplus for export.

Natural gas was also becoming an important commodity for Oman. Gas development was centered around the Yibal Gasfield, where reserves of nonassociated gas were estimated at 5 trillion cubic feet. Oman's NGL plant, located near Muscat, came onstream late in 1979. The gas was transported from Yibal, near the Saudi border, to Muscat by way of a 20-inch, 325-kilometer pipeline. Another gas liquefaction plant was under construction at Fahud, and plans were made to construct a similar unit at Lakhwair.

Yibal gas was also used to fuel the 225-megawatt power generation-desalinization complex at al-Ghubra. Gas was transported by pipeline to al-Ghubra. Oman planned to extend the pipeline along the coast to Sohar, to be used in the $120 million copper mining and smelting complex of the Oman Mining Co. The Ministry of Petroleum and Mineral Resources signed a $40 million contract with Dodsal Private Ltd. to build the pipeline. In addition to providing fuel for the smelter, the gas was to be used in the industrial area of Rusayl. PDO was also constructing a liquefied petroleum gas (LPG) plant at Yibal. The plant was to produce propane, to be used in the cooling systems of the company's gas plant, and butane, which was to be supplied to a local company for bottling. Lean residue gas was to be fed into the al-Ghubra pipeline, while condensate above propane was to be fed into the crude oil stream to upgrade heavier crude oil for export.

Oman's major nonoil mineral development project was the Sohar copper mine and smelter, under construction by the Oman Mining Co. (OMC). The OMC was set up in 1978 to exploit copper deposits near the Gulf of Oman. Original shareholders in the company were the Omani Government (75%); Marshall Oman Exploration Inc., a subsidiary of the U.S. Marshall Group (22.5%); and Prospection Ltd. of Canada (2.5%). In April 1979, the Government took over Marshall Oman's equity share and, in May 1980, the company completed the takeover by buying out Prospection Ltd.

The copper project was to mine three deposits, Lasail, Aarja, and Bayda, all located about 25 kilometers west of Sohar. Reserves at the deposits were estimated at 8 million, 3 million, and 1 million tons, respectively. The mining rate was to be about 3,000 tons per day, giving the mine a life of 11 to 12 years. The mining method to be used was trackless sublevel caving, with access to the deposit by declines. By the end of 1980, the main shaft and several secondary shafts had been dug.

Plans were finalized in 1980 for a 20,000-ton-per-year electrolytic refinery to be built adjacent to the mine. Initial plans were only for production of concentrated and blister copper, but higher metal prices and the potential for recovering gold and silver slimes led to plans for a refinery. The mine, concentrator, and refinery were expected onstream sometime in mid-1982. Power for the entire complex was to be supplied by a new 30-megawatt power station, to be supplied by General Electric Co. (United States). The plant was to be fueled by gas from the Muscat pipeline.

The sultanate's other large industrial project was a cement plant, currently under construction at the industrial center of Rusayl. The project was initiated by the Oman Cement Co., originally owned jointly by the Oman Government (60%) and the Kuwait Cement Co. (40%). The Kuwaitis withdrew from the company in 1980, and the planned capacity of the plant was scaled down from 1 million to 600,000 tons per year. Costain International signed a contract with Krupp Polysius A.G. of the Federal Republic of Germany for civil engineering works for the plant. The main contractor for the plant was Krupp Polysius, and the consulting engineer for the Oman Cement Co. was Basse Sambre E.R.I. of Bel-

gium. Construction was to start early in 1981, with production commencing in the latter part of 1983.

Production from Amiantit Oman's pipe plant, located in the Rusayl industrial zone, was running at 40% capacity during 1980. Amiantit Oman was an Omani company affiliated with the Swiss Eternit Group, with 40% local shareholding. The plant produced four types of pipe, including fiberglass reinforced plastic pipe and cement pipe.

The Ministry of Petroleum and Mineral Resources continued its investigation of Oman's nonoil resources. The northwest Oman mountains have already proved to be heavily mineralized. Scattered podiform chromite deposits, with reserves totaling 5 million to 10 million tons, have been located in the mountains, and were under study. Other mineral occurrences include asbestos (8 million to 10 million tons), coal (10 million tons), iron, lead-zinc, and manganese. Gypsum deposits at Salalah, together with local shale and limestone, were being considered for use in the country's new cement plant. To further explore the country's resources, Japan agreed to undertake a 3-year mineral survey, covering 5,500 square miles in northern Jaalaan and southern Dhofar. The cost was to be covered by the Japanese Government.

PEOPLE'S DEMOCRATIC REPUBLIC OF YEMEN

The mineral industry of the People's Democratic Republic of Yemen (PDRY) consisted of the refining of imported petroleum and the mining of salt. Exports of refined petroleum products accounted for nearly 75% of total exports in 1980, valued at about $250 million.[7] Other income was derived from exports of fish, tobacco, coffee, and salt. The country's major imports were food ($227 million), cement and construction materials ($20 million), crude oil and oil byproducts ($87 million), and industrial raw materials ($41 million). PDRY's balance-of-trade deficit in 1980 amounted to over $200 million. The overall balance of payments was rescued by about $200 million in foreign assistance in the form of soft loans, project assistance, and outright aid grants. Over $20 million in loans was granted by International Development Association, an affiliate of the International Bank for Reconstruction and Development (World Bank), to assist in agricultural development and petroleum exploration. Other foreign assistance was largely from Eastern Europe, mainly the Soviet Union, Bulgaria, and Czechoslovakia.

Infrastructure development continued to be a top priority of the PDRY Government. The country was in the last year of the 1976-80 5-year development plan. During the course of the plan, industrial production rose 167%, fish production rose 137%, building and construction went up 318%, the transportation and communications sector grew 234%, while the agricultural sector grew only 30%. Slightly less than 50% of the productive resources in the economy were under the control of the public sector. The Government planned to fuel new development by promoting these public sector industries. The Government's major project was the construction of two power stations, in Mukalla and Aden, where generation capacity was to be increased by over 200 megawatts and extended into rural areas. The U.S.S.R. was financing both projects.

The Government was also in the process of modernizing port facilities at Aden to accommodate greater transshipments of oil and petroleum products. The renovation was being sponsored by a $14 million loan from the Arab Fund for Economic and Social Development and a supplementary loan from the World Bank. Aden was one of the world's largest oil bunkering facilities prior to the closure of the Suez Canal. New movement through the canal was expected to significantly increase the commercial importance of the port.

The Petroleum and Minerals Board (PMB) offered five onshore areas for bids for petroleum exploration in 1979, all under production-sharing rules. The bids required a minimum of two wells within 3 years. Equity was to be split 40% for the operator, from which costs could be recovered, and 60% for the PMB. Other areas undergoing exploration were the Socotra Island offshore area, where Siebens Oil and Gas Ltd. (Canada) abandoned its first wildcat in 1979. Technoexport of Romania and Azienda Generale Italiani Petroli S.p.A. were exploring offshore areas near the Thalmud coast and the Sayud coast, but no details were available on drilling operations. The World Bank was financing a $9 million petroleum exploration project to aid the Government in evaluating its oil potential. The study involved a 15-month seismic survey to

provide a loose grid of profiles over a large portion of the onshore area. Included in the grant were technical assistance for local Yemeni staff, project management, and data evaluation services. The Government was to pay for $1 million of the total $10 million cost.

Aden's petroleum refinery, originally owned by British Petroleum (BP) until nationalized in 1977, continued to operate at about 35% of its 160,000-barrel-per-day capacity, while still providing over 80% of the country's industrial output. Petroleum products were exported mainly to Africa. Crude oil was imported from Kuwait, Qatar, and the United Arab Emirates at an estimated cost of $100 million. The Government was in the process of adding a butane gas unit to the refinery, which was expected to significantly increase the total value of products. There were no details available on the progress of the project or a startup date for the new unit.

Salt production from the General Salt Organization's facility at Khawr Maksoir continued to provide the country with domestic supplies of salt and an easily marketed export. The plant, located northeast of Aden, was capable of producing 80,000 tons per year of unrefined marine salt from the evaporation of seawater. Salt exports were directed mainly to Africa.

The Government, in cooperation with the Soviet Union, was planning to investigate the feasibility of setting up new industrial projects to be based on local raw materials. Among the projects under consideration were a cement factory and projects to prospect for gold, iron ore, and precious stones. The Government was also interested in establishing a limestone quarry to supply the planned cement factory and possibly a marble quarry for export.

QATAR

The production of hydrocarbons remained the most important economic activity in Qatar, while other oil- and gas-based industries began to diversify the country's industrial base. As part of a major industrialization scheme, Qatar commenced production of petrochemical products, fertilizer, steel, cement, and NGL, all within the past 2 years. The total capital cost of the ventures was expected to exceed $4 billion.[8]

Crude oil was, however, the most important mineral commodity, accounting for 95% of the country's export earnings and over 90% of Government revenues. Oil revenues for 1980 exceeded $5.8 billion, as Qatar increased its official oil price from $27 per barrel at the end of 1979 to $36 per barrel by January 1981. The oil revenues created one of the highest per capita incomes in the world; slightly over $14,000. The country's major exports were crude oil, natural gas, steel, and fertilizer.

Qatar's crude oil production declined 6.7% in 1980, from approximately 506,000 barrels per day in 1979 to 472,000 barrels per day in 1980. Petroleum production was under the control of the Qatar General Petroleum Corp. (QGPC), a wholly Government-owned company. The oil industry was originally owned by two companies: The Qatar Petroleum Co. (QPC), composed of Shell Oil Co. (United States), CFP (France), BP, Standard Oil Co. of New Jersey (United States), Mobil Oil Corp. (United States), and Partex (Portugal) and the Shell Co. of Qatar (SCQ), owned by Royal Dutch/Shell (Netherlands). These foreign companies' assets were nationalized in 1976-77, and the Qatar Petroleum Producing Authority (QPPA) was established as a subsidiary of QGPC to administer these assets. In July 1980, QPPA was merged with QGPC, completing the Government's takeover of the oil industry. QGPC was responsible for oil exploration, oil and gas production, petroleum refining and marketing, and supervision of petroleum projects under construction at the industrial zone of Umm Said.

All onshore oil production in 1980 came from the Dukhan Oilfield, which began producing in 1949. Three main areas, Khatiyah, Fahahil, and Jaliha, make up the field. There were a total of 172 wells in the three areas, 70 of which produce oil, 11 produce natural gas, and the remainder were for water and pressure control. Onshore production for the year averaged 228,000 barrels per day, which represents about 48% of total production.

Offshore production came from three main fields; Idd Al-Shargi, Maydan Mahzam, and Bul Hanine, which began producing in 1964, 1965, and 1973, respectively. Average output from the offshore fields was 244,000 barrels per day in 1980, an 11.5% drop from the 1979 level. Offshore oil was exported through the Halul Island termi-

nal, which had a storage capacity of 6 million barrels. Offshore oil had an average API gravity of 36.6 and a sulfur content of 1.4%, which was slightly lower in quality than onshore oil.

The Bunduq Field, located in the gulf between Qatar and the United Arab Emirates, was exploited by both countries and operated by the Abu Dhabi Marine-Areas Operating Co. The field was shut down in 1979 owing to pressure maintenance problems and did not reopen in 1980.

Further oil exploration by the QGPC in the Dukhan, Bul Hanine, and Maydan Mahzam Fields uncovered additional reserves. A study to evaluate these reserves was being carried out by U.S. Scientific Software and Core Laboratories (both United States). In 1979, 39 new wells were drilled and 3 offshore platforms, including 1 owned by QGPC, were conducting drilling operations.

QGPC's crude oil output was sold under contract to the former shareholders in the company and other Japanese customers. The former shareholders in QPC were entitled to 130,000 barrels per day of crude oil, while Shell of SCQ was entitled to another 145,000 barrels per day. The Japanese contract customers were Mitsubishi (45,000 barrels per day), Sumitomo (30,000 barrels per day), Mitsui (20,000 barrels per day), and Nichimen, Nissho-Iwai and C. Itoh and Co. (10,000 barrels per day each). The remainder was sold on the spot market.

Qatar had one operating refinery in 1980, and planned to construct another by 1983. The National Oil Distribution Co., which was owned by QGPC, operated an 11,000-barrel-per-day refinery at Umm Said. The refinery, brought onstream in 1975, had an initial production capacity of 6,300 barrels per day, but was expanded to meet the local demand for petroleum products. In October 1980, Qatar awarded Technip of France a $138 million contract for the construction of a new 50,000-barrel-per-day refinery, to be located near the existing refinery at Umm Said. The new refinery, to be constructed on a turnkey basis, was to be completed by 1983. It was designed to process oil produced onshore. Included in the contract were storage facilities for intermediate and refined products and new export facilities. The new refinery was expected to satisfy domestic requirements until 1995. Surplus production in the first several years of operation was to be exported.

The production utilization of natural gas was expected to become the fuel to drive Qatar's development in the future. Associated gas was produced from both onshore and offshore oilfields. Onshore gas reserves were estimated at 60 trillion cubic feet. The onshore gas was used for local power generation, and the remainder was transported by pipeline to the Umm Said industrial zone, for use in the Government power generation-water desalinization complex, the Qatar Fertilizer Co. (QAFCO), a new NGL facility, and the Qatar Petrochemical Co. (QAPCO).

In November 1980, Qatar's two fully integrated NGL plants (NGL-1 and NGL-2) were brought onstream. The two plants cost an estimated $738 million, and began production at well below their capacity. Initially, both plants were to utilize Dukhan onshore gas. Meanwhile, the three offshore fields were completing gas gathering and pipeline facilities to make available another 250 million cubic feet per day of associated gas for the plants. A 290-kilometer pipeline was being completed to transport gas from offshore fields to Umm Said. Full rated capacity of NGL-1 and NGL-2 was as follows:

	NGL-1	NGL-2
Propane ---------- tons per day	740	220
Butane ---------- do	470	730
Condensate ---------- do	370	73
Methane-enriched gas million cubic feet per day	140	110
Ethane-enriched gas ---------- do	24	28

The propane, butane, and natural gasoline were for export, while the ethane- and methane-enriched gas was to be used as feedstock for the petrochemical plant. Some methane and residual gas was to be used by the fertilizer plant, the steel mill, and other power stations.

Qatar's future as a world leader in natural gas production was guaranteed by the presence of the Northwest Dome, a large offshore gasfield in the Permian Khuff Formation. Reserve estimates of nonassociated gas range from a conservative 70 trillion cubic feet to 250 trillion cubic feet, which makes this field one of the largest in the world. Qatar was moving cautiously on development, apparently waiting for oil supplies to dwindle and natural gas prices to achieve parity with crude oil. It has, however, invited tenders for a $4 billion gas project to develop the field. Several companies have shown an interest, including Exxon (United States), Mobil, Royal/Dutch Shell, CFP, Wintershall A.G., and BP. The last four have submitted proposals. The

QGPC planned to allow the foreign contractor a 20% equity share in the project, while allowing another foreign firm to handle marketing operations. The project being considered would cost about $4 billion; $1.5 billion for drilling operations and production facilities, $2 billion for an NGL plant, and another $500 million for onshore facilities and related infrastructures. The earliest possible production date was 1983.

The QAPCO petrochemical complex at Umm Said was nearing completion at the end of 1980. QAPCO was owned 84% by QGPC and 15% by Charbonnages de France (CDF)-Chimie. The complex was built by Technip of France under a $200 million turnkey, lump sum contract. The plant was to utilize ethane-enriched gas from NGL-1 and NGL-2 to produce 280,000 tons per year of ethylene, 140,000 tons per year of low-density polyethylene, and 46,000 tons per year of sulfur. Aside from the ethylene unit built by Technip, a $27 million, 50-megawatt power station was supplied by Turbotechnica of Italy. Associated ancillary facilities worth $81 million were supplied by Japan Gasoline Co. The plant was due onstream early in 1981.

QAFCO was producing near capacity by the end of 1980, owing mainly to a halt in fertilizer supplies from Iran and Iraq. QAFCO-1, which came onstream in 1976, had a production capacity of 900 tons per day of ammonia and 1,000 tons per day of urea. QAFCO-2 began producing fertilizer early in 1978, and effectively doubled the capacity of the complex. Ammonia output reached rated capacity near the end of the year to make up for the shortage of supply in the Middle East. QAFCO was located in Umm Said, and was owned by the Government (70%), Norsk Hydro A.S. (Norway) (25%), U.S. Davy Powergas Corp. Ltd. (3%), and Hambros Bank (United Kingdom) (2%). Natural gas feedstock for the plant was derived from the Dukhan Oilfield and residual gases were derived from NGL plants.

The Qatar Steel Co. (QASCO) has become one of the most successful industries in Qatar since its opening in 1978. Output in 1978 was about 85,000 tons, rising to 350,000 tons in 1979, and operating at full capacity of 400,000 tons for all of 1980. The ministeelworks, located in Doha, consisted of a single 400,000-ton-per-year Midrex direct-reduction plant, two 70-ton capacity electric arc furnaces, two 4-strand continuous billet casters, and a tandem rolling mill. Total design capacity was 400,000 tons per year of raw steel and 330,000 tons per year of rolled steel. Iron ore was supplied by Sweden and Brazil, and scrap was from the United States. Approximately 90% of the output of the plant was exported. Steel was exported to Saudi Arabia (42%), the United Arab Emirates (24%), Kuwait (15%), Iraq (8%), and 2% to other countries. QASCO was owned 70% by the Government, 20% by Kobe Steel of Japan, and 10% by Tokyo Boeki, also of Japan. Kobe Steel supplied the casting machines and the rolling mill for the plant, and was also to supply management services to QASCO for its first 8 years of operation.

Cement production from the Qatar National Cement Co. remained well below capacity in 1980, at about 209,000 tons. Capacity of the country's only plant was 1,000 tons per day. This low production level forced Qatar to import over 250,000 tons of cement in 1980. To alleviate the situation, Qatar signed a contract with the Belgian company, IRI, for a new cement works with a capacity of 2,000 tons per day. This amount was expected to meet the country's domestic requirements well into the decade. No specifics on the contract were available.

SYRIA

Syria's mineral industry made a significant contribution to the 1980 GDP, estimated at nearly $11 billion.[9] The principal mineral commodities were, in order of decreasing value, petroleum, phosphate rock, cement, fertilizers, and iron and steel. Syria's economy continued to expand in 1980, despite a growing trade deficit and an annual inflation rate of nearly 25%. The GDP grew an estimated 9% in real terms in 1980, twice the rate of 1979. One of the country's main economic problems, its chronic balance-of-trade deficit, continued to worsen, from $1.4 billion in 1979 to $1.9 billion in 1980. Official transfer payments, mostly from other Arab nations, amounted to over $1.6 billion, but still left the country with a small deficit ($244 million) in the overall balance of payments. The Government attempted to narrow the deficit near the end of the year by establishing a two-tier currency exchange rate. The old official rate remained in effect for the major exports (oil, cotton, and phosphates), while all other exports were governed by a new parallel rate determined by market forces. The new structure was intended to promote exports and encourage increased remittances from Syrians working abroad.

Syria's crude oil production in 1980 increased slightly from the 1979 average of 167,000 to 173,000 barrels per day. Production is likely to stabilize at this level for several years, unless additional reserves are located. Recoverable reserves were estimated at 1.6 billion barrels. Five oilfields were being exploited in Syria: Rumeilan, Karachuk, Suweidiyah, Jebisseh, and Alayan.

All of the fields, except Jebisseh, produced low-quality (average API gravity 20°) and high-sulfur (4.5% to 9.5%) crude. Jebisseh produced 40° API low-sulfur crude.

Despite continuing exploration efforts, no substantial new reserves have been discovered in the country. Enhanced secondary and tertiary recovery techniques were thought to be the most likely cause of any increase in recoverable reserves. The state-owned Syrian Petroleum Co. (SPC), which controlled the country's oil industry, was active in exploraton near al-Hasakah. Rompetrol of Romania was also exploring in the northeast of the country. Three U.S. companies, including the Pecten Syria Co., a subsidiary of U.S. Shell, and the Syrian American Oil Co. (SAMOCO) (Coastal States Corp., Houston, Tex., United States) obtained adjacent joint concessions with SPC in central Syria. Deminex of the Federal Republic of Germany joined SAMOCO in the joint concession in 1979. Two other exploration agreements were signed in 1979, one with Marathon Oil Co. (United States) for a 10,000-square-kilometer tract centered around Homs, and the other with Challenger Desert Oil Co. (Chadoil) (Panama) for 17,000 square kilometers south of Palmyra. By yearend 1980, Pecten and SAMOCO had spudded test wells, but no details were available.

Syria's refining industry more than doubled its capacity in 1980, when the Baniyas refinery came onstream late in the year. The older refinery at Homs was built in 1959 and its capacity was upgraded to 38 million barrels per year of crude oil input. Bids were invited during the year for adding additional capacity to the refinery through installation of kerosine and gasoline beneficiation units. These improvements were to raise capacity to 38.5 million barrels per year.

The country's new refinery, at Baniyas, had an annual capacity of 45 million barrels of crude oil. The refinery was built by Industrialexport of Romania, and Romanian personnel began trial runs late in the year. The refinery managed to process 12 million barrels of oil in 1980, which produced 22 tons of butane, 1,300 tons of fuel oil, and 360 tons of naphtha.

Syria's crude oil exports were destined for Western Europe (80%), North America (11%), Eastern Europe (8%), and the Middle East (1%). Most petroleum product exports were delivered to Western Europe. Petroleum trade for the year (exports minus imports) showed an overall surplus of $500 million.

Syria planned to start utilizing its reserves of associated and nonassociated gas. The Syrian Oil Ministry awarded Entrepose of France a $62 million contract for utilization of associated gas from the oilfields of northeast Syria for the manufacture of industrial solvents and condensates. Gas was to be collected from nine gathering stations and pumped through 52 kilometers of pipeline to a main treatment plant. Theoretical input capacity was 660,000 cubic meters of gas per day. The plant was expected to produce 58,000 tons of LPG per year. The project was to be completed by 1982.

The Syrian Government tentatively selected the Soviet Union to aid in its efforts to utilize the country's nonassociated gas reserves. A gas liquefaction plant was to be constructed in al-Jibsah, near the city of al-Hasakah. The project was still in the feasibility study stage in 1980, but the plan was to drill several gas wells, build a pipeline network to a main treatment plant, and construct the necessary ancillary facilities, all by 1986.

The production of phosphate rock in Syria increased about 4% from the 1979 level of 1.27 million to 1.32 million tons in 1980. Phosphate was mined in three main areas: Al-Tadmuria, Al-Shargiya, and Khunayfis, all located just south of Palmyra in central Syria. Phosphate production was under the direction of the state-owned General Co. for Phosphate and Mines. The mines produced an average 66% to 68% TPL rock, most of which was exported. Exports declined slightly, from 1.2 million tons in 1978 to 823,000 tons in 1980. Most of the output was exported to eastern Europe where Romania received 58%; Bulgaria, 9%; Poland, 1.6%; and Yugoslavia, 1.2%. Other exports were to Lebanon (12%), mainland China (7%), and North Korea (9.3%). The remainder (1.9%) went to Western Europe.

For the first time in 1980, domestic deliveries of rock were made to the new phosphate fertilizer facility at Homs. The new plant, built by Industrialexport of Romania, was to produce 150,000 tons per year of phosphoric acid and another 450,000 tons per year of triple superphosphate. The plant began test runs in 1980, and was scheduled for commissioning sometime in 1981.

In addition to new phosphatic fertilizer capacity, a second ammonia-urea plant was

brought onstream in December 1980. The new plant, capable of producing 1,000 tons per day of ammonia and 1,050 tons per day of urea, was built adjacent to the existing facility at Homs. Creusot Loire Enterprises of France was the managing contractor, with Pullman-Kellogg (United States) handling design and engineering for the ammonia unit, and Heurtey Industries responsible for construction of the urea plant. Ammonia feedstock for the plant was naphtha from the country's refinery. The existing facility at Homs was already capable of producing 110,000 tons of nitrogenous fertilizer per year, although production remained well below that capacity. Both plants were under the control of the state-owned General Establishment of Chemical Industries. The new capacity was to eliminate the need for imports and probably provide a surplus for export. Fertilizer was to be exported from the Port of Tartous, where most of the country's phosphates were shipped from, after shipment by rail from the plant.

Syria's cement industry, for several years unable to meet domestic requirements, was to almost double existing capacity by the end of 1981. Ten plants were operating in Syria, with a combined capacity of about 2.3 million tons per year. In 1980, the Chaba Cement Co.'s New Sheikh Said plant, to be located adjacent to the old Sheikh Said plant at Aleppo, came onstream with an annual capacity of 400,000 tons per year. Also in 1980, a new plant at Adra began production at the rate of 150,000 tons per year. The next plant scheduled to start up was a 2-million-ton-per-year plant at Tartous. This new capacity was expected to make Syria a large exporter of cement by 1982.

Iron and steel production in Syria remained fairly stable in 1980, averaging 100,000 tons per year of steel reinforcing bars and galvanized pipe. The General Co. of Iron and Steel Products operated three steel plants at its complex at Hama, using billets imported from Italy, Bulgaria, and the Soviet Union. Feasibility studies evaluating the Zabadani iron ore deposits continued in 1980, but no plans were made to exploit the deposit. Reserves at Zabadani were estimated at 150 million tons of hematite with an iron oxide content of 27% to 30%.

Other minerals produced in Syria include marble, ornamental stone, and gypsum from the Damascus and Latakia areas, asphalt from Oeir ez Zoor, and approximately 80,000 tons of salt.

YEMEN ARAB REPUBLIC

The mineral industry of the Yemen Arab Republic consisted of the mining of rock salt and gypsum and the production of cement. Salt was the only mineral export, and brought in revenues of approximately $65,000[10] in 1980. Exploration for petroleum, copper, and iron ore continued during the year, but there have been no commercial discoveries for any of these commodities.

The Yemeni economy cooled off considerably in 1980, as workers' remittances fell and business activity declined. Foreign aid and remittances from the estimated 1 million Yemenis working abroad were the country's top sources of revenue and the major stimulants of the economy. In 1980, the Yemen Arab Republic's balance of payments slipped to a $2.1 million deficit, for the first time in 5 years. The balance-of-trade deficit was also at an alltime high of $1.7 billion.

Approximately $300 million in foreign aid was channeled into the country from a variety of sources. The United States contributed $12.7 million in grants during the year, with the remainder coming from Saudi Arabia, Kuwait, and other Arab states and Arab development funds. Western Europe and the Soviet Union also contributed some assistance, as well as various agencies of the United Nations. The World Bank approved a $12 million credit to aid in financing local industry through the Industrial Bank of Yemen. The German Democratic Republic and Czechoslovakia also agreed to sponsor some industrial projects including a leather tannery, rural electrification projects, and a marble quarry.

Agriculture remained the largest productive sector of the economy, contributing about 60% to the 1980 GNP of approximately $3.5 billion. Agricultural output consisted mostly of qat, sorghum, millet, barley, corn, wheat, and coffee. Despite its relatively large agricultural sector, the Yemen Arab Republic was a net importer of foodstuffs.

In the minerals sector, production was registered for only two commodities, rock salt and cement, although some gypsum

was probably recovered along with the salt and sold to the cement plant. The Yemen Salt Mining Corp. continued to mine its open pit deposit in the coastal plain adjacent to the Port of Salif. Reserves at the deposit were estimated at 250 million tons of rock salt with an average NaCl content of 98.23%. Rock salt production increased from 50,000 tons in 1979 to 65,000 tons in 1980, as the company was able to market its output more smoothly. Marketing operations had been interrupted from 1972 to 1976 when the mine was undergoing modernization.

A small amount of gypsum was also recovered along with the rock salt at Salif. Gypsum output was sold to the Government-owned cement plant at Banjil, 100 kilometers to the southeast. In 1978, the U.S.S.R., which built the original plant, agreed to extend the plant's capacity to 100,000 tons per year. The new capacity appeared to be onstream in 1980, as cement production increased from 50,000 tons in 1979 to over 81,000 tons in 1980.

In 1979, the Yemen Government awarded a $110 million contract to Ishikawajima-Harima Heavy Industries and Nissho-Iwai (Japan) for the construction of a 500,000-ton-per-year cement plant at Amran, northeast of Sana. No details were available as to the progress of this project.

Petroleum exploration efforts continued in 1980, despite the lack of any commercial discovery. Shell was exploring a 10,000-square-kilometer coastal concession on the Tihana coastal plain, and CFP (France) was also involved in exploration in the Fahda desert region in northern Yemen.

The Yemen Arab Republic imported all of its domestic requirements of petroleum products in 1980. Crude oil supplies were derived from Kuwait and were refined in south Yemen and transported by road to north Yemen. Approximately 5.4 million barrels of products, mostly gasoline, diesel oil, and fuel oil, were imported in this fashion. Another 11,150 tons of liquefied gas was imported from Saudi Arabia. This roundabout route for refined products led to the development of a large smuggling operation bringing refined products in from Saudi Arabia and undercutting the official Government price by as much as two-thirds. A new agreement was signed in 1980 in which Saudi Arabia was to market oil products through Shell and BP directly into north Yemen. In addition to increasing the Government's revenues, lowering the official price for gasoline, and thwarting the smuggling operation, the agreement was also likely to strengthen political and economic ties between Saudi Arabia and the Yemen Arab Republic.

Investigations continued to examine the possibility of mining other minerals in the Yemen Arab Republic. A group of West German and Yemini technicians were examining the possibility of exploiting iron ore deposits in the Sa'dah region. The team was drilling ore samples to determine the quantity and grade of the ore. Copper deposits at Hamurah near Taiz were also under study to determine the size of the deposit. The Government planned to commission an economic feasibility study after the initial tests were completed.

ECUADOR

After becoming an oil exporter in 1972, Ecuador experienced a remarkable economic upswing until 1978. However, in 1979 and 1980, a combination of only slight improvements in agricultural output and stagnating petroleum output lowered rates of real gross domestic product (GDP) expansion to 5.3% and 4.3%, respectively. In current prices, the GDP in 1980 was estimated at $11.3 billion.[2] The slowdown in growth is attributable in large part to the low level of petroleum exploration in the 1972-79 period.

Ecuador's production of petroleum declined 4.5% in 1980 compared with that of 1979. The consortium of Corporación Estatal Petrolera Ecuatoriana (CEPE), the State oil company, and Texaco, Inc., operating in Ecuador's eastern jungle region was responsible for nearly all of 1980 production. The volume of total crude petroleum exports from Ecuador dropped from 44.7 million barrels in 1979 to 40 million barrels in 1980, although crude petroleum export revenues rose from $1,032 million in 1979 to $1,294 million in 1980. The latter figure represented 54% of Ecuador's 1980 merchandise exports. Crude oil exports accounted for about 46% of the value of 1979 merchandise exports. The total nonfuel mineral exports in 1980 were valued at less than $1 million.

Falling petroleum production and the low level of investment in petroleum caused the petroleum and mining sector to record negative real growth of about 6.2% during 1980. Nonfuel mineral activity in the country continues to be negligible. The petroleum sector (including refining) contributes 17% to Ecuador's GDP, although the sector employs less than 1% of Ecuador's economically active population. The increase in total export revenues in 1980 was due entirely to the increase in prices that Ecuador obtained for its exports of crude petroleum and petroleum products, which accounted for 62% of total 1980 export revenues.

The United States probably remains the most important purchaser of Ecuadorean exports. According to Ecuadorean statistics, the United States imports 19,000 barrels per day of Ecuadorean crude petroleum and 20,000 barrels per day of fuel oil. Approximately 40% to 50% of Ecuador's exports are destined for the United States. As the Or-

ganization of Petroleum Exporting Countries' smallest member, with reserves of 1 billion to 1.3 billion barrels of oil, Ecuador has decided to use its oil resources to finance other development projects. CEPE envisaged drilling 300 wells between 1980-85 as part of a new exploration program, of which $17 million was spent in 1980. The rapid expansion of spending by the Government and the failure to set aside some funds has created a difficult situation for the exploration of additional oil reserves. Ecuador may become an oil importer by 1985 if oil production continues to fall while domestic consumption grows rapidly.

The most promising areas for further exploration of hydrocarbons are the Amazon region and near the Peruvian border. Exploration for natural gas has been scheduled for the Gulf of Guayaquil. CEPE was planning a $300 million fertilizer project at Pasorja using natural gas from the Amistad Field in the Gulf of Guayaquil. The first phase of the project would be completed in 1984 and would produce 1,000 tons per day of ammonia and 1,000 tons per day of urea. The Amistad natural gas deposit was discovered 10 years ago but has remained undeveloped because of disagreement with U.S. contractors on the most economical use for the gas.

Texaco and CEPE agreed to a $41 million package for 1981 to further develop the country's oil-production capacity. The program will include bringing into production the Yuca, Auca Sur, Yulebra, and Dureno Fields. CEPE will bear 62.5% of the cost and Texaco the remainder.

In a significant departure from long-standing policy, the Government has enacted a variety of price increases, including a trebling of retail gasoline prices from the equivalent of 18 cents per gallon to 60 cents per gallon. Prices for other oil products were increased by a lesser extent. Maintaining the increased prices could pave the way for increased investment in Ecuador's oil industry and may have been a factor in the new agreement with Texaco. Still pending, but ready for implementation, was Texaco's ambitious program for secondary recovery by water flooding at the Shushufindi Oilfield, later to be extended to the Sacha Field. These are Ecuador's largest fields, with output of about 150,000 barrels per day. It is estimated that the Shushufindi Field alone contains more than 300 million barrels of crude oil recoverable by water flooding, and Sacha's prospects are considered to be equally promising. If the estimates are correct, the fields could produce an additional 80,000 barrels per day over a 20-year period.

CEPE was planning to construct a new 75,000-barrel-per-day refinery, scheduled for operation before 1983 or 1984. Government sources have estimated that at least 20% of the gasoline sold in Ecuador, or 5,000 barrels per day, is exported illegally for use in Perú or Colombia. Such a figure exceeded the amount of gasoline Ecuador was required to import in 1980. Given the difference between the domestic price of gasoline and its price in neighboring countries, contraband exports from Ecuador are likely to remain substantial.

While several stimuli exist for the exploration of oil, the nonfuel minerals industry in Ecuador has few incentives. There were a number of small mines producing copper, zinc, gold, and other minerals. The most important was the La Plata copper, lead, and zinc mine, near Santo Domingo de los Colorados in Cotopaxi Province. Earlier this year, Compañía Minera Toachi S.A. announced a $5.2 million investment program at this mine designed to double production of ore over the next 2 years. Financing for the project is coming from the International Bank for Reconstruction & Development (World Bank), a West German bank, and from Toachi's Venezuelan, Finnish, and Peruvian partners. Production from this mine is 100 tons per day of copper, lead, and zinc concentrate. Some gold and silver in concentrate form is also produced. Value of the mine's output is estimated at $8,000 per day.

In mid-1980, Cía. Minera Austral began exploitation of the Peggy Mine (in Azuey Province). Reportedly, current production involves 50 tons per day of copper and zinc concentrate with an estimated value of $5,000 per day.

Ownership of the Portovelo Mine has passed to the Dirección General de Geología y Minas (DGGM), which is in the process of rehabilitating the mine, in part to provide employment opportunities for residents of El Oro Province. Reportedly, the mine was producing 10 tons of concentrate daily. The international call for tenders for the development of the San Bartolomé silver and zinc mine, which has been under discussion for over a year, has not yet been announced. DGGM proceeded with other activities, such as developing reported deposits of iron in

Zamora-Chinchipe Province, doing further development work at the Chaucha copper deposit, and investigating the possibility of exploiting gypsum deposits in Guayas Province. The DGGM had hopes of receiving financing from the Inter American Development Bank and World Bank for some of these activities.

Limited mining activity is likely to continue despite Ecuador's varied geology. The mining sector is not expected to grow in the near future because the outdated mining law "Ley de Fomento Minero," which was approved by the military Government in early 1974, offers few incentives or guarantees to potential investors. Labor and financial problems have driven certain companies close to bankruptcy. Other companies have experienced interruptions in exporting minerals because of accounting and royalty problems with the Ecuadorean Government. Lacking proper encouragement and incentive, the nonfuel minerals industry in Ecuador is not likely to become a meaningful revenue source. Most private sector Ecuadorean and foreign investors interested in Ecuador's virtually unexploited nonfuel mineral sector agree that little development of the sector is likely to occur unless mining legislation and regulations are made more attractive to private investors.

A new, more liberal, mining law has been under discussion within the DGGM and the Ministry of Natural Resources for 4 years. The Ministry approved and sent to the Office of the President a comprehensive new mining law proposal for his approval. Initial reactions from the mining sector have been generally positive, although guarded. The centerpiece of the draft legislation provides for the creation of a public sector mining development corporation, Corporación de Fomento Minero (COFEMIN), as the executive agency for prospecting, exploration, and exploitation activities within the mining sector. The new entity would have the legal authority to develop mines on its own or enter into service or association contracts with private or public sector interests, including foreign mining companies. The draft legislation specifically authorizes the proposed mining development corporation to enter into joint ventures. Under the draft legislation, the role of the DGGM would apparently be restricted somewhat, particularly in exerting control over mining companies that have signed exploitation contracts with the new COFEMIN.

Congressional review of the proposed mining law was expected to be lengthy, with many members of Congress making the legislation more protective of Ecuador's national patrimony and hence less likely to be of interest to prospective foreign investors. Congressional passage of mining legislation will be only the first, although important, step. The proposed mining law would establish the basic framework for the mining sector; it would then be up to the Ministry of Natural Resources to draw up implementing regulations and formally establish the proposed COFEMIN.

Despite approval by the military Government of substantial revisions to Ecuador's hydrocarbons law in May 1978, the Ministry has yet to issue the crucial, implementing regulations, including the model hydrocarbons operating contract that would form the basis for negotiations with prospective foreign investors. Release of the model contract continues to be held up because the Government apparently has not found a formula that is both attractive enough to prospective investors and sufficiently protective of Ecuador's national interests.

Several small companies were mining for nonmetallic minerals, but few have shown any interest in metals because of the lack of detailed information about reserves, the difficulties in obtaining credit, the lack of state support and investment incentives, and the poor infrastructure in the areas where deposits exist. In the future, however, an improvement was expected. A geological metallogenic map of Ecuador developed with technical assistance from Great Britain, the United Nations, and other private firms, was published by the DGGM.

The map identifies around 300 known and possible deposits of minerals within Ecuadorean territory. The metallogenic map and the explanatory report, which includes an alphabetical listing of actual deposits of minerals and indications of some, are in Spanish and are unlikely to appear in English.

Minor exploration continued in the Southern Andes for copper, molybdenum, lead, silver, zinc, phosphorous, and coal. Uranium was also believed to be present in that area. Uranium discoveries would fall under the jurisdiction of the Ecuadorean Atomic Energy Commission. The single most promising development in the mineral industry is the proven copper deposit at Chaucha. A $24 million contract to build a

cement plant was awarded to Allis-Chalmers Canada, Ltd., a unit of Allis-Chalmers Corp. The facility, with a planned capacity of 345,000 tons per year, is to be constructed for Cementos Selvalegre of Quito. Fuller Co. was awarded a $17 million contract by Empresa Industrias Guapán, S.A., to expand to 1,100-ton-per-day-capacity the Guapán cement plant at Azogues by the end of 1980.

Ecuador officials are confident that when present hydroelectric projects become fully operational, hydroelectricity will be the country's predominant source of energy. At this time, hydrocarbons account for only 19% of the total energy reserves compared with 78% for hydroelectric potential. However, at present, oil is providing 54% of the energy and hydroelectricity less than 5%. The state agency, Instituto Ecuatoriano de Electrificacion, has announced that an investment of $4 billion will be needed for the ongoing 1980-85 electricity development plan. New projects should come onstream by 1985 to increase the country's present 658-megawatt capacity to 1,200 megawatts. The major projects include the 550-megawatt Daule-Peripa project, the 1,981-megawatt Naiza project, and the 152-megawatt-capacity Agoyán project.

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.

[1]Includes data available through Sept. 1, 1981.

[2]In addition to the commodities listed, a variety of crude construction materials (common clays, sand and gravel, and stone) undoubtedly is also produced, but output is not reported and available information is inadequate to make reliable estimates of output levels.

[3]Reported figure.

[4]Gem and industrial diamond production is estimated based upon reported total production.

[5]Data represent exports.

[6]Less than 1/2 unit.

[7]Refinery fuel apparently included with products for sale, mainly residual fuel oil and liquefied petroleum gas.

FRENCH GUIANA

The mineral industry of French Guiana remains insignificant in the Nation's economy, except for minor quantities of gold, crushed rock, sand and gravel, and clay domestically consumed.

Gold has been mined in small quantities since 1950, when foreign interests were allowed to enter the country to engage in geological and mining explorations. Gold placer mining has been practiced in French Guiana ever since. The local Government of French Guiana is actively engaged in promoting the mineral development of this overseas department. Direct French investment in mineral-related enterprises would be preferred but failing that, the country would welcome foreign participation to some extent. Bauxite deposits in the Kaw Mountains in southern French Guiana appeared to be the only promising mineral resource upon which to base a mineral economy. However, the low grade and small reserves made this prospect unattractive to foreign investors. Zones of Government reserves with petroleum potential are excluded from foreign control.

Gold production increased in 1980 in response to higher world prices. Major export trade partners were 78% United States, 11% France, and 5% Martinique; major import partners were 49% France, 10% United States, and 3% Trinidad and Tobago. French Guiana's future development prospects depend upon programs of the French Government for building the infrastructure necessary for sustained industrial development.

The total labor force amounted to 18,000, of which 50% is engaged in services, 21% in construction, 18% in agriculture, 8% in transportation, and 3% in information. Organized labor constituted about 7% of the labor force.

GUYANA

The Cooperative Republic of Guyana's production of bauxite and its processing into alumina accounts for just under 20% of GDP estimated at $520 million[3] and about 40% of total foreign exchange earnings. In addition to being one of the world's significant producers of bauxite, Guyana supplies 85% of the world's calcined bauxite (for specific use in the refractory industry) and 80% of chemical-grade bauxite. Bauxite and alumina output for 1980 totaled 1.8 million tons, 200,000 tons short of the target of 2.0 million tons. Output of calcined bauxite was an 800,000-ton target (601,000 tons); metal and chemical-grade, 979,000-ton target (900,000 tons); and alumina, 211,000-ton target (300,000 tons). The Guyanese economy continued the downward trend in 1980. The real growth rate was minus 2.0% compared with minus 3.7% in 1979.

Total export earnings of the bauxite industry were $190 million, 14% below the projected level but significantly above the 1979 amount of $128 million. The increase in earnings over 1979 was largely due to higher world market prices.

The production shortfall derived in part from a lack of functioning equipment, both in the mines and in the bauxite and alumina plants at Linden, and a continued exodus of skilled and managerial personnel dissatisfied with the overly politicized approach the Government has used to staff and run the industry. Green Construction Co., a U.S. firm, expects to complete half of its job of removal of overburden at some of the Linden mines shortly and to finish its operation by November 1, 1981, 8 months ahead of schedule.

The Guyána Government held preliminary discussions with the World Bank in January 1980 for assistance in funding Guyana's multibillion dollar hydropower and aluminum smelter projects. Because of increased energy cost, the Guyana Government has estimated petroleum fuel impact costs for 1980 in the vicinity of $10 million against $8 million in 1979; in the absence of any hydropower development, this figure was expected to reach $171 million by 1990. Given the World Bank's interest in the development of alternative energy sources, the World Bank was expected to contribute the major portion of the financing required for the hydropower project. The proposed installation would include a 1,200-foot-long dam in the Upper Mazaruni area in the northwest region of the country. Govern-

ment officials indicated that the World Bank considered the 750-megawatt hydropower project to be technically viable and financially sound. The revised cost estimate is between $700 million and $750 million, depending on the ultimate size of the installation.

Foreign participation in the financing of the $700 million aluminum smelter, with a projected capacity of 150,000 tons per year, was expected to be forthcoming since the conditions necessary for such a project are already present in the country. These conditions include the availability of bauxite reserves and a 320,000-ton-per-year-capacity alumina plant, a skilled work force of 7,000, and availability of water, land, and the cheap power that would be provided by the proposed hydropower project.

The Guyana Government has affirmed the need for a partner for the smelter that would bring needed technology. A 1985 target date was set for the smelter and hydropower projects. The proposals were under study by the World Bank. The state-owned Bauxite Industrial Development Co. (BIDCO) signed an agreement with Brazil's Companhia Vale Do Rio Doce for the supply of bauxite and alumina amounting to $70 million. BIDCO has scheduled deliveries to begin in July 1981 until 1984.

Owing to the doubling in the average price of gold in 1980, Guyana, a land with potential in gold and other precious metals, was taking measures to step up its gold production and thus benefit from the price rise. Legislation was enacted for establishing a National Gold Board, which is to become the country's sole trader in gold. Production of gold in 1980 increased 4%.

An agreement was signed between the Cooperative Republic of Guyana and the Canadian-based Republic Mining Co., which is expected to employ mechanical means for gold extraction.

Another Canadian mining company, the Marudi Mining, Ltd., an associate of the Norman Mines, was negotiating with the Guyana Government to carry out gold mining operations in the Rupununi region. The Guyana Geology and Mines Commission proposed to start two small state-owned gold mining operations as part of its current mining program. Local mining engineers were expected to work closely with foreign mining concerns to acquire valuable knowledge of large-scale mining operations.

Another important development in the minerals field was the signature of an initial agreement between the Guyana Government and the state-owned Cogema of France, giving the latter nonexclusive rights to explore for uranium in Guyana. Deposits with particularly high potential are believed to exist close to the Venezuelan border, where monazite and euxenite mineralization has been found. Grundstofftechnik of Essen, in the Federal Republic of Germany, was also reported to have signed an agreement to explore for uranium.

BIDCO has carried out various investigations during the last few years, which have indicated that there are sufficient reserves of kaolin ores associated with bauxite deposits in the country to sustain a large-scale kaolin mining operation. BIDCO has decided to commission a consulting firm to carry out a comprehensive preliminary feasibility study of the project. Bids for this work have already been closed but no announcement has been made.

An investment code was published in 1979 to define the role of private investment in the economy, which is recognized by the Government to comprise the private, cooperative, and public sectors. The code permits foreign investment in manufacturing (whether for local market or for export), oil exploration, and tourism (subject to arrangements worked out with the Government), fishing, forestry, and mining (except for bauxite mining and again subject to arrangements to be worked out with the Government). Within these areas, foreign investment is permitted individually or in association with one or more Guyanese firms. While the code does not give a guarantee that investments will be protected, whether licensed or registered, the Guyanese Government's attitude is that foreign investment generally would be nationalized as long as it operates within the Government's development framework. The Government has indicated that it would be reviewing existing legislation and treating various aspects of foreign investment and consolidating it into an investment act, which would contain implementing regulations for the code.

No legal regulations exist on technology transfer, payments for royalties or trademarks, or profit repatriation. An agreement between the United States and Guyana guaranteeing investments exists and forms the basis for the Overseas Private Investment Corp.'s insurance coverage for inconvertibility, expropriation, and war risks. Many of the U.S. investments in Guyana have coverage.

PARAGUAY

Paraguay continued to enjoy, for the fourth consecutive year, one of the most rapid rates of economic growth in Latin America. The country's continued prosperity was based on the expansion of agricultural production for export and the beginning of the exploitation of the hydroelectric potential of the Paraná River. The combination of these factors set off an unprecedented boom in the country. In real terms the economy in 1980 grew by 10% with an estimated GDP of over $2 billion.[4] This growth rate was expected to continue providing the basis for further industrial development.

Construction of the second dam on the Paraná River was expected to begin within a year, and given present plans, Paraguay will have the benefit of significant amounts of hydroelectric plant construction through the 1990's. However, a major economic problem was the high rate of inflation, which reached 28% in 1979 but dropped to 22% in 1980, owing mainly to the considerable inflows of funds for the massive hydroelectric projects under construction and an increase in the cost of oil imports.

The minerals industry of Paraguay continued to be limited to the production of a number of nonmetallic mineral commodities, including common clays, cement, gypsum, common sand, limestone for cement, and crushed and rough stone. Mineral production was at a record high level in 1980. The volume of production of nonmetallic minerals expanded 14% to 12.1 million tons in 1980 compared with that of 1979, and the value of nonmetallics produced increased 31% to $88.1 million. The value of petroleum refinery products increased to $52.5 million. New annual records were established for each nonmetallic mineral.

To meet the growing demand of the construction industry, particularly that arising from dam construction, the expansion of the cement industry was given considerable official priority. Feasibility studies were being undertaken in 1980 for the increase in capacity of the country's only cement plant, operated by the state-owned Industria Nacional del Cemento from the present 200,000 metric tons per year to around 720,000 metric tons per year. A second cement plant, with a capacity of 600,000 metric tons per year, was to be constructed with Brazilian financial aid. Shipments of cement increased 13% to 177,000 metric tons in 1980 compared with that of 1979, and the value of cement went up 39% to $18 million.

Another priority project in 1980 was the establishment of a 100,000-ton-per-year steel mill, Paraguay's first, at Villa Hayes north of Asunción, which has been under consideration for several years; the mill is currently under construction, while bidding for equipment is underway. Aceros del Paraguay, S.A. (ACEPAR), is a joint venture formed to operate Paraguay's first steel mill. It will concentrate its production on satisfying local demand and will be dependent upon iron ore imported from the Urucum iron ore deposits in the Brazilian State of Mato Grosso. The smelter will be fueled by locally produced "carbón vegetal" or charcoal.

ACEPAR is owned 39% by a Brazilian consortium, Empresa Brasileña, F.L.M., 1% by Técnica Nacionál de Engenharía S.A., the Brazilian firm responsible for the construction and erection of the facility, and 60% by Siderúrgia Paraguaya, a Paraguayan enterprise that is wholly owned by the Government and administered by the Ministry of Defense. The official estimated cost of the project is $81.0 million. Cost increases and delays, however, are expected to push

the final cost to approximately $100 million. Carteira do Comercio Exterior do Banco de Brasil (CACEX) was expected to provide $77 million with the remaining amount to be provided by ACEPAR or other financial sources.

Deposits of iron ore and manganese occur in Paraguay, as do other minerals including uranium and copper. Exploration for uranium and other minerals was carried out in 1980 by the U.S. company, Teton Exploration and Drilling Co., over an area of 25 million hectares in western Paraguay. Anschutz Corp., also of the United States, and two Asian electrical utility companies, have discovered uranium at an undisclosed site in Paraguay. The Taiwan Power Co., the Korean Electric Co., and Anschutz Corp. have jointly sponsored the prospecting project. Further drilling is being carried out to determine the extent of the deposits and the commercial feasibility of mining them. The exploration program has cost between $6 to $7 million per year of which the U.S. company was providing 50% and the Asian utilities, 25% each.

Paraguay's energy requirements and its future growth are dependent on three binational hydroelectric projects, all stemming from the vast hydroelectric potential of the Paraná River, which were at various phases of planning and construction. The three projects are Itaipú, Yaciretá-Apipé, and Corpus, with a total planned capacity of 21,650 megawatts.

The most important hydroelectric project is a Paraguayan—Brazilian joint venture at Itaipú, claimed to be the world's largest. The first generating unit, which is to begin operating in 1983, with full capacity of 12,600 megawatts, was scheduled to be installed by 1988. The cost of the Itaipú project, being met mainly by Brazil, is estimated at $12.7 billion. By the time it is finished, the project will cost an estimated $17 billion. Although energy generation at Itaipú will begin in 1983, significant earnings from the sale of power to Brazil will not be seen until Itaipú approaches full output a few years later. Brazil wants and needs all the power that Itaipú will generate, and the agreement signed between the two countries is heavily biased toward the sale of Paraguay's 50% share of electricity to Brazil and against its use domestically.

Also to be constructed, in conjunction with Argentina, is the 3,700-megawatt Yacyretá-Apipé station, which was to be completed by yearend 1980. The Comisión Mixta Paraguayo-Argentina del Río Paraná decided to build the Corpus hydroelectric plant in the Itacus area with a total capacity of 4,000 megawatts.

Oil exploration continued in different parts of the country by both local and U.S. companies. Texaco-Marathon has a drilling program within a 1.6-million-hectare concession area along the Paraguayan River frontier with Brazil, and Chaco Exploration Co. spent about $6 million in 1980 on test drilling in the Chaco Boreal region of northwestern Paraguay where significant resources of oil and natural gas have been reported.

SURINAME

Suriname continued to be dependent on bauxite as the most important industry of the economy. Bauxite, alumina, and aluminum accounted for 80% to 90% of all exports and for about 30% of GDP estimated at $890 million.[5] The economy is also heavily dependent on inflows of foreign aid from the Netherlands. Expansion of real GDP has slowed down from the 6% per year growth recorded in 1976 and 1977 to about a 4% per year rate in the past 3 years.

Bauxite production in 1980 was about 5 million tons and output of alumina and aluminum was about 1.3 million tons and 46,000 tons, respectively. Suriname Aluminum Co., a wholly owned subsidiary of the Aluminum Co. of America (Alcoa), and Billiton Maatschappij Suriname, N.V., owned by Royal/Dutch Shell, accounted for the major part of this output. Since bauxite reserves in existing concession areas near Parabaribo are expected to approach exhaustion within 15 years, negotiations were underway with the joint venture companies for the exploitation of new reserves in the western part of the country. This western development project will involve the construction of two large dams to produce more than 500 megawatts of hydroelectricity, a new industrial and agricultural port city at Apoera, a 72-kilometer railroad for surface transport of bauxite deposits in the Bakhuys Mountains to the river port of Apoera, and an optional smelter.

It appears now that more emphasis will be placed on the development of the Kabale-

bo hydroelectric project, contingent upon Suriname's ability to obtain international financing. The Bakhuys bauxite exploitation apparently has been shelved, at least for the near future. The Kabalebo project, sheduled for completion in 7 years, together with the existing Afobaka hydroelectric dam, would provide 90% of Suriname's projected power requirements.

Billiton B.V. of the Netherlands has announced that it has awarded a contract to Bos Kalis International for the removal of 13 million cubic meters of overburden from a site near Billiton's current mining operation. The overburden removal will prepare bauxite for mining during the second half of the 1980's. Bauxite production from Billiton's Suriname operations was about 2 million tons per year.

The Suriname Government established the Bauxite Institute to monitor the production of the ore and the performance of the local industry. Considering recent trends in bauxite production worldwide, the Government felt that the formation of such an institute was of vital importance to the country's main foreign exchange earner.

The French concern, Cogema, undertook some prospecting for uranium during 1980. It was also reported that two companies were studying plans to develop gold deposits.

In September 1980, the Government of Suriname and Gulf Oil Co. signed an agreement outlining the terms and conditions under which Gulf would begin offshore oil exploration, and if appropriate, exploitation. Some of the important elements of the agreement are: (1) The Government of Suriname is to form a state oil company which will be responsible for oil exploration throughout Suriname and its economic zone. (2) Gulf will act as a contractor for the state oil company for the exploration and exploitation of oil in a 13,000-square-kilometer sector off the western segment of Suriname's northern coast. (3) Percentage breakdown of the production-sharing agreement (considered by Gulf to be commensurate with that offered by other oil-producing nations). (4) Gulf expects to complete surveys and test drillings in 1981 and begin exploitation in 1982. Gulf's plan is to invest $8 million in exploration, but that figure would increase substantially if initial activity produces positive results. (5) Gulf has agreed to explore the feasibility of constructing a refinery in Suriname. (6) Gulf's concession covers only a part of Suriname's offshore area, running for 150 kilometers along the coast with a width of almost 100 kilometers.

In May 1980, an economic policy statement was released by the new Government known as the new "Crash Program" to be completed in 2 years. The program is largely devoted to basic projects involving construction of bridges across two major rivers, beginning of the Kabalebo hydroelectric project, establishing a "Bauxite Bureau" to create an effective mineral policy, controlling the Nation's resources by passing new mining and land allocation laws, reforming the Investment Law, and establishing a Government Center for Industrial Development and Export Promotion. All of these programs were either underway or in the planning stage.

About 65% of Suriname's oil imports were used for electricity production and only 10% for transportation. When Kabalebo's first planned electric generators come online, the country's foreign oil requirements will be cut to a very low level. The new Government State Oil Corp. was negotiating with other foreign oil companies interested in acquiring concessions.

URUGUAY

Uruguay's economic growth in 1979 was the highest for over two decades. However, the growth rate in 1980 slowed down to 4.5%, giving a real GDP estimated at $7.6 billion.[6] An exchange rate policy in combination with the import liberalization program, and the anti-inflationary measures have placed local industry under growing pressure, reflected in the sharp fall in the sector's growth in 1980. A further deceleration in overall economic growth was expected in 1981 from the anti-inflation policy. The 1980 inflation rate was 43%, only a little over half the inflation rate recorded in 1979 and lower than the 50% projection. Inflation in 1981 was expected to be in the 35% to 40% range.

Uruguay's trade deficit increased again in 1980, reaching, according to preliminary estimates, around $570 million compared with $418 million in 1979. Increased expenditure on imported oil, which increased about 45% to $420 million in 1980, accounted for over 25% of total imports compared

with $217 million in 1979.

In 1980, Uruguay managed to overcome the disruption of its supply of crude petroleum from Iraq. Despite this interruption in shipments from Iraq late in 1980, imports of crude petroleum increased 13% to 13.4 million barrels compared with 11.7 million barrels imported in 1979. Almost 50% of Uruguay's needs were imported from Venezuela and Nigeria.

The mineral industry in Uruguay is of minor significance for the country and the world economy. Mining activity was concentrated in the nonmetallic sector of which cement and other construction materials were the most important. Owing to the factors mentioned above, production of cement decreased 62% in 1980 compared with 1979 production. Fuller Co. of the United States, through its South African subsidiary, received a multimillion dollar contract from the Administración Nacionál de Combustibles, Alcohol, y Portland for expansion of the existing 400-ton-per-day cement plant at Paysandú to 900 tons per day. All the equipment was to be supplied from South Africa by Fuller-GATX (Pty), Ltd., with the plant scheduled to be in operation in 1980.

Brazil's major private sector steel group, Gerdau, announced late in 1980, that it had reached an agreement to take over two steel plants in Uruguay. Gerdau plans to pay $12.4 million for ALIS, S.A., and Laminadora Industrial, S.A. (LAISA) of Montevideo, which together produce about 30% of the rolled steel consumed in Uruguay.

Gerdau planned to operate both plants through a holding company based in the southern Brazilian city of Porto Alegre. ALIS is the raw steelmaker and is the major ingot steel producer in Uruguay. LAISA has rolling mills producing rods, bars, and sections and is the country's major nonflat product plant with an output of 12,000 tons per year. Gerdau hoped to double production to take a larger share of the Uruguayan market and provide for exports. Gerdau was awaiting authorization from the Banco Central before finalizing the mergers.

Production of rolled steel products in 1980 decreased 23% compared with that of 1979 production.

Consumption of petroleum products fell by 10% in 1980 compared with 1979, owing to a drop in thermal electricity production resulting from a greater availability of hydroelectric power from Salto Grande and other hydroelectric plants. To minimize consumption of petroleum in the country, the Government of Uruguay approved, in October 1980, a plan for rationalization of energy use. The plan establishes immediate measures as well as medium- and long-term procedures to improve the use of energy from traditional sources and to develop new sources of energy. Some of these procedures are: (1) The Ministry of Industry and Energy (MIE) will study the results of petroleum exploration carried out and the reinterpretation of seismic studies of the Continental Shelf to assist Government agencies in studying the possibility of new explorations. (2) MIE will study agreements for electrical interconnections with Argentina and Brazil. (3) MIE will coordinate the exploration for and the use of coal, peat, and shale. (4) MIE will study the possibilities of joint exploitation with Brazil of the coal deposits along their common border. (5) MIE, through the Geological Institute, plans to negotiate with a French company a contract for uranium exploration. (6) MIE will accelerate the study of alternative sources of energy (solar, biomass, and geothermal) and plans for their utilization.

Sharply rising expenditures for imported oil have led to increased attention being paid to domestic energy supplies in recent years. A number of hydroelectric facilities were under construction, the largest of which is the 1,980-megawatt Salto Grande project on the Río Uruguay, a binational venture with Argentina. An agreement was reached between the two countries calling for feasibility studies for a new hydroelectric plant on the Río Uruguay, downstream from the Salto Grande project. Work on the Palmar hydroelectric project on the Río Negro was progressing on schedule, and in December 1981, the first turbine is scheduled for operations. The 330-megawatt Palmar hydroelectric plant is being built with Brazilian assistance at a total estimated cost of $220 million.

Oil exploration continued during 1980 and the Minister of Industry and Energy was expecting financial assistance with seismic research. An agreement was made with Argentina regarding the construction of an experimental nuclear reactor. Argentina also will supply natural gas through pipelines beginning in 1983, which will also contribute to a reduction in the country's dependence on imported oil.

FIJI

In 1980, gold, silver, and pit and quarry construction materials were the principal minerals produced in the Dominion of Fiji. The combined value of these minerals totaled some $7.2 million,[2] over 85% of all mineral production. Production of cement, sand and gravel, and quarry products continued to increase, but gold and silver production from Fiji's only operating mine declined slightly from the previous year's level.

Mineral exploration has been carried out by U.S., Australian, British, Canadian, West German, and South African companies since the early 1960's, and a high level of activity was maintained throughout 1980. At the end of 1980, some 40 mineral prospecting licenses covering over 4,300 square kilometers were in force, and 19 applications were under consideration by the Mineral Resources Department. Total expenditures by mining companies on land base projects exceeded $6 million in 1980.

As in previous years, most activity was on the main island of Viti Levu. However, there was an increased interest in previously less well prospected islands. In the Namosi District of southeast Viti Levu, exploration and development work have indicated several occurrences of porphyry copper, molybdenum, and gold mineralization. In south and central Viti Levu, geological mapping and geophysical surveys were completed over areas containing small massive sulfide copper-zinc deposits. In western Viti Levu, gold mineralization was reported, and systematic sampling was commenced, but the presence of economic mineralization has yet to be demonstrated.

At Mount Kasi on Vanua Levu, where gold has been mined, the diamond drilling program was completed. Again, no major new ore extensions were reported, but based on the drilling results and on detailed

Table 1.—Other South Pacific Islands: Production of mineral commodities[1]

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.

[1]Table includes data available through July 15, 1981.

[2]Reported figure.

[3]Produced from an unreported amount of domestically quarried limestone.

[4]In addition to the commodities listed, crude construction materials (common clays, sand and gravel, and stone) are produced, but output is not reported quantitatively and available general information is inadequate to make reliable estimates of output levels.

[5]Data represent exports.

[6]Total cobalt content of nickel ores mined based on average nickel-cobalt ratio in metallurgical products for 1880-1972.

[7]Cobalt actually recovered for use as cobalt; excludes cobalt content of nickel-cobalt alloys, and/or included in ferronickel.

[8]Nickel-cobalt content of ore produced as reported by New Caledonia's Mines Service. Of the total, about 97.323% is nickel; the balance is cobalt (based on average nickel-cobalt ratio in metallurgical products for 1880-1972).

[9]Data represent Japanese imports.

[10]Data revised to represent actual production rather than Japanese imports, as given in previous editions.

surveys in the area, some followup work was planned.

Four offshore oil exploration licenses were in force to U.S. oil companies in areas of the Fiji Platform known as Bligh Water, Yasawa, Lomaiviti, and Great Sea Reef. The Mineral Resources Department's research vessel *RV Bulikula* was used on charter to carry out detailed surveys in Bligh Water. This work, together with further interpretation of geophysical and geochemical data, defined targets for a drilling program that commenced in mid-1980 by Chevron Overseas Inc.

COMMODITY REVIEW

Metals.—*Copper.*—Copper Resource Ltd. (a subsidiary of Conzinc Riotinto of Australia Ltd.) delivered a full report to the Fijian Government on the economics of the Namosi copper deposits on Viti Levu. In its report, the company informed the Government that the deposits were currently uneconomical, in view of the copper content of the deposits and the current forecast for copper prices. As a result of the prefeasibility study's findings, the Ventures (also including Anglo Pacific Ltd., subsidiary of Australian Anglo American Ltd., and Preussag Fiji Ltd. of the West German Preussag Group) decided against undertaking a full feasibility study. The deposit remains a significant potential resource, and the companies have indicated to the Fijian Government that they wish to retain their special prospecting license. The study, which included diamond drilling and geological sampling, indicated an ore body of 450 million tons at 0.4% to 0.5% copper. The study also indicated that the deposit was minable by open pit, with a waste-to-ore ratio of approximately 2:1.

Gold.—Emperor Gold Mining Co. Ltd., the wholly owned operating subsidiary of Emperor Mines Ltd., mined sulfotelluride gold ores at Vatukoula on the north coast of Viti Levu. During 1980, the company employed about 700 men to mine and treat 238,000 tons of ore and recovered 27,900 troy ounces of gold and 10,200 troy ounces of silver. The greatly improved gold prices enabled the company to report a small operating profit of $7,000, following losses of over $2 million in 1978-79. Emperor Mining was planning to increase gold ore output and intensify its prospecting for new gold in areas along the Tavua Basin.

Emperor Mining made a complete recalculation of reserves tonnages and grade during the year, and on June 30, the total underground reserves using a cutoff grade of 6.12 grams per ton stood at 1.1 million tons of measured ore at an average grade of 9.95 grams per ton. Indicated ore reserves totaled 187,000 tons at an average grade of 8.57 grams per ton. Indicated reserves in the open cut amounted to 71,000 tons at an average grade of 6.89 grams per ton.

The recent high gold prices stimulated interest in the industry in Fiji and a number of companies have taken out prospecting licenses. Pacific Energy and Minerals Co. of Golden, Colo., started exploring the inland areas of Viti Levu near Vatukoula gold mine. Consolidated Gold Fields of Australia (CGFA) began prospecting on the islands of Kadavu and Ono, where gold traces have been reported.

Nonmetals.—Emperor Gold Mines continued to produce burnt lime from its limestone quarry at Tau but did not report production. The number of sand and gravel licenses granted continued to increase, although procedures providing for determination of compensation for damages to fishing grounds remained in force.

Fiji Industries Ltd. dredged 186,000 tons of coral sand from Suva Harbor and 56,000 tons of common sand and gravel from the Rewa River and tributaries in 1980. Some 470,000 tons of quarried stone was also recovered.

The Government's Mineral Resources Division continued evaluating a phosphate clay deposit on the island of Tuvutha, where 1.5 million tons of 10% P_2O_5 was reported.

Mineral Fuels.—*Petroleum.*—Mapco Ltd. and Pacific Energy & Minerals Ltd. began drilling for oil in Fiji. Drilling began in the Bligh Waters in April, and other areas scheduled for drilling include Yasawa, Lomaiviti, and Great Sea Reef.

Table 2.—Fiji Islands: Exports and reexports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1978	1979	Destinations, 1979	
			United States	Other (principal)
METALS				
Aluminum metal including alloys, all forms	2	7	--	Wallis and Futuna Islands 5; Australia 1; New Zealand 1.
Copper metal including alloys:				
Waste and scrap	284	234	--	All to Australia.
Unwrought and semimanufactures	21	10	--	Mainly to Taiwan.
Gold, nonmonetary:				
Bullion, troy ounces	25,866	29,069	--	All to Australia.
Sweepings and waste, kilograms	--	3	--	Do.
Metal including alloys, unwrought and wrought, troy ounces	--	622	--	Australia 621; Vanuatu 1.
Iron and steel metal:				
Waste and scrap	1,389	1,192	--	New Zealand 1,074; Australia 118.
Steel, primary forms	30	10	--	Wallis and Futuna Islands 6; Australia 3; Tuvalu 1.
Semimanufactures	648	[1]959	--	Tonga 353; Vanuatu 156; Wallis and Futuna Islands 67.
Lead metal including alloys:				
Waste and scrap	96	82	--	Republic of Korea 46; Singapore 30; Australia 6.
Unwrought and semimanufactures, value	$2,627	$7,727	--	All to Australia.
Silver:				
Bullion, troy ounces	9,900	10,915	--	Australia 10,901; Vanuatu 14.
Waste and sweepings, kilograms	--	9	--	All to Singapore.
Metal including alloys, unwrought and wrought, value	--	$11,127	--	All to Australia.
Titanium oxides, kilograms	1,466	--		
Zinc metal including alloys:				
Unwrought, do	40	47	--	All to Tuvalu.
Semimanufactures, value	$1,002	$41,124	--	Mainly to New Zealand.
Other:				
Ash and residue containing nonferrous metals	145	65	--	All to Australia.
Oxides, hydroxides, peroxides, kilograms	20	--		
NONMETALS				
Abrasives, n.e.s.:				
Grinding and polishing wheels and stones, value	$1,027	$541	--	New Zealand $460; Tonga $51.
Natural and artificial powders and grains, do	$159	$24	--	All to Tuvalu.
Cement	9,664	3,310	1,106	Wallis and Futuna Islands 1,309.
Chalk and earth colors, kilograms	130	100	--	All to Australia.
Clays and clay products including all refractory brick:				
Crude clays, do	140	315	--	All to Tonga.
Products:				
Refractory including nonclay brick, value	--	$1,934	--	All to New Zealand.
Nonrefractory, do	$17,313	$19,632	--	Tonga $14,419; Western Samoa $3,967; Tuvalu $1,246.
Fertilizer materials, manufactured, kilograms	3,529	150	--	All to Tuvalu.

[4]Excludes imports of silver bullion in 1979 of 42 troy ounces.

NAURU AND KIRIBATI

The Republic of Nauru and Kiribati (the latter includes Ocean Island) lie halfway between Honolulu, Hawaii, and Melbourne, Australia. Kiribati, the former British colony consisting of Ocean Island, Gilbert Islands, Line Islands, and Phoenix Islands, became independent on July 12, 1979.

Phosphate rock production by Nauru Phosphate Corp. totaled 2.0 million tons in 1980; no production was reported from Kiribati. Nauru exported 55% of its total output to Australia and 30% to New Zealand, with the remaining 15% to Japan and South Korea. The price of Nauru's phosphate generally follows Florida price trends, with allowance for quality.

Most of the phosphate was mined from between limestone pinnacles using grab buckets. Means were being investigated to recover the residual phosphate estimated to be 6% to 7% of the total.

Present reserves of phosphate rock in Nauru were estimated at 36 million tons.

Table 4.—Nauru and Kiribati:[1] Shipments of phosphate rock, by destination

(Thousand metric tons)

Destination	Nauru		Banaba Island	
	1978	1979	1978	1979

New Zealand	609	321	166	210
Total	1,999	1,828	468	446

[1]Data presented for the Republic of Kiribati represent shipments from the island of Banaba, which, prior to the establishment of the Republic, was known as Ocean Island.

Source: International Superphosphate and Compound Manufacturers' Association, Ltd. Table on "Exports by Destination From the Countries Included in Various."

NEW CALEDONIA

The French island territory of New Caledonia was the second largest producer of nickel in the market economy countries in 1980. Output of nickel by Société Métallurgique le Nickel (SLN), New Caledonia's only producer, declined in 1980, resulting from lower demand throughout most of the year. In addition to nickel products (nickel matte and ferronickel), byproduct cobalt matte resulting from nickel smelting operations was also produced by SLN. Other minerals produced in New Caledonia included chromite, and pit and quarry construction materials. Nickel exports remained at about the 1979 level.

Nickel ore was produced at four major locations, three (Thio, Kouaoua, and Poro) near the east coast and one (Népoui) near the west coast. Work to expand output on Népoui to 2 million tons of ore per year and at Kouaoua to 1.5 million tons per year was nearing completion. Production of nickel ore totaled some 4.3 million tons in 1980.

In 1979, operations of SLN's refinery were severely affected by a fire, but the refinery operated normally throughout 1980. The output of metallurgical products (nickel matte and ferronickel) totaled 44,500 tons, compared with 43,000 in 1979.

Exports in 1979 were valued as follows (in thousands): Ore—$49,398;[3] matte—$54,644; and ferronickel—$125,755. The export value for nickel matte declined slightly, but the values for ore and ferronickel showed substantial improvements.

The cobalt content of the nickel ore mined in New Caledonia during 1980 was 2,239 tons, but the total recovered metal was estimated at 180 tons. The cobalt content in either the total ore production or in the intermediate metallurgical products was recoverable as cobalt or cobalt chemicals. A significant part of the total remained in nickel products.

Amax Nickel Inc. and Bureau de Recherches Géologiques et Minières (BRGM), the French Government-controlled agency, began work that would lead to a joint

development of an integrated nickel project in the Tiebaghi, Poum, and Isle d'Art regions at the northern end of New Caledonia. The agreement covers feasibility and financing studies and ultimate mine and plant construction and operation. The cost of the project was estimated at $600 million. Reserves of 55 million dry tons of ore at 2.5% nickel in garnierite, including 10 million tons of 3% nickel, would be mined at a rate of 1 million tons per year. Amax was interested in shipping nickel matte from this smelter to its Port Nickel refinery in Louisiana.

Inco Ltd. of Canada, under agreement with the New Caledonian Government, continued studying the possibility of development of lateritic nickel deposits in the southern part of the Island. Inco was required to take a French partner before the project reaches its development stage.

Production of chromite ore in 1980, containing 34.6% Cr_2O_3, in the Tiebaghi area, exceeded that for 1979. Chromite exports, principally to Japan, had a combined value of $505,247 in 1980. Société de la Tiebaghi, subsidiary of Inco Ltd., continued a drilling program that began in 1977.

Energy requirements were considered a potential problem since New Caledonia had no domestic energy resources. All fuel oil was imported to New Caledonia, and there were no known domestic energy resources except for the possibility of developing hydroelectric energy sources in the Plaine de Lacs area. SLN used 85% of the industrial electricity in its mining and smelting operations.

Table 5.—New Caledonia: Exports of selected mineral commodities

(Metric tons unless otherwise specified)

Commodity	1977	1978	1979

PAPUA NEW GUINEA

Papua New Guinea (PNG) has abundant mineral resources, particularly copper, but only one operating mine. The only other minerals produced were small quantities of limestone and sand for local use, and some gold in the Bulolo-Wau area. However, in addition to the operating mine (Bougainville), which produced copper, gold, and silver, exploration work on two other major deposits has begun. These two deposits, OK

Tedi located in the Star Mountains in the center of PNG and Frieda River near Madang, also have large copper resources. The principal obstacles to commercial development have been the current depressed price of copper and the difficulty of access to these remote areas. Nevertheless, these mines are expected to be operational in the late 1980's. Bougainville Copper Ltd.'s mine at Panguna on North Solomon Island (Bougainville) contributed significantly to Government revenues and the gross domestic product (GDP), estimated at $1.96 billion[4] in 1980. Values of 1980 output were as follows: Copper—$175 million, gold—$128 million, and silver—$7 million. Total production value of $310 million was nearly 16% of the GDP. Despite the mineral industry's importance financially, it employed only about 7,200 people out of a total work force of over 350,000.

The Government of PNG sponsored its first investment seminar in the United States during 1980. The stated objective of the seminar was to offer U.S. corporations opportunities to invest in PNG's minerals resources. The newly enacted legislation relating to the exploitation of mineral resources was discussed. Development of mining and petroleum projects was considered to be of the highest priority, and the basic principles of the legislation adopted were as follows:

Mineral resources belong to the people of Papua New Guinea and the Government, and the people must receive a fair price in return for extraction of the minerals.

Foreign enterprises exploiting Papua New Guinea's mineral resources deserve a reasonable return on their investment, but extraordinary gains above a reasonable return on investment will go in large part to the Government.

The Government has the right to regulate extractive enterprises so as to maximize the benefits to the local community, while minimizing the potentially harmful social and economic costs.

A number of porphyry copper and hydrocarbon projects were under investigation in 1980. There are proven gasfields, although there are so far no reports of oil being found in commercial quantities. Exploration was also underway for chromite, nickel, bauxite, manganese, and mercury.

COMMODITY REVIEW

Metals.—*Chromite.*—A joint venture formed by Nord Resources Corp., Highlands Energy Corp., and Nord Australex Ltd. has found chromite mineralization at several locations in PNG and plans to develop one area. Reserves in excess of 5 million tons have been discovered at the Ramu River concession. The find was on part of a 246-square-kilometer concession in the Ramu River area, close to the deepwater port of Madang. Amax Exploration Australia Inc., a subsidiary of Amax, continued evaluating chromite and other minerals in beach sands along the Morobe coast, between Salamaua and Salua. Preliminary estimates indicated reserves of 200 million tons of mineralized sands containing 1.5% chromium.

Copper.—Bougainville Copper Pty. Ltd.'s (BCL) mine at Panguna remained the only significant mining operation in Papua New Guinea. The 1980 output of all three commodities—copper, gold, and silver—was below the 1979 level. This resulted from both a decline in tonnage and grade of ore milled. About 34 million tons of ore were treated in 1980, compared with 36 million tons in 1979. In 1980, the copper content declined to 0.47%, while gold and silver were 0.024 troy ounce per ton and 0.058 troy ounce per ton, respectively. The content of these constituents was expected to continue the downward trend, as mining operations extend into lower grade sections of the ore body. The company was building its 11th primary ball mill.

In 1980, sales totaled 142,240 tons of copper, 440,037 troy ounces of gold, and 900,000 troy ounces of silver. Concentrates were shipped under long-term contracts to Japan, the Federal Republic of Germany, and Spain.

The Papua New Guinea Government formally announced its conditional approval for the development of the copper-gold deposits at OK Tedi, in the remote Star Mountains in the center of Papua New Guinea. The feasibility study of the porphyry copper deposit, which included engineering design work, metallurgical testing, and economic evaluation, was continued. The study was being carried out by a consortium under the leadership of Broken Hill Pty. (BHP), which began work at OK Tedi in 1976. The consortium consisted of Dampier Mining Co. Ltd., a subsidiary of BHP Co. (30%); Mount Fubilan Development Co. Pty. Ltd., a subsidiary of Amoco Minerals Ltd. (30%); Kupferexploration GmbH, a West German group, (20%); and PNG Government (20%). Situated near the West Irian

border, the deposit has ore reserves estimated at 300 million tons. Ore grade averaged 0.85% copper and 1.8 troy ounce per ton of gold, with some molybdenum. Under the agreement with Papua New Guinea, the consortium presented the feasibility study to the Government on May 31, 1979. A hydrographic, geophysical, and geological investigation of the Fly River to assess the feasibility of transporting copper concentrates from OK Tedi via barge from Kiunga on the Fly River to an as-yet-to-be-selected deepwater port on the Gulf of Papua was continued.

Exploration also continued on the Frieda River porphyry ore body estimated to contain 500 million tons, averaging 0.5% copper. Although this is a major ore body located in the Western Sepik Province, development could be hampered by its low grade. The leases were held by MIM Holdings Ltd., and work carried out by Japanese interests earned them a 40% share in the holding.

On Manus Island, 360 kilometers north of the PNG mainland in the Admiralty Group, joint venture exploration by Exoil NL and Transoil NL indicated 160 million tons of ore at 0.32% copper, associated with gold, silver, and molybdenum, in ore of several known prospects. Some factors acting in favor of the Manus prospect were the limited infrastructural development required and relatively good accessibility compared with the mainland deposits.

Gold and Silver.—With high prices, gold continued to be an important byproduct of BCL's Panguna copper mine. The gold sales totaled some 600,000 troy ounces during 1980. Byproduct silver recovery was about 1.3 million troy ounces.

Output by New Guinea Goldfields Ltd. at Wau, where ore averaged 0.08 ounce per ton, remained relatively small.

At Porgera in Papua New Guinea's central mountain range, Placer Development Ltd., MIM, and Consolidated Goldfields of Australia were engaged in a joint venture to explore and develop an alluvial gold deposit. Two zones have been explored; one was estimated to be 250 meters long, 150 meters wide, and up to 250 meters deep, and to average 0.07 ounce per ton of gold and 0.13 ounce per ton of silver. The other had a length of 420 meters, a width of 250 meters, and a depth of 240 meters, and averaged 0.08 ounce per ton of gold and 0.13 ounce per ton of silver. The results suggest the possibility of a large gold mine, but work was still at an early stage of development.

Mineral Fuels.—*Petroleum.*—Petroleum prospecting continued, but no significant discoveries were reported. The Papua New Guinea Government signed petroleum prospecting concession agreements with Gulf Oil Corp., Australasian Oil Ltd., and BP Petroleum Development Australia Pty. Ltd. The concession areas involve two permits (76 and 77). Permit 76 covered 7,300 square kilometers in the Western Province, and permit 77 covered 13,400 square kilometers in the Western and Southern Highlands Provinces. The cost of exploration over a 3-year period was estimated at $7 million. In another development, Esso Papua New Guinea Inc. announced it had spudded the Goari No. 1 well on the Paibuna River, 415 kilometers northwest of Port Moresby. Planned depth is 11,500 feet, and it is estimated that the well would take 55 days to complete.

Recently passed legislation by the PNG Government would entitle it to receive 60% to 80% of any future revenues from oil or gas production. This would be in the form of a 1.25% royalty based on wellhead values, a petroleum income tax of 50% of taxable income, a profits tax after an agreed rate of return is achieved, and a Government equity up to 22.5% with payment from the Government's share of production.

Total	182,029	195,050	171,997

SOLOMON ISLANDS

In 1980, Solomon Islands' minerals output consisted of small quantities of alluvial gold and silver, valued at an estimated $260,000.[5] In addition, marine shells were harvested for lime, but production was not reported.

The Government continued to actively seek foreign investors as a major force in the country's resource development. A bauxite mine and refinery project on Rennell and Vaghena Islands have been surveyed but temporarily shelved due to low world bauxite prices. Conzinc Riotinto Australia Ltd. (CRA), in partnership with Mitsui Mining and Smelting Co. Ltd. and the Solomon Islands Government, withdrew from the project, and Mitsui decided to defer further work because of the lack of market for aluminum. The project was to produce 1.5 million tons of bauxite and 600,000 tons of alumina per year from reserves estimated at 60 million tons of 45% to 50% Al_2O_3.

In addition to bauxite, other minerals known to exist in Solomon Islands were phosphate on Bellona and Rennell, copper on Guadalcanal and Florida, nickel on Isabel, manganese on Florida, and gold on Guadalcanal. Currently, these mineral deposits were regarded as uneconomic prospects because of the small size of known occurrences.

The Government was particularly interested in receiving proposals for prospecting for hydrocarbons both onshore and offshore. A Petroleum Act establishing the framework to enable orderly prospecting and development to be carried out by commercial companies was completed. Within the terms of the act, detailed agreements between individual companies and the Solomon Islands Government concerning work programs, expenditure levels, and the extent and nature of Government participation were considered.

TONGA ISLANDS

In 1980, there were no active mineral exploration ventures in Tonga. In the future, there may be some mineral potential in the country resulting from mining manganese nodules and precious coral. Also, the Tonga Government and Webb Resources of Colorado, an independent U.S. oil company, were conducting negotiations for Webb to drill two offshore wells.

VANUATU (NEW HEBRIDES)

Vanuatu (formerly New Hebrides) was granted independence in July 1980. A condominium government between Britain and France had ruled the 70-island territory since 1906.

Vanuatu's only mine, located at Forari, 55 kilometers northwest of Port Vita on Vate (Efaté) Island, remained closed in 1980. The mine, which produced manganese concentrate, was operated by Le Manganese de Vate (LMV) and owned by Southland Mining Ltd. of Australia (87.5%) and public shareholders (12.5%). The closure was attributed to the decline in world steel demand. The mine is expected to reopen at some future date, although only some 120,000 tons of commercially minable reserves remain in the Forari Mine. The

company had 100 employees, largely native Vanuatuans, and shipped a 40% to 42% manganese concentrate of metallurgical grade. The market value was $35 per ton for 40% manganese products.

Manganese concentrate was the only mineral exported in recent years, but various mineral deposits were under investigation. Samples of pozzolan, a consolidated volcanic ash, on Efaté and other islands, were being evaluated in Australia and Fiji for use in cement. Surveys have taken place in recent years in search of nickel, copper, bauxite, sulfur, and zinc. None of these commodities were expected to be mined in the foreseeable future.
